21

## Abstract

22 Zero trust is a set of cybersecurity principles used when planning and implementing an enterprise  
23 architecture. Input and cooperation from various stakeholders in an enterprise is needed in order  
24 for a zero trust architecture to succeed in improving the enterprise security posture. Some of these  
25 stakeholders may not be familiar with risk analysis and management. This document provides a  
26 quick overview of the NIST Risk Management Framework (NIST RMF) and how the NIST RMF  
27 can help in developing and implementing a zero trust architecture.

28

## Keywords

29 architecture; information technology; risk; zero trust.

30

## **Acknowledgments**

51 The author would like to thank the members of the NIST Risk Management Framework team  
52 and the Zero Trust Architecture project team for their input and review.

53

## **Audience**

54 This document was written to help enterprise administrators and system operators understand  
55 how the various roles and tasks in the NIST Risk Management Framework (RMF) can be used  
56 when moving to a zero trust architecture. This document briefly introduces zero trust, and how  
57 the RMF process can be used in a zero trust migration process. It is assumed that the reader is  
58 familiar with the concepts of zero trust as described in NIST SP 800-207 and has had exposure to  
59 federal information security practices.

# 1 Zero Trust

Zero trust (ZT) is the set of principles upon which information technology architectures are planned, deployed, and operated [1]. ZT uses a holistic view that considers all potential risks to a given mission or business process and how they are mitigated. As such, there is no single specific infrastructure implementation or architecture, but it depends on the workflow (i.e., part of the enterprise mission) being analyzed and the resources that are used in performing that workflow. Zero trust strategic thinking can be used to plan and implement an enterprise IT infrastructure, which then could be said to be a zero trust architecture (ZTA).

Enterprise administrators and system operators need to be involved in the planning and deployment for a ZTA to be successful. ZTA planning requires input and analysis from system and workflow owners as well as professional security architects. Zero trust cannot be imposed from above onto an existing workflow but needs to be integrated into all aspects of the enterprise. This paper introduces some of the concepts in the NIST Risk Management Framework (RMF) to administrators and operators. The RMF lays out a set of processes and tasks that is integrated into enterprise risk analysis, planning, development, and operations. Administrators who may normally not perform the tasks detailed in the RMF may find that they will need to become familiar with them as they migrate to a ZTA.

NIST Special Publication 800-207 [1] gives a conceptual framework for zero trust. While not comprehensive to all information technology it can be used as a tool to understand and develop a ZTA for an enterprise. NIST SP 800-207 also provides an abstract logical architecture that can be used to map solutions and gaps upon. The abstract architecture is repeated in figure 1 below.

