Foreword

The Federal Information Processing Standards Publication Series of the National Bureau of Standards is the official publication relating to standards adopted and promulgated under the provisions of Public Law 89-306 (Brooks Act) and under Part 6 of Title 15, Code of Federal Regulations. These legislative and executive mandates have given the Secretary of Commerce important responsibilities for improving the utilization and management of computers and automatic data processing in the Federal Government. To carry out the Secretary's responsibilities, the NBS, through its Institute for Computer Sciences and Technology, provides leadership, technical guidance, and coordination of Government efforts in the development of guidelines and standards in these areas.

Comments concerning Federal Information Processing Standards Publications are welcomed and should be addressed to the Director, Institute for Computer Sciences and Technology, National Bureau of Standards, Gaithersburg, MD 20899.

James H. Burrows, *Director*
Institute for Computer Sciences and Technology

Abstract

This document describes a set of verification tests designed by the Institute for Computer Sciences and Technology (ICST) at the National Bureau of Standards (NBS) to evaluate the conformance to the joint Federal Information Processing Standard Publication 100 (FIPS PUB 100)/Federal Standard 1041 (FED-STD 1041) for the interface to an X.25 packet switched network. A fundamental objective of these verification tests is concerned with establishing uniform verification testing and unambiguous evaluation procedures to aid government users in acquiring ADP and telecommunications facilities or services based on the X.25 specifications. These tests are designed for use by vendors and suppliers so as to provide government users with assurance the products they acquire are in conformance with the FIPS PUB 100/FED-STD 1041 specifications and can inter-work.

KEY WORDS: data circuit-terminating equipment; data terminal equipment; Federal Information Processing Standards Publication; FIPS PUB 100/FED-STD 1041; interoperability; verification tests; X.25 packet switched networks.

Announcing the Conformance Tests for
FIPS PUB 100/FED-STD 1041 Version of
CCITT 1980 Recommendation X.25

Interface Between Data Terminal Equipment (DTE)
and Data Circuit-Terminating Equipment (DCE)
for Operation with Packet-Switched Data
Communications Networks

Federal Information Processing Standards Publications are developed and issued by the National Bureau of Standards pursuant to section 111(f)(2) of the Federal Property and Administrative Services Act of 1949, as amended, Public Law 89-306 (79 Stat. 1127), Executive Order 11717 (38 FR 12315, dated May 11, 1973), and Part 6 of Title 15 Code of Federal Regulations (CFR).

Name of Document: Conformance Tests for FIPS PUB 100/FED-STD 1041 Version of CCITT 1980 Recommendation X.25, Interface Between Data Terminal Equipment (DTE) and Data Circuit-Terminating Equipment (DCE) for Operation with Packet-Switched Data Communications Networks.

Category of Document: Conformance Tests.

Explanation: This FIPS specifies a standard set of tests to evaluate DTE/DCE conformance to FIPS PUB 100/FED-STD 1041. It is intended to aid users in acquiring telecommunications facilities or services based on the CCITT Recommendation X.25. The conformance tests are designed for use by test evaluators, test suite designers or implementors, or users implementing the CCITT 1980 Recommendation X.25.

Approving Authority: U.S. Department of Commerce, National Bureau of Standards (Institute for Computer Sciences and Technology).

Maintenance Agency: U.S. Department of Commerce, National Bureau of Standards (Institute for Computer Sciences and Technology).

Cross Index:

- (a) FIPS PUB 100/FED-STD 1041, Interface Between Data Terminal Equipment (DTE) and Data Circuit-Terminating Equipment (DCE) for Operation with Packet-Switched Data Communications Networks, July 6, 1983.

- (b) CCITT Recommendation X.25, Interface Between Data Terminal Equipment (DTE) and Data Circuit-Terminating Equipment (DCE) for Terminals Operating in the Packet Mode on Public Data Networks, 1980.

Applicability: The use of this FIPS is encouraged, but not mandatory.

Implementation: This FIPS should be referenced by Federal agencies having requirements for the use of networks or terminals implementing the CCITT 1980 Recommendation X.25 as specified in FIPS PUB 100/FED-STD 1041.

Specifications: Federal Information Processing Standards, Publication 122 (FIPS PUB 122), Conformance Tests for FIPS PUB 100/FED-STD 1041 Version of CCITT Recommendation X.25 (affixed).

Special Information: This FIPS is based upon knowledge obtained by NBS staff members from various departments and agencies of the Federal Government, in addition to input received from other sources both within and outside the Government. The technical contents of this FIPS have been widely distributed to, and adopted and implemented by, Federal agencies and industry.

All comments and recommendations are welcomed and will be considered in any future revisions. These comments should be addressed to:

Where to Obtain Copies: Copies of this publication are for sale by the National Technical Information Service, U.S. Department of Commerce, Springfield, VA 22161. When ordering, refer to Federal Information Processing Standards Publication 122 (FIPS PUB 122) and title. Payment may be made by check, money order, purchase order, credit card, or deposit account.

