The Thermophysical Properties of Methane from 90 to 500 K
at Pressures to 700 Bar*

R. D. Goodwin

Thermophysical properties of methane are tabulated at uniform temperatures from 90.68 to 500 K along isobars to 700 bar. A novel equation of state is employed for the first time, having origin on the vapor-liquid coexistence boundary. Computations are based almost entirely on ideal gas specific heats and experimental P - ρ - T data via the equation of state, without weighting to data for derived properties. Good agreement with such data confirms validity of the equation and method. New P - ρ - T data are reported at 0.3 to 1.7 times the critical density.

Key words: densities; enthalpies; entropies; equation of state; internal energies; isobars; isochores; isotherms; Joule-Thomson inversion; latent heats of vaporization; melting line; orthobaric densities; PVT data; specific heats; speeds of sound; vapor pressures.

1. Introduction

Methane is the major component of natural gas, and hence of great economic importance. For the processes of liquefaction, separation, storage, pumping, transport and custodial transfer there is required a knowledge of physical and thermodynamic properties. For mixtures, some properties can be approximated by those of pure methane. For computations on the properties of LNG mixtures, the dominant thermodynamic data required again are those of methane. In the following work it is possible to test the thermodynamic computations against experimental data for specific heats, heats of vaporization, and speeds of sound available over wider ranges than for other components of LNG. Some of the experimental data obtained here on methane, for example the saturated liquid densities, also have been useful to others for calibrating experimental apparatus.

Extreme accuracy is needed in physical and thermodynamic properties data for engineering plant design, as demonstrated recently by Zudkevitch [73]. Two monographs on methane [61, 72] show, however, that low temperature data necessary for thermal computations either are non-existent or are inaccurate. In view of the importance of the low-temperature, liquid states of methane and natural gas, our objective has been to supply the needed properties data directly by experiment, and then to produce a set of self-consistent tables of thermodynamic functions over the entire range of fluid states.

* This work was carried out at the National Bureau of Standards under sponsorship of The American Gas Association.

This report culminates three years of work in acquiring available physical properties data, in performing experimental measurements, and in formulating these data for use in thermal computations. Nearly all of these formulations are new: designed to be consistent with critical-point behavior. Where appropriate, they are constrained both at the triple point and at the critical point for consistency in the derived thermodynamic network. New physical properties data which we have measured or derived are listed in Appendix D.

Our new equation of state is a contribution to the present task. An outstanding feature is that it originates on the vapor-liquid coexistence boundary, thus eliminating the long-standing problem of consistency between equations of state and this independently-derived locus. The equation also is consistent with the nonanalytic behavior of $C_v(\rho, T)$ about the critical point. It has only nine coefficients to be found by least squares from experimental P - ρ - T data, and these will be similar for most simple substances [30]. As compared with equations which employ a much greater number of arbitrary coefficients, we believe the present form to be advantageous for thermal computations because the derivatives, $\partial P/\partial T$, $\partial^2 P/\partial T^2$, and $\partial P/\partial \rho$ are more likely to be simple, monotonic functions of the independent variables, as demonstrated below by computed tabulations. We believe that a proper behavior of these derivatives is more important than the mere "representation" of experimental P - ρ - T data. In particular, experimental data from different laboratories often must be used which are not accurate, as proven by their lack of consistency. An equation of state with excess freedom then is most likely to give serious irregularities in the derivatives. As a reward for minimizing the number of arbitrary coefficients, we find in the present work that derived properties such as specific heats and speeds of sound, calculated "a priori" via the equation of state, do agree with experimental data within combined uncertainties, without any weighting of the equation of state to such data. This accomplishment, we believe, never before has been realized. It suggests that where such data do not exist experimentally, they might be estimated with some reliability via the present type of equation of state.

Symbols and units of this report are given in Appendix A. Temperatures are on the kelvin scale of IPTS-1968 [1]. Pressures are related to the International System by use of the bar, 1 bar = 10^5 Newton/square meter [3]. For the engineer we have computed

tables in British engineering units at integral pressures in psi and integral temperatures on the Fahrenheit scale. The conversion of units is given in Appendix C. Deviations in this report are expressed uniformly as the departure of an experimental value, Y , from the smooth function for a calculated value, Y_{calc} , in the form for relative deviation in percent, $100 \cdot (Y - Y_{\text{calc}}) / Y$.

2. Physical Properties and Their Representation

2.1 Fixed-Point Constants

Selected values for the triple- and critical-point constants are listed in Appendix B. The triple-point temperature and pressure are from our vapor-pressure equation [52]. The liquid density is an extrapolation of our accurate, saturated liquid densities [30] to the triple-point temperature. The vapor density is given by eq (4-c) of this report.

The critical-point temperature is from an analysis of dielectric constants by Verbeke [68]. The pressure is given by the vapor-pressure equation (3) below. The density is selected within the uncertainty in [68] to minimize the mean of relative pressure deviations via the present equation of state.

2.2 Melting Line and Vapor Pressures

These pressures $P(T)$ are reported in [52], where they are compared with other data. Melting pressures are formulated by the Simon equation

$$P/P_t = 1 + A \cdot [(T/T_t)^\epsilon - 1] , \quad (1)$$

with constants $\epsilon = 1.85$, $A = 16,259.1$. The precision is better than 0.1 percent in pressure [52].

