ANALYSIS OF LIQUID VOLUME AND LIQUID MASS FRACTIONS AT 
COEXISTENCE FOR PURE FLUIDS
Lambert John Van Pooien

An analysis of the behavior of liquid volume and liquid mass fractions at coexistence for pure fluids is made. Scaled equations for the saturation liquid and vapor densities are analyzed and relationships between various exponents and among constant coefficients are presented. Inequalities which exist among the saturation densities and their derivatives are developed. A procedure to correlate saturation data with the critical point is applied to ethylene. An experimental procedure to determine, simultaneously, saturated liquid and vapor densities at a given temperature is presented.

Key words: Coexistence densities; critical density; critical point; liquid mass fraction; liquid volume fraction; phase equilibria; pure fluids.

1. INTRODUCTION

A complete description of a pure fluid at liquid-vapor coexistence from a P-V-T perspective is given by the intensive variables:
P, vapor pressure,
T, vapor temperature,
ρₖ, saturated liquid density,
ρᵥ, saturated vapor density,
and the following extensive variables:
mₖ, mᵥ, masses of the two phases (mₖ + mᵥ = mₜ = total mass),
Vₖ, Vᵥ, volumes of the two phases (Vₖ + Vᵥ = Vₜ = total volume).

Of the four intensive variables only one is independent, i.e., there is one degree of freedom as described by the Gibbs phase rule. For the purpose of this work, T is assumed the independent variable.

An analysis of the extensive variables reveals that any two are independent variables. Hence, to completely describe the pure fluid at coexistence it is sufficient to specify one intensive variable and two extensive variables, i.e., the overall system has three degrees of freedom.

It is not obvious that useful information about the coexistence state is to be gained by considering the extensive variables along with the intensive ones. However, an investigation of these extensive variables when normalized by the total volume and/or total mass has proven interesting.

Consider the mass balance at coexistence,
mₜ = mₖ + mᵥ,
normalized by Vₜ, utilizing the fact that

\[ mₜ = mₖ + mᵥ, \] (1)
\[ \rho_L = \rho_L V_L \text{ and } \rho_V = \rho_V V_V, \quad (2) \]

with the result that
\[ \frac{m_T}{V_T} = \rho_L V_L + \rho_V (V_V/V_T). \quad (3) \]

Now define:
- \( \rho_T \equiv m_T/V_T \), overall or total density,
- \( \chi_{LV} \equiv V_L/V_T \), liquid volume fraction,

and since
\[ 1 - \chi_{LV} = \frac{V_V}{V_T}, \]

the overall density is
\[ \rho_T = \rho_L \chi_{LV} + \rho_V (1 - \chi_{LV}), \quad (4) \]
or rewriting,
\[ \chi_{LV} = \frac{(\rho_T - \rho_V)}{(\rho_L - \rho_V)}. \quad (5) \]

Now, \( \rho_V = \rho_V(T) \) and \( \rho_L = \rho_L(T) \), therefore, eq. (5) describes a variable field having two degrees of freedom - one from the intensive variable set \( T \) and one from the extensive variable set \( (m_T/V_T = \rho_T) \). Another extensive variable, perhaps \( V_T \), would also have to be explicitly known to completely describe a system at coexistence. However, eq. (5) does provide a connection between the intensive and extensive variables and it is that connection, \( \chi_{LV} \), which provides the interest.

The liquid mass fraction:
\[ \chi_{LM} \equiv \frac{m_L}{m_T} \]
is found directly from the liquid volume fraction, i.e.,
\[ \chi_{LM} \equiv \frac{m_L}{m_T} = \frac{V_L \rho_L}{V_T \rho_T} = \frac{\rho_L}{\rho_T} \chi_{LV}. \quad (6) \]
The two variable fields to be explored are then (from (5)):
\[ f(\chi_{LV}, \rho_T, T) = 0, \text{ i.e., } \chi_{LV} = \frac{(\rho_T - \rho_V)}{(\rho_L - \rho_V)} \]
and from (6) and (5),
\[ g(\chi_{LM}, \rho_T, T) = 0, \text{ i.e., } \chi_{LM} = \frac{(\rho_L/\rho_T)(\rho_T - \rho_V)}{(\rho_L - \rho_V)}. \quad (7) \]

2. MATHEMATICAL DESCRIPTION OF \( \chi_{LV} \) AND \( \chi_{LM} \)

For \( f(\chi_{LV}, \rho_T, T) = 0 \) we expect:
\[ \frac{\partial \chi_{LV}}{\partial T} \bigg|_{\rho_T} \frac{\partial \rho_T}{\partial \rho_T} \bigg|_{\chi_{LV}} = -1 \quad (8) \]
and from eq. (5) the derivatives are:

\[
\frac{\partial X_{LV}}{\partial T} \bigg|_{p_T} = \frac{-\rho'_V}{(\rho'_k - \rho'_v)} - \chi_{LV} \frac{(\rho'_k - \rho'_v)}{(\rho'_k - \rho'_v)}
\]

(9)

\[
\frac{\partial X_{LV}}{\partial p_T} \bigg|_{T} = \frac{1}{(\rho'_k - \rho'_v)}
\]

(10)

\[
\frac{\partial p_T}{\partial T} \bigg|_{X_{LV}} = \rho'_V + \chi_{LV}(\rho'_k - \rho'_v)
\]

(11)

Indeed eqs. (9), (10), and (11) together satisfy eq. (8) - the chain rule. It can also be shown that for:

\[
dX_{LV} = \frac{\partial X_{LV}}{\partial p_T} \bigg|_{T} dp_T + \frac{\partial X_{LV}}{\partial T} \bigg|_{p_T} dT
\]

(12)

that:

\[
\frac{\partial^2 X_{LV}}{\partial T \partial p_T} = \frac{\partial^2 X_{LV}}{\partial p_T \partial T}
\]

indicating that \(dX_{LV}\) is an exact differential and that \(X_{LV}\) is a thermodynamic property.

For \(g(X_{LM}, \rho_T, T) = 0\) we have:

\[
\frac{\partial X_{LM}}{\partial T} \bigg|_{\rho_T} \frac{\partial T}{\partial p_T} \bigg|_{X_{LM}} = -1
\]

(13)

and from eq. (7) the derivatives are:

\[
\frac{\partial X_{LM}}{\partial T} \bigg|_{\rho_T} = \frac{-\rho'_v}{\rho_T(\rho'_k - \rho'_v)} + \chi_{LM} \frac{(\rho'_k - \rho'_v)}{\rho'_k(\rho'_k - \rho'_v)}
\]

(14)

\[
\frac{\partial X_{LM}}{\partial p_T} \bigg|_{T} = \frac{\rho'_v \rho'_k}{\rho'_T(\rho'_k - \rho'_v)}
\]

(15)

\[
\frac{\partial p_T}{\partial T} \bigg|_{X_{LM}} = \frac{\rho'_T \rho'_v}{\rho'_T} - \chi_{LM} \rho'_T \frac{(\rho'_k - \rho'_v)}{\rho'_k \rho'_v}
\]

(16)

Indeed eqs. (14), (15), and (16) satisfy eq. (13). It can also be shown that for:
\[ \frac{dX_{LM}}{dT} = \left( \frac{\partial X_{LM}}{\partial \rho} \right)_T \frac{d\rho}{dT} + \left( \frac{\partial X_{LM}}{\partial T} \right)_\rho \frac{dT}{dT} \] (17)

that:

\[ \frac{\partial^2 X_{LM}}{\partial T \partial \rho} = \frac{\partial^2 X_{LM}}{\partial \rho \partial T} \]

indicating that \(dX_{LM}\) is an exact differential and that \(X_{LM}\) is a thermodynamic property.

3. ANALYSIS OF \(X_{LV}\) AND \(X_{LM}\)

3.1 Maxima and Minima Analysis for \(T_{TP} < T < T_c\)

The fields \(f(X_{LV}, \rho, T) = 0\), and \(g(X_{LM}, \rho, T) = 0\), are plotted from smoothed methane data presented by IUPAC [1]. The results are shown in figs. 1-6.

For the maximum in \(X_{LV}\), shown in fig. 1, eq. (9) can be set to zero, i.e.,

\[ \frac{\partial X_{LV}}{\partial T} \bigg|_{\rho_T} = -\frac{\rho'_V}{\rho'_L - \rho'_V} - \frac{X_{LV}}{\rho_L - \rho_V} \left( \frac{\rho'_L - \rho'_V}{\rho_L - \rho_V} \right) = 0 . \]

Designating the subscript "MAX" for the point where the maximum occurs,

\[ X_{LV,\text{MAX}} = -\frac{\rho'_V}{\rho'_L - \rho'_V} \text{ for } (\rho_L - \rho_V) \neq 0 . \] (18)

Now there is a corresponding \(\rho_{T,\text{MAX}}\) such that:

\[ X_{LV,\text{MAX}} = (\rho_{T,\text{MAX}} - \rho_V)/(\rho_L - \rho_V) \]

or,

\[ \rho_{T,\text{MAX}} = -\frac{\rho'_V}{(\rho'_L - \rho'_V)} \left( \rho_L - \rho_V \right) + \rho_V = \frac{(\rho_V \rho'_L - \rho'_V \rho'_L)}{(\rho'_L - \rho'_V)} . \] (19)

Later on (see figs. 8, 9, and 10), when dealing directly with the critical liquid volume fraction, \(X_{LV,c} (\rho_T = \rho_c)\), it is shown that it is unlikely that a maximum occurs along the curve describing it for \(T < T_c\). The implication is that if a maximum does occur, the \(X_{LV}\) curve is turning towards zero and hence the \(\rho_T\) is a \(\rho_V\) (refer to fig. 1).

We can then conclude that \(\rho_{T,\text{MAX}} = \rho_V < \rho_c\) and hence:

\[ X_{LV,c} > X_{LV,\text{MAX}} . \] (20)

Figure 5. $X_{LV}$ vs $\rho_T$ for CH$_4$ at constant T.
Figure 6. $X_{LM}$ vs $\rho_T$ for CH$_4$ at constant $T$. 
The tendency towards zero for the \( \rho_T = \rho_v \) curves (or towards one for \( \rho_T = \rho_L \)) is literally true in the absence of gravity effects. Indeed Hohenberg, et al. [2] indicate that within a very narrow range of temperature and overall density near the critical the meniscus, under the effect of gravity, disappears somewhere other than at the top or bottom of the test cell.

