PREFACE

This report is one of a group documenting National Bureau of Standards (NBS) research and analysis efforts in developing water conservation test methods, models for technical and economic analysis, and strategies for implementation and acceptance of practices. This work is sponsored by the Department of Housing and Urban Development, Office of Policy Development and Research, Building Technology and Standards Division, under HUD Interagency Agreement H-48-78.

SUMMARY

The criteria governing the development of steady partially filled supercritical pipe flow are presented together with the necessary techniques to determine the water surface profile in the pipe entry transition length.

The establishment of full bore flow is predicted for a range of flow rates and pipe design parameters. Based on the water surface profile calculation technique pipe length predictions are presented to avoid the air pressure fluctuations in the drainage system that result from full bore flow establishment.

Tabular data are presented to allow design decisions to be made that link pipe slope, diameter and roughness to the need to avoid full bore flow. A graphical technique is also presented that removes the necessity to interpolate from the tabular data.

The effect of entry geometry loss coefficients is included in the techniques presented.

CONTENTS

LIST OF FIGURES AND TABLES

NOTATION

A	Channel cross sectional area
C	Chezy constant
D	Pipe diameter
E	Specific energy
g	Acceleration due to gravity
h	Flow depth
h_c	Critical flow depth
h_e	Entry flow depth
h_n	Normal flow depth
L	Transition length
m	Hydraulic mean depth
n	Manning coefficient
P	Wetted perimeter
Q	Flow rate
S	Slope of energy grade line
S_o	Channel slope
T	Water surface width in channel
V	Local average velocity
x	Axial flow direction
Z	Elevation channel above some datum
ρ	Fluid density
θ_1	Approach pipe slope
θ_2	Test pipe slope

1. INTRODUCTION

In the design of building drainage systems the maintenance of appliance trap seals is a major criterion. Trap seal depletion may occur as a result of either negative or positive air pressure transients in the drainage pipework. Positive pressures may be generated if the water flow in the system becomes full bore at some downstream location. The most common cause of such a closure of the air passage above the water surface is the flow depth change that accompanies a change in pipe slope. The transition from vertical stack flow to the near horizontal building drain, commonly set at gradients in the range 1/40 to 1/80, results in a rapid depth increase downstream of the slope change that may result in the establishment of local full bore flow. Transition from the entry depth to a greater depth can be erroneously interpreted in experimental observations as an hydraulic jump; the theoretical predictions developed here indicate that a monotonically increasing (smooth) depth change can occur. The conditions under which a hydraulic jump exist are discussed in an earlier study [1].

The design criteria necessary to avoid this condition are set out in this report, together with the necessary computing techniques and design table examples for a range of typical pipe diameters, gradients and flow rates.

1

2. THEORETICAL CONSIDERATIONS

2.1 STEADY, UNIFORM FLOW IN PARTIALLY FILLED PIPE FLOW

Figure 1 illustrates the force balance equation for steady flow in an open
channel or partially filled duct. The common expression of this relationship
is known as the Chezy equation where

$$V = C \sqrt{m S_o} \tag{1}$$

m = hydraulic mean depth A/P, m
S_o = sin θ, duct slope
V = mean velocity, m/s
C = Chezy constant.

The value of loss coefficient C was found by Manning to be dependent on
hydraulic mean depth and duct surface roughness n. The Manning formula is the
simplest of the open channel equations:

$$V = \frac{1}{n} m^{2/3} S_o^{1/2}$$

$$Q = \frac{1}{n} A m^{2/3} S_o^{1/2} \tag{2}$$

where Q is the flow rate m^3/s
A is the flow cross sectional area, m^2

The value of the Manning coefficient, n, varies with pipe or channel material.
Chow [2] suggests values in the range 0.009 to 0.020 for materials commonly
found in building drainage systems. The utilization of n as a variable with
depth can be introduced (in the computer program) for more detailed calculations.
The effects of wall accumulations on n as a function of deposited materials is
unknown.

