I. Introduction

The National Bureau of Standards supported by the Department of Commerce Maritime Administration did some preliminary studies to establish an upper limit for the tank volume uncertainty of a spherical transport tank calibrated by photogrammetry [1]. Additional support from the Maritime Administration and the LNG Ship Custody Transfer Committee [2], has made possible a considerably expanded study of the calibration uncertainties of LNG transport tanks. The tank calibrations examined in this work are those of the three LNG Transports built by Newport News Shipbuilding and Drydock Company for El Paso Marine Company.

II. The Tanks

The cargo tanks on these 125000 m³ (approximate) capacity ships are membrane types of the Technigaz design described in reference [3]. The tanks are ten-sided prismatic solids and rectangular in horizontal cross section. The walls are all plane surfaces. The end walls are vertical as are the side walls. The side walls are connected to the horizontal floor and ceiling by sloping chine planes. All eight of the longitudinal planes are parallel to the longitudinal axis of the ship. The supporting walls of the tanks are the inner hull of the ship. Layers of insulation are attached to these walls and the internal surfaces of the insulation are covered with a liquid-tight 1.2 mm stainless steel membrane. This membrane has corrugations stamped into it forming a waffle pattern.

III. Tank Calibration Methods

The measurements used to calculate the tank volume were generally made after the membrane installation was complete but before the removal of the construction scaffolding since it is needed to provide access to the tank surface. Briefly, the calibration method used by the calibration contractor consisted of measuring horizontal cross sectional areas of the tank at intervals from the bottom to the top of the tank. The products of these areas and the separation from the area immediately below summed to the level gives the volume to that level. This method is discussed in reference [4]. The cross sectional areas of these tanks were determined by measuring short distances to the wall from the sides of a horizontal rectangle of known dimensions defined by laser beams.

A calibration method developed at NBS and reported in reference [5] was used by NBS to assess the accuracy of the method used by the calibration contractor. The method used by NBS consists, in brief, of inscribing with laser planes a slightly smaller closed volume with the same shape as the tank. The dimensions of this laser-plane-defined volume are accurately measured. Perpendicular distances from the laser planes to the tank walls are measured at several hundred specified points distributed around the tank. The integration method used to determine volume as a function of height is also outlined in reference [5].

IV. Results

The calibration reports for each of the six tanks of the three ships, the El Paso Southern, the El Paso Arzew and the El Paso Howard Boyd, appear in Appendix I, II, and III respectively. Each individual tank report supplies the following information:

- a. A calibration report or a report of test describing the measurement technique, measurement conditions, and error estimate.
- b. A summary main gaging table showing tank volume as a function of gage height.
- c. Summary list and trim correction tables to supplement the main table under expected conditions of ship list and trim.
- d. A plot comparing the NBS main gaging tables at selected intervals to the gage books for each tank provided by the calibration contractor.

The staging was removed in four of the tanks before the NBS measurements were made; hence the calibration check was done only to the height accessible from the bottom of the tank.

The calibration accuracy required by the ship owner is $\pm 0.2\%$ of total tank volume. The NBS results range in accuracy from $\pm 0.05\%$ to $\pm 0.1\%$ as indicated in the Reports of Calibration. In every case, the calibration contractor's results are well within $\pm 0.2\%$ of the NBS results. It therefore appears that the accuracy requirement has been achieved for the tanks at ambient temperature. The tank volume tables at ambient temperature are used by the transporter to determine LNG volume at operating temperature because the tank dimensions have been assumed independent of cargo temperature. This assumption is based on the fact that the shape of the tank is determined by the external tank wall which is the inner hull of the ship. The membrane wall is supported by this wall via the insulation. The corrugated design of the membrane allows the membrane to shrink on cooling without altering the internal volume.

In actual operation, the external tank wall might be as cold as 0°C depending on weather conditions. The temperature of the interior of the tanks was as high as 30°C during calibration of the tanks. Provided the external tank wall reached temperatures that high, the difference between the calibration and operating temperature could be as large as 30°C .

The thermal expansion coefficient of iron as well as iron containing small quantities of nickel [6] is approximately $11.6 \times 10^{-6} \text{ m/m}^{\circ}\text{C}$. This contraction only affects the length and width of the tank with regard to calibration since the liquid height is determined by the level gage rather than the tank height. Thus the tank volume change between the calibration and operating temperature could be as much as

$$\begin{aligned} \Delta V/V &= -(2 \times 30 \times 11.6)/100 \\ &= -0.07\% \end{aligned}$$

The shrinkage of the balsa wood insulation upon cooling (since the balsa is not a rigid body) as well as any bulging of the tank sides counteract the reduction in volume due to cooling the walls. The balsa shrinkage contributes a negligible change in tank volume. If this is also true with respect to tank wall bulging due to hydrostatic head, then the maximum systematic error introduced into the tank calibrations due to cooling is estimated to be no more than -0.07%.