For the minimum in \( X_{LM} \), shown in fig. 2, eq. (14) can be set to zero, i.e.,

\[
\frac{\partial X_{LM}}{\partial T} \bigg|_{\rho_T} = -\frac{\rho_L \rho_v'}{\rho_T (\rho_L - \rho_v)} + \frac{X_{LM}}{\rho_L (\rho_L - \rho_v)} = 0.
\]

Using the subscript "MIN" for the point where the minimum occurs,

\[
X_{LM,MIN} = \frac{\rho_L}{\rho_T,MIN} \left[ \frac{(\rho_L \rho_v')}{(\rho_L \rho_v' - \rho_L \rho_v)} \right].
\]

Now the corresponding \( \rho_T,MIN \) is that for which

\[
X_{LM,MIN} = \frac{\rho_L}{\rho_T,MIN} \left[ \frac{(\rho_T,MIN - \rho_v)}{(\rho_L - \rho_v)} \right],
\]

or,

\[
\rho_T,MIN = \frac{\rho_L \rho_v'}{\rho_L \rho_v' - \rho_L \rho_v} (\rho_L - \rho_v) + \rho_v = (\rho_L \rho_v^2 - \rho_L \rho_v)/(\rho_L \rho_v' - \rho_L \rho_v). \tag{22}
\]

In an argument similar to that for \( X_{LV,c} > X_{LV,MAX} \) it can be shown, based on fig. 2, that values of \( \rho_T,MIN \) are \( \rho_L \)'s and hence:

\[
X_{LM,MIN} > X_{LM,c}, \tag{23}
\]

where \( X_{LM,c} \) is the critical liquid mass fraction (\( \rho_T = \rho_c \)).

If \( \rho_c \) is substituted for \( \rho_T \) in eqs. (5) and (7), the critical liquid volume fraction and critical liquid mass fraction are explicitly:

\[
X_{LV,c} = (\rho_c - \rho_v)/(\rho_L - \rho_v) \tag{24}
\]

\[
X_{LM,c} = (\rho_L/\rho_c)(\rho_c - \rho_v)/(\rho_L - \rho_v) \tag{25}
\]

Now, \( X_{LM,c} > X_{LV,c} \) at a given temperature by inspection of eqs. (24) and (25) since, \( \rho_L > \rho_c \), therefore:

\[
X_{LM,MIN} > X_{LM,c} > X_{LV,c} > X_{LV,MAX} \tag{26}
\]

and
\[ \rho_{T,\text{MIN}} > \rho_{c} > \rho_{T,\text{MAX}} \text{,} \]  \hspace{1cm} (27)

where \( \rho_{k} > \rho_{c} > \rho_{v} \).

Also, considering the value of \( \chi_{\text{LM}} \) at the temperature and \( \rho_{T,\text{MAX}} \) for which \( \chi_{\text{LV}} \) is a maximum, i.e.,

\[ \chi_{\text{LM,MAX}} = \frac{\rho_{k}}{\rho_{T,\text{MAX}}} \chi_{\text{LV,MAX}} \text{ (form of eq. 6)} \]

Substituting for \( \rho_{T,\text{MAX}} \) eq. (19) and for \( \chi_{\text{LV,MAX}} \) eq. (18) the result is:

\[ \chi_{\text{LM,MAX}} = \frac{\rho_{k} \rho'_{V}}{(\rho_{k} \rho'_{V} - \rho'_{k} \rho_{V})} \text{.} \]  \hspace{1cm} (28)

Also, consider the value of \( \chi_{\text{LV}} \) at the temperature and \( \rho_{T,\text{MIN}} \) for which \( \chi_{\text{LM}} \) is a minimum, i.e.,

\[ \chi_{\text{LV,MIN}} = \frac{\rho_{T,\text{MIN}}}{\rho_{k}} \chi_{\text{LM,MIN}} \text{ (form of eq. 6)} \]

Substitute for \( \rho_{T,\text{MIN}} \) eq. (22) and for \( \chi_{\text{LM,MIN}} \) eq. (21) to obtain

\[ \chi_{\text{LV,MIN}} = \frac{\rho_{k} \rho'_{V}}{\rho_{k} \rho'_{V} - \rho'_{k} \rho_{V}} \text{,} \]  \hspace{1cm} (29)

which is the same as \( \chi_{\text{LM,MAX}} \) for the same temperature (see eq. (28)). Now \( \chi_{\text{LV,MIN}} \) is the liquid volume fraction at a density \( \rho_{k} = \rho_{T,\text{MIN}} > \rho_{c} \). Therefore:

\[ \chi_{\text{LV,MIN}} > \chi_{\text{LV,c}} \]  \hspace{1cm} (30)

and \( \chi_{\text{LM,MAX}} \) is the liquid mass fraction at a density \( \rho_{v} = \rho_{T,\text{MAX}} < \rho_{c} \) so

\[ \chi_{\text{LM,MAX}} < \chi_{\text{LM,c}} \text{.} \]  \hspace{1cm} (31)

Combining eqs. (26), (28), (29), (30), and (31) results in:

\[ \chi_{\text{LM,MIN}} > \chi_{\text{LM,c}} > \chi_{\text{LM,MAX}} = \chi_{\text{LV,MIN}} > \chi_{\text{LV,c}} > \chi_{\text{LV,MAX}} \text{.} \]  \hspace{1cm} (32)

An investigation of the individual terms in eq. (32) and their related equations indicates they are only functions of temperature. This is interesting since the field describing the coexistence states has two degrees of freedom. Therefore, these are loci of points, having only one degree of freedom. This reduction comes via the "zero" condition on the first derivative. Also, some conclusions can be drawn about the derivatives,
\[ \frac{\partial x_{LM}}{\partial T} \bigg|_{\rho_{T,\text{MAX}}} = \frac{\partial x_{LV}}{\partial T} \bigg|_{\rho_{T,\text{MIN}}} \text{, at the same temperature.} \]

From eq. (6),
\[ \frac{\partial x_{LM}}{\partial T} \bigg|_{\rho_{T}} = \frac{1}{\rho_{T}} \left[ \rho_{l} \frac{\partial x_{LV}}{\partial T} \bigg|_{\rho_{T}} + \rho_{l} \frac{\partial \chi_{LM}}{\partial T} \right] \] (33)

Now at a minimum, \( \frac{\partial x_{LM}}{\partial T} \bigg|_{\rho_{T}} = 0 \) and from eq. (33),
\[ \rho_{l} \frac{\partial x_{LV}}{\partial T} \bigg|_{\rho_{T,\text{MIN}}} + \rho_{l} \frac{\partial \chi_{LV,\text{MIN}}}{\partial T} = 0 \] (34)

and from,
\[ \chi_{LV} = \frac{\rho_{T}}{\rho_{l}} \chi_{LM} \text{, (form of eq. 6)} \]

obtain:
\[ \frac{\partial x_{LV}}{\partial T} \bigg|_{\rho_{T}} = \rho_{T} \left[ \frac{1}{\rho_{l}} \frac{\partial x_{LM}}{\partial T} \bigg|_{\rho_{T}} - \frac{\chi_{LM} \rho_{l}'}{\rho_{l}^2} \right] \] (35)

At a maximum, \( \frac{\partial x_{LV}}{\partial T} \bigg|_{\rho_{T}} = 0 \), therefore from eq. (35):
\[ \rho_{l} \frac{\partial x_{LM}}{\partial T} \bigg|_{\rho_{T,\text{MAX}}} - \chi_{LM,\text{MAX}} \rho_{l}' = 0 \] (36)

Combining eqs. (34) and (36):
\[ \frac{x_{LV,\text{MIN}}}{x_{LM,\text{MAX}}} = -\frac{\frac{\partial x_{LV}}{\partial T} \bigg|_{\rho_{T,\text{MIN}}}}{\frac{\partial x_{LM}}{\partial T} \bigg|_{\rho_{T,\text{MAX}}}} \] (37)

and as previously shown from eqs. (28) and (29):
\[ x_{LV,\text{MIN}} = x_{LM,\text{MAX}} \] (38)

therefore:
\[ \frac{\partial x_{LV}}{\partial T} \bigg|_{\rho_{T,\text{MIN}}} = -\frac{\partial x_{LM}}{\partial T} \bigg|_{\rho_{T,\text{MAX}}} \] (39)
The methane data of IUPAC [1] was analyzed to check the validity of eqs. (27), (32), (38), and (39). The results are shown in fig. 7 for one temperature, 344 K (160°F). The data used is published at two degree intervals and the slight errors in the equality of \(X_{LM,\text{MAX}}\) to \(X_{LM,\text{MIN}}\) and \(\frac{\partial X_{LM}}{\partial T} \bigg|_{T,\text{MIN}}\) to \(\frac{\partial X_{LM}}{\partial T} \bigg|_{T,\text{MAX}}\) reflect the effect of using this large temperature increment in the numerical calculation of the derivatives.

An examination of fig. 3 reveals a minimum in \(\rho_T\) versus \(T\) at constant \(X_{\text{LM}} \leq X_{c,\text{LIM}}\) (limit of critical liquid volume fraction).

Substituting eq. (5) into eq. (11) and setting the derivative to zero,

\[
\frac{\partial \rho_T}{\partial T} \bigg|_{\rho_T,\text{MIN}} = 0 = \rho_v^i + \frac{(\rho_T - \rho_v)}{(\rho_v^i - \rho_v)} (\rho_v^i - \rho_v) ,
\]

the expression for \(\rho_T\) at the minimum is:

\[
\rho_{T,\text{ZERO}} = \frac{\rho_v^i - \rho_v}{(\rho_v^i - \rho_v)} ,
\]

which is the same as eq. (19). Thus these minimums in fig. 3 correspond to the maximums in fig. 1.

A similar analysis of the maximums in fig. 4 reveal that they correspond to the minimums in fig. 2.

An interesting inequality arises from the fact that the second derivative of \(X_{\text{LM}}\) at the maximum shown in fig. 1 must be less than zero. The derivative of eq. (9) is calculated recognizing that at the point of consideration:

\[
\frac{\partial X_{\text{LM}}}{\partial T} \bigg|_{\rho_T,\text{MAX}} = 0 \quad \text{by definition, and } X_{\text{LM,MAX}} \text{ is given by eq. (18)},
\]

with the result:

\[
\frac{\partial^2 X_{\text{LM}}}{\partial T^2} \bigg|_{\rho_T,\text{MAX}} = \frac{(\rho_v^i \rho_v^i) + (- \rho_v^i \rho_v^i)}{(\rho_v^i - \rho_v^i)(\rho_v^i - \rho_v)} \quad \text{(40)}
\]

Now by inspection of figs. 3 or 4,

\[
\rho_v^i > 0 , \quad \rho_v^i < 0
\]

\[
\rho_v^i > 0 , \quad \rho_v^i < 0 \quad \text{(41)}
\]

In terms of signs, eq. (40) is:
Figure 7. Verification of $X_{LV} - X_{LM}$ structure.
\[
\frac{3^2 x_{LV}}{\alpha T^2} \text{ evaluated at } T_{MAX} = \frac{(+)}{(-)(+)}.
\]

Therefore if \( \frac{3^2 x_{LV}}{\alpha T^2} \text{ evaluated at } T_{MAX} \) is to be less than zero,

\[
\left| \frac{\rho'' \rho_L^1}{\rho_L' \rho_V} \right| > \left| \frac{\rho'' \rho_L^1}{\rho_L' \rho_V} \right|,
\]

This same conclusion can be reached from the minimum of eq. (42)

\[
\frac{3^2 \rho_T}{\alpha T^2} \text{ evaluated at } x_{LV} = \rho'' + \frac{3x_{LV}}{\alpha T} \left( \rho_L' - \rho_V' \right) + x_{LV} \left( \rho''_L - \rho''_V \right).
\]

Now, as seen in an earlier analysis, at this minimum:

\[
\frac{3x_{LV}}{\alpha T} \text{ evaluated at } \rho_T = 0,
\]

and:

\[
x_{LV} = x_{LV,MAX} = -\frac{\rho_L' - \rho_V'}{\rho_L' - \rho_V'}.
\]

After substitution of these in eq. (43):

\[
\frac{3^2 \rho_T}{\alpha T^2} \text{ evaluated at } x_{LV,MAX} = \frac{(\rho''_L \rho_L^1) + (-\rho''_V \rho_V^1)}{(\rho_L' - \rho_V')^2 (\rho_L' - \rho_V')^2}.
\]

If this is a true minimum \( \frac{3^2 \rho_T}{\alpha T^2} \text{ evaluated at } x_{LV,MAX} \) should be greater than zero. This is true if again:

\[
\left| \frac{\rho'' \rho_L^1}{\rho_L' \rho_V} \right| > \left| \frac{\rho'' \rho_L^1}{\rho_L' \rho_V} \right|.
\]

And since we have already indicated that a maximum in \( x_{LV} \) exists for all \( T_{TP} < T < T_c \), eq. (42) is true for this temperature range.

