

## The Third Spectrum of Copper (Cu III)\*

A. G. Shenstone\*\*

(January 14, 1975)

An analysis of Cu III based on observations from 500 to 6900 Å is presented. The low structures  $3d^9$  and  $3d^84s$  are complete, including the rarely, if ever before, found  $3d^8(^1S)4s^2S$ . The  $3d^74s^2$  includes  $4F$ ,  $2F$ ,  $2G$ , and  $2H$  but the  $4P$ ,  $2P$ ,  $a^2D$ ,  $b^2D$  have eluded all attempts to find them. The ionization potential calculated from  $4s$ ,  $5s$ ,  $6s$   $4F_{1/2}$  is 296 980 cm $^{-1}$  but by a comparison with Ni II which has a longer series an approximate value of 297 140 can be estimated. The  $3d^84d$  group is complete, except for one level, as is  $5d$  based on  $3F$  and  $1G$ , the other  $5d$  groups being incomplete.  $3d^8(^3F)4f$  is complete and 26 levels based on  $^1D$ ,  $^3P$ ,  $^1G$  are known.  $3d^8(^3F)5g$  is incomplete and a few levels based on  $^1D$  and  $^1G$  have been found. A discussion of the validity of the analysis of Cu IV by J. F. Schröder and Th. A. M. Van Kleef is given.

**Key words:** Atomic energy levels; atomic spectrum; copper; doubly ionized copper; electron configuration; ionization potential; wavelengths.

### 1. Introduction

The analysis of the third spectrum of copper (Cu III) which is described in this paper, is the result of research by a number of spectroscopists. The work up to 1951 is summarized in the paper published in that year by A. G. Shenstone and L. Wilets [1]<sup>1</sup> in which a correct description was given of the low structures and of a few higher ones. It was restricted, however, by the inadequacy of the condensed spark source which was the usual means, at that date, of exciting spectra of ionization above the second.

In 1956, Dr. W. C. Martin and I began to make a new description of the spectrum using the pulsed hollow cathode tube which had been recently introduced. The result was a new and much expanded line list which was adequate for the discovery of many new odd and even levels including  $3d^7 4s^2 4F$ . Along with work on other spectra, I continued to work on that description of Cu III until 1965, when I came to the conclusion that I might gain a great deal by first making a very complete analysis of the isoelectronic spectrum Ni II. A second spectrum is more easily

observed and analyzed because it can be produced with great purity and with fine lines by the hollow cathode tube discharge sometimes called a Schüler tube. An additional advantage was that the Bureau of Standards was then in a position to supply me with plates in the Schumann region taken with their 10.7 meter vacuum spectrograph. The Ni II analysis was published in 1970 [2] and I then returned to Cu III. In both Ni II and Cu III, I was greatly assisted by the kindness of Victor Kaufman of NBS who photographed the vacuum spectra on the 10.7 meter instrument using the hollow cathode, the pulsed hollow cathode, and the sliding spark. The dispersion of about .78 Å per mm. on the NBS plates much improved the accuracy of the data, in spite of the fact that the Doppler and Stark broadening of the lines reduced the resolution considerably. The six 18" plates from NBS, which I measured several times with great care, consisted of the following:

(1) 2 plates 1400 to 2100 Å with a lithium fluoride filter to eliminate second order lines. The spectra consisted of two exposures using the ordinary hollow cathode, one exposure of the pulsed hollow cathode, and three of the sliding spark with increasing pulse current.

(2) 2 plates 820 to 1520 Å. Six spectra were taken,

<sup>1</sup> Figures in brackets indicate the literature references at the end of this paper.

one being the ordinary hollow cathode and five being the pulsed hollow cathode. It was fortunate that those exposures are very good because that wavelength range includes a very large number of important transitions.

(3) 2 plates 0 to 950 Å with two hollow cathode exposures, one sliding spark and three pulsed hollow cathode exposures. The sliding spark exposure is obviously impure and the weakest pulsed hollow cathode does not extend below 850 Å. The other two are good but lack standards. Many of the strong lines are, however, calculable approximately, and almost all of them occur in second order on other plates where standards are available. Throughout the U-V spectrum, except as just mentioned, there are adequate standards of Cu II [3], C I [4], Si II [5], and Cl I [6] so that there are few regions where too long interpolations must be used. I made all measurements by eye, using a Societe Genevoise Comparator of 40 cm travel and accuracy about 2 μm. Intensity estimates were made on three exposures wherever available in order to obtain as much data as possible to distinguish Cu III and Cu IV lines. This is important because of the existence of the paper on Cu IV by Schröder and Van Kleef [7].

