ABSTRACT

In order to reduce the lengthy computational labor and costs common to most existing hourly simulation computer programs, a simplified energy calculation procedure suitable for a handheld calculator was developed for the evaluation of home retrofitting with respect to energy conservation. The procedure utilizes monthly normal weather parameters such as temperature, humidity, wind data, and solar radiation, in lieu of the traditional degree-day procedure.

The thermal time constant was used to account for the effect of building thermal mass on seasonal heat transfer performance. In addition to standard retrofit procedures such as addition of thermal insulation, use of storm windows, and sealing of cracks, this calculation includes energy conservation effect due to the use of solar collectors, hot water tank insulation, and insulation around the heat distribution systems such as ducts and pipes.

Also included are comparative annual heating and cooling requirements determined by the simplified procedure and that calculated by the DOE-2 computer program for a typical residence.

Keywords: Energy analysis calculation; energy retrofit; home audit; thermal time constant.

TABLE OF CONTENTS

1. INTRODUCTION

The purpose of this report is to describe detailed algorithm, data base and Fortran listing of a simplified home energy analysis procedure suitable for small computer or pocket calculator. This simplified procedure was originally developed for DOE to assist the state and local government energy officials who are making economic benefit analyses of various home improvement options, such as insulation, storm windows, hot water tank insulation, insulation around pipes and ducts, etc.

The procedure calculates the annual energy requirement calculations for heating and cooling of single-family residences in conjunction with the Department of Energy Project Home Energy Audit questionnaire and economic analysis. Since the Project Home Energy Audit Program mandated that the computation time, equivalent to the UNIVAC 1100 CPU (Central Processing Unit) time, is to be within 3 seconds, it precluded the comprehensive hourly simulation procedures such as used in BLAST, DOE-2, and NBSLD.

A scheme adopted in the DoE Home Energy Audit calculation procedure is to develop a simplified yet relatively comprehensive heating and cooling load calculation routine where most of the major building heat transfer elements are addressed in an approximate manner. The results of the calculation obtained by this simplified routine are then compared against those obtained from a DOE-2,[2/] the comprehensive hourly simulation computer program designated as the Standard Evaluation Technique for Building Energy Performance Standards, for a ranch house.

2. OVERALL ALGORITHMIC STRUCTURE

The flow chart for the simplified procedure is shown in Figure 1, and detailed algorithms, including Fortran listing, for each of the subroutines are given in the following sections.

The basic scheme of the calculation is to detemine monthly normal values of daytime and nighttime heat gains (heat loss will be considered a negative heat gain) separately for all of the major heat exchange components, and to integrate them into monthly normal daytime and nighttime heating and cooling requirements.

In Figure 1, all of the major heat gain (loss) through various elements of building envelope is denoted with symbols ending with D and N, indicating daytime heat gain and nighttime heat gain, respectively.

Although not described in detail in this report, a special subroutine, SOLDAT, was developed to generate daily total solar radiation data for the normal day for each of 12 months for any given orientation and tilt angle of the wall in a given locality, while a separate routine called SAT determines the normal daily average sol-air temperature to be applicable for the calculation of heat gain through walls, roofs, and doors. Detailed documentation for SOLDAT can be found in reference 2.

NBS HOME ENERGY AUDIT CALCULATION

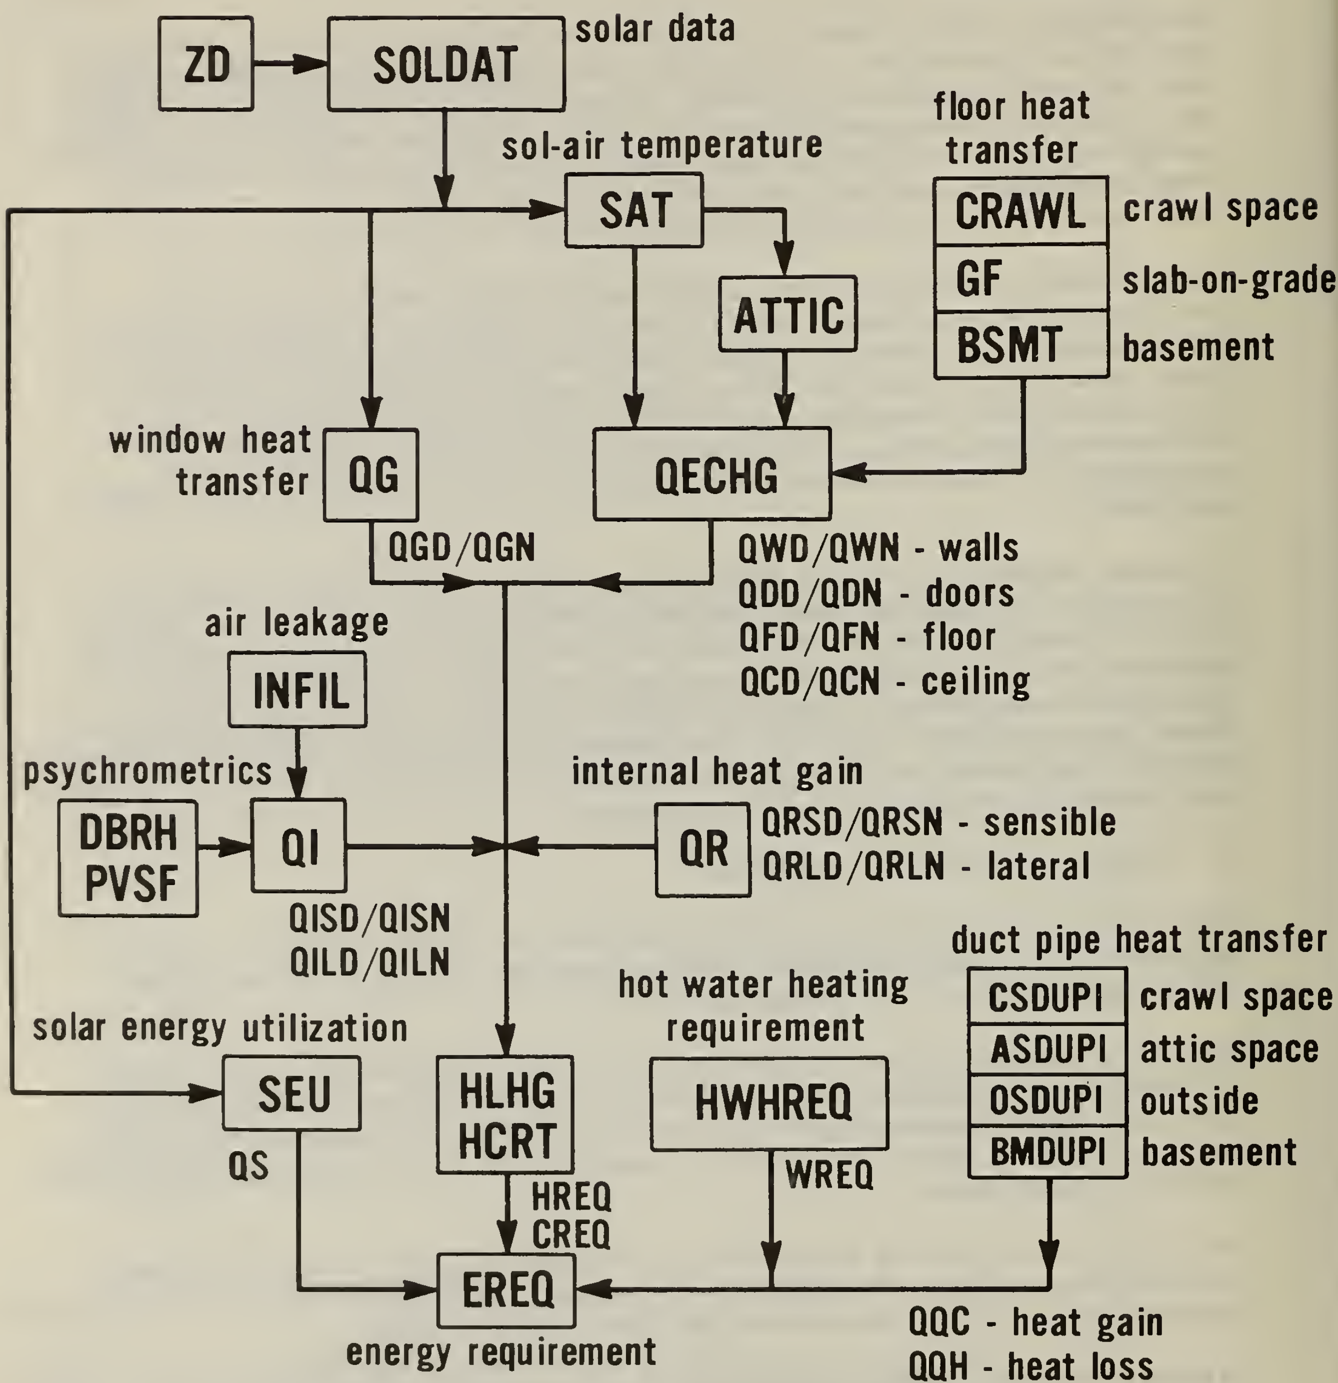

Figure 1. Flow chart of the Heating and Cooling Load Program

Where the roof has ventilated attic space, the program determines the attic space temperature based upon heat balance, which is in turn used to determine the heat gain through the ceiling.

The SOLDAT routine will also provide the solar radiation data for the solar collectors, which may be available in some of the energy conservation designs. The solar collector performance will be simulated by a simplified linear relationship between the collector efficiency and $\Delta T/I$, where ΔT represents the average temperature difference between the outdoor air and collector inlet fluid temperatures, while I represents the daily average of hourly solar insolation.

