ABSTRACT

Selected values are given for the thermochemical properties of the more common compounds of sodium and potassium. A more extensive set of selections is provided for rubidium compounds. The properties included, where data are available, are enthalpy of formation at 0 K and 298.15 K, $\Delta Hf(0)$ and $\Delta Hf(298)$, Gibbs energy of formation, entropy and heat capacity at 298.15 K; $\Delta Gf(298)$, S(298) and Cp(298), and the enthalpy difference between 0 K and 298.15 K, H(298)-H(0). The values are consistent with the tables issued earlier in the NBS Technical Note 270 series.

Keywords: Enthalpy; entropy; Gibbs energy; heat capacity; potassium compounds; rubidium compounds; sodium compounds; standard reference data; thermochemical tables.

1. Introduction

This is an interim report on the evaluation of chemical thermodynamic properties of compounds of three of the alkali metals. It supplements the extensive set of selected values of chemical thermodynamic properties published as NBS Technical Note 270, parts 1-7. [1]. The values contained in this report are consistent with those in NBS Technical Note 270 and may be combined with them to establish the thermodynamic properties of processes.

Three tables are given here for the more common compounds of sodium and potassium and for all rubidium compounds for which data are available.

The tables contain values of the enthalpy and Gibbs energy of formation, $\Delta Hf°$ and $\Delta Gf°$, entropy, S°, and heat capacity, Cp°, all at 298.15 K (25°C), the enthalpy of formation at 0 K, $\Delta Hf°$, and the enthalpy difference between 0 K and 298 K, H°(298)-H°(0). The substances included are inorganic compounds of these elements, compounds containing organic ligands that have one or two carbon atoms and their aqueous solutions.

No values are given in these tables for metal alloys or other solid solutions, fused salts, or for substances of undefined chemical composition.

The sodium and potassium tables are incomplete. They list properties of compounds evaluated in the course of preparing selections for compounds already published in the NBS Technical Note 270 series and an extensive collection of the properties of neutral electrolytes in aqueous solution at the hypothetical standard state of unit activity. The latter were calculated as the sum of the properties of the ions. Although selections will be needed for the properties of many more compounds of sodium and potassium, the selections given here should be sufficient for solution of a wide range of thermochemical problems.

The rubidium table is the complete set of selections now planned for inclusion in NBS Technical Note 270. It was prepared late in 1975. There may be a few revisions and additions based on newly reported data.

Users of these three tables are invited to comment on the selections, suggest substances for which values of properties are needed, correct errors and bring new measurements to our attention. All of these will help us improve the final tables.

2. Explanation of the contents of the tables

The following material, adapted from NBS Technical Note 270, provides definitions and conventions used in the tables.

2.1 Chemical Formulae and Physical States

The tables were reproduced from computer printout in which only capital (upper case) letters are available. Normal one-line chemical formulae are used, with the following modifications:

- Subscripts (counts of atoms) and superscripts (charge) are printed on line: NA2O2 = Na_2O_2, NA+ = Na^+.

- The digit "1" appears wherever necessary to separate the symbols of two chemical elements: NA1N1O3 = $NaNO_3$.

- The centered dot, used in hydrates and minerals, is shown as a colon: NA1V1O4:2H2O = $NaVO_4 \cdot 2H_2O$.

- The physical state of the substance is appended to the chemical formula in parentheses: NA1O1H(C) = NaOH, crystalline. The abbreviations most commonly used to denote physical states are listed in Table A. Any other notations are explained in comments within the tables.

2.2 Definition of Symbols for Thermochemical Properties

The headings used in the tables and their meanings are:

DHO $\equiv \Delta Hf^\circ_0$, standard heat of formation at 0 K;

DH298 $\equiv \Delta Hf^\circ$, standard heat of formation at 298.15 K;

DG298 $\equiv \Delta Gf^\circ$, standard Gibbs energy (formerly free energy), G, of formation at 298.15 K;

H298-HO $\equiv H^\circ_{298}-H^\circ_0$, enthalpy, H, of the compound in the indicated state at 298.15 K referred to its value at 0 K. If the indicated state at 298 K is gas, the corresponding state at 0 K is the hypothetical ideal gas; if the state at 298 K is solid or liquid, the corresponding state at 0 K is the thermodynamically stable crystalline solid, unless otherwise specifically indicated.