Consider the minimum in \( x_{LM} \) as seen in fig. 2. The related derivative is given by eq. (14).

If the minimum is truly so, the curve is concave upward and the second derivative is positive at that point.
We had at this minimum, \( \frac{\partial X_{LM}}{\partial T} \bigg|_{\rho_{T,MIN}} = 0 \), and from previous work eqs. (21) and (22) apply.

Taking the derivative of eq. (14) and substituting eqs. (21) and (22) the result is:
\[
\frac{\partial^2 X_{LM}}{\partial T^2} \bigg|_{\rho_{T,MIN}} = \frac{(- \rho_v \rho_{x,\rho} \rho_{x,\rho}' + 2 \rho_v \rho_{x,\rho}' (\rho_{x,\rho}' - \rho_{x,\rho}')) + (\rho_v \rho_{x,\rho} \rho_{x,\rho}' \rho_{x,\rho}' \rho_{x,\rho}')} {\rho_{x,\rho} - \rho_v} (\rho_{x,\rho}' \rho_{x,\rho}' - \rho_{x,\rho}' \rho_{x,\rho}')
\]

Equation (45) in terms of signs using eq. (41) is:
\[
\frac{\partial^2 X_{LM}}{\partial T^2} \bigg|_{\rho_{T,MIN}} = \frac{(+)}{(+)}
\]

If \( \frac{\partial^2 X_{LM}}{\partial T^2} \bigg|_{\rho_{T,MIN}} \) is to be greater than zero,
\[
\left| - \rho_v \rho_{x,\rho} \rho_{x,\rho}' + 2 \rho_v \rho_{x,\rho}' (\rho_{x,\rho}' - \rho_{x,\rho}') \right| > \left| \rho_v \rho_{x,\rho} \rho_{x,\rho}' \rho_{x,\rho}' \rho_{x,\rho}' \right|
\]

This is true for \( T_{TP} \leq T \leq T_c \) for which a minimum in \( X_{LM} \) occurs. (No doubt eq. (46) can also be found by considering the maximum in fig. 4. This was not done.)

3.2 Maxima and Minima Analysis as \( T \) Goes to \( T_c \)

To aid in this limit analysis, use is made of the following coexistence dome equations based on those given by Green, et al. [3], and Sengers, et al. [4] with the exception that the exponents are not assumed the same for each phase, i.e.,
\[
\rho_{x} - \rho_c = B_1 \epsilon^{\beta_x} + B_2 \epsilon^{\phi_x} + B_3 \epsilon^{\psi_x}
\]
\[
\rho_v - \rho_c = B_1 \epsilon^{\beta_v} + B_2 \epsilon^{\phi_v} + B_3 \epsilon^{\psi_v}
\]

where,

\( B ' s \) are constants,
\( \beta_x, \beta_v \approx .35 \)
\( \phi_x, \phi_v \approx 1.00 \)
\( \psi_x, \psi_v > 1.00 \)
\( \epsilon = T_c - T \).

To analyze the limits of various mass and liquid fractions in eq. (32) it is helpful to develop the relationship between the exponents \( \beta_v \) and \( \beta_x \) in eqs. (47) and (48).
To that end, form the critical liquid volume fraction \( \chi_{LV,c} = (\rho_c - \rho_v)/(\rho_L - \rho_v) \) using eqs. (47) and (48), i.e.:

\[
\chi_{LV,c} = \frac{-B_1v^\beta_v - B_2v^\phi_v - B_3v^\psi_v}{B_1v^\beta_L - B_2v^\phi_L - B_3v^\psi_L} \quad (49)
\]

Now fig. 1 indicates the generally accepted fact that the liquid volume fraction in the limit along the critical isochore is neither one (a liquid) nor zero (a vapor). A recent detailed critical point investigation by Moldover [5] reinforces such an opinion.

With that in mind, it may be assumed in eq. (49) that \( \beta_L > \beta_v \), and each term can be divided by \( \varepsilon^\beta_v \) obtaining:

\[
\chi_{LV,c} = \frac{-B_1v^\beta_v + \text{TERMS} (\varepsilon^{\text{EXP}>0})}{-B_1v^\beta_v + \text{TERMS} (\varepsilon^{\text{EXP}>0})} \quad (50)
\]

where "EXP" means the exponent of \( \varepsilon \). In the limit as \( T \to T_c (\varepsilon \to 0) \)

\[
\lim_{T \to T_c} \chi_{LV,c} = 1 \quad \text{for } \beta_L > \beta_v \quad (51)
\]

Or if it is assumed that, \( \beta_v > \beta_L \), and each term of eq. (49) is divided by \( \varepsilon^{\beta_L} \) the result is:

\[
\chi_{LV,c} = \frac{\text{TERMS} (\varepsilon^{\text{EXP}>0})}{\beta_L + \text{TERMS} (\varepsilon^{\text{EXP}>0})} \quad (52)
\]

In the limit then as \( T \to T_c (\varepsilon \to 0) \)

\[
\lim_{T \to T_c} \chi_{LV,c} = 0 \quad \text{for } \beta_v > \beta_L \quad (53)
\]

Neither of these conclusions, eqs. (51) and (53), agree with the accepted fact that

\[
0 < \lim_{T \to T_c} \chi_{LV,c} < 1 \quad (54)
\]

The only possible conclusion is:

\[
\beta_L = \beta_v = \beta \quad (55)
\]

In most of the current work with eqs. (47) and (48) the "\( \beta \) exponents" are assumed equal. However, the behavior of the critical liquid volume fraction gives a rational reason for their equality. If this is true each term of eq. (49) can be divided by \( \varepsilon^\beta \) obtaining,
\[ X_{LV,c} = \frac{-B_{1v} + \text{TERMS } (e^{\exp>0})}{(B_{1\perp} - B_{1v}) + \text{TERMS } (e^{\exp>0})} \]  

(62)

In the limit, then, as \( T \to T_c \) (\( e \to 0 \)):

\[ \lim_{T \to T_c} X_{LV,c} = \frac{-B_{1v}}{B_{1\perp} - B_{1v}} \equiv X_{c,LIM} \]  

(63)

We note that obviously \( B_{1v} \) nor \( B_{1\perp} \) is zero leading again to limits of zero and one respectively. Also, Sengers, et al. [4] indicate that for first order "dome" symmetry at the critical point,

\[ B_{1\perp} = -B_{1v} \]  

(64)

indicating also (see eq. (63)) that \( B_{1\perp} \) and \( B_{1v} \) are of opposite algebraic sign. Normally \( B_{1\perp} \) is positive while \( B_{1v} \) is negative (see eqs. (47) and (48)).

Also, the limit, \( T \to T_c \), in eq. (6), i.e.,

\[ \lim_{T \to T_c} X_{LM,c} = \lim_{T \to T_c} \frac{B_{1\perp}}{\rho_c} \lim_{T \to T_c} X_{LV,c} \]

results in:

\[ \lim_{T \to T_c} X_{LM,c} = \lim_{T \to T_c} X_{LV,c} = X_{c,LIM} \]  

(65)

The critical isochores in figs. 1 and 2 can then be extended to the point "X" = \(-B_{1v}/(B_{1\perp} - B_{1v})\), i.e., to \( X_{c,LIM} \) at \( T_c = 190.555 \) K for the methane.

The limits of the liquid mass and volume fractions found in eq. (32) can be analyzed. Substituting the derivatives of eqs. (47) and (48) into eq. (18) and dividing each term by, \( e^{\beta-1}, \)

\[ X_{LV,\text{MAX}} = \frac{-\beta B_{1v} + \text{TERMS } (e^{\exp>0})}{+\beta (B_{1\perp} - B_{1v}) + \text{TERMS } (e^{\exp>0})} \]  

(66)

In the limit (\( e \to 0 \)):

\[ \lim_{T \to T_c} X_{LV,\text{MAX}} = \frac{-B_{1v}}{(B_{1\perp} - B_{1v})} = X_{c,LIM} \]  

(67)

and for eq. (21), in the limit (\( e \to 0 \)), by inspection,

\[ \lim_{T \to T_c} X_{LM,MIN} = \lim_{T \to T_c} X_{LV,\text{MAX}} = X_{c,LIM} \]  

(68)
The results given in eqs. (67) and (68) allow the extension of the locus of maximum and minimum points to at and to on figs. 1 and 2 and to on figs. 3 and 4 at 

Examining and in the context of eq. (38) it can be seen by inspection that as 

Thus eq. (32) can be rewritten for the limit at the critical as: 

Since all these "x's" collapse to a single value at the critical point it might be expected that the derivatives of these curves at the points in eq. (32) would also go to a single value in the limit. 

