Economic Evaluation of Windows in Buildings: Methodology

U.S. DEPARTMENT OF COMMERCE • NATIONAL BUREAU OF STANDARDS

NATIONAL BUREAU OF STANDARDS

The National Bureau of Standards¹ was established by an act of Congress March 3, 1901. The Bureau's overall goal is to strengthen and advance the Nation's science and technology and facilitate their effective application for public benefit. To this end, the Bureau conducts research and provides: (1) a basis for the Nation's physical measurement system, (2) scientific and technological services for industry and government, (3) a technical basis for equity in trade, and (4) technical services to promote public safety. The Bureau's technical work is performed by the National Measurement Laboratory, the National Engineering Laboratory, and the Institute for Computer Sciences and Technology.

THE NATIONAL MEASUREMENT LABORATORY provides the national system of physical and chemical and materials measurement; coordinates the system with measurement systems of other nations and furnishes essential services leading to accurate and uniform physical and chemical measurement throughout the Nation's scientific community, industry, and commerce; conducts materials research leading to improved methods of measurement, standards, and data on the properties of materials needed by industry, commerce, educational institutions, and Government; provides advisory and research services to other Government Agencies; develops, produces, and distributes Standard Reference Materials; and provides calibration services. The Laboratory consists of the following centers:

Absolute Physical Quantities² — Radiation Research — Thermodynamics and Molecular Science — Analytical Chemistry — Materials Science.

THE NATIONAL ENGINEERING LABORATORY provides technology and technical services to users in the public and private sectors to address national needs and to solve national problems in the public interest; conducts research in engineering and applied science in support of objectives in these efforts; builds and maintains competence in the necessary disciplines required to carry out this research and technical service; develops engineering data and measurement capabilities; provides engineering measurement traceability services; develops test methods and proposes engineering standards and code changes; develops and proposes new engineering practices; and develops and improves mechanisms to transfer results of its research to the ultimate user. The Laboratory consists of the following centers:

Applied Mathematics — Electronics and Electrical Engineering² — Mechanical Engineering and Process Technology² — Building Technology — Fire Research — Consumer Product Technology — Field Methods.

THE INSTITUTE FOR COMPUTER SCIENCES AND TECHNOLOGY conducts research and provides scientific and technical services to aid Federal Agencies in the selection, acquisition, application, and use of computer technology to improve effectiveness and economy in Government operations in accordance with Public Law 89-306 (40 U.S.C. 759), relevant Executive Orders, and other directives; carries out this mission by managing the Federal Information Processing Standards Program, developing Federal ADP standards guidelines, and managing Federal participation in ADP voluntary standardization activities; provides scientific and technological advisory services and assistance to Federal Agencies; and provides the technical foundation for computer-related policies of the Federal Government. The Institute consists of the following divisions:

Systems and Software — Computer Systems Engineering — Information Technology.

¹Headquarters and Laboratories at Gaithersburg, Maryland, unless otherwise noted; mailing address Washington, D.C. 20234.

²Some divisions within the center are located at Boulder, Colorado, 80303.

PREFACE

The work covered in this report has been conducted within the framework of a National Bureau of Standards (NBS) Interdisciplinary Research project on the energy-related performance of windows. This effort has been supported in part by NBS and in part by the Energy Research and Development Administration (Mode 2 of Contract E(49-1) 3800), jointly with the Department of Housing and Urban Development (Contract No. RT 193012), in conjunction with the Building Energy Performance Standards Program.

COVER: *Windows in houses and in offices can have important effects on their life-time costs and benefits.*

ACKNOWLEDGEMENTS

The authors wish to thank all of those persons in the Center for Building Technology who contributed to the preparation of this report. Special appreciation is extended to Dr. Harold Marshall, Chief of the Applied Economics Program, for his assistance throughout the project; to Dr. Stephen Weber, Dr. Belinda Collins, and Mr. Heinz Trechsel for reviewing the draft report and making many helpful comments; to Ms. Kimberly Hockenbery for her assistance with the computer analysis; and to Ms. Bobbie Cassard and Ms. Cynthia Broussalian for their assistance in preparing the tables, graphs, and figures. Appreciation is also extended to Dr. Douglas Shier of the Center for Applied Mathematics for his excellent review of the report.

Economic Evaluation of Windows in Buildings: Methodology

by

Rosalie T. Ruegg and Robert E. Chapman

Abstract

This study, which is one part of a National Bureau of Standards interdisciplinary project on windows, is aimed at improving the cost-effectiveness of window selection and use in buildings. It develops and illustrates a life-cycle costing evaluation model and computer program for assessing for alternative window systems the net dollar impact of acquisition, maintenance and repair, heating and cooling energy gains and losses, and artificial lighting and daylighting trade-offs. The method is applicable to the evaluation of many different window sizes, designs, accessories, and uses, both for new and existing residential and commercial buildings. Two step-by-step examples of evaluating selected window alternatives in a residence and in an office building in Washington, D.C. serve to illustrate the application of the method.

A companion report, A Regional Economic Assessment of Selected Window Systems, presents the results of eight additional residential case studies and eight additional commercial case studies. While the emphasis of this report is on the method of evaluation, the companion report focuses on summarizing the results of a regional analysis in a form that will be convenient for use by building owners, operators, designers, financiers, and builders, those whose interest centers on the actual implementation of research results.

Key Words: Building economics; daylighting; economic analysis; energy conservation; engineering economics; life-cycle costs; solar heat gain; thermal efficiency; window; window management

SI CONVERSION

In view of the presently accepted practice of the building industry in the United States, common U.S. units of measurement are used throughout this paper. Because the United States is a signatory to the Eleventh General Conference on Weights and Measures, which defined and gave official status to the Metric SI system, the following conversion factors are given to assist users of SI units.

Length 1 in = 0.0254* meter

1 ft = 0.3048* meter

Area 1 in² = 6.4516* x 10⁻⁴ meter²

1 ft² = 0.0929 meter²

Volume 1 in³ = 1.638 x 10⁻⁵ meter³

1 gal (U.S. liquid) = 3.785 x 10⁻³ meter³

1 liter = 1.000* x 10⁻³ meter³

Energy 1 Btu (International Table) = 1.055 x 10³ joule

Power 1 Btu/hr = 0.2930 watt

Temperature °C = $\frac{5}{9}$ (°F - 32)

Illumination 1 ft candle (fc) = 10.76 lux

* Exactly

Facing page: Exterior shading devices and interior draperies are two strategies for reducing the energy costs of windows.

1. INTRODUCTION

1.1 Background

This report is concerned with the impact of window selection and use on the life-cycle costs of office and residential buildings. Particular attention is given to the effect of windows on heating, cooling and lighting costs and to the cost effectiveness of alternative energy conserving strategies. Not all window strategies for conserving energy are necessarily cost effective when their life-cycle costs, including purchase, installation, and maintenance costs, are taken into account. The emphasis here is on a method of identifying energy conserving window strategies that are also cost effective.

As shown in Table 1.1, nearly 27 million windows costing more than \$1 billion are estimated to be installed yearly in new residential units alone. It is estimated that these 27 million windows will subsequently

TABLE 1.1

^a Pittsburgh Plate Glass Marketing Research Department, Pittsburgh, PA.^b The figures for 1 and 2 family houses and apartments are derived as yearly averages of total windows of all materials used in new construction during the period 1970 to 1974, as reported in Architectural Aluminum Industry Statistical Review, Architectural Aluminum Manufacturers Association, Publication No. AAMA-MIR-1-1975, 1975, p. 17. The figure for mobile homes is estimated by multiplying the average number of windows per mobile homes times the average number of mobile home shipments per year during the period 1970 to 1975, as reported in National Association of Homebuilders, "Economic News Notes," Housing Starts Bulletin, Vol. XXIII, No. 1, January 20, 1977.^c This is a conservative estimate based on an average window size of 10 ft².^d This estimate is based on an average cost of \$4.34 per ft² of window area.^e This estimate is based on an average cost of cleaning of \$.10 per ft² of window area.^f This estimate is based on an average cost for recaulking, scraping, and repainting of \$1.50 per ft² of window area once every five years, or an approximate average of \$.30 per ft² every year.^g This conclusion is based on the changes in yearly energy costs observed in applying the model developed in this report to 18 case studies for nine cities in different regions of the U.S. The case studies looked at a range of window systems and uses, ranging from the use of single glazed windows without shading or insulating devices and without utilization of their potential for daylighting to the use of double glazed windows with shading and insulating devices and provision of daylight. [See Rosalie T. Ruegg and Robert E. Chapman, A Regional Economic Assessment of Selected Window Systems, National Bureau of Standards, NBSIR (in Press).]

require an expenditure of almost \$27 million each year for maintenance (cleaning), about \$80 million on the average for yearly repair costs. According to the results of this study, these windows may substantially raise or lower the energy costs of the buildings in which they are installed, depending on how they are designed, sized, located, fitted, and used.¹

Table 1.1 illustrates the potential costs of windows in new residential buildings only. If the total United States stock of residential and nonresidential buildings were considered, the yearly costs of acquisition, replacement, maintenance and repair, and energy would total many billions of dollars. According to an ERDA-sponsored window research program at the Lawrence Berkeley Laboratory in California, about 5 percent of the total national energy consumption is due to windows.² This loss amounts to about one-fourth of the total energy used for heating and cooling buildings in the U.S. each year, the equivalent of 1.7 million barrels of oil per day averaged over the year.³ According to another recent article, the "development of more efficient windows (is) a high priority on ERDA's (DoE's) energy conservation checklist."⁴

While the costs associated with windows can be greatly affected by their selection and use, architects, builders, and building owners often find it difficult to know what is the cost-effective choice regarding windows. The cost-effective choice is often obscured by the multitude and diversity of effects from windows, by the difficulty of measuring certain effects, and also by the fact that there are many available alternative window designs, sizes, and accessories (hereafter referred to collectively as "window systems") which may differ significantly in their costs and benefits. In many cases neither intuition nor attention

¹ For example, results of applying the model developed in this study in a number of case studies showed the yearly energy costs for a typical single family residence to rise or fall by 25 percent by having a window as compared to not having a window, depending on how the window was sized, oriented, and used. [See Rosalie T. Ruegg and Robert E. Chapman, A Regional Economic Assessment of Selected Window Systems, National Bureau of Standards, NBSIR (In press).

² S. M. Berman and S. D. Silverstein, "Energy Conservation and Window Systems," Efficient Use of Energy; The APS Studies on the Technical Aspects of the More Efficient Use of Energy, Part III, LC 75-18227, 1975.

³ "Science and the Citizen," Scientific American, April 1977, p. 58.

⁴ Engineering News-Record, April 21, 1977, p. 12.

to single attributes of windows, such as U values,¹ is adequate to answer the following kinds of questions: (1) Which window system and size will be most cost-effective? (2) How much will it cost to enjoy the benefits of a good view? (3) How will window orientation affect costs? (4) How much should be spent to up-grade the thermal characteristics of windows? and (5) What window accessories will it pay to add? A better method than subjective judgment is needed to evaluate the diverse effects associated with different window strategies in order to arrive at economically sound decisions.

Economic analysis offers a logical approach to bringing together and summarizing, using common measures, the architectural, thermal, and, to a lesser extent, the psychological consequences of alternative window strategies. Although complete quantification may not be possible, measurement of even part of the different kinds of benefits and costs in common dollar terms should substantially improve the ability of the building community to make informed decisions regarding windows.

1.2 Purpose

The broad purpose of this study is to promote cost-effective energy conservation in buildings through improved window selection and use. The specific purposes are (1) to provide a conceptual model for determining the impact of alternative window systems on life-cycle capital, maintenance, and energy costs; (2) to provide a computer program that can be used by the building community to exercise the method of evaluation; (3) to illustrate the use of the method by applying it in two selected case studies; and finally (4) in carrying out the above tasks, to lay the analytical groundwork for the future preparation of a comprehensive set of general guidelines for window selection and use. It develops and illustrates the economic evaluation method that is subsequently applied in a companion report for 18 regional case studies.²

1.3 Scope and Approach

A focus of this report is on determining the impact of alternative window systems on the energy costs of a building. The main focus, however, is on determining the total life-cycle costs of providing alternative window systems. The inclusion of capital, maintenance, and repair costs enlarges the scope of the report from energy-efficient windows to cost-effective windows. By measuring the cost effects of alternative

¹ U = coefficient of thermal transmission. See "Design Heat Transmission Coefficients," ASHRAE Handbook of Fundamentals (New York: American Society of Heating, Refrigerating and Air-Conditioning Engineers, Inc., 1972) pp. 347-371.

² Rosalie T. Ruegg and Robert E. Chapman, A Regional Economic Assessment of Selected Window Systems.

window systems, sizes, orientations, accessories, and management for different scenarios, the model can provide cost information which will be of interest to designers of new buildings who are relatively free to select complete window systems, as well as to owners of existing buildings who are constrained to making their existing windows more economically efficient.

To provide a broader perspective of window performance than previous studies, the window research at the National Bureau of Standards was undertaken as an inter-disciplinary effort. In addition to the economists, the research team included architects, a thermal engineer, and a research psychologist. This economic evaluation of windows draws upon the results of the companion architectural, thermal, and psychological studies for its technical underpinning in these other areas. In the following description of the approach, the particular contributions from the other disciplines are noted.¹

1.3.1 Delineation of Costs and Benefits Treated

The first task in the economics study was to define the kinds of costs and benefits that may arise from windows. These are listed in Table 1.2. This list provided a basis from which to select the items for economic analysis.

"Costs" and "benefits" as listed in Table 1.2 are defined broadly to encompass any sacrifice or gain, respectively, from windows, in terms of money, goods, leisure time, safety, prestige, comfort, or pleasure. Costs of windows arise from the purchase and installation of the windows, their maintenance and repair, their heat loss during the heating season and heat gain during the cooling season, and from undesirable effects on users such as privacy loss, noise, hazards, visual distractions, and reductions in usable interior wall space. Benefits of windows arise from passive solar heat gains during the heating season, the availability of natural ventilation when needed, beneficial daylight, and other desirable features, such as view out and contact with the outside world, enhancement of the appearance of the interior and exterior of the building, and improvement of the morale of building users. An indication of the importance of some of these costs and benefits to users of buildings was provided by a recent literature survey of user reactions to windows made by the psychologist member of the NBS window research team.²

¹ For an overview of the inter-disciplinary project, see Belinda L. Collins, Rosalie T. Ruegg, et. al., A New Look at Windows, National Bureau of Standards, NBSIR 77-1388, January 1978.

² Belinda L. Collins, Windows and People, National Bureau of Standards, Building Science Series 70, June 1975.

TABLE 1.2
Costs and Benefits of Windows

Costs	Benefits
Purchase and Installation	Passive Solar Heat Gain
Maintenance and Repair Costs	Daylight
Undesirable Heat Loss and Gain	Natural Ventilation
Safety Hazard	Higher User Productivity
Noise and Visual Distractions Which Reduce User Comfort or Productivity	User Sense of Well-Being View Out
Undesirable Light, Glare, and Contrast	Enhanced Interior and Exterior Appearance
Loss of Privacy	User Source of Information
Inflexibility in Interior Space Arrangement	Safety Aid for Emergency Entrance and Egress
Undesired Air Infiltration	

It is assumed that the owners of buildings will desire to maximize their net benefits (i.e., benefits minus costs) from the combination of glazed and opaque surfaces in their exterior walls. Ideally, an economic analysis would look for the solutions which maximize net benefits. However, this would require the assigning of dollar measures to each of the items listed in Table 1.2. While there is some precedence for developing dollar measures for safety and psychological factors in other areas, it is difficult to develop dollar measures for windows which are broadly applicable.

For this reason, the focus here is on those costs and benefits whose effects can be measured in dollars with a relatively high degree of confidence. These include the purchase and installation costs, thermal gains

and losses,¹ energy savings through daylighting, and repair and maintenance costs. These are the first three cost items and the first two benefit items listed in Table 1.2. In addition, insurance and tax effects for window systems in commercial buildings are treated.

This focus on owning and operating costs does not mean that the equally important, but difficult to measure, psychological effects are totally ignored. The net dollar costs or savings provided by the life-cycle cost approach can be regarded as measures against which decision makers can compare their estimates of the value of these other effects. While a large element of judgment remains in the decision, the decision maker need not rely completely on subjective choice. The development of economic measures for those types of window effects not presently covered in the economic evaluation model would further guide the selection of cost-effective windows.

