A MODIFIED BENEDICT-WEBB-RUBIN EQUATION OF STATE FOR PARAHYDROGEN

Robert D. McCarty

A 32 term modified Benedict-Webb-Rubin equation of state has been applied to data for parahydrogen. The adjustable parameters in the equation of state were determined using data from the triple point to 2500 K, with pressures to 680 atmospheres. Extensive modifications have been made to the previously accepted PVT surface for the saturated liquid and vapor phases in the near critical region. These modifications have been made on the basis of subsequent refractive index data and the application of scaling law equations. Comparisons between experimental and calculated data are given.

Key words: Critical point; equation of state; hydrogen; index of refraction PVT; saturation properties; scaling laws

1. Introduction

For some applications of the equation of state for cryogenic fluids, it is advantageous to use a modified Benedict-Webb-Rubin equation of state (hereafter referred to as MBWR). One part of the work performed under NASA-LeRC Purchase Request C-32369-C was to provide a MBWR equation of state for hydrogen. Another part of the work to be performed here for NASA is an experimental program to supplement the existing data for parahydrogen (Roder, et al., 1965) with PVT data to higher pressures and temperatures. The equation of state work was to include these new experimental data in the estimation of the coefficients to a MBWR type of an equation of state. At the time of this writing, the experimental part of the total program is in progress and the funds for the continuation of the equation of state work do not seem to be available, at least in the near future. The purpose of this report is to collect and document the equation of state work performed to date. There are two reasons for reporting the equation of state work at this time. First, the work already accomplished is of sufficient importance that it should be made available to prospective users; and second, should the funds become available in the future to allow the continuation of the study, the earlier work will be preserved here.

2. Summary of Data Used

The PVT data of Goodwin, et al. (1963) and the specific heat capacity data of Younglove and Diller (1962) were used as the primary set of experimental data in the estimation of the coefficients to the equation of state. These data cover the pressure range of 0 to 340 atmospheres with temperatures from the triple point to 100 K. The NBS 1955 temperature scale was used to determine the temperatures of these data;

therefore, a conversion of the experimental temperatures to the International Practical Temperatures Scale of 1968 was made. In addition to the data set just mentioned, 173 PVT points from McCarty and Weber (1972) were used. These points were generated from equations which were used to extrapolate the PVT surface to higher pressures and higher temperatures. The equations used by McCarty and Weber are based on thermodynamic data selected from the literature and rely heavily on the data by Michels et al. (1963). Appendix A contains complete tables of deviations between the data used in the fit and the values predicted by the equation of state.

3. Saturated Liquid and Vapor PVT

Equations for the density of the saturated liquid and vapor were published by Roder, et al. (1963). These equations were based on the single phase experimental PVT data by Goodwin, et al. (1963) and the vapor pressure by Weber, et al. (1962). Since the data of Goodwin, et al. (1963) were converted to the 1968 International Practical Temperature Scale, these older equations for the saturation densities were no longer consistent with the experimental data, and it was decided to derive new equations for the saturation densities as well as the vapor pressures. After the saturation densities were published by Roder, et al. (1963), an index of refraction experiment by Diller (1968) indicated that the saturation densities in the very near critical region were in error by as much as 6%. This conclusion is based on the behavior of the saturation boundary shown on Diller's plot which is given here as fig. 1.