Conformance Tests for FIPS PUB 100/FED-STD 1041 Version of CCITT 1980 Recommendation X.25

Abstract: NBS has developed a set of verification tests which can be applied by any organization to determine compliance with Federal Information Processing Standard Publication 100/Federal Standard 1041, the government's standard for interfacing data terminals and computers to public data networks operating in packet mode. A fundamental objective of these verification tests is concerned with establishing uniform verification testing and unambiguous evaluation procedures to aid government users in acquiring ADP and telecommunications facilities or services based on the X.25 specifications. These tests are designed for use by vendors and suppliers so as to provide government users with assurance the products they acquire are in conformance with the FIPS PUB 100/FED-STD 1041 specifications and can interwork.

Index Terms: X.25 verification, X.25 certification, public data network, Recommendation X.25, Federal Information Processing Standard, telecommunications.

1.0 PURPOSE

This document describes a set of verification tests designed by the Institute for Computer Sciences and Technology (ICST) at the National Bureau of Standards (NBS) to evaluate the conformance to the joint Federal Information Processing Standard Publication 100 (FIPS PUB 100)/Federal Standard 1041 (FED-STD 1041) for the interface to an X.25 packet switched network. A fundamental objective of these verification tests is concerned with establishing uniform verification testing and unambiguous evaluation procedures to aid government users in acquiring ADP and telecommunications facilities or services based on the X.25 specifications. These tests are designed for use by vendors and suppliers so as to provide government users with assurance the products they acquire are in conformance with the FIPS PUB 100/FED-STD 1041 specifications and can interwork.

2.0 REFERENCES

2.1 Federal Information Processing Standards Publication 100/Federal Standard 1041, July 6, 1983, entitled "Interface Between Data Terminal Equipment (DTE) and Data Circuit-Terminating Equipment (DCE) for Operation with Packet-Switched Data Communications Networks," designated in this manual as the FIPS PUB 100/FED-STD 1041.

2.2 CCITT Recommendation X.25 (1980), entitled "Interface Between Data Terminal Equipment (DTE) and Data Circuit-Terminating Equipment (DCE) for Terminals Operating in the Packet Mode on Public Data Networks," designated in this manual as the CCITT X.25.

3.0 DEFINITIONS

DEVICE UNDER TEST (DUT): The DTE or DCE that interacts with the Verification Test Equipment (VTE) operating under the test procedures specified in this document.

TEST MODULE: A series of test sequences that are selected to test the DUT at a particular state.

TEST PROCEDURE: Test sequences that a DUT is required to perform under both normal and abnormal conditions.

TEST SEQUENCE: A sequence of test steps that constitute the testing of a complete VTE generated input.

TEST STEP: A part of a test sequence.

VERIFICATION: Execution of a series of tests and evaluation of the test results to determine whether an X.25 implementation conforms to the requirements of the FIPS 100.

VERIFICATION PROGRAM: The set of verification tests that is described in this manual.

VERIFICATION TEST EQUIPMENT (VTE): The equipment that is used to perform the verification test procedures designated in this manual as the VTE.

VERIFICATION TESTS: The actual tests that implement the verification program.

4.0 BACKGROUND

The CCITT Recommendation X.25 (1980) specifies a recommended method for any data terminal equipment (DTE) to interface to any data-circuit terminating equipment (DCE). This recommendation represents a consensus among the various public data network and terminal suppliers, and aims to achieve compatibility between DTE and DCE. However, a DTE, claimed to be X.25-compatible, at times, may not be able to communicate with a public data packet switching network. This is because the recommendation contains a large number of options and implementation alternatives, which if exercised in different ways could limit or prevent the interoperability of equipment and services.

On July 6, 1983, the Secretary of Commerce and the Administrator of the General Services Administration jointly approved the adoption of a subset of the CCITT Recommendation X.25 for use by the Federal Government. This is called the Federal Information Processing Standard Publication 100 (FIPS PUB 100)/Federal Standard 1041 (FED-STD 1041), and was developed by the Institute for Computer Sciences and Technology (ICST) of the National Bureau of Standards (NBS), and the National Communications System (NCS). It requires that Federal automated data processing equipment, services, and telecommunication equipment using public packet switched data networks based on CCITT X.25 shall employ the interface and protocol specified in the FIPS PUB 100/FED-STD 1041.

In parallel with the development of FIPS PUB 100/FED-STD 1041, the ICST proceeded to develop and implement a verification methodology to evaluate conformance to the standard interface. Such a verification methodology is expected to be used by Federal agencies who are acquiring automated data processing and telecommunications services based on the X.25 specifications. The objective of this

parallel approach was to be able to ensure a high degree of interoperability among X.25 based facilities and services acquired by the government beginning at the time when FIPS 100 became effective.

The initial version of this verification program document was distributed to selected public and private sector reviewers for comment. The ICST has incorporated the comments and suggestions resulting from that review in preparing this document.

5.0 THEORY OF OPERATION OF THE ICST VERIFICATION PROGRAM

The conformance tests described in this document are based on a state-matrix approach which involves pass-failure checking of all mandatory features of the FIPS PUB 100/FED-STD 1041 specifications. Should the specifications allow two or more alternative features, at least one of the alternatives must be implemented.