By inspection of figs. 1 and 2 and considering eq. (68) it is concluded that: 

Further, consideration of eq. (69) suggests that the following limits also be considered: 

The values of these derivatives can be found by combining eqs. (18), (19), (28), (36) and (39), to obtain: 

\[ \frac{\partial X}{\partial t} \bigg|_{\rho_T = \rho_T, \text{MAX}} = -\frac{\partial X}{\partial t} \bigg|_{\rho_T = \rho_T, \text{MIN}} = \frac{-\rho_L^* \rho_L^*}{(\rho_L^* \rho_L^* - \rho_L^* \rho_L^*)} \]
Substituting the derivatives from eqs. (47) and (48) into eq. (73) and dividing each term by \((- β_ε^{β-1})\) results in:

\[
\frac{\partial X_{LM}}{\partial T} \bigg|_{\rho_T = \rho_{T,\text{MAX}}} = - \frac{\partial X_{LV}}{\partial T} \bigg|_{\rho_T = \rho_{T,\text{MIN}}} = \frac{\beta \left( B_{1L}B_{1V}e^{β-1} + \text{TERMS (e^{EXP≥0})} \right)}{\rho_c \left( B_{1L} - B_{1V} \right) + \text{TERMS (e^{EXP≥0})}}
\]  

(74)

Noting that, \(B_{1L} B_{1V} < 0\) and \((B_{1L} - B_{1V}) > 0\), in the limit \(ε \to 0\):

\[
\lim_{T \to T_c} \frac{\partial X_{LV}}{\partial T} \bigg|_{\rho_T = \rho_{T,\text{MIN}}} = + ∞
\]  

(75)

\[
\lim_{T \to T_c} \frac{\partial X_{LM}}{\partial T} \bigg|_{\rho_T = \rho_{T,\text{MAX}}} = - ∞
\]  

(76)

So rather than uniformity in the derivatives at the critical point eqs. (71), (72), (75) and (76) indicate different values depending on whether the approach to \(ρ_c\) is from "below" or "above" and whether the function is \(X_{LV}\) or \(X_{LM}\). These results are sensible in light of figs. 1 and 2. Also, since the maxima and minima of figs. 3 and 4 are shown to extend to the critical point, the limits,

\[
\lim_{T \to T_c} \frac{\partial ρ_T}{\partial T} \bigg|_{X_{LV} \text{ at } ρ_{T,\text{MAX}}} = 0
\]  

(77)

\[
X_{LV} \leftarrow X_{c,\text{LIM}}
\]

\[
\lim_{T \to T_c} \frac{\partial ρ_T}{\partial T} \bigg|_{X_{LM} \text{ at } ρ_{T,\text{MIN}}} = 0
\]  

(78)

\[
X_{LM} \leftarrow X_{c,\text{LIM}}
\]

seem reasonable. Also by analogy to eqs. (75) and (76) as well as by inspection of figs. 3 and 4,

\[
\lim_{T \to T_c} \frac{\partial ρ_T}{\partial T} \bigg|_{X_{LV} \text{ at } ρ_{T,\text{MIN}}} = - ∞
\]  

(79)

\[
X_{LV} \leftarrow X_{c,\text{LIM}}
\]

\[
\lim_{T \to T_c} \frac{\partial ρ_T}{\partial T} \bigg|_{X_{LM} \text{ at } ρ_{T,\text{MAX}}} = + ∞
\]  

(80)

\[
X_{LM} \leftarrow X_{c,\text{LM}}
\]

seem to be rational conclusions.
3.3 Analysis Along $\rho_c$ and $X_{C,\text{LM}}$ as $T$ Goes to $T_c$

It appears that to obtain a derivative at the critical point, unambiguously, the approach to the critical point must be along the critical isochore in figs. 1 and 2 and along the line $X_{C,\text{LM}}$ in figs. 3 and 4. Furthermore, the $X_{LV,c}$ function has been utilized by this author [6] to both check the internal consistency data and critical density values and to predict $\rho_c$ from saturation data. (These procedures are discussed further later in this report.) A knowledge of the derivative is an obvious help to these ends.

The ambiguity in the limit prompts reconsideration of the function map and the areas of applicability of eqs. (8) and (13), i.e., the chain rules.

Now $f(X_{LV}, \rho_T, T) = 0$, becomes, along the critical isochore, $f_c(X_{LM,c}, T) = 0$. Likewise $g(X_{LM}, \rho_T, T) = 0$ becomes $g_c(X_{LM,c}, T) = 0$. This reduction in dependent variables is also true on the saturation boundaries, i.e., $f(X_{LV}, \rho_T, T) = f_v(\rho_v, T) = 0$ for $X_{LV} = 1$, and $f(X_{LV}, \rho_T, T) = f_v(\rho_v, T) = 0$ for $X_{LV} = 0$. This would occur also for $g(X_{LM}, \rho_T, T) = 0$.

Therefore the chain rule only holds in the regions between the saturation boundaries and the critical isochore for both the liquid volume and liquid mass fractions in figs. 1 and 2 respectively. This may be a reason for the ambiguity of the limits for the derivatives when the critical point is approached from these regions. To avoid this ambiguity then, approach the critical point along $\rho_c$ (figs. 1 and 2) or $X_{C,\text{LM}}$ (figs. 3 and 4).

Along $\rho_c$,

$$\frac{\partial X_{LV,c}}{\partial T} \bigg|_{\rho_T = \rho_c} = \frac{dX_{LV,c}}{dT} \equiv X'_{LV,c}$$

$$\frac{\partial X_{LM,c}}{\partial T} \bigg|_{\rho_T = \rho_c} = \frac{dX_{LM,c}}{dT} \equiv X'_{LM,c}$$

(81)

independent of the derivatives and their limits found previously.

Figure 1 shows that $X_{LV,c}$ has positive values virtually to the critical point. The argument that $X_{LV,c}$ does not have a maximum (i.e., $X'_{LV,c} = 0$) except perhaps at $T_c$ is as follows. There are only two possibilities for a maximum in $X_{LV,c}$ in the interval $T_p < T < T_c$. The first is illustrated graphically in fig. 8.

The locus of $X_{LV, \text{MAX}}$ in fig. 8, stops at point "a" for some $T < T_c$. But it has been shown that eq. (18) describes, for all $T < T_c$, $X_{LV, \text{MAX}}$. In addition, eq. (67) indicates that $X_{LV, \text{MAX}} = X_{C,\text{LM}}$ at $T_c$. Therefore this case could not exist, i.e., point "a" and $X_{C,\text{LM}}$ of fig. 8 must be the same point. This leads to the second possibility shown graphically in fig. 9.
Figure 8. \( X_{LV}, \text{MAX First Possibility} \)
Figure 9. $X_{LV,\text{MAX}}$ Second Possibility.
Here the locus of the zeros in \( X_{LV} \) is shown going into the critical point. However, for \( \rho_T > \rho_c \) a maximum and a minimum occurs in \( X_{LV} \). Now at these "zero slope points" the value of \( \rho_T \) is given by eq. (19).

In order for the case of fig. 9 to exist, it would be necessary, at two different temperatures, for the right hand side of eq. (19) to be the same (for \( \rho_T > \rho_c \) in the example). This behavior in \( X_{LV} \) has never been found by this author even when working with data very near the critical point. An example of data close to the critical point is shown in fig. 10 based on oxygen data of Weber [7] in a one-half degree interval before the critical point. The departures from smooth curves can only be attributed to experimental error and certainly the points lie on the smooth curves "within" that error. The only data which might cause the reader to suspect the phenomena suggested in fig. 9 is that at 154.560 K in fig. 10 (second to the last temperature). But this "upward" trend appears at densities above and below the critical point and can most likely be attributed to an experimental bias. (The critical isochore appears to approach a value of \( X_{c,\text{LIM}} \) very near one-half.)

To further amplify the idea that the case of fig. 9 does not occur, data based on "dome" equations similar to eqs. (47) and (48) are presented. The equations are those of Douslin, et al. [8] for ethylene. They are:

\[
\rho_L = 7.635 + 1.9695 \epsilon^{.350} + 0.2669 \epsilon^{.984} - 0.2731 \times 10^{-3} \epsilon^{1.618} \quad (82)
\]

\[
\rho_V = 7.635 - 1.9695 \epsilon^{.350} + 0.1404 \epsilon^{.984} + 0.6783 \times 10^{-3} \epsilon^{1.618} \quad (83)
\]

These were substituted into eq. (24) for \( X_{LV,c} \) and eq. (18) for \( X_{LV,\text{MAX}} \). The results are given in table 1.

Equations (82) and (83), based on theory and fit to actual data, result in an \( X_{LV,c} \) which has a positive slope and is monotonic to the critical point. Also \( X_{LV,\text{MAX}} \), with a positive slope, increases monotonically into the critical point. The behavior shown in table 1 coincides with that of fig. 1 and also reinforces the result of the last section that

\[
\lim_{T \to T_c} X_{LV,\text{MAX}} = X_{c,\text{LIM}}.
\]

The conclusion is that the cases shown in figs. 8 and 9 do not occur. Therefore \( X_{LV,c} \) does not have a zero slope except perhaps at the critical point. That is, the behavior of \( X_{LV,c} \) in fig. 8 is incorrect mathematically and there is no evidence for the behavior of \( X_{LV,c} \) as shown in fig. 9. The result is as suggested in fig. 1, that \( X_{LV,c} \) continues monotonically into \( X_{c,\text{LIM}} \) and, that the possibilities for \( X_{LV,c} \) are:

\[
0 \leq \lim_{T \to T_c} X_{LV,c}' \leq + \infty \quad (84)
\]

</table>
Having established eq. (84), further analysis can be done by developing the derivative $X_{LV,c}'$ in terms of eqs. (47) and (48). For convenience set $\phi_L = \phi_V$, an assumption usually made. (See eqs. (82) and (83) where Douslin, et al. [8] have $\phi_L = \phi_V = .984$.) The equation is as follows:

$$X_{LV,c}' = \frac{(B_1\phi_2 - B_2\phi_1)(\phi - \beta) e^{\beta + \phi - 1} + \text{TERMS (e EXP > 0)}}{(B_1\phi - B_1\phi)^2 + \text{TERMS (e EXP > 0)}}$$

(85)

and eq. (84) allows the limit of this derivative to be either zero, positive finite, or positive infinity.

Before the exponents are examined, the nature of the constant coefficient $(B_1\phi_2 - B_2\phi_1)$ should be analyzed. The possibilities for it are either zero or greater than zero based on eq. (85). If it is to be zero then:

$$\frac{B_1\phi}{B_1\phi} = \frac{B_2\phi}{B_2\phi}$$

(86)

Since it has been previously shown that $B_1\phi$ and $B_1\phi$ have opposite algebraic signs, eq. (86) would mean that $B_2\phi$ and $B_2\phi$ would also have opposite signs. Sengers, et al. [4] in an extensive study of data near the critical point suggest that no conclusion can be made that $B_2\phi = B_2\phi$ but indicate that when taking the difference $\rho_L - \rho_V$ the $B_2\phi$ and $B_2\phi$ terms are nearly equal in magnitude and are of the same sign. The eqs. (82) and (83) of Douslin, et al., indicate that $B_2\phi = .02669$ and $B_2\phi = .01404$, i.e., they are of the same sign.

It is reasonable then to suggest that since no evidence exists for assuming eq. (86),

$$(B_1\phi_2 - B_2\phi_1) > 0.$$  

(87)

An examination of eq. (85) in the light of eq. (87) would result in the virtual elimination of zero as a limit for the derivative. Also, since the exponent $(-\beta + \phi - 1)$ is not equal to zero itself the choice of the positive finite limit is also removed. The only reasonable choice left is that:

$$\lim_{T \rightarrow T_c} X_{LV,c}' = + =$$

(88)

$$\lim_{T \rightarrow T_c} X_{LV,c}' = + =$$

The derivative $X_{LV,c}'$ behaves as though the fluid were a "liquid" at the critical point (see fig. 1) and eq. (75).

A check of eqs. (82) and (83) for ethylene indicates that indeed eq. (87) is satisfied, i.e., $(1.9695)(.01404)-(1.9695)(.02669) > 0$, affirming that:

$$\lim_{T \rightarrow T_c} X_{LV,c}' = + =$$

28
The data of table 1 indicates that the $X_{LV,c}$ function comes into $X_{c,\text{LIM}}$ with a very small slope and therefore must then turn upward virtually at $T_c$.