1.3.2 Choices in Design and Use

There are numerous choices available in the selection, location, and use of windows.² Many of these choices will affect the energy usage and life-cycle costs of buildings.³ In their recent report, Window Design Strategies to Conserve Energy,³ the architects working on the NBS interdisciplinary window project catalogued the following six broad areas of opportunities for making windows more energy efficient: (1) site selection; (2) use of exterior appendages; (3) choice and treatment of frame; (4) choice of glazing material; (5) use of interior accessories; and (6) treatment of the building interior.

Within these six groups, thirty-three specific "strategies" for making windows more energy efficient are explained. These include, for example, the reduction of winter heat loss through the use of multiple glazing,

¹ Although the economic evaluation model is capable of incorporating the cost effects of natural ventilation, these effects are not included in the case illustrations of the model because at the time of this report the NBS thermal analysis model, which was used to obtain the thermal data needed for the economic model, did not treat natural ventilation.

² A general reference to the different types of window design; the available materials for glazing, frames, and weatherstripping; the various kinds of fittings; the features of design and construction which affect the performance of windows; their costs; and available window accessories is provided by H. E. Beckett and J. A. Godfrey, Windows: Performance, Design, and Installation (New York: Van Nostrand Reinhold Company, 1974).

³ Robert Hastings and Richard Crenshaw, Window Design Strategies to Conserve Energy, National Bureau of Standards, Building Science Series 104, June 1977.

storm sashes, edge-sealed transparent roll shades, and windbreaks; the reduction of night-time heat loss through the use of tight-fitting draperies, opaque roll shades, and insulating shutters; and the reduction of solar heat gain in summer by the use of heat-absorbing and reflective glass, shade tress, and exterior appendages such as sun screens and awnings. Their report describes each strategy; explains the physical phenomena that account for the effect of the strategy; gives the energy and non-energy advantages and disadvantages of the strategy; discusses aesthetic factors to consider in adopting the strategy; indicates the approximate acquisition cost of the strategy; and provides results of applicable laboratory studies, illustrative examples, and references to relevant literature.

The economic evaluation model presented in Section 2 is suitable for analyzing the cost effectiveness of most of the strategies detailed in the NBS report on window design strategies.¹ Similarly, the economic evaluation model is capable of receiving energy data based on comprehensive analysis of the impact of the strategies on the thermal and lighting characteristics of a building. The model's main limitation in this regard is the difficulty in obtaining comprehensive energy data.

In the case illustrations presented in Sections 3 and 4 of this report and in the regional analyses presented in the companion report, a limited number of window strategies are examined. These include choice of window size; choice of orientation; choice of single, double, or triple glazing; use of two interior accessories--venetian blinds and insulating shutters; and use of windows for daylighting.

1.3.3 Method of Treatment

The economic evaluation model--a life-cycle cost model--provides a means of assessing the dollar consequences of choosing alternative options for windows. The model enables us to include relevant costs or savings occurring in the past, present, and future, and to take into account changing prices over time. It brings together the costs of purchasing, installing, maintaining and repairing, and operating a specified window system in a given type of building with a specified orientation, geographical location, and mode of use.

The data required for the model are the purchase and installation costs of the window systems under consideration and of the wall system which would be used in lieu of the windows; the sizes of the windows under consideration; the current maintenance and repair costs per unit size; the different quantities of energy used in the building space for

¹ The only strategies which the model is not capable of handling are those which affect the energy performance of the other elements of the building. An example would be the addition of a fence as a wind barrier. The model cannot apportion capital costs between the window and the other affected building elements.

each of the alternative window options and cases of use; the current price of energy and the expected rate of future price escalation; the technical efficiency of the mechanical heating, cooling, and lighting systems; the interest rate(s) which indicates the opportunity cost of money; and the life expectancy of the window.

For the purpose of the case illustrations in this report and the regional studies in the companion report, purchase, installation, maintenance, and repair costs of the previously listed window options were estimated by consulting manufacturers, builders, and written sources. The operating (energy) costs were obtained by applying a thermal evaluation model developed as part of the NBS inter-disciplinary study of windows.¹ Realistic values for energy costs, system efficiency, interest rates, and expected life were assumed.

A computer program, written in BASIC,² is used to apply the life-cycle cost model. The program calculates life-time energy costs for the interior space with the designated window system, the life-time additional costs of the envelope with the designated window system (as compared with having no window), and the life-time costs of any designated accessories used with the window system, and then sums the results. These calculations are reiterated for specified sizes of the designated window system and for specified orientations. For each orientation, the least-cost window system and size are then identified from among those alternatives for which data are entered into the program. For each least-cost window system, the program computes the net present value of costs and savings, the years to discounted payback (i.e., the elapsed time until cumulative savings offset the purchase and installation costs of the window system),³ and the break-even rate of future fuel price escalation (i.e., the fuel price escalation rate for which the combined costs of accessories, energy, and the windows for the least-cost window system are identical to the corresponding costs associated with having no window).

¹ For a description of the model and case results see, Tamami Kusuda and Belinda L. Collins, Simplified Analysis of Thermal and Lighting Characteristics of Windows: Two Case Studies, National Bureau of Standards, Building Science Series 109, February 1978.

² "BASIC" is an acronym for Beginners All-purpose Symbolic Instructions Code. For a description of the use of BASIC, see BASIC LANGUAGE, Honeywell Software Series 400, Honeywell Information Systems, Inc., August 1971.

³ The payback calculation can be made only if the life-cycle cost of the least-cost window is less than that associated with having no window.

1.4 Organization

The report is organized in five major sections and has a supporting appendix. Section 2 presents the methodology. It provides an overview of life-cycle costing, presents the economic evaluation mode for windows, and formulates a computer program to implement the model. (The computer program is described in the text and is listed in detail in Appendix A.)

In Section 3, the method is applied step-by-step in a case study for a residence in Washington, D.C. In Section 4, the method is again applied step-by-step in a case study for an office building in Washington, D.C. Four measures of life-cycle costs are provided, based on four different levels of thermal analysis.

The final part, Section 5, gives a summary, conclusions and suggestions for further research.

Facing page: The interactive computer program described here can be used to evaluate the life-cycle costs associated with windows in new and existing residential and commercial buildings.

2. LIFE-CYCLE COST METHODOLOGY

2.1 General Description of the Life-Cycle Cost Method

Life-cycle cost analysis is an economic evaluation technique which is used to measure costs over the life of a system. The technique can be applied to alternative systems (investment choices) in order to compare them on an equivalent basis and select the most cost-effective system. The technique involves four main steps: (1) the identification of the relevant cost items for each alternative, (2) the determination of the amounts and timing of cash flows, (3) the conversion of cash flows to a common point in time, and (4) the calculation of net life-cycle costs by summing the discounted cash flows.

In the evaluation of windows, the time adjustment of cash flows, step three, is necessary because windows give rise to cash flows that are spread over time. While purchase and installation costs, i.e., "first costs", are incurred at the outset, other effects, such as maintenance and repair and heat losses and gains, are usually more-or-less continuous over the life of the window. Given that the life of the window generally corresponds rather closely to the life of the building in which it is located, the cash flows associated with a window may extend over a period of 20 to 100 years.¹

There are two factors in the time adjustment: (1) possible changes in prices and (2) the time value of money. With respect to price changes, it is necessary to ensure that all costs and benefits are stated in terms of comparable prices. This requires that past and future prices be adjusted for purely inflationary or deflationary price changes. One way of adjusting "current" (inflated or deflated) dollar amounts to "constant" (level purchasing power) dollars is to apply a price index² to the current dollar amount. For example, based on the 1975 annual average wholesale price index for industrial commodities (1975 = 171.5, where 1967 = 100), a window component that cost \$100 in 1967 would cost roughly \$172 in 1975.³

¹ Assumptions as to the useful life of a building vary greatly. For example, a recent study of educational facilities assumes a life of 40 years for a school. [Educational Facilities Laboratories, The Economy of Energy Conservation in Educational Facilities, (New York: Education Facilities Laboratories, Inc., November 1973), p. 10.] A recent report on public buildings suggests the assumption of a 50 year life for purposes of analysis, but acknowledges that some buildings will have a shorter economic life because replacement will become cost effective and that some buildings will have substantially longer lives than 50 years. [Booz-Allen and Hamilton, Inc., Life-Cycle Costing in the Public Building Service, Volume 1, (A Report Prepared for the General Services Administration, Public Building Service), undated, pp. I-2 and IV-2.] A recent study of university buildings in Canada uses a 60 year cost horizon. [Report on Building Life Costs, (a report prepared by the Council of Ontario Universities), Toronto, Ontario, November 1973, p. 1.14.] Because of the uncertainty associated with future energy prices, as well as with intended use of the building, the period of the analysis is often set substantially less than the expected physical life of the building. As is explained in the discussion of assumptions in Section 3.1, for example, the "period of analysis" for purpose of the case illustrations in this report is defined as 25 years.

² A price index is a statistical measure of the average change in prices over time for a given item or "market basket" of items.

³ U.S. Department of Labor, Bureau of Labor Statistics, Monthly Labor Review, Volume 99, Number 2, February 1976, p. 93.

It is also necessary to take into account changes in prices of particular goods or services relative to general price changes. Altered supply and demand factors can cause some prices, such as for energy, to rise more sharply than is warranted by changes in the purchasing power of the dollar in general. A life-cycle cost analysis needs to take into account any "real" price changes that occur over time.

With respect to the second factor, the time value of money, it is necessary to adjust cash flows to incorporate the opportunity cost which is incurred by using resources for the purpose at hand rather than for the best alternative purpose (i.e., the foregone earnings on alternative investments). The concept of opportunity cost applies regardless of whether there is inflation or deflation and regardless of whether borrowed or equity funds are used, as long as alternative productive investments are possible. If there is a positive opportunity cost, an individual investor or firm will prefer to delay expenditures (costs) and hasten receipts (benefits). The opportunity cost is generally stated as a compound interest rate referred to as the "discount rate." For example, if our opportunity cost were indicated by a discount rate of 10%, compounded annually, we would just break even if we spent \$385.54 today to save \$1,000 ten years from now. (That is, \$385.54 invested at 10% for ten years = \$1000). Similarly, we would be indifferent, other things being equal, between paying \$564.47 now and paying \$1000, six years from now.

Interest formulas, which are listed and explained in most engineering economics textbooks, can be used to discount cash flows to a common time for comparison.¹ Interest factors derived from the interest formulas, and also contained in most engineering economics textbooks, can be used to simplify the discounting calculations.²

2.2 Development of the Model

Table 2.1 lists the main elements in the life-cycle cost model for windows. The impact of windows on energy consumption is the most difficult item of information to estimate. The NBS thermal model,³ used to estimate energy consumption for use in the life-cycle cost model, takes into account climate; thermal resistance of glazed and unglazed portions of exterior wall; window size, directional orientation of the windows; the effects on energy usage of window accessories, internal heat loads such as equipment, people, and lights; and operational factors including

¹ See, for example, Gerald W. Smith, Engineering Economy: Analysis of Capital Expenditures, 2nd Ed. (Ames, Iowa: The Iowa State University Press, 1973) pp. 47 and 50.

² Ibid., pp. 575-621.

changing the thermostat and utilizing daylight. The thermal model, however only applies to a single room in a larger structure and does not take into account natural ventilation effects of operable windows.

An algebraic statement of the life-cycle cost model is given below.¹ The model is designed to assess the life-cycle cost implications of

¹ The model as stated in equation 2.1 is deterministic. As such, it assumes that the timing and values of all cash flows are known. In the event that the timing or values of future cash flows are non-deterministic but governed by a probability distribution (i.e., the timing and values of cash flows are random variables) it is necessary to use probabilistic methods to calculate the present value of the window system cost. [See A. Reisman and A. Rao, "Stochastic Cash Flow Formulae Under Conditions of Inflation," The Engineering Economist, Vol. 18, No. 1, Fall 1972, pp. 49-69; and Young, D. and Contreras, L., "Expected Present Worths of Cash Flows Under Uncertain Timing," The Engineering Economist, Vol. 20, No. 4, Summer 1975, pp. 257-268.]

windows in either residential or commercial buildings. It enables the determination of the least-cost window system and its savings relative to alternative window systems and relative to the wall with no windows. The model also enables the calculation of time to payback and the performance of sensitivity analysis. Assessing sensitivity to fuel prices is particularly important because of the uncertainty attached to present forecasts of long-term increases in fuel prices. The model is also able to assess the impact that different tax structures and depreciation allowances have on the cost-effectiveness of window systems for commercial buildings.

Present Value Costs =

ENERGY COSTS

$$PV = [E_H \times C_H + E_C \times C_C + E_{LE} \times C_{LE}] \times R(1) \times T(1) \\ +$$

PURCHASE AND INSTALLATION

$$+ [PW + IW - A \times CW + ACC \times [PB_A + IB_A + PS_A + IS_A]] \times T(2) \\ +$$

MAINTENANCE, REPAIR, AND REPLACEMENT

$$+ [M_A \times R(2) + M_{BA} \times R(3) + INS_A \times R(2)] \times T(1) \quad 2.1$$

where,

PV = the present value of the acquisition, maintenance and repair costs for the window and its accessories, plus the energy costs for the interior space with the designated window system.

E_H, E_C, E_{LE} = the quantities of energy required for heating, cooling, and lighting and equipment. These quantities incorporate values for the efficiency of heating, cooling and lighting systems.

C_H, C_C, C_{LE} = the current prices per unit of the energy sources used for heating, cooling, and lighting and equipment.

$R(1)$ = the uniform present value factor for a series of end-of-period sums changing by a constant rate, FPE, per period. It adjusts fuel prices for future escalation and sums the per unit expenditure over the expected life. It is defined algebraically as

$$R(1) = \sum_{t=1}^L \frac{(1+FPE)^t}{1+DIS}$$

where, FPE = the rate of fuel price escalation,
DIS = the discount rate, and
L = the expected system life in years.

T(1) = the proportion of operating expenses remaining after taxes.
For residential case applications T(1)=1.

PW = the purchase price of the window.¹

IW = the framing and installation costs associated with the window.

A = the area of the window in square feet.

CW = the cost per square foot for the windowless exterior wall.

ACC = 1 if management accessories are used; 0 otherwise.

PB_A = the purchase price of venetian blinds of area A.

IB_A = the installation price of venetian blinds of area A.

PS_A = the purchase price of a thermal shutter of area A.

IS_A = the installation price of a thermal shutter of area A.

T(2) = a factor which adjusts for the present value of capital depreciation allowances in computing taxable income.

M_A = the cleaning cost in the base year for a window of area A.

R(2) = the uniform present worth factor, used to calculate the present value of constant yearly recurring costs, i.e., cleaning and insurance expenditures. It is defined as

$$R(2) = \sum_{t=1}^L \frac{1}{(1 + DIS)^t} .$$

M_{BA} = the repainting and recaulking costs for a window area A assumed to occur in the fifth year, but evaluated in base year dollars. (M_{BA} is equal to 0 in the commercial case application).

R(3) = the uniform present worth factor used to find the present value of constant future expenditures that occur periodically but not yearly, i.e., repainting and recaulking every fifth year. It is defined algebraically as

¹ Prices would reflect taxes, contractor discounts and contractor markup for overhead and profit.

$$R(3) = \sum_{t=1}^{L/5} \frac{1}{(1 + DIS)^{5t}} .$$

INS_A = the annual insurance cost in the base year for a window of area A. (If yearly recurring repair and replacement costs are not available, insurance premium costs can be used as a proxy for these costs. If the data are available, insurance costs should be expressed inclusive of nonreimbursable expenses and exclusive of reimbursable expenses.)

(Note: $R(2)$ and $R(3)$ are based on M_A , M_{BA} , and INS_A being given in constant dollars and DIS representing a "real" discount rate adjusted to exclude inflation. If, however, the analysis is performed in current dollars, using "nominal" rates that include inflation, it would be necessary to include a price inflation escalation rate in $R(2)$ and $R(3)$, similar to $R(1)$.)

2.3 Flowcharting of the Computer Program

To perform a comparative evaluation of alternative window systems, window sizes, and orientations, and to perform sensitivity analysis, equation 2.1 must be applied a number of times. To facilitate these calculations a computer program was developed. The program, written in BASIC computer language, is designed to provide users flexibility in specifying the values of the critical variables upon which analysis is based. This approach was taken in order to satisfy the dual objectives in developing the evaluation model: to provide a method which others can apply to their particular problem of window selection, and to provide a method for performing the case studies of this and the companion report.