This document does not cover the testing of optional features. However, if an implementation does include such features, it should be in the manner as stated by the standard and its inclusion should be declared.

Performance testing is also not covered by this document. The X.25 specification does provide a definition suitable for performance evaluation.

5.1 DESIGN CRITERIA

The verification test equipment (VTE) will operate with the device under test (DUT) and automatically evaluate its implementation of the FIPS PUB 100/FED-STD 1041 specifications by performing a series of test sequences. These test sequences require the DUT to perform under both normal and abnormal conditions and include procedures for testing timing constraints and intentional protocol violations to ensure that the DUT responds in a reasonable and acceptable manner in each case. All of the predefined error conditions that could occur are tested to ensure that the error conditions result in the appropriate message or response.

The link level and the packet level are verified separately. The link level is always tested first since the packet level uses the link level in its tests.

Automated procedures are used to accelerate testing progress, reduce errors, and minimize costs. The commands, responses, test parameters, and test sequences are designed to employ the same terminology as that used in specifications. A post-test analysis is performed to provide step-by-step comparisons between the expected results and actual results. To the extent practical, this analysis is performed automatically so that comparisons are done quickly; discrepancies are noted in the form of exception reports, and tests can be run with steps being repeated without extensive operator intervention.

5.2 TESTING METHODOLOGY

The VTE implements a form of functional testing. The functional testing is used to evaluate whether the interface implementation in the DUT can perform all of the required functions. The test sequences are deduced from the specification while the

implementation in the DUT is treated by the VTE as a black box. The following criteria are used to measure the test coverage:

- (1) All required functions defined by the FIPS PUB 100/FED-STD 1041 specifications are executed correctly at least once.
- (2) Certain combinations of the defined functions are executed correctly at least once.
- (3) The DUT must be able to recover from all incorrect actions on the part of its correspondent.

5.2.1 DETERMINATION OF TEST CASES

State matrices (see Appendices A and B of this document), derived from the CCITT X.25 specification have been used to determine the test sequences. The fundamental idea of these state matrices is to identify conditions or combinations of conditions which are relevant for the correct execution of the implementation. The matrices are arranged in a way that the columns represent the current state of the DUT, and the rows represent all possible valid and invalid incoming packets. The matrix element entries define the action to be performed and the new state to be entered when certain inputs are received in that state. This means, if the VTE knows what state the DUT is in, it can apply a selected set of inputs to the DUT. Based on these inputs, the VTE expects the DUT to change to a certain new state, and generate a certain response. This kind of interaction between the VTE and the DUT defines a series of interface sequences. A series of interface sequences constitutes a verification test sequence.

The VTE can be used to verify a DTE as well as a DCE. There are two similar sets of state matrices, one set for testing the DTE, and another for the DCE. Since the CCITT X.25 is not a symmetrical protocol, different testing sets are needed for the DTE and DCE sides of the interface.

State matrices for the DCE are based on Annex C of the CCITT X.25 specification, with further expansion to meet the requirements of the FIPS PUB 100/FED-STD 1041 specification. The DTE state matrices are not part of the CCITT X.25 and were developed by ICST.

5.2.2 VERIFICATION TEST SEQUENCE PREPARATION

After the determination of appropriate test cases for verification, it is necessary to prepare test sequences representing each of the test cases.

Assisted by the state matrices, requirement specifications, and the state diagrams given in CCITT X.25, verification test sequences are built by using the appropriate X.25 command/response packet interchanges.

Each individual test is generally divided into the following steps:

- (1) The DUT is driven to a known starting state by the VTE.

- (2) The DUT is then driven by the VTE to the necessary initial state for the selected test sequence.
- (3) The VTE provides a prescribed input to the DUT; or if the test must be originated by the DUT, the DUT must send a selected command/response to the VTE.
- (4) Verify that the actual response from the DUT compares with the expected response.

In situations where more than one output from the DUT is valid, any one of those outputs is considered acceptable.

If the results obtained disagree with those expected, that particular test is aborted and the incorrect results are automatically documented by the VTE. Testing is continued from the next test sequence until all test sequences in that module are completed.

5.2.3 MODULAR TESTING

A test module is defined to be all of the test sequences that are necessary to test the DUT at a particular state. There is a total of 22 test modules (corresponding to the 22 possible states defined for X.25) for any DUT. Each module is tested automatically. The sequences for each module are queued and applied to the DUT sequentially. For each test sequence (or interface sequence), the output of the DUT is captured by the VTE and evaluated for correctness.

5.2.4 DYNAMIC MODIFICATION

Under operator control, the VTE is able to skip or accept modified test sequences in order to correct or bypass certain test steps without completely aborting a test run. The reasons for this dynamic test modification capability are to provide the following:

- (a) To retest specific sequences that previously had problems.
- (b) To enable manual inputting of augmented or new test sequences for the identification or evaluation of potential problem areas.
- (c) To sort out a subset of tests in order to supplement the testing services that have been provided by some other testing organization.

5.2.5 LOGGING

In addition to the success or failure of each test step, the test log maintained by the VTE records all interface sequences consisting of the individual frames or packets sent or received.

