## Announcing—The Building Science Series

The "Building Science Series" disseminates technical information developed at the Bureau on building materials, components, systems, and whole structures. The series presents research results, test methods, and performance criteria related to the structural and environmental functions and the durability and safety characteristics of building elements and systems.

These publications, similar in style and content to the NBS Building Materials and Structure Reports (1938-59), are directed toward the manufacturing, design, and construction segments of the building industry, standards organizations, officials responsible for building codes, and scientists and engineers concerned with the properties of building materials.

The material for this series originates principally in the Building Research Division of the NBS Institute for Applied Technology. Published or in preparation are:

- BSS0. Building Research at the National Bureau of Standards. (In press)
- BSS1. Performance of Buildings—Concept and Measurement. Man and His Shelter. \$2.75
- BSS2. Interrelations Between Cement and Concrete Properties: Part 1, Materials and Techniques, Water Requirements and Trace Elements. 35 cents
- BSS3. Doors as Barriers to Fire and Smoke. 15 cents
- BSS4. Weather Resistance of Porcelain Enamels: Effect of Exposure Site and Other Variables After Seven Years. 20 cents
- BSS5. Interrelations Between Cement and Concrete Properties: Part 2, Sulfate Expansion, Heat of Hydration, and Autoclave Expansion. 35 cents
- BSS6. Some Properties of the Calcium Aluminoferrite Hydrates. 20 cents
- BSS7. Organic Coatings. Properties, Selection, and Use. \$2.50
- BSS8. Interrelations Between Cement and Concrete Properties: Part 3, Compressive Strengths of Portland Cement Test Mortars and Steam-Cured Mortars. 55 cents
- BSS9. Thermal-Shock Resistance for Built-Up Membranes. 20 cents
- BSS10. Field Burnout Tests of Apartment Dwelling Units. 25 cents
- BSS11. Fire Resistance of Steel Deck Floor Assemblies. 25 cents
- BSS12. Performance of Square-Edged Orifices and Orifice-Target Combinations as Air Mixers. 15 cents
- BSS13. Shrinkage and Creep in Prestressed Concrete. 15 cents
- BSS14. Experimental Determination of Eccentricity of Floor Loads Applied to a Bearing Wall. 15 cents

# 1964 Exposure Test of Porcelain Enamels on Aluminum—Three Year Inspection

Margaret A. Baker \*

An exposure test of porcelain enamels on aluminum was initiated by the National Bureau of Standards and the Porcelain Enamel Institute in 1964. The enamels were returned from the exposure sites to the laboratory at NBS to be measured for changes in gloss and color after exposures of six months, one year, and three years. Changes were found to be greatest at Kure Beach and least at Montreal and Los Angeles, with moderate changes occurring at Washington and New York.

Although the boiling citric acid test is used as an acceptance test for these enamels, the correlation with color change, particularly at Kure Beach, was not as good as expected. A cupric chloride test was developed which shows an improvement in this correlation.

Key words: Color; gloss; porcelain enamel on aluminum; weather resistance.

## 1. Introduction

The application of porcelain enamels to aluminum is a relatively recent development in the field of porcelain enameling. A few of the early porcelain enamels on aluminum included in an exposure test initiated in 1956 [1]<sup>1</sup> indicated that accelerated tests used with confidence for porcelain enamels on steel were not reliable indicators of the weatherability of the new, lower firing porcelain enamels on aluminum. Therefore the Aluminum Council of the Porcelain Enamel Institute agreed to sponsor, with the National Bureau of Standards, an exposure test consisting solely of porcelain enamels on aluminum. Nine colors used in

porcelain enamels on aluminum and enamels varying in initial gloss and thickness were tested.

The enamels in this test are exposed at Kure Beach, North Carolina; New York, New York; Washington, D.C.; Los Angeles, California; and Montreal, Canada. They were inspected after exposures of six months, one year, and three years and were returned to the exposure racks for further exposure. This report is a summary of the results of these three inspections. The next inspection is tentatively scheduled after five years of exposure.