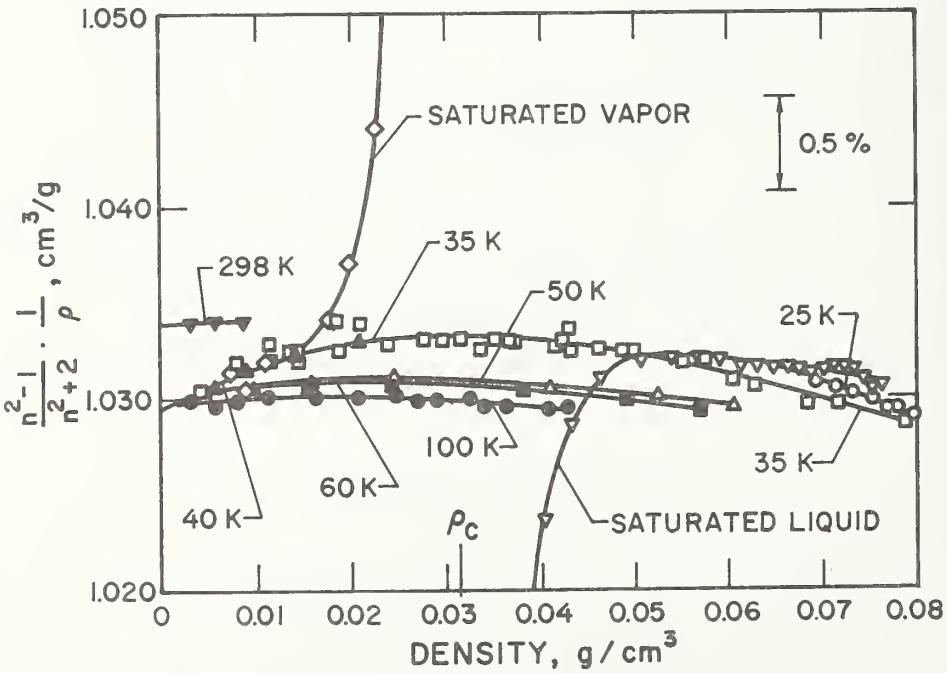

Figure 1. The Lorentz-Lorenz Function for Hydrogen

The Lorentz-Lorenz function of the saturation boundary, shown in fig. 1, should have the same general shape as do the isotherms.

The experiment involved measuring the index of refraction, the temperature and the pressure. The densities were then obtained from the data of Goodwin, et al. (1963). The reason for the two legs of the saturation curve not meeting in a smooth manner at the critical point is ascribed to incorrect densities in the critical region. To adjust the saturation densities in the critical region the function

$$\rho = \sum_{K=1}^{N} A_K n^{K-1}, \qquad (1)$$

was fit to the 35 K isotherm, where ρ is density in g/cm^3 and n is the index of refraction. Equation (1) was fit to 24 points ranging in density from 0.003969 to .078833 g/cm^3. Statistical significance of the coefficients to eq (1) was lost when more than 4 terms were used and the 4 term equation was chosen, the coefficients to eq (1) are given in table 1.

Table 1. Lease Squares Estimates of the Coefficients for Equation (1)

$A_1 = -1.0880215243 \pm 0.214$

$A_2 = 1.8280271481 \pm 0.604$

$A_3 = -1.0378774469 \pm 0.567$

$A_4 = 0.29788205862 \pm 0.177$

The measured index of refraction along the saturation liquid and vapor lines were then used to calculate the corresponding densities according to eq (1). A comparison of densities reported by Roder, et al. (1963) and those calculated by eq (1) is given in table 2.

Table 2. Comparison of Densities Near the Critical Point

To estimate the critical density and critical temperature, the equation

$$\rho = G_1 + G_2 |\Delta T|^{\beta} + \qquad (2)$$

was fit to the corrected densities above 28 K. The liquid and vapor densities were fit separately, where $\Delta T = (T_c - T)/T_c$ and ρ and T are the density and temperature respectively. The parameters G_1, (G_1 corresponds to the critical density) G_2, T_c and β were estimated from the least squares fit of the data. Equation (2) is the first two terms of eq (6) and is only valid for densities very near the critical point. The truncation of eq (6) was used with the densities near the critical point to prevent any influence on the estimation of ρ_c and T_c by densities too far removed from the critical region. A critical density of 0.03254 g/cm^3 and a critical temperature of 32.433 K resulted from this fit. The ρ_c and T_c from the fit seemed reasonable, but the estimate of β was 0.407 which is higher than the 0.35 predicted by theory. The higher value of β suggests that some of the input densities may not be within the range of validity of eq (2).

The method of rectilinear diameters was tried next. A plot of $(\rho_\ell + \rho_g)/2$ against temperature, fig. 2, quickly shows that under the rectilinear diameter assumption, the critical density cannot possibly be much greater than 0.314 g/cm^3 and the 0.325 g/cm^3 estimated by eq (2) is not possible.