Equation 1 effectively determines the flow depth, h, under steady, uniform
conditions, only one value of h yielding the values of A and m necessary to
satisfy the equation. As this depth is by definition constant downstream,
dh/dx = 0, it must also be the terminal depth corresponding to the flow
terminal velocity at that channel slope.

This depth, h_n, is commonly referred to as the normal depth.

The specific energy of the flow may be defined as

$$E = h + \frac{V^2}{2g} \tag{3}$$

where h = local flow depth, m
       V = local average flow velocity, m/s

Figure 2 illustrates the alternate depths that will satisfy equation (3) and their significance in terms of the flow definition.

From equation (3) and figure 2 it may also be seen that the flow specific energy has a minimum value below which the given flow conditions cannot exist. In a general, non rectangular channel this value may be determined:

$$E = h + \frac{Q^2}{2gA^2}$$

$$\frac{dE}{dh} = 0 = 1 - \frac{Q^2}{gA^3}\frac{dA}{dh} \tag{4}$$

From figure 3

$$dA = T\,dh \tag{5}$$

where   T is the surface width at any depth, h.

From equations (4) and (5) the minimum value of E will occur at a depth value, h_c, that satisfies the expression

$$1 - Q^2T/gA^3 = 0 \tag{6}$$

This value of h is referred to as the flow critical depth h_c.

If the normal flow depth h_n exceeds h_c then the terminal flow would be termed subcritical, or tranquil flow. If h_n is less than h_c then the flow is termed rapid or supercritical.

It should be stressed that h_c is independent of pipe slope and pipe surface roughness; while the normal depth is dependent on both. Thus the same volume flow rate in any particular pipe may be rapid or tranquil depending on pipe slope, and similarly the same flow rate in a series of constant diameter pipes will be tranquil or rapid depending on roughness.

Pipes or channels in which rapid flow is normal are termed steep, pipes or channels in which tranquil flow is normal are termed of mild slope.

2.2   ENTRY TRANSITION LENGTH IN PARTIALLY FILLED PIPE FLOW

It will be seen from figure 2 that the flow depth at any point along a partially filled drain is dependent on both flow rate and specific energy. However the only stable depth is that represented by the normal flow equation, (2), thus a transition region may be expected in any partially filled pipe flow when the inlet flow conditions, expressed in terms of Q and E, do not match the normal depth characteristic values.

At the base of a vertical stack it is unlikely that the flow rate and specific energy will match the downstream drain normal depth values. In general the specific energy at the drain inlet will be higher than the normal depth and

3

flow characteristic specific energy, so that the entry flow depth will be less than the downstream normal depth.

Under these conditions frictional forces acting on the fluid flow result in an increase in flow depth downstream until the flow normal depth is reached. Thus a transition regime may be identified whose length is dependent on the pipe slope, diameter and roughness and the entry flow rate and specific energy. Figure 3 illustrates this transition region. This description is generally true whether the flow downstream is classified as subcritical or supercritical.

For the subcritical flow case, the normal depth to be achieved is greater than the flow critical depth and hence its establishment requires the generation of a hydraulic jump. This topic was dealt with in an earlier report [1].

For the supercritical flow case the depth profile may increase downstream until the normal depth is achieved without the generation of a hydraulic jump, or local flow depth discontinuity.

It is however necessary to distinguish clearly between the generation of local full bore flow due to a hydraulic jump and the observation of full bore flow as a result of a "smooth" transition to normal depth in supercritical flow. Comparison of the normal depth, calculated from equation (2), to the critical depth, as calculated from equation (6), is sufficient to determine whether a jump will occur, or whether it is sufficient to only consider the developing supercritical flow depth profile.

Care should be taken in any literature survey of drainage studies in this area as the term "hydraulic jump" is often used loosely to identify both the true jump condition and the establishment of full bore flow as a result of the supercritical depth transition described above.

In both cases the likelihood of full bore flow is predictable from a comparison of the target normal depth with the pipe diameter.