5.2.6 TEST CAPABILITIES

The link and the packet levels are tested separately. The link level is always tested first. While the packet level testing is being performed, all link level functions are handled automatically and are transparent to the packet level testing.

5.2.6.1 LINK LEVEL MANUAL MODE: When operating in the link level manual mode, the VTE will accept commands and responses from the DUT, but will not automatically return the required command and response. The operator can elect to cause the VTE to transmit any valid or invalid frame and observe the reaction of the DUT. The link level manual mode permits the operator to:

- (a) set link level system parameters including the baud rate and the values of K, N1, N2, and T1;
- (b) generate link level errors; and
- (c) generate specific command or response frames.

5.2.6.2 LINK LEVEL AUTOMATIC MODE: When operating in the link level automatic mode, the VTE acts as a fully implemented DTE or DCE automatically performing complete test sequences while still permitting manual inputting between test sequences. The link level automatic mode employs preselected parameter values and interface sequences but the operator may:

- (a) set link level system parameters;
- (b) generate link level errors; and
- (c) generate specific command or response frames.

5.2.6.3 PACKET LEVEL MANUAL MODE: When operating in the packet level manual mode, the VTE accepts command and response packets from the DUT, but will not automatically transmit the required command and response. The operator may elect to have the VTE transmit any valid or invalid packet, and observe the reaction of the DUT. The packet level manual mode permits the operator to:

- (a) define packet level system parameters to include the range of logical channel numbers, assigning logical channels for permanent virtual circuits, and the packet level window sizes;
- (b) generate specific correctly or incorrectly formatted packets or packet sequences;
- (c) send any bit pattern; and
- (d) create packet level exception conditions.

5.2.6.4 PACKET LEVEL AUTOMATIC MODE: The VTE acts as a fully implemented DTE or DCE with optional manual inputting capability. The packet level automatic mode employs preselected sequences and parameters while still permitting the operator to:

- (a) set packet level system parameters;
- (b) allow packets from one or more logical channels to be transmitted or received;
- (c) create exception conditions;
- (d) send any bit pattern; and
- (e) generate specific packets.

5.3 ANOMALIES OF THE TESTING PROCESS

One of the design criteria is that the DUT be treated by the verification system as a black box. This condition eliminates the burden of the DUT equipment supplier to implement software driver in the DUT. For this reason, the testing of the DTE during the DCE defined states (e.g., Restart Indication, Incoming Call, Clear Indication, or Reset Indication) may end up in testing of some other states (e.g., Packet Level Ready, Data Transfer, or Flow Control Ready). Conditions of this type occur if the DTE accepts and processes the incoming packets one at a time. For example, if a test is set up to verify a DCE Restart Request state, the verification system tries to set up the initial condition by transmitting a Restart Indication, immediately followed by an error packet. The verification system is expecting the DTE to discard the error packet, then send a Restart Request in response. However, the DTE responds to the Restart Indication with a Restart Confirmation. As far as the DTE is concerned, the packet level is now in the Packet Level Ready state. The DTE then processes the next packet in sequence--in this case, the error packet which the DTE was intended to process in Restart Indication state. The DTE responds to the error packet as it was in Packet Level Ready state.

Similar situations occur in testing of a DCE. The testing of the DTE defined states (e.g., Restart Request, DTE Waiting, Clear Request, or Reset Request) may end up in actually testing of some other states (e.g., Packet Level Ready, Data Transfer, or Flow Control state).

Another difficulty is that the CCITT X.25 does not require that the DUT send a DISC command. Therefore, the initial condition to test the Link Disconnect state may not be realizable. Testing of this state has to be skipped if this condition occurs.

6.0 TEST PROCEDURES

This section summarizes the verification tests and outlines all of the steps required to execute a complete verification as well as the criteria for the success of each test on a step-by-step basis. It also provides a general functional overview of the VTE test driver software.

The detailed tests are listed respectively in Appendix A and Appendix B for the verification of a DTE and for the verification of a DCE.

Each appendix is further divided into link and packet level testing sections.

When operating with the (DTE) procedures listed in Appendix A, the VTE interacts as an X.25 DCE operating under the procedures specified in FIPS PUB 100/FED-STD 1041. The DTE, in this test configuration, is the device under test (DUT).

When operating with the (DCE) procedures listed in Appendix B, the VTE interacts as an X.25 DTE operating under the procedures specified by FIPS PUB 100/FED-STD 1041. The DCE, in this test configuration, is the device under test (DUT).

The VTE is capable of interacting with the DUT and performing all required tests in either a local or remote configuration. When connected locally, the VTE employs a direct connection to the DUT (e.g., through an RS-232-C connection). For remote testing, the VTE and DUT are connected through modems and transmission facilities appropriate for the user class of service (signalling speed) being tested.

In either the local or remote configuration, the tests performed by the VTE exercise and evaluate the ability of the DUT to properly:

- (1) operate under the procedures and electrical constraints of the physical level interface, as specified in FIPS PUB 100/FED-STD 1041 and at the chosen signalling speed(s).
- (2) operate under the link level procedures specified in FIPS PUB 100/FED-STD 1041.
- (3) operate under the packet-level procedures specified in FIPS PUB 100/FED-STD 1041 in the permanent virtual circuit (PVC) service.