S298 $\equiv S^\circ$, standard entropy, S, at 298.15 K;

C298 $\equiv Cp^\circ$; specific heat at constant pressure at 298.15 K.

The Gibbs free energy is related to the other quantities by: $G = H-TS$, where T is the thermodynamic temperature. The enthalpy is related to the internal energy, E, by: $H = E + PV$, where P = pressure and V = volume.

All values refer to one mole of substance for the formula given.

2.3 Conventions Regarding Pure Substances

The values of the thermodynamic properties of the pure substances given in these tables are for the substances in their standard states. These standard states are defined as follows:

For a pure solid or liquid, the standard state at any temperature is the substance in the condensed phase under a pressure of one atmosphere.

For a gas the standard state at any temperature is the hypothetical ideal gas at unit fugacity, in which state the enthalpy is that of the real gas at the same temperature and at zero pressure.

The phase of a substance is indicated in parentheses at the end of the chemical formula. See section 2.1.

The values of ΔHf° and ΔGf° given in the tables represent the change in the appropriate thermodynamic quantity when one mole of the substance in its standard state is formed, isothermally at the indicated temperature, from the elements, each in its appropriate standard reference state. The standard reference state at 25°C for each element except phosphorus has been chosen to be the standard state that is thermodynamically stable at 25°C and at one atmosphere pressure.

For phosphorus the standard reference state is the crystalline white form; the more stable forms have not been well characterized thermochemically. The same reference states have been maintained for the elements at 0 K except for the liquid elements bromine and mercury for which the reference states have been chosen as the stable crystalline forms. The standard reference states for the elements are indicated in the tables by the fact that the values of $\Delta Hf°$ and $\Delta Gf°$ are exactly zero.

The values of S° represent the virtual or "thermal" entropy of the substance in the standard state at 298.15 K, omitting contributions from nuclear spins. Isotope mixing effects, etc., are also excluded except in the case of the hydrogen-deuterium (^1H-^2H) system. Where data have been available only for a particular isotope, they have been corrected when possible to the normal isotopic composition.

The values of the enthalpies of formation of gaseous ionic species are computed on the convention that the value of $\Delta Hf°$ for the electron is zero. Conversions between 0 and 298.15 K are calculated using the value of $H^\circ_{298}-H^\circ_0 = 1.481$ kcal per mole of electrons, and assuming that the values of $H^\circ_{298}-H^\circ_0$ for the ionized and un-ionized molecules are the same.

2.4 Convention Regarding Solutions

For all dissolved substances the composition of the solvent is indicated in parentheses following the chemical formula. Except in special cases, discussed below, the number of moles of the solvent associated with one mole of solute is stated explicitly. See section 2.1 and Table A for the conventions used.

In some cases the concentration of the solute can not be specified. These are indicated as "AU" (aqueous, unspecified) for water solutions and by "U" for non-aqueous and mixed media. In all these cases the solution may be assumed to be "dilute".

The standard state for a non-dissociated solute in aqueous solution is taken as the hypothetical ideal solution of unit molality, which has been designated as "std. state, m = 1". For strong electrolytes in aqueous solution the conventional standard state is the ideal solution of unit activity (unit mean molality). For non-aqueous solutions the standard state of the solute is the hypothetical ideal solution of unit mole fraction of solute (std. state, $x_2 = 1$). The designation "A" is used for strong electrolytes in the standard state and "AO" for undissociated species in water solution. In non-aqueous media the standard state defined above is indicated by appending "X" to the formula of the solvent. The convention "std. state, m = 1" is used only rarely for non-aqueous media. For it, an "M" is appended to the formula of the solvent.

The value of $\Delta Hf°$ for a solute in its standard state is equal to the apparent molal enthalpy of formation of the substance in the infinitely dilute real solution, since the enthalpy of dilution of an ideal solution is zero. At this dilution the partial molal enthalpy is equal to the apparent molal quantity. At concentrations other than the standard state, the value of $\Delta Hf°$ represents the apparent enthalpy of the reaction of formation of the solution from the elements comprising the solute, each in its standard reference state, and the appropriate total number of moles of solvent. In this representation the value of $\Delta Hf°$ for the solvent is not required. The experimental value for a heat of dilution is obtained directly as the difference between the two values of $\Delta Hf°$ at the corresponding concentrations. At finite concentrations the partial molal enthalpy of formation differs from the apparent enthalpy.