## 2. Materials and Procedures

### 2.1. Enamels

Sixteen enamel systems were included in this test. These enamel systems were represented by nine colors, three gloss ranges, and both one- and two-coat enamels as indicated in table 1.

The enamels in this test were coded for identification. Each enamel system can be identified by the first two code letters. The first letter is always A and indicates an enamel on aluminum. This letter may seem redundant but it is included because the manufacturers recognize their enamels by the three letter code. The second letter indicates the enamel system—color, number of coats, and gloss range—while the third letter indicates the different fabricators for each system. The differences between the enamel systems are apparent (see table 1) for all systems except AA and AZ, which were planned to have significantly different thicknesses. However, this difference was not attained during manufacture.

When variations in milling and firing of the enamels by the different fabricators are taken into account, there are, in effect, 51 different enamels included in this test.

### 2.2. Test Specimens

Each enamel was sprayed onto a 3 × 5-ft sheet of 0.064-in 6061 aluminum alloy. After the enamel was fired the sheet was cut with a band saw into a seventy-eight 4<sup>7</sup>/<sub>16</sub>-in-square and nine 4 × 6-in exposure specimens. This was done to obtain more uniform specimens than could be obtained by spraying and firing small individual metal blanks. Also, the specimens thus obtained would more closely simulate actual production enamels than small individually prepared specimens.

### 2.3. Exposure Sites

Three of the 4<sup>7</sup>/<sub>16</sub>-in-square specimens of each enamel were exposed on the roofs of Federal Government Buildings in New York, N.Y.; Los Angeles, California; and Washington, D.C.; as well as on the roof of the Stores Department Building in Montreal, Canada. Three of the 4 × 6-in specimens of each enamel

\* Research Associate from the Porcelain Enamel Institute at the National Bureau of Standards, 1964 to present.

<sup>1</sup> Figures in brackets indicate the literature references at the end of this paper.

were exposed at a ground site of the International Nickel Company's Corrosion Laboratory at Kure Beach, North Carolina, 80 feet from the ocean. In addition to the exposed specimens, three specimens of each enamel were stored for reference purposes. The remaining specimens of each enamel were kept for use in laboratory tests and for the development of new test methods.

## 2.4. Cleaning of Specimens

The enamel surface was cleaned before being measured for gloss and color. The cleaning treatment consisted of (1) scouring 30 strokes with a sponge that had been dampened with a 1 percent solution of trisodium phosphate and sprinkled with calcium carbonate, (2) rinsing with tap water, (3) rinsing with

<sup>a</sup> The 45° specular gloss was measured in accordance with ASTM designation C-346.

<sup>b</sup> The thickness was measured in accordance with ASTM designation E-376.

<sup>c</sup> The boiling acid solubilities were determined in accordance with ASTM designation C-283.

<sup>d</sup> The acid spot test ratings were determined in accordance with ASTM designation C-282.

distilled water, and (4) rinsing with alcohol. Before adopting this cleaning procedure, representative specimens of low, medium, and high gloss enamels were scoured with calcium carbonate for 650 strokes. No change in gloss was noted on the high gloss enamels while an increase of about 5 percent was noted after 350 strokes on both the medium and low gloss enamels. The gloss increased by about 15 percent after 650 strokes. The increase caused by the scouring may be the result of a smoother surface which reflects light better than the original surface. Since the increase was only 5 percent after 350 strokes (enough for 10 inspections) it was thought that this treatment would not significantly affect the exposure test results. The scouring treatment produced no noticeable color change.

### 2.5. Acid Resistance

The acid resistance of porcelain enamels on aluminum is measured by either the boiling acid solubility test [2] or by the citric acid spot test [3]. The enamels are rated by the boiling acid solubility test on the basis of weight loss per unit area; the enamels with the best acid resistance have the lowest weight loss. In the citric acid spot test the enamels are divided into five categories: AA, A, B, C, or D, with respectively decreasing acid resistance. Both

the boiling acid solubility and citric acid spot test ratings for the enamels included in this test are presented in table 1.