Calibration Reports for the Six Tanks of the El Paso Southern

U.S. DEPARTMENT OF COMMERCE
NATIONAL BUREAU OF STANDARDS
WASHINGTON, D.C. 20234

REPORT OF CALIBRATION

For: Tank #1 on the LNG Tanker
El Paso Southern

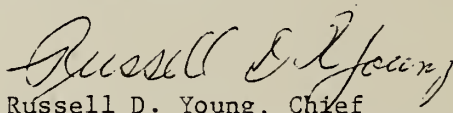

Requested by: El Paso Marine Company
2919 Allen Parkway
P. O. Box 1592
Houston, TX 77001

The following tables have been calculated from dimensional measurements on tank number 1 of the liquefied natural gas tanker El Paso Southern while berthed at Newport News Shipbuilding and Drydock Company, Newport News, VA. These tables represent the volume of a liquid enclosed in the tank as a function of the height of the liquid surface, measured along a straight line, fixed with respect to the tank. This line is defined as being located at the longitudinal center line of the tank's capacitance gage. Secondary tables are also presented which allow correction of the main tables for specific angles of ship orientation with respect to gravity, as referred to the six sets of draft marks on the ship's hull. Both the measurement method and the computational algorithms are outlined in the paper "Multiple Redundancy in the Measurement of Large Structures," Annals of the International Institution of Production Engineering Research (CIRP), Volume 27/1, 1978.

The tank was measured empty while at an average temperature of 9.0°C. The tabulated volumes and the error estimates apply to the tank under these conditions. The volumes have also been corrected for the volume occupied by the corrugations (deadwood) which was measured in the laboratory using a hydrostatic displacement technique.

The measurement method used includes geometrically redundant cross checks which allow assessment of the random error in the measurement process. For this tank, the total volume, excluding the vapor domes, was 12566.0 m³ with an uncertainty of 1.3 m³ (0.01% of total volume) at the three standard deviation limit of random error. Including an analysis of probable systematics by adding the absolute magnitude of the error sources, we estimate that the total uncertainty, at the 99% confidence level, is $\pm 0.05\%$ of the total volume. No estimates of the errors in the individual table entries are included, since without an estimate of the height error introduced by the liquid level gage such estimates would of necessity be incomplete.

REPORT OF CALIBRATION

For: Tank #3 on the LNG Tanker
El Paso Southern

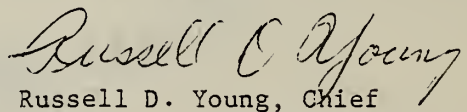

Requested by: El Paso Marine Company
2919 Allen Parkway
P. O. Box 1592
Houston, TX 77001

The following tables have been calculated from dimensional measurements on tank number 3 of the liquefied natural gas tanker El Paso Southern while berthed at Newport News Shipbuilding and Drydock Company, Newport News, VA. These tables represent the volume of a liquid enclosed in the tank as a function of the height of the liquid surface, measured along a straight line, fixed with respect to the tank. This line is defined as being located at the longitudinal center line of the tank's capacitance gage. Secondary tables are also presented which allow correction of the main tables for specific angles of ship orientation with respect to gravity, as referred to the six sets of draft marks on the ship's hull. Both the measurement method and the computational algorithms are outlined in the paper "Multiple Redundancy in the Measurement of Large Structures," Annals of the International Institution of Production Engineering Research (CIRP), Volume 27/1, 1978.

The tank was measured empty while at an average temperature of 16.4°C. The tabulated volumes and the error estimates apply to the tank under these conditions. The volumes have also been corrected for the volume occupied by the corrugations (deadwood) which was measured in the laboratory using a hydrostatic displacement technique.

The measurement method used includes geometrically redundant cross checks which allow assessment of the random error in the measurement process. For this tank, the total volume, excluding the vapor domes, was 27655.0 m³ with an uncertainty of 5.5 m³ (0.01% of total volume) at the three standard deviation limit of random error. Including an analysis of probable systematics by adding the absolute magnitude of the error sources, we estimate that the total uncertainty, at the 99% confidence level, is $\pm 0.10\%$ of the total volume. No estimates of the errors in the individual table entries are included, since without an estimate of the height error introduced by the liquid level gage such estimates would of necessity be incomplete.

REPORT OF TEST

For: Tank #4 on the LNG Tanker
El Paso Southern

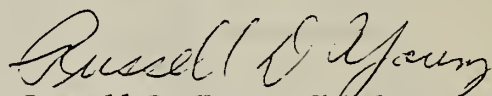

Requested by: El Paso Marine Company
2919 Allen Parkway
P. O. Box 1592
Houston, TX 77001

The following tables have been calculated from dimensional measurements on tank number 4 of the liquefied natural gas tanker El Paso Southern while berthed at Newport News Shipbuilding and Drydock Company, Newport News, VA. These tables represent the volume of a liquid enclosed in the tank as a function of the height of the liquid surface, measured along a straight line, fixed with respect to the tank. This line is defined as being located at the longitudinal center line of the tank's capacitance gage. Secondary tables are also presented which allow correction of the main tables for specific angles of ship orientation with respect to gravity, as referred to the six sets of draft marks on the ship's hull.