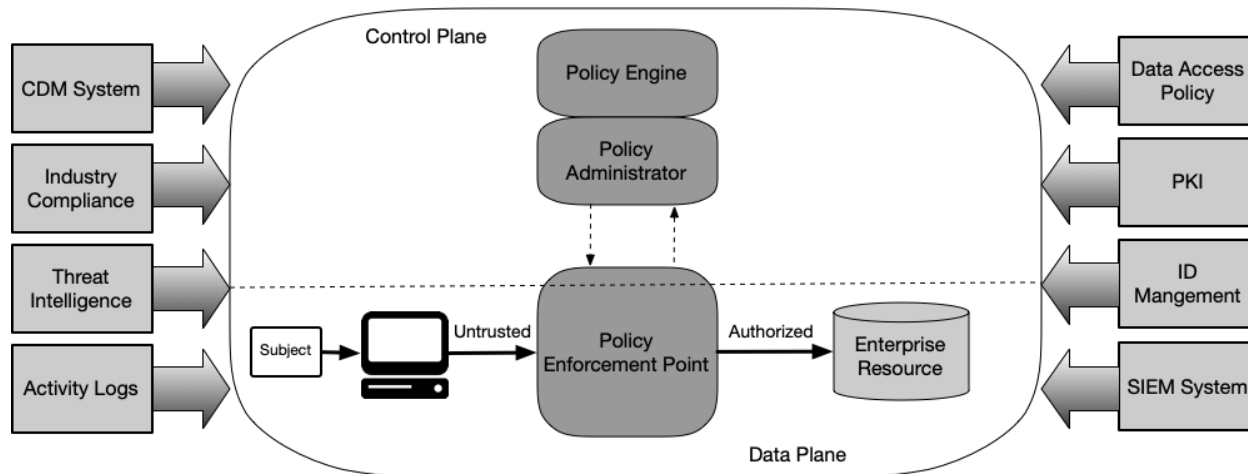

Figure 1: Abstract Zero Trust Logical Architecture

In this diagram, the components are listed as their logical function, and thus do not necessarily represent a single operational system. It is possible that multiple components may serve one logical function in a distributed manner, or a single solution may fulfill multiple logical roles. The roles are described in the SP, but to summarize:

- **Policy Engine (PE):** The “brain” of a ZTA implementation and the components that ultimately evaluate resource access requests. The PE relies on information from the

- 100 various data sources (access logs, threat intelligence, device health and network ID  
101 authentication checks, etc.)
- 102 • **Policy Administrator (PA):** The executor function of the PE. The PA’s role is to  
103 establish, maintain and ultimately terminate sessions in the data plane. The PA, PE and  
104 PEP communicate on a logically (or physically) separate set of channels called the  
105 control plane. The control plane is used to establish and configure the channels used to  
106 send application traffic (i.e. the data plane).
  - 107 • **Policy Enforcement Point (PEP):** The component that applications, devices, etc. will  
108 interact with to be granted access permission to a resource. The PEP is responsible for  
109 gathering information for the PE and following the instructions issued by the PA to  
110 establish and terminate communication sessions. All data plane communications (i.e. all  
111 workflow application traffic) between enterprise resources must go through a PEP.
  - 112 • **Information Feeds:** This is the set of policies, identity and device attributes,  
113 environmental factors and historical data used by the PE to generate resource access  
114 decisions.

## 115 1.1 Tenets of Zero Trust

116 Zero trust could be summarized as a set of principles (or tenets) used to plan and implement an  
117 IT architecture. The tenets below were originally defined in NIST SP 800-207 [1] but are  
118 repeated here and grouped as tenets relating to network identity, device health, or data flows.  
119 Some discussion of the tenets is included, and some considerations that planners should keep in  
120 mind when developing a zero trust architecture.

### 121 1.1.1 Tenets that Deal with Network Identity Governance

- 122 I. **All resource authentication and authorization are dynamic and strictly enforced**  
123 **before access is allowed.** A typical enterprise has a wide collection of network  
124 identities: end users, service accounts, etc. Some end users may have multiple network  
125 identities, and some identities may only be used by hardware/software components. The  
126 enterprise needs to have a governance policy and structure in place so that only  
127 authorized operations are performed, and only when the identity has properly  
128 authenticated itself. The enterprise needs to consider if their current identity governance  
129 policies are mature enough and where and how are authentication and authorization  
130 checks currently performed.  
131

### 132 1.1.2 Tenets that Deal with End Devices

- 133 I. **All data sources and computing services are considered resources.** An enterprise  
134 relies on different resources to perform its mission: mobile devices, data stores,  
135 compute resources (including virtual), remote sensors/actuators, etc. All of these  
136 components need to be considered in a ZTA. Some components (e.g. IoT sensors) may  
137 not be able to support some solutions such as configuration agents, app sandboxing, etc.  
138 so alternatives that use the underlying network infrastructure may be needed. If the  
139 resource lack certain security capabilities, the enterprise may need to add a PEP  
140 component to provide that functionality.