In the analysis presented steady flow conditions are assumed at a range of flow rates. In practice the entry flow to the drain will follow some flow vs time profile. Thus the establishment of full bore flow will depend on the peak entry flow rate and its attenuation as the inflow surge progresses down the pipe. A study of attenuation in supercritical free surface flow [2] indicates that the effect will be small over the first 5 to 6 m of drain so that it is reasonable to base design tables on the assumption that the entry profile may be represented by a series of increasing steady flow rates. Adjustments for the flow increase to permit adjustment for the series of stepwise increased rates may be made in the integrands of the equations in this report.

In order to provide design data two calculation techniques are required:

(1) Comparison of flow normal depth with both the drain critical depth value to determine the applicable flow regime, and the pipe diameter, to determine whether full bore flow is possible at this combination of flow rate, pipe diameter, gradient and roughness.

4

(2) Calculation of the water surface profile from the pipe entry downstream to either the establishment of normal depth flow or full bore flow. The necessary equations for (1) above have been established. The calculation of the water surface profile requires the use of gradually varied flow analysis.

2.3 GRADUALLY VARIED FLOW IN PARTIALLY FILLED PIPES

Gradually varied flow is steady non-uniform flow of a special type. The flow parameters are assumed to change slowly, if at all, in the flow direction. The basic assumption in the treatment of this type of flow is that the local head loss at any section is given by the Manning expression, (2), for the identical local flow depth and rate under assumed steady, uniform flow conditions.

Depth profile predictions by numerical integration are based on this assumption, expressed in terms of figure 4 by

$$\frac{d}{dL} \left\{ \frac{V^2}{2g} + (Z_o - S_o L) + h \right\} = -\left\{ \frac{nQ}{Am^{2/3}} \right\}^2 \tag{7}$$

where $(Z_o - S_o L)$ is the elevation at distance L along the channel, measured in the downstream direction; S_o is sin Θ, channel bed slope,

hence $$-\frac{V}{g}\frac{dV}{dL} + S_o - \frac{dh}{dL} = \left(\frac{nQ}{Am^{2/3}} \right)^2 \tag{8}$$

and as, Q = VA

$$\frac{dV}{dL} A + V \frac{dA}{dL} = 0$$

and as $\frac{dA}{dh} = T$ from equation 5 it follows that

$$\frac{dV}{dL} = \frac{V}{A}\frac{dA}{dL} = -\frac{VT}{A}\frac{dh}{dL} = -\frac{QT}{A^2}\frac{dh}{dL}$$

and substituting in equation (8) yields

$$\frac{Q^2 T}{gA^3}\frac{dh}{dL} + S_o - \frac{dh}{dL} = \left\{ \frac{n Q}{A\, m^{2/3}} \right\}^2 \tag{9}$$

$$dL = \left\{ \frac{1 - Q^2 T/g\, A^3}{S_o - (nQ/Am^{2/3})} \right\} dh$$

or

5

$$L = \int_{h_o}^{h_1} \frac{1 - Q^2T/gA^3}{S_o - (nQ/Am^{2/3})^2} \, dh \tag{10}$$

where L is the distance between two known depths h_o, h_1.

Figure 5 illustrates this numerical integration, which may be conveniently achieved by Simpson's rule.

The numerator and denominator of equation (10) will be recognized as the equations determining the critical and normal flow depths in an open channel.

When the term $(1 - Q^2T/gA^3)$ is zero the flow is at critical depth, i.e., there is no change in L for a change in h.

For uniform cross section channels with constant roughness, n, and slope, S_o, the expression (10) becomes solely a function of flow depth h.

In order to numerically evaluate (10) it is necessary to define boundary conditions from which the integration may proceed. It should be stressed that the integration may be carried out either upstream or downstream from a known depth point. This ability is central to the use of this technique to determine the position of a profile continuity, such as a hydraulic jump.

Figure 5 illustrates the control depths used in the prediction of the water surface profiles in the case being investigated, namely the change in slope of an open channel.