Figure 2.1 shows a detailed flowchart of the computer program. At the beginning of the program the operator is called upon to enter the values of the rate of fuel price escalation (FPE) over the specified life cycle and the discount rate (DIS), and to indicate the types of glazing and building that will be considered. The program automatically assesses the life-cycle cost impacts of single and double glazing; if triple glazing is to be considered 1 is entered; otherwise 0 is entered. To specify whether the building type is residential or commercial, the variable CO is assigned a value of 0 or 1, respectively. If a commercial application is specified, the program will request that an income tax rate be entered.¹

¹ If greater flexibility on the part of the user is desired, additional variables now given in the program may be changed to input variables. For example, expected life is given in the program as 25 years, but the program could easily be modified to allow the life to be entered by the user.

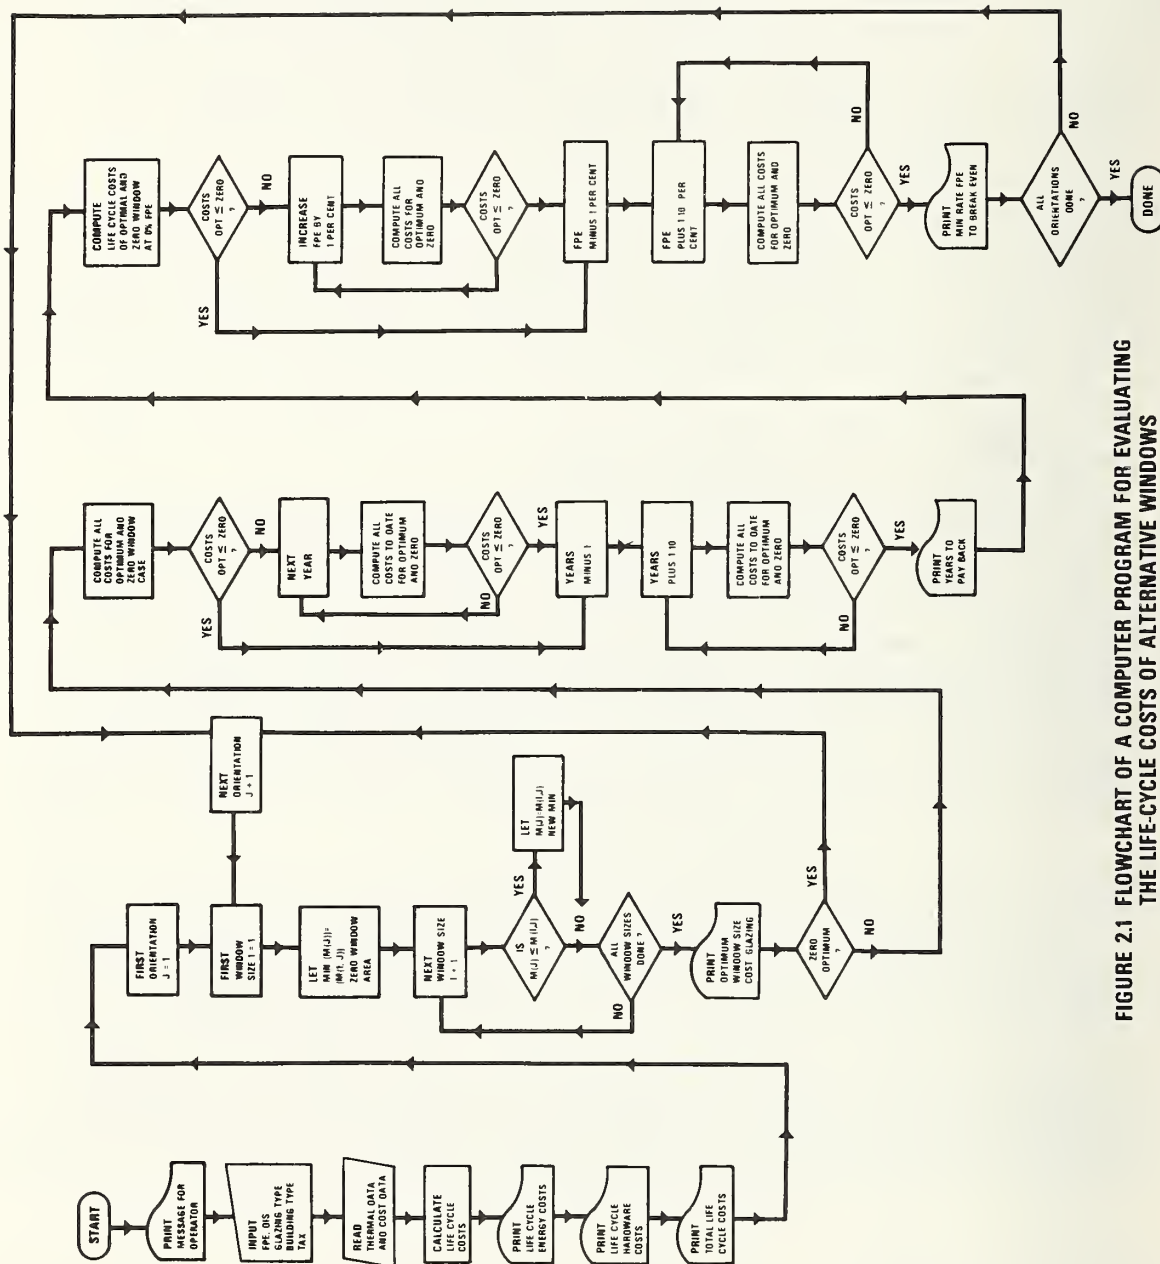

FIGURE 2.1 FLOWCHART OF A COMPUTER PROGRAM FOR EVALUATING THE LIFE-CYCLE COSTS OF ALTERNATIVE WINDOWS

After the values for the key variables have been entered, the computer reads thermal and cost information from its data bank. The data bank is entered at the outset by the user and consists of three sets of thermal data:¹ (1) the heating requirement in therms, (2) the cooling requirement in therms, and (3) the number of kilowatt hours required for lights and equipment; and four sets of cost data: (1) the cost per unit of energy for heating and cooling and of electricity for lighting, (2) the purchase and installation cost of the window less the cost of a comparable wall system, (3) the costs of maintaining, repairing, and replacing the window system, e.g., cleaning, painting, caulking, and insuring, and (4) the cost of window accessories.² Using these data and the values of the variables entered by the user, the computer program calculates and prints three sets of life-cycle cost values for each window size, glazing type, and orientation: one set for life-cycle energy costs; one set for life-cycle purchase, installation, maintenance, repair and replacement (insurance) costs (referred to hereafter as "envelope costs"); and one set for total life-cycle costs (the sum of the first and second sets).

A sample printout of the life-cycle cost tables is shown in Table 2.2. The first two sections of the table give the life-cycle energy costs for single and double glazing, respectively, for designated window sizes and orientations. The third section of the table gives the life-cycle envelope costs. The fourth and fifth sections of the table give total life-cycle costs, again for first single and then double glazing.

Table 2.3 shows the additional outputs of the computer program: (1) the identification of the window system which minimizes life-cycle building costs for each orientation,³ (2) the total life-cycle costs and cost savings resulting from the least-cost window system, (3) the years required for the least-cost system to pay back, and (4) the rate of future fuel price escalation required for the least-cost system to break even.

To derive the above outputs, first the life-cycle costs are examined for the first orientation in the computer program, which is south (J=1),

¹ As the window life-cycle costing program becomes more widely used, thermal and cost data files on selected cities could be established for referencing directly by the user, by inputting only a city file ID. This step would greatly simplify usage of the program and reduce error.

² This thermal and cost data should fit the particular case of window use being examined.

³ The routine for this computation is contained within the second column of blocks in Figure 2.1.

^a South orientation (J = 1).

^b A negative value indicates that the window system would break even relative to the life-cycle costs of a windowless section of wall even if fuel prices declines by 1 percent per annum. A positive value means that the system would break even even if fuel prices increased by the designated percentage rate per annum.

and for the first window size, which is 0 (I=1).¹ These are defined initially as the minimum life-cycle costs. That is, the least-cost window system for orientation J, M(J), is taken to be the zero window case for orientation J; hence, initially M(J) = M(1,J). The next window size (I=2) is then compared with the prior least-cost window. The comparison is performed by testing whether the life-cycle costs of the new window system are less than the life-cycle costs of the preceding window system. If the life-cycle costs of the new window system are less, then a new least-cost window system is designated. The process is repeated for each glazing type and window size until the ones which minimize the window system's life-cycle costs are identified. The computer then prints the following information for the least-cost window system for the given orientation, J: (1) the orientation, (2) the window area, (3) the glazing type, (4) the total life-cycle cost, and (5) the life-cycle savings over the zero window case. If the least-cost window system costs less than an unwindowed section of wall in terms of total life-cycle costs, the program enters the payback routine.² The time to payback is calculated to the nearest tenth of a year. The program then

¹ Throughout this discussion J refers to the orientation of the window and I refers to the size of the window.

² This routine is contained within the third column of blocks in Figure 2.1

enters the sensitivity routine which assesses the effect of the rate of fuel price escalation (FPE) on the cost of the least-cost window.¹

2.4 Graphical Representations

The relationship that exists between life-time energy costs and envelope costs determines the size of the least-cost window. Figure 2.2, parts a through c, illustrates three of the relationships that may exist between these two components of costs. On the vertical axes, life-cycle costs are measured; on the horizontal axes, window area as a percentage of total wall area is measured. The curves labeled "E" represent energy costs; the curves labeled "C", envelope costs for a window minus the cost of a wall of equal size; and the curves "TC," combined energy and envelope costs. The slopes of the curves indicate the impact on costs of changing the window size.²

If the window costs more to purchase, install, maintain, repair, and accessorize than an unglazed portion of the wall of equal size, and also raises the building's energy consumption as its size increases, the least-cost window is no window. This relationship is demonstrated in Figure 2.2a which shows the area of least-cost window, designated A', to be zero.

If the window costs less than an equal area of unglazed wall to purchase, install, maintain, repair, and accessorize, and also reduces energy consumption, the least-cost approach is to glaze the entire wall area. This relationship is illustrated by Figure 2.2b, which shows the least-cost window, A', to be 100 percent of the wall area.

A third possible relationship is for the window to cost more to purchase, install, maintain, repair, and accessorize than an equal area of unglazed wall, but to reduce energy consumption. In this case, the the energy savings potential of the window may be sufficient to more than offset the extra investment costs of the window, and life-cycle building costs may be minimized by having a window larger than zero, but smaller than the entire wall area. This relationship is illustrated by Figure 2.2.c.³

¹ This routine is contained within the fourth column of blocks in Figure 2.1.

² The least-cost window size may be defined in terms of incremental (marginal) costs as that window size for which the last dollar investment in a larger window area produces a dollar in life-cycle energy savings.

³ Other possible relationships between window envelope and energy costs include the following: (1) rising envelope (energy) costs might more than offset falling energy (envelope) costs as window size is increased such that the least-cost window is zero; (2) falling energy (envelope) (continued on page 24)

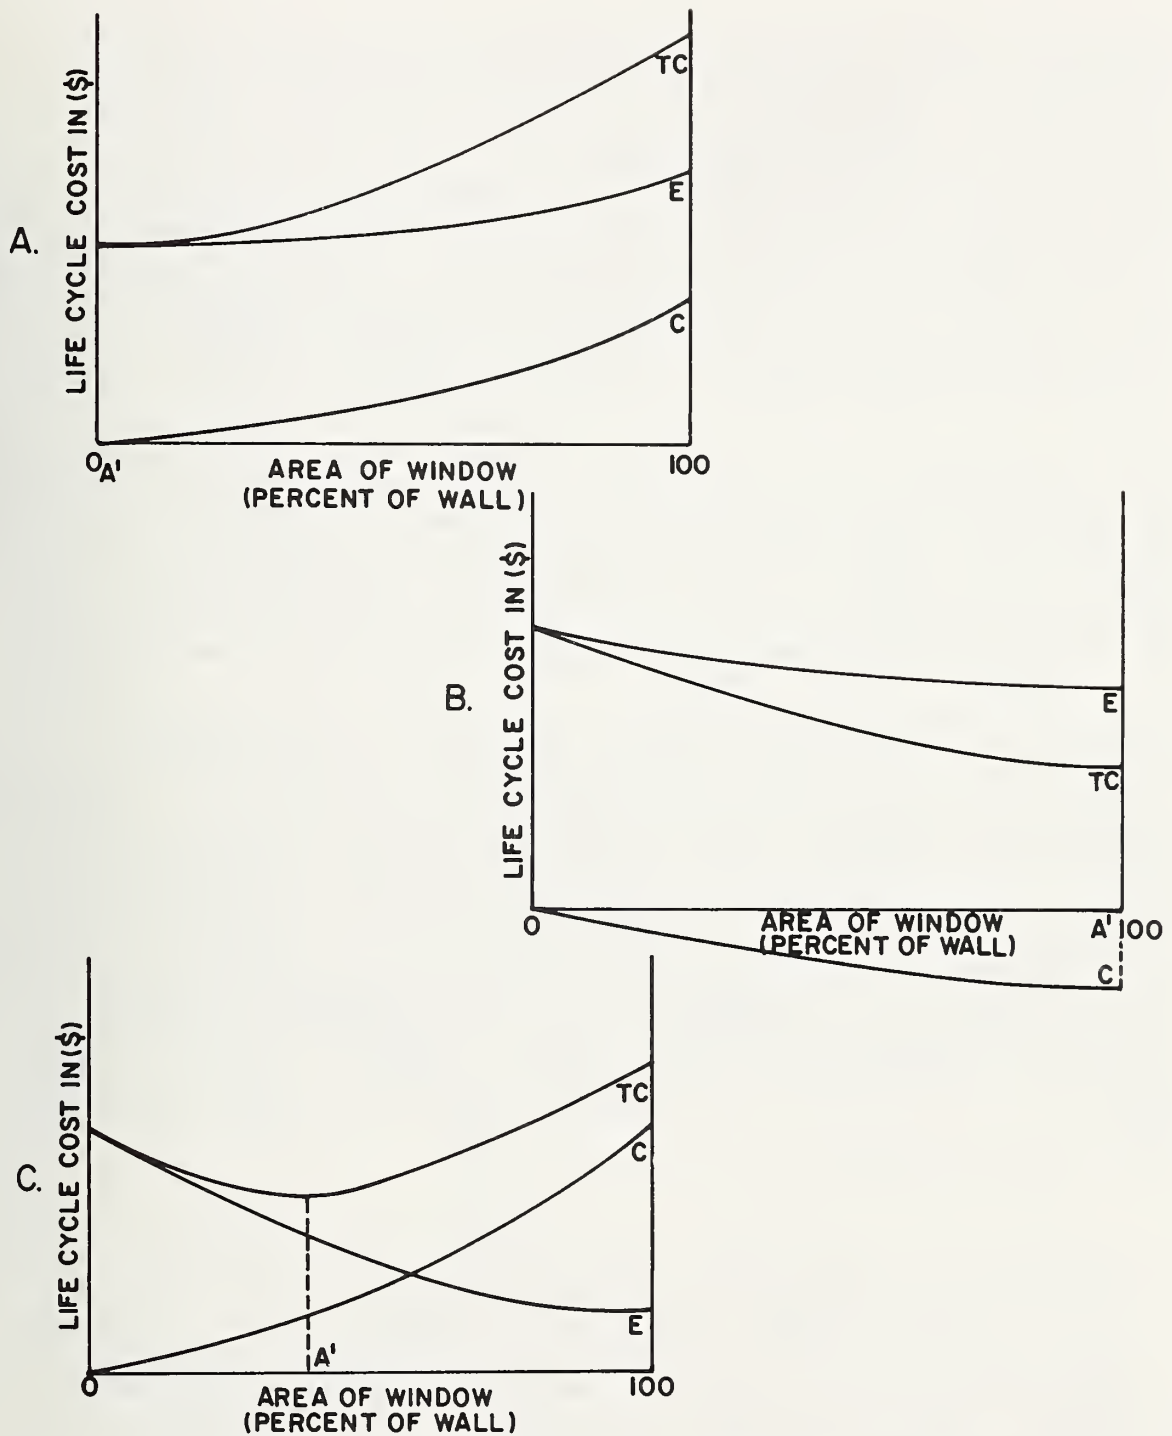

Figure 2.2 Alternative Relationships Between Window Envelope and Energy Costs

Notation: E = Energy costs of the interior space with a window of designated size,
 C = Envelope costs attributable to a window of designated size,
 TC = Combined energy and envelope costs.

