DEPARTMENT OF COMMERCE
NATIONAL BUREAU OF STANDARDS
WASHINGTON, D. C.
SEPTEMBER 26, 1934.

Letter Circular
LC-425
(Superseding #359)

SOUND ABSORPTION COEFFICIENTS OF THE MORE COMMON MATERIALS.

The following figures have been obtained at the National Bureau of Standards for the sound absorption coefficients of a number of materials now on the market as acoustic correctives. The inclusion of a material in this letter circular is not to be construed as a general approval. Each material should be judged on its merits in any particular case as there are other requirements such as fire resisting qualities; light reflection, appearance, etc. Figures are also given for the absorption of an audience seated in chairs of different kinds. All the results have been obtained by the reverberation method.

The sound absorption coefficient of a material is defined as the fractional part of the energy of a sound wave which is absorbed at each reflection. Experimental figures such as are given here must be regarded as approximate only. This branch of applied science is new and in a state of development. The methods and formulas used in obtaining these figures are those which, while not entirely satisfactory, are open to the least objection. The uncertainty involved is such that all the coefficients are probably somewhat too large.

The "noise coefficient" given in the table is the average of the coefficients for 256, 512, 1024 and 2048 cycles. It has been recommended by many consultants that such a coefficient be used when the problem is one of reducing the noise level, as in offices, restaurants, etc.

Fibrous materials and acoustic tiles may exhibit large variations in coefficient arising from different methods of mounting. The figures here given apply only to cases where the materials are mounted in the same manner as when tested.

Acoustic plasters require special skill in their application, as improper manipulation may reduce the coefficient. Moreover, the figures given for plasters without a base coat will be considerably reduced if a base coat is used.

It is not necessarily the case that the materials of highest coefficient are the most advantageous. When there is room enough to apply the requisite quantity, a material of low coefficient will give better results than one of higher absorption, because of the more uniform distribution of material. Also in comparing different materials it should be borne in mind that there is

some variation in manufacture, hence the sample which was measured may have more or less absorption than the material delivered on the job. Minor differences in coefficients, therefore, should be disregarded in choosing between materials.

For the foregoing reasons it is advisable in drawing up specifications for auditoriums to lay emphasis upon the reverberation time desired rather than upon coefficients of material. See Bureau of Standards Circular #396 entitled "Architectural Acoustics", which may be obtained of the Superintendent of Documents, Government Printing Office, Washington, D. C., at 5 cents per copy. Additional details regarding any of the materials mentioned in this letter circular will be furnished on application.

Additional information regarding the absorption coefficients of acoustical materials may be obtained from the Acoustical Materials Association, 919 North Michigan Avenue, Chicago, Illinois.

Sound Absorption Coefficients and Description of Test Samples

Table 1
Acoustical Tiles, Boards and Blankets.

The coefficients given in the following table have been modified to some extent from those given in previous Letter Circulars. The reason for these changes is to be found in the August, 1934 number of the Journal of Research of the National Bureau of Standards (Research Paper No. 700) entitled "Dependence of Sound Absorption upon the Area and Distribution of the Absorbent Material".

1. The first part of the document discusses the importance of maintaining accurate records of all transactions. It emphasizes that every entry should be supported by a valid receipt or invoice. This ensures transparency and allows for easy verification of the data.

2. The second section details the various methods used to collect and analyze the data. It includes a list of the different types of transactions recorded, such as sales, purchases, and transfers. Each method is described in detail, including the steps involved in the process.

3. The third part of the document provides a comprehensive overview of the results of the analysis. It includes a summary of the total amounts for each category and a breakdown of the data by time period. This information is used to identify trends and make informed decisions about the business.

4. Finally, the document concludes with a series of recommendations for improving the accuracy and efficiency of the data collection process. It suggests implementing stricter controls and using more advanced software tools to streamline the workflow.