Forming an equation for the rectilinear diameter from eq (2) results in

$$(\rho_\ell + \rho)_g/2 = G_1 + \tfrac{1}{2}(G_{2\ell} + G_{2g})|\Delta T|^{\beta}, \qquad (3)$$

however, $G_{2\ell}$ is usually assumed to be equal to $-G_{2g}$ and the second term of eq (3) vanishes. There is some doubt about the validity of this assumption, but in this particular case at least, the assumption cannot be disproved on the basis of the available data, and the problem of estimating β is eliminated. Taking the next two terms from eq (6) gives

$$\rho_g + \rho_\ell = 2\rho_c + (G_{3g} + G_{3\ell})|\Delta T|^{1-\alpha} + (G_{4g} + G_{4\ell})|\Delta T| \qquad (4)$$

assuming $\alpha = 0.1$ and $T_c = 32.933$ K, a least squares fit of the eight pairs of liquid-vapor data in table 2 resulted in a critical density of 0.03136 g/cm^3. The fit was repeated several times with values of α and T_c ranging from $\alpha = 0.1$ to $\alpha = 0.25$ and $T_c = 32.938$ to $T_c = 32.95$. The resulting estimates of ρ_c did not vary significantly (i.e., maximum variation was less than $\pm.00001$ g/cm^3).

A refit of eq (2) fixing the critical density to the value found by the rectilinear diameter analysis gave results essentially the same as the first fit, i.e., a β of about 0.4 and T_c of 32.933 K. To achieve an interpolation formula for temperatures between 32.0 and 32.9 K, the function