Life-cycle costs may also be represented graphically as a function of window orientation. The results convey considerable information simply and compactly. The graphs shown in Figures 2.3a through c use polar coordinates to represent the different orientations. For example, the top vertical line may be designated as north and the bottom vertical line as south, as is shown in the graphs. The curves that are equally distant from the center of the graph are designated as equal-cost, or isocost, curves. For example, on Figure 2.3a, the first curve from the center indicates life-cycle costs of \$250, the second indicates \$500, the third \$750, and the fourth, \$1000. To complete the diagram, a series of curves can be drawn that plot life-cycle costs against orientation for each window size.

To differentiate these curves from the isocost curves, they are referred to as equal-window area, or "isoarea", curves. On Figure 2.3a, the curve designated "0" is the isoarea curve for a window of size zero. It shows the life-cycle costs associated with the windowless case for the alternative orientations. The case with no window is shown because the cost effectiveness of alternative window systems can be measured by comparing their life-cycle costs with those of the alternative wall investment.¹

Figure 2.3b shows, in addition to the isoarea curve for the case with no window, two isoarea curves designated "A₁" and "A₂" that represent a single-glazed window system and a double-glazed window system, respectively, both of size A. With these three curves overlaid, it is possible to construct a least-cost envelope, and to see which of these window areas and glazing types are least costly with respect to orientation. The envelope is constructed by making a fourth curve which consists of the innermost segments of the three existing curves. This envelope, illustrated in Figure 2.3c by a heavy solid line, shows for each orientation how large the window should be and whether single or double glazing should be used in order to achieve the lowest life-cycle cost. In this illustration, for example, when facing north, a windowless wall results in lowest costs; when facing south, a single-glazed window of

(Continued from page 22)

costs might more than offset rising envelope (energy) costs such that the least-cost window size is 100 percent of the wall area; (3) the fall in envelope (energy) costs might just offset the rise in energy (envelope) costs such that there is indifference from a cost standpoint between having and not having windows. The possibility of non-monotonic energy and envelope costs means that more than one minimum may occur for certain cases.

¹ It may be noted that any positive window area could be used as a standard for comparison. However, using the case of no window as the standard has the following advantages: (1) it explicitly allows for the option of having no windows, and (2) it does not favor any particular minimal window size.

Figure 2.3 Window Life-Cycle Costs in Relationship to Window Area and Orientation

area A; and on the east and west, a double-glazed window of area A. By comparing the least-cost envelope with the other curves, 0, A₁, and A₂, the extra costs may be seen of using the same size and type of window system for all orientations.

2.5 Limitations of the Model

In interpreting the results obtained from the life-cycle cost model, the potential importance of factors omitted from the model should not be overlooked. Factors such as the influence of windows on the physical and psychological comfort of occupants, the internal and external appearance of the building, and safety may cause the optimal window to differ from the least-cost window as defined in the model.

Furthermore, the results of the model apply only to the particular situation described by the data and assumptions used. It should be recognized, for example, that the NBS thermal model used here to generate thermal data for the life-cycle cost model is itself based on many assumptions about thermal loads, climate, functional properties of windows, and user operational behavior. In addition, it omits certain factors such as natural ventilation, and there is uncertainty about other factors such as its daylight, artificial light trade-off routine.

The life-cycle cost model nevertheless serves to reduce uncertainty about the energy costs and economic efficiencies of alternative window choices, although it does not provide a truly comprehensive measure of all benefits and costs. The life-cycle costs of alternative window systems can be viewed as measures against which decision makers can compare the importance of other factors.

Facing page: Nearly 27 million windows costing more than \$1 billion are estimated to be installed in new residential units each year.

3. ILLUSTRATION OF THE METHODOLOGY: RESIDENTIAL CASE STUDY

The following is a detailed illustration of the method of evaluation developed in Section 2 of this report. The illustration is for selected window systems in a room of a residence assumed to be located in Washington, D.C. (The room is referred to hereafter as the "residential module.")

The primary purpose of the illustration is to demonstrate the evaluation approach in sufficient detail to guide others in using the model with their own data. A secondary purpose is to derive results which are useful to the building community in selecting, accessorizing, and using windows. Because the primary objective is that of illustration, a detailed, step-by-step approach is provided.

3.1 Basic Assumptions

The residential module is assumed to be a kitchen/family room in a one story ranch-style house with a full basement. The overall dimensions of the house are 28 feet wide by 50 feet 6 inches long, and the total floor area is 1414 square feet. The layout of the house including the location of windows and doors is shown in the floorplan in Figure 3.1. The kitchen/family room shown shaded in the floorplan, is used for the purposes of both the thermal and the economic analysis of the alternative window systems. The dimensions of the room are 15 feet wide by 18 feet long by 8 feet high.

The exterior wall of the house has 4" brick veneer over 8" cinder block, and contains 3-1/2" of blown-in insulation (cellulose). The U value of the wall is 0.07.

The windows used in the economic analysis are wooden and double hung. Both single and double glazing are examined for window sizes ranging from 0 to 60 square feet. Figure 3.2 shows the four window sizes examined in relationship to the size of the exterior wall. Additional assumptions, such as lighting requirements, heating and cooling system efficiencies, and occupancy patterns are given in Table 3.1.

The NBS thermal model which is used to provide input to the economic model assumes that all heat flows entering or leaving the room are through the exterior wall which contains the window. It is therefore explicitly assumed that no heat flows occur between the room under examination and the basement, attic, or adjacent rooms. (Such a system is usually referred to as adiabatic.)

Furthermore, the thermal model does not take into account the interdependencies between building components that may result in a change in one factor affecting the thermal performance of other factors. To account for all possible heat flows and thermal interdependencies would require a considerably more sophisticated thermal model than that which was used in the case studies.

The simplifying assumptions employed in the thermal model result in specific limitations for the life-cycle cost measures produced by the economic model for the case study. One limitation is that the life-cycle costs of the windows for the single room cannot be multiplied by a constant, say, 6 or 8 depending upon the size of the house, in order to get the life-cycle window costs for the entire house. One reason is that the computer program assumes that there is only one exterior wall in the room. Since all residences have some corner rooms which have two or more exterior walls, the assumption that there are no heat flows through these walls is overly strict. Another reason is that most houses do not have basements and attics with regulated temperature. The fact that the thermal model makes no allowance for the effects of natural ventilation on energy usage further limits the reliability of the life-cycle cost measures produced by the case study. But the most tenuous aspect of

Figure 3.1 Plan of House Used in the Case Study

TABLE 3.1 Assumptions for Residential Case Study^a

Building Specifications	Assumptions
Dimensions of Module ^a	15' wide x 18' long x 8' high
Type of Construction	Block with brick veneer; 3-1/2" cellulose insulation; U = 0.07
Exterior Wall Area	144 ft ²
Window Size	0, 12, 18, 30, 60 ft ²
Window Construction	Wood; double hung; weatherstripped
Internal Loads ^b	
Lights	0.65 watts/ft ²
Equipment	0.52 watts/ft ²
Air Leakage	0.5 air changes/hour
Occupancy	0.5 persons
Heat Load/person	260 But/hour/person
System Efficiency	Specifications
Furnace Efficiency	0.65
Cooling COP ^c	2.0
Electric Heating	1.0
Fuel Type	Costs
Electricity	\$0.03 per kWh
Gas	\$0.30 per therm
Operation	Conditions
Thermostat Adjustment	72° to 62° F winter nights 78° to 84° F summer nights
Window Management	Times
Thermal Shutters	Winter nights
Venetian Blinds	Summer days

^a Due to the difficulty of modeling the thermal exchange between rooms, only a single room was modeled. The model assumes no heat transfer to adjacent surfaces such as walls, floors, or ceilings. Study of windows within a single room of a house may not necessarily reflect the performance of windows in the house in general.

^b All loads are averaged over the 16 hour period from 7:00 AM to 11:00 PM. The assumptions underlying the thermal calculations are described in greater detail in Tamami Kusuda and Belinda Collins, Simplified Analysis of Thermal and Lighting Characteristics of Windows: Two Case Studies, February 1978, pp. 10-20.

^c COP = Coefficient of Performance.

the case study is the assumption made in the thermal model concern daylighting. Although the amount of daylight predicted by the daylight computer subroutine has now been validated against two other considerably different computer programs,¹ available amounts of daylight and the concomitant savings in electric energy for lighting and cooling have not been adequately validated by laboratory and field testing.²

In addition, there are questions about people's actual use of daylighting to supplement or replace electric lighting. Typical lighting levels and duration of use in residences are not well established, nor is the human response to available daylight well determined.

A further limitation of the case study is that it compares daylighting only with general lighting of the room by incandescent bulbs; for other solutions, such as task lighting, daylighting might have less value.

3.2 Envelope Costs

In general, purchasing and installing windowed areas in a home is more expensive than providing windowless walls. However, because windows displace portions of the wall, they raise initial building costs by substantially less than their full purchase and installation costs. To estimate their additional acquisition costs, window costs are compared with wall costs in Table 3.2. This table shows that purchase and installation of good quality wood windows are estimated to add between \$18 and \$76 to initial building costs for single-glazed windows and from \$48 to \$216 for double-glazed windows, depending on their size. Window prices are distributor-quoted for the Washington, D.C. area. The wall costs are the estimates of a builder of homes in the Washington, D.C. area.

If management devices are used, additional acquisition costs are incurred. Costs of venetian blinds and wooden shutters based upon averages of currently quoted prices in the Washington, D.C. area are given in Table 3.3.

Window areas also usually require somewhat more maintenance than windowless wall areas. Estimates of window cleaning costs, based on a current cost of \$0.10/ft², are shown in the first row of Table 3.4. Estimates of maintenance and repair costs based on scraping, recaulking, and repainting once every five years at a current cost of \$1.50/ft², are shown in the second row of Table 3.4.

¹ The other computer programs are LUMEN II and GLIM, two more complex programs used for lighting calculations in the United States and in Great Britain.

² A research program is currently underway at NBS to validate both the predicted daylight amounts and the energy savings.

TABLE 3.2

Residential Case Study:

Acquisition Costs of a Window in Excess of the
Cost of a Windowless Wall

Component	Dollar Cost By Size of Window			
	12 ft ²	18 ft ²	30 ft ²	60 ft ²
Windows ^a				
Single Glazed	52.20	70.70	122.55	245.10
Double Glazed	81.80	109.36	192.61	385.23
Wall ^b	33.72	50.58	84.30	168.60
Window Cost Less Wall Cost ^c				
Single Glazed	18.48	20.12	38.25	76.50
Double Glazed	48.08	58.78	108.31	216.63

^a Purchase prices are list retail prices, reduced 10 percent to reflect a typical builder's discount, for good quality wood double-hung windows, provided by a distributor in the Washington, D.C. area. A typical contractor markup of 25 percent for overhead and profit is then applied to the purchase price. Prices are for single and multiple units of windows of a size which comes close to providing the designated areas of the exterior wall in glazing. The 12 ft² area is provided by a 3' x 3'11" window; the 18 ft² area, by a 3' x 6' window; the 30 ft area by two 3' x 5' windows, and the 60 ft² area, by four 3' x 5' windows. An installation cost of \$5.00 per window or pair of window is used, based on an estimate given by a home builder in the Washington, D.C. area. The installation cost and the purchase cost are then added together to get the acquisition cost.

^b Costs of non-windowed wall areas corresponding in size to the windowed areas are based on a price of \$2.81/ft² as estimated by a home builder in the Washington, D.C. area. The wall section is assumed to be face brick veneer over 8" cinder block with building paper sheathing, 3 1/2" of cellulose insulation, and 1/2" of painted interior drywall.

^c The additional costs incurred for windows are calculated by taking the difference between the costs of windows and the costs of a comparably sized wall area.

TABLE 3.3

Residential Case Study:
Cost of Window Accessories

Type of Accessory	Dollar Cost by Size of Window			
	12 ft ²	18 ft ²	30 ft ²	60 ft ²
Venetian Blinds ^a	17.00	20.00	36.00	72.00
Wood Thermal Shutters ^b	42.00	51.00	96.00	192.00

^a Prices shown are average of several quoted prices. Installation is assumed to be done by the homeowner at negligible costs.

^b Estimates are those of a Washington area building contractor for building, installing, and finishing solid, tight-fitting wooden shutters. (Prices quoted by custom drapery shops in the area were considerably higher.)

(Recurring 5th Year Cost)				
Scraping, Recaulking, Repainting ^a every 5th Year at \$1.50/ft ²	18.00	27.00	45.00	90.00

^a Costs are based on a large sample of data collected in conjunction with a lead paint abatement program at NBS (R. Chapman, Economic Analysis of Experimental Lead Paint Abatement Methods: Phase I, National Bureau of Standards, Technical Note 922, September 1976.)

3.3 Energy Costs

Due to the uncertainty about future energy prices, energy costs of the windows are evaluated first based on no future escalation in energy prices and then on a relatively rapid rate of increase of 12 percent compounded annually, to establish a range of possible costs. In addition, energy costs are assessed for both natural gas, a currently less expensive energy source, and electric resistance energy, a more expensive energy source. (The room is assumed to be electrically cooled regardless of whether heating is by natural gas or electric resistance energy.)

In order to take into account the fact that windows are used in diverse building situations, their energy effects are evaluated for four different cases.

In the first case (referred to hereafter as the "unmanaged window, not used for daylighting" case), it is assumed that no energy conserving devices such as shutters and blinds (hereafter, referred to as "management devices") are installed in the window. The thermal calculations are based on traditional ASHRAE methods.¹ Included in the calculations is the heat generated by the people occupying the room and by lights and equipment (e.g., televisions, dishwashers, stoves, garbage disposals), as well as climate-determined heat gains or losses.² The climatological data are monthly mean daily temperature and solar radiation figures published by Kusuda and Ishii.³

The second and third evaluation cases are extensions of the first case. The second case (referred to as the "managed window not used for daylighting" case) assumes that management devices are used and that the desired room temperature is changed between day and night by adjusting the thermostat. Venetian blinds are used during the summer day to reduce excessive solar heat gain. Thermal shutters are used during winter nights to cut heat losses. It is assumed that the thermal shutters are custom fitted into the window opening. The combination of single glazing and the shutters result in a U value of 0.5; the combination of double glazing and the shutters result in a U value of 0.2. The resetting of the thermostat at night permits both heating and cooling costs to be reduced regardless of whether the room is windowless or has windows. During the heating season the thermostat is reset from 72°F to 62°F, and during the cooling season the thermostat is reset from 78°F to 84°F.

¹ ASHRAE, Handbook of Fundamentals, 1972.

² In this study a base temperature of 65°F is used for heating degree day calculations (See ASHRAE Handbook of Fundamentals, 1972); a base temperature of 80° is used for cooling calculations.

³ Kusuda, T. and Ishii, K., Hourly Solar Radiation Data for Vertical and Horizontal Surfaces on Average Days in the United States and Canada, National Bureau of Standards, BSS 96, April 1977.

In all other ways, the analysis for the second case of window use is identical to that of the first.

The third case of window use (referred to as the "unmanaged window used for daylighting" case) assumes that daylighting is substituted for electric lighting when the quantity of daylight available exceeds 6.7 fc (72.1 lux) measured at a reference point 15 ft (4.2 m) from the window and 3 ft (0.9 m) from the floor. This case further assumes that no management devices have been installed and that the thermostat is not reset at night. Hence, the third case is identical to the first with the exception of the trade-off between natural and artificial lighting.

In the fourth case of window use (referred to as the "managed window used for daylighting" case), daylighting is substituted for electric lighting, window management is practiced, and the thermostat is reset at night. Thus the fourth case brings together all of the elements of the first three cases. It is the case that would be expected to have the greatest potential for energy conservation.

As was indicated above, the third and fourth modes of operation--those which utilize daylighting--are unfortunately subject to more uncertainty than those which do not use daylighting. As was explained earlier, this is because the computer program which calculates the natural/artificial light trade-off has not yet been adequately validated.