### 2.6. Thickness

The enamel thickness was measured at four locations on each specimen with an eddy current thickness gage [4]. The average thickness for each enamel is presented in table 1.

### 2.7. Gloss and Color

The 45-degree specular gloss of the enamels was measured [5] at four orientations near the center of the specimen before and after exposure. The average initial gloss for each enamel is given in table 1. The gloss after exposure is reported as the percentage gloss retained.

The color is measured before and after exposure with a color difference meter [6]. One of the three average storage specimens of each enamel was selected as the color standard to obtain the maximum efficiency possible with this type of instrument. The color change was calculated [7] from the color values and is reported as color retention which is 100 minus the color change in NBS units.

## 3. Results and Discussion

### 3.1. Visual Observation of Enamels

#### a. Amount of Soil Retained

A visual examination revealed that enamels exposed at New York City had the most dirt adhering to them while those exposed at Los Angeles, Washington, Montreal, and Kure Beach had respectively cleaner surfaces. The dirt deposits were readily removed from the enamels exposed at all sites except New York by the cleaning procedure outlined in section 2.4. The enamels exposed at New York required vigorous scouring with a sponge that was sprinkled with calcium carbonate to remove the dirt film.

#### b. Spalling

After the specimens were cleaned it was observed that "fishscale" type spalling occurred on some enamels exposed at all sites. In no case was the spalled area large enough to constitute failure [8].

#### c. Visual Evaluation of Color and Gloss

The enamels exposed at Washington, New York, Montreal, and Los Angeles appeared to have good color and gloss retention with the exception of the red enamels, which appeared lighter than the unexposed enamels. Many of the enamels exposed at Kure Beach had obviously undergone substantial color changes. The reds, blacks, dark greens, and blues lightened considerably. The red, dark green, and blue enamel surfaces had the appearance of light particles

surrounded by a darker colored matrix, while the black enamel surfaces appeared uniformly lightened. Many of the white enamels exposed at Kure Beach appeared to be yellowing. The weathering of some of the enamels exposed at Kure Beach had progressed to a point where changes in the gloss were readily apparent and the surfaces appeared chalky.

### 3.2. Instrumental Determinations of Color and Gloss

The average color- and percentage gloss-retention values obtained from the six-months', one-year's and three-years' inspections of these enamels are presented in tables 2 and 3. The data in figures 1 and 2 indicate that gloss does not change as uniformly with exposure time as color. The nonuniformity is probably caused by the exceptionally large percentage changes which result from small gloss changes for the low gloss enamels. For example, a change of one gloss unit will produce a 17 percent change in the gloss retained for low gloss enamel, AR-C, but only a 1 percent change for high gloss enamel, AO-A. The increase in percentage gloss retained for many of the low gloss enamels after three years' exposure (see table 3) may be caused by a smoothing of the surface by the weather.

An increase in the gloss-retention values of many low and medium gloss enamels exposed at New York City was also observed. These increases are attributed more to the severe scouring treatment necessary to

FIGURE 1. The effect of exposure time at the five weathering sites on the color retention of porcelain enamel on aluminum.

FIGURE 2. The effect of exposure time at the five weathering sites on the gloss retention of porcelain enamel on aluminum.

clean these specimens than to the action of the weather.

Since the percentage gloss-retention values were more variable than the color-retention values, the remainder of this report will be based primarily on color retention.

### 3.3. Comparison of Exposure Sites

The color-retention data were subjected to a two-sided sign test [9] to determine if the exposure conditions at the various sites caused significant differences in the color retention of the enamels. The exposure sites were divided into three categories on the basis of the observed results of the sign test. Kure Beach was in a category by itself and caused the greatest color change in the enamels. New York and Washington were grouped together and caused less severe color changes than Kure Beach but more severe than the sites in the third category, Montreal and Los Angeles.

### 3.4. Effect of Different Colors

The average color retentions for the nine enamel colors are presented in table 4 and figure 3. It can be seen that large color changes occurred for the red enamels exposed at all sites. This was expected since all the red enamels included in this test failed the nitric acid test for color retention [10] and would not be recommended for outdoor exposures.