141  
142       II. **The enterprise monitors and measures the integrity and security posture of all**  
143 **owned and associated assets.** This tenet deals with the aspects of cyber hygiene:  
144 configuration, patching, application loading, etc. The state of resources should be  
145 monitored and appropriate action taken when new information such as a new  
146 vulnerability or attack is reported or observed. The confidentiality and integrity of data  
147 on the resource should be protected. This requires enterprise admins to know how  
148 resources are configured, maintained, and monitored.  
149

### 150 1.1.3 Tenets that Apply to Data Flows

151       I. **All communication is secured regardless of network location.** In zero trust, the  
152 network is always considered contested. There should be an assumption that an attacker  
153 is present on the network and could observe/modify communications. Appropriate  
154 safeguards should be in place to protect the confidentiality and integrity of data in  
155 transit. If the resources cannot provide this functionality natively, a separate PEP  
156 component may be necessary.  
157

158       II. **Access to individual enterprise resources is granted on a per-session basis.** In an  
159 ideal zero trust architecture, every unique operation would undergo authentication and  
160 authorized before it is performed. For example, a delete operation following a read  
161 operation to a database should trigger an authentication and authorization check. This is  
162 may not always possible and other mitigating solutions such as logging and backups  
163 may be needed to detect and recover from unauthorized operations. Enterprise  
164 administrators will need to learn how to enforce fine grain access policies on individual  
165 resources. If the current set of tools do not allow this, other solutions such as logging,  
166 versioning tools, or backups may help mitigate risk.  
167

168       III. **Access to resources is determined by dynamic policy—including the observable**  
169 **state of client identity, application/service, and the requesting asset—and may**  
170 **include other behavioral and environmental attributes.** In zero trust, the default  
171 behavior for all resources is to deny all connections with an allow list. The members of  
172 this allow list must authenticate themselves and prove they meet the enterprise policy to  
173 be granted the session. This may include meeting requirements such as client software  
174 versions, patch level, geolocation, historical request patterns, etc. Note that it may not  
175 be possible to perform all check immediately prior to the access request, but some may  
176 be performed recently (e.g. daily software versioning checks).  
177

178       IV. **The enterprise collects as much information as possible about the current state of**  
179 **assets, network infrastructure and communications and uses it to improve its**  
180 **security posture.** Zero trust adds a dynamic response factor that was lacking (or not  
181 possible) in previous perimeter based architectures. System logs and threat intelligence  
182 are used to refine or change policy in response to new information. For example, a new  
183 vulnerability in a software component in use in the enterprise is announced. A zero trust  
184 enterprise would move quickly to quarantine the affected resources until they can be

185 patched or modified to mitigate the newly discovered vulnerability. Enterprise admins  
186 will need to set up and maintain a comprehensive monitoring and patching program for  
187 the enterprise and should consider how automated tools could assist in responding to  
188 newly discovered threats.  
189

## 190 **2 Getting Started on the Journey**

191 Moving to a zero trust architecture will likely never start from scratch, but will involve a series  
192 of upgrades and changes over time. Some changes may be simple configuration changes, and  
193 some may involve the purchase and deployment of new infrastructure; it all depends on what is  
194 currently used and available to the enterprise.

195 The process of migrating to a ZTA is not a unique process and is similar to other cybersecurity  
196 upgrades, improvements, etc. Existing frameworks such as the NIST Risk Management  
197 Framework (RMF) [2] and Cybersecurity Framework (CSF) [3] can help an enterprise discuss,  
198 develop, and implement a ZTA. In the following sections, the RMF will be used to describe a  
199 series of steps and processes that could be used to migrate a workflow to a ZTA.

200 Additionally, there is the Federal CIO Handbook [4] that provides information and links to  
201 relevant policies, mandates and programs that apply to federal agencies. This includes programs  
202 like the DHS Continuous Diagnostics and Mitigation (CDM) program and the Trusted Internet  
203 Connection (TIC) policy that can provide additional guidance and tools for federal agency  
204 administrators as well as planners and managers.