3.3.1 Energy Costs for Unmanaged Windows Not Used for Daylighting

First the energy costs for different window sizes and glazing types are analyzed based on a bare, unmanaged window, not used for daylighting. Figure 3.3 shows base-year energy costs for single glazing in Part A and for double glazing in Part B, for two orientations. On the vertical axis of both graphs the estimated base-year energy expenditure is given in 1977 dollars. On the horizontal axis the window area in square feet is given.¹

Parts A and B of Figure 3.3 show that base-year energy costs rise rapidly as window area is increased whether it is single or double glazed, although the rise is more rapid with single glazing. In the base-year, energy costs of the room heated by natural gas range from \$66 for a windowless wall with a southern orientation, to \$83 for a 60 ft² single-glazed window with a southern orientation. On the north side, costs range from \$66 to \$90.

If the room is heated by electricity, the base-year energy costs range from \$70 for a windowless wall on the south side, to \$102 for a 60 ft² single-glazed window on the south side. For a northern orientation,

¹ The format used in Figure 3.3 will be followed throughout the chapter. Recall that these energy costs are for the room indicated on Figure 3.1 and not for the entire house.

PART A: SINGLE GLAZED

PART B: DOUBLE GLAZED

Figure 3.3 Base-Year Energy Costs for the Residential Module for North (N) and South (S) Facing Unmanaged Windows Not Used for Day-lighting (Gas and Electric (Elec) Heating and Electric Cooling)

costs range from \$70 to \$118. Thus, room energy costs in the base year are increased as much as \$24 by a large single-glazed window when gas heating is used and as much as \$48 when electric heating is used. This means that the additional energy costs attributable to windows will be substantial over the life-cycle.

Part B of Figure 3.3 shows that double glazing reduces the additional energy costs from a maximum yearly amount of \$24 to \$9 when gas heating is used, and from \$48 to \$14 when electric heating is used.¹ Although double glazing reduces the base-year energy costs of the window, it does not altogether eliminate the negative effects of increasing window size.²

Figure 3.4 shows the annual energy costs of Figure 3.3 converted to a life-cycle basis, assuming no change in future energy prices. Part A shows that when gas heating is used, even at fixed energy prices, a 60 ft² single-glazed window can raise life-cycle energy costs for the room by about \$175 (from \$720 to \$895) for southern orientations, and by about \$250 (from \$720 to \$970) for northern orientations. Life-cycle energy costs are raised even higher when electric heating is used, ranging from an increase of about \$350 (from \$740 to \$1090) for southern orientations, to about \$500 (from \$745 to \$1245) for northern orientations. Part B of Figure 3.4 shows that the increases in life-cycle energy costs are significantly reduced by the use of double glazing.

The assumption that energy costs will not rise is very conservative in light of the current energy crisis. With escalating energy prices, the the energy costs attributable to bare, unmanaged windows could be considerably higher than shown in Figure 3.4. For example, Figure 3.5 indicates the impact on life-cycle costs of energy prices rising at a rate of 12 percent compounded annually.

The reference point (i.e., the room's life-cycle energy costs when it has no windows) increases from \$720 with gas heat fixed in price, to \$2800 with gas heat escalating in price at a 12 percent rate. With large, single-glazed windows on the north side, the life-cycle energy costs for the room may now exceed \$3700 for gas heating and \$4800 for electric heating. This means that the windows would raise life-cycle energy costs by between \$1,000 and \$2,000, depending on the type of energy used. Part B of Figure 3.5 indicates that the savings potential of double glazing becomes more important the higher the rate of energy price escalation.

¹ Similar reductions would result if storm windows are installed initially or later retrofitted over single-glazed windows.

² It was found that annual energy costs increased for all orientations and for both glazing types as window area increased whenever the case of window use was assumed to be a bare unmanaged window.

Figure 3.4 Life-Cycle Energy Costs at Constant Energy Prices for the Residential Module for North (N) and South (S) Facing Unmanaged Windows Not Used for Daylighting (Gas and Electric (Elec) Heating and Electric Cooling)

Figure 3.5 Life-Cycle Energy Costs at 12% Escalation for the Residential Module for North (N) and South (S) Facing Unmanaged Windows Not Used for Daylighting (Gas and Electric (Elec) Heating and Electric Cooling)

3.3.2 Energy costs for Managed Windows Not Used for Daylighting

Let us now see how the second case of window use, the addition of window management devices complimented by a nighttime temperature adjustment, affects energy costs. The evaluation procedure follows that of the first case.

Figure 3.6 plots the base-year energy costs for single glazing in Part A and for double glazing in Part B. In both Parts A and B of Figure 3.6, the energy cost curves remain approximately horizontal as the window area is increased, with the exception of single-glazed windows facing north. This means that the energy costs of the room are not substantially different whether it is windowless or has windows, even large ones, provided they are not single-glazed windows facing north. The use of management devices and adjustment of the thermostat have reduced dramatically the energy costs below those found in the first case.

With no escalation in fuel prices, the life-cycle costs follow about the same trend as the base-year costs, and there is little difference in the life-cycle energy costs of the room with and without windows. The exception is for single-glazed windows facing north, and even those differences are not large.

When energy prices rise at a rate of 12 percent per year, life-cycle energy costs are about quadrupled. The windowless room now requires an expenditure of \$2700, as shown by Figure 3.7, Parts A and B.

The energy costs attributable to the windows, however, continue to be considerably lower than those for the first case. Double glazing, though still important as a means of reducing energy use, does not result in as large a savings when blinds and shutters are used and the thermostat is adjusted at night, as when the windows are bare. The higher the rate of fuel price escalation, the more important double glazing becomes.

3.3.3 Energy Costs for Unmanaged Windows Used for Daylighting

Let us now examine the third case which includes the utilization of daylight as an alternative to electric lighting, but excludes the use of window management and thermostat adjustment.

Figure 3.8 shows base-year energy costs for the residential module to range from \$68 with no windows, to as high as \$98 with a large, single-glazed window facing north and with electric heat, to as low as \$44 with a moderate size, double-glazed window facing south and with gas heat. In both Parts A and B of Figure 3.8, energy costs fall off quickly as window area is increased. However, as window area is increased further, energy costs begin to rise. This pattern of initially falling and then rising energy prices reflects the fact that once the level of daylight is sufficient to turn off the electric lights the model ceases

Figure 3.6 Base-Year Energy Costs for the Residential Module for North (N) and South (S) Facing Managed Windows Not Used for Daylighting (Gas and Electric (Elec) Heating and Electric Cooling)

Figure 3.7 Life-Cycle Energy Costs at 12% Escalation for the Residential Module for North (N) or South (S) Facing Managed Windows Not Used for Daylighting (Gas and Electric (Elec) Heating and Electric Cooling)

Figure 3.8 Base-Year Energy Costs for the Residential Module for North (N) or South Facing Unmanaged Windows Used for Daylighting (Gas and Electric (Elec) Heating and Electric Cooling)

to attribute energy savings to daylighting.¹ Undesirable heat flows, on the other hand, tend to increase as window area increases, offsetting beyond a certain window size the potential gains from daylighting.

The life-cycle energy costs for the third case are particularly interesting because a large potential for savings exists. For example, with constant energy prices, gas heating and no windows, life-cycle energy costs for the room amount to \$720. Adding a 12 ft² single-glazed, south-facing window causes energy costs to fall to \$510. Increasing its size to 60 ft² raises energy costs to \$610, still significantly below the room's energy cost with no windows.

The utilization of daylight becomes more attractive the higher the rise in the cost of electric lighting. (The heating and cooling costs associated with windows, however, continue to rise, the higher the energy costs.) Figure 3.9, which assumes that all energy prices increase at the rate of 12 percent per year, shows the life-cycle costs for the windowless room to be about \$2800. It further shows that, with the use of daylighting, double-glazed windows facing north side may save as much as \$900 when gas heating and electric lighting is used, and \$630 when electric heating and electric lighting is used. By comparing Figure 3.9 with Figure 3.5 (the first case), we can see the considerable potential of daylighting for conserving scarce energy resources and for reducing the homeowner's utility bills.

3.3.4 Energy Costs for Managed Windows Used for Daylighting

In the fourth case, we examine the effects on energy costs of combining window management with daylighting. Figure 3.10 shows that the management devices and thermostat adjustment keep undesirable heat flows substantially in check, thereby reducing the costs for large windows that were observed in the preceding case when only daylighting was considered. The mitigating effect of management devices on winter nighttime heat losses and summer heat gains, plus the beneficial effects of daylighting result in a significant potential for windows to save energy.

Only with relatively large single-glazed windows on the north side of the electrically heated room do life-cycle energy costs with windows exceed the energy costs without windows.

Should a 12 percent rate of energy price escalation prevail over the next 25 years, the windowless room would require a life-cycle energy expenditure of \$2700. This is almost four times the required energy costs of the same room if constant prices were to prevail. As is shown

¹ In the trade-off analysis, supplementary electric lighting is assumed to be added whenever room illumination supplied by daylighting falls below 6.7 fc at a distance 15 ft. from the window within the room, such that a minimum illumination level of 6.7 fc is maintained.

PART A: SINGLE GLAZED

PART B: DOUBLE GLAZED

Figure 3.9 Life-Cycle Energy Costs at 12% Escalation for the Residential Module for North (N) and South (S) Facing Unmanaged Windows Used for Daylighting (Gas and Electric Heating and Electric Cooling)

PART A: SINGLE GLAZED

PART B: DOUBLE GLAZED

Figure 3.10 Base-Year Energy Costs for the Residential Module for North (N) and South (S) Facing Managed Windows Used for Daylighting. (Gas and Electric (Elec) Heating and Electric Cooling)

in Figure 3.11, life-cycle energy savings increase as single-glazed windows up to about 30 ft² in size are added if gas heat is used. Life-cycle energy savings may be as high as \$1140 when 60 ft² double-glazed windows are used facing south if gas heat is used.

3.4 Life-Cycle Costs¹

Let us now see how combining life-cycle energy costs with life-cycle envelope costs will affect overall life-cycle building costs. We do this for each of the preceding four cases of window use.

3.4.1 Life-Cycle Costs for Unmanaged Windows Not Used for Daylighting

Table 3.5 shows that combined life-cycle costs, for five orientations, for unmanaged windows not used for daylighting, both when energy prices are fixed and when they are escalating at a rate of 12 percent. It can be seen that in every case, life-cycle costs increase as window area increases. Although double glazing was shown to be effective in reducing energy costs, when the extra acquisition costs are also considered, the two almost exactly offset one another when energy prices are constant, and the overall life-cycle costs for single and double glazing are nearly equal. However, with rapid energy price escalation, double glazing becomes more cost effective than single glazing for all window sizes and orientations, but particularly for large, north-facing windows. At the same time, the table indicates that life-cycle costs are not raised substantially by adding small windows, particularly small, south-facing windows.

A comparison of the upper and lower portions of Table 3.5 demonstrates the increased weight which would need to be given to window investment decisions for this case of window use as the price of energy increases. As the table shows, the life-cycle costs for a south-facing, double-glazed window of 12 ft² increases from about \$820 at constant energy prices to about \$2,924 when energy prices rise at 12 percent. The entire increase of more than \$2,000 is due to changing energy prices. The appropriate design practice for cost control would be to size windows as small as possible and use double glazing on all windowed areas.

3.4.2 Life-Cycle Costs for Managed Windows Not Used for Daylighting

The upper portion of Table 3.6 shows the total life-cycle costs, including envelope and energy costs, when energy prices remain constant over the 25 year period. It can be seen that life-cycle costs are increased by windows of all sizes, regardless of orientation and glazing type when they are managed but not used for daylighting. It can also be seen that

¹ "Life-Cycle Costs for Windows" refers to the combination of life-cycle envelope costs given in Section 3.2 and life-cycle energy costs for the residential module with alternative window systems given in Section 3.3.

12% Energy Price Escalation

when equipped with venetian blinds and thermal shutters, single glazing is more cost effective than double glazing except when facing north with rapidly escalating energy prices.

By comparing Table 3.6 with Table 3.5, it can be seen that the energy savings from the blinds and shutters are not sufficient to offset their extra capital costs when energy prices are constant, but more than pay for themselves when energy prices escalate rapidly.

3.4.3 Life-Cycle Costs for Unmanaged Windows Used for Daylighting

In both the upper portion of Table 3.7 which assumes constant energy prices and the lower portion which assumes 12 percent energy price escalation, life-cycle costs are shown first to decline and then to increase as window size is increased. With rapid price escalation, however, even the large window area is shown to result in lower costs than the windowless wall. The initial decline in costs reflects the electric energy savings from daylighting. The rise in costs as the window area is expanded past 12 ft² reflects the loss in the value attributed by the model to daylighting once the target illumination level of 6.7 fc is reached, together with the strong negative effects on heating and cooling costs of larger unmanaged windows. The life-cycle savings due to daylighting are greater at a high rate of energy price escalation because the cost of the electricity for lighting is greater.

While there is little difference in the life-cycle costs of single and double-glazed windows at constant energy prices, double glazing is cost effective when energy prices rise rapidly. Double glazing is shown to be more important in this case where windows are unmanaged than in the previous case where thermal shutters functioned in large measure as a substitute for double glazing.

Table 3.8 indicates: (1) the least-cost window size; (2) the life-cycle energy costs of the room combined with the differential costs of the least-cost window system; (3) the savings that result from having the window as compared with having a windowless room; (4) the years required for the energy savings of the window to pay back its added cost to purchase, maintain, and repair; and (5) the minimum rate of fuel price escalation for which the window will continue to pay back. With constant energy prices, the least-cost window is shown by the upper portion of the table to be 12 ft² and single glazed, except for northerly exposures where it is 12 ft² and double glazed. These windows can pay for themselves in 1.1 to 2.7 years depending on the orientation. The last column of Table 3.8 shows that these windows could pay for themselves even if energy prices were falling.¹

¹ This information on least-cost window, savings, and payback was not presented for the preceding cases because the least-cost window was no window.

	N	Double	2027	766	2.3	< 0

With rising energy prices, the least-cost window systems are shown by the lower portion of Table 3.8 to be in all cases double glazed. For all except northerly orientations, the least-cost window size is 18 ft^2 ; for northerly orientations, 12 ft^2 is the least-cost size. The additional acquisition, maintenance, and repair costs of the least-cost windows can be recovered through energy savings in 2.2 to 2.6 years. As in the previous case, the windows can pay for themselves in the 25 year period even if energy prices fall.

3.4.4 Life-Cycle Costs for Managed Windows Used for Daylighting

Table 3.9 shows the combined life-cycle envelope and energy costs. The upper portion of the table indicates that when energy prices are constant, single-glazed windows are slightly more economical than double-glazed windows. Second, it indicates that both single- and double-glazed windows are more economical than a windowless wall as long as their area does not exceed about 18 ft^2 , but that large windows can raise life-cycle costs substantially. A comparison of the upper portions of Tables 3.9 and 3.7 show life-cycle costs to be greater with the management devices than without them; that is, when energy prices remain constant, the added costs of the management devices are not offset by the resultant energy savings.

The lower portion of Table 3.9 indicates that if energy prices were to increase at a rate of 12 percent per year, windows of all sizes and orientations tend to reduce life-cycle building costs compared to a windowless wall, provided they are managed and used for daylighting.

With constant energy prices, the least-cost window system is indicated by Table 3.10 to be 12 ft^2 and single glazed. This window system can pay for itself in 6.6 to 7.5 years depending on its orientation. Savings of between \$70 and \$90 can result over the 25 year period by having this least-cost window system as opposed to having no window. With 12% price escalation, the least-cost window size is shown in Table 3.10 to be 18 ft^2 . For southerly orientations there is little difference in the potential savings of single- and double-glazed windows, although single glazing is slightly more cost effective. For northerly orientations double glazing is more cost effective. The least-cost windows can pay for themselves in 4.9 to 6.4 years depending on the orientation.

The polar coordinate graphing technique introduced in Section 2.4 is used here to compare the life-cycle costs associated with the single- and double-glazed 18 ft^2 windows and the windowless room.

In Figure 3.12, it can be seen that the curve labeled "A", indicating the life-cycle costs associated with the windowless room, is well outside of the curves "B" and "C" which give the costs associated with single- and double-glazed 18 ft^2 window. By closer inspection, it can also be seen that curve B (single glazed) lies slightly inside curve C (double glazed) for the southerly coordinates and slightly outside curve C for the

Constant Energy Prices

12% Energy Price Escalation

^a By comparing this table with Table 3.6, it may be seen that double glazing is more cost effective than single glazing when windows are both managed and used for daylighting. Double glazing becomes the cost-effective choice as a result of the net effect of increased heating loads and decreased cooling loads due to daylighting.

northerly coordinates, thus indicating slightly lower costs by using single glazing for southerly exposures and double glazing for northerly exposures. Costs of single and double glazing are essentially equal for easterly and northerly applications.