Densities of the freezing liquid were obtained at three points to a maximum pressure of 220 bar at intersections of our experimental isochores with the melting line, as reported in [23]. They are represented within the precision of 0.02% in density by our simple expression

$$(d/d_t) = (T/T_t)^{1/4} . \quad (2)$$

Our recent vapor pressure measurements are compared with other data in [52]. Our vapor pressure equation (3) is adjusted for the value of T_c in the present report. Define the argument $x(T) \equiv (1-T_t/T)/(1-T_t/T_c)$, when the equation is--

$$\ln(P/P_t) = a \cdot x + b \cdot x^2 + c \cdot x^3 + d \cdot x \cdot (1-x)^{3/2} \quad (3)$$

$$a = 4.7774 \ 8580,$$

$$c = -0.5678 \ 8894,$$

$$b = 1.7606 \ 5363,$$

$$d = 1.3278 \ 6231.$$

The rms deviation for 103 points is 0.014%.

2.3 The Orthobaric Densities

The data were reviewed in [26]. We now have omitted data near the critical point in finding coefficients for the fitting functions, equations 4-a, 4-b, 4-c, because these data are least accurate, and the fitting functions in the critical region are influenced only slightly by these data. We include all data, however, in the comparison tables 1-A, 1-B, 1-C. Identifications in these tables are: ID = 1 for vapor densities obtained from the virial and vapor pressure equations [23]; ID = 1 for liquid densities obtained from our isochore intersections with the vapor pressure equation [30]; ID = 2 for vapor densities via the virial equation of this report; ID = 5 for data of Jansoone et al. [39]; ID = 6 for data derived via Ricci et al. [53]; and ID = 7 for privately-communicated data of O. B. Verbeke [68]. Some of the latter data are assigned two temperatures, differing by 0.02 K, due to uncertainties between different laboratories. Identifications given by three or four digits are for densities via our dielectric constant measurements [29].

a) For the saturated vapor, define the variables--

$$x(T) \equiv (T_c - T)/(T_c - T_t),$$

$$u(T) \equiv (T_c/T - 1)/(T_c/T_t - 1).$$

The function now is--

$$\ln(\rho/\rho_c) = a \cdot x^\epsilon + b \cdot x + c \cdot x^{4/3} + d \cdot x^{5/3} + e \cdot x \cdot u, \quad (4-a)$$

$$\epsilon = 0.46,$$

$$c = -8.657 \ 3409,$$

$$a = -2.703 \ 6003,$$

$$d = 5.264 \ 0362,$$

$$b = 3.166 \ 1552,$$

$$e = -3.526 \ 9034.$$

The comparisons are given in table 1-A.

b) For the saturated liquid we use $x(T)$ as defined above, and also,

$$W(x) \equiv a \cdot (1-x)^{2/3} + b \cdot (1-x)^{4/3} + c \cdot (1-x)^2,$$

in a function which is constrained both at the triple- and at the critical-points--

$$(\rho - \rho_c) / (\rho_t - \rho_c) = x^\epsilon \cdot \exp[W(x)], \quad (4-b)$$

$$\epsilon = 0.36,$$

$$b = 0.0483\ 8475,$$

$$a = -0.1788\ 60165,$$

$$c = -0.0184\ 8987.$$

The comparisons are given in table 1-B.

c) The single-valued function $T_\sigma(\rho)$, given by eq (4-c), is used for the equation of state. Densities are obtained by iteration, using eqs (4-a) and (4-b) only to find the initial density. Define the variables.

$$Y(T_\sigma) \equiv (T_c/T_\sigma - 1) / (T_c/T_t - 1),$$

$$U(\sigma) \equiv \exp\left[\epsilon \cdot \sigma \cdot (\sigma - \sigma_t) / |\sigma - 1|\right],$$

$$W(\rho) \equiv A_1 + A_2 \cdot \ln(\rho) + A_3 \cdot \rho^{1/3} + A_4 / (1 + E \cdot \rho^{2/3}) + \sum_{i=5}^{10} A_i \cdot \rho^{i-4},$$

where $\sigma_t \equiv d_t/d_c$ is a constant, $\epsilon = 1/2$, and $E = 8$. The function now has the simple form,

$$Y(T_\sigma) = U(\sigma) \cdot \left[1 + (\rho - 1) \cdot W(\rho)\right], \quad (4-c)$$

$$A_1 = 0.8432\ 0686,$$

$$A_6 = 10.8869\ 3606,$$

$$A_2 = 0.1597\ 2304,$$

$$A_7 = -32.4204\ 8700$$

$$A_3 = 0.9783\ 7869$$

$$A_8 = 63.1616\ 6459,$$

$$A_4 = 0.2865\ 4081$$

$$A_9 = -62.7209\ 0242,$$

$$A_5 = -1.7150\ 5402,$$

$$A_{10} = 25.9249\ 8181.$$

The comparisons are given in table 1-C.

The exponential form, $U(\sigma)$, used for $T_\sigma(\rho)$ in eq (4-c) was developed to give a well-behaved critical isotherm (non-negative slopes, $\partial P/\partial \rho$) for all reasonable assignments (within the experimental uncertainties) of the critical point (ρ_c, T_c) in the equation of state (6)

Whereas the thermal computations circumvent this near-critical region, the equation of state is tied to the saturation boundary described as a function of density by eqs (4-c) and (3). This may be the reason that we find the greatest deviations from experimental P - ρ - T data along isochores near the critical density, table 4.