The spectra above 2000 Å were photographed on the Princeton 21 ft Paschen circle at about 1.3 Å per mm or, where necessary, in the first or second orders of our 21 ft Wadsworth spectrograph which uses a 15,000 line-per-inch grating.

Table 1 is the list of all lines attributed to Cu III. The total number of lines measured is about 3200 including both Cu III and Cu IV, and all were measured at least twice and many four or five times. Many small sections were remeasured wherever there was a question of close pairs or impurities.

## 2. Analysis

Table 2 is a synopsis of all the levels found. The chief structures expected in Cu III are due to the addition of an electron to  $3d^8(3F, 3P, ^1S, ^1D, ^1G)$ . This includes the lowest term of all,  $3d^92D$ .

The much improved line list required the redetermination of the levels of the principal terms of  $3d^84s$  and  $3d^84p$ . That then led to the determination of the levels of  $3d^84d$  which had previously been the stumbling block which led to my analysis of Ni II [2]. The difficulty was revealed when 31 levels were found in the group, ten based on  $3d^83F_4$ , twelve instead of ten apparently on  $3F_3$  and nine on  $3F_2$ . The extra two levels in the middle group have  $J$ -values of  $5\frac{1}{2}$  and  $4\frac{1}{2}$  and must be the two components of the term  $3d^74s^22H$ . They perturb the  $3d^84d$  levels quite badly. As in Ni II, the  $4d^22D$  term is several thousand wave numbers above the other levels of the configuration.

The structure  $3d^84s$  was known previously except for the predicted level  $3d^8(^1S)4s2S$ . The corresponding  $2P$  was identified when I noticed two strong lines at 542.902 Å and 553.012 Å which could hardly be anything but combinations with the two levels of  $3d^92D$ . This was confirmed by the discovery of the necessary satellite at 549.075 Å, completing the multiplet. It then became clear that the term involved must be

$3d^8(^1S)4p2P$ , and knowing the approximate position of  $2S$ , it was possible to find the combinations of  $2S$  and  $2P$ , thus fixing the true position of  $2S$ . I believe this is the first spectrum in which those levels have been found with certainty.

It is pertinent to make a few remarks about the naming of levels. It is obvious that in Ni II and Cu III we are dealing with spectra in which there is no pure Russell-Saunders coupling except in  $3d^92D$ . However, it has meaning and is useful to use  $R-S$  nomenclature throughout the analysis for the following reasons. The argument starts with the lowest term  $3d^92D$  which is pure  $R-S$  coupling and the  $3d^84s4F$  and  $2F$  terms which are quite close to  $R-S$  coupling, the doublet being well removed from the quartet. Those levels combine with 18 levels of  $3d^8(^3F)4p$  to give a pattern of intensities that reveals the characters of the 18 levels with very little doubt. There is evidently some mixing of  $4G_{41/2}$  and  $4F_{41/2}$ , but there is enough evidence to distinguish them. Within the higher levels of  $3d^84s$ , there is some ambiguity between  $2D_{21/2}$  and  $4P_{21/2}$  but the intensities favor the choice made here. The  $4s'''2G$  and its triad of odd terms are quite close to  $R-S$  coupling. The argument can be carried on step by step up to  $3d^85g$ .

I have carried out that system of naming by intensities throughout the spectrum, and the nomenclature used is the same as that used in "Atomic Energy Levels" except that the levels are not grouped together in terms but are arranged numerically. The right-hand superscript has been omitted from the odd levels as unnecessary except in the case of a few numbered levels. Tables 3 and 4 are the lists of the even and odd levels found in this research.

Throughout this work I was very much helped by calculations made for me at NBS by Sugar and Martin [8]. They included  $3d^8(4d \& 5s) + 3d^74s^2; 3d^8(5d \& 6s); 3d^84p; 3d^85p; 3d^84f; 3d^85g$ . Their calculations made possible the discovery of a large number of levels, especially many of the levels of the prime, double-prime and triple-prime groups (Table 2) as well as the  $4f$  and  $5g$  configurations.

The  $s^24F$  was found some years ago from its combinations with the  $4p$  levels and by extrapolation from Co I and Ni II. The  $2H$  was identified in the  $4d$  group and  $2G$  and  $2F$  were named by using the calculated predictions. It is strange that the  $s^24P$  has evaded all my efforts to find it, though it must be fairly close to the predicted position.