An exception to eq. (87) was found in the recent paper of Haar, et al. [9] for ammonia. His values are:

- $B_{1L} = 2.117$
- $B_{1V} = -2.117$
- $B_{2L} = -1.4097$
- $B_{2V} = -1.1390$

Indeed, $B_{2L}$ and $B_{2V}$ have the same sign but

$$(2.117)(-1.4097) - (-2.117)(-1.1390) < 0$$

which would indicate $\lim_{T \to T_c} X_{LV,c} = -\infty$. However the equations are based mainly on data by Cragoe, et al [10,11] which are at best some 30 K away from the critical point. These equations were used only to estimate $T_c$ and $\rho_c$ and were not used in the determination of the published saturation data.

To check the ammonia data for the slope $X'_{LV,c}$ at the critical point, this author fit the published saturation data from 116 - 132°C to the function $X_{LV,c} (T_c = 132.24^\circ\text{C})$. The procedure is outlined in a previous paper [6]. The results for an unweighted least squares fit is ($\text{Var} (\text{data}) = .2547 \times 10^{-7}$):

$$X_{LV,c} = (1/2) [1 - 3.903 \times 10^{-3} \epsilon^{.97}]$$

(89)

from which:

$$X'_{LV,c} = (1.893 \times 10^{-3}) \epsilon^{-0.03}$$

(90)

Clearly the limit is: $+\infty$, which agrees with eq. (88).

The equation for the derivative of the critical liquid mass fraction, $X'_{LM,c}$, is developed from eqs. (47) and (48) assuming $\phi_c = \phi_L$. The result is:

$$X'_{LM,c} = \left[ \beta (B_{1L} - B_{1V}) (B_{1L} B_{1V}) \epsilon^{\beta-1} + \rho_c^2 (\phi - \beta) [B_{1L} B_{1V} B_{2L} B_{2V}] \epsilon^{\phi-1} \right.$$

$$+ \rho_c \left[ \left( \frac{2B_{2L}}{B_{2L} - B_{2V}} \right) + 2 \phi B_{2L} \right] B_{1L} B_{1V}$$

$$+ \phi \left[ (B_{1L} - B_{1V}) B_{1L} B_{1V} - (B_{1V} + B_{1L}) B_{2L} B_{1V} \right] \epsilon^{\phi-1}$$

$$+ \text{TERMS (EXP>0)} \right]$$

$$\rho_c^2 (B_{1L} - B_{1V})^2 + \text{TERMS (EXP>0)}$$

(91)
The term containing $e^{0.1}$ would have the strongest influence since

$$\begin{align*}
\beta &- 0.65 \\
d\beta &- 0.35 \\
\beta &- 0.0.
\end{align*}$$

The coefficient of $e^{0.1}$, i.e., $\beta(B_\psi - B_\nu)(B_\psi B_\nu)$ is $< 0$ (assuming as before, $B_\psi > 0$ and $B_\nu < 0$). Hence the only choice for the limit of $X'_{LM,c}$ is:

$$\lim_{T\to T_c} X'_{LM,c} = -\infty$$

This limit is also strongly suggested by the graph of fig. 2 for the critical isochore. The derivative $X'_{LM,c}$ behaves as though the fluid were a "vapor" at critical point (see eq. (76)).

As previously stated, the liquid volume fraction derivative behaves as a "liquid" derivative, hence there is some ambiguity at the critical point in the derivatives in addition to the non-liquid, non-vapor ambiguous behavior of $X'_{LV,c}$ and $X'_{LM,c}$ themselves at the critical point.

From eq. (6):

$$X'_{LV,c} = \frac{X'_{LM,c} \rho_c}{\rho_L}$$

The derivative with respect to temperature is

$$X'_{LV,c} = X'_{LM,c} \frac{\rho_c}{\rho_L} - \frac{X'_{LM,c} \rho_c \rho'_L}{\rho'_L^2}$$

In the limit:

$$\lim_{T\to T_c} X'_{LV,c} = \lim_{T\to T_c} X'_{LM,c} - \frac{X'_{c,LIM} \rho_c}{\rho_c} \lim_{T\to T_c} \rho'_L$$

Since $\rho'_L$ and $X'_{LM,c}$ in the limit are $-\infty$,

$$\lim_{T\to T_c} X'_{LV,c} = -\infty + \infty,$$

an indeterminate form. Thus the limit could be anything. The limit as given by eq. (75) (+ $\infty$) is allowed by eq. (95).

The ambiguity in the limit of the derivatives of eqs. (77), (78), (79) and (80), is avoided by accessing the critical point along the lines $X'_{LV} = X'_{c,LIM}$ in fig. 3 and $X'_{LM} = X'_{c,LIM}$ in fig. 4.

To that end, in eq. (11), substitute the derivatives from eqs. (47) and (48) and eq. (63) for $X'_{c,LIM}$ resulting in:

30
\[
\begin{align*}
\frac{\partial p}{\partial T} & = \frac{\beta [B_{1L}B_{1v} - B_{1L}B_{1v}]e^{B-1} + \phi [B_{1v}B_{2L} - B_{1L}B_{2v}]e^{\phi-1} + \text{TERMS} (e^{\text{EXP} \geq 0})}{(B_{1L} - B_{1v})}. \quad (96)
\end{align*}
\]

But the coefficient of \(e^{B-1}\) is zero hence:

\[
\begin{align*}
\frac{\partial p}{\partial T} & = \frac{- \phi [B_{1L}B_{2v} - B_{1v}B_{2L}]e^{\phi-1} + \text{TERMS} (e^{\text{EXP} \geq 0})}{(B_{1L} - B_{1v})}. \quad (97)
\end{align*}
\]

Earlier analysis indicates that it is reasonable to have \((B_{1L}B_{2v} - B_{1v}B_{2L}) > 0\), and since \(\phi\) and \((B_{1L} - B_{1v})\) are greater than zero the possibilities are:

\[
- \infty \leq \lim_{T \to T_C} \frac{\partial p}{\partial T} \bigg|_{x_{LV} = x_{c,\text{LIM}}} \leq 0 \quad (98)
\]

where the actual value is then determined by the value of \(\phi\), i.e.,

\[
0 < \phi < 1, \quad \lim_{T \to T_C} \frac{\partial p}{\partial T} \bigg|_{x_{LV} = x_{c,\text{LIM}}} = - \infty, \quad (99)
\]

\[
\phi = 1, \quad \lim_{T \to T_C} \frac{\partial p}{\partial T} \bigg|_{x_{LV} = x_{c,\text{LIM}}} = - \text{finite}, \quad \text{and} \quad (100)
\]

\[
\phi > 1, \quad \lim_{T \to T_C} \frac{\partial p}{\partial T} \bigg|_{x_{LV} = x_{c,\text{LIM}}} = 0. \quad (101)
\]

There is much interest in the literature of today in the slope of the rectilinear diameter, \((p'_L + p'_v)/2\), especially at the critical point. Theoretical work by Green, et al. [3] and experimental work by Weiner, et al. [12] indicate the possibility of a slight "hook" in the rectilinear diameter, i.e., the hypothesis is that

\[
\lim_{T \to T_C} \frac{(p'_L + p'_v)}{2} = - \infty \quad (102)
\]
If in eq. (11), \( \chi_{LV} = 1/2 \), then:

\[
\frac{\partial \rho_T}{\partial T} \bigg|_{\chi_{LV}=1/2} = \frac{\rho_v + \rho_x'}{2}
\]

(103)

the slope of the rectilinear diameter.

The slope of the rectilinear diameter may be obtained by using the derivatives of eqs. (47) and (48) directly for \( \rho_x' \) and \( \rho_v \) obtaining,

\[
\rho_x' + \rho_v' = -\beta (B_{1x} + B_{1v})e^{\beta-1} - \phi (B_{2x} + B_{2v})e^{\phi-1} + \text{TERMS} (e^{\text{EXP} > 0})
\]

(104)

The variables of interest in eqs. (97), (103), and (104) are \( B_{1x} \), \( B_{1v} \), and the exponent \( \phi \). In eq. (104), it is assumed that if \( (B_{1x} + B_{1v}) \neq 0 \) the \( e^{\phi-1} \) dominates.

Table 2 summarizes the effect of varying \( B_{1x} \), \( B_{1v} \) \( (\chi_{c,LIM} = -B_{1v}/(B_{1x} - B_{1v})) \) and \( \phi \).

| \( \chi_{c,LIM} \) | \( \phi \) | \( \lim_{T \rightarrow T_C} \frac{\partial \rho_T}{\partial T} \bigg|_{\chi_{LV}=\chi_{c,LIM}} \) | \( \lim_{T \rightarrow T_C} (\rho_x' + \rho_v') \) |
|-------------------|-------|---------------------------------|-----------------|
| \( B_{1v} = -B_{1x} \) | \( <1 \) | \( - = (97)^{1} \) | \( - = (104) \) |
| \( \phi = 1 \) | \( -FINITE (97) \) | \( -FINITE (97) \) |
| \( \phi > 1 \) | \( 0 (97) \) | \( 0 (97) \) |
| \( \phi = 1 \) | \( -FINITE (97) \) | \( -FINITE (97,103) \) |
| \( \phi > 1 \) | \( 0 (97) \) | \( 0 (97,103) \) |
| \( B_{1v} > -B_{1x} \) | \( <1 \) | \( - = (97) \) | \( + = (104) \) |
| \( \phi = 1 \) | \( -FINITE (97) \) | \( + = (104) \) |
| \( \phi > 1 \) | \( 0 (97) \) | \( + = (104) \) |

1The number in parentheses refers to the related equation.

When \( B_{1x} = -B_{1v} \) \( (\chi_{c,LIM} = 1/2) \), the rectilinear diameter slope is found from eq. (97) as

\[
\frac{\partial \rho_T}{\partial T} \bigg|_{\chi_{LV}=\chi_{c,LIM}} = \frac{\rho_x' + \rho_v'}{2}
\]

and \( \rho_x' + \rho_v' \) are equal (see eq. (103)). These should match the values obtained from eq. (104) where at first order symmetry, \( B_{1x} = -B_{1v} \), eq. (104) reduces to:
\[ \rho_v^t + \rho_v' = - \Phi (B_{2\ell} + B_{2v}) e^{\Phi - 1} + \text{TERMS (e}^{\Phi > 0}) \]  

(105)

From the values in table 2 for \( \lim (\rho_v^t + \rho_v') \), at \( B_{1\ell} = -B_{1v} \) (based on eq. (97)) there are the following implications, given in table 3, for \( (B_{2\ell} + B_{2v}) \) since, as said above, the values in eq. (105) should match.

<table>
<thead>
<tr>
<th>( \Phi )</th>
<th>( \lim_{T \to T_c} (\rho_v^t + \rho_v') )</th>
<th>( (B_{2\ell} + B_{2v}) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;1</td>
<td>(-\infty)</td>
<td>( &gt;0 )</td>
</tr>
<tr>
<td>=1</td>
<td>(-\text{FINITE})</td>
<td>( &gt;0 )</td>
</tr>
<tr>
<td>&gt;1</td>
<td>0</td>
<td>( \text{NO RESTRICTION} )</td>
</tr>
</tbody>
</table>

The number in parentheses refers to the related equation.

If first order symmetry is assumed \( (B_{1\ell} = -B_{1v}) \), and if \( \Phi < 1 \), both generally assumed to be valid, then:

\( (B_{2\ell} + B_{2v}) > 0 \).