3.5 Implications of Results

The preceding Section 3.4 presented the life-cycle costs of the alternative window systems used in a single room of a house, which in turn reflects the life cycle costs of the building, for four different cases of window use. This section summarizes conclusions drawn from the four cases. These conclusions are first listed below in some detail for each case, the results of the four cases are then compared, and, finally, the principal findings are summarized in Figure 3.13.

When Windows Are Unmanaged and Not Used for Daylighting

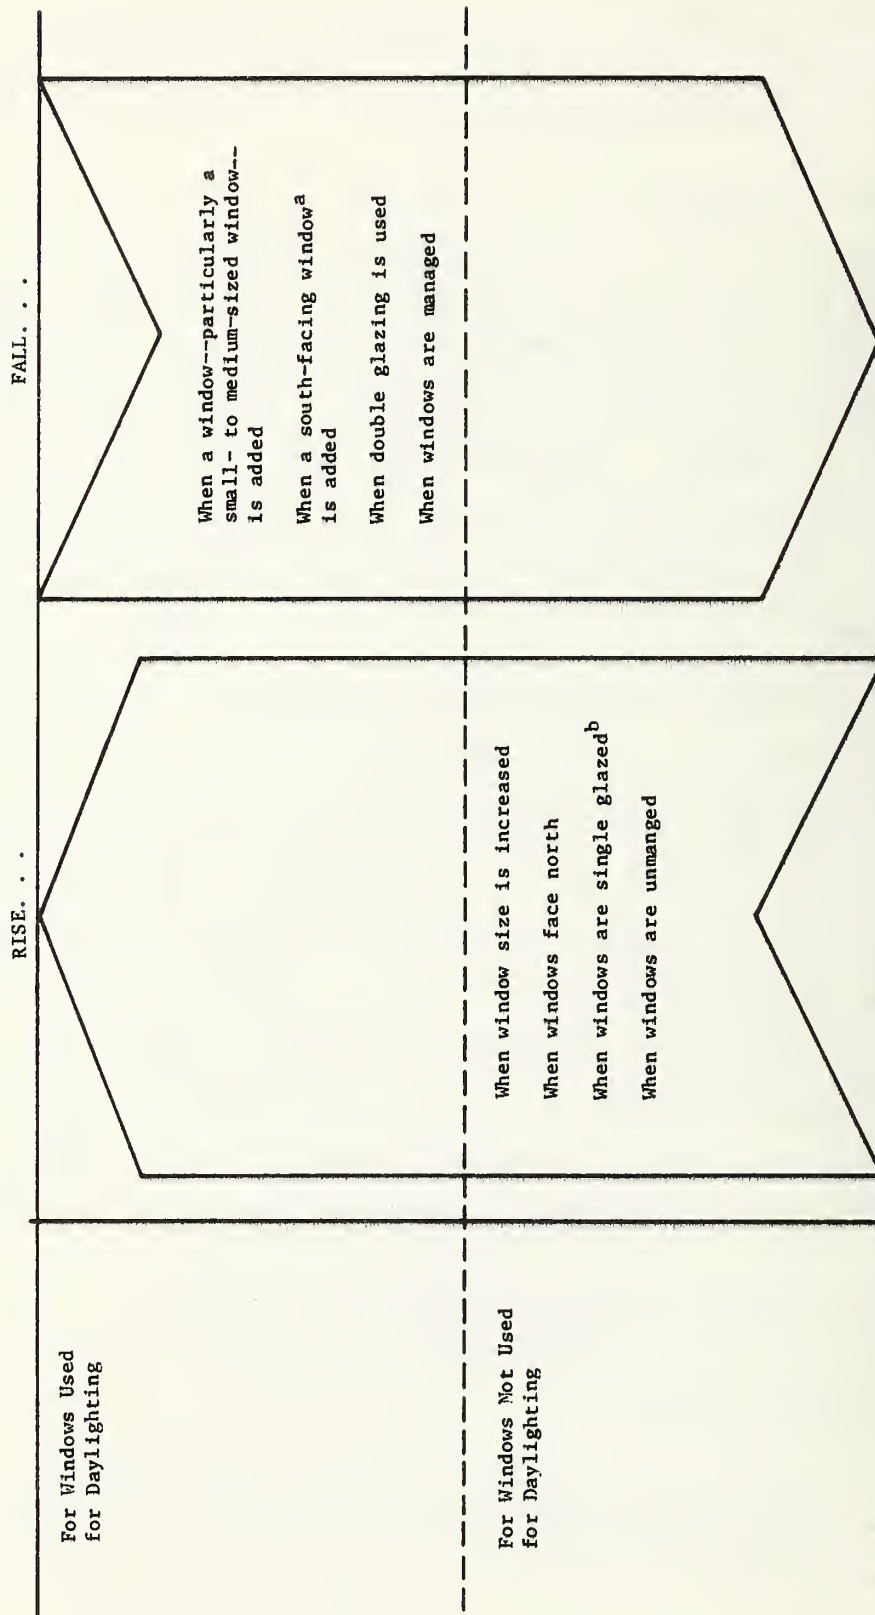

1. The larger the window, the larger its life-cycle cost as well as the life-cycle cost of the building.
2. If windows are used, their costs are lowest when facing south and highest when facing north.
3. Rising fuel prices raise window costs.
4. If fuel prices escalate rapidly, double glazing is economical for all window sizes examined and for all orientations.
5. If fuel prices remain about constant, it makes little difference from a cost standpoint whether the window is single or double glazed.

When Windows Are Managed But Not Used For Daylighting

1. The larger the window, the larger its life-cycle costs.
2. If windows are used, their costs are lowest if they face south and highest if they face north.
3. Window management greatly dampens the negative impact of energy price escalation on window costs.
4. Life-cycle building costs are not raised greatly by adding small windows.
5. Double glazing, used in addition to window management, tends not to be economical except for northerly orientations when energy prices are rising rapidly.

Figure 3.13 KEY RESULTS

LIFE CYCLE COSTS (With rapid Energy Price Escalation) WILL

^aAn exception is that double glazing was not shown to be cost effective for small-to-medium windows on the south, even with rapidly escalating energy prices.

^bAn exception is that single glazing tends to be more cost effective than double glazing for southerly orientations when management is not used.

When Windows Are Unmanaged But Used For Daylighting

1. The life-cycle cost of the building can be reduced by adding a window if care is taken in its sizing or orientation.
2. If fuel prices remain about constant, life-cycle building costs are lowest if a small, single-glazed window facing south is added.
3. If fuel prices rise rapidly, life-cycle building costs are lowest if a small to medium, double-glazed window facing south is added.
4. It generally pays to use double glazing for all unmanaged windows if energy prices are expected to increase rapidly.
5. Rising energy costs, by increasing the savings of electricity for lighting, tend to improve the cost effectiveness of a window despite the concomitant rising costs of heating and cooling.
6. When energy prices rise rapidly, even large windows may be had at a lower life-time cost than a windowless wall area, provided that the windows are either facing south or are double-glazed.
7. The net energy savings from installing a window used for daylighting can pay back the additional costs for window acquisition, maintenance, and repair in just several years.

When Windows are Both Managed and Used for Daylighting

1. The life-cycle cost of the building can be reduced by adding a window, particularly if energy prices rise rapidly.
2. Whether fuel prices remain about constant or rise rapidly, life-cycle building costs are lowest if a relatively small, single-glazed window facing south is added.
3. Double glazing tends not to pay even on the north side if energy prices remain about constant, but if they escalate sharply, double glazing tends to pay for all window sizes and orientations examined, except for south-facing, small-to-medium sized windows.
4. The net energy savings from installing a window that is managed and used for daylighting can pay back the additional costs of window acquisition, maintenance, and repair in about six to seven years.

When Energy Prices Are Constant (All Four Cases of Use Considered)

1. Life-cycle building costs can be minimized by adding a small (12 ft²), single-glazed window facing south and utilizing it for daylight, but not equipping it with venetian blinds or thermal shutters.¹
2. Regardless of window size, orientation, and glazing type, the least-cost mode of window use is the third case examined, i.e., using the window for daylighting but not investing in accessories. In descending order of cost effectiveness, the other cases rank as follows: the fourth, i.e., using the window for daylight and accessorizing it; the first, i.e., neither using the window for daylight nor accessorizing it; and, lastly, the second, i.e., accessorizing the window but not using it for daylight.
3. When venetian blinds and thermal shutters are used, it does not appear to pay to invest additionally in double glazing, and vice-versa.
4. Even when venetian blinds and thermal shutters are not used, double glazing appears to be cost effective only for window areas with northern exposures, and even then it is only slightly preferable to single glazing.
5. Small windows appear to be less costly than large windows; very large windows tend to raise life-cycle building costs even with the most favorable method of window use.

When Energy Prices Rise Rapidly at 12 Percent, Compounded Annually (All Four Cases of Use Considered)

1. Life-cycle building costs are minimized by adding a medium-sized (18 ft²), single-glazed window facing south, by equipping it with venetian blinds and thermal shutters, and by using it for daylighting.
2. Regardless of window size, orientation, and glazing type, the least-cost case of window use is the fourth examined, i.e., using the window for daylighting and managing it. In descending order of cost effectiveness, the other cases rank as follows: the third, i.e., using the window for daylight but not investing in accessories; the second,

¹ Here specific reference is made to the accessories as opposed to the more general term "window management" because "window management" includes thermostat adjustment, an action which generally is cost effective since it can save energy at little or no cost.

i.e., using accessories but not daylight; and lastly, the first, i.e., neither using the window for daylight nor accessorizing it.

3. Double glazing pays for all of the window sizes and orientations examined whenever they are not accessorized.
4. For most window sizes, single glazing is more cost effective on southerly exposures and double glazing is more cost effective on northerly exposures, if the windows are accessorized.
5. Double glazing and the use of venetian blinds and thermal shutters appear to have closely comparable impacts on the life-cycle costs of windows even though double glazing has the advantage, accounted for in the evaluation model, of not requiring daily attention for effective use.
6. Small- to moderate-sized windows tend to be less costly than large ones in all cases examined.
7. If used for daylighting and managed for energy conservation, even a relatively large window (60 ft²) will tend to reduce life-cycle building costs below what they would be without a window.
8. If neither managed nor utilized for daylighting, large windows can greatly increase life-cycle building costs.

The key results that can be drawn from this case study are summarized in Figure 3.13 for the condition of rapidly rising energy prices. One major finding is that life-cycle costs of the room, thus the building, tend to be raised by the windows examined if they are not used for daylighting, particularly if they are large in size, oriented to the north, single glazed,¹ and unmanaged. A second major finding is that life-cycle costs tend to be lowered by the windows examined if they are used for daylighting, particularly if they are small to medium in size, oriented to the south, double glazed,² and managed. The negative cost impact of windows not used for daylighting can be lessened by reducing their size as much as possible, orienting them to the south, and managing them. (As was indicated by the more detailed listing of conclusions, the cost-effective rules for double glazing and window management become somewhat more complex when the uncertainty in energy price escalation is taken into account.)

¹ Note the exceptions in footnote b of Figure 3.13.

² Note the exceptions in footnote a of Figure 3.13.

Apart from the consideration of psychological or other factors, these conclusions suggest that a homeowner, builder, or designer in the Washington, D.C. area could reduce life-cycle building costs by keeping window areas as small as possible in those rooms which are not used much during the day or for which for some other reason cannot be used substantially to reduce electric lighting requirements. But if a large savings potential from daylighting exists and is to be utilized,¹ it is better from a life-cycle cost standpoint to have windows -- even relatively large ones, but preferably small- to moderate-sized ones -- than to have a windowless exterior wall.

¹ It should be recognized that an individual occupant's use of windows may not closely fit any of the four cases of use described here. In fact, individual use will likely shift over time. If this is the case, a homeowner may seek to minimize the maximum losses that could be expected from windows. This behavior, which can be explained in part by game theory, would lead to the choice of smaller windows even though the potential for significant savings might exist from larger windows. Such an unstable equilibrium might persist for some time if the public were not made aware of the potential that daylight utilization has for permitting homeowners to achieve significant dollar savings in life-time building costs.

Facing page: Two major challenges in using windows more efficiently in office buildings is ensuring proper management of interior shading devices and integrating the use of daylighting and artificial lighting.

4. ILLUSTRATION OF THE METHODOLOGY: COMMERCIAL CASE STUDY

The application of the life-cycle cost model in this section is different from the preceding residential case study in two ways: (1) it includes income tax considerations and depreciation allowances which are currently accorded commercial structures; and (2) it is based on a different set of data and assumptions.

4.1 Basic Assumptions

The wall construction of the office building used in the case study is representative of curtain wall construction which has become increasingly important in recent years. The office building under consideration is assumed to be between 5 and 10 stories in height. However, for purposes of the economic analysis, we shall focus on one room, an office module,

to evaluate the alternative window systems. The floor area of the office module is 180 square feet and the volume of the module is 1800 cubic feet. It is assumed that two people are assigned to the office during the normal working hours of 9:00 AM to 5:00 PM. Their occupancy is averaged over the day and the resultant figure of 1.8 persons is used in the computer model to calculate heat loads generated by the occupants. The calculation of expected heat gains also takes into account the effects of office equipment, such as typewriters, electric adding machines/desk calculators, and computer time-sharing terminals as well as lighting.

The exterior wall of the office building consists of a dark glass spandrel panel with 1 inch of rigid fiberglass insulation applied with a mastic. The mullions which hold the spandrel panels are dark anodized aluminum with a thermal break. The interior surface of the exterior wall is cut out and installed. The size of the cutouts is determined by the size and type of glazing. The U value of the non-windowed wall is approximately 0.15.

The windows used in the economic analysis are fixed. The framing is dark anodized aluminum with a thermal break. No tints or low emissivity coatings are assumed to be used. All glazing is erected from the inside of the building as a stick wall; elastomeric gaskets¹ (dryset) are used on all windowed areas. Both single and double glazing are examined. Window sizes range from 0 to 90 square feet. Figure 4.1 illustrates the shape of the office module and the window sizes in relationship to the size of the exterior wall. Additional assumptions, such as lighting requirements, heating and cooling system efficiencies, and occupancy patterns are given in Table 4.1.

As in the residential case studies, the thermal model² which is used to provide input to the economic model assumes that all heat flows entering or leaving the office module are through the exterior wall which contains the window. It is therefore explicitly assumed that no heat flows occur between the office module under examination and adjacent office modules. (Such a system is usually referred to as adiabatic.)

Furthermore, the thermal model does not account for the interdependencies between building components whereby a change in one factor affects the thermal performance of other factors. To account for all possible heat flows and thermal interdependencies would require a considerably more sophisticated thermal model than that which was used in the case studies.

¹ The use of elastomeric gaskets reduces the likelihood of repairs which would probably result from chemical sealants applied at the site. The elastomeric gaskets are assumed to perform satisfactorily throughout the 25 year life cycle.

Figure 4.1 Window Sizes in Relationship to the Size of the Exterior Wall of the Office Module

TABLE 4.1

Assumptions for Commercial Case Study^a

Building Specifications	Assumptions
Dimensions of Module	12' wide x 15' long x 10' high
Floor Area	180 ft ²
Volume of Module	1800 ft ³
Type of Construction	Curtain Wall
Exterior Wall Area	120 ft ²
Window Size	0, 12, 30, 60, 90 ft ²
Window Construction	Anodized aluminum with thermal break
Internal Loads	
Lights	3.25 watts/sq. ft.
Equipment	0.50 watts/sq. ft.
Air Leakage	0.25 air changes/hour
Occupancy	1.8 persons
Heat Load/Person	260 Btu/hour/person
System Efficiency	Specifications
Gas Furnace Efficiency	0.65
Cooling COP ^b	3.0
Electric Heating (Heat Pump)	2.0
Fuel Type	Cost
Electricity	\$0.03 per kWh
Gas	\$0.30 per therm
Operation	Conditions
Thermostat Adjustment	72° to 62° F winter nights 78° to 84° F summer nights
Window Management	Times
Thermal Shutters	Winter nights
Venetian Blinds	Summer days

^a The model assumes no heat transfer to adjacent surfaces such as walls, floors, or ceilings.