In finding the levels of configurations built on  $3F$ , I have used a general regularity which impressed me in the analysis of Ni II. Taking as an example the group  $5p^4 \& 2DFG$ , the higher two  $J$ -values of each quartet are based on  $3F_4$ , the next three quartet levels and the three doublet levels of higher  $J$  are based on  $3F_3$ , and the remaining three quartet and three doublet levels are based on  $3F_2$ . The same scheme is applicable to the  $4d$ ,  $5d$ , and  $4f$  levels with some modifications because  $4S$  and  $4P$  do not have the requisite number of components. In  $5g$  the scheme reaches an extreme which makes it possible to identify some, but not all of the levels. In fact, the number of combinations

of a level is reduced in most cases to just two, a very strong one for which both  $\Delta L$  and  $\Delta J$  are in the same direction as  $\Delta l$ , and a second much weaker line for which  $\Delta L$  and  $\Delta J$  are zero. The result is that many levels must be represented by just one combination and consequently there is no real evidence for choosing them.

### 3. Differences Between Observed and Calculated Levels

Among the low even levels,  $4s''$   $^4$ P $_{11/2}$ ,  $^4$ P $_{1/2}$ ,  $^2$ P $_{11/2}$ ,  $^2$ P $_{1/2}$  all differ by over 100 cm $^{-1}$  from the calculated positions, but there can be no doubt of the experimental values.  $4s^{IV}$   $^2$ S is 536 cm $^{-1}$  below the calculated value but, again, the evidence is conclusive.

The  $s^2$   $^2$ F $_{21/2}$  level mentioned above is 497 cm $^{-1}$  too high, and the  $4d'$   $^2$ F $_{21/2}$  is 202 cm $^{-1}$  too low. Although those two levels are 4500 cm $^{-1}$  apart, I suggest that the deviations from theory may be due to their mutual repulsion.

After the  $4f$  levels were identified there remained in the same part of the spectrum a considerable number

of strong lines which had to be due to transitions between the  $4d$  and  $4f$  configurations, but there did not appear to be much agreement between them and the theoretical predictions. Accordingly, I tried for levels which might be about 300 cm $^{-1}$  from the predicted values. That led to the definite identification of five  $4f'$  levels and two less certain ones. There still remained some of the strongest lines and several of them appeared in pairs. Ignoring the calculations, I tried the strongest pair as the diagonals of the multiplet  $4d'''$   $^2$ I –  $4f'''$   $^2$ K and found two levels very close together, as they should be. The next two strongest lines were then assumed to be  $4d''$   $^2$ H –  $4f'''$   $^2$ I, and I found two levels 8 cm $^{-1}$  apart. The reality of the levels was confirmed by two additional combinations of  $4f'''$   $^2$ I $_{51/2}$ . Continuing the analysis by this method, I found  $4f''$   $^2$ H,  $^2$ G, and  $^2$ F $_{31/2}$  with sufficient combinations to confirm the whole set. The differences between observed and calculated values were very large,<sup>3</sup> ranging from +1366 to +1512 cm $^{-1}$ . Having eliminated from consideration most of the strong lines as due to

<sup>3</sup> These large deviations of the predicted levels have since been corrected by the addition of effective interactions to the matrices for this configuration [8].

$4f'''$ , I then found it possible to identify with some certainty ten  $4f''$  levels with differences from predicted values from -181 to +121. It should be noticed that the differences for the  $4f'$  and  $4f'''$  levels were of opposite sign. None of the levels combines with any level except those of its own family or with  $s^2 2F$ , which is very much mixed with the  $4d''$  levels.

The  $5g$  levels produced a considerable number of diffuse lines in the region of 22,500 to 23,000  $\text{cm}^{-1}$ , which are very difficult to measure. I have found it possible, however, to identify 31 of the 41 levels based on  $3F$  with some certainty. From the remaining lines it was possible to make a definite identification of  $5g' 2G$  and tentative identifications of  $5g' 2I$  and  $5g' 2H$ . A possible  $5g'' 2L$  is also given in table 3.