2.4 The Virial Equation

For the virial equation of state,

$$Pv/RT = 1 + B(T) \cdot \sigma + C(T) \cdot \sigma^2 + \dots \quad (5)$$

the second and third coefficients, $B(T)$ and $C(T)$, here are dimensionless via reduced density, $\sigma \equiv d/d_c$. We reduce the temperature, $x \equiv T/T_t$, at the triple point. Sources of selected data in Tables 2-A, 2-B are: ID1 = Douslin [17], ID2 = Hoover [37], ID3 = Byrne [8], ID4 = Pope [51], and ID5 = Sengers [56]. The virial coefficients are formulated by completely new functions as follows,

$$B(T) = \left[B_1 + B_2/x^{1/2} + B_3/x + B_4/x^2 + B_5/x^3 \right] \cdot f(x) \quad (5-a)$$

where

$$f(x) \equiv 1 - (T_0/T)^{1/4},$$

$T_0 = 505.0 \text{ K},$	$B_3 = 123.540 \ 958,$
$B_1 = 16.974 \ 318,$	$B_4 = -92.601 \ 354,$
$B_2 = -80.055 \ 038,$	$B_5 = 42.974 \ 121.$

The third virial coefficient is represented by

$$C(T) = \left[C_1/x^{1/2} + C_2/x^2 + C_3/x^4 + C_4/x^6 \right] \cdot f(x), \quad (5-b)$$

where

$f(x) \equiv 1 - T_0/T,$	$T_0 = 139.922 \text{ K},$
$C_1 = 0.36 \ 212,$	$C_3 = 18.69 \ 531,$
$C_2 = 0.83 \ 584,$	$C_4 = 9.15 \ 517.$

In the above equations we have defined the arguments, $(1/x)^n$, such that they have a maximum value of unity at the triple point. We therefore may keep the same number of decimal digits in all of the least-squares coefficients. In this way one may ascertain that the constants given here contain more than a sufficient number of digits for the precision of data in tables 2-A and 2-B.

2.5 The Equation of State

Experimental compressibility (P - ρ - T) data are given in various ranges by several publications [9, 17, 30, 32, 39, 41, 44, 49, 54, 65, 66, 72]. Michels' data [49] are reviewed by Douslin [17]. Compressed liquid data of van Itterbeek [65], as well as those found in the monograph by Zagoruchenko [72], appear to be of lower accuracy than needed for thermal computations.

Data reproduced in the present report are summarized by table 3. For adjusting our equation of state we have used only three sets of data: 1) as computed by our virial equation; 2) our published data [30] and our new data given in this report; and 3) the data of Douslin et al. [17].

The present equation of state is novel in that it originates on the vapor-liquid coexistence boundary. The melting line, however, is not a part of this equation of state. It must be introduced independently.

By means of our function $T_{\sigma}(\rho)$, eqn (4-c), we obtain the vapor-liquid coexistence temperature for any density (isochore). Placing this in the vapor-pressure equation gives the coexistence pressure $P_{\sigma}[T_{\sigma}(\rho)]$. This defines the equation of state as a function of density on the vapor-liquid coexistence boundary. By subtraction we shift the origin to this boundary.

This novel equation of state may be written in concise form by use of the variables,

$$\begin{aligned} x(T) &\equiv T/T_c, & x_{\sigma}(\rho) &\equiv T_{\sigma}(\rho)/T_c, \\ Y(P, \rho, T) &\equiv (Z-1) \cdot x/\rho, & Y_{\sigma}(\rho) &\equiv (Z_{\sigma}-1) \cdot x_{\sigma}/\rho, \end{aligned}$$

as follows

$$(Y - Y_{\sigma}) = B(\rho) \cdot X_b(\rho, T) + C(\rho) \cdot X_c(\rho, T) + D(\rho) \cdot X_d(\rho, T), \quad (6)$$

where $B(\rho)$, $C(\rho)$, $D(\rho)$ are polynomial coefficients to be found by least squares, and the $X_i(\rho, T)$ are functions both of density and temperature as a consequence of subtracting the values at coexistence,

$$X_b(\rho, T) \equiv x \cdot [1 - \exp(-\beta/x)] - x_{\sigma} \cdot [1 - \exp(-\beta/x_{\sigma})],$$

$$X_c(\rho, T) \equiv 1/x - 1/x_{\sigma},$$

$$X_d(\rho, T) \equiv [1 - w \cdot \ln(1+1/w)]/u - [1 - w_{\sigma} \cdot \ln(1+1/w_{\sigma})]/u_{\sigma}.$$

The last of these functions gives nonanalytic behavior for $C_v(\rho, T)$ about the critical point by use of the variables,

$$\begin{aligned} u(\rho, T) &\equiv T/\theta(\rho), & w(\rho, T) &\equiv \delta \cdot (u-1), \\ u_{\sigma}(\rho) &\equiv T_{\sigma}(\rho)/\theta(\rho), & w_{\sigma}(\rho) &\equiv \delta \cdot (u_{\sigma}-1), \end{aligned}$$

where δ is an arbitrary constant, $\theta(\rho)$ is our locus of temperatures [18] inside the "dome" of figure 1,

$$\theta(\rho) \equiv T_{\sigma}(\rho) \cdot \exp \left[-\alpha \cdot |\sigma - 1|^3 \right],$$

and $T_{\sigma}(\rho)$ is given by eq (4-c) above. As described also in [26, 30], this is an empirical equation which is qualitatively consistent with the experimental behavior of $C_v(\rho, T)$ about the critical point.