### 205 **2.1 The Process**

206 NIST SP 800-37, Revision 2 [2] describes the Risk Management Framework methodology and  
207 its seven steps:

- 208 • Organizational and system preparation (PREPARE step)
- 209 • System categorization (CATEGORIZE step)
- 210 • Control selection (SELECT step)
- 211 • Control implementation (IMPLEMENT step)
- 212 • Control assessment (ASSESS step)
- 213 • System authorization (AUTHORIZE step)
- 214 • Control monitoring (MONITOR step)

215 While the steps are described in order, after initial implementation, they may be carried out or  
216 revisited in any sequence. The individual tasks that make up the seven steps could be conducted  
217 and revisited as needed, and possibly in parallel with other steps/tasks. The transitions between  
218 steps can be fluid (see figure 2). This is true when developing and implementing a ZTA, as the  
219 dynamic nature of zero trust may require a reiteration or rapid transitions in the RMF steps to  
220 respond to new information or technology changes. The details of the individual steps are  
221 documented in NIST SP 800-37r2 [2] and the accompanying Quick Start Guide [5].

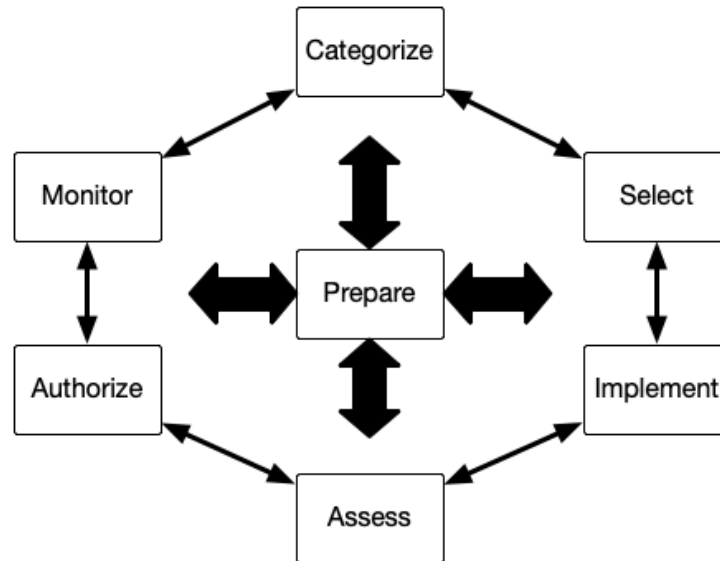

Figure 2: RMF State Machine

222

223

224 For an initial migration, the steps are usually followed in order (but it is not necessary). The  
225 RMF steps are very similar to the high-level steps developed for zero trust by John Kindervag  
226 [11-12] and are partially mapped below. This process assumes the authorization boundary has  
227 been created and the system components used in the workflow are known (i.e. the PREPARE  
228 step has been performed and data collected). There is no explicit CATEGORIZE step as this high  
229 level description was not developed with federal agencies in mind.

- 230 1. Map the attack surface of the resource and identify the key parts that would be targeted  
231 by a malicious actor. These will be covered by the tasks in the SELECT step.
- 232 2. From the PREPARE step (tasks P-12 and P-13), the data flows should be identified and  
233 mapped.
- 234 3. The IMPLEMENT step: Focus on implementing the controls from the SELECT phase on  
235 the resource and related PEP. The PEP may be a separate software component from the  
236 resource itself and is used to meet authentication/authorization related controls. The  
237 underlying network should not be considered trusted, so links between individual  
238 resources must pass through a PEP.
- 239 4. The ASSESS Step: Make sure all access policies developed and put in place during the  
240 IMPLEMENT step are implemented and operating as intended. This would conclude  
241 with the AUTHORIZE step, where the system and workflow is considered in a state to  
242 begin actual operation.
- 243 5. The MONITOR step: Implement the monitoring and management process for the  
244 resource (and its security posture).

245

### 246 2.1.1 Prepare

247 The first step in the RMF process is the PREPARE. When starting the zero trust transition, this  
248 step will may be the longest as a full inventory of roles and enterprise resources is the foundation  
249 of ZT. The Prepare step includes steps and tasks applicable to the Organization and

250 mission/business levels and at the system level. System architects, administrators and operators  
251 will likely only focus system level-based tasks in the PREPARE step but may have valuable  
252 input to the mission/business level tasks. The PREPARE step is primarily focused on preparing  
253 the organization to manage its security and privacy risks using the NIST RMF, and setting up  
254 essential activities at the organization, mission and business process, and system levels.