Heat gain from the floors is determined by the use of special algorithms to simulate the heat transfer process of basement, slab-on-grade, and crawl space under the floor, respectively.

In addition, there are several other subroutines in the calculation, such as INFIL to determine the air leakage rate, DBRH to determine the moist air properties, and subroutines to determine the energy loss from hot water tanks, ducts and pipes.

The major distinction of the present method from the existing degree-day or bin procedures is that the new method is based upon the monthly normal day data for each of the 12 months of the year. The monthly normal data needed are:

daytime average temperature
nighttime average temperature
total solar radiation upon horizontal surface
average relative humidity (morning and afternoon)
average wind speed
ground temperature

for the normal days of the month.

Fortunately, these data are available in the existing literature for most of the major Weather Bureau stations throughout the United States. The Liu and Jordan paper, entitled, "Availability of Solar Energy for Flat-Plate Solar Collectors," ASHRAE Symposium on Low Temperature Engineering Applications of Solar Energy, 1967, provides the average daytime temperature and the solar radiation data for more than 80 stations in the United States (see Appendix A). A U.S. Weather Bureau publication called "Comparative Climatic Data Through 1976"* provides the long-period (30 years or more) normals and extremes of monthly average temperature, precipitation, relative humidity, and wind data.

Ground temperature data, previously developed by Kusuda and Achenbach, shown in Appendix B, are also employed for the heat transfer calculation for slab-on-grade floor, basement walls and basement floor.

---

* For sale by the National Climatic Center, Federal Bldg., Asheville, N.C., 28801 (Tel. 704-258-2850, X 683). $1.50 copy.

3. THERMAL TIME CONSTANT, THTC

Although the calculation methodology used in this procedure basically treats the building heat transfer process as a steady state problem, the thermal time constant concept is used to determine the heat capacity effect upon the transient temperature change after the heating and cooling system is shut off as well as upon the early morning hour pickup load when the system is started. Details of the thermal time constant concept are explained in Appendix E.

4. ENVELOPE DATA

Figure 2 indicates various types of physical characteristics needed to describe the thermal performance of various components of envelopes, most of which are commonly found in standard engineering building handbooks such as the ASHRAE Handbook of Fundamentals.

4.1. TYPE DESIGNATION

Envelope components, including the solar collector, are classified in eleven distinctive types such as follows:

Type No.

1. roof = total roof area less solar collector and skylight
2. ceiling
3. end walls or gable walls of attic space
4. vertical walls, which are vertical envelopes less window and door area
5. windows
6. doors
7. slab-on-grade floor
8. basement-type floor
9. floor over crawl space
10. basement wall
11. solar collector.

4.2. AREA, A

Each envelope component must be assigned an appropriate area. Futhermore, this must be done separately for each wall orientation (see section 4.7) The orientation effects on gable-end walls and basement walls are ignored, and only the total area is to be considered. If a door is made of transparent material, it should be considered as a window.

4.3. OVERALL HEAT TRANSFER COEFFICIENT U

Overall heat transfer coefficients are to be provided as input for each envelope component. They are standard winter design values which can be found in the ASHRAE Handbook of Fundementals. In the case of solar collectors no heat transfer coefficient U is needed since it is included in the basic efficiency curve data.

OPERATION CONSERVE INPUT DATA

BUILDING NAME ______________________

TYPE ______________________

LOCATION, LATITUDE, ZIPCODE ZONE ______________________

Climatic Data (Monthly)
TOT: Daily average temp
TOD: Daytime average temp
RH: Relative humidity
WS: Wind speed
H: Daily total horizontal solar insolation
ZT: Liu/Jordan Factor
RHO: Ground surface reflectance

Standard Air Leakage Data
ACHS: Room air change/hr
ACAT: Attic space air change/hr
ACCS: Crawl space air change/hr
ACNV: Natural ventilation air change/hr

Building Mass Data
THTC: Thermal Time Constant

Envelope Data		I Type	A Area	U	AB Solar Abs	SHDW Shadow Factor	SC Shading Coeff	WAZ Orien-tation	WTLT Tilt Angle	Perimeter Length
Roof		1							0

EB: Boiler efficiency
COP: Air conditioner COP
SA,SB: Solar collector efficiency factors

Indoor Data - Seasonal (Winter/Summer)
NP: Number of occupants
WT: Lighting power, Watt

WE: Equipment power, Watt
TID: Daytime thermostat setting
TIN: Nighttime thermostat setting
RHIN: Indoor humidity level

Figure 2. Data needed for the Heating and Cooling Load Calculations

4.4. SOLAR ABSORPTIVITY, ABS

These data are used to determine the outside surface temperature of exterior walls as influenced by the solar radiation data. Typical values are:

for very dark surface	0.95
medium dark surface	0.7
light surface	0.4

4.5. SHADOW FACTORS,SHDW

This factor indicates how much of the exterior surface is shaded from direct sun by adjacent buildings, exterior shading devices, or by trees. Typical figures are:

if completely shaded	1.0
if partially shaded	0.5
if not shaded at all	0.

4.6. SHADING COEFFICIENT, SC

This factor relates to the internal shading devices used for the windows. Typical values for a single glaze window are:

for venetian blinds	0.5
roller shades	0.4
tinted films	0.3.

4.7. WALL ORIENTATION, WAZ

These data indicate the orientation of walls and windows, measured clockwise from the south. Thus, for example,

WAZ = 0 for south-facing wall/window/door
WAZ = 90 for west
WAZ = 180 for north
WAZ = 270 for east.

4.8. WALL TILT ANGLE, WTLT

These data are for the slant angle of the walls or windows. For most construction, the value is 90° for walls and windows and 0° for roofs. For solar collectors, the actual tilt angle will be used and will usually be an angle other than 0° or 90°.

5. SUBROUTINE ALGORITHMS

5.1. SOLDAT

Using the Liu/Jordan method [2/], this program generates 12 monthly values of total solar radiation over the roofs, floors, walls, windows, and solar collectors. The details of the calculation procedure are given in NBS Building Sciences Series 96 entitled "Hourly Solar Radiation Data for Vertical and Horizontal Surfaces on Average Days in the United States and Canada." This routine also includes the shadow effect of the roof overhang upon the direct radiation incident on a given vertical surface.

Input:
- XLAT = latitude, degree
- WAZ = wall azimuth angle, degrees from south
- WTLT = wall tilt angle, degree from horizontal surface
- ZKT = Liu/Jordan constants
- H = daily normal solar radiation over a horizontal surface Btu/ft^2 [1]
- RHO = ground reflectance
- TOWN = zip code
- OVHANG = roof overhang, ft
- WALLHT = wall height, ft

Output:
- XIDT = daily total solar radiation, Btu/hr ft^2
- XIDD = daily total diffuse sky radiation, Btu/hr ft^2
- HRDAY = daytime hours, hr
- HRNIT = nighttime hours, hr

5.2. SAT

Sol-air temperature routine

Input:
- WTLT = tilt angle, degrees from horizontal surface
- It = incident total solar insolation, Btu/day ft^2
- Id = incident sky radiation, Btu/day ft^2
- SHDW = shadow factor
  - 0 = no shadow
  - 0.5 = partial shadow
  - 1.0 = complete show
- AB = surface absorptivity
- FO = surface heat transfer coefficient, Btu/h ft^2 °F
  - = 4 for J,J,A
  - = 5 for M,A,M,S,O,N
  - = 6 for D,J,F
- TOD = daytime temperature, °F
- TON = nighttime temperature, °F
- HRDAY = daytime hours, hr

Total radiation incident upon a surface

I = (It-Id) * (1-SHDW) + Id

Output: Sol-air temperature

$$\text{Daytime} \quad SATD = TOD + \frac{AB*I}{HRDAY*FO} - \frac{10^{*/}}{FO} * \cos(WTLT)$$

$$\text{Nighttime} \quad SATN = TON - \frac{10^{*/}}{FO} * \cos (WTLT)$$

5.3. INFIL

Infiltration calculation, cfm

Input:
- V = volume of the room, ft^3
- ACHS = standard air change data, air change/hr
- TO = outdoor temperature, °F = (TOD + TON)/2
- TI = indoor temperture, °F = (TID + TIN)/2
- WS = wind speed, mph

AC (air leakage rate) = (ACHS/0.695)* [0.15 + 0.013 * WS + 0.005 * ABS (TO-TI)]±/

Standard Air Leakage Data (ACHS)

In lieu of the crack method, hourly air-change values are to be provided because there are more experimentally measured data reported by the use of He and SF_6 tracer gas dilution technique. Recommended values are as follows:

Living space: 1.5 for leaky building
1.0 for standard building
0.5 for modern-type building

Attic space: mechanical ventilation 20 Ac/hr
natural ventilation 6 Ac/hr

Crawl space: 3 Ac/hr

Output: Air leakage rate

$$RINFIL= (V) * \frac{AC}{60} \quad , ft^3/m \text{ (cfm)}$$

---

*/ Assumed average sky heat loss: 10 Btu/hr, ft^2.