The coefficients of (6) result from tedious investigations of various combinations of polynomials,

$$B(\rho) \equiv B_0 + B_1 \cdot \rho,$$

$$C(\rho) \equiv C_0 + C_1 \cdot \rho + C_2 \cdot \rho^2 + C_3 \cdot \rho^3,$$

$$D(\rho) \equiv (\sigma - 1) \cdot (D_0 + D_1 \cdot \rho + D_2 \cdot \rho^2).$$

For application of the least squares technique, each of the above polynomials is multiplied throughout by its temperature-dependent factor, $X_i(\rho, T)$ from eqn (6), to give nine least-squares coefficients.

The constants for eq (6) are

$$\alpha = 0.2, \quad \beta = 7, \quad \delta = 1,$$

$$B_0 = 1.5991\ 01971,$$

$$C_2 = -22.5567\ 15826,$$

$$B_1 = 2.4837\ 86733,$$

$$C_3 = 12.2896\ 65719,$$

$$D_0 = 0.9937\ 50233,$$

$$C_0 = -1.0760\ 88156,$$

$$D_1 = -1.2430\ 35021,$$

$$C_1 = 10.4821\ 92754,$$

$$D_2 = 0.3185\ 23715.$$

Table 4 gives a comparison of the experimental and calculated densities and pressures. The reader should note that $\partial\rho/\partial T$ and $\partial\rho/\partial P$ become infinite at the critical point. Density deviations therefore should be ignored in the critical region $0.95 \leq T/T_c \leq 1.1$. For compressed liquid at low temperatures the derivative $\partial P/\partial\rho$ becomes extremely large, such that small experimental errors in density will yield (via the equation of state) deviations of calculated pressures greatly exceeding the accuracy of pressure measurements. In this domain the equation of state should be used only to find $\rho(P, T)$.

2.6 Representation of $C_v(T)$ at 18.5 mol/l

For use below in 3.4 we have adjusted experimental specific heats of several runs by Younglove [71] to the density of 18.5 mol/l, and then have represented these data by use of the argument, $x(T) \equiv T/\theta(\rho)$, $\theta = 164.1171$ K:

$$C_v/C_v^0 = 1 + a/x + b/x^2 + c/x^3/(x-1)^{0.1} \quad (7)$$

$$a = 0.472\ 950, \quad b = -0.502\ 717, \quad c = 0.214\ 2134$$

where $C_v^0(T)$ is the ideal gas specific heat as tabulated in [21], and as calculated by our SUBROUTINE IDEAL reproduced in Appendix E.

3. Computational methods

The numerical values for E and H in this report are on the same absolute basis as those of Tester [61], obtained by use of $E_o^0 = (4.1868) \cdot (2191.3)$ J/mol. This not only permits a direct comparison of results; it also precludes negative values for these functions in compressed liquid states.

3.1 The Homogeneous Domain

With reference to figure 1, we start our computations with ideal gas values described in [21] as a function of temperature at zero density, and then integrate along isotherms by use of the equation of state in the following relations,

$$\Delta E = \int [P - T \cdot (\partial P / \partial T)] \cdot d\rho / \rho^2, \quad (8)$$

$$\Delta C_v = -T \cdot \int (\partial^2 P / \partial T^2) \cdot d\rho / \rho^2, \quad (9)$$

$$\Delta S = R \cdot \ln [P^0 / (\rho R T)] + \int [R - (\partial P / \partial T) / \rho] \cdot d\rho / \rho. \quad (10)$$

Equation (10) is for use with initial entropies in hypothetical ideal gas states at $P^0 = 1$ atm. In the compressed liquid at $T < T_c$ we use

$$\Delta S = - \int (\partial P / \partial T) \cdot d\rho / \rho^2 \quad (10-a)$$

In each (ρ, T) state, reached by above integrations, we compute

$$H = E + P / \rho, \quad (11)$$

$$C_p = C_v + T \cdot (\partial P / \partial T)^2 / (\partial P / \partial \rho) / \rho^2, \quad (12)$$

$$W^2 = C_p \cdot (\partial P / \partial \rho) / C_v. \quad (13)$$

3.2 The Vapor-Liquid Transition

At $T < T_a$ of figure 1 we traverse the vapor-to-liquid "dome" by use of the Clapeyron equation, and $\Delta v \equiv (v_\ell - v_g)$,

$$\Delta H = T \cdot (dP/dT) \cdot \Delta v , \quad (14)$$

$$\Delta E = \Delta H - P \cdot \Delta v , \quad (15)$$

$$\Delta S = \Delta H/T \quad (16)$$

where (dP/dT) is slope of the vapor pressure curve. We then obtain the specific heat of liquid along the coexistence path via

$$C_\sigma(T) = T \cdot (dS_\sigma/dT) . \quad (17)$$

The single-phase specific heats $C_v(\rho, T)$ may be estimated on the saturated liquid boundary from the following difference [55] ,

$$C_v(\rho, T) = C_\sigma(T) + T \cdot (\partial P/\partial T) \cdot (d\rho_\ell/dT)/\rho_\ell^2 , \quad (18)$$

where $(d\rho_\ell/dT)$ is the (negative) slope of saturated liquid density vs T . Each term on the right of (18) approaches infinity at the critical point, where the accuracy of computation vanishes. For this and other reasons we have computed around the critical point, by use of experimental C_v data at 18.5 mol/l, as discussed below for the cross-hatched region of figure 1.