Cu IV 3d <sup>8</sup> 3F <sub>4</sub>		297140

The numerical differences between observed and calculated levels are quite definite. Differences between the names assigned by the two methods are fairly frequent, and are of course based on less definite evidence. In particular, in the  $4d$  groups of levels, there are 17 cases of differing names. This is partly due to the presence of the  $s^2 2H$  term and the thorough way in which it is embedded amongst the  $4d$  levels. In no case, however, in any of the various structures is there as extreme a disagreement as is described in [2, Addenda] for the case of  $4p\ 4G_{4/2}$ ,  $4p\ 4F_{4/2}$ ,  $4p\ 2G_{4/2}$  in Ni II.

After much of the analysis was done, there were many unidentified lines in the short wavelength end of the spectrum. On examination, I found that most of them could be paired off by differences between  $4s^4F$  and  $4s^24F$ . Since they had to be due to levels of  $3d^74s4p$ , I plotted them on a graph with the levels of Co I and Ni II and was able to identify the origin of the majority of them. They appear in the term table with the same names as the corresponding levels in Ni II [2]. There are six numbered levels which could not be included amongst those identified.

#### 4. Ionization Potential

The most important and reliable series from which to calculate a limit is the series  $ns\ 4F_{4/2}$ , in which there are three members quite accurately determined and a fourth which is undependable. A Ritz calculation of  $4s$ ,  $5s$ ,  $6s\ 4F_{4/2}$  yields a limit  $296980\text{ cm}^{-1}$ , the formula being  $n^* = n + \mu - \alpha T'$  where  $T' = \frac{T}{9}$ ,  $\mu = 0.12070$ , and  $\alpha = 2.886 \times 10^{-6}$ . When the series  $ns'\ 2D_{2/2}$ ,  $ns''\ 4P_{2/2}$  and  $ns'''\ 2G_{4/2}$  each of three terms are fitted to Ritz formulae without reference to the analysis of Cu IV [7] they yield the following results:

Series	Limit	Limit above $3F_4$	Limit level in Cu IV [6]	Diff.
$ns\ 4F_{4/2}$	296980	00.	00	00
$ns'\ 2D_{2/2}$	313198	16213.	16249	+ 36
$ns''\ 4P_{2/2}$	316622	19642.	19696	+ 54
$ns'''\ 2G_{4/2}$	323881 ?	26901	27074	+ 173

The values of the limits of the  $2D$  and  $4P$  series cannot be much in error, but there is some doubt about the  $2G$  because the  $6s'''\ 2G$  term is not well established. It is, however, close to the calculated value.

The comparison of the four series listed above is legitimate because they are all calculated from  $4s$ ,  $5s$ , and  $6s$  levels. It is known of course that, if higher series levels are found, it is possible to derive a more probable value of the true limit. In Ni II, where the series is known up to  $9s$ , the limit from  $(4, 5, 6s)$  is  $146462\text{ cm}^{-1}$ , from  $(5, 6, 7s)$  it is  $146521\text{ cm}^{-1}$ , and from  $(6, 7, 8, 9s)$  it is  $146532\text{ cm}^{-1}$ . The Ni II limit obtained from the  $ng\ 4K_{8/2}$  series, which should be close to

the true limit, is  $146541\text{ cm}^{-1}$ . If those four values are plotted, they appear to form a curve converging towards the last one at very large values of  $n$ . If we accept the limit of  $146541\text{ cm}^{-1}$  as being very near the true value and assume that the same relative increase can be applied to Cu III, we can calculate as a probable true ionization potential the value  $296980\text{ cm}^{-1} \times 1.00054 = 297140\text{ cm}^{-1}$ .

#### 5. Analysis of Cu IV

I regret very much that it is incumbent upon me to criticize the paper on Cu IV published in 1970 by J. F. Schröder and Th. A. M. Van Kleef [7]. My criticism is known to Dr. Van Kleef, with whom I have had a considerable correspondence on the subject.

The sources used to excite the spectra in that paper and in this were very similar and the observed spectra were obviously also very similar. Apparently the Cu IV measurement of the lines used fewer good standards than I did for the Cu III spectra, in which I found many Cu II, Si II, C I and Cl I lines given to  $10^{-4}\text{ Å}$ . The resulting wavelengths differ so much that it would, in many cases, be difficult to identify the same line in the two spectra if it were not for the fact that all the lines of any intensity appear in both spectra. A wavelength difference may be as high as  $0.03\text{ Å}$ , but the identity cannot be questioned. It is very odd also that there are about 140 weak lines which I do not observe at all, in spite of immense over-exposure of the strong lines.

My criticism of the Cu IV paper is based on the following facts.