If the flow rate Q and specific energy are known at pipe entry, at B, figure 3 then the depth at B may be calculated by choosing the lower depth root of equation (4). In the study reported a range of entry specific energy values for a constant inflow were obtained by considering the entry flow at B to have attained terminal flow conditions in an approach pipe, AB figure 3, set at a range of gradients from 15° to 90°, however this artifice is not strictly necessary as any suitable energy values could have been utilized.

The choice of dh values in the numerical integration is based on the difference between the control depth at entry and the "target" depth, representing the normal flow depth to be achieved downstream.

For the example in figure 5 the dh value is

$$dh = (h_n - h_e)/N \tag{11}$$

where N is a reasonable number in the range 10-30. Since the change from h_e to h_n can be expected to fall within an order of magnitude and the monotonic change (except for the jump condition) in the function h(L) is not rapid the size of incremental steps can be of the order of unity.

6

If the normal depth, h_n, exceeds the pipe diameter, D, then the numerical
integration is terminated when the predicted flow depth exceeds the pipe
diameter value.

2.4 LOSS COEFFICIENTS FOR SLOPE TRANSITIONS IN PARTIALLY FILLED PIPE FLOW

No data could be obtained on the loss coefficients for slope transitions in
open channel flow. For this reason the results presented assume no loss at the
pipe entry. The computer program as written has been designed to include such
a loss coefficient, in the range 0 to 1, should such data become available from
a future experimental program. The effect of such a loss would be to increase
the flow depth at pipe entry, with a consequent decrease in the kinetic energy
term at pipe entry. In turn this would have the effect of generally moving
the energy transition upstream towards pipe entry. Experimental work is
required as a back up to the computer simulation to clarify this area.

3. CALCULATION TECHNIQUES AND PRESENTATION OF RESULTS

3.1 DETERMINATION OF NORMAL AND CRITICAL DEPTHS

The bisection method was used to solve the equation defining both critical flow depth

$$X = 1 - Q^2 T / g A^3$$

and normal flow depth

$$Y = S_o - (n Q/Am^{2/3})^2.$$

It may be assumed that both X and Y have zero values for some value of depth h in the range $0 < h < D$ for pipe case or $0 < h < W$ for the square section case.

This initial interval is bisected and h = D/2 or w/2 for the square section) used to evaluate X, Y. If the resulting values are positive then the root is less than the midpoint. The upper limit is then reset equal to the h value just used and the remaining interval bisected. The process repeats until a root is obtained. If the X or Y value had been negative then the root would be greater than the trial h value. In this case the lower limit is reset to the trial h value and incremented with the remaining interval bisected.

Due to the need to include the area depth relationship this solution must be undertaken by an iterative process. The computer time taken depends on the complexity of the area-depth function.

3.2 NUMERICAL INTEGRATION FOR SURFACE PROFILES

The integration of the position vs depth profile

$$L = \int_{h_o}^{h_1} \frac{1 - Q^2 T / g A^3}{S_o - (nQ/Am^{2/3})^2} \, dh$$

is achieved by means of Simpson's Rule. Let the integral $X = \int_{h_0}^{h_1} F(h) \, dh$, then if the interval $h_1 - h_0$ is divided into 2 equal increments, the value of X is given by

$$X = \frac{1}{3} dh \, [F(h_o) + 4F(h_o + dh) + F(h_o + 2 \, dh)]$$

As the integration moves on the length traversed may be accumulated as L = L + X at the completion of each integration.

3.3 PRESENTATION OF RESULTS

The transition profiles for the following cases are presented in tabular form in Appendix I:

Flow rates 2 to 12 ℓ/s, extended to 22 ℓ/s for the 0.15 m diameter pipe case

Pipe diameters: 0.075 m, 0.10 m and 0.15 m

Roughness coefficients: 0.009, 0.012, 0.015, 0.018

Pipe gradients: 1/20, 1/40, 1/60, 1/80

Entry specific energy range simulated by varying the approach pipe slope from 15° to 90°.

In addition to tabular data, an alternative graphical technique is presented.