3.3 Representation of $E_{\sigma}(T)$ and $S_{\sigma}(T)$

Having computed these functions for saturated liquid, we give them analytical representations to avoid repetitive integrations. The following representations are accurate within 0.001% at any point, and each gives an rms deviation less than 0.0005% for 52 points at $T_t \leq T \leq T_c$. For consistency in the thermal network we compute $C_{\sigma}(T)$ by eq (17), above.

For internal energy, use these variables

$$x(T) \equiv (T_c - T)/(T_c - T_t) ,$$

$$Y(E) \equiv (E - E_t)/(E_c - E_t) ,$$

$$W(x) \equiv A_1 \cdot x \cdot \ln(1 + B/x) + A_2 \cdot x^{\epsilon} + \sum_{i=3}^9 A_i \cdot x^{i-2} ,$$

when the function is

$$Y(E) = (1-x) \cdot \exp[W(x)] , \quad (19)$$

B =	0.10,	A ₁ =	-0.0294 0994,	A ₅ =	-9.7180 4579,
ϵ =	0.19,	A ₂ =	-01915 4778,	A ₆ =	17.1576 6593,

		A ₈ =	2.4352 9834.

3.4 Circumventing the Critical Domain

The computations of section 3 become inaccurate along isotherms near T_c . As $T \rightarrow T_c^-$ the heats of vaporization become increasingly uncertain, and the accuracy obtained from eq (18) vanishes. As $T \rightarrow T_c^+$ the slopes and curvatures of isochores are insufficiently well known to give reliable results. We therefore have used the following procedure to compute around the critical point into the cross-hatched region of figure 1:

We select the isochore of experimental specific heats at $\rho' = 18.5 \text{ mol/l}$, which intersects the liquid-vapor boundary at $T_a = 174.516 \text{ K}$. We then select $T_b = 220 \text{ K}$, obtaining --

$$E(\rho', T_b) = 9874.3 \text{ J/mol}, \quad S(\rho', T_b) = 113.912 \text{ J/mol/K}.$$

By use of (7) for $C_v(\rho', T)$ we then integrate down to any $T_a < T < T_b$,

$$\Delta E = \int_{T_b}^T C_v \cdot dT, \quad \Delta S = \int_{T_b}^T C_v \cdot dT/T.$$

We finally integrate along isotherm T as described among eqs (8) through (13). For the cross-hatched region of figure 1 we thus obtain all of the thermofunctions without crossing the "dome" near T_c , and without passing close to the critical point at $T > T_c$.

In the above computation around the critical point (on isotherm T_b and then along isochore ρ' of figure 1) we wish, for consistency, to obtain values of functions for the saturated liquid at T_a which agree with values obtained by computing across the vapor-liquid "dome" on isotherm T_a . To obtain agreement for the internal energy, E , and for the entropy, S , it is necessary to multiply the specific heats along isochore ρ' , eq (7), by the factor 0.9737. This adjustment of about 2.6% is larger than the estimated uncertainty in experimental, single-phase specific heats [71]. One must remember, however, that until recently it was considered by many that specific heats computed via the second derivative $\partial^2 P / \partial T^2$ from an equation of state were considered "good" if they were within 10% of the experimental measurements.

4. Comparison of Derived and Experimental Properties

4.1 Heats of Vaporization

This property is notoriously difficult to measure accurately, and results from two laboratories are not in good agreement [36, 70]. Their data have been tabulated in [21]. Present results agree best with those of Hestermans and White [36], namely within about

two percent at worst (high temperature). At 100 K our heat of vaporization of 8512 J/mol is in excellent agreement with the experimental value, 8514 ± 21 J/mol, obtained by Cutler and Morrison [11].

4.2 Specific Heats, $C_{\sigma}(T)$, $C_v(\rho, T)$, $C_p(\rho, T)$

Specific heats $C_{\sigma}(T)$ on the coexistence path have been derived from heat capacity measurements on the two-phase, liquid-vapor system by use of existing vapor pressure and saturated liquid density data [71]. Results therefore are not directly experimental, and may have greater uncertainty than the observations [31]. These recent data of Younglove are compared with our derived results in table 5. The maximum deviations between calculated and measured $C_{\sigma}(T)$ are about two percent. Cutler and Morrison [11] give specific heats of the saturated liquid from 93.95 to 106.96 K. Our calculated value of 53.31 J/mol/K at 95.85 K may be compared with 54.13 from [71], and with 53.43 at 95.77 K from [11].

Experimental specific heats $C_v(\rho, T)$ for compressed fluid methane [71] are compared with our derived results in table 6. The maximum deviations between calculated and measured $C_v(\rho, T)$ are about four percent.

Specific heats at constant pressure $C_p(\rho, T)$ have been measured with a flow-calorimeter over a wide range of conditions. These data are smoothed and interpolated [40]. Table 7 gives these data on the first row of each isotherm. The second row was computed by present methods. Except near the critical point the maximum deviations between calculated and measured $C_p(\rho, T)$ are about two percent, which we consider to be excellent.