^b COP = Coefficient of Performance.

As was the case for the residential case example, the simplifying assumptions employed in the thermal model result in specific limitations for the life-cycle cost measures produced by the economic model.

The thermal model's limitations, however, are less serious for the commercial case than they were for the residential case. Since most office buildings have a large number of office modules which have only one exterior wall, the majority of these office modules are surrounded mostly by other modules which are maintained at approximately the same temperature such that an adiabatic system is probably typical in most cases.¹

Again the thermal model's assumptions about daylighting are tenuous. However, the problem is somewhat less severe in the commercial case study than in the residential case study. For the office module the assumption of a fixed level of illumination appears more reasonable than for the residential module. (We have followed the GSA guidelines and used 50 fc as the reference level.) The fixed level of illumination could be maintained by the use of automated controls, a much more feasible approach for the office module than for the residential module. (The cost of automated controls is, however, not included in this life-cycle cost analysis.)

The method of presentation of this case study is similar to the preceding residential case study. First, the life-cycle envelope costs, including the costs of purchasing and installing the windows, equipping them with management devices and maintaining and repairing them, are presented. Second, the life-cycle energy costs of the office module with alternative window sizes, orientations, and glazing types are presented based on four different cases of window use: (1) unmanaged windows² not used for daylighting; (2) managed windows not used for daylighting; (3) unmanaged windows used for daylighting; and (4) managed windows used for daylighting. Third, the total life-cycle costs are presented, again for each of the four different cases of window use. Conclusions and the implications of these conclusions for the building community are then summarized.

¹ There would, of course, be some office modules which are not adiabatic even though they have only one exterior wall. For example, offices adjacent to unconditioned areas (e.g., equipment rooms and/or garages) would generally not be adiabatic.

² As explained earlier, "unmanaged windows" means those windows that are used bare; "managed windows" means those windows that are equipped, in this case study, with venetian blinds and thermal shutters which are used to reduce undesired daytime heat gain in the summer and nighttime heat loss in the winter, and, in addition are used in a room in which nighttime adjustment of the thermostat is practiced for energy conservation.

4.2 Envelope Costs

In commercial buildings, unlike private residences, the cost of windowed areas may either increase or decrease initial construction costs, that is, a wall with windows may cost more or less to purchase and install than a windowless wall. For this reason the costs presented in Table 4.2 are the acquisition costs of the 10' x 12' exterior wall (bay) and not the net costs of the windowed area above or below those of the exterior wall. These costs include the purchase and installation prices for all glazing (spandrel panel and window), mullions, and the interior curtain wall. A 25 percent markup for contractor overhead and profit is included.

TABLE 4.2

Commercial Case Study:

Acquisition Costs^a

Glazing Type	<u>Dollar Cost by Size of Window</u>				
	0 ft ²	12 ft ²	30 ft ²	60 ft ²	90 ft ²
Single	1238	1229	1204	1257	1009
Double	1238	1301	1323	1446	1255

^a Cost figures are for the entire exterior wall (bay) and include materials, installation, and markup costs. The cost differential associated with a given window size/type is thus equal to the difference between the cost of the bay with that window size/type and the windowless bay. The area of the exterior wall is 120 square feet. Variations in cost among window sizes are due both to differences in framing costs and to the costs of glazing. Lower framing costs are particularly evident in the case where the window area is 90 square feet.

Source: A leading manufacturer and distributor of building materials provided the cost estimates.

The exterior wall used in the case studies was chosen for two reasons. First, it is typical of those currently used in commercial buildings. Second, it is relatively less expensive than the alternative exterior walls which are sometimes used in commercial buildings. The lower cost reflects the factory fabrication and the design for inside glazing and stick wall erection. The building envelope used in the economic analysis is on the low end of the cost range for envelopes currently being used in commercial applications. The costs of the glazed portions of the envelope, unlike the rest of the envelope, should remain about constant even if more expensive opaque portions of the envelope are substituted for those used in the economic analysis. Consequently, if the window system is found to be economically viable (cost effective) in this case it will also be cost effective for those cases where more expensive exterior walls are used, other things being equal.

If management devices are used, additional acquisition costs are incurred. Costs of venetian blinds and insulated thermal shutters based upon large volume sales are given in Table 4.3. All costs reflect purchase, installation, and contractor markup. If management devices are used it is assumed that their costs are added to the capital costs of the exterior wall system and then depreciated along with the rest of the exterior wall system.

Most commercial buildings usually have a schedule for window washing which may be done by contract. The cost-of-cleaning data presented in Table 4.4 reflect estimated contract prices for annual washing of all windows of a specified size in the building. The annual insurance premium is used as a proxy for repair/replacement costs. These figures are quoted in Table 4.4 as a function of the size of the window and the glazing type.

4.3 Energy Costs

4.3.1 Energy Costs for Unmanaged Windows Not Used for Daylighting

Base-year energy costs for the office module heated by natural gas start at \$53 for a windowless wall and go as high as \$70 for a 90 ft² single-glazed window with a southern orientation, with energy costs rising steadily in relationship to window size. For a northern

orientation, costs range from \$53 to \$91. With heating by electricity, base-year energy costs range from \$52 for the windowless module, to \$70 for the module equipped with a 90 ft² single-glazed window facing south. For a northern orientation, costs range from \$52 to \$89. Base-year energy costs are increased by as much as \$18 by a large, south-facing, single-glazed window when either gas or electric resistance heating is used.¹

Figure 4.2 shows the base-year energy costs converted to a life-cycle basis, both for constant future energy prices and for 12 percent escalation. The lower portion of Figure 4.2, Part A, shows that even at fixed energy prices, life-cycle energy costs for the office module may be raised by about \$160 (from \$480 to \$640) by using 90 ft² single-glazed windows for southern orientations, and by about \$350 (from \$480 to \$830) for northern orientations. Part B of Figure 4.2 shows that the increases in life-cycle energy costs are limited to between \$70 and \$110 by the use of double glazing.

The upper portion of Figure 4.2 shows that with energy prices escalating at a rate of 12 percent, the energy costs for the reference point (i.e., the windowless office module) are \$1670, as compared with \$480 with constant energy prices. With large, single-glazed windows facing north, the life-cycle energy costs for the office module now approach \$2900, indicating an increase in life-cycle energy costs of approximately \$1200 attributable to the windows. Part B of Table 4.2 indicates that the savings potential of double glazing becomes more important the higher the rate of energy price escalation (net losses attributable to windows are now limited to \$400).

4.3.2 Energy Costs for Managed Windows Not Used for Daylighting

The addition of window management causes base-year energy costs to remain approximately level as the window area is increased, with the exception of single-glazed windows on the north side. Energy costs are reduced dramatically below those found in the preceding case.

¹ The coefficient of performance (COP) for electric heating is 2.0; therefore the equivalent energy cost per therm is

$$\frac{(100,000 \text{ Btu}) \times \$/\text{kwh}}{(3413 \text{ Btu/kwh}) \times \text{COP}} = \$0.44 .$$

The equivalent energy cost per therm for gas heating is \$0.46. Thus electric resistance heating is, in this case, less expensive than gas heating by virtue of the relatively high coefficient of performance for electric heating. Since the energy costs are nearly equal, all future references in the text to the figures plotting energy costs will refer only to the orientations and glazing type and ignore energy type.

Figure 4.2 Life-Cycle Energy Costs for the Office Module for North (N) and South (S) Facing Unmanaged Windows Not Used for Day-lighting (Gas Heating and Electric Cooling Evaluated for both 0 and 12% Price Escalation)

With constant fuel prices, there is, therefore, little difference in the life-cycle energy costs of the room with and without windows. The exception is for north-facing, single-glazed windows which raise costs by about \$120.

When energy prices rise at a rate of 12 percent per year, life-cycle energy costs are about quadrupled. The windowless office module now requires an energy expenditure of \$1,620, as shown by Figure 4.3A, and the office with a single-glazed 90 ft² window facing north now has an energy cost of about \$2,050. Part B of Figure 4.3 shows that double glazing used in conjunction with management tends to reduce energy consumption, but not by as much as in the preceding case when the windows were unmanaged. (By comparing Figure 4.3 with Figure 4.2, it may be seen that the nighttime temperature adjustment reduces life-cycle costs by approximately \$50.)

4.3.3 Energy Costs for Unmanaged Windows Used for Daylighting

When the use of daylight is considered, but window management is not, base-year energy costs start at \$53 and decline as window area is initially increased. However, as window area is increased past 30 ft² with single glazing or past 60 ft² with double glazing, energy costs begin to rise. As in the residential case, this pattern of initially falling and then rising energy prices reflects the fact that once the reference illumination level of 50 fc is met, additional daylight provided by increasing window size is not treated as energy savings in the evaluation model, while undesirable heat flows that tend to increase as window area increases continues to be treated as costs.

The life-cycle energy costs for this third mode of operation are particularly interesting since a large potential for savings exists. With constant energy prices, the life-cycle energy costs of the windowless office module are approximately \$480. Even with a 90 ft² window area, costs remain below the initial energy cost provided the window area is either facing south or double glazed.

The utilization of daylight becomes even more important with a rise in energy costs. This relationship is demonstrated by Figure 4.4 which assumes that energy prices increase at the rate of 12 percent per year. The energy costs for the windowless room are now about \$1670. (They are about \$50 more than in the preceding case because there is no thermostat adjustment in this case.) If used for daylighting, south-facing, single-glazed windows may reduce energy costs to as low as \$965, and south-facing, double-glazed windows to as low as \$625. By comparing Figure 4.4 with Figure 4.2 (the first case), we can see the considerable potential that daylight utilization has to conserve scarce energy resources.

By comparing Parts A and B of Figure 4.4, the large potential savings for double glazing may be seen. For example, the energy costs associated with a 90 ft² double-glazed window facing north are nearly \$900 less

Figure 4.3 Life-Cycle Energy Costs for the Office Module for North (N) and South (S) Facing Managed Windows Not Used for Daylighting (Gas Heating and Electric Cooling Evaluated for 12% Price Escalation)

Figure 4.4 Life-Cycle Energy Costs for the Office Module for North (N) or South (S) Facing Unmanaged Windows Used for Daylighting (Gas Heating and Electric Cooling Evaluated for 12% Price Escalation)

than the energy costs associated with a single-glazed window of the same size also facing north.

4.3.4 Energy Costs for Managed Windows Used for Daylighting

When both window management and daylighting are practiced, base-year energy costs for the module with either single or double glazing are lower than in the preceding case. Except for single-glazed windows facing north, costs now continue to decline for window sizes up to 90 ft². However, the decline in costs slows down as window size is enlarged.

With constant energy prices, energy requirements over the 25 year period for the windowless room are approximately \$460, \$20 less with the thermostat adjustment than without it. For southern exposures, the life-cycle costs fall to \$250 when a single-glazed window of 40 ft² is added, and fall further to \$150 when the window area is expanded to 60 ft². Life-cycle energy savings may range as high as \$340 by having a window.

With energy price escalation at 12 percent, the life-cycle costs of the windowless module again almost quadruple, and the potential energy benefit from using windows becomes quite large. As is shown by Figure 4.5, energy costs for the module decline for all the sizes of single- and double-glazed windows facing south, as well as for double-glazed windows facing north. Costs are shown to increase if single-glazed windows larger than 60 ft² are used facing north. Using a combination of daylighting and window management results in a potential (before tax) savings from windows as high as \$1,200.

4.4 Life-Cycle Costs

4.4.1 Life-Cycle Costs for Unmanaged Windows Not Used for Daylighting

Let us now examine the effects of combining life-cycle energy costs for the office module with life-cycle envelope costs for the window.¹

Table 4.5 shows the combined life-cycle costs associated with unmanaged windows not used for daylighting. For all cases, life-cycle costs are higher with windows than without, although single-glazed windows add relatively little to total costs if energy prices are constant. In every

¹ For the life-cycle cost calculations, the deductibility from taxable income of energy costs and depreciation for capital investment costs are taken into account in the model.

The depreciation allowance $D(n)$ in year n is given as

$$D(n) = \frac{1.5}{N} \times BV(n-1)$$

^a Life-cycle costs are lower for 90 ft² of single-glazing than 60 ft² due to reductions in framing costs.

case, the fuel savings of double glazing are more than offset by its extra acquisition and repair¹ costs, causing overall life-cycle costs for double glazing to be significantly higher than for single glazing.

4.4.2 Life-Cycle Costs for Managed Windows Not Used for Daylighting

Table 4.6 shows that the total life-cycle costs are higher with windows that are managed but not used for daylighting than with no windows, regardless of window size, orientation, glazing type, and energy price escalation. It can also be seen that single glazing is more cost effective than double glazing for all sizes and orientations examined.

By comparing Table 4.6 with Table 4.5, it can be seen that the energy savings from the blinds and shutters are not sufficient to offset their extra capital costs,² especially for the larger window areas. Life-cycle

(continued from page 78)

where N is the period over which the capital asset is depreciated and $BV(n-1)$ is the book value of the capital asset in the previous period. $BV(0)$ is assumed to be the acquisition cost of the system. The present value, $P_t V(n)$, of the depreciation allowance in year n is then given as

$$P_t V(n) = \frac{D(n)}{(1 + \text{DISCOUNT RATE})^n} .$$

The present value, $PV(n)$, of the reduction in income taxes due to the depreciation allowance is then given as

$$PV(n) = P_t V(n)(1 - \text{TAX RATE}) .$$

The present value of all tax reductions due to depreciation allowances PV is given as

$$PV = \sum_{n=1}^N PV(n) .$$

¹ Recall that insurance costs are used in this case study as a proxy for repair costs.

² At this time there do not appear to be any commercially available insulated shutters that would be appropriate for office buildings. Those used in the case study are custom and have an acquisition cost of approximately \$13 per square foot on the average. This figure is thought to be prohibitively expensive. However, in the fourth case of window use, two separate analyses are conducted. The first uses the custom made shutter and the second assumes an in place cost of \$5 per square foot. Although the \$5 per square foot figure is an assumed value, price reduction through competition may result if building owners demand insulated shutters.

Constant Energy Prices

12% Energy Price Escalation

costs are actually higher for the second case than for the first, despite the beneficial results of thermostat adjustment in the second case. However, management does become relatively more worthwhile with the escalation in energy prices.

4.4.3 Life-Cycle Costs for Unmanaged Windows Used for Daylighting

Perhaps the most striking result of Table 4.7, which shows the life-cycle costs when the window system is unmanaged but used for daylighting, is that double glazing is in all cases uneconomical. Nevertheless, daylighting, as in the residential case, is sufficiently beneficial to cause the life-cycle costs with a window system, whether double or single glazed, to be less than the costs without a window system despite the fact that winter heat losses and summer heat gains are not being mitigated by window management. However, this does not hold for all combinations of window sizes, glazing types, and orientations.

When energy prices are assumed to remain constant, the least-cost window, for all cases except northerly exposures, is 90 ft² and single glazed. This condition is shown in Table 4.8. Notice also from Table 4.8 that due to reduced capital costs, the use of this window system results in an immediate payback indicated by an "I" entry in the column "Years to Payback."

Single glazing is also indicated as the least-cost glazing when energy prices escalate at 12 percent. The least-cost window size is smaller (30 ft²) with price escalation. Through energy savings and reduced capital costs the use of these windows again results in an immediate payback. They can pay for themselves within the 25 year period even if energy prices fall somewhat.

4.4.4 Life-Cycle Costs for Managed Windows Used for Daylighting

Table 4.9 gives total life-cycle costs for the fourth case when windows are both managed and used for daylighting. Several facts are apparent from this table. First, the single-glazed windows are more economical over the life-cycle than the double-glazed windows for all window sizes and orientations, and for both constant and escalating energy prices. Second, the large savings that were found in the residential example when windows were both managed and used for daylighting do not materialize in this example; neither single- nor double-glazed windows are more economical than the windowless wall. In fact, large windows raise life-cycle costs between \$700 and \$1,300, depending on orientation and glazing type. The fact that real reductions in life-cycle costs resulted in the third case when daylight alone was used indicates that daylighting is very beneficial. The increase in costs in the fourth case indicates that the added costs of the management devices are not offset by energy savings through reduced window heat loss and summer heat gain.