NOTE: This requirement is not applicable to DTE's which do not support permanent virtual circuit service.

- (4) operate under the packet-level procedures specified in FIPS PUB 100/FED-STD 1041 in the virtual call (VC) service.

NOTE: This requirement is not applicable to DTE's which do not support virtual call service.

While exercising each of the physical, link, and packet-level procedures permitted to be used by FIPS PUB 100/FED-STD 1041, the ability to operate simultaneously with combinations of one or more PVC and VC logical channels is also tested.

The VTE also initiates packet level, link access procedure B (LAPB), and physical level procedures not permitted by FIPS PUB 100/FED-STD 1041 but permitted by CCITT X.25. The DUT should treat those procedures not permitted by FIPS PUB 100/FED-STD 1041 but permitted by CCITT X.25 as error conditions.

The VTE also evaluates the ability of the device under test to perform each of the error procedures specified in FIPS PUB 100/FED-STD 1041.

Each test step results in a summary printout that includes the identification of the DUT, its response to each test step, the acceptability of the response, as well as any appropriate timing information.

7.0 ICST IMPLEMENTATION OF THE FIPS PUB 100/FED-STD 1041 VERIFICATION PROGRAM

Figure 1 shows the configuration of the ICST's implementation of the verification program. The DUT can be connected to the VTE directly or remotely. For remote connection, a separate telecommunication terminal (300/1200 b/s, asynchronous, full duplex) must be available and located in close proximity to the DUT to accept test status and reports from the VTE via a separate data link.

The test procedures have been implemented in a protocol tester DYNAPAC NET/18¹ and used to verify a number of implementations. It has been demonstrated that this automated verification system is able to find a significant number of errors in different implementations. Codes for more than 400 tests, contained in diskettes, were written for the testing of DTE. The contents of these codes are subject to periodic revision, taking into consideration its correctness to the specifications of the FIPS PUB 100/FED-STD 1041.

The Defense Communications Engineering Center of the Defense Communications Agency (DCA) is employing these verification techniques for evaluating equipment conformance to the Defense Data Network. Programming and coding for that system is also completed. DCA's system hardware is based on another protocol tester, the Chameleon from Tekelec, Inc.,¹ and conformance between the DCA and ICST implementations has been determined.

Hewlett Packard¹ and Atlantic Research Corporation¹ have also implemented the FIPS PUB 100/FED-STD 1041 verification program in their protocol testers HP 4955A and Interview COMSTATE II, respectively.

8.0 APPLICATION NOTES

The following notes are applicable to parties interested in using this document for evaluating their equipment conformance to FIPS PUB 100/FED-STD 1041:

- (a) Copies of this document, the FIPS PUB 100/FED-STD 1041, and the CCITT X.25 are for sale by the National Technical Information Service, U.S. Department of Commerce, Springfield, VA 22161. When ordering, refer to the complete title of each document.
- (b) The full set of test procedures should be implemented as part of a user's X.25 verification test procedures.
- (c) The ICST's DTE verification software can be optionally obtained by directly writing ICST. The software programs are in machine language and are designed to be employed with the following specific configuration of equipment:
 - A high speed DYNAPAC NET/18 protocol tester with dual auxiliary floppy drive.
 - System disk NET/18 HS LEARN/DEBUG version 2.18 or above.
 - Utility disk version 1.6.

¹The equipment is identified in this document in order to adequately specify the experimental procedure. Such identification does not imply recommendation or endorsement by the ICST, nor does it imply that the equipment identified is necessarily the best available for the purpose.

While ICST provides this software and instructions for its use, no warranty is to be expected or implied. In addition, ICST does not approve, recommend, or endorse any commercial product. The user assumes the responsibility for the use of this software. Should this software be found defective, the user is responsible for all costs resulting from its malfunction as well as the cost of correcting.

- (d) The contents of the test procedures and these software programs are subject to periodic revision, taking into consideration the corrections and completeness of the software for testing the specifications of FIPS PUB 100/FED-STD 1041 and the CCITT X.25. Any suggestions for changes which would make future revisions more useful, are welcome, and should be addressed to the National Bureau of Standards, Institute for Computer Sciences and Technology, Gaithersburg, MD 20899, Attention: X.25 Verification Program.

9.0 EQUIPMENT CLASSIFICATION TERMINOLOGY

This section describes equipment classification terminology whose intent is to allow a precise description of the nature of the conformance to these test procedures. Users should inquire which classification best describes a product.

9.1 STATE MODEL CONFORMANCE

The equipment or services gives a clear indication of pass or failure after each test. State Model Conformance means passing all tests.

Suppliers of this type of equipment shall use the designation "Full State Model Conformance."

9.2 GENERAL INTEROPERABILITY CONFORMANCE

The equipment or services do not pass all tests. However, the capability for interoperability of such equipment or services with any other standard equipment or services may not be compromised or affected by the inability to properly perform certain tests. For example, upon receipt of a reset on a switched virtual call, a DTE may choose to initiate clearing of the call, rather than acknowledging the reset. This condition will not affect the interoperability between DTE's. It will, however, affect the system throughput.