The tank was measured empty while at an average temperature of 10.0°C. The tabulated volumes and the error estimates apply to the tank under these conditions. The volumes have also been corrected for the volume occupied by the corregations (deadwood) which was measured in the laboratory using a hydrostatic displacement technique.

These tables are not based on a complete survey of the tank, since scaffolding necessary for complete interior access was not present at the time of measurement. As a consequence, geometrically redundant cross checks reported of tanks 1, 2 and 3 were not made on this tank to assess random measurement errors. The estimated uncertainty of the tables is instead based on the comparison of measurements on tanks 1, 2 and 3 against their respective nominal construction dimensions. These comparisons showed measured dimensions were in general within 0.2% of the nominals so an estimated uncertainty of $\pm 0.2\%$ of total volume is assigned to the tables.

REPORT OF TEST

For: Tank #5 on the LNG Tanker
El Paso Southern

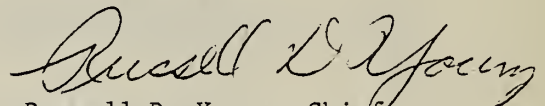

Requested by: El Paso Marine Company
2919 Allen Parkway
P. O. Box 1592
Houston, TX 77001

The following tables have been calculated from dimensional measurements on tank number 5 of the liquefied natural gas tanker El Paso Southern while berthed at Newport News Shipbuilding and Drydock Company, Newport News, VA. These tables represent the volume of a liquid enclosed in the tank as a function of the height of the liquid surface, measured along a straight line, fixed with respect to the tank. This line is defined as being located at the longitudinal center line of the tank's capacitance gage. Secondary tables are also presented which allow correction of the main tables for specific angles of ship orientation with respect to gravity, as referred to the six sets of draft marks on the ship's hull.

The tank was measured empty while at an average temperature of 6.4°C. The tabulated volumes and the error estimates apply to the tank under these conditions. The volumes have also been corrected for the volume occupied by the corregations (deadwood) which was measured in the laboratory using a hydrostatic displacement technique.

These tables are not based on a complete survey of the tank, since scaffolding necessary for complete interior access was not present at the time of measurement. As a consequence, geometrically redundant cross checks reported of tanks 1, 2 and 3 were not made on this tank to assess random measurement errors. The estimated uncertainty of the tables is instead based on the comparison of measurements on tanks 1, 2 and 3 against their respective nominal construction dimensions. These comparisons showed measured dimensions were in general within 0.2% of the nominals so an estimated uncertainty of $\pm 0.2\%$ of total volume is assigned to the tables.

REPORT OF TEST

For: Tank #6 on the LNG Tanker
El Paso Southern

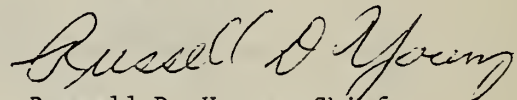

Requested by: El Paso Marine Company
2919 Allen Parkway
P. O. Box 1592
Houston, TX 77001

The following tables have been calculated from dimensional measurements on tank number 6 of the liquefied natural gas tanker El Paso Southern while berthed at Newport News Shipbuilding and Drydock Company, Newport News, VA. These tables represent the volume of a liquid enclosed in the tank as a function of the height of the liquid surface, measured along a straight line, fixed with respect to the tank. This line is defined as being located at the longitudinal center line of the tank's capacitance gage. Secondary tables are also presented which allow correction of the main tables for specific angles of ship orientation with respect to gravity, as referred to the six sets of draft marks on the ship's hull.

The tank was measured empty while at an average temperature of 3.8°C. The tabulated volumes and the error estimates apply to the tank under these conditions. The volumes have also been corrected for the volume occupied by the corrugations (deadwood) which was measured in the laboratory using a hydrostatic displacement technique.

These tables are not based on a complete survey of the tank, since scaffolding necessary for complete interior access was not present at the time of measurement. As a consequence, geometrically redundant cross checks reported of tanks 1, 2 and 3 were not made on this tank to assess random measurement errors. The estimated uncertainty of the tables is instead based on the comparison of measurements on tanks 1, 2 and 3 against their respective nominal construction dimensions. These comparisons showed measured dimensions were in general within 0.2% of the nominals so an estimated uncertainty of $\pm 0.2\%$ of total volume is assigned to the tables.