Figure 4.6 uses the polar coordinate chart to compare the life-cycle costs of the 30 ft² single-glazed, managed window used for daylighting

Figure 4.6 Graphical Determination of Least-Cost Window System for the Commercial Office Module

(the curve labeled "C") with two alternatives: (1) the windowless wall (labeled "A"), and (2) the 30 ft² single-glazed, unmanaged window used for daylighting (labeled "B"). The fact that curves A and B lie everywhere on a lower cost line than curve C indicates that the 30 ft² single-glazed, managed window used for daylighting is not the most economical of the three choices.

It was noted earlier that the cost figures for the thermal shutter used in the commercial case study were quite high due to its small market size at present. In order to test the cost impact of a lower price for the shutter, the analysis was repeated using a price of \$5 per ft² rather than \$13 per ft² that was based in all of the preceding commercial window management calculations. The results are shown in Table 4.10.

The thermal performance of the shutter is assumed to remain constant. Because the \$5/ft² cost is purely hypothetical, the results presented in Table 4.10 should be viewed as an illustration of sensitivity analysis rather than as a guide for window sizing.

With the lower priced shutters, the life-cycle costs associated with the windowed wall that is both managed and used for daylighting are lower than for the non-windowed wall, provided energy prices escalate rapidly, and the windows are single glazed and kept to 30 ft² when used for northerly exposures. However, by comparing Table 4.10 with Table 4.7, the third case, we can see that the unmanaged windowed wall used for daylighting continues to be more cost effective than the managed windowed wall used for daylighting.

4.5 Implications of Results

This section summarizes the major conclusions that can be drawn from the analyses of the life-cycle costs of the alternative window systems in the office module. The two cases of window operation which do not make use of daylighting are grouped together.

When Windows Are Not Used for Daylighting

1. In all situations examined, life-cycle costs were higher with windows than without windows.
2. If management devices are used, the larger the window, the larger the life-cycle cost of the office module.
3. If windows are used, their costs are lowest if they are located with southern exposures, and highest if located with northern exposures.
4. Rising fuel prices raise the costs of having windows of all sizes as compared to the windowless wall.

TABLE 4.10

Life-Cycle Costs When the Window System is
Managed and Used for Daylighting;
Testing the Sensitivity to \$5/ft² Shutter Cost
(Gas Heating and Electric Cooling)

Window Area (FT ²)	Life-Cycle Costs in Dollars									
	Single Glazed					Double Glazed				
	Orientation					Orientation

90	1612	1666	1797	1928	1942	2149	2174	2229	2277	2271
12% Energy Price Escalation										

5. Even if fuel prices escalate rapidly, double glazing, due to its higher capital and insurance costs, is less economical than single glazing regardless of window size and orientation.

When Windows Are Unmanaged, But Used for Daylighting

1. The life-cycle cost of the office can be reduced by adding a window if care is taken in its sizing and orientation.
2. For some window areas, there may be savings relative to the windowless wall, as well as energy savings from using the window for daylighting.
3. When the value of trading daylight for electric lighting is considered, rising energy costs tend to improve the cost effectiveness of the window.
4. If fuel prices remain about constant, life-cycle costs of the office are lowest if a large, single-glazed, south-facing window is added.
5. If fuel prices rise rapidly, life-cycle costs of the office are lowest if a medium-to-large, single-glazed, south-facing window is added.
6. Even if energy prices are expected to increase rapidly, single glazing is more cost effective than double glazing.

When Windows Are Both Managed and Used for Daylighting

1. At the current market price for the thermal shutter examined, none of the window systems examined was found to reduce life-cycle costs below those for the windowless module.
2. Double glazing was less cost effective than single glazing for all window sizes and orientations examined.
3. Even at a moderate cost of \$5 per square foot for the thermal shutter, the managed window is not as cost effective as the unmanaged window.
4. If a thermal shutter could be purchased and installed for a cost of \$5 per square foot and fuel prices rise rapidly, life-cycle costs of the office module can be lowered by adding a window, particularly a large, single-glazed window facing south.

When Energy Prices Are Constant

1. Life-cycle building costs are minimized by adding a large (90 ft²), single-glazed window facing south and utilizing it for daylight, but not equipping it with management devices.¹
2. Regardless of window size, orientation, and glazing type, the least-cost case of window use is the third examined, i.e., using the window for daylighting but not investing in management devices. In descending order of cost effectiveness, the other cases rank as follows: the first case, i.e., neither using the window for daylight nor using management devices; the fourth case, i.e., using the window for daylight and using management devices; and, lastly, the second case, i.e., using management devices with the window but not using it for daylight.
3. Regardless of whether or not window management is practiced, it does not appear to pay to invest additionally in double glazing.
4. Small areas are preferred if management devices are used, whereas large window areas are preferred if management devices are not used.

When Energy Prices Escalate at a Rate of 12 Percent

1. Life-cycle costs are minimized by placing a medium-sized (30 ft²), single-glazed window facing south and using it bare for daylighting.
2. Regardless of window size, orientation, and glazing type, the least-cost case of window use is the third examined, i.e., using the window for daylighting but not investing in management devices. In descending order of cost effectiveness, the other cases rank as follows: the first, i.e., neither using the window for daylight nor using management devices; the fourth, i.e., using the window with management devices for daylight; and lastly, the second, i.e., equipping the window with management devices but not using it for daylight.

¹ Recall that the term window management includes not only the use of selective management devices such as thermal shutters and venetian blinds but also nighttime thermostat adjustments. Although selective management devices may not be cost effective, a nighttime thermostat adjustment would generally be cost effective since it produced energy savings at little or no cost.

3. Single glazing is preferred for all of the window sizes and orientations examined.
4. The thermal shutter is not cost effective due to its high current market price.
5. If the thermal shutter examined could be installed at a cost of \$5 per square foot and large windows were used, it would be more cost effective to use the shutter than double glazing, but it would be still more cost effective to use neither.

Apart from the consideration of psychological or other factors, these results suggest that a building owner, builder, or designer in the Washington, D.C. area could reduce life-cycle costs by keeping window areas as small as possible or eliminating them altogether in those office modules which are not used much during the day or which for some other reason cannot be used substantially to reduce electric lighting requirements. The results, however, suggest that it is better from a life-cycle cost standpoint to have windows -- even relatively large ones -- than to have a windowless exterior wall if the windows can be used successfully to reduce electric lighting requirements.

If energy prices continue to rise rapidly, some consideration might be given to the use of either window accessories like those described or double glazing but not both. However, in all cases, even for northern exposures, single glazing should be given precedence.

The results further suggest that double glazing is generally not cost effective for the type of office module examined, nor is the use of management devices unless the thermal shutters examined could be acquired at very low cost or unless energy prices rise much more rapidly than the 12 percent rate examined here.

Facing page: *The provision of a view through windows can be an important factor in window design but is difficult to assess in dollar terms.*

5. SUMMARY, CONCLUSIONS, AND SUGGESTIONS FOR FURTHER RESEARCH

This report has developed a life-cycle costing model and computer program for evaluating the dollar costs of acquisition, maintenance, and repair for windows of alternative design, size, orientation, geographical location, and with various accessories and modes of use, as well as the energy costs for the interior space with the alternative windows. It has described the importance of windows to energy costs, delineated the costs and benefits of windows, presented the economic evaluation model verbally, algebraically, and in BASIC computer language, provided step-by-step illustrations of the application of the model to the windows in a residence and in an office building, and has drawn tentative conclusions based on the illustrations.

The results of the illustrations have indicated that window size, orientation, thermal resistance, accessories, and use--particularly the substituting of daylight for electric lighting--can affect significantly the energy consumption and life-cycle costs of windows. By examining the impact of windows on the life-cycle costs for four different levels of thermal analysis, the illustrations have shown how energy and overall building costs are influenced by the use of selected window accessories, thermostat adjustment, and daylighting. By examining energy and other costs separately and in combination, the approach has demonstrated the relationship between the energy efficiency and the cost effectiveness of different window designs. If energy costs can be reduced with little or no additional investment cost, as by changing window orientations, the least-cost energy decision is also the least-cost building decision. However, if capital and labor costs are increased by choosing one window design or accessory over another, it is important to weigh these costs against the value of energy savings to determine the cost-effective decision.

Considerable work remains to be done in the economic evaluation of windows. One task is to apply this or other evaluation models to develop guidelines for cost-effective window decisions for many types of window features, buildings, geographical locations, and uses. The companion to this report¹ takes a step in this direction by analyzing selected window features for two types of buildings in nine locations under alternative conditions. Much remains to be done, however, to develop a comprehensive set of guidelines for the nation.

Another important task is to extend and improve the thermal model to incorporate important effects now omitted. The inclusion in the model of the effects of natural ventilation from operable windows is a prime example of a needed improvement. An additional critical task is to raise the quality and reliability of the data with which the model must be used. For example, there is notable uncertainty about the utilization of excess heat gain in the winter and the available daylight under various sky conditions, room configurations, and window designs. Further research in both the laboratory and in the field is needed to provide reliable estimates of the energy impacts of windows.

With these suggested improvements in the evaluation model and in the input data to the model, a high payoff could be expected from the intensive application of the model to window alternatives and the analysis of the results. Development of easy-to-use, reliable guides to energy efficient and cost-effective windows could result in better decisions by the building community and in energy and dollar savings to the nation.

16. ABSTRACT (A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here.) This study, which is one part of a National Bureau of Standards interdisciplinary project on windows, is aimed at improving the cost-effectiveness of window selection and use in buildings. It develops and illustrates a life-cycle costing evaluation model and computer program for assessing for alternative window systems the net dollar impact of acquisition, maintenance and repair, heating and cooling energy gains and losses, and artificial lighting and daylighting trade-offs. The method is applicable to the evaluation of many different window sizes, designs, accessories, and uses, both for new and existing residential and commercial buildings. Two step-by-step examples of evaluating selected window alternatives in a residence and in an office building in Washington, D.C. serve to illustrate the application of the method. A companion report, <u>A Regional Economic Assessment of Selected Window Systems</u> , presents the results of eight additional residential case studies and eight additional commercial case studies. While the emphasis of this report is on the method of evaluation, the companion report focuses on summarizing the results of a regional analysis in a form that will be convenient for use by building owners, operators, designers, financiers, and builders, those whose interest centers on the actual implementation of research results.

JOURNAL OF RESEARCH

of the National Bureau of Standards

Subscribe now — The new National Bureau of Standards Journal

The expanded Journal of Research of the National Bureau of Standards reports NBS research and development in those disciplines of the physical and engineering sciences in which the Bureau is active. These include physics, chemistry, engineering, mathematics, and computer sciences. Papers cover a broad range of subjects, with major emphasis on measurement methodology, and the basic technology underlying standardization. Also included from time to time are survey articles on topics closely related to the Bureau's technical and scientific programs. As a special service to subscribers each issue contains complete citations to all recent NBS publications in NBS and non-NBS media. Issued six times a year. Annual subscription: domestic \$17.00; foreign \$21.25. Single copy, \$3.00 domestic; \$3.75 foreign.

- Note: The Journal was formerly published in two sections: Section A "Physics and Chemistry" and Section B "Mathematical Sciences."

NBS Board of Editors
Churchill Eisenhart,
Executive Editor (Mathematics)
John W. Cooper (Physics)
Donald D. Wagman (Chemistry)
Andrew J. Fell (Engineering)
Joseph O. Harrison (Computer Science)
Helmut W. Hellwig (Boulder Labs.)

NBS TECHNICAL PUBLICATIONS

PERIODICALS

JOURNAL OF RESEARCH—The Journal of Research of the National Bureau of Standards reports NBS research and development in those disciplines of the physical and engineering sciences in which the Bureau is active. These include physics, chemistry, engineering, mathematics, and computer sciences. Papers cover a broad range of subjects, with major emphasis on measurement methodology, and the basic technology underlying standardization. Also included from time to time are survey articles on topics closely related to the Bureau's technical and scientific programs. As a special service to subscribers each issue contains complete citations to all recent NBS publications in NBS and non-NBS media. Issued six times a year. Annual subscription: domestic \$17.00; foreign \$21.25. Single copy, \$3.00 domestic; \$3.75 foreign.

Note: The Journal was formerly published in two sections: Section A "Physics and Chemistry" and Section B "Mathematical Sciences."

DIMENSIONS/NBS

This monthly magazine is published to inform scientists, engineers, businessmen, industry, teachers, students, and consumers of the latest advances in science and technology, with primary emphasis on the work at NBS. The magazine highlights and reviews such issues as energy research, fire protection, building technology, metric conversion, pollution abatement, health and safety, and consumer product performance. In addition, it reports the results of Bureau programs in measurement standards and techniques, properties of matter and materials, engineering standards and services, instrumentation, and automatic data processing.

Annual subscription: Domestic, \$11.00; Foreign \$13.75

NONPERIODICALS

Monographs—Major contributions to the technical literature on various subjects related to the Bureau's scientific and technical activities.

Handbooks—Recommended codes of engineering and industrial practice (including safety codes) developed in cooperation with interested industries, professional organizations, and regulatory bodies.

Special Publications—Include proceedings of conferences sponsored by NBS, NBS annual reports, and other special publications appropriate to this grouping such as wall charts, pocket cards, and bibliographies.

Applied Mathematics Series—Mathematical tables, manuals, and studies of special interest to physicists, engineers, chemists, biologists, mathematicians, computer programmers, and others engaged in scientific and technical work.

National Standard Reference Data Series—Provides quantitative data on the physical and chemical properties of materials, compiled from the world's literature and critically evaluated. Developed under a world-wide program coordinated by NBS. Program under authority of National Standard Data Act (Public Law 90-396).

NOTE: At present the principal publication outlet for these data is the Journal of Physical and Chemical Reference Data (JPCRD) published quarterly for NBS by the American Chemical Society (ACS) and the American Institute of Physics (AIP). Subscriptions, reprints, and supplements available from ACS, 1155 Sixteenth St. N.W., Wash., D.C. 20056.

Building Science Series—Disseminates technical information developed at the Bureau on building materials, components, systems, and whole structures. The series presents research results, test methods, and performance criteria related to the structural and environmental functions and the durability and safety characteristics of building elements and systems.

Technical Notes—Studies or reports which are complete in themselves but restrictive in their treatment of a subject. Analogous to monographs but not so comprehensive in scope or definitive in treatment of the subject area. Often serve as a vehicle for final reports of work performed at NBS under the sponsorship of other government agencies.

Voluntary Product Standards—Developed under procedures published by the Department of Commerce in Part 10, Title 15, of the Code of Federal Regulations. The purpose of the standards is to establish nationally recognized requirements for products, and to provide all concerned interests with a basis for common understanding of the characteristics of the products. NBS administers this program as a supplement to the activities of the private sector standardizing organizations.

Consumer Information Series—Practical information, based on NBS research and experience, covering areas of interest to the consumer. Easily understandable language and illustrations provide useful background knowledge for shopping in today's technological marketplace.

Order above NBS publications from: Superintendent of Documents, Government Printing Office, Washington, D.C. 20402.

Order following NBS publications—NBSIR's and FIPS from the National Technical Information Services, Springfield, Va. 22161.

Federal Information Processing Standards Publications (FIPS PUB)—Publications in this series collectively constitute the Federal Information Processing Standards Register. Register serves as the official source of information in the Federal Government regarding standards issued by NBS pursuant to the Federal Property and Administrative Services Act of 1949 as amended, Public Law 89-306 (79 Stat. 1127), and as implemented by Executive Order 11717 (38 FR 12315, dated May 11, 1973) and Part 6 of Title 15 CFR (Code of Federal Regulations).

NBS Interagency Reports (NBSIR)—A special series of interim or final reports on work performed by NBS for outside sponsors (both government and non-government). In general, initial distribution is handled by the sponsor; public distribution is by the National Technical Information Services (Springfield, Va. 22161) in paper copy or microfiche form.

BIBLIOGRAPHIC SUBSCRIPTION SERVICES

The following current-awareness and literature-survey bibliographies are issued periodically by the Bureau:

Cryogenic Data Center Current Awareness Service. A literature survey issued biweekly. Annual subscription: Domestic, \$25.00; Foreign, \$30.00.

Liquified Natural Gas. A literature survey issued quarterly. Annual subscription: \$20.00.

Superconducting Devices and Materials. A literature survey issued quarterly. Annual subscription: \$30.00. Send subscription orders and remittances for the preceding bibliographic services to National Bureau of Standards, Cryogenic Data Center (275.02) Boulder, Colorado 80302.