The values of the thermodynamic properties tabulated for the individual ions in aqueous solution are based on the usually convention that the values of $\Delta Hf°$, $\Delta Gf°$, $S°$ and $Cp°$ for H^+ (aq, std. state, m = 1) are zero. The properties of a neutral electrolyte in aqueous solution in the standard state are equal to the algebraic sum of these values for the appropriate kinds and numbers of individual ions assumed to constitute the molecule of the given electrolyte. For an ionic species e.g., HSO_4^-, the properties tabulated refer to that undissociated ion, i.e. they are not equal to the sum of those for its constituent ions. By adopting the above convention with respect to aqueous H^+, it follows that the thermodynamic relation $\Delta Hf° = \Delta Hf° - T(\Delta Sf° + n \cdot 0.5 S°(H_2))$ holds for individual ionic species, with n equal to the algebraic value of the charge. For neutral electrolytes (and gaseous ions) the normal consistency relationship applies. See section 4.

3. Unit of Energy and Fundamental Constants

All of the energy values given in these tables are expressed in terms of the thermochemical calorie. This unit, defined as equal to 4.1840 joules, is generally accepted for the presentation of chemical thermodynamic data. Values reported in other units have been converted to calories by means of the conversion factors for molecular energy given in Table B.

The following values of the fundamental physical constants have been used in these calculations:

R = gas constant = 8.3143 ± 0.0012 J/deg mol = 1.98717 ± 0.00029 cal/deg mol

F = Faraday constant = 96487.0 ± 1.6 coulombs/mol = 23060.9 ± 0.4 cal/volt equivalent

$Z = Nhc = 11.96258 \pm 0.00107$ J/cm^{-1} mol = 2.85912 ± 0.00026 cal/cm^{-1} mol

c_2 = second radiation constant = hc/k = 1.43879 ± 0.00015 cm deg

0°C = 273.15 K

These constants are consistent with those given in the Table of General Physical Constants, recommended by the National Academy of Sciences-National Research Council [2].

These values differ slightly from those recommended by CODATA [3] in 1973. However, adoption of the CODATA recommendations would change the values in the present tables by far less than their uncertainties (see section 4.1). Thus the present values may be said to be consistent with the 1973 set of fundamental constants. The formula weights in the tables have been calculated from the molecular formula using the 1961 Table of Relative Atomic Weights based on the atomic mass of $^{12}C = 12$ exactly [4]. Values are given to four decimals places for convenience in the computer processing. Use of the more recent atomic weights [8] would produce only insignificant changes in the tabulated thermodynamic values.

4. Internal Consistency of the Tables

All of the values given in these tables have been calculated from the original articles, using consistent values for all subsidiary and auxiliary quantities. The original data were corrected where possible for differences in energy units, molecular weights, temperature scales, etc. Thus we have sought to maintain a uniform scale of energies for all the substances in the tables. In addition the tabulated values of the properties of a substance satisfy all the known physical and thermodynamic relationships among these properties. The quantities $\Delta Hf°$, $\Delta Gf°$, and $S°$ at 298.15 K satisfy the relation:

$$\Delta Gf° = \Delta Hf° - T\,\Delta Sf°.$$

to the precision given. The special case of solutions is discussed in section 2.4. Furthermore the calculated value of any thermodynamic quantity for a reaction is independent of the path chosen for the evaluation.

In some cases newer data may have become available on certain substances after the values were selected for these tables. Because of the need to maintain the internal consistency of the tables, it is not always possible to incorporate these newer data into the tables without a detailed analysis of the effect of such a change. Unless great care is used, relatively significant errors in calculated values of $\Delta H°$ or $\Delta G°$ for specific reactions may result from the introduction of such data. See section 4.2.

4.1 Uncertainties

The uncertainty in any value in the tables depends on the uncertainties of all the determinations in the total chain of reactions used to establish the value.

In general, when uncertainties are not stated explicitly certain rules have been followed with respect to the number of significant figures recorded. Values are tabulated such that the overall uncertainty lies between 2 and 20 units of the last figure. On the other hand, values are given so that the experimental data from which they are derived may be recovered with an accuracy equal to that of the original quantities. Thus the number of significant figures for any one value in the tables need not represent the absolute accuracy of that value. For solutions of varying composition, values are frequently tabulated to more figures to make possible the recovery of enthalpies of solution and dilution. Similarly values of ΔHf°_{0} and $\Delta Hf^{\circ}_{298.15}$ may be given to different numbers of significant figures. In this instance the quantity with the lesser number of figures is used to represent the uncertainty estimate. The larger number of figures is used for the other quantity to retain the significance of the temperature correction term.