(106)

We see that for Douslin's [8] eqs., (82) and (83), both \( B_{2\ell} \) and \( B_{2v} \) are positive so the criterion is met. The \( B_{2\ell} \) and \( B_{2v} \) of Haar, et al. [9] for ammonia are both negative but see the previous discussion regarding the validity of these values in light of the data range from which they were derived.

Figure 11 indicates that if the rectilinear diameter is to have a slope in the limit of \( +\infty \), the diameter must have the value of \( p_c \) two times, i.e., once at \( T_a \) (point "a") and again at the critical point. This author does not know of any evidence in the literature for such an occurrence. A reasonable hypothesis is then:

\[ X_{c,\text{LIM}} \leq 1/2 \].

(107)

An expression for the derivative \( \frac{3p_T}{3T} \bigg|_{X_{LM}} \) along \( X_{c,\text{LIM}} \) (see fig. 4) can also be developed. Utilizing eqs. (7), (16), (67), (68) and the derivatives of eqs. (47) and (48),

33
Figure 11. Implications of $X_{c,LIM} > 1/2$. 
\[
\frac{\partial p}{\partial t} \bigg|_{X_{LM}=X_{c,LIM}} = \left[ \left( B_{1\ell} - B_{1\ell} \right) B_{1\ell} B_{1\ell} B_{2\ell} \phi_c^2 e^{2B-1} \right. \\
\left. - \left( B_{1\ell} B_{2\ell} - B_{1\ell} B_{2\ell} \right) \phi_c^2 e^B \right] + \text{TERMS (\(e^{\text{EXP}>0}\))} + \text{FINITE NO. + TERMS (\(e^{\text{EXP}>0}\))} \\
\] (108)

Since, \((B_{1\ell} - B_{1\ell}) > 0, B_{1\ell} B_{1\ell} < 0, \) and the term \(e^{2B-1}\) dominates near the critical point,

\[
\lim_{T \to T_c} \frac{\partial p}{\partial t} \bigg|_{X_{LM}=X_{c,LIM}} = + \infty \\
\] (109)

regardless of what \(X_{c,LIM}\) is.

A brief analysis was made regarding insights into the rectilinear diameter in light of eq. (108). No additional information was found beyond that already reported.

The inequalities of eqs. (42) and (46) were investigated in the limit as \(T \to T_c\).

By use of the derivatives of eqs. (47) and (48) it can be shown that,

\[
\lim_{T \to T_c} \left| \rho \phi_\ell \phi_\ell \right| = \lim_{T \to T_c} \left| \phi_\ell \phi_\ell \right| \\
\] (110)

Equations (82) and (83) for ethylene were used to demonstrate the validity of eq. (42) and eq. (110). The results are given in table 4.

A similar limit analysis for the inequality of eq. (46) was attempted with no conclusive result. However, the computer generated results of table 4 indicate that, not only is eq. (46) valid but also most likely,

\[
\lim_{T \to T_c} \left| - \rho \phi_\ell \phi_\ell \phi_\ell + 2 \phi_\ell \phi_\ell \left( \rho_\ell \phi_\ell - \phi_\ell \phi_\ell \right) \right| = \lim_{T \to T_c} \left| \rho \phi_\ell \phi_\ell \phi_\ell \right| \\
\] (111)

3.4 Maxima and Minima Analysis as $T$ Goes to $T_{TP}$

Figures 3 and 4 indicate that the following limits obtain at the triple point:

$$\lim_{T \to T_{TP}} \frac{\partial \rho_T}{\partial T} \bigg|_{X_{LV} \to 0^+} = 0 \quad (112)$$

$$\lim_{T \to T_{TP}} \frac{\partial \rho_T}{\partial T} \bigg|_{X_{LV} \to 1^-} = - \text{FINITE VALUE} \quad (113)$$

$$\lim_{T \to T_{TP}} \frac{\partial \rho_T}{\partial T} \bigg|_{X_{LM} \to 0^+} \neq 0 \quad \text{or} + \text{FINITE} \quad (114)$$
Hypothesize that eqs. (32) and (112) simultaneously hold at the triple point. Equation (112) implies that \( X_{LM, MAX} + 0 \) and \( \rho_{T, MAX} + \rho_{v, TP} \) as \( T \rightarrow T_{TP} \). The corresponding \( X_{LM, MAX} \) at \( \rho_{T, MAX} = \rho_{v, TP} \) is:

\[
X_{LM, MAX} = \frac{\rho_{v, TP}}{\rho_{v, TP}} \left[ \frac{\rho_{v, TP} - \rho_{v, TP}}{\rho_{v, TP} - \rho_{v, TP}} \right] = 0 .
\]

But eq. (32) says that \( X_{LM, MAX} > X_{LV, c} \) and \( X_{LV, c} \) is usually about .3 or .4 at the triple point (see fig. 1) so our original hypothesis is wrong.

Hypothesize that eqs. (32) and (115) simultaneously hold at the triple point. Equation (115) implies that \( X_{LM, MIN} + 1 \) and \( \rho_{T, MIN} + \rho_{v, TP} \). The corresponding \( X_{LV, MIN} \) at \( \rho_{T, MIN} = \rho_{v, TP} \) is:

\[
X_{LV, MIN} = \frac{\rho_{v, TP} - \rho_{v, TP}}{\rho_{v, TP} - \rho_{v, TP}} = 1
\]

But eq. (32) says that \( X_{LM, c} > X_{LV, MIN} \). While \( X_{LM, c} \) is very close to one, about .998, or so, at the triple point it can never be one because \( \rho_{c} \neq \rho_{v, TP} \) (also see fig. 1). So this hypothesis is also wrong. The conclusion is that eq. (32) does not hold at the triple point.

Equations (112) and (114) would appear to be expressions for \( \rho_{v}' \) at the triple point and eqs. (113) and (115) appear to be values of \( \rho_{v}' \) at the triple point. However, the ambiguity is obvious. Again, as at the critical point, this ambiguity of definition of the derivative may be due to the inapplicability of eqs. (8) and (13) along the saturation lines as has been already mentioned. Thus, the only non-ambiguous limit for \( \rho_{v}' \) and \( \rho_{v}' \) at the triple point can be found along the saturated vapor and saturated liquid lines respectively as \( T \rightarrow T_{TP} \).

In the light of the behavior of the liquid volume and liquid mass fractions, the triple point exhibits singularities of the same sort as the critical point particularly as to ambiguity in the derivatives.

4. CORRELATING COEXISTENCE - CRITICAL POINT DATA USING THE LIQUID VOLUME FRACTION

An earlier paper by this author [6] outlined a method of testing whether or not the saturation density data correlated with published critical point data. The technique is based on fig. 1 and its subsequent analysis. If, as the critical liquid volume fraction
approached $T_c$, it went through a maximum, the $\rho_c$ used was too low, i.e., in reality it was a $\rho_v$. Or, if, as the critical liquid volume fraction approached $T_c$, it increased beyond one-half and kept increasing, the $\rho_c$ used was too high, i.e., in reality it was a $\rho_v$.

In that earlier paper it was assumed that the critical liquid volume fraction is one-half at the critical point. This assumption was based on the work by Sengers, et al. [4]. The macroscopic approaches of this current paper, could only indicate that the fraction concerned is equal to or less than one-half at the critical point. The value one-half is, however, assumed for the work that follows. The one-half is a reasonable answer to the ambiguity at the critical, i.e., the fraction is not zero (a vapor) or one (a liquid). A further aspect of the value one-half is that it implies a first order symmetry ($B_{1L} = -B_{1V}$) at the critical point, i.e., from eq. (63):

$$X_{c,LIM} = -B_{1V}/(B_{1L} - B_{1V}) = 1/2$$ for $B_{1L} = -B_{1V}$

A look at the ratio of the derivatives $\rho^l$ and $\rho^v$ further emphasizes the nature of first order symmetry. From eqs. (47) and (48) and ($\beta_L = \beta_v = \beta$) the following ratio may be calculated:

$$\frac{\rho^l}{\rho^v} = \frac{-B_{1L}e^{-\beta} \dot{e}^{-1} - B_{2L}e^{\psi} \dot{e}^{\psi} \dot{e}^{-1} - B_{3L}e^{\psi} \dot{e}^{\psi} \dot{e}^{-1}}{-B_{1V}e^{-\beta} \dot{e}^{-1} - B_{2V}e^{\psi} \dot{e}^{\psi} \dot{e}^{-1} - B_{3V}e^{\psi} \dot{e}^{\psi} \dot{e}^{-1}}$$

Dividing by $e^{-\beta} \dot{e}^{-1}$, taking the limit $\lim T \to T_c (\dot{e} \to 0)$, the result is

$$\lim_{T \to T_c} \frac{\rho^l}{\rho^v} = \frac{B_{1L}}{B_{1V}}$$

and if ($B_{1L} = -B_{1V}$) (first order symmetry),

$$\lim_{T \to T_c} \frac{\rho^l}{\rho^v} = -1$$

This ratio of minus one also agrees with the idea that at the critical point neither the liquid or vapor is dominant thus carrying out the theme of ambiguity at the critical point. As a further indication that $X_{c,LIM}$ is one-half, the reader may refer to fig. 1 for methane and fig. 10 for oxygen. In both cases the graph indicates that the critical isochore on a $X_L$ vs $T$ plot comes to nearly one-half at the critical point. It is assumed, in the analysis that follows, that $X_{c,LIM}$ is one-half.

The behavioral test for $X_L$ is applied below to argon data published by Gosman, et al. [13]. The results are shown in table 5.

The published $\rho_c$ (13.4123 mol/L) is behaving more like a $\rho_v$ since the $X_{LV,c}$ function turns down before $T_c$ is reached. These same six data points were fit to a functional form of $X_{LV,c}$ by this author. From this fit an estimate of $\rho_c$ can be made. (The details of this procedure are outlined later.)

The result from the unweighted least squares fit at a minimum variance of the data is:

$\rho_c = 13.6138$ mol/L

$\sigma_{\rho_c} = 0.0031$

for an $X_{c,LIM}$ assumed to be one-half.

This "correctly correlated" $\rho_c$ is indeed higher than the published value as the "X" analysis predicts.

A similar analysis was done on more recent data - that of ammonia by Haar, et al. [9]. The results are shown in table 6. The second column of table 6 indicates that the proposed $X_{LV,c}$ goes through a maximum and decreases towards zero. These data (116 - 132°C) were then fit to an $X_{LV,c}$ function with one-half at the critical point (Haar's assumption). The result is:

$\rho_c = .23652$ g/cm$^3$

Again the properly correlated $\rho_c$ is slightly higher than the published value as the analysis would indicate. The results for $X_{LV,c}$ using this new $\rho_c$ are given in column three of Table 6. The values go monotonically towards .5000 which is expected by the earlier analysis in this report. (This type of analysis had been done previously by this author [6] for data published by ASHRAE-American Society of Heating, Refrigeration, and Air Conditioning Engineers, Inc., 1969.)

The foregoing procedure for testing the correlation of saturation/critical data may be useful to those whose task it is to evaluate thermodynamic property data.