±/ Modified Achenbach/Coblenz equation.
"Field Measurements of Air Infiltration in Ten Electrically Heated Houses" ASHRAE Trans. 69, 1963, pp. 358-365.
DoE - 2 program uses, however, different equations such as
AC = 0.252 + 0.0218 * WS + 0.0084 * ABS (TO-TS)

5.4. ATTIC

Attic temperature calculation

Input:

AR = roof area, ft^2
TRD = daytime roof sol-air temperature, °F
TRN = nighttime roof sol-air temperature, °F
AC = ceiling area, ft^2
TAD = daytime room temperature, °F
TAN = nighttime room temperture, °F
AW = end wall area, ft^2
TWD = daytime end wall sol-air temperature, °F (average of two end walls)
TWN = nighttime end wall sol-air temperature, °F
CFM = air flow, ft^3/min
UR, UC, UW = U-value for roof, ceiling and end walls, Btu/h ft^2 °F
TOD = daytime outdoor air temperature, °F
TON = nighttime outdoor air temperature, °F

Output: Attic temperature (daytime and nighttime)

$$ATTICD = \frac{UR*AR*TRD + UW*AW*TWD + UC*AC*TAD + 1.08*CFM*TOD}{UR*AR + UW*AW + UC*AC + 1.08*CFM}$$

$$ATTICN = \frac{UR*AR*TRN + UW*AW*TWN + UC*AC*TAN + 1.08*CFM*TON}{UR*AR + UW*AW + UC*AC + 1.08*CFM}$$

ATTICD = TID
ATTICN = TIN
if attic temperature is controlled

5.5. CRAWL

Crawl space temperature routine

Input: Daytime and nighttime crawl space temperatures

TOD = daytime outdoor temperature, °F
TON = nighttime outdoor temperature, °F
TG = ground temperature, °F
TAD = daytime room temperature, °F
TAN = nighttime room temperature, °F
TWD = daytime wall sol-air temperature, °F
TWN = nighttime wall sol-air temperature, °F
CFM = air flow rate, ft^3/min
UF = floor heat transfer coefficient, Btu/h ft^2 °F
UW = wall heat transfer coefficient,Btu/hr ft^2 °F
UG = ground surface heat transfer coefficient = 0.1, Btu/h ft^2 °F

AW = crawl space wall area, ft^2
AF = floor area, ft^2

Output:

$$CRAWLN = \frac{UF*TAD*AF + UW*TWD*AW + UG*(TG + TOD)*AF/2 + 1.08*CFM*TOD}{UF*AF + UW*AW + UG*AF + 1.08*CFM}$$

$$CRAWLN = \frac{UF*TAN*AF + UW*TWN*AW + UG*(TG + TON)*AF/2 + 1.08*CFM*TON}{UF*AF + UW*AW + UG*AF + 1.08*CFM}$$

5.6. GF

Ground floor heat transfer routine (slab-on-grade floor)

Input:

AF = floor area, ft^2
P = exposed perimeter length, ft
WT = wall thickness, ft
TAD = daytime room temperature, °F
TAN = nighttime room temperature, °F
TOD = daytime outdoor temperature, °F
TON = nighttime outdoor temperature, °F
R = Thermal resistance of hour layers, which is between the room air and the floor slab-ground interface,
ZK = Ground thermal conductivity Btu-in/h ft^2 °F

Calculation Procedure

The slab-on-grade heat transfer calculation presented herein is based upon an exact solution of Muncey and Spencer[3/].

The Base Ground Thermal Resistance RS shown in Fig. 3 was precalculated for a square slab of 40 ft x 40 ft over a ground of thermal conductivity 12 Btu-in/h ft^2 °F.

In order to correct the value of RS for the specific slab under consideration, which would be different from the basic structure, the three correction factors α, β and FS are needed.

The Perimeter length correction factor

$$\alpha = P/160$$

The Conductivity correction factor

$$\beta = ZK/12$$

The slab shape correction factor FS can be determined from Fig. 4 by knowing $AF/\left(\frac{P}{4}\right)^2$

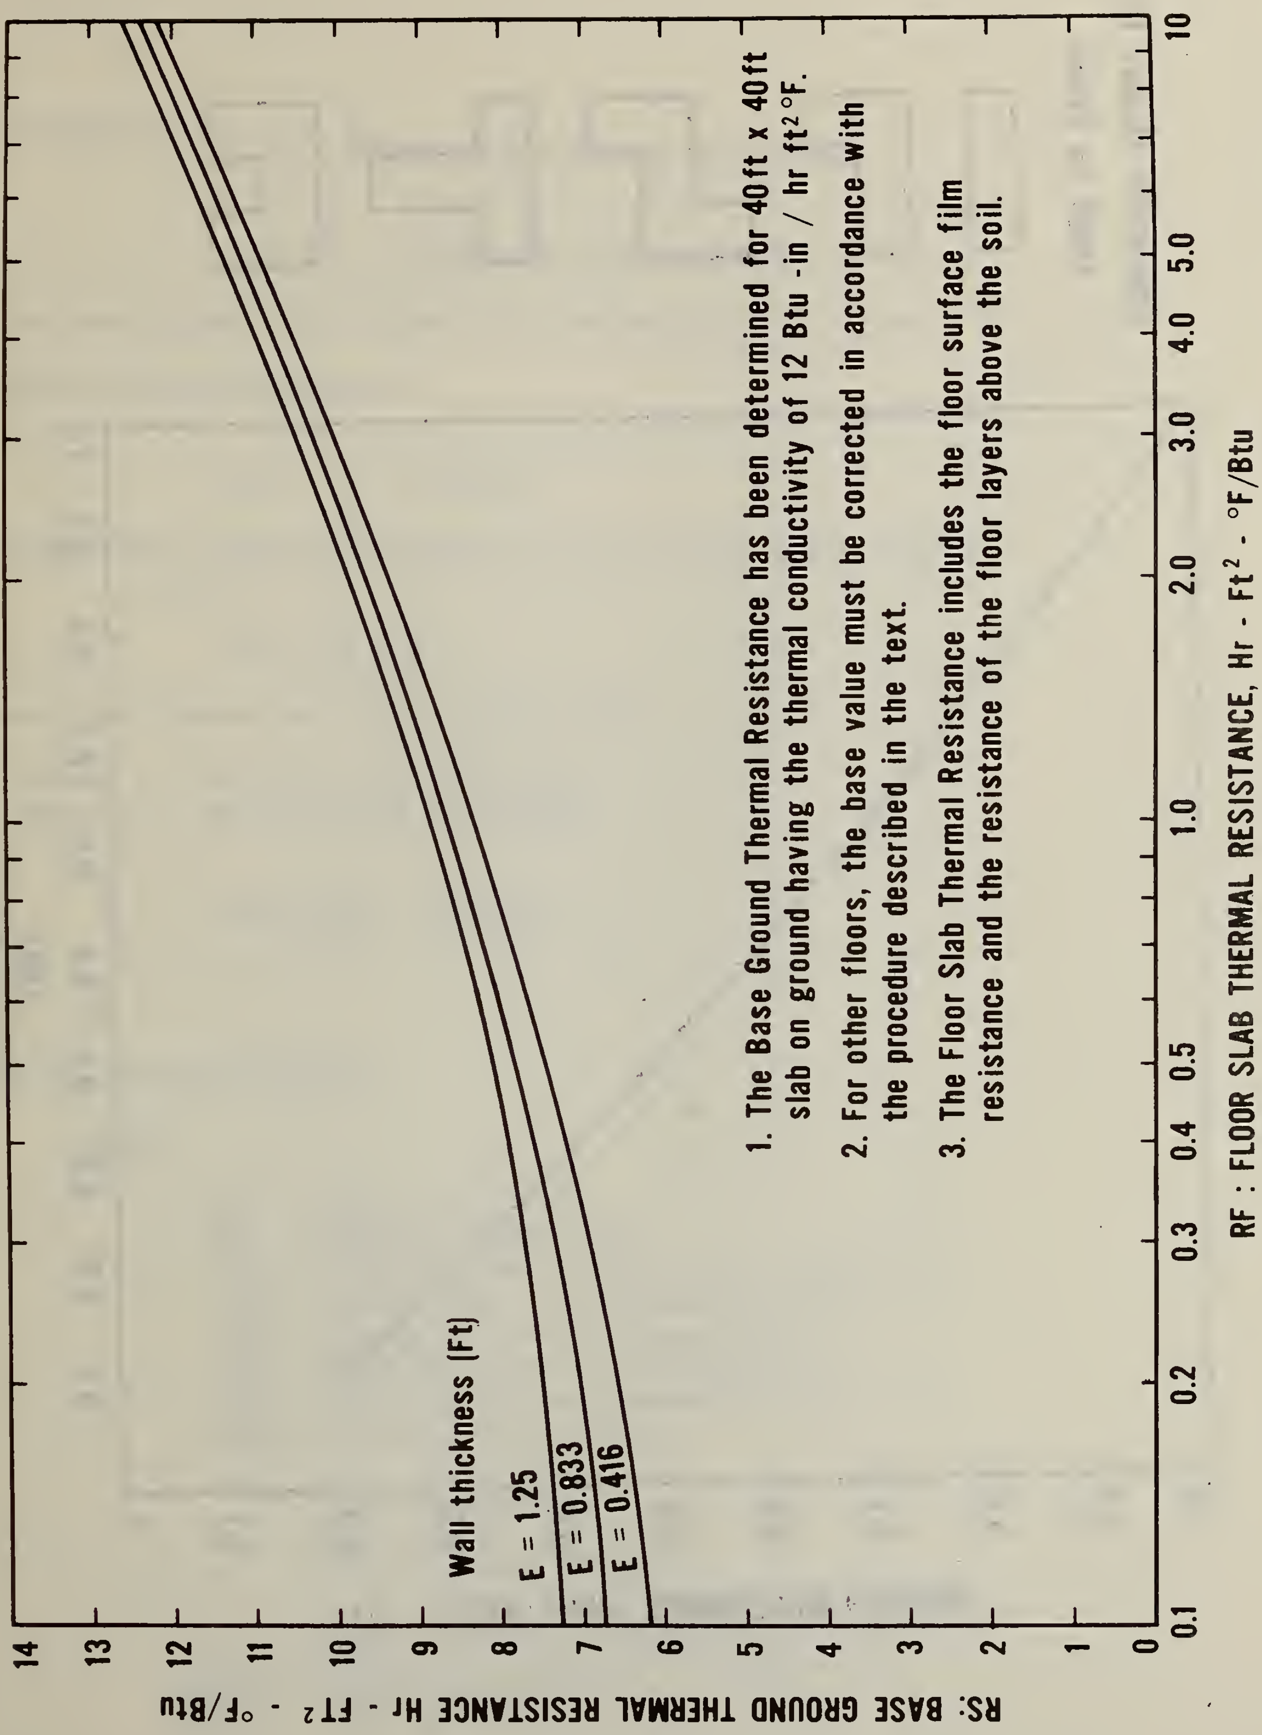

Figure 3. Thermal resistance of slab-on-grade floor.