Another example might be that, when a DTE sends or receives a frame reject, it goes into disconnect state and reports this condition to the higher level protocols. Some manufacturers may choose to operate this way to protect the higher level protocol integrity.

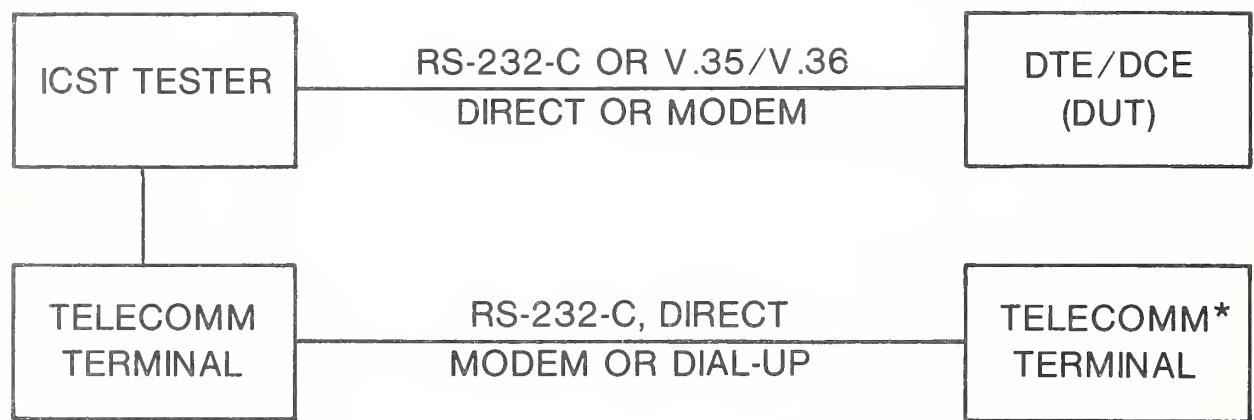

Suppliers of this type of equipment shall use the designation "General Interoperability Conformance" and provide a list of conditions that failed and the reasons why they believe that these conditions will not affect the interoperability between any other fully conforming equipment. Users should request this list and description to ascertain whether the qualifications affect their particular application.

9.3 GROUP INTEROPERABILITY CONFORMANCE

The equipment or services do not pass all tests. However, the interoperability among the same type of equipment or services in a closed user group operating environment is not compromised or affected by the failed tests. For example, in the disconnected mode (not power-down mode), a DTE may not monitor the incoming link level commands unless it is directed by the higher level protocols to do so. This condition occurs in DTE's that need the higher level protocols to initialize the link level activities. Interoperability with the group using the same default conditions will not normally be impaired.

As another example, in some DTE's, the higher level functions do not support expedited data. Therefore, the interrupt packet type will not be supported in this user group environment. However, this type of DTE shall not reject an incoming interrupt packet unless it knows the remote DTE has not implemented the interrupt packet type.

Suppliers of this type of equipment shall list all exceptions and use the designation "Group Interoperability Conformance."

*Only needed for remote testing

APPENDIX A

DTE LINK AND PACKET LEVEL VERIFICATION TESTS

This appendix establishes the verification tests to be used on an X.25 data terminal equipment (DTE) operating under the procedures specified by FIPS 100. In general, a DTE will pass the verification if it has been tested and no significant deviations have been identified.

There are a total of eight (8) modules for the verification of the link level. For each module, the tests are broken down into categories which evaluate the DTE's ability to respond to:

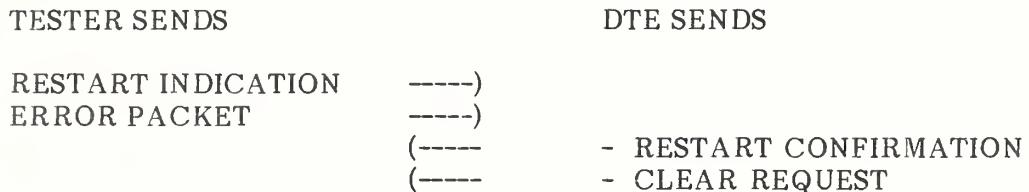

- 1) link setup
- 2) link disconnect
- 3) information transfer
- 4) error recovery
- 5) invalid N(s) and N(r)
- 6) window overruns
- 7) invalid length
- 8) invalid command or response
- 9) timer

There are a total of 14 modules for the verification of the packet level. Each module generally has the following tests:

- 1) proper packet procedures
- 2) packet format
- 3) invalid packet
- 4) packet length
- 5) invalid P(r) and P(s)
- 6) non-octet aligned data field
- 7) invalid facility code and value
- 8) virtual call and permanent virtual circuit
- 9) timers
- 10) invalid general format identifier

NOTES

1. The test result will not affect the outcome of the verification.
2. "Local Busy" state has not been included in the link level matrix. This is because the "Local Busy" state cannot be tested.
3. This text is not applicable to DTE's at level 2 frames that are not octet aligned.
4. The test is not applicable to DTE that does not support switched virtual call service.
5. If the diagnostic codes are different from those as given, ICST will determine their correctness as appropriate.
6. The testing of the DCE defined states (e.g., r3, p3, p7, or d3) may result in actually testing of state r1, p4, p1, or d1. This condition occurs if the DTE processes the incoming packets on a one by one basis. For example, if a test is set up to verify a r3 DCE restart request state:

Once the initialization is completed, the DTE responds to the restart indication with a restart confirmation. As far as the DUT is concerned, the packet level interface is now in the r1 state. The DTE then proceeds to process the next packet in sequence. In this case, the error packet which the DTE was intended to process in r3. The DTE responds to the error packet as prescribed in r1 (p1) state.