Appendix B

Calibration Reports for the Six Tanks of the El Paso Arzew

U.S. DEPARTMENT OF COMMERCE
NATIONAL BUREAU OF STANDARDS
WASHINGTON, D.C. 20234

REPORT OF CALIBRATION

For: Tank #1 on the LNG Tanker
El Paso Arzew

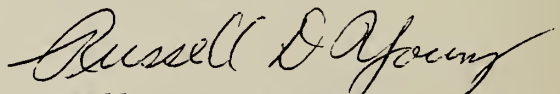

Requested by: El Paso Marine Company
2919 Allen Parkway
P. O. Box 1592
Houston, TX 77001

The following tables have been calculated from dimensional measurements on tank number 1 of the liquefied natural gas tanker El Paso Arzew while berthed at Newport News Shipbuilding and Drydock Company, Newport News, VA. These tables represent the volume of a liquid enclosed in the tank as a function of the height of the liquid surface, measured along a straight line, fixed with respect to the tank. This line is defined as being located at the longitudinal center line of the tank's capacitance gage. Secondary tables are also presented which allow correction of the main tables for specific angles of ship orientation with respect to gravity, as referred to the six sets of draft marks on the ship's hull. Both the measurement method and the computational algorithms are outlined in the paper "Multiple Redundancy in the Measurement of Large Structures," Annals of the International Institution of Production Engineering Research (CIRP), Volume 27/1, 1978.

The tank was measured empty while at an average temperature of 23.0°C. The tabulated volumes and the error estimates apply to the tank under these conditions. The volumes have also been corrected for the volume occupied by the corregations (deadwood) which was measured in the laboratory using a hydrostatic displacement technique.

The measurement method used includes geometrically redundant cross checks which allow assessment of the random error in the measurement process. For this tank, the total volume, excluding the vapor domes, was 12571.8 m³ with an uncertainty of 6.3 m³ (0.05% of total volume) at the three standard deviation limit of random error. Including an analysis of probable systematics by adding the absolute magnitude of the error sources, we estimate that the total uncertainty, at the 99% confidence level, is $\pm 0.10\%$ of the total volume. No estimates of the errors in the individual table entries are included, since without an estimate of the height error introduced by the liquid level gage such estimates would of necessity be incomplete.

REPORT OF CALIBRATION

For: Tank #2 on the LNG Tanker
El Paso Arzew

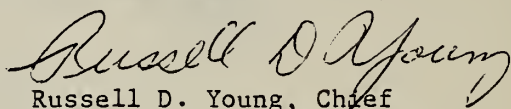

Requested by: El Paso Marine Company
2919 Allen Parkway
P. O. Box 1592
Houston, TX 77001

The following tables have been calculated from dimensional measurements on tank number 2 of the liquefied natural gas tanker El Paso Arzew while berthed at Newport News Shipbuilding and Drydock Company, Newport News, VA. These tables represent the volume of a liquid enclosed in the tank as a function of the height of the liquid surface, measured along a straight line, fixed with respect to the tank. This line is defined as being located at the longitudinal center line of the tank's capacitance gage. Secondary tables are also presented which allow correction of the main tables for specific angles of ship orientation with respect to gravity, as referred to the six sets of draft marks on the ship's hull. Both the measurement method and the computational algorithms are outlined in the paper "Multiple Redundancy in the Measurement of Large Structures," Annals of the International Institution of Production Engineering Research (CIRP), Volume 27/1, 1978.

The tank was measured empty while at an average temperature of 23.5°C. The tabulated volumes and the error estimates apply to the tank under these conditions. The volumes have also been corrected for the volume occupied by the corrugations (deadwood) which was measured in the laboratory using a hydrostatic displacement technique.

The measurement method used includes geometrically redundant cross checks which allow assessment of the random error in the measurement process. For this tank, the total volume, excluding the vapor domes, was 24885.3 m³ with an uncertainty of 12.4 m³ (0.05% of total volume) at the three standard deviation limit of random error. Including an analysis of probable systematics by adding the absolute magnitude of the error sources, we estimate that the total uncertainty, at the 99% confidence level, is + 0.10% of the total volume. No estimates of the errors in the individual table entries are included, since without an estimate of the height error introduced by the liquid level gage such estimates would of necessity be incomplete.

REPORT OF CALIBRATION

For: Tank #3 on the LNG Tanker
El Paso Arzew

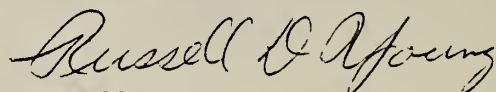

Requested by: El Paso Marine Company
2919 Allen Parkway
P. O. Box 1592
Houston, TX 77001

The following tables have been calculated from dimensional measurements on tank number 3 of the liquefied natural gas tanker El Paso Arzew while berthed at Newport News Shipbuilding and Drydock Company, Newport News, VA. These tables represent the volume of a liquid enclosed in the tank as a function of the height of the liquid surface, measured along a straight line, fixed with respect to the tank. This line is defined as being located at the longitudinal center line of the tank's capacitance gage. Secondary tables are also presented which allow correction of the main tables for specific angles of ship orientation with respect to gravity, as referred to the six sets of draft marks on the ship's hull. Both the measurement method and the computational algorithms are outlined in the paper "Multiple Redundancy in the Measurement of Large Structures," Annals of the International Institution of Production Engineering Research (CIRP), Volume 27/1, 1978.