255 The enterprise architecture team should focus on identifying relevant business processes  
256 (workflows) and systems at the RMF mission/business level. A risk analysis should be done on  
257 each workflow. The owners and key personnel involved in the workflow should be identified  
258 and have input in the analysis, as they may have knowledge and experience about the workflows  
259 that deviate from existing workflow or system documentation. This maps to the organization  
260 level tasks (P-3 to P-7) of the PREPARE step [2].

261 System administrators and operators should focus on identifying the resources that are used to  
262 conduct the identified business processes. These map to the system level tasks (P-8 through P-  
263 18) of the PREPARE step [2]. This covers:

- 264 • Resources involved in each workflow that will be the subject of the security plan. Resources  
265 could fall under two different categories:
  - 266 ○ Workflow specific resources that are used to directly support the given workflow.  
267 Examples would include a single purpose report database and cloud-based application  
268 used to submit reports to that database.
  - 269 ○ General infrastructure resources that are shared by several (or all) workflows.  
270 Examples include network infrastructure (switches, wireless network access points,  
271 etc.), DNS, email, etc.
- 272 • Network identities and governance tools used within the organization. This is not just a list of  
273 end user accounts, but includes service accounts used by software components, device IDs,  
274 etc.
- 275 • Any data classification programs and procedures used within the organization.
- 276 • The current state of monitoring of enterprise resources. One of the foundations of zero trust is  
277 knowledge of data flows in the enterprise. It is vital that an enterprise have a solid continuous  
278 monitoring plan and toolset that can be leveraged before implementing a zero trust  
279 architecture.

280  
281 Once the foundational work of identifying unique workflows and enterprise resources has been  
282 done, the authorization boundaries can be produced (task P-11). Architects and security advisors  
283 should “draw” the boundaries to include only the core required components of the system. The  
284 authorization boundary will likely include any PEP component that provides security  
285 capabilities. Connection between resources within the authorization boundary must also be  
286 secure and not implicitly trusted. Zero trust principles consider the network contested and so  
287 connections between resources within the authorization boundary are subject to the same  
288 controls as connections crossing the authorization boundary (i.e., from outside to within the  
289 boundary and vice versa). Controls that are covered by PEP components may be reusable in  
290 other systems if the same PEP solution is used with other resources, such as some cloud secure  
291 access broker (CASB) or similar solutions when used to provide the PEP component for multiple  
292 different resources (see NIST SP 800-37r2 Appendix G).

293 **2.1.2 Categorize**

294 This step does not change in a ZT planning process. FIPS 199 [5] and FIPS 200 [7] are used to  
295 place resources in a LOW, MODERATE or HIGH category based on its confidentiality,  
296 integrity, and availability requirements in the workflow. The owners of the resource and  
297 workflows that use the resource can be valuable input in this set of tasks.

298 **2.1.3 Select**

299 This step also does not change in a ZT planning process. The baseline controls for LOW,  
300 MODERATE and HIGH-impact systems are listed in NIST SP 800-53B [8]. Additional controls  
301 may be added or removed as part of control tailoring, adjusting the controls to manage risk to the  
302 resource and its position in the workflow. The use of overlays<sup>1</sup> may assist in this, but the overlay  
303 should not be considered immutable, but may need to be adjusted for the unique resource. The  
304 planners should also consider what controls will be met by the PEP, and what may need to be  
305 implemented in the resource itself. As with the CATEGORIZE step, the resource owners and  
306 owners of the workflows that use the resource may provide valuable input in this step. As zero  
307 trust places importance on continual monitoring and updating of security postures, cybersecurity  
308 architects and administrators need to develop a comprehensive monitoring process that can  
309 handle the volume of data needed for the dynamic nature of ZT.

310 In addition to NIST SP 800-53 [9] and SP 800-53B [10], enterprise architects and administrators  
311 may wish to consult other resources as necessary such as the CIO Handbook [4] and TIC 3.0  
312 documents and use cases [9] for other requirements. In particular the TIC 3.0 use case documents  
313 may provide a high level, initial playbook for a potential architecture. These documents may help  
314 in developing the desired set of requirements and security properties for the resource.