If the sequence as described above occurs, the DTE's response will be accepted as a valid response.

TABLES

- A4. DTE Data Transfer State Matrix
- A5. DTE Timer Values

MODULES

- A1. Verification of Link Level Disconnect Phase (DUT=DTE)
- A2. Verification of Link Level Link Disconnect (DUT=DTE)
- A3. Verification of Link Level Link Setup (DUT=DTE)
- A4. Verification of Link Level Frame Reject (DUT=DTE)
- A5. Verification of Link Level Information Transfer (DUT=DTE)
- A6. Verification of Link Level Remote Busy (DUT=DTE)
- A7. Verification of Link Level Reset (DUT=DTE)
- A8. Verification of Link Level Send Reject (DUT=DTE)
- A9. Verification of Packet Level Restart r1 (DUT=DTE)
- A10. Verification of Packet Level Restart Request r2 (DUT=DTE)
- A11. Verification of Packet Level Restart Indication r3 (DUT=DTE)
- A12. Verification of Packet Level Ready p1 (DUT=DTE)
- A13. Verification of Packet Level Call Request p2 (DUT=DTE)
- A14. Verification of Packet Level Incoming Call p3 (DUT=DTE)
- A15. Verification of Packet Level Data Transfer p4 (DUT=DTE)
- A16. Verification of Packet Level Call Collision p5 (DUT=DTE)
- A17. Verification of Packet Level Clear Request p6 (DUT=DTE)
- A18. Verification of Packet Level Clear Indication p7 (DUT=DTE)
- A19. Verification of Packet Level Flow Control Ready d1 (DUT=DTE)
- A20. Verification of Packet Level Reset Request d2 (DUT=DTE)
- A21. Verification of Packet Level Reset Indication d3 (DUT=DTE)
- A22. Multiple Logical Channels Testing (DUT=DTE)

MODULE A22
MULTIPLE LOGICAL CHANNELS TESTING
(DUT=DTE)

PURPOSE: Test DUT capability of handling simultaneously more than one VC's and more than one PVC's.

Data transfer simultaneously operate on 9 virtual calls and 2 permanent virtual circuits. Packet size = 128 octets. Determine the length it takes to transmit 15 data packets.

APPENDIX B

DCE LINK AND PACKET LEVEL VERIFICATION TESTS

This appendix establishes the verification tests to be used on an X.25 data circuit terminating equipment (DCE) operating under the procedures specified by FIPS 100. In general, a DCE will pass the verification if it has been tested and no significant deviations have been identified.

There are a total of eight (8) modules for the verification of the link level. For each module, the tests are broken down into categories which evaluate the DCE's ability to respond to:

- 1) link setup
- 2) link disconnect
- 3) information transfer
- 4) error recovery
- 5) invalid N(s) and N(r)
- 6) window overruns
- 7) invalid length
- 8) invalid command or response
- 9) timer

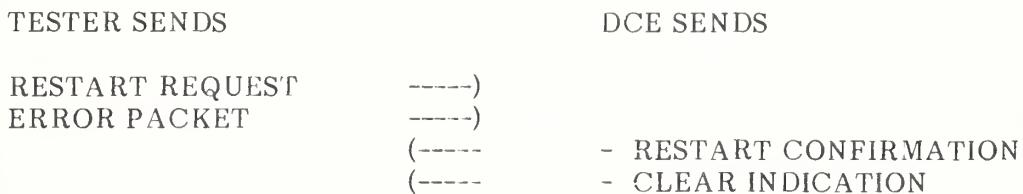

There are a total of 14 modules for the verification of the packet level. Each module generally has the following tests:

- 1) proper packet procedures
- 2) packet format
- 3) invalid packet
- 4) packet length
- 5) invalid N(s) and N(r)
- 6) non-octet aligned data field
- 7) invalid facility code and value
- 8) virtual call and permanent virtual circuit
- 9) timers
- 10) invalid general format identifier

A complete test including all test modules will be executed at the line speed of 9,600 bits per second. Spot checks will be performed at line speeds of 2,400 and 4,800 bits per second.