Large color changes also occurred on the black, dark green, grey, and blue enamels exposed at Kure Beach. These changes were not predicted by any of the current tests for porcelain enamels on aluminum.

### 3.5. Effect of Initial Gloss

The enamels included in this test program were produced in three gloss ranges; low, having an initial 45-degree specular gloss of 35 or less; medium, between 36 and 69; and high, 70 or over. The average color-retention data (top section of table 5) indicate

<sup>a</sup> Computed from three specimens at each site.

no difference between the low and medium gloss enamels at any site but the high gloss enamels have lower color retentions at all sites. When the enamels were separated into individual colors, it was found that only the white, black, and light green enamels were produced in more than one gloss range. Study of the gloss-retained values for these colors (bottom of table 5) indicated no consistent correlation between color retention and initial gloss.

### 3.6. Effect of Coating Thickness

The average color retention for the one- and two-coat enamels (top part of table 6) indicates a difference in these systems. However, since the enamel colors weather differently, the only valid comparison is between white enamels, the only color produced in both one- and two-coat forms. This comparison is given in the lower part of table 6. Although the

FIGURE 4. Correlation between boiling acid solubility test and color retention for the enamels exposed at (a) Kure Beach, (b) Los Angeles.

differences in color retention of the one- and two-coat systems are small, less than one NBS unit at all sites, they may prove significant after longer exposure times. The one-coat enamels had consistently higher color retentions than the two-coat enamels.

### 3.7. Correlation with Accelerated Tests

The correlation between color retention and the boiling acid solubility test is illustrated for Kure Beach and Los Angeles in figure 4. It can be seen that at the mild site, Los Angeles, the color retention remains high regardless of the boiling acid solubility, while at the severe site, Kure Beach, the color retention may be as low as 70 or as high as 98 for approximately the same value of boiling acid solubility.

The relatively poor correlation between color retention and boiling acid solubility led to the development of another test which could be useful in predicting the color retentions of these enamels. The new test uses the same apparatus as the boiling acid solubility test but the reagents and time of treatment were changed. Fifty ml of 12.5 percent aqueous cupric chloride solution are substituted for 150 ml of 6 percent citric acid. The specimen surface is exposed to boiling cupric chloride solution for one hour. The treated area is then rinsed with 10 ml of a 1 percent solution of oxalic acid to remove any green copper stains that may have accumulated. The specimen is removed from the apparatus, washed with a mild detergent solution, rinsed with tap water, distilled