The tank was measured empty while at an average temperature of 23.5°C. The tabulated volumes and the error estimates apply to the tank under these conditions. The volumes have also been corrected for the volume occupied by the corregations (deadwood) which was measured in the laboratory using a hydrostatic displacement technique.

The measurement method used includes geometrically redundant cross checks which allow assessment of the random error in the measurement process. For this tank, the total volume, excluding the vapor domes, was 27646.0 m³ with an uncertainty of 13.8 m³ (0.05% of total volume) at the three standard deviation limit of random error. Including an analysis of probable systematics by adding the absolute magnitude of the error sources, we estimate that the total uncertainty, at the 99% confidence level, is $\pm 0.10\%$ of the total volume. No estimates of the errors in the individual table entries are included, since without an estimate of the height error introduced by the liquid level gage such estimates would of necessity be incomplete.

REPORT OF TEST

For: Tank #4 on the LNG Tanker
El Paso Arzew

Requested by: El Paso Marine Company
2919 Allen Parkway
P. O. Box 1592
Houston, TX 77001

The following tables have been calculated from dimensional measurements on tank number 4 of the liquefied natural gas tanker El Paso Arzew while berthed at Newport News Shipbuilding and Drydock Company, Newport News, VA. These tables represent the volume of a liquid enclosed in the tank as a function of the height of the liquid surface, measured along a straight line, fixed with respect to the tank. This line is defined as being located at the longitudinal center line of the tank's capacitance gage. Secondary tables are also presented which allow correction of the main tables for specific angles of ship orientation with respect to gravity, as referred to the six sets of draft marks on the ship's hull.

The tank was measured empty while at an average temperature of 27.3°C. The tabulated volumes and the error estimates apply to the tank under these conditions. The volumes have also been corrected for the volume occupied by the corregations (deadwood) which was measured in the laboratory using a hydrostatic displacement technique.

These tables are not based on a complete survey of the tank, since scaffolding necessary for complete interior access was not present at the time of measurement. As a consequence, geometrically redundant cross checks reported of tanks 1, 2, 3, 5, and 6 were not made on this tank to assess random measurement errors. The estimated uncertainty of the tables is instead based on the comparison of measurements on tanks 1, 2, 3, 5, and 6 against their respective nominal construction dimensions. These comparisons showed measured dimensions were in general within 0.2% of the nominals so an estimated uncertainty of $\pm 0.2\%$ of total volume is assigned to the tables.

REPORT OF CALIBRATION

For: Tank #5 on the LNG Tanker
El Paso Arzew

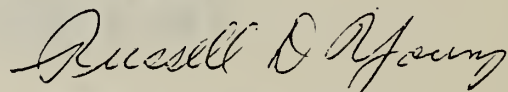

Requested by: El Paso Marine Company
2919 Allen Parkway
P. O. Box 1592
Houston, TX 77001

The following tables have been calculated from dimensional measurements on tank number 5 of the liquefied natural gas tanker El Paso Arzew while berthed at Newport News Shipbuilding and Drydock Company, Newport News, VA. These tables represent the volume of a liquid enclosed in the tank as a function of the height of the liquid surface, measured along a straight line, fixed with respect to the tank. This line is defined as being located at the longitudinal center line of the tank's capacitance gage. Secondary tables are also presented which allow correction of the main tables for specific angles of ship orientation with respect to gravity, as referred to the six sets of draft marks on the ship's hull. Both the measurement method and the computational algorithms are outlined in the paper "Multiple Redundancy in the Measurement of Large Structures," Annals of the International Institution of Production Engineering Research (CIRP), Volume 27/1, 1978.

The tank was measured empty while at an average temperature of 27.1°C. The tabulated volumes and the error estimates apply to the tank under these conditions. The volumes have also been corrected for the volume occupied by the corregations (deadwood) which was measured in the laboratory using a hydrostatic displacement technique.

The measurement method used includes geometrically redundant cross checks which allow assessment of the random error in the measurement process. For this tank, the total volume, excluding the vapor domes, was 27622.9 m³ with an uncertainty of 13.8 m³ (0.05% of total volume) at the three standard deviation limit of random error. Including an analysis of probable systematics by adding the absolute magnitude of the error sources, we estimate that the total uncertainty, at the 99% confidence level, is $\pm 0.10\%$ of the total volume. No estimates of the errors in the individual table entries are included, since without an estimate of the height error introduced by the liquid level gage such estimates would of necessity be incomplete.