3.4 INPUT DATA CHOICE

As far as possible the choice of input test conditions was governed by the range of values likely to be found in drainage systems. The pipe diameters chosen, 0.075, 0.10 and 0.15 conform to this criterion as do the pipe gradients used for all test cases, 1/40 to 1/80. The choice of pipe roughness or Manning coefficient was more difficult, however values in the range 0.009 to 0.015 are recommended in many texts, i.e. Jaeger [3] and Chow [4].

Losses at the change of slope that produces the conditions conducive to full bore flow have been ignored in this treatment. No available data on open channel transition loss coefficients for partially filled pipes or channels could be obtained. The program is capable of dealing with transition losses however via an input data control variable provided the loss can be expressed as a factor, 0 to 1.0, of the specific energy of the flow at pipe entry.

4. DISCUSSION OF RESULTS

The water surface profile integration downstream from pipe entry is illustrated by figures 6 and 7. It will be seen that the transition length, or the distance to full bore flow or normal depth, whichever is less, depends on both the flow rate and entry specific energy and hence any simplified prediction technique would have to include both these parameters.

The determination of whether or not full bore flow will occur at any particular combination of flow, Q, roughness, n, and pipe slope, S_o, is rather simpler, depending on a comparison of normal depth to pipe diameter.

Figure 8 presents the normal depth to pipe diameter ratio as a function of a term $nQ/S_o^{1/2}$ that may be seen to determine normal depth from the Manning expression, equation (2). It will be seen that the curves for each of the three pipe diameters tend to become linear at the higher values of h_n/D. Thus a general equation may be proposed to indicate whether full bore flow is achievable, from figure 8,

$$\frac{h_n}{D} = 0.14 + 0.0018 \, D^{-2.67} \cdot \frac{nQ}{S_o^{1/2}} \tag{12}$$

Once the establishment of full bore flow has been predicted it becomes necessary to determine whether this will occur within the system pipe length. The tables presented in Appendix 1 allow this calculation provided that the inflow rate and specific energy are known together with pipe slope, roughness and diameter.

Obviously if the transition length predicted is less than the required pipe length then design alternatives would include an increase in pipe slope, an increase in pipe diameter or the use of a smoother pipe, although it is recognized that this last alternative is unlikely to be employed.

The use of such tabular data is considered practical, however a graphical technique would have advantages in terms of the appreciation of effect of rapid design changes.

The problem to be solved here is the dependence of transition length on entry energy, however this may be bypassed if the entry depth is calculated.

Figure 9 presents the entry depth for any flow rate and specific energy combination for the three pipe diameters condensed in the form

$$h_e/D = f(Q, E)$$

$$(h_e/D)/Q = f_1(E)$$

Thus for any Q and E values the entry depth h_e may be read off figure 9.

It was found that the transition length at any pipe roughness, gradient, inflow rate and specific energy could be expressed in terms of

$$L/D \ = \ f(h_n/D - h_e/D)$$

as illustrated in figure 10.

For example, for a given flow rate the entry depth will decrease as the entry specific energy increases. Hence the depth change to be achieved to either full bore flow or normal depth increases as the entry energy rises. Therefore it would be reasonable to expect that the transition length would increase as the entry depth decreased, as shown in figure 10.

The curves in figure 10 apply to the specified one pipe diameter at one pipe slope at a range of pipe roughness coefficients. Obviously such curves may be generated from the data presented in appendix 1 for all the test cases.

It will be noted that individual points are plotted in figure 10 in the manner normal for test results and display a degree of scatter. This is due to the use of either pipe diameter or normal depth as the depth downstream target, whichever is the smaller value. This leads to a slight incompatibility between transition lengths to either D or h_n. However this scatter of the order of 2 to 3 percent and is well within the other uncertainties in the design of drainage systems, so that this technique may be proposed as a rapid visual method of determining the effect of design changes.