NOTES

1. The test result will not affect the outcome of the verification.
2. "Local Busy" state has not been included in the link level matrix. This is because the "Local Busy" state cannot be tested.
3. This text is not applicable to DCE's at level 2 frames that are not octet aligned.
4. If the diagnostic codes are different from those as given, ICST will determine their correctness as appropriate.
5. The testing of the DTE defined states (e.g., r2, p2, p6, or d2) may result in actually testing of state r1, p4, p1, or d1. This condition occurs if the DCE processes the incoming packets on a one by one basis. For example, if a test is set up to verify a r2 DTE restart request state:

Once the initiation is completed, the DCE responds to the restart request with a restart confirmation. As far as the DCE is concerned, the packet level interface is now in the r1 state. The DCE then proceeds to process the next packet in sequence. In this case, the error packet which the DCE was intended to process in r2. The DCE responds to the error packet as prescribed in r1 (p1) state.

If the sequence as described above occurs, the DCE's response will be accepted as a valid response.

Any Pkt with unassigned LCN			Discard, Diagnostic, #36				

DEFINITION:

NORMAL: Procedure as defined in the standard.

DISCARD: Discard the received packet and take no subsequent action.

ERROR: Procedure is defined as follows:

I. Error condition in virtual calls:

1. Discard the received packet.
2. Send Clear Indication with cause of local procedure error
3. Send remote DTE a Clear Indication with cause of remote procedure error.

II. Error condition in permanent virtual circuits:

1. Discard the received packet.
2. Send Reset Indication with cause of local procedure error.
3. Send remote DTE Reset Indication with remote procedure error.

MODULE B22
MULTIPLE LOGICAL CHANNELS
(DUT=DCE)

PURPOSE: Test DUT capability of handling simultaneously more than one VC's and more than one PVC's.

Data transfer simultaneously operates on 9 virtual calls and 2 permanent virtual circuits. Packet size = 128 octets. Determine the length it takes to transmit 15 data packets.

NBS Technical Publications

Periodical

Journal of Research—The Journal of Research of the National Bureau of Standards reports NBS research and development in those disciplines of the physical and engineering sciences in which the Bureau is active. These include physics, chemistry, engineering, mathematics, and computer sciences. Papers cover a broad range of subjects, with major emphasis on measurement methodology and the basic technology underlying standardization. Also included from time to time are survey articles on topics closely related to the Bureau's technical and scientific programs. Issued six times a year.

Nonperiodicals

Monographs—Major contributions to the technical literature on various subjects related to the Bureau's scientific and technical activities.

Handbooks—Recommended codes of engineering and industrial practice (including safety codes) developed in cooperation with interested industries, professional organizations, and regulatory bodies.

Special Publications—Include proceedings of conferences sponsored by NBS, NBS annual reports, and other special publications appropriate to this grouping such as wall charts, pocket cards, and bibliographies.

Applied Mathematics Series—Mathematical tables, manuals, and studies of special interest to physicists, engineers, chemists, biologists, mathematicians, computer programmers, and others engaged in scientific and technical work.

National Standard Reference Data Series—Provides quantitative data on the physical and chemical properties of materials, compiled from the world's literature and critically evaluated. Developed under a worldwide program coordinated by NBS under the authority of the National Standard Data Act (Public Law 90-396).

NOTE: The Journal of Physical and Chemical Reference Data (JPCRD) is published quarterly for NBS by the American Chemical Society (ACS) and the American Institute of Physics (AIP). Subscriptions, reprints, and supplements are available from ACS, 1155 Sixteenth St., NW, Washington, DC 20056.

Building Science Series—Disseminates technical information developed at the Bureau on building materials, components, systems, and whole structures. The series presents research results, test methods, and performance criteria related to the structural and environmental functions and the durability and safety characteristics of building elements and systems.

Technical Notes—Studies or reports which are complete in themselves but restrictive in their treatment of a subject. Analogous to monographs but not so comprehensive in scope or definitive in treatment of the subject area. Often serve as a vehicle for final reports of work performed at NBS under the sponsorship of other government agencies.

Voluntary Product Standards—Developed under procedures published by the Department of Commerce in Part 10, Title 15, of the Code of Federal Regulations. The standards establish nationally recognized requirements for products, and provide all concerned interests with a basis for common understanding of the characteristics of the products. NBS administers this program as a supplement to the activities of the private sector standardizing organizations.

Consumer Information Series—Practical information, based on NBS research and experience, covering areas of interest to the consumer. Easily understandable language and illustrations provide useful background knowledge for shopping in today's technological marketplace.

Order the above NBS publications from: Superintendent of Documents, Government Printing Office, Washington, DC 20402.

Order the following NBS publications—FIPS and NBSIR's—from the National Technical Information Service, Springfield, VA 22161.

Federal Information Processing Standards Publications (FIPS PUB)—Publications in this series collectively constitute the Federal Information Processing Standards Register. The Register serves as the official source of information in the Federal Government regarding standards issued by NBS pursuant to the Federal Property and Administrative Services Act of 1949 as amended, Public Law 89-306 (79 Stat. 1127), and as implemented by Executive Order 11717 (38 FR 12315, dated May 11, 1973) and Part 6 of Title 15 CFR (Code of Federal Regulations).

NBS Interagency Reports (NBSIR)—A special series of interim or final reports on work performed by NBS for outside sponsors (both government and non-government). In general, initial distribution is handled by the sponsor; public distribution is by the National Technical Information Service, Springfield, VA 22161, in paper copy or microfiche form.