REPORT OF CALIBRATION

For: Tank #6 on the LNG Tanker
El Paso Arzew

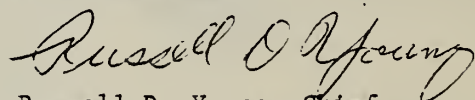

Requested by: El Paso Marine Company
2919 Allen Parkway
P. O. Box 1592
Houston, TX 77001

The following tables have been calculated from dimensional measurements on tank number 6 of the liquefied natural gas tanker El Paso Arzew while berthed at Newport News Shipbuilding and Drydock Company, Newport News, VA. These tables represent the volume of a liquid enclosed in the tank as a function of the height of the liquid surface, measured along a straight line, fixed with respect to the tank. This line is defined as being located at the longitudinal center line of the tank's capacitance gage. Secondary tables are also presented which allow correction of the main tables for specific angles of ship orientation with respect to gravity, as referred to the six sets of draft marks on the ship's hull. Both the measurement method and the computational algorithms are outlined in the paper "Multiple Redundancy in the Measurement of Large Structures," Annals of the International Institution of Production Engineering Research (CIRP), Volume 27/1, 1978.

The tank was measured empty while at an average temperature of 29.0°C. The tabulated volumes and the error estimates apply to the tank under these conditions. The volumes have also been corrected for the volume occupied by the corregations (deadwood) which was measured in the laboratory using a hydrostatic displacement technique.

The measurement method used includes geometrically redundant cross checks which allow assessment of the random error in the measurement process. For this tank, the total volume, excluding the vapor domes, was 27639.1 m³ with an uncertainty of 13.8 m³ (0.05% of total volume) at the three standard deviation limit of random error. Including an analysis of probable systematics by adding the absolute magnitude of the error sources, we estimate that the total uncertainty, at the 99% confidence level, is + 0.10% of the total volume. No estimates of the errors in the individual table entries are included, since without an estimate of the height error introduced by the liquid level gage such estimates would of necessity be incomplete.

Calibration Reports for the Six Tanks of the El Paso Howard Boyd

U.S. DEPARTMENT OF COMMERCE
NATIONAL BUREAU OF STANDARDS
WASHINGTON, D.C. 20234

REPORT OF CALIBRATION

For: Tank #1 on the LNG Tanker
El Paso Howard Boyd

Requested by: El Paso Marine Company
2919 Allen Parkway
P. O. Box 1592
Houston, TX 77001

The following tables have been calculated from dimensional measurements on tank number 1 of the liquefied natural gas tanker El Paso Howard Boyd while berthed at Newport News Shipbuilding and Drydock Company, Newport News, VA. These tables represent the volume of a liquid enclosed in the tank as a function of the height of the liquid surface, measured along a straight line, fixed with respect to the tank. This line is defined as being located at the longitudinal center line of the tank's capacitance gage. Secondary tables are also presented which allow correction of the main tables for specific angles of ship orientation with respect to gravity, as referred to the six sets of draft marks on the ship's hull. Both the measurement method and the computational algorithms are outlined in the paper "Multiple Redundancy in the Measurement of Large Structures," Annals of the International Institution of Production Engineering Research (CIRP), Volume 27/1, 1978.

The tank was measured empty while at an average temperature of 22.6°C. The tabulated volumes and the error estimates apply to the tank under these conditions. The volumes have also been corrected for the volume occupied by the corregations (deadwood) which was measured in the laboratory using a hydrostatic displacement technique.

The measurement method used includes geometrically redundant cross checks which allow assessment of the random error in the measurement process. For this tank, the total volume, excluding the vapor domes, was 12554.3 m³ with an uncertainty of 6.3 m³ (0.05% of total volume) at the three standard deviation limit of random error. Including an analysis of probable systematics by adding the absolute magnitude of the error sources, we estimate that the total uncertainty, at the 99% confidence level, is + 0.10% of the total volume. No estimates of the errors in the individual table entries are included, since without an estimate of the height error introduced by the liquid level gage such estimates would of necessity be incomplete.

WASHINGTON, D.C. 20234

REPORT OF CALIBRATION

For: Tank #2 on the LNG Tanker
El Paso Howard Boyd

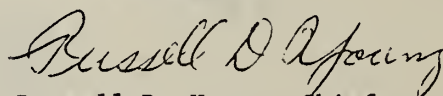

Requested by: El Paso Marine Company
2919 Allen Parkway
P. O. Box 1592
Houston, TX 77001

The following tables have been calculated from dimensional measurements on tank number 2 of the liquefied natural gas tanker El Paso Howard Boyd while berthed at Newport News Shipbuilding and Drydock Company, Newport News, VA. These tables represent the volume of a liquid enclosed in the tank as a function of the height of the liquid surface, measured along a straight line, fixed with respect to the tank. This line is defined as being located at the longitudinal center line of the tank's capacitance gage. Secondary tables are also presented which allow correction of the main tables for specific angles of ship orientation with respect to gravity, as referred to the six sets of draft marks on the ship's hull. Both the measurement method and the computational algorithms are outlined in the paper "Multiple Redundancy in the Measurement of Large Structures," Annals of the International Institution of Production Engineering Research (CIRP), Volume 27/1, 1978.