(1) There are nine lines of Cu II included in the analysis and a tenth, the strongest line of Cu II in the Schumann region,  $1358.773\text{ Å}$ , which appears as two strong lines due to reversal. The lines are as follows.

Cu II lines	
$\lambda$ [7]	$\lambda$ [3]
2161.995	0.999
2130.763	.758
2085.983	.938 and 973 (AGS)
1929.757	.752
1522.587	.577
1517.918	.930
1472.421	.395
1358.770	.773
1358.732	
1044.748	.744
1039.589	.582

The two lines at  $2085\text{ Å}$  are both Cu II, observed in the direct current hollow cathode tube. The two lines at  $1358\text{ Å}$  are the two sides of the most heavily reversed line in the Cu II spectrum,  $3d^{10}1S_0 - 3d^94p\ 1P_1$ . The line at  $1472\text{ Å}$  is the companion line  $3d^{10}1S_0 - 3d^94p\ 3P_1$ .

(2) There are five impurity lines.

$\lambda$ [7]		
1602.960	0.972 C I	[4]
1467.423	.402 C I	[4]
1280.353	.333 C I	[4]
1261.132	.122 C I	[4]
580.970	.967 O II	[9]

(3) Nine second order lines are included.

$\lambda$ [7]	$\lambda$ (AGS)	Origin
1576.895	$788.460 \times 2 = 1576.920$	Cu III
1404.247	$702.118 \times 2 = 1404.236$	Cu III
1400.527	$700.261 \times 2 = 1400.522$	Cu III
1373.812	$686.902 \times 2 = 1373.804$	Cu III
1301.999	$651.000 \times 2 = 1302.000$	Cu III
1216.910	$608.453 \times 2 = 1216.906$	Cu III
1165.308	$582.657 \times 2 = 1165.314$	Cu III
1098.151	$549.075 \times 2 = 1098.150$	Cu III
1051.588	$525.795 \times 2 = 1051.590$	O III [9]

(4) Other questionable lines

1654.655	1654.559	Cu III
1549.288	1549.215	Cu III and 0.306 Cu III?
1348.880	1348.831	Cu III and 0.919 Cu IV
1312.948	Obs-Calc is 13.4 not 0.4 cm <sup>-1</sup>	
1245.691	1245.643 ?	and 0.724 both Cu III
1240.160	1240.126	and 0.216 both Cu III

#### (5) Cu III lines used as Cu IV

There are 69 lines in table 1 of this paper which are identified as Cu IV in [7] but which, on my evidence, belong to Cu III. They have been examined individually with great care in all available exposures. It is possible that a few of the lines in my list may be partly IV and partly III, but it can only be a very small number.

In the course of examining the question of the origin of lines, I made a complete square array of the Cu IV analysis. On that diagram I marked all the questionable lines and it then appeared that a considerable number of levels must be spurious. To be certain of the whole analysis, it would be necessary to make a completely new and more accurate description of the spectrum, but from the diagram some examples can be given. The  $^5P_3$  at 139604 may be correct, but its accompanying  $^5P_2$  and  $^5P_1$  are based on many lines included in my various categories above. The deletion of those 2

levels destroys the  $^5S_2$  at 204149 and all of the  $^5D_0$  at 214225 except  $^5D_4$ .

As a second example, the  $^3G_5$  at 140070 is probably correct, but  $^3G_4$  and  $^3G_3$  must be spurious and they, in turn, make many of the odd levels based on the  $^2G$  term of Cu V very doubtful, indeed. A very dubious level is the  $^1G$  at 148885 which includes four Cu III lines among its few combinations. The two even  $^3P$  terms are both dubious and they lead to doubt about the odd terms based on the same ion terms. The highest  $^3D$  term includes four Cu III lines amongst its rather few combinations.

From all the evidence I can only conclude that the Cu IV spectrum should be re-examined in its entirety.

## 6. Conclusion

In spite of the fact that the analysis of Cu III presented in this paper has been worked on for so many years, it is obviously incomplete and it is disappointing that some lines of considerable strength remain unclassified. Perhaps it is inherent in the kind of source that one must use to excite spectra above the second that it suppresses the less probable transitions and makes high levels very difficult to find. As an example, one can contrast the many transitions of the  $ng$  levels in Ni II with the great paucity of such transitions in Cu III. If it becomes possible to devise sources which overcome such difficulties, Cu III will have to be more completely observed and analysed by someone else, not me, and this paper will then serve as a useful guide.