Ethylene data are also analyzed. Whereas, for the argon and ammonia, smoothed published data were used, the weighted experimental values of Douslin, et al. [8] are used for ethylene. The intent of the following is to present a method for obtaining a correctly correlated value for $\rho_c$ directly from data. Arguments are presented to indicate the statistical soundness of the approach.

An outline of the procedure (reported in a previous paper [6]), used to fit $X_{LV,c}$ to the data follows.

Substituting eqs. (47) and (48) into eq. (24) for the critical liquid volume fraction, results in a series of terms of $\epsilon$ having exponents (not necessarily integers). For convenience, a truncated form of this series of terms for $X_{LV,c}$ is assumed as follows:
\[ X_{LV,c} = (X_{c,LIM})[1 + b(\varepsilon)^P + c(\varepsilon)^R] \]  \hspace{1cm} (120)  

where:
- \( b, c \) are constants,
- \( P, R \) are exponents (not necessarily integers),
- \( \varepsilon = T - T_c \)

and:
- \( X_{LV,c} + X_{c,LIM} \) as \( \varepsilon \to 0 \).

Combining eqs. (24) and (120) and doing some algebraic manipulation the result (with \( X_{c,LIM} = \) one-half) is:

\[ \rho_v + \rho_\lambda = A + B(\varepsilon)^P(\rho_\lambda - \rho_v) + C(\varepsilon)^R(\rho_\lambda - \rho_v) \]  \hspace{1cm} (121)  

where:
- \( A = 2\rho_c \), \( B, C \) are constants.

The exponents \( P \) and \( R \) are varied until the variance of the data for a least squares fit is minimized. The digital computer utilizes a Gauss Jordon pivoting technique yielding, among other things, the best estimate of \( \rho_c \) (A/2) and its standard deviation.

Whereas eq. (121) looks like the rectilinear diameter, it really is quite different as far as the data used in the fit is concerned. A normal fit of the rectilinear diameter uses only values of \( (\rho_\lambda + \rho_v)/2 \) while eq. (121) also utilizes the difference \( (\rho_\lambda - \rho_v) \) which is inherently quite accurate (see Weber [7] for this opinion). Also eq. (121) is not an extrapolation to the critical point but (from eq. (120)) is a fit constrained to a particular value, \( X_{c,LIM} = \) one-half, at the critical point.

Equation (120) was fit (via eq. (121)) to the fourteen weighted data points presented by Douslin, et al. [8] for ethylene from 238.15 to 282.15 K (\( T_c = 282.35 \) K). The data used are given in table 7 below. In fitting the data, first one exponential term in eq. (121) is utilized, and a minimum variation in the data is found. Then a second term is added in eq. (121) until a lower minimum in the variation of the data is found. Then the "local" area of these exponents is searched by successive approximations to check on a further minimization of the variance. A more sophisticated approach could be utilized in which the computer finds the "best fit" of exponents using a non-linear fit procedure. However, the \( \rho_c \) found is certainly correct in the first four significant figures - well within experimental accuracy. The results given in table 8, later presented, attest to the "goodness" of fit.

The use of only one term resulted in a systematic rather than a random error distribution found when using two exponential terms. The result of the weighted least squares fit is (for \( X_{c,LIM} = \) one-half which Douslin assumes):

\[ \rho_v + \rho_\lambda = A + B(\varepsilon)^P(\rho_\lambda - \rho_v) + C(\varepsilon)^R(\rho_\lambda - \rho_v) \]
\rho_L + \rho_V = 15.258577 + 0.011666548 \varepsilon^{0.528} (\rho_L - \rho_V) + 0.65778747 \times 10^{-3} \varepsilon^{1.088} (\rho_L - \rho_V)

or in \chi_{LV,c} form:

\chi_{LV,c} = (0.5)[1 - 0.011666548 \varepsilon^{0.528} - 0.65778747 \times 10^{-3} \varepsilon^{1.088}]

(123)

and with a \rho_c found to be:

\rho_c = 7.6292884 \text{ mol/dm}^3

\sigma_{\rho_c} = 0.0000270 \text{ mol/dm}^3

</tbody>
</table>

\footnote{This \rho_c is from a straight line extrapolation of the rectilinear diameter.}

If the derivative of eq. (123) is taken as \( T - T_c \), a limit of \( + \infty \) is obtained. This is in accordance with previous findings (see eq. (88)). Further, in reference to eq. (122), if, from scaling laws:

\rho_L - \rho_V \sim \varepsilon^\beta

(124)
the derivative \((p_x' + \rho_v')\) goes to \(-\infty\) which is predicted for \(\phi < 1\) \((.350 + .528 = .878 < 1)\) and \(X_{c,LIM} = \text{one-half}\). This is in accordance with the results previously predicted and listed in table 2.

The critical temperature utilized is Douslin's value of 282.35 K. The \(\rho_c\) value calculated comes out slightly less than the value \((7.635 \text{ mol/dm}^3)\) presented by Douslin. An analysis of \(X_{LV,c}\) versus \(T\) using this value of 7.635, resulted in an \(X_{LV,c} = .5002\) at 282.15 K < \(T_c\). This indicates that a correlated value for \(\rho_c\) must be slightly lower.

The fit of eqs. (122) and (123) to the data is shown in table 8. The percent differences are very small and indicate a random error which is statistically desirable. The results of the weighted least squares fit for ethylene are given below. For,

\[
\rho_v + \rho_x = A + B(\epsilon)^P (\rho_x - \rho_v) + C(\epsilon)^R (\rho_x - \rho_v),
\]

Table 8. \(X_{LV,c}\) and \((\rho_x' + \rho_v')\) Comparison for Ethylene

\(^4\text{Density units is mol/dm}^3\).
A = \(0.15258577 \times 10^{42} = 2p_\text{c}\); Var(A) = \(0.29216971 \times 10^{-8}\)

B = \(0.11666548 \times 10^{-1}\); Var(B) = \(0.82952522 \times 10^{-11}\)

C = \(0.65778747 \times 10^{-3}\); Var(C) = \(0.10371048 \times 10^{-12}\)

\(\text{Cov}(A,B) = -0.13428749 \times 10^{-9}\)

\(\text{Cov}(A,C) = +0.13600825 \times 10^{-10}\)

\(\text{Cov}(B,C) = -0.91386470 \times 10^{-12}\)

Correlation Coefficient (A,B) = -0.86258752

Correlation Coefficient (A,C) = 0.78133331

Correlation Coefficient (B,C) = -0.98527119

An analysis of each coefficient with its variance indicates that the value zero does not lie within a 3σ confidence limit; hence, each coefficient is statistically significant. It is also desirable that the value (A = 2p_\text{c}) be quite insensitive to the values of the coefficients B and C. Indeed, the correlation coefficients indicate that A does not correlate highly (statistically speaking) with B or C. The coefficients B and C are more highly correlated with each other. This is to be expected since they are each involved in similar type terms in eq. (121).

Another consideration is the sensitivity of p_\text{c} to changes in the exponents P and R. To analyze this, each exponent was held at its value found for the best fit while the other was varied until p_\text{c} could no longer be reproduced as 7.629 mol/dm\(^3\) within four significant figures. The results are shown below:

\[
\begin{align*}
R = 1.079, & \quad p_\text{c} = 7.62947 \text{ (mol/dm}^3) \\
P = 0.528 & , \quad p_\text{c} = 7.62929 \text{ (Best Fit)} \\
R = 1.088, & \quad p_\text{c} = 7.62685 \\
R = 1.126, & \quad p_\text{c} = 7.62949 \\
P = 0.5306, & \quad p_\text{c} = 7.62929 \text{ (Best Fit)} \\
P = 0.5184, & \quad p_\text{c} = 7.6285
\end{align*}
\]

The results indicate that p_\text{c} is relatively insensitive to the exponents P and R, i.e., the critical density is not highly dependent on the functional form - a desirable result.

The fit, if statistically sound, should result in a randomly distributed error or percent error. Data given in table 8 indicate a random error. Also, fig. 12 gives error data in a deviation plot for eq. (122). The figure indicates a relatively random error.

Also, the question arises concerning the sensitivity of the critical density to changes in the critical temperature. Moldover [5] and Sengers [14] report values of T_\text{c}
Figure 12. Percent Deviation Plot of $p_x + p_y$ for Ethylene.
for ethylene differing slightly from Douslin's value of 282.35 K. Each of these temperatures was utilized in the $X_{LV,c}$ fit with no change in the critical density to four significant figures. These results are summarized in table 9 below.

Table 9. Critical Properties of Ethylene

<table>

</tr>
</tbody>
</table>

Having found $\rho_c$ from the data and $X_{LV,c}$ correlation it is possible to obtain an equation for $\rho_k$ of the form:

$$\rho_k = \rho_c + B_{1k} \epsilon^\beta + B_{2k} \epsilon^\phi + B_{3k} \epsilon^\psi$$

where, following Douslin, et al. [8]:

$$\beta = .350$$ (found from a graph of $(\rho_k - \rho_v)$ vs $\epsilon$)

$$\phi = \beta + 1/\epsilon$$

$$\psi = \beta + 2/\epsilon$$

The equation resulting from a weighted least squares fit for $\rho_k - \rho_c$ is:

$$\rho_k = 7.6292884 + 1.9752911 \epsilon^{.350} + .025699752 \epsilon^{.986} - .23107950 \times 10^{-3} \epsilon^{1.622}$$

compared to Douslin's equation repeated below.

$$\rho_k = 7.635 + 1.9695 \epsilon^{.350} + .02669 \epsilon^{.984} - .2731 \times 10^{-3} \epsilon^{1.618}$$

The fit of eq. (125) compared to eq. (82) is slightly better for one-half of the fourteen data points and slightly worse for the other half. The results are shown in table 10.

The next problem is to obtain values of $\rho_v$. Two approaches were utilized. The first approach was to combine eqs. (123) for $X_{LV,c}$ and (125) for $\rho_k$ and solve for $\rho_v$, i.e.,

$$\rho_{v,calc} = (\rho_c - X_{LV,c}\rho_k)/(1 - X_{LV,c})$$

The results for this calculation are shown in table 11. The overall fit is slightly better than that for Douslin's fit given in eq. (83).

</table>
The other approach is to utilize the $\rho_c$ found from $X_{LV,c}$, assume first order symmetry, and assume the exponents in the equation are the same as for $\rho_2$ in eq. (125), and fit:

$$\rho_v - 7.6292884 + 1.9752911 e^{3.50} = B_{2v} e^{0.986} + B_{3v} e^{1.622}$$

(127)

The results are not as good as those obtained using eq. (126). The differences between $\rho_v, DATA$ and $\rho_v, CALC$ are about one order of magnitude higher than those in table 11. This is not satisfactory. The equation obtained was:

$$\rho_v = 7.6292884 - 1.9752911 e^{3.50} + 0.16287155 \times 10^{-1} e^{0.986}$$

$$+ 0.50890319 \times 10^{-3} e^{1.622}$$

(128)

Equations (125) for $\rho_2$ and (128) for $\rho_v$ meet the criteria of eqs. (87) and (106).

The following procedure is suggested for obtaining the critical temperature, density, and smooth saturation density values from experimental saturation data.