The tank was measured empty while at an average temperature of 15.2°C. The tabulated volumes and the error estimates apply to the tank under these conditions. The volumes have also been corrected for the volume occupied by the corregations (deadwood) which was measured in the laboratory using a hydrostatic displacement technique.

The measurement method used includes geometrically redundant cross checks which allow assessment of the random error in the measurement process. For this tank, the total volume, excluding the vapor domes, was 24844.4 m³ with an uncertainty of 12.4 m³ (0.05% of total volume) at the three standard deviation limit of random error. Including an analysis of probable systematics by adding the absolute magnitude of the error sources, we estimate that the total uncertainty, at the 99% confidence level, is $\pm 0.10\%$ of the total volume. No estimates of the errors in the individual table entries are included, since without an estimate of the height error introduced by the liquid level gage such estimates would of necessity be incomplete.

REPORT OF CALIBRATION

For: Tank #3 on the LNG Tanker
El Paso Howard Boyd

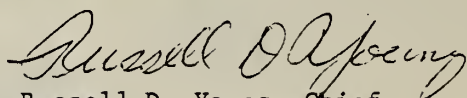

Requested by: El Paso Marine Company
2919 Allen Parkway
P. O. Box 1592
Houston, TX 77001

The following tables have been calculated from dimensional measurements on tank number 3 of the liquefied natural gas tanker El Paso Howard Boyd while berthed at Newport News Shipbuilding and Drydock Company, Newport News, VA. These tables represent the volume of a liquid enclosed in the tank as a function of the height of the liquid surface, measured along a straight line, fixed with respect to the tank. This line is defined as being located at the longitudinal center line of the tank's capacitance gage. Secondary tables are also presented which allow correction of the main tables for specific angles of ship orientation with respect to gravity, as referred to the six sets of draft marks on the ship's hull. Both the measurement method and the computational algorithms are outlined in the paper "Multiple Redundancy in the Measurement of Large Structures," Annals of the International Institution of Production Engineering Research (CIRP), Volume 27/1, 1978.

The tank was measured empty while at an average temperature of 15.0°C. The tabulated volumes and the error estimates apply to the tank under these conditions. The volumes have also been corrected for the volume occupied by the corregations (deadwood) which was measured in the laboratory using a hydrostatic displacement technique.

The measurement method used includes geometrically redundant cross checks which allow assessment of the random error in the measurement process. For this tank, the total volume, excluding the vapor domes, was 27615.6 m³ with an uncertainty of 13.8 m³ (0.05% of total volume) at the three standard deviation limit of random error. Including an analysis of probable systematics by adding the absolute magnitude of the error sources, we estimate that the total uncertainty, at the 99% confidence level, is $\pm 0.10\%$ of the total volume. No estimates of the errors in the individual table entries are included, since without an estimate of the height error introduced by the liquid level gage such estimates would of necessity be incomplete.

REPORT OF CALIBRATION

For: Tank #4 on the LNG Tanker
El Paso Howard Boyd

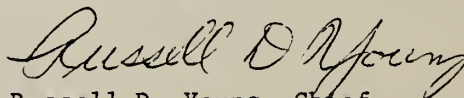

Requested by: El Paso Marine Company
2919 Allen Parkway
P. O. Box 1592
Houston, TX 77001

The following tables have been calculated from dimensional measurements on tank number 4 of the liquefied natural gas tanker El Paso Howard Boyd while berthed at Newport News Shipbuilding and Drydock Company, Newport News, VA. These tables represent the volume of a liquid enclosed in the tank as a function of the height of the liquid surface, measured along a straight line, fixed with respect to the tank. This line is defined as being located at the longitudinal center line of the tank's capacitance gage. Secondary tables are also presented which allow correction of the main tables for specific angles of ship orientation with respect to gravity, as referred to the six sets of draft marks on the ship's hull. Both the measurement method and the computational algorithms are outlined in the paper "Multiple Redundancy in the Measurement of Large Structures," Annals of the International Institution of Production Engineering Research (CIRP), Volume 27/1, 1978.

The tank was measured empty while at an average temperature of 25.8°C. The tabulated volumes and the error estimates apply to the tank under these conditions. The volumes have also been corrected for the volume occupied by the corregations (deadwood) which was measured in the laboratory using a hydrostatic displacement technique.

The measurement method used includes geometrically redundant cross checks which allow assessment of the random error in the measurement process. For this tank, the total volume, excluding the vapor domes, was 6249.3 m³ with an uncertainty of 3.1 m³ (0.05% of total volume) at the three standard deviation limit of random error. Including an analysis of probable systematics by adding the absolute magnitude of the error sources, we estimate that the total uncertainty, at the 99% confidence level, is ± 0.10% of the total volume. No estimates of the errors in the individual table entries are included, since without an estimate of the height error introduced by the liquid level gage such estimates would of necessity be incomplete.