315 **2.1.4 Implement**

316 The IMPLEMENT step, like the two previous steps, does not have any ZT specific concerns.  
317 However, as with the RMF and ZT, future monitoring/maintenance operations should be kept in  
318 mind. Administrators may want to avoid solutions that involve frequent human required actions  
319 or do not easily fit into monitoring systems. ZT encourages automation to have dynamic  
320 responses to changing security concerns and manual changes may not be able to keep up with  
321 frequent changes.  
322

323 **2.1.5 Assess**

324 In a zero trust architecture, the assessment of security controls should be continual in the face of  
325 a changing environment. Modern IT environments and trends like DevOps/DevSecOps mean  
326 that a snapshot in time assessment of a system quickly becomes outdated as improvements and

---

<sup>1</sup> An overlay offers organizations additional customization options for control baselines and may be a fully specified set of controls, control enhancements, and other supporting information (e.g., parameter values) derived from the application of tailoring guidance. Overlays also provide an opportunity to build consensus across communities of interest and develop a starting point of controls that have broad-based support for very specific circumstances, situations, and/or conditions.

327 configuration changes are done to mitigate newly discovered threats or changes to the enterprise  
328 infrastructure.

329 In response, the ASSESS step should be thought of as comprising two assessment processes:  
330 continual assessment of the system, and one of the processes used to manage the system. The  
331 process must be assessed as the dynamic nature of zero trust means that the system will likely  
332 change quicker than a human performed assessment program can manage at scale. This  
333 assessment takes factors like the change process into consideration to assess how the system is  
334 modified.

335 The assessment of the system itself should have a continual assessment component based on a  
336 monitoring program [13]. Frequent automated checks or scans should be conducted to detect  
337 changes in the system. Logging data should be used to detect possible malicious behavior that  
338 requires further investigations or remediation. This assessment may also include active processes  
339 such as red team testing of the system as input into the assessments.

#### 340 **2.1.6 Authorize**

341 This step may evolve interpretation in a zero trust architecture (as in the ASSESS step above),  
342 but the goal remains the same. As a ZTA is built to be more dynamic and fluid to respond to  
343 changing network conditions, authorizations should not be viewed as to a static system, but the  
344 system and its processes for changes or updates.

#### 345 **2.1.7 Monitor**

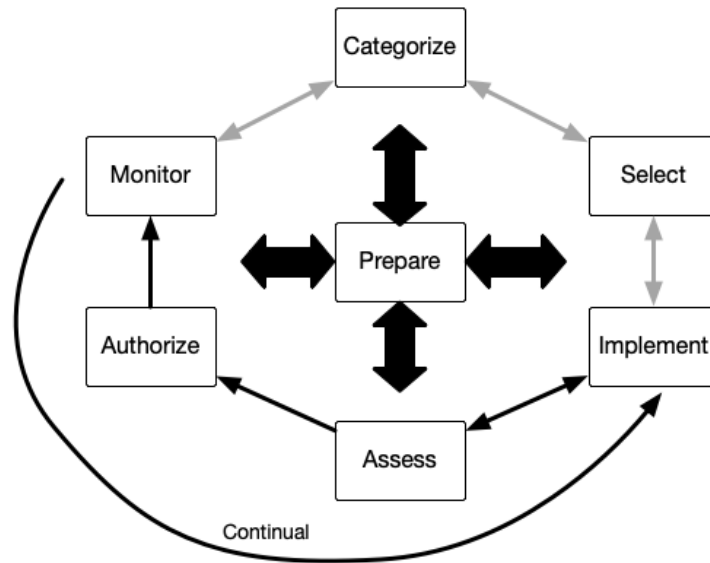

346 As stated previously, zero trust requires the enterprise to monitor the resources used to conduct  
347 its primary mission(s). Exactly how this is done depends on the technology solutions in place in  
348 the enterprise. However, regardless of the technology, the enterprise should have policies in  
349 place to trigger actions based on behaviors seen in monitoring. This may include reacting to  
350 security events or tied to a DevOps process to modify or improve the system.