The remarks above apply directly to the tables on sodium and potassium compounds. For rubidium uncertainties are stated explicitly immediately below the value of each property. (The form is +-0.05, where +- means ±).

4.2 Relationship to Other Tables of Thermodynamic Properties

The chemical thermodynamic properties in the present table may be combined with those published in NBS Technical Note 270 [1] in order to calculate the change in a property for a process. However we recommend against these values being combined with those in any other tabulation or with a property reported in an original research paper. In particular, we warn against indiscriminate combination with the CODATA Key Values for Thermodynamics [5-7].

There are several reasons for avoiding the combination of thermochemical data from more than one table. The most important is that different large-scale tables use different thermochemical properties of formation for substances that are ubiquitous in thermochemical measurements. Outstanding examples are the common inorganic acids and their ions. Another reason is that the groups preparing different tables may have relied on different measurements as the basis for selecting property values.

It is difficult to predict a priori how a change in one selected formation property would affect values assigned to other substances because of the way these are linked by complex networks. In general, it may be expected that the advantage of internal consistency of a table will be lost if values from several sources are combined and that experimental measurements may be reproduced poorly.

No general, simple algorithm can be suggested for overcoming this problem. If it becomes necessary to extend a table of data to substances other than those tabulated, the user is advised to consult the group that prepared the table about the procedure that he plans to use.

5. Arrangement of the Tables

The compounds in the tables are entered according to the Standard Order of Arrangement, (see Figure 1), by the principle of latest position. In this scheme, a compound is listed under the element occurring latest in the list; water of hydration is neglected. Within a given element-table will be found all of the compounds of that element with elements occurring earlier in the order; the arrangement within a table follows the same ordering.

The selections for rubidium compounds were made late in 1975 by W. H. Evans. Those for sodium and potassium have been made by all of us and by former members of the Chemical Thermodynamics Data Center during the past decade. The extensive collection of properties of electrolytes in aqueous solution was prepared by R. H. Schumm. The tables have been printed using computer programs that are modifications of ones developed by Dr. J. B. Pedley, University of Sussex, Brighton, England, for the CATCH System of Thermochemical Tables.

TABLE A: Physical State Conventions

The following conventions are used to designate the physical state of a substance. These apply to the attached table and to the NBS Thermochemical Data Bank. This information appears in a parenthetical expression appended to the molecular formula. Some of the explanations imply a thermochemical value, particularly those for solutions. These normally are used in describing enthalpy measurements.

Basic Symbols	Explanation
(G)	Gaseous, e.g., in H1CL(G) for $HC\ell(g)$
(GS)	Gaseous reference standard state for an element, e.g., O2(GS) for $O_2(g)$
(C)	Crystalline, e.g., in N1H4CL(C) for $NH_4C\ell(c)$
(CS)	Crystalline reference standard state for an element, e.g., in RB(CS) for Rb(c)
(L)	Liquid, e.g., in H2O(L) for $H_2O(\ell)$
(LS)	Liquid reference standard state for an element, e.g., in BR2(LS) for $Br_2(\ell)$
(AM)	Amorphous
(GL)	Glassy
(A)	Hypothetical standard state of the ideal aqueous solution at unit activity. For a neutral electrolyte the value of a property is equal to the algebraic sum of the values for the ions assumed to constitute the molecule of the electrolyte, e.g. $HC\ell(A) = H^+(A) + C\ell^-(A)$. For an ionic species this notation is commonly used to refer to the undissociated ion as written. e.g. $HSO_4^-(A)$

Symbol	Explanation
(AO)	Hypothetical standard state of the ideal aqueous solution at unit activity of the undissociated (non-ionized) species, e.g. HF(AO), HF_2^-(AO). May also be used whenever the designation (A) could be ambiguous. Note that the descriptions HSO_4^-(A) and HSO_4^-(AO) are equivalent, but that HF(A) and HF(AO) are not.
(AU)	Aqueous solution of undefined, but usually dilute, concentration, e.g. XeO_3(AU).