REPORT OF CALIBRATION

For: Tank #5 on the LNG Tanker
El Paso Howard Boyd

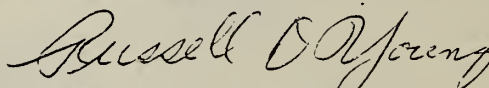

Requested by: El Paso Marine Company
2919 Allen Parkway
P. O. Box 1592
Houston, TX 77001

The following tables have been calculated from dimensional measurements on tank number 5 of the liquefied natural gas tanker El Paso Howard Boyd while berthed at Newport News Shipbuilding and Drydock Company, Newport News, VA. These tables represent the volume of a liquid enclosed in the tank as a function of the height of the liquid surface, measured along a straight line, fixed with respect to the tank. This line is defined as being located at the longitudinal center line of the tank's capacitance gage. Secondary tables are also presented which allow correction of the main tables for specific angles of ship orientation with respect to gravity, as referred to the six sets of draft marks on the ship's hull. Both the measurement method and the computational algorithms are outlined in the paper "Multiple Redundancy in the Measurement of Large Structures," Annals of the International Institution of Production Engineering Research (CIRP), Volume 27/1, 1978.

The tank was measured empty while at an average temperature of 22.2°C. The tabulated volumes and the error estimates apply to the tank under these conditions. The volumes have also been corrected for the volume occupied by the corrogations (deadwood) which was measured in the laboratory using a hydrostatic displacement technique.

The measurement method used includes geometrically redundant cross checks which allow assessment of the random error in the measurement process. For this tank, the total volume, excluding the vapor domes, was 27637.4 m³ with an uncertainty of 13.8 m³ (0.05% of total volume) at the three standard deviation limit of random error. Including an analysis of probable systematics by adding the absolute magnitude of the error sources, we estimate that the total uncertainty, at the 99% confidence level, is $\pm 0.10\%$ of the total volume. No estimates of the errors in the individual table entries are included, since without an estimate of the height error introduced by the liquid level gage such estimates would of necessity be incomplete.

REPORT OF CALIBRATION

For: Tank #6 on the LNG Tanker
El Paso Howard Boyd

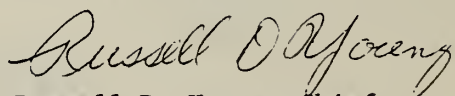

Requested by: El Paso Marine Company
2919 Allen Parkway
P. O. Box 1592
Houston, TX 77001

The following tables have been calculated from dimensional measurements on tank number 6 of the liquefied natural gas tanker El Paso Howard Boyd while berthed at Newport News Shipbuilding and Drydock Company, Newport News, VA. These tables represent the volume of a liquid enclosed in the tank as a function of the height of the liquid surface, measured along a straight line, fixed with respect to the tank. This line is defined as being located at the longitudinal center line of the tank's capacitance gage. Secondary tables are also presented which allow correction of the main tables for specific angles of ship orientation with respect to gravity, as referred to the six sets of draft marks on the ship's hull. Both the measurement method and the computational algorithms are outlined in the paper "Multiple Redundancy in the Measurement of Large Structures," Annals of the International Institution of Production Engineering Research (CIRP), Volume 27/1, 1978.

The tank was measured empty while at an average temperature of 20.6°C. The tabulated volumes and the error estimates apply to the tank under these conditions. The volumes have also been corrected for the volume occupied by the corregations (deadwood) which was measured in the laboratory using a hydrostatic displacement technique.

The measurement method used includes geometrically redundant cross checks which allow assessment of the random error in the measurement process. For this tank, the total volume, excluding the vapor domes, was 27631.2 m³ with an uncertainty of 13.8 m³ (0.05% of total volume) at the three standard deviation limit of random error. Including an analysis of probable systematics by adding the absolute magnitude of the error sources, we estimate that the total uncertainty, at the 99% confidence level, is $\pm 0.10\%$ of the total volume. No estimates of the errors in the individual table entries are included, since without an estimate of the height error introduced by the liquid level gage such estimates would of necessity be incomplete.

For the Director,

Russell D. Young, Chief
Mechanical Processes Division
Center for Mechanical Engineering
and Process Technology

16. ABSTRACT (A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here.) The National Bureau of Standards has completed a study on the calibration uncertainty of ship cargo tanks used to transport Liquid Natural Gas (LNG). The data from measurements made on 18 such tanks is presented, along with a comparison to measurement determined from an independent technique. Calibration reports for each tank measured by NBS are presented, including tables that relate tank volume to liquid level in the tank. The measurement technique used was accurate to $\pm 0.05\%$ of total volume and agreed with the independent measurement data to $\pm 0.2\%$.