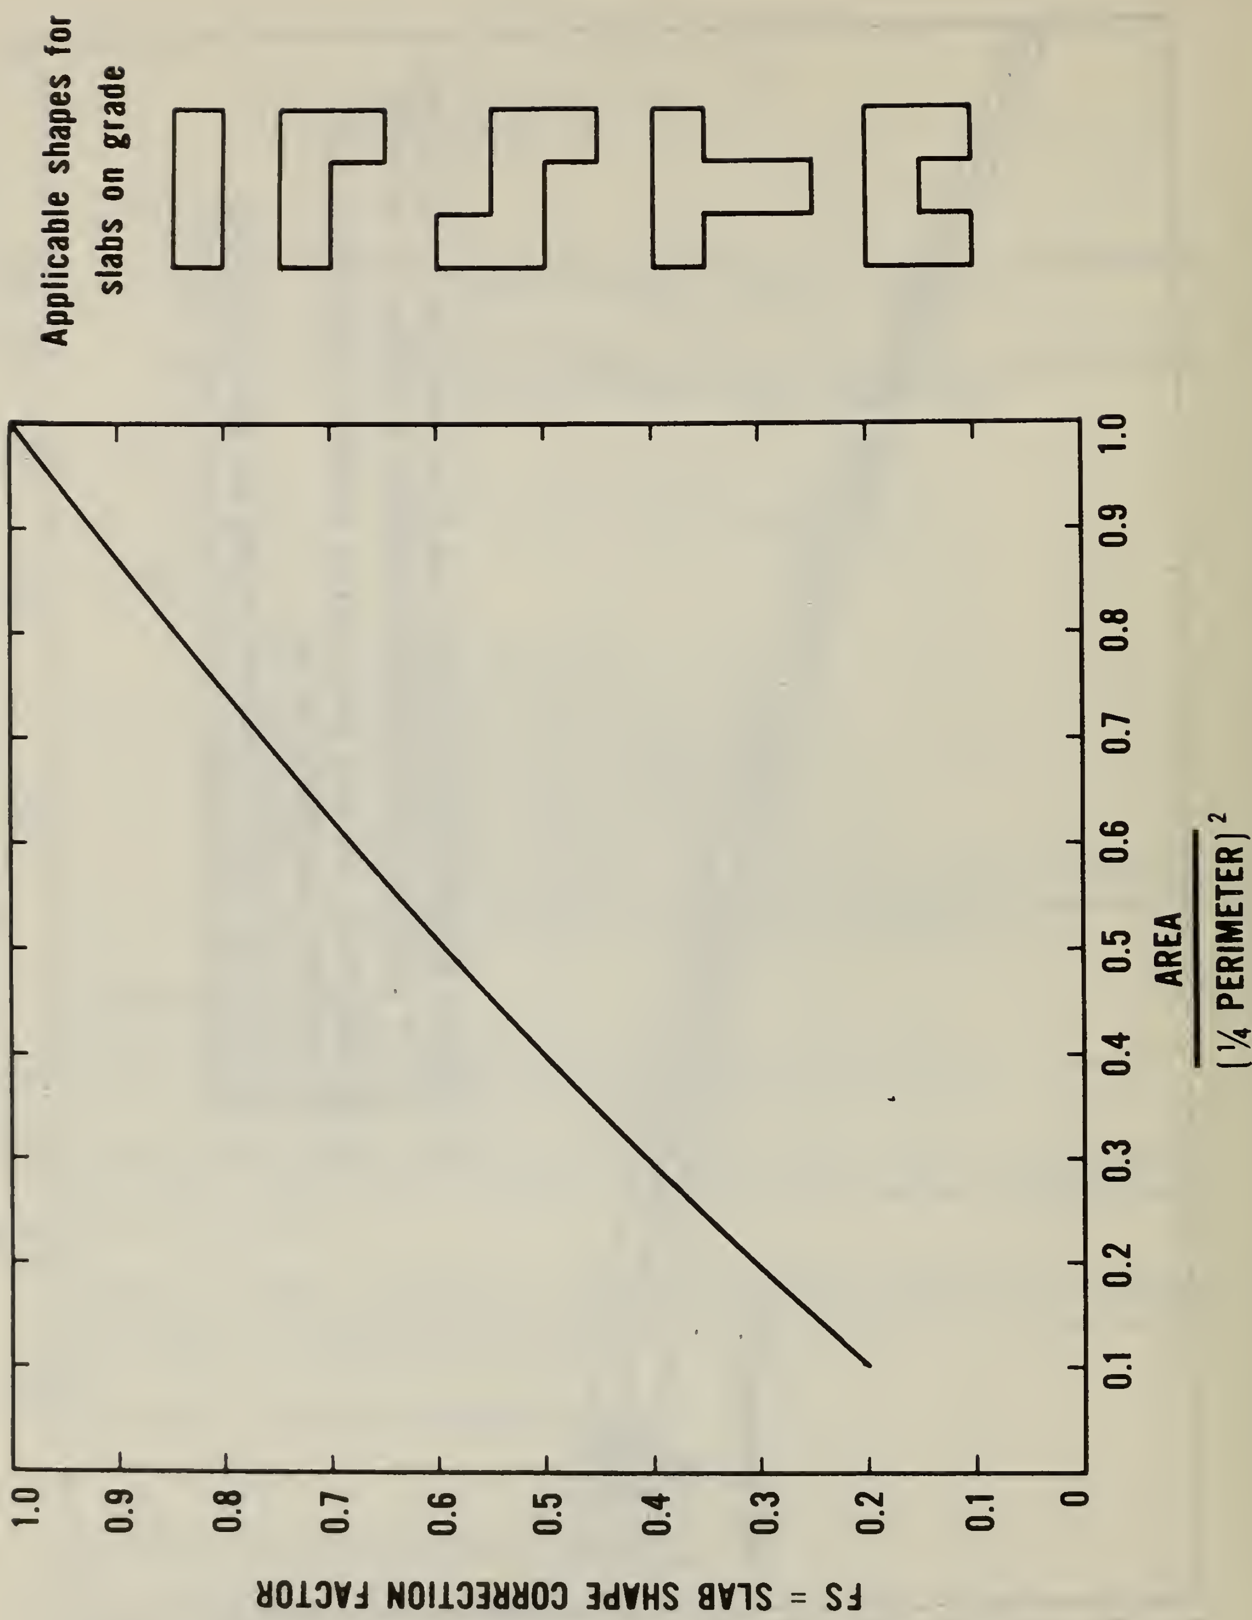

Figure 4. Shape correction factor for the slab-on-grade floor.

Calculation

$$RF = \frac{\beta}{(\alpha * UF)}: \text{ adjusted floor resistance}$$

$$E = \frac{WT}{\alpha} \quad \text{adjusted wall thickness}$$

Read from Figure 2 the value of RS corresponding to these RF and E data.

Ground Thermal Resistance:

$$RG = \frac{\alpha}{\beta} * RS * FS$$

Overall heat transfer coefficient of the slab-on-grade floor:

$$UF = \frac{1}{(RG + R)}$$

Heat loss through the slab-on-grade floor:

daytime: QFD = UF * AF * (TAD-TO)
nighttimes: QFN = UF * AF * (TAN-TO)

$$\text{where } TO = \frac{TOD+TON}{2}$$

5.7. QG

Window heat gain routine

Input:

AG = glass area, ft^2
SC = shading coefficient
UG = heat transfer coefficient, Btu/h ft^2 °F
TOD = daytime outdoor temperature, °F
TON = nighttime outdoor temperature, °F
TID = daytime indoor temperature, °F
TIN = nighttime indoor temperature, °F
SHDW = external shadow factor

0. = no shadow
0.5 = partial shadow
1.0 = complete shadow

It = total incident solar radiation, Btu/day ft^2
Id = diffuse sky radiation, Btu/day, ft^2
HRDAY = daytime hours, hr
HRNIT = nighttime hours, hr

Output: Daytime and nighttime window heat gain

I = (It-Id)*(1-SHDW) + Id

Daytime QGD = AG* [I*(SC)*0.87 + UG* (TOD-TID)* HRDY]
Nighttime QGN = AG* [UG*(TON-TIN)* HRNIT]

5.8. HLHG

Heat loss and heat gain calculations

Input:

QID = daytime infiltration heat gain, Btu/day
QIN = nighttime infiltration heat gain, Btu/day
QWD = daytime wall heat gain, Btu/day
QWN = nighttime wall heat gain, Btu/day
QDD = daytime door heat gain, Btu/day
QDN = nighttime door heat gain, Btu/day
QCD = daytime ceiling heat gain, Btu/day
QCN = nighttime ceiling heat gain, Btu/day
QGD = daytime window heat gain, Btu/day
QGN = nighttime window heat gain, Btu/day
QFD = daytime floor heat gain, Btu/day
QFN = nighttime floor heat gain, Btu/day
QRD = daytime internal heat gain, Btu/day
QRN = nighttime internal heat gain, Btu/day

The above values will be negative if they are heat loss.