The symbols used above occasionally are modified by numbers to distinguish two substances in the same state that have the same molecular weight, as for isomers,: (AU2), (C3). They are also used in combination with descriptive material, e.g. (C:HE), (C:AL) etc. to mean "crystalline, hexagonal", "crystalline, alpha form" etc.

Special notations for substances in solutions

The notations for the "state" of a substance in solution may combine a definition of the system, e.g. HCℓ in 220 moles of water, and a specification of the thermochemical property associated with it. Usually the thermochemical property is the apparent integral enthalpy or free energy of formation or an absolute entropy, i.e. the formation properties of the solvent are not included. If a partial molal property is tabulated the notation D: ("D" for "differential") occurs as the first term in the state bracket. The notations given below illustrate the differences for integral and differential (partial molal) properties, and extrapolated values. Examples are given for aqueous, mixed, and non-aqueous solvents.

Symbol	Explanation
H1CL(200H2O)	An aqueous solution of specified composition, e.g. one mole of HCℓ in 200 moles H_2O. The value of ΔHf represents the apparent integral enthalpy of formation.
H1CL(D:200H2O) and H2O(D:H1CL+200H2O)	These represent the partial molal (enthalpy) of formation of the substance in a solution of specified concentration, e.g. the partial molal enthalpy of formation of HCℓ and H_2O respectively, in a solution consisting of 1 mole HCℓ and 200 moles H_2O.
U1CL4(H1CL104+50H2O)	This describes a solute dissolved in a mixed solvent, e.g. one mole of $UCℓ_4$ in a mixture of 1 mole of $HCℓO_4$ and 50 moles H_2O. The value of ΔHf represents the apparent integral enthalpy of formation of the substance, $UCℓ_4$, in the medium.
U1CL4(H1CL104+ 50H2O:AU)	This represents a solute at an unspecified but usually dilute concentration in a solvent mixture of fixed composition.

Symbol	Explanation
U1CL4(D:H1N103+50H20)	Specifies the partial molal (enthalpy) of formation of a substance in a mixed medium, e.g. the enthalpy of formation of 1 mole of $UC\ell_4$ in a large amount of a solution containing $UC\ell_4$, HNO_3 and H_2O in the molar ratios 1:1:50.
U1CL4(L(H1CL):AU)	Specifies a thermochemical value extrapolated from those in a particular type of solution, e.g. the integral (enthalpy) of formation of $UC\ell_4$ at an unspecified concentration in water solution obtained by extrapolation from values in solutions containing $HC\ell$ at varying concentrations.
RB1I(C1H3C1N:S)	Ideal solution of a substance (RbI) in a non-aqueous solvent (CH_3CN), the substance being in the standard state of unit activity on the molal scale unless otherwise indicated. (In some early entries in the Data Bank these are written ambiguously as (C1H3C1N)).
RB1I(C1H3C1N:U)	Solution of a substance (RbI) in a non-aqueous solvent (CH_3CN) at an unspecified concentration. This is analogous to (AU).
RB1I(1000C1H3C1N)	Solution of a substance (RbI) in a non-aqueous solvent (CH_3CN) at a specified concentration.

TABLE B

CONVERSION FACTORS FOR UNITS OF MOLECULAR ENERGY

	J/mol	cal/mol	cm^3 atm/mol	kWh/mol	Btu/lb-mol	cm^{-1}/molecule	eV/molecule

15. SUPPLEMENTARY NOTES

16. ABSTRACT *(A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here.)*

Selected values are given for the thermochemical properties of the more common compounds of sodium and potassium. A more extensive set of selections is provided for rubidium compounds. The properties included, where data are available, are enthalpy of formation at 0 K and 298.15 K, $\Delta Hf(0)$ and $\Delta Hf(298)$, Gibbs energy of formation, entropy and heat capacity at 298.15 K, $\Delta Gf(298)$, $S(298)$ and $Cp(298)$ and the enthalpy difference between 0 K and 298.15 K, $H(298)-H(0)$. The values are consistent with the tables issued earlier in the NBS Technical Note 270 series.

17. KEY WORDS *(six to twelve entries; alphabetical order, capitalize only the first letter of the first key word unless a proper name; separated by semicolons)* Enthalpy; entropy; Gibbs energy; heat capacity; potassium compounds; rubidium compounds; sodium compounds; standard reference data; thermochemical tables.