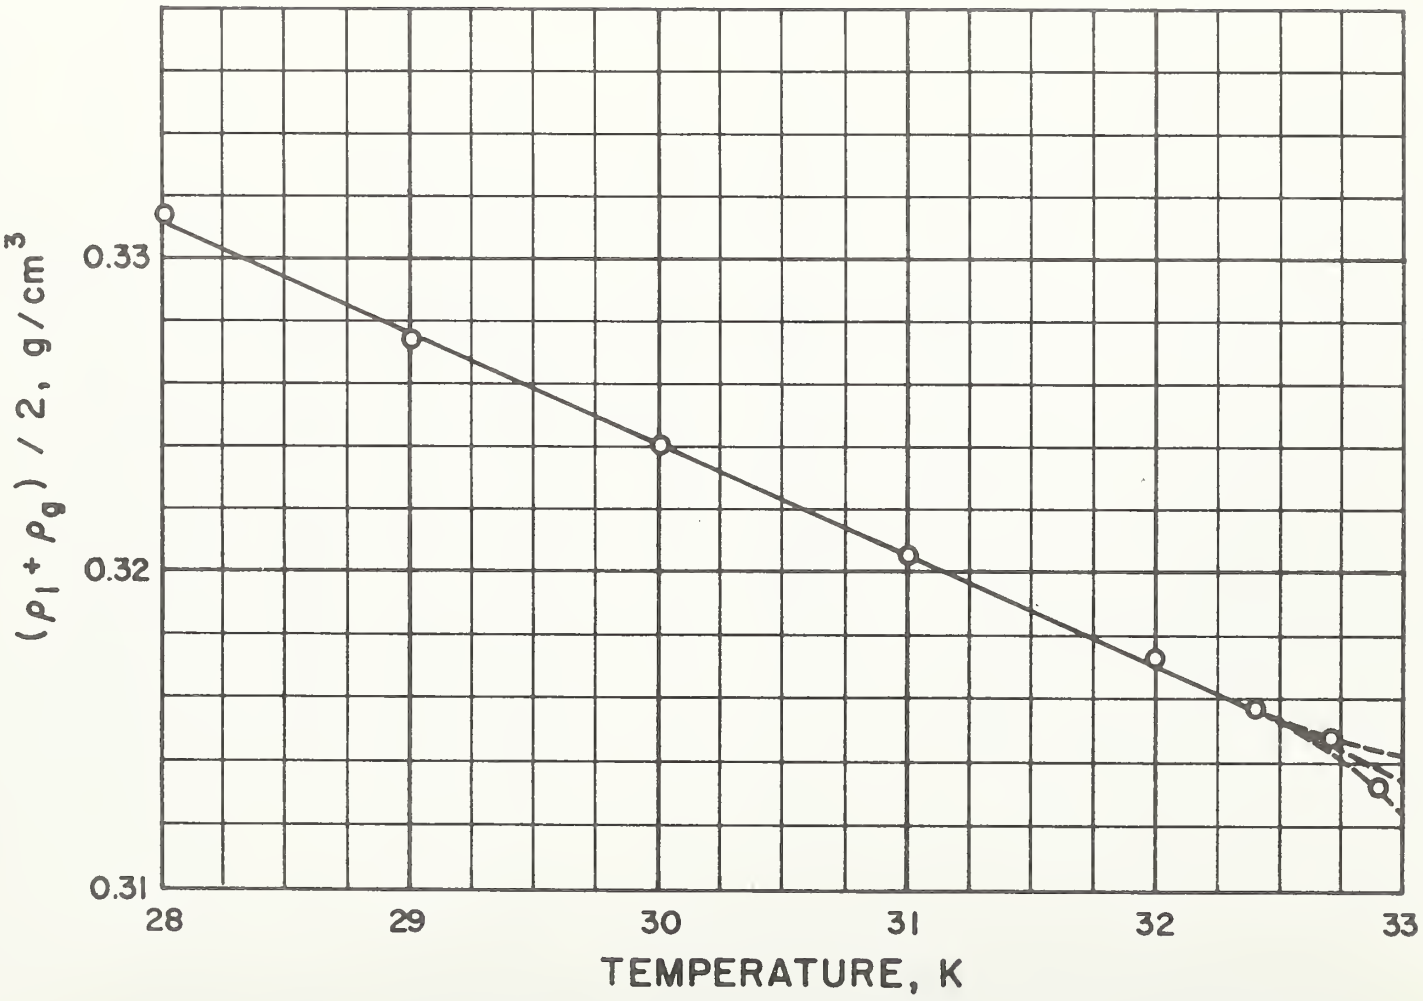

Figure 2. Rectilinear Diameters for Parahydrogen

$$n = r_c + r_1 (\Delta T)^{\beta'} , \qquad (5)$$

where n is the index of refraction and $\Delta T = (T_c - T)/T_c$, was fit to the index of refraction data of the saturation boundary between 28 and 32.9 K. Table 3 gives the coefficients to eq (5). Combining eq (5) with eq (1) densities were calculated every 0.1 K between 31.9 and 32.8 K. These interpolated data were then used in a refit of eq (2) which resulted in $T_c = 32.938$, $\beta_{gas} = 0.3483$, and $\beta_{\ell q} = 0.3478$. Using these values for β and T_c the equation

$$\rho_{Sat} - \rho_c = G_1 (\Delta T)^{\beta} + \sum_{I=1}^{8} G_{(I+1)} (\Delta T)^{[1 + (I-1)/3]} , \qquad (6)$$

was fit to the saturated liquid and vapor data of Roder, et al. (1963). The coefficients for eq (6) are given in table 4. Table 5 gives the deviations between calculated and input densities.

The vapor pressure data of Weber, et al. (1962) was converted to the 1968 International Practical Temperature Scale and fit to the vapor pressure equation of Goodwin (1969). That equation is

$$\ell n\ (P/P_t) = B_1 X + B_2 X^2 + B_3 X^3 + B_4 X\ (1-X)^{B_5}\ , \qquad (7)$$

where $X = (1-T_t/T)/(1-T_t/T_c)$, T is in kelvins. The coefficients to eq (7) are given in table 6. The two data points given by Weber, et al. (1962) for T = 22 and 23 K were left out of the fit because their inclusion degraded the representation of the rest of the data. The IPTS-68 triple point temperature of hydrogen of 13.81 K was not used because it also degraded the fit. Table 7 gives the vapor pressures from Weber, et al. (1962) and the deviations between the experimental and calculated data points.

4. The Equation of State for Hydrogen

Since the first major modification of the Benedict-Webb-Rubin equation of state by Strobridge (1962), there have been many more. Each author claims his particular modification to be the best of several he has tried for the particular fluid being correlated. In some cases the particular form was chosen because it worked well for a number of fluids.

Two of these MBWR's have been used with good success for several different fluids. The first is a 19 term version by Bender (1970) and the other is a 32 term version by Jacobsen (1972). The data set mentioned in section 2 was fit to both of these equations and not too surprisingly the 32 term equation worked the best, and consequently is used here. In addition to the data summarized in section 2, PVT values for the saturated liquid and vapor phases were generated from the equations in section 3 and included in the fit. The equation of state is

\end{aligned} \tag{8}
$$

where ρ is in moles per liter, P is in atmospheres, T is in kelvins, and R is 0.08205616 ℓ.atm/mol.K. The critical point was constrained to the value P = 12.670 atm, ρ = 15.556 moles per liter, T = 32.938 K and $\partial P/\partial\rho = \partial^2 P/\partial\rho^2 = 0$. The thermodynamic conditions for phase equilibrium for the coexisting liquid and vapor phases have been included as data in the least squares estimating procedure. The least squares estimates of the parameters (N_i) are given in table 8.