4.3 Speeds of Sound, $W_{\sigma}(T)$, $W(\rho, T)$

Tables 8 and 9 compare experimental speeds of sound for saturated [63] and compressed liquid [64] methane with our calculated results. In eqn (13) of section 3, above, we have seen that this calculation is complicated. It is based on all previous calculations via the derived specific heats. In view of this complexity, we consider that the agreement within two percent between calculated and measured speeds of sound is good, and supports our use of the present, simple form of equation of state.

5. Tables of Physical and Thermodynamic Properties

5.1 Calculated P- ρ -T Isochores and Isotherms

A selection of calculated isochores and isotherms is given by tables 10 and 11. They are useful to examine behavior of the surface generated by the equation of state, and to supplement the isobars of table 14 in obtaining P- ρ -T values and their derivatives. Table 11 includes derivatives with respect to density of functions composing the equation of state, to verify that the analytical expressions used for these derivatives are correct.

5.2 The Joule-Thomson Inversion Locus

Tables 12 and 15 give our calculated P - ρ - T locus for the J. T. Inversion, $(\partial T/\partial P)_H = 0$. These results are obtained from the equation of state under the condition, $T \cdot (\partial P/\partial T) = \rho \cdot (\partial P/\partial \rho)$. They are in good agreement with earlier results [24, 61], considering sensitivity of the computation and engineering requirements.

5.3 Thermophysical Properties of the Saturated Liquid

Tables 13 and 16 give physical and thermodynamic properties for the saturated liquid. Column headings are interpreted on the first pages of these tables. Results are similar to our earlier tabulation [24] except at $T > 160$ K where the effect of our recently measured vapor densities is evident. Saturated vapor volumes and heats of vaporization are smaller than in [24] by up to 1.5 percent as $T \rightarrow T_c$. At temperatures above $T_a = 174.516$ K, however, we have computed around the critical point as described in section 3.4.

5.4 Thermophysical Properties Along Selected Isobars

Tables 14 and 17 give physical and thermodynamic properties on isobars, as computed by methods of section 3. Explanations for the tables are given on the first pages. These tables are extrapolated beyond the range of P - ρ - T data used for adjusting the equation of state ($T \sim 400$ K, $P \sim 350$ bar).

6. Tables in British Engineering Units

Thermophysical properties in engineering units are given in tables 15, 16, and 17 at integral temperatures on the Fahrenheit scale and at integral pressures in psi. The conversions of units, given in Appendix C, are taken from [3, 48]. Explanations for the tables are given on the first page of each table.

7. Comments on Uncertainties

For the important saturated liquid densities, the precision of about 0.01% in representation by eq (4-b) greatly exceeds the estimated absolute accuracy of about 0.1% in the data.

For other P - ρ - T data, the differences between calculated and experimental values are detailed by table 4. Greatest experimental uncertainties of about 0.1% occur in the determination of density. Deviations of table 4 are no greater than 0.1% over most of the P - ρ - T surface. Approaching the critical point, however, they become much greater (up to about 1.0%) over the critical region: $0.9 \leq T/T_c \leq 1.2$, $0.3 \leq \rho/\rho_c \leq 1.7$. The equation of state (6), however, is qualitatively correct in the behavior of its derivatives about the critical point. We may generalize by the statement that the densities of table 14 (isobars) are accurate to 0.1% except in the critical region.

The absolute accuracy of thermodynamic functions, computed by equations of section 3, necessarily is less than that of P- ρ -T data, due to the use of derivatives of the P- ρ -T surface, and especially to taking differences, eq (8). This fact, mentioned in [22], places extreme demands on the equation of state. The accuracy of enthalpy differences is estimated by comparing our specific heats at constant pressure with experimental data in table 7. Except very close to the critical point (190.5 K, 46.0 bar), the differences mostly are no greater than 2%. With this exception, therefore, we estimate the accuracy of enthalpy differences in table 14 (isobars) to be about 2%.

The experimental specific heats C_v from [71] were estimated to be accurate to 0.5%, except approaching the critical point. For the saturated liquid, however, we mentioned above that other data used to derive $C_g(T)$ could produce higher uncertainty. Table 5 shows maximum deviations of about 2% near 145 K. We estimate the accuracy of our calculated $C_g(T)$ to be 1%. Excepting the critical region, we estimate the accuracy of our calculated $C_v(\rho, T)$ to be about 3%, and of $C_p(\rho, T)$ to be about 2%.

The experimental speeds of sound were estimated to be accurate to a few tenths of one percent [63, 64]. As our results in tables 8, 9 differ by a maximum of about 2%, we conclude that calculated values in table 14 (isobars) have an accuracy of 2%.

8. Acknowledgments

We are indebted to The American Gas Association for generous support of this work, to Robert D McCarty for the essential least-squares program [38, 47], and to Dwain E. Diller and Lloyd A. Weber for discussions and valuable suggestions.

Appendix A. Symbols and Units

Subscripts *c* and *t* refer to critical and liquid triple points.

Subscripts *g* and *l* refer to saturated vapor and liquid.

Subscripts *σ* or *s* refer to liquid-vapor coexistence (usually the liquid).