THTC = thermal time constant, hr
SGD = daytime solar heat gain through windows, Btu/day
CFM = air leakage, cu ft/min
U_i (i = 1,2,..N) = overall heat transfer coefficient of each of the building envelope elements, Btu/h ft^2 °F
Ai(i=1,2,..N) = area of each of the building envelope elements, ft^2
N = total number of building envelope elements
IACNV = natural ventilation index: = 1 if open windows in summer when oudoor temp. < thermostat setting.
= 0 if never open windows.
PUH = pick-up time or pull-down time (see Appendix E)
HRDAY = daytime hours, hr
HRNIT = nighttime hours, hr

Output:

HLD = daytime sensible heating load, Btu/day
HLN = nighttime sensible heating load, Btu/day
CLD = daytime sensible cooling load, Btu/day
CLN = nighttime sensible cooling load, Btu/day

Calculation Procedure

This routine uses the building thermal time constant (THTC) concept, detail of which is given in the Appendix E.

Total envelope heat gain

daytime

$$QTD = QID + QWD + QDD + QGD + QFD + QRD + QCD$$

nighttime

$$QTN = QIN + QWN + QDN + QGN + QFN + QRN + QCN$$

If TID = TIN

HLD = QTD if OTD<0
HLN = QTN if QTN<0
CLD = QTD if QTD>0
CLN = QTN if QTN>0

otherwise the following calculations are necessary

Envelope heat transfer factor

$$ZK = \sum_{i=1}^{N} U_i A_i + 1.08 * CFM$$

also let

$$ZX = EXP\left(\frac{-PUH}{THTC}\right)$$

$$ZY = EXP\left(\frac{-12+PUH}{THTC}\right)$$

Cooling season calculations: (QTD>0 and QTN>0)

PULDWN: Evening pull-down cooling requirement necessary to lower the building temperature from TID of daytime to TIN of nighttime within a specified pickup period of PUH hours.

$$PULDWN = ZK * \left(TON - TID + \frac{(TID-TIN)}{1-ZX}\right) *PUH$$

DH = duration of morning warm-up hour during which the cooling is off

$$DH = THTC * \ln\left(\frac{ZQ-TIN+TOD+TD}{ZQ-TID+TOD}\right)$$

$$\text{where } ZQ = \frac{SGD+QRD}{HRDAY*ZK}$$

CON: total daytime cooling hour

$$CON = HRDAY - DH$$

daytime cooling load

$$QTD = QTD * CON/12$$

QTN: actual nighttime cooling requirement

$$CLN = \frac{QTN*(HRNIT-PUH)}{HRNIT} + PULDWN * PUH$$

If the natural cooling is used as

if IACNV=1, CLD=0 for TOD $\leq$ TID

CLN=0 for TON $\leq$ TIN

Heating season calculations: (QTD<0 and QTN<0)

PICKUP: early morning pick-up heating requirement necessary to raise the building temperatures from TIN to TID within PUH hours

$$PICKUP = ZK * \left((TIN - TOD) + \frac{(TID-TIN)}{1-ZX}\right)*PUH$$

DH: duration of evening cool-down hours during which the heating system is off

$$DH = THTC* \ln\left(\frac{TID+TD-TON-ZQ}{TIN-TON-ZQ}\right)$$

$$\text{when } ZQ = \frac{QRN}{ZK*HRNIT}$$

CON: total heating hours

$$CON = HRNIT-DH$$

daytime heating load

$$HCD = \frac{QTD*(HRNIT-PUH)}{HRNIT} - PICKUP * PUH$$

nighttime heating requirement

HLN = QTN*CON/HRNIT

5.9. HCRT: Heating and cooling requirement calculations

Input:

HLD = daytime sensible heating load, Btu/day
HCN = nighttime sensible heating load, Btu/day
CLD = daytime sensible cooling load, Btu/day
CLN = nighttime sensible cooling load, Btu/day
HL = daily sensible heat load = HLD + HLN
HG = daily sensible cooling load = CLD + CLN
RLGH = latent heat gain
AIRLOS = air leakage through ducts = $\frac{\text{AIR LOSS}}{\text{supply air}} \times 100\%$

Heating requirement: HREQ = HL * (1.0 + AIRLOS/100)

if cooling season, HREQ = 0

Cooling requirements: CREQ = (HG + LHG) * (1.0 + AIRLOS/100)

if open windows in summer when outdoor temp. < thermostat setting, LHG = 0

if heating season, CREQ = 0

5.10. EREQ: Energy requirement

Input:

HREQ = heating requirement
CREQ = cooling requirement
EH = heating efficiency
EC = cooling efficiency
WHREQ = hot water heating requirement
QS = energy from solar collector
QQC = heat gain through ducts and pipes
QQH = heat loss through ducts and pipes
ISYS = system index

1 = heating + no cooling
2 = no heating + cooling
3 = heating + cooling

Output:

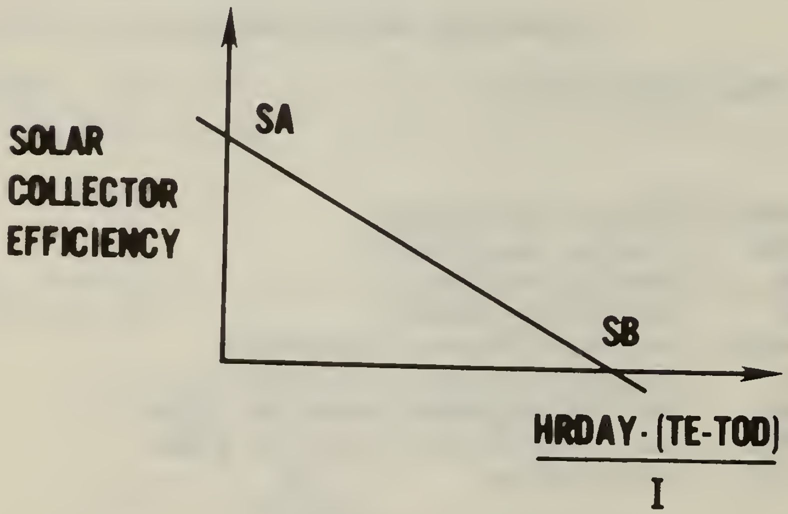
EREQ (Energy Requirement)

System Index	Heating Energy Requirement	Cooling Energy Requirement
ISYS = 1	(HREQ + WHREQ + QS + QQH)/EH	0
2	(WHREQ + QS + QQH)/EH	(CREQ + QQC)
3	(HREQ + WHREQ + QS + QQH)/EH	(CREQ + QQC)

5.11. SEU: Solar collector heat gain

Input:

SA, SB = Collector efficiency curve data



Typical solar collector performance.

	SA	SB
High Performance	0.8	1.2
(double glaze, selective surface)		
Medium Performance	0.75	1.0
(double glaze, common black)		
(single glaze, selective surface)		
Low Performance (single glaze, common black)	0.7	0.8

TE = inlet fluid temperature to the collector, °F
TOD = daytime outdoor temperature, °F
I = daily total solar radiation, Btu/day
SUF = solar heat utilization factor

0.8 for large storage tank system
0.5 for small storage tank system

AS = collector area, ft^2
HRDAY = daytime hours, hr

Solar heat utilized

$$QS = AS*SA*\left(1 - \frac{HRDAY*(TE-TOD)}{SB*I}\right)*SUF*I$$

5.12. QI: Infiltration heat gain

Input:

INFIL = infiltration rate, cfm
TOD = daytime outdoor temperature, °F
TON = nighttime outdoor temperature, °F
TID = daytime indoor temperature, °F
TIN = nighttime indoor temperature, °F
RH = room relative humidity, %
RHA = afternoon outdoor relative humidity, %
RHM = morning outdoor relative humidity, %
HRDAY = daytime hours
HRNIT = nighttime hours

Output:

Daytime sensible heat gain
QID = 1.08*INFIL* (TOD-TID)*HRDAY
Nighttime sensible heat gain
QIN = 1.08*INFIL*(TON-TIN)*HRNIT

Latent heat

Determine the humidity ratio of indoor and outdoor air from psychrometric chart or by calling the psychrometric routine described in (5.15).
Calculate indoor humidity ratio WIN and WID by nighttime Call DBRH (TIN, RH, WIN) and daytime Call DBRH (TID, RH, WID).
Determine the daytime and nighttime humidity ratios of outdoor air, WOD and WON by

Call DBRH (TOD, RHA, WOD)
Call DBRH (TON, RHM, WON)

Daytime latent heat gain:
QILD = 4.5*INFIL*(WOD-WID)*1061*HRDAY
Nighttime latent heat gain:
QILN = 4.5*INFIL*(WON-WIN)*1061*HRNIT
It is important to note that QID, QIN, QILD and QILN are all zero when the natural cooling is used to minimize or eliminate the need for mechanical cooling.

5.13. QECHG: Opaque envelope conduction heat gain (walls, doors, roofs and floors)

Input: For all the opaque envelope such as atticless roofs, walls and doors, the following input data should be provided:

SATD = daytime sol-air temperature, °F
SATN = nighttime sol-air temperature, °F
U = overall heat transfer coefficient, Btu/h ft^2 °F
A = area, ft^2
TID = daytime indoor temperature, °F
TIN = nighttime indoor temperature, °F
HRDAY = daytime hours, hr
HRNIT = nighttime hours, hr

For daytime heat gain, QD = U*A*(SATD-TID)*HRDAY Btu/day
For nighttime heat gain, QN = U*A*(SATN-TIN)*HRNIT Btu/day
For the attic ceiling and crawl space floor, the sol-air temperature should be replaced by the attic temperature and crawl-space temperature.