The following table provides a detailed breakdown of the data collected during the period from January 1st to December 31st, 2023. The table is organized into columns representing different categories of transactions and rows representing individual entries.

Date	Description	Amount	Category
2023-01-01	Opening Balance	1000.00	Assets
2023-01-15	Sales Revenue	500.00	Revenue
2023-01-20	Purchase of Inventory	200.00	Expenses
2023-02-01	Transfer to Savings	100.00	Transfers
2023-02-10	Interest Income	50.00	Income
2023-02-25	Dividend Payment	75.00	Income
2023-03-05	Salary Payment	1200.00	Expenses

2023-12-31	Closing Balance	1000.00	Assets

The data presented in the table above shows a consistent pattern of transactions throughout the year. Revenue is primarily generated through sales, while expenses are dominated by salaries and rent. The company also maintains a steady flow of income from dividends and interest, which is used to fund savings and loan repayments.

Overall, the financial performance of the company appears to be stable and well-managed. The consistent recording of transactions and the use of clear, standardized categories have allowed for a thorough analysis of the data. This information is essential for making strategic decisions and ensuring the long-term success of the business.

This document is a confidential record of the company's financial activities. It is intended for internal use only and should not be distributed to any other parties without the explicit permission of the management. Any unauthorized disclosure of this information could result in legal action.

The information contained herein is accurate as of the date of preparation. It is subject to change based on future transactions and adjustments. The company reserves the right to modify or update this document as needed.

FOOTNOTES:

1. Cemented to gypsum wall board. This is considered equivalent to cementing to plaster or masonry.
2. Placed on 13/16" x 2" furring 12" o.c. unless otherwise indicated.
3. Metal supports attached to 13/16" x 2" wood furring.
4. Laid directly on laboratory floor. As a rule the results obtained this way are the same as when the tile is cemented to gypsum wall board.
5. Placed on 2 x 4's 24" o.c. unless otherwise indicated.
6. Cemented to the floor of the reverberation room.
7. Back of sample covered with concrete.

Table 2
Acoustical Plasters

Unless otherwise stated each sample of acoustical plaster was mixed according to the specifications furnished by the manufacturers and applied by a skilled plasterer. The panels were laid on the floor of the Sound Chamber for test.

Suggestions Concerning the Proper Use
of Acoustical Material.

As there has been considerable misconception as to the proper use of acoustical material it is considered desirable to call attention to two of the fundamental principles underlying the formulas which are used in acoustical design. It is assumed in all of the formulas that (1) the absorption is proportional to the area of the absorbing material and that (2) there is a uniform distribution of sound energy. As a rule neither one of these assumptions is true.

It has been found from experiment when very small areas are used, such as the panels in a coffered ceiling having areas from 1 to 4 square feet and separated from each other by a foot or more, that the effective absorption of the material in these panels is greater than when the material is installed in one large area. In fact, for materials having large coefficients, this effective absorption may be as much as 50 per cent more than one would expect from the coefficient.

It has also been found when all of the acoustical material is applied on one surface of a relatively small room, say 50,000 cubic feet or under, that this creates a non-uniform distribution of sound energy in the following manner. Let us assume that the ceiling of a room is covered with a highly absorbent material. Under these conditions the sound energy which is traveling between the floor and ceiling is absorbed quite rapidly, while that traveling between the untreated wall surfaces, having very little to absorb it, may continue for some considerable time. This persistence of sound energy between the untreated surfaces may cause the measured reverberation time to be considerably longer than would be computed using the ordinary reverberation formula and the coefficient usually given. For this reason, it is essential in small rooms that the acoustical material be distributed on the side walls as well as on the ceiling, if the effective absorption of the material is to be anywhere near that which one would expect from the coefficient of the material.

We also wish to call attention to the fact that a proper distribution of the acoustical material should be worked out in the initial plans of a building, as it is frequently impossible to obtain a satisfactory distribution after the interior design has been completed without taking into account the acoustical treatment.
