RCB:HLS VII-3 Letter Circular LC 106.

DEPARTMENT OF COMMERCE BUREAU OF STANDARDS Washington, D.C.

(November 14, 1923).

NOTES ON UPHOLSTERY LEATHER SPECIFICATIONS II.

NTRODUCTION

This letter is a supplement to Letter Circular 97 which contained general notes on upholstery leather specifications together with physical test results on a number of vegetable tanned samples. Physical tests have been made on chrome tanned grain and split samples since LC 97 was issued. The results of these tests to-gether with the results of chemical analyses on vegetable and chrome samples are presented in this supplement.

PHYSICAL TEST DATA

The physical tests on the chrome tanned samples were conducted in the same manner as for the vegetable tanned. The block numbers in the following tables indicate the locations on the hide as shown by sheet L7 in LC 97.

SUMMARY.

From Table 5 it will be noted that the chrome tanned leather has greater tensile strength than vegetable tanned leather and also more resistance to the tearing action of the grab and tear tests. This was to be expected from previous knowledge regarding the comparative properties of leathers tanned by these two processes as was also the fact that the chrome tanned leather had a greater percentage of stretch.

The chemical analyses show that the leather is either neutral or very low in acidity. Although it does not appear in the manufacture of these leathers that it is necessary to use any acid, one sample had .5% which is certainly the maximum that should be allowed in any specification.

It is essential that these leathers be stuffed with greases to give long life but the grease contents of the samples tested gave some results of larger magnitude than was expected. The average value for the grain leather was approximately 15%, for machine buffed leather approximately 11% and split leather approximately 8%. It is possible that some grease may have been extracted from the coatings although an analysis of a sample of grain leather ready for the coating showed 12% and 6% for machine buffed leather.

The ash content for the vegetable leathers varied from .93% to 2.48%. For two uncoated samples the result was .77% showing that the high ash is probably due to materials in the coatings. The analysis of one ash sample showed that the leather contained slightly in excess of 1% of lime. If this amount was present in the uncoated leather it would have the effect of making it harsh but it is 1% present a matter of speculation as to whether it would effect the durability of the leather.