5.14. QR: Internal heat gain

Input:

NPD = number daytime occupants
NPN = number nighttime occupants
WTD = average daytime lighting power, w

WTN = average nighttime lighting power, w
WED = average daytime equipment power, w
WEN = average nighttime equipment power, w
HRDAY = daytime hours, hr
HRNIT = nighttime hours,

Sensible heat gain

It is assumed that 1/3 of the equipment heat is used for the evaporation of water vapor such as from cooking.

Daytime: QRSD = [NPD*240 + [WTD+(WED*0.66)]*3.413]*HRDAY
Nighttime: QRSN = [NPN*240 + [WTN+(WEN*0.66)]*3.413]*HRNIT

Latent heat gain

Daytime: QRLD = [NPD*160 + (WED*0.34)*3.413]*HRDAY
Nighttime: QRLN = [NPN*160 + (WEN*0.34)*3.413]*HRNIT

5.15. DBRH: Relative humidity routine (see Appendix C-27)

Input:

DB = dry-bulb temperature, °F
RH = relative humidity, %

Calculation algorithms for psychrometric routines are provided in reference [4].

Output:

W = humidity ratio, lb/lb

5.16. BSMT: Basement temperature and heat loss calculation

Input:

ZK = ground thermal conductivity Btu-in/hr ft^2 °F
UBW = basement wall heat conductance, Btu/hr ft^2 °F*/
UBF = basement floor heat conductance, Btu/hr ft^2 °F*/

UFLR1 = heat conductance of floor above the basement, Btu/hr ft^2°F
BWAEX = Area of the exposed section of the basement wall, ft^2
BWA = basement wall area, ft^2
BFA = basement floor area, ft^2
L = height of the basement wall which is ground covered, ft

---

*/ UBW and UBF are to be determined from the room air to the external surface of the wall/slab (soil interface).

TID = daytime temperature of the room above, °F
TIN = nighttime temperature of the room above, °F
TOD = daytime outdoor temperature, °F
TON = nighttime outdoor temperature, °F
TG = ground temperature, °F
HRDAY = daytime hours, hr
HRNIT = nighttime hours, hr

QBHG = basement heat gain from furnace, boiler, or other equipment, Btu/hr

Output:

BSMTD = daytime basement temperature, °F

BSMTN = nighttime basement temperature, °F

BQFD = daytime basement heat loss, Btu/day
BQFN = nighttime basement heat loss, Btu/day
TO = (TOD + TON)/2.0

There are no exact solutions, similar to those described in the slab-on-grade calculation, for the basement wall heat condition. An approximate value of UW may be obtained by the following equation.

$$UW = \frac{1}{\frac{1}{UFW} + \frac{1}{HO}} \quad \text{for the exposed section.}$$

$$UW = \frac{2*ZK}{(\pi *L)} * \ln\left(1 + \frac{\pi * UFW * L}{2 * ZK}\right) \quad \text{for the ground-covered section.}$$

The latter equation was derived from the assumption that the heat flow path between the basement wall and the ground surface is a quarter circle.

Basement flow heat transfer coefficient.

UF = The value should be determined by the same procedure used in the calculation of slab-on-grade floor heat transfer coefficient described in section 5.6.

$$BSMTD = \frac{QBHG+UW*BWA*TO+UF*BFA*TG+UFLR1*BFA*TID}{UW*BWA+UF*BFA+UFLR1*BFA}$$

$$BSMTN = \frac{QBHG+UW*BWA*TO+UF*BFA*TG+UFLR1*BFA*TIN}{UW*BWA+UF*BFA+UFLR1*BFA}$$

If basement is heated

BQFD = (-UW*(TID-TO)*BWA-UF*(TID-TG)*BFA)*HRDAY
BQFN = (-UW*(TIN-TO)*BWA-UF*(TIN-TG)*BFA)*HRNIT
BSMTD = TID, BSMTN = TIN

If basement is not heated BQFD & BQFN are calculated by using Subroutine QECHG (=7.13. Opaque envelope conduction heat gain calculations) and the basement temperatures, BSMTD and BSMTN above.

5.17. HWHREQ: hot water heating requirement

Input:
TOUT = hot water outlet temperature °F
TIN = hot water inlet temperature = ground temperature °F
HWT = hot water usage, gallons/day
A = total jacket area, ft^2
BSMTD = daytime basement or indoor temperature, °F
BSMTN = nighttime basement or indoor temperature, °F
D1 = thickness of existing tank insulation, ft
RAM1 = thermal conductivity of existing insulation, Btu/hr, ft, °F
D2 = thickness of additional insulation, ft
RAM2 = thermal conductivity of additional insulation, Btu/h, ft, °F
HRDAY = daytime hour, hr
HRNIT = nighttime hours, hr

Output: Heat loss through existing jacket insulation around the hot water tank

HLHWH1 = U1*A*((BSMTD-TOUT)*HRDAY) + (BSMTN-TOUT)*HRNIT)

where U1 = 1.0/(0.685 + D1/RAM1)

Heat loss through additional jacket insulation of hot water tank

HLHWH2 = U2*A*((BSMTD-TOUT)*HRDAY) + (BSMTN-TOUT)*HRNIT)

where U2 = 1.0/(0.685 + D1/RAM1 + D2/RAM2)

Energy saving by additional insulation over the hot water tank

SAVE = HLHWH2-HLHWH1

Hot water heating requirement, including jacket heat loss

WHREQ = 500.0/60.0*(TIN-TOUT)*HWT + HLHWH2

If WHREQ > 0, WHREQ = 0

Hot water heating requirement, excluding jacket heat loss

WHREQ2 = WHREQ - HLHWH2

5.18. CSDUPI: heat loss and gain through ducts and pipes in crawl space

Input: ADUCT = total surface area of duct in crawl space, ft^2
UDUCT = U value of duct, Btu/h ft^2 °F
APIPE = total surface area of pipe in crawl space, ft^2
UPIPE = U value of pipe, Btu/h ft^2 °F
TCSUPA = supply chilled air temperature, °F
TCSUPW = supply chilled water temperature, °F
THSUPA = supply hot air temperature, °F
THSUPW = supply hot water temperature, °F
CRAWLD = daytime crawl temperature, °F
CRAWLN = nighttime crawl temperature, °F
CFAC = factor for estimating operation time of cooling equipment
HFAC = factor for estimating operation time of heating equipment
HRDAY = daytime hours, hr
HRNIT = nighttime hours, hr

Output: Heat gain through ducts and pipes

QC = ADUCT*UDUCT*((CRAWLD - TCSUPA)*HRDAY + (CRAWLN - TCSUPA)*HRNIT) *CFAC + APIPE*UPIPE*((CRAWLD - TCSUPW)*HRDAY + (CRAWLN - TCSUPW)*HRNIT)*CFAC

Heat loss through ducts and pipes

QH = ADUCT*UDUCT*((CRAWLD - THSUPA)*HRDAY + (CRAWLN - THSUPA) *HRNIT) *HFAC + APIPE*UPIPE*((CRAWLD - THSUPW)*HRDAY + (CRAWLN - THSUPW)*HRNIT)*HFAC

If cooling season, QH = 0
If heating season, QC = 0

5.19. ASDUPI: heat loss and gain through ducts and pipes in attic space

Input: ADUCT = total surface area of duct in attic space, ft^2
UDUCT = U value of duct, Btu/h, ft^2, °F
APIPE = total surface area of pipe in attic space, ft^2
UPIPE = U value of pipe, Btu/h, ft^2, °F
TCSUPA = supply chilled air temperature, °F
TCSUPW = supply chilled water temperature, °F
THSUPA = supply hot air temperature, °F

THSUPW = supply hot water temperature, °F
ATD = attic daytime temperature, °F
ATN = attic nighttime temperature, °F
CFAC = factor for estimating operation time of cooling equipment
HFAC = factor for estimating operation time of heating equipment
HRDAY = daytime hours
HRNIT = nighttime hours

<u>Output</u>:

Heat gain through ducts and pipes

QC = ADUCT*UDUCT*((ATD - TCSUPA)*HRDAY + (ATN - TCSUPA)*HRNIT)*CFAC + APIPE*UPIPE*((ATD - TCSUPW)*HRDAY + (ATN - TCSUPW)*HRNIT)*CFAC

Heat loss through ducts and pipes

QH = ADUCT*UDUCT*((ATD - THSUPA)*HRDAY + (ATN - THSUPA)*HRNIT)*HFAC + APIPE*UPIPE*((ATD - THSUPW)*HRDAY + (ATN - THSUPW)*HRNIT)*HFAC

If cooling season, QH = 0
If heating season, QC = 0

5.20. <u>BMDUPI</u>: heat loss and gain through ducts and pipes in basement

<u>Input</u>: ADUCT = total surface area of duct in basement, ft^2
UDUCT = U value of duct, Btu/h ft^2 °F
APIPE = total surface area of pipe in basement, ft^2
UPIPE = U value of pipe, Btu/h ft^2 °F
TCSUPA = supply chilled air temperature, °F
TCSUPW = supply chilled water temperature, °F
THSUPA = supply hot air temperature, °F
THSUPW = supply hot water temperature, °F
BSMTD = basement daytime temperature, °F
BSMTN = basement nighttime temperature, °F

CFAC = factor for estimating operation time of cooling equipment
HFAC = factor for estimating operation time of heating equipment
HRDAY = daytime hours, hr
HRNIT = nighttime hours, hr

<u>Output</u>:

Heat gain through ducts and pipes

QC = ADUCT*UDUCT*((BSMTD - TCSUPA)*HRDAY + (BSMTN - TCSUPA)*HRNIT)*CFAC + APIPE*UPIPE*((BSMTD - TCSUPW)*HRDAY + (BSMTN - TCSUPW)*HRNIT)*CFAC

Heat loss through ducts and pipes

```
QH     = ADUCT*UDUCT*((BSMTD - THSUPA)*HRDAY + (BSMTN - THSUPA)
         *HRNIT)*HFAC + APIPE*UPIPE*((BSMTD - THSUPW)*HRDAY +
         (BSMTN - THSUPW)*HRNIT)*HFAC
```

If cooling season, QH = 0
If basement heated, QH = 0
If heating season, QC = 0

5.21. OSDUPI: heat loss and gain through outdoor ducts and pipes

Input:
ADUCT = total surface area of outdoor duct, ft^2
UDUCT = U value of duct, Btu/h ft^2 °F
APIPE = total surface area of outdoor pipe, ft^2
UPIPE = U value of pipe, Btu/h ft^2 °F
TCSUPA = supply chilled air temperature, °F
TCSUPW = supply chilled water temperature, °F
THSUPA = supply hot air temperature, °F
THSUPW = supply hot water temperature, °F
TOD = daytime outdoor temperature, °F
TON = nighttime outdoor temperature, °F
CFAC = factor for estimating operation time of cooling equipment
HFAC = factor for estimating operation time of heating equipment
HRDAY = daytime hours, hr
HRNIT = nighttime hours, hr

Output:

Heat gain through ducts and pipes

```
QC     = ADUCT*UDUCT*((TOD - TCSUPA)*HRDAY + (TON - TCSUPA)
         *HRNIT)*CFAC + APIPE*UPIPE*((TOD - TCSUPW)*HRDAY +
         (TON - TCSUPW)*HRNIT)*CFAC
```

Heat loss through ducts and pipes

```
QH     = ADUCT*UDUCT*((TOD - THSUPA)*HRDAY + (TON - THSUPA)
         *HRNIT)*HFAC + APIPE*UPIPE*((TOD - THSUPW)*HRDAY +
         (TON - THSUPW)*HRNIT)*HFAC
```

If cooling season, QH = 0
If heating season, QC = 0

The routines described above are incorporated into a Fortran program, listing of which is given in Appendix C.

Appendix D presents a description of the data file and suggested default values to be used for the heating and cooling requirement calculations.

6. COMPARISON WITH DOE-2 RUNS

Figures 5 and 6 are comparisons of annual heating and cooling requirements obtained by the simplified procedure described herein with those obtained by DOE-2, a comprehensive hourly simulation program for building energy analysis, for ten cities and for a combination of several energy conservation options as shown in Table 1. The basic building data used for these comparative calculations are described in a recent report of the Lawrence Berkeley Laboratory[5].

As can be seen, the total annual heating and cooling requirements obtained by the simplified procedure do not agree well with those determined by the DOE-2.

Since the DOE-2 uses TRY (Typical Reference Year) weather data, a set of monthly normal day data were generated from the TRY weather data tape and used in the simplified calculation procedure. The infiltration routine was also modified to be consistent with the DOE-2 algorithm. Figures 7 and 8 show the improved relationships between the two calculations as the result of these two adjustments.

Table 1. Building Data for the Comparative Calculations with DOE-2

City	Base Case				Additions to Base Levels of Insulation, Glazing							
					Options							
	Wall	Attic	Windows	Floor	1	2.	3	4	5	6	7	8

AVERAGE EARTH TEMPERATURE FOR UNDERGROUND HEAT DISTRIBUTION SYSTEM DESIGN

The following list presents the average earth temperature from 0 to 10 feet below the surface for the four seasons of the year and for the whole year for the indicated locals. The temperatures were computed on the basis of the method described in the 1965 ASHRAE technical paper entitled "Earth Temperature and Thermal Diffusivity at Selected Stations in the United States" by T. Kusuda and P. R. Achenbach (in ASHRAE Transactions, Volume 71, Part I, p. 61, 1965) using the monthly average air temperatures published by the U.S. Weather Bureau for the listed localities in the United States. Earth temperatures are expressed in fahrenheit degrees.

APPENDIX E

Thermal Time Constant and Its Application

The thermal time constant of a building is a parameter to indicate the speed of indoor temperature response to a sudden change of building heating and cooling operation. The heavier the thermal mass of a building, the slower its response, compared to a lighter building, to cool down or heat up when the building heating system is turned off and on, respectively. The thermal time constant is defined as a ratio between the equivalent thermal mass of the building and the building overall heat transfer factor. Whereas the overall heat transfer factor may be approximated by the heat transfer coefficients, U value, multiplied by the areas, A, of all the elements, such as walls, doors, windows, roof and floors, and the air leakage rate multiplied by the specific heat of air, the equivalent building thermal mass is rather difficult to ascertain. The building mass is distributed in a complex manner, with respect to its size and shape, position in the insulated structure, and floor interface with the earth.

Although difficult to calculate, the overall building thermal time constant can readily be determined by a simple cool-down test during a heating season based upon the following mathematical relationship.

When the heating system and all the heat sources in a house are suddenly shut off during a steady cold night (outdoor temperature of To), its temperature would decay from the initial setpoint of T_1 according to the following equation:

$$MC^* \frac{dT}{dH} = -K^* (T-To) \qquad \text{E-(1)}$$

where

MC = overall thermal mass, Btu/°F
K = overall heat transfer factor, Btu/hr, °F
H = hour

The thermal time constant, THTC, is defined as

$$THTC = \frac{MC}{K}, \text{ in the unit of hour}$$

The differential equation E-(1) becomes then

$$\frac{dT}{T-To} = -\frac{dH}{THTC}, \qquad \text{E-(2)}$$

which has a following solution:

$$THTC = \frac{H}{\ln\left(\frac{T_i - T_o}{T - T_o}\right)} \qquad E-(3)$$

Thus by measuring a logarithmic decay of the building temperature, from initial value of T_1 to T during a time span of H hours, one can readily calculate the value of the thermal time constant.

According to Nash's data[7/], typical THTC for residences are:

	Light Weight	Medium Weight	Heavy Weight
One-story house	10	15	20
Two-story house	30	35	40

When a building heat transfer process is simulated by a simple thermal capacity model, its temperature change may similarly be represented by the following first order differential equation

$$MC^* \frac{dT}{dH} = - K^* (T-To) + SPHG \qquad E-(4)$$

T = building temperature, °F
To = outdoor temperature, °F
MC = building thermal capacity, Btu/°F
K = overall heat transfer factor, Btu/hr °F
SPHG = total space heat gain due to internal heat, heating systems, solar heat gain through windows, and occupancy, Btu/hr
H = elapsed time, hour.

General solution to the above equation is

$$\frac{Q-T_1 + To}{Q-T + To} = e^{\frac{H}{THTC}} \qquad E\text{-}(5)$$

where

$$Q = \frac{SPHG}{K} = \text{heat source constant, °F}$$

$$THTC = \frac{MC}{K} = \text{thermal time constant, hr}$$

$$T_1 = \text{value of T when H = 0, °F.}$$

Equation E-(5) permits, for example, the determination of the duration, DH, for which the house temperature reaches from the daytime set point TID to the nighttime set point TIN, which is usually lower.

Since Q is very small during that period, referring to Figure E-(1),

$$DH = THTC*\ln\left[\frac{TID-TON}{TIN-TON}\right] \qquad E\text{-}(6)$$

Likewise equation E-(5) may be used to determine the early morning pick-up heating load (or the early evening pull-down cooling load), MPUL, by specifying the required temperature recovery time or pick-up time, PUH, (or pull down time, PHD) as follows

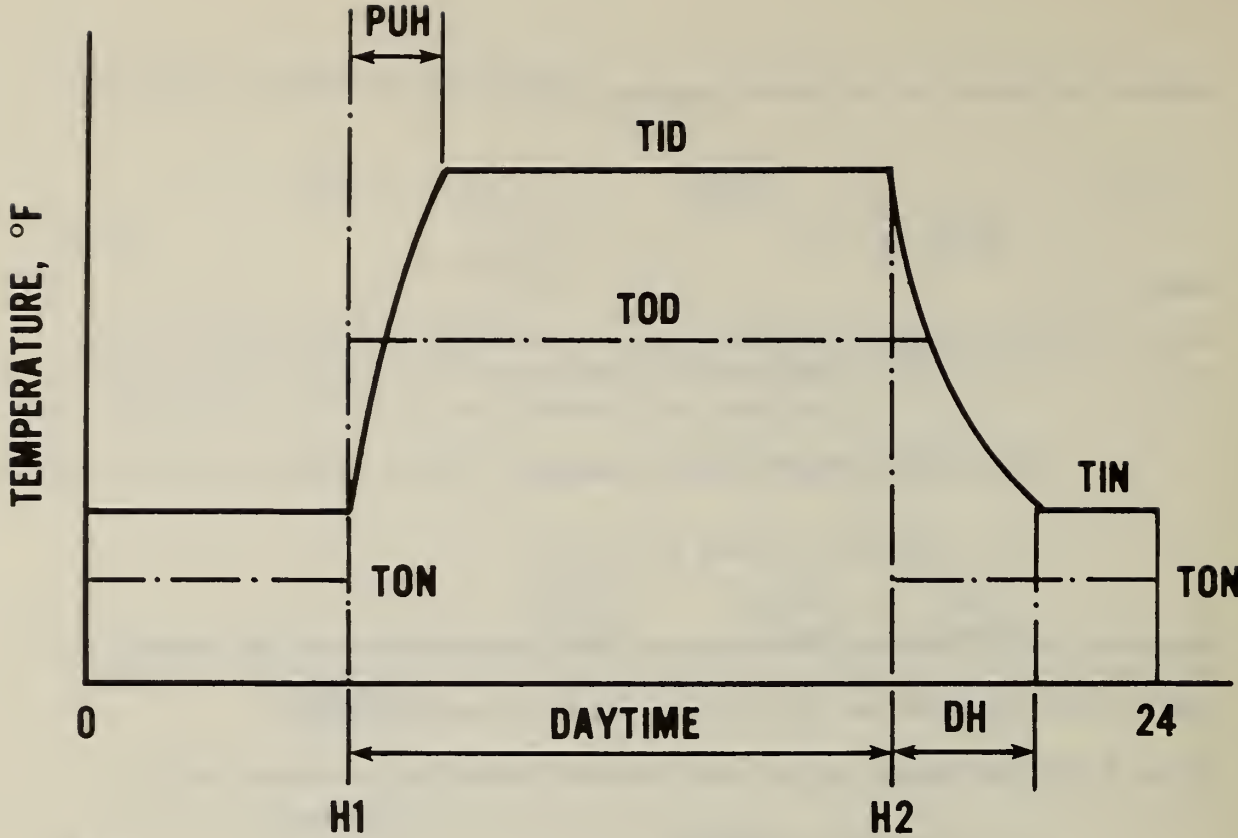
$$\frac{\frac{MPUL}{K} - TIN + TOD}{\frac{MPUL}{K} - TID + TOD} = e^{\frac{PUH}{THTC}} \qquad E\text{-}(7)$$