α, β, δ	non-linear constants in the equation of state
B, C, D,	density-dependent coefficients in the equation of state
$C_v(\rho, T)$,	molal heat capacity at constant volume, J/(mol·K)
$C_p(\rho, T)$,	molal heat capacity at constant pressure, J/(mol·K)
$C_\sigma(T)$,	molal heat capacity for saturated liquid, J/(mol·K)
<i>d</i> ,	density, mol/l
$E(\rho, T)$,	the internal energy, J/mol
$H(\rho, T)$,	the enthalpy, J/mol
J,	the joule, 1 N·m,
l,	the liter, 10^{-3}m^3 ,
mol,	16.043 grams of methane ($C^{12} = 12$ scale)
P,	pressure in bars, 1 bar = 10^5 N/m ²
Q_{vap} ,	ΔH_{vap} , the heat of vaporization, J/mol
R,	the gas constant, 8.31434 J/(mol·K), 0.0831434 bar·l/(mol·K),
ρ ,	d/d_t , density reduced at the liquid triple point
σ ,	d/d_c , density reduced at the critical point
$S(\rho, T)$,	the entropy, J/(mol·K)
T,	temperature, K, on the IPTS-1968, [1]
<i>v</i> ,	1/ <i>d</i> , molal volume, l/mol
$W(\rho, T)$,	the speed of sound, meters/second
<i>x</i> ,	T/T_c , temperature reduced at the critical point
Z,	Pv/RT , the "compressibility factor"

Appendix B. Fixed-Point Values*

Triple Point

$$d_t = 0.01567865 \text{ mol/l, vapor}$$

$$d_t = 28.1470 \text{ mol/l, liquid}$$

$$P_t = 0.11590 \text{ atm}$$

$$= 0.117435675 \text{ bar}$$

$$T_t = 90.680 \text{ K (IPTS-1968)}$$

Critical Point

$$d_c = 10.0 \text{ mol/l}$$

$$P_c = 45.98825 \text{ bar}$$

$$T_c = 190.555 \text{ K (IPTS-1968)}$$

* These values were used for the thermodynamic computations exactly as given.

Temperature,	1.8 Rankine (R) = 1 Kelvin, (K)	
Pressure,	14,69595 psi	= 1 atm = 1.01325 bar
Volume,	1 cu ft	= 28.31685 liter, (ℓ)
Mol. Wt., CH ₄ ,	1 mol	= 16.043 gram, (g), (C ¹² scale)
Mass,	1 lb (avoir.)	= 453.5924 g
Density, CH ₄ ,	1 lb/cu ft	= 0.998 470 mol/ℓ
Isochore slope,	1 PSI/R	= 0.1241 056 bar/K
Isotherm slope, CH ₄ ,	1 PSI·cu ft/lb	= 0.0690 5319 bar·ℓ/mol
Energy	1 BTU	= 1054.350 joule, (J)
Specific energy for methane,	1 BTU/lb	= 37.291 055 J/mol
Specific entropy and heat capacity for methane,	1 (BTU/lb)/R	= 67.123 912 (J/mol)/K
Speed of sound,	1 ft/s	= 0.30480 m/s

Appendix D. List of New Data

1. The melting pressures, [52].
2. The vapor pressures. [52]
3. Freezing liquid densities, [23].
4. Saturated liquid densities, [30].
5. Saturated vapor densities, [29].
6. P- ρ -T compressibility data [30].
7. P- ρ -T compressibility data [this report].
8. Dielectric constants on isotherms [29].
9. Dielectric constants for saturated liquid [29].
10. Dielectric constants for saturated vapor [29].
11. Specific heats $C_{\sigma}(T)$ for saturated liquid [71].
12. Specific heats $C_{\nu}(\rho, T)$ over a wide range [71].

Table 3, Summary of P- ρ -T data*

I. D.	Authors	Range of the Variables					Deviations, %	
		mol/l	T, °K	P, bar	N	$\Delta d/d$	$\Delta P/P$	
2	virial equation, this report	1.0 - 2.0	150 - 270	10 - 40	46	0.04	0.03	
xxx	NBS [30], and this report	3.0 - 28.2	92 - 300	3 - 350	554	0.19	0.50	
3	Vennix [66]	2.6 - 22.3	173 - 273	25 - 650	279	---	0.63	
4	van Isterbeek [65]	16.3 - 27.6	115 - 188	9 - 320	163	0.37	6.55	
6	Douslin [17]	0.8 - 12.5	273 - 398	16 - 400	171	0.07	0.05	
8	Kvalnes [41]	0.03 - 25.3	203 - 473	1 - 1010	158	0.93	0.81	
10	Cheng [9]	14.0 - 29.0	111 - 309	220 - 1100	66	0.33	2.04	

* The equation of state was adjusted only to data of ID = 2, 6, and NBS.

Table 4. Comparison of experimental and calculated P- ρ -T values

The following pages compare experimental P- ρ -T (compressibility) data with densities and pressures computed by the equation of state (6). The first column identifies sources of the data (as in table 3) --

ID = 2, Via Virial and Vapor-Pressure equations;

ID = 3, Vennix [66];

ID = 4, van Itterbeek [65];

ID = 6, Douslin [17];

ID = 8, Kvalnes [41];

ID = 10, Cheng [9];

ID = xxx, xxxx, this laboratory [30].