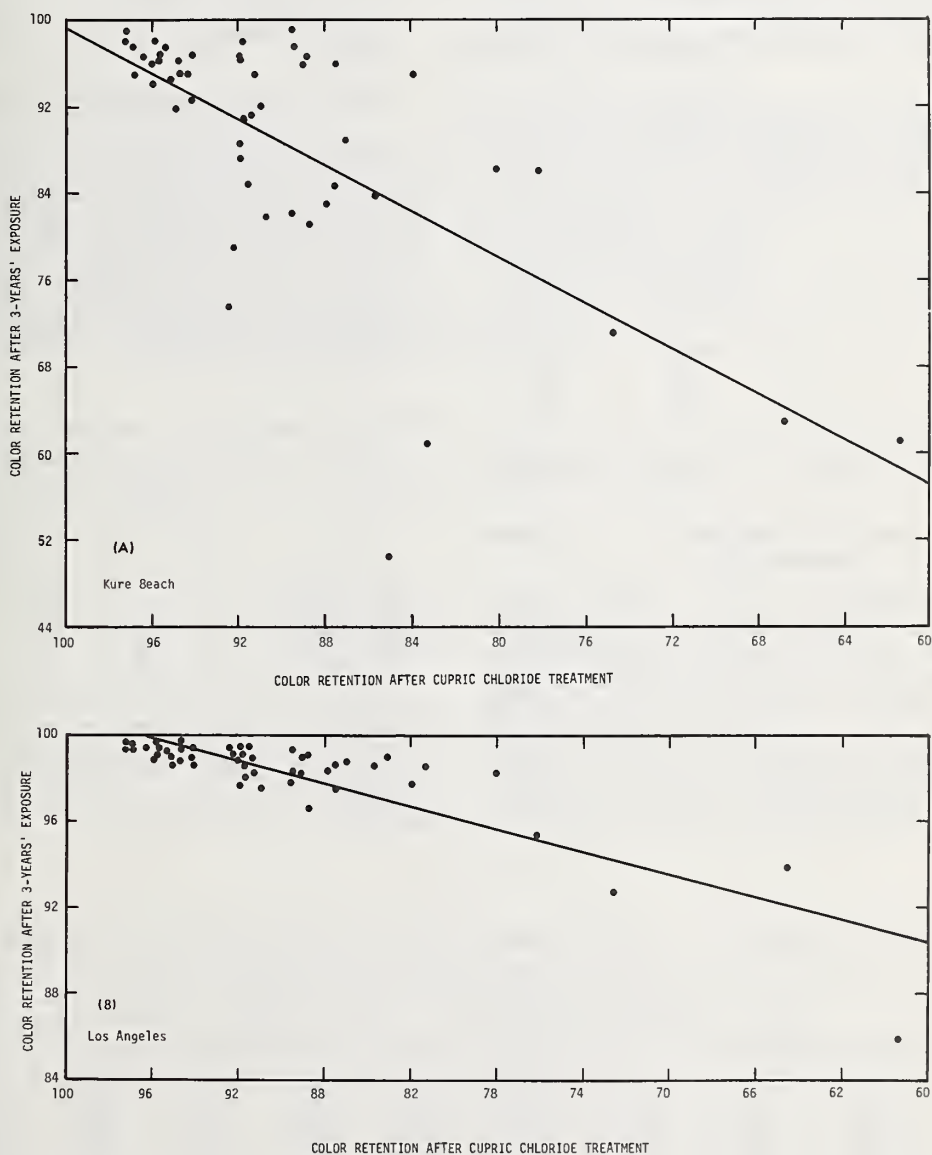

FIGURE 5. Correlation between boiling cupric chloride treatment and color retention for the enamels exposed at (a) Kure Beach, (b) Los Angeles.

water, and alcohol, and allowed to dry in a near vertical position. After the specimens are dry the color difference between the tested and untested portions of the specimens is determined and is used as a measure of the specimens' weather resistance. These values are plotted as a function of the color-retention values after three years' exposure in figure 5. The correlation is improved over that obtained for the boiling acid solubility as indicated by the smaller residual standard deviations (see table 7) for the fits of the least squares lines. Although the correlation between the color retention and the results of the boiling cupric chloride test is better than that with the boiling acid solubility test, it is felt that longer exposure times are necessary before any recommendations for specification changes are made. This increased exposure time is necessary because the color retention after three years' exposure of the enamels that passed the boiling acid solubility test is adequate (more than 94) at all sites except Kure Beach.

TABLE 7. Comparison of the residual standard deviations <sup>a</sup> for the least squares fits for boiling acid solubility and cupric chloride tests versus color retention of exposed enamels

Exposure site	Residual standard deviation of fit	
	Boiling acid solubility	Cupric chloride
Kure Beach-----	10.24	8.14
Washington-----	4.39	3.11
New York-----	2.45	1.48
Montreal-----	3.00	1.85
Los Angeles-----	2.23	1.20

<sup>a</sup> These residual standard deviations were computed by a subroutine called "Ortho", Walsh, P., Ortho, Commun. Assoc. Computing Mach. 5 511-13 (1962).

### 3.8. Correlation with Enamels in a Previous Exposure Test

Kure Beach, Washington, and Los Angeles are three sites common to both the current test and a test initiated in 1956 [11]. The average color-retention data for the enamels exposed at these sites in both tests are included in table 8. These data indicate that the enamels in the current test are as durable as the early porcelain enamels on aluminum at all sites, and at the milder sites, Washington and Los Angeles, are as good as the acid resistant enamels on steel. Since it was

shown (sec. 2.4) that the initial color has a marked effect on the color retention, only the white, yellow, and green enamels on aluminum were used in this comparison.