Step One: Plot $\rho_2 - \rho_v$ vs $\epsilon$ on log-log paper to obtain a value for $\beta$. Use in addition, a computer analysis of this plot to obtain a best value of $T_c$. For this procedure see Weber [7]. This utilizes the well known scaling law:

$$\rho_2 - \rho_v \sim \epsilon^\beta.$$  

(124)

Step Two: Utilize this $T_c$ in a fit of the data to $X_{LV,c}$ finding the best value of $\rho_c$.

Step Three: Utilize the $\rho_c$, $T_c$, and $\beta$ to fit the $\rho_2$ data to an equation.

Step Four: Utilize the $X_{LV,c}$ and $\rho_2$ equations to generate smooth data for the saturation densities both $\rho_2$ and $\rho_v$.

This procedure allows a rational integration of the critical and saturation properties. The $X_{LV,c}$ function is the integration tool.

One of the major problems left in coexistence data work is to obtain equations which will fit the entire range from the triple to the critical point. The "dome" equations which are used here are not thought to be valid over this entire range. However, the relative flatness of the $X_{LV,c}$ curves over this entire temperature range (see fig. 1) may be helpful in solving this problem.

Now, $\rho_2$ from eq. (125) and $\rho_v$ from eq. (126) can be utilized in a final statistical analysis of the original fit of eq. (121). This test is to look at the shape and magnitude of the 3σ confidence band over the temperature range of interest. The standard deviation with temperature of the fit can be found from the square root of the variation of $(\rho_2 + \rho_v)$. This variance, from well known statistical considerations, is:
\[
\text{Var}(\rho_L+\rho_V) = \frac{\partial(\rho_L+\rho_V)}{\partial A} \text{Var}(A) + \frac{\partial(\rho_L+\rho_V)}{\partial B} \text{Cov}(A,B) + \frac{\partial(\rho_L+\rho_V)}{\partial C} \text{Cov}(A,C) + \frac{\partial(\rho_L+\rho_V)}{\partial B} \text{Var}(B) + \frac{\partial(\rho_L+\rho_V)}{\partial C} \text{Cov}(B,C) + \frac{\partial(\rho_L+\rho_V)}{\partial C} \text{Cov}(B,C) + \frac{\partial(\rho_L+\rho_V)}{\partial C} \text{Var}(C)
\]

where from eq. (121):
\[
\frac{\partial(\rho_L+\rho_V)}{\partial A} = 1,
\]
\[
\frac{\partial(\rho_L+\rho_V)}{\partial B} = e^p (\rho_L - \rho_V),
\]
\[
\frac{\partial(\rho_L+\rho_V)}{\partial C} = e^R (\rho_L - \rho_V),
\]

obtaining \( \rho_L \) and \( \rho_V \) from eqs. (125) and (126) respectively. The variances and covariances are those previously given. The standard deviation of \((\rho_L+\rho_V)\) at each temperature is multiplied by three and the result is plotted to show the 3\( \sigma \) confidence limit band. The results are shown in fig. 13.

The behavior of the band deviates from the so-called classical form in the temperature range from about 238 - 250 K. The classical form is found from the latter temperature to the critical. The graph indicates that \( \rho_c \) is found to four significant figures at a high degree of confidence, i.e.,
\[
7.62921 \leq \rho_c \leq 7.62937 \text{ (mol/dm}^3)\)

within a 3\( \sigma \) confidence band.

Finally an analysis of the effect of the data weights on the \( \rho_c \) value was made. The unweighted fit of \( X_{LV,c} \) resulted in a value of \( \rho_c = 7.629 \text{ (mol/dm}^3) \) to four significant figures with a slightly higher variance of the data. All in all, the value of \( \rho_c \) found by the fit of \( X_{LV,c} \) to the saturation data, results in a statistically reliable number. The foregoing analysis supports the use of the \( X_{LV,c} \) method to obtain a correlated \( \rho_c \) from saturation data.
Figure 13. 3σ Confidence Limit Band on $\rho_0 + \rho_v$ of Ethylene.
5. EXPERIMENTAL APPROACH TO SIMULTANEOUS DETERMINATION OF COEXISTENCE DATA
This section presents a method for obtaining saturation density data simultaneously. Current experimental approaches obtain \( \rho_L \) and \( \rho_V \) in separate experiments. Usually the \( \rho_L \) is obtained directly while the \( \rho_V \) is found from the intersection of isochores with the vapor pressure curve. See Kleinrahm, et al. [15] for a review of these techniques.

The method proposed here is based on the straight line plots found in fig. 5. Theoretically, all one needs to know is two pairs of liquid volume fraction - total density data at the same temperature to establish a line. Simple extrapolation to \( X_{LV} = 1 \) for \( \rho_L \) and to \( X_{LV} = 0 \) for \( \rho_V \) produces the saturation values from the same set of data. This should enhance internal consistency.

Currently, in many cases, the coexistence data takes a secondary role in property fitting to equations of state. For example, the procedure used by Haar, et al. [9] for ammonia is to obtain the saturation data from a surface described by an equation of state explicit in Helmholtz free energy. The coexistence data (mainly those of Cragoe, et al. [10,11] were used only to obtain estimates of the critical properties. Perhaps a more internally consistent set of \( \rho_V, \rho_L \) data can provide the foundation for an equation of state.

To test the validity of using data such as that illustrated in fig. 5, liquid volume fraction data is needed. Unfortunately, the thermodynamic property literature yields very little total density-liquid volume fraction information. However, Cragoe, et al. [10,11] in obtaining \( \rho_L \) and \( \rho_V \) for ammonia did measure and publish such data. They did not use them, however, in the manner suggested here. To test this idea, one needs saturated liquid and vapor density values data at the same temperature. Unfortunately, this occurs at only one point in all the data taken by Cragoe and his co-workers. In their report on the liquid densities [10] at \( T = -46.43^\circ C \) the values are:

\[
\begin{align*}
\rho_T &= .5370715 \, \text{g/cm}^3, \quad \text{and} \\
X_{LV} &= .7695038
\end{align*}
\]

and in the vapor density report [11] at \( T = -46.42^\circ C \) the values of

\[
\begin{align*}
\rho_T &= .0037965898 \, \text{g/cm}^3, \quad \text{and} \\
X_{LV} &= .0047679271
\end{align*}
\]

are given. These two points determine a straight line. Then \( X_{LV} = 0 \) is substituted to obtain \( \rho_V \), and \( X_{LV} = 1 \) is substituted to obtain \( \rho_L \). See fig. 14 for a sketch of the data and procedure. (Because of the relative sizes of the numbers, they are not plotted precisely on the linear scales.)

Table 12 gives some comparisons related to the data in fig. 14. The first column gives the results from the straight line. The second column gives the experimental values of Cragoe, et al. [10,11] while the third column gives the values of Haar, et al. [9] linearly interpolated to \(-46.42^\circ C\).

</table>

Another approach which could be taken would be to utilize accurate $\rho_x$ data ($X_{LV} = 1$) along with ($X_{LV} < 1, \rho_T$) data and obtain a straight line. This line could be extrapolated to $X_{LV} = 0$ to obtain a value for $\rho_v$. This was done utilizing data presented by Cragoe, et al. [10] in their report on liquid densities only.

The results are presented in table 13. Data is taken from Haar, et al. [9] at the nearest even temperature for comparison. A $\rho_{v,CALC}$ is found at the same temperature from the equations presented in Cragoe, et al. [11] when dealing only with $\rho_v$. The values for $\rho_v$ in table 13 not only reflect the range of error involved in $\rho_v$ determination but also the wide disagreement as to what the $\rho_v$ actually are. The straight line values for $\rho_v$ are at least correlated with the experimental $\rho_x$ values.

If the $\rho_v$ is specified along with a point ($X_{LV} < 1, \rho_T$), $\rho_x$ can be determined from the straight line at $X_{LV} = 1$. Here the results are even more surprising. For very small $X_{LV}$ ($\sim 0.005$) there is good agreement in the $\rho_x$ values at $X_{LV} = 1$. See table 14.

The results shown in tables 12, 13, 14, may motivate experimentalists to obtain coexistence data from $(\rho_T, X_{LV})$ plots. Cragoe, although he did not use the above method, did measure liquid volume fractions using sight lines determined by careful volumetric calibration. (In evaluating the coexistence data of ammonia, Haar, et al. [9] concludes that the data of Cragoe, et al. [10,11] is the best-indicating that accurate measurements can be made of the liquid volume fraction.)
An even earlier effort than Cragoe's to determine saturation densities by measuring liquid volumes is that of Young [16]. He utilized pairs of measured liquid volumes and total mass values in calculations based on mass balances. The approach is similar in concept to the ideas expressed in figs. 5 and 14 of this paper. He did not utilize, however, the reduced variable form, i.e., liquid volume fraction vs. total density nor did he explore the implication of these as thermodynamic functions as is done in this report.

An examination of fig. 5, indicates that these lines should be significantly different (statistically speaking) over a small range of temperature just below the critical. This is in contrast to the (P vs T) isochores near the critical point which are extrapolated to the vapor pressure to find \( \rho_\text{v} \). When utilizing the \( X_{LV} \) vs \( \rho_\text{T} \) plots to obtain coexistence data it appears that the large changes in \( \rho_\text{k} \) and \( \rho_\text{v} \) near the critical point may actually be helpful, whereas up to this time these changes were a problem.

The goal then is to obtain a good measurement of the liquid level. Aside from the visual method utilized by Cragoe, newer techniques such as time-domain reflectometry [17] or fiber optics [18] should be investigated.

6. SUMMARY

An analysis of the liquid volume and liquid mass fractions has been made over the temperature range from the triple point to the critical point. Limits of the functions and derivatives have been studied both at the triple and critical points. Also the slope of the rectilinear diameter at the critical was studied in some detail. Conclusions were made about the constants and exponents in the \( \rho_\text{k} \) and \( \rho_\text{v} \) coexistence dome equations. A procedure for correlating saturation data with the critical point has been presented using ethylene as an example. Finally, an experimental approach for obtaining \( \rho_\text{k} \) and \( \rho_\text{v} \) simultaneously is presented.

7. ACKNOWLEDGMENTS

I wish to thank the staff of the Thermophysical Properties Division of the National Bureau of Standards, Boulder, Colorado for making office, digital computer, and data resources available during my tenure as a guest worker. Thanks also to those staff members who took the time for stimulating discussions, especially Robert McCarty regarding the statistical analysis of the \( X_{LV,c} \) fit. Salary support was provided by Calvin College, Grand Rapids, Michigan during my Sabbatical leave.

An analysis of the behavior of liquid volume and liquid mass fractions at coexistence for pure fluids is made. Scaled equations for the saturation liquid and vapor densities are analyzed and relationships between various exponents and among constant coefficients are presented. Inequalities which exist among the saturation densities and their derivatives are developed. A procedure to correlate saturation data with the critical point is applied to ethylene. An experimental procedure to determine, simultaneously, saturated liquid and vapor densities at a given temperature is presented.

Coexistence densities; critical density; critical point; liquid mass fraction; liquid volume fraction; phase equilibria; pure fluids.