By rearranging the term, MPUL can be determined by

$$MPUL = K*\left[(TIN-TOD) + \frac{TID-TIN}{1-e^{-PUH/THTC}}\right] \qquad E\text{-}(8)$$

Another example of the use of THTC is to approximate the benefit of excess solar heat gain during a sunny winter day to offset the heat loss during the night.

The procedure used is first to determine the indoor temperature rise TR, due to the excess heat gain, above the daytime indoor temperature setpoint TID by the following equation



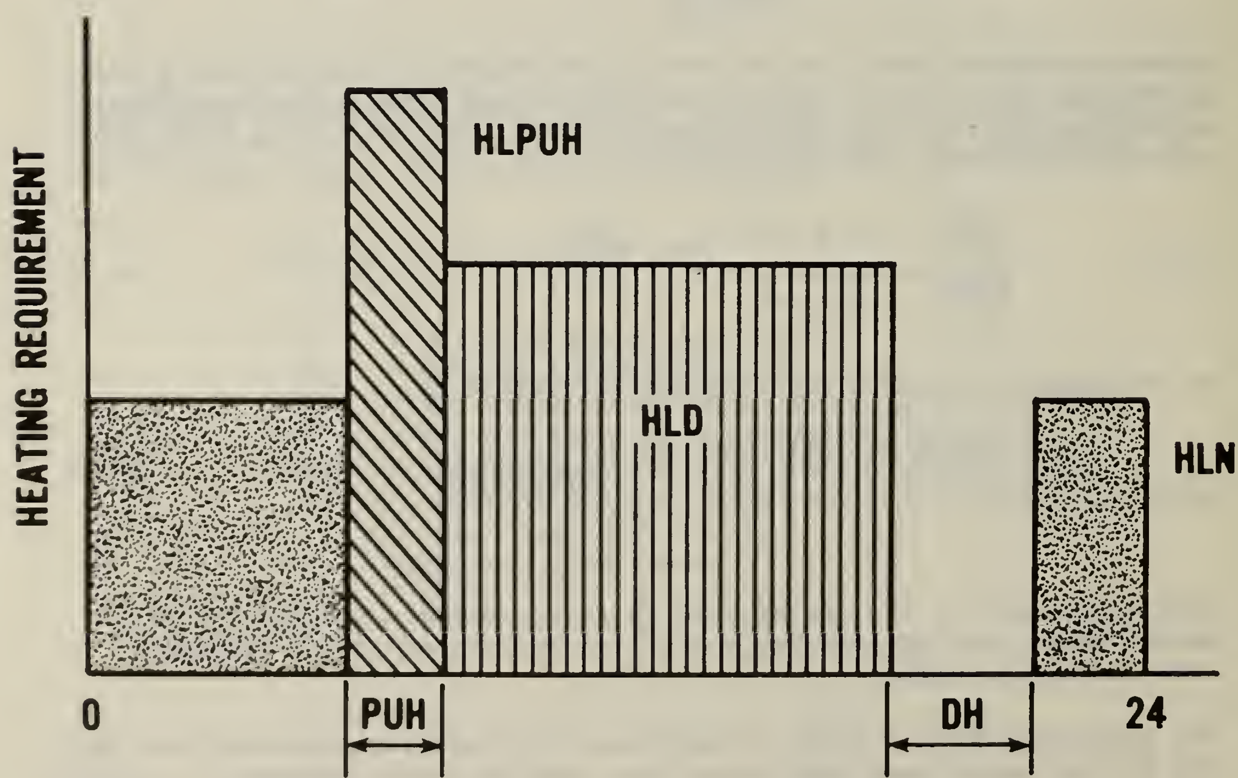


Figure E-1. Temperature and heating requirement profile during the nighttime thermostat setback.

$$TR = \frac{QTD}{K*12} * [1-e^{\frac{-(H_2-H_1)}{THTC}}] \qquad E\text{-}(9)$$

where QTD is the excess daytime heat gain during hour from H_1 to H_2, which is the balance of heat gain above what is required to cancel the envelope heat loss.

The equation E-(6) will now be used to determine the "off" period of the heating system except that TID in equation (6) is now replaced by the new starting temperature TID + TR.

A similar concept may be used to determine the effect of night heat loss during the cooling season to offset the daytime cooling requirement as follows:

The temperature drop of the room air from the set point of TIN during the cool night due to the excess heat loss QTN is

$$TD = \frac{QTN}{K*12} * (1-e^{-\frac{HN}{THTC}}) \qquad E\text{-}(10)$$

where HN is the nighttime hours

The period when the air-conditioning system could be off due to this night cooling is then

$$DH = THTC * \ln \left(\frac{\frac{QTD}{K*12} - TIN + TD + TOD}{\frac{QTD}{K*12} - TID + TOD} \right) \qquad E\text{-}(11)$$

provided that (TIN-TD) < TID.

Figure E-2 depicts indoor temperatures, cooling and heating periods, and other notations such as DH, PDH, PUH and TD in cooling season. Figure E-2(a) shows indoor temperatures and cooling period in a day when QTD $\geq$ 0 and QTN $\geq$ 0. The daytime indoor temperature rises from TIN to TID during early morning pickup hours, DH, while the cooling system is turned off. After this period, the temperature is maintained at TID during daytime, followed by a pull down to TID at the beginning of nighttime for a period of PHD hours. The cooling system is, therefore, assumed to be running all day except for the period of DH.

Figure E-2(b) shows the case of QTD $\geq$ 0 and QTN $\geq$ 0. In this case, the nighttime indoor temperature decreases from TIN to TIN-TD according to the nighttime heat losses, while the cooling system is turned on during a period of PDH. Because of the night heat loss the indoor temperature is lower than TIN by TD at the beginning of daytime. During an early morning period of DH, the temperature naturally rises to TID because of the daytime heat gains. Consequently, the cooling system continues to operate throughout the day except periods DH and PDH.

There is a limitation on input of daytime and nighttime indoor temperatures, TID and TIN, in that TID is always equal to or higher than TIN. The reason of this limitation is to avoid algorithmic complexities.

Figures E-2(c) and (d) depict indoor temperatures profile during the heating period.

Figure E-2(c) shows indoor temperatures and heating period in a day when QTD > 0 and QTN $\leq$ 0. The daytime indoor temperature goes up to TID + TD at the end of daytime because the cooling system is not running in spite of QTD > 0 during the daytime. The nighttime indoor temperature goes down from TID + TR to TIN during a period of PH because QTN $\leq$ 0 and the heating system is turned off. After the temperature reached to TIN, the heating system is turned on.

Figure E-2(d) shows indoor temperatures and heating period in a day when QTD $\leq$ 0 and QTN $\leq$ 0. The nighttime indoor temperature decreases to TIN from TID because of night setback. during a period of DH, the heating system is turned off. PUH is pick-up time, during which the indoor temperature goes up to TID from TIN because of the heating system.

If there is a case of QTD $\leq$ 0 and QTN $\geq$ 0, it is neglected, meaning that the heating and cooling requirements should be equal to zero because the case should seldom occur in the cooling season.

The heating and cooling requirement are both set equal to zero during the heating season when the daytime and nighttime heat balance, QTD and QTN, are both positive. Likewise QTD and QTN are both set equal to zero during the cooling season if QTD and QTN are both negative.

☐ Document describes a computer program; SF-185, FIPS Software Summary, is attached.

16. ABSTRACT *(A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here.)*

In order to shorten the lengthy computational labor and cost common to most existing hourly simulation computer programs, a simplified energy calculation procedure was developed for the evaluation of energy conservation effectiveness of home retrofitting. The procedure utilizes monthly normal weather parameters such as temperature, humidity, wind data, and solar radiation, in lieu of the traditional degree-day procedure.

The thermal time constant was used to account for the effect of building thermal mass on seasonal heat transfer performance. In addition to standard retrofit procedures such as addition of thermal insulation, use of storm windows, and sealing of cracks, included in the procedure are the energy conservation effects due to the use of solar collectors, hot water tank insulation, and insulation around the heat distribution systems such as ducts and pipes.