TABLE 8. Comparison of the color retention of the enamels in this test with those in an earlier test

Exposure test	Type of enamel	Average color retention <sup>a</sup> for enamels exposed at:		
		Kure Beach	Washington	Los Angeles
1956 b	Acid resistant, on steel-----	97.9	98.2	98.4
1956 b	On aluminum, (green, white, and yellow)-----	93.3	97.1	97.1
1964	On aluminum, (green, white, and yellow)-----	94.0	98.4	98.7

<sup>a</sup> Color retention is 100 minus the color change in NBS units.

<sup>b</sup> Data taken from Reference 11.

### 3.9. Nature-Tone Enamels on Aluminum

Seven nature-tone or mat enamels on aluminum were added to the test program after the one-year inspection. The initial gloss, color, and thickness of these enamels are presented in table 9 while the color-retention and percentage gloss-retained data for these enamels are presented in table 10. These data indicate good gloss and color retention for most enamels at all sites. One enamel, AM-7, spalled enough to constitute failure at all sites.

TABLE 9. Initial data for nature-tone enamels on aluminum

Enamel	Color	45-deg <sup>a</sup> Specular gloss	Thick-ness <sup>b</sup>	Boiling <sup>c</sup> acid solubility	Acid <sup>d</sup> spot test
			<i>mils</i>	<i>mg/in<sup>2</sup></i>	
AM-2	Lt. brown-----	19.5	2.3	10.0	A
AM-3	Blue-----	10.5	2.6	13.0	A
AM-4	Lt. blue-----	7.6	2.1	9.3	A
AM-5	Green-----	17.4	2.7	13.6	A
AM-6	Lt. green-----	16.5	3.1	8.0	A
AM-7	Gray-----	11.2	2.1	11.7	B
*AM-8	Lt. gray-----	45.3	2.0	15.7	B

<sup>a</sup> The 45-deg specular gloss was measured in accordance with ASTM designation C-346.

<sup>b</sup> The thickness was measured in accordance with ASTM designation E-376.

<sup>c</sup> The boiling acid solubility was determined in accordance with ASTM designation C-283.

<sup>d</sup> The acid spot test ratings were determined in accordance with ASTM designation C-282.

TABLE 10. Gloss and color retention of nature-tone enamels on aluminum after two years' exposure

Enamel	Average color retention <sup>a</sup> for enamels exposed at:					Average percentage gloss retained for enamels exposed at:				
	Kure Beach	Washington	New York	Montreal	Los Angeles	Kure Beach	Washington	New York	Montreal	Los Angeles
AM-2	92.9	97.1	98.9	97.5	98.8	76.8	91.5	119.2	87.3	85.7
AM-3	92.5	95.1	99.3	98.1	98.8	74.0	88.8	103.0	95.2	92.9
AM-4	95.2	98.9	99.3	99.2	99.1	79.9	82.4	108.3	105.6	103.0
AM-5	96.2	99.0	99.7	98.3	99.6	88.0	92.5	113.1	95.1	95.1
AM-6	96.4	98.9	99.5	99.7	98.9	77.3	89.9	110.7	91.4	85.2
AM-7	91.3	98.2	99.4	99.3	98.7	76.6	77.3	155.3	88.9	87.7
AM-8	93.9	97.8	98.7	97.7	98.6	65.0	93.0	84.9	84.9	82.2

<sup>a</sup> Color retention is 100 minus the color change in NBS units.

## 4. Summary

The 3-year inspection of the enamels included in the 1964 Exposure Test of Porcelain Enamels on Aluminum indicated that:

1. The color retention of all colors except reds was good at all sites except Kure Beach.
2. There was no significant spalling on any of the enamels originally included in this test. One nature-tone enamel added to the test after one year's exposure did spall.
3. The atmosphere at Kure Beach was extremely aggressive on many of the enamels included in this test.
4. There were no significant effects attributable either to initial gloss or coating thickness.
5. The correlation between color retention and boiling acid solubility was poor.
6. The results of the boiling cupric chloride test correlated better with color retention than did those of the boiling acid solubility test.