R = 0.8205616 ℓ.atm/mol.K

A complete listing of the computer program which was used to estimate the coefficients in table 8 is given in Appendix A. The listing includes a point by point comparison of the input experimental data with the corresponding values calculated using eq (8).

Conclusion

The equation of state, eq (8), is the best MBWR representation of the PVT surface of hydrogen which could be formulated at this time, as is always the case with the MBWR, the behavior at the critical point is analytic and, therefore, does not qualitatively or quantitatively represent the specific heat capacity at constant volume. When new experimental data for the high pressure region become available, the parameters for eq (8) should be re-estimated using the new data. The saturation boundary (liquid-vapor) as defined by eqs (6) and (7) need no further numerical treatment until new experimental data become available or the international practical temperature scale is re-defined. One of the objectives of this task was to develop an equation of state explicit in density. The curtailment of funding did not allow the pursuit of this objective to a degree of completion which could be reported here.

      FUNCTION ATKINT(X,YMAT,XMAT,NELMTS,NMAX,NESSY,ACRCY)
C     THIS PROGRAM HAS BEEN CHANGED SO THAT THE OSCILLATING NATURE OF
C     THE MATRIX TO BE INTERPOLATED EXISTS ONLY AT THE UPPER END OF THE
C     TABLE
C     THIS ROUTINE WILL TAKE INPUT MATRICES OF UP TO 999 ELEMENTS EACH,
C     ARRANGED SO THAT THE X MATRIX(XMAT) IS IN EITHER ASCENDING OR
C     DESCENDING ORDER,SELECT NMAX OF THESE POINTS,CHOSEN SO THAT
C     SUCESSIVE X VALUES OSCILATE ABOUT THE VALUE OF THE ARGUMENT X
C     UNLESS THE ENDS OF THE XMATRIX INTERFERE (IN THIS CASE THE
C     OSCILATORY NATURE IS LOST BUT THE PROGRAM WILL STILL PERFORM AN
C     INTERPOLATION), INTERPOLATE ON THESE NMAX PAIRS OF DATA BY
C     AN OSCILATING VARIABLE POINT AITKEN INTERPOLATION ALGORITHM
C     EITHER UNTIL THE PERCENTAGE CHANGE IN THE INTERPOLANT IS LESS
C     THAN THE ACRCY ARGUMENT(THE ARGUMENT NESSY INDICATES THE
C     NUMBER OF THE POINT JUST BEFORE THE LAST ONE CHECKED) OR UNTIL
C     THE NMAX POINTS ARE ALL USED.  IT IS SUGGESTED THAT NMAX
C     BE LESS THAN 10, AND OF COURSE LESS THAN NELMTS.  NELMTS
C     INDICATES THE NUMBER OF ELEMENTS IN XMAT OR YMAT.
C     IF NESSY IS ZERO IT INDICATES THAT THE INTERPOLATION REQUIREMENT
C     HAS NOT BEEN SATISFIED.  IF NESSY IS 1 IT MEANS THAT THE VALUE OF
C     X LIES OUT SIDE THE RANGE OF XMAT.

Appendix B. Table of Symbols

A = parameters for equation 1

B = parameters for vapor pressure equation

G = parameters for equation for saturation densities

N = parameters for equation of state

n = index of refraction

P = pressure

R = gas constant

r = parameters for index of refraction equation

T = temperature

x = reduced temperature

β = scaling law parameter

ρ = density

Subscripts:

c = critical point

g = gaseous phase

ℓ = liquid phase

t = triple point

16. ABSTRACT *(A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here.)*

A 32 term modified Benedict-Webb-Rubin equation of state has been applied to data for parahydrogen. The adjustable parameters in the equation of state were determined using data from the triple point to 2500 K, with pressures to 680 atmospheres. Extensive modifications have been made to the previously accepted PVT surface for the saturated liquid and vapor phases in the near critical region. These modifications have been made on the basis of subsequent refractive index data and the application of scaling law equations. Comparisons between experimental and calculated data are given.

17. KEY WORDS (Alphabetical order, separated by semicolons)
Critical point; equation of state; hydrogen; index of refraction; PVT; saturation properties; scaling laws.