351 In addition to monitoring the current activity and state of enterprise resources, cybersecurity  
352 planers should consider how external threat intelligence can help in pre-emptive responses to  
353 new conditions. A tool like the .GOVCAR [14] may be useful in prioritizing threats to be  
354 addressed. For federal agencies there are also additional monitoring programs that may assist  
355 such as DHS CDM dashboards [15] and the AWARE [16] program.

#### 356 **2.1.8 RMF Operational Loops**

357 Zero trust lends itself to the use of more dynamic DevOps and DevSecOps style operations. The  
358 cycles of security updates and reviews could be described as involving a subset of the RMF  
359 process. For example, a DevOps cycle for the cybersecurity posture could be expressed as figure  
360 3 below:

361

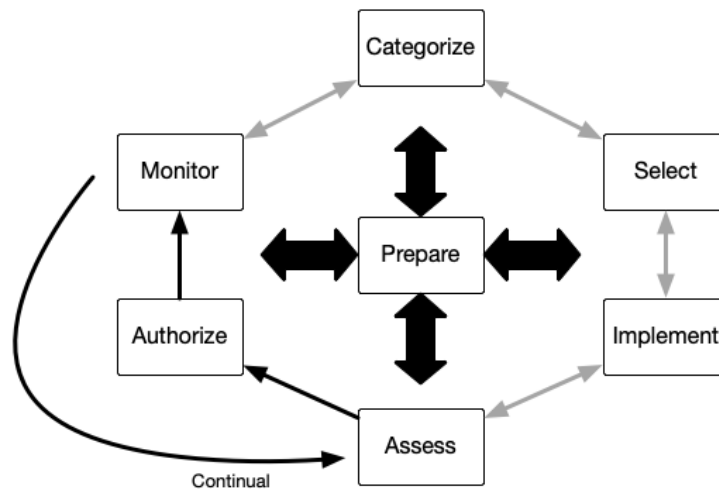

362

363

Figure 3: DevOps Cycle

364 In this loop, the data collected in the MONITOR step then feed back into the  
365 IMPLEMENTATION step as improvements and refinements are implemented, they are then  
366 assessed and follow the continual AUTHORIZE step to enter operations. If necessary, the  
367 DevSecOps team may even fall back to the SELECT step if new information leads to new  
368 controls to be added or existing controls to be removed.

369 Even in a more static IT operational environment (i.e., no DevOps), a zero trust model could be  
370 seen as a loop of only operations. In this loop, there is no DevOps component so the ASSESS  
371 and AUTHORIZE steps are continually cycled as new information is gathered from system logs,  
372 threat intelligence, etc. This may lead to new configuration changes or policy updates. Larger  
373 changes to the operations will be less frequent and involve a longer cycle as other steps outside  
374 of the loop are performed if new information requires a larger change.

375

376

Figure 4: Operations Cycle

377

### 378 **3 Conclusion**

379 Zero trust is not a single technology solution, but a larger cybersecurity strategy and operational  
380 practice. A successful zero trust architecture requires the cooperation of cybersecurity planners,  
381 management, and administration/operations. Zero trust also requires the involvement of system,  
382 data, and process owners who may not traditionally provide input on the risks to their charges.  
383 This input is vital; zero trust is a holistic approach to enterprise cybersecurity and therefor needs  
384 support from every individual in the enterprise.

385 The NIST Risk Management Framework provides a toolset developed to help those who conduct  
386 risk assessments. However, it can also help administrators and operators and others that do not  
387 primarily focus on cybersecurity. This white paper provides a quick overview of the NIST RMF  
388 and provides links and pointers on how administrator and operators can begin understanding the  
389 steps of RMF and how these steps support zero trust. The goal is to provide pointers to IT staff to  
390 help them understand how their roles may evolve in a ZTA and where risk management staff  
391 need to bring in other IT staff to assist in their analysis.