The equation of state was adjusted only to data of ID = 2, 6 and this laboratory. Remaining data validate our extrapolation to higher pressures. Density deviations should be ignored near the critical point, and pressure deviations should be ignored for compressed liquid at low temperatures for reasons given in the text. A few of Vennix' data near the critical point have spurious, extreme density deviations because our computer search assigns the opposite phase via eq (6), (i.e. vapor vs. liquid).

Table 10. Calculated P(T) isochores

The following pages give P(T) along isochores, as computed by the equation of state (6). The third column DP/DD is the isotherm slope ($\partial P/\partial \rho$) in units of the bar and mol/l. The last two columns give the isochore slopes and curvatures $\partial P/\partial T$, $\partial^2 P/\partial T^2$, in units of the bar and K.

These tables show that the isochore curvatures are qualitatively consistent with a maximum in the specific heat $C_v(\rho, T)$ near the critical point.

Table 11. Calculated $P(\rho)$ isotherms

The following pages give $P(\rho)$ isotherms, as computed by the equation of state (6). The third column DP/DD is the isotherm slope ($\partial P/\partial \rho$) in units of the bar and mol/l. The fourth column DP/DT is the isochore slope ($\partial P/\partial T$) in units of the bar and kelvins. Remaining columns validate the analytical expressions used to compute derivatives of functions composing the equation of state.

These tables show that $\partial P/\partial \rho$ is non-negative, and that it increases monotonically with density to pressures about twice those used for adjusting the equation of state.

Table 13. Thermophysical properties of the saturated liquid

For the following table we have used the Clapeyron equation to make the vapor-liquid transition at temperatures $T \leq T_a = 174.516$ K. For higher temperatures we have computed around the critical point as described in section 3.4 of the text, with aid from figure 1.

Column headings have the following interpretations--

- DP/DT \equiv dP/dT, vapor pressure,
- DDL/DT \equiv $d\rho_l/dT$, saturated liquid,
- Q, VAP \equiv ΔH_{vap} , heat of vaporization,
- CV \equiv $C_v(\rho, T)$,
- CS \equiv $C_\sigma(T)$,
- CP \equiv $C_p(\rho, T)$.

Table 14. Thermophysical properties along isobars *

The following pages give physical and thermodynamic properties along selected isobars, as computed by methods of section 3 of the text.

The first table is for the triple-point pressure, $P_t = 0.117\ 436$ bar (1.70326 psi).

The first line of each table refers to freezing liquid on the P(T) melting line.

Each table at $T < T_c$ contains a blank line for the transition from saturated liquid to vapor, as seen by the abrupt decrease of density.

Table headings for partial derivatives have the following interpretations--

$$DP/DT \equiv \partial P/\partial T,$$

$$DP/DD \equiv \partial P/\partial \rho.$$

The specific heat interpretations are--

$$CV \equiv C_v(\rho, T),$$

$$CP \equiv C_p(\rho, T).$$

* These tables are extrapolated beyond the range of P- ρ -T data used for adjusting the equation of state ($T \sim 400$ K, $P \sim 350$ bar).

METHANE ISOBAR AT P = 0.117 436 BAR

Table 16. Thermophysical properties of the saturated liquid

For the following table we have used heats of vaporization to make the vapor-liquid transition at temperatures $T \leq T_a \cong 174.516$ K. For higher temperatures we have computed around the critical point as described in section 3.4 of the text with aid from figure 1.

Column headings have the following interpretations--

- DP/DT \equiv dP/dT , vapor pressure,
- DDL/DT \equiv $d\rho_\ell/dT$, saturated liquid
- Q, VAP \equiv ΔH_{vap} , heat of vaporization,
- CV \equiv $C_v(\rho, T)$,
- CS \equiv $C_\sigma(T)$,
- CP \equiv $C_p(\rho, T)$.

Table 17. Thermophysical properties along isobars*

The following pages give physical and thermodynamic properties along selected isobars, as computed by methods of section 3 of the text.

The first table is for the triple-point pressure, $P_t = 0.117\,436$ bar (1.70326 psi).

The first line of each table refers to the freezing liquid on the P(T) melting line.

Each table at $P < P_c$ contains a blank line for the transition from saturated liquid to vapor, as seen by the abrupt decrease of density.

Table headings for partial derivatives have the following interpretations--

$$DP/DT \equiv \partial P / \partial T,$$

$$DP/DD \equiv \partial P / \partial \rho.$$

The specific heat interpretations are--

$$CV \equiv C_v(\rho, T),$$

$$CP \equiv C_p(\rho, T).$$

* These tables are extrapolated beyond the range of P- ρ -T data used for adjusting the equation of state ($T \sim 400$ K, $P \sim 350$ bar).

METHANE ISOBAR AT P = 1.703 26 PSI

15. SUPPLEMENTARY NOTES			
<p>16. ABSTRACT (A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here.)</p> <p>Thermophysical properties of methane are tabulated at uniform temperatures from 90.68 to 500 K along isobars to 700 bar. A novel equation of state is employed for the first time, having origin on the vapor-liquid coexistence boundary. Computations are based almost entirely on ideal gas specific heats and experimental P-ρ-T data via the equation of state, without weighting to data for derived properties. Good agreement with such data confirms validity of the equation and method. New P-ρ-T data are reported at 0.3 to 1.7 times the critical density.</p>