# NATIONAL BUREAU OF STANDARDS

The National Bureau of Standards<sup>1</sup> was established by an act of Congress March 3, 1901. Today, in addition to serving as the Nation's central measurement laboratory, the Bureau is a principal focal point in the Federal Government for assuring maximum application of the physical and engineering sciences to the advancement of technology in industry and commerce. To this end the Bureau conducts research and provides central national services in four broad program areas. These are: (1) basic measurements and standards, (2) materials measurements and standards, (3) technological measurements and standards, and (4) transfer of technology.

The Bureau comprises the Institute for Basic Standards, the Institute for Materials Research, the Institute for Applied Technology, the Center for Radiation Research, the Center for Computer Sciences and Technology, and the Office for Information Programs.

**THE INSTITUTE FOR BASIC STANDARDS** provides the central basis within the United States of a complete and consistent system of physical measurement; coordinates that system with measurement systems of other nations; and furnishes essential services leading to accurate and uniform physical measurements throughout the Nation's scientific community, industry, and commerce. The Institute consists of an Office of Measurement Services and the following technical divisions:

Applied Mathematics—Electricity—Metrology—Mechanics—Heat—Atomic and Molecular Physics—Radio Physics<sup>2</sup>—Radio Engineering<sup>2</sup>—Time and Frequency<sup>2</sup>—Astrophysics<sup>2</sup>—Cryogenics.<sup>2</sup>

**THE INSTITUTE FOR MATERIALS RESEARCH** conducts materials research leading to improved methods of measurement standards, and data on the properties of well-characterized materials needed by industry, commerce, educational institutions, and Government; develops, produces, and distributes standard reference materials; relates the physical and chemical properties of materials to their behavior and their interaction with their environments; and provides advisory and research services to other Government agencies. The Institute consists of an Office of Standard Reference Materials and the following divisions:

Analytical Chemistry—Polymers—Metallurgy—Inorganic Materials—Physical Chemistry.

**THE INSTITUTE FOR APPLIED TECHNOLOGY** provides technical services to promote the use of available technology and to facilitate technological innovation in industry and Government; cooperates with public and private organizations in the development of technological standards, and test methodologies; and provides advisory and research services for Federal, state, and local government agencies. The Institute consists of the following technical divisions and offices:

Engineering Standards—Weights and Measures—Invention and Innovation—Vehicle Systems Research—Product Evaluation—Building Research—Instrument Shops—Measurement Engineering—Electronic Technology—Technical Analysis.

**THE CENTER FOR RADIATION RESEARCH** engages in research, measurement, and application of radiation to the solution of Bureau mission problems and the problems of other agencies and institutions. The Center consists of the following divisions:

Reactor Radiation—Linac Radiation—Nuclear Radiation—Applied Radiation.

**THE CENTER FOR COMPUTER SCIENCES AND TECHNOLOGY** conducts research and provides technical services designed to aid Government agencies in the selection, acquisition, and effective use of automatic data processing equipment; and serves as the principal focus for the development of Federal standards for automatic data processing equipment, techniques, and computer languages. The Center consists of the following offices and divisions:

Information Processing Standards—Computer Information—Computer Services—Systems Development—Information Processing Technology.

**THE OFFICE FOR INFORMATION PROGRAMS** promotes optimum dissemination and accessibility of scientific information generated within NBS and other agencies of the Federal government; promotes the development of the National Standard Reference Data System and a system of information analysis centers dealing with the broader aspects of the National Measurement System, and provides appropriate services to ensure that the NBS staff has optimum accessibility to the scientific information of the world. The Office consists of the following organizational units:

Office of Standard Reference Data—Clearinghouse for Federal Scientific and Technical Information<sup>3</sup>—Office of Technical Information and Publications—Library—Office of Public Information—Office of International Relations.