The tabular data presented in appendix 1 may be utilized if the entry flow rate and specific energy are known. Referring to table 1, reproduced from appendix 1, it will be seen that it will be necessary to employ an interpolation technique to determine the transition length if the flow entry rate and specific energy do not match the values given. The curves based on the tabular data presented above indicate that a simple linear interpolation would be sufficient. The format of the data, table 1, could be simplified as the approach pipe slope is, as mentioned, only included as a convenient method of determining a range in inflow specific energies.

Similarly the data could be rearranged in terms of constant inflow rate blocks instead of the constant approach pipe slope utilized in appendix 1 and table 1.

The data presented has been based on inflow rate and specific energy and does not include an entry loss coefficient. In practice the form of the entry junction from, for example, a vertical stack to the building drain would lead to a junction loss coefficient that would appear, for any given flow rate, as a reduced specific energy.

Although this loss coefficient is not included in the presented data, it is automatically accounted for in the prediction method outlined above. A reduction in specific energy for any flow rate effectively increases the entry depth, figure 9, and hence reduces the transition length, figure 10, for any one set of pipe design parameters.

11

In the absence of published data on such loss coefficients, experimental work is suggested to fill this gap and the inclusion of an estimated loss coefficient is recommended in the application of the presented data.

5. CONCLUSIONS

In supercritical flow in a partially filled pipe a transition region may be identified at the pipe entry that allows the flow depth to increase to that compatible with the flow rate and pipe parameters (slope, roughness, diameter, etc.).

This transition may lead to the establishment of full bore flow if the pipe exceeds the necessary transition length at flow rates where the normal depth, as predicted by Mannings equation, exceeds the pipe diameter.

This study has identified the conditions necessary for full bore flow and has determined the transition lengths at a range of flow rates and pipe design parameters compatible with current drainage design.

It is stressed that the design data presented is based on entry flow and specific energy. Although no entry loss coefficient has been included, this effect is automatically accounted for in the design curves presented as an entry loss would merely reduce the flow specific energy at entry and would not affect the validity of predictions based on the data presented.

Table 1. Typical Tabular Data for 0.10 m Diameter Pipe

APPENDIX 1

TABULAR DATA RELATING FLOW NORMAL DEPTH AND TRANSITION
LENGTH TO FLOW AND PIPE PARAMETERS

Cases included:

$$D \; = \; 0.075 \; m, \; Q = \; 2 - 12 \; \ell/s, \; n = 0.009 - 0.018$$
$$D \; = \; 0.10 \; m, \; Q = \; 2 - 12 \; \ell/s, \; n = 0.009 - 0.018$$
$$D \; = \; 0.15 \; m, \; Q = \; 2 - 12 \; \ell/s, \; n = 0.009 - 0.018$$
$$D \; = \; 0.15 \; m, \; Q = 14 - 22 \; \ell/s, \; n = 0.009 - 0.018$$

$$D = 0.075$$

APPENDIX 2

DESCRIPTION OF PROGRAM PROFIL 2

Program PROFIL 2

This appendix presents a complete print out of this program together with sample input data. The program was run on the NBS CBT Perkin Elmer 732 computer.

The program accepts data in SI units with the exception of flow rate which is read in liters/second and corrected to m^3/s within the program.

The program is effectively the first section of the hydraulic jump prediction program fully described in reference [1]. For this reason no detailed flow chart is included in this report.

☐ Document describes a computer program; SF-185, FIPS Software Summary, is attached.

11. ABSTRACT *(A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here)*

The criteria governing the development of steady partially filled supercritical
pipe flow are presented together with the necessary techniques to determine the
water surface profile in the pipe entry transition length.

The establishment of full bore flow is predicted for a range of flow rates and
pipe design parameters. Based on the water surface profile calculation technique
pipe length predictions are presented to avoid the air pressure fluctuations in the
drainage system that result from full bore flow establishment.

Tabular data is presented to allow design decisions to be made that link pipe
slope, diameter and roughness to the need to avoid full bore flow. A graphical
technique is also presented that removes the necessity to interpolate from the
tabular data.

The effect of entry geometry loss coefficients is included in the techniques
presented.

12. KEY WORDS *(Six to twelve entries; alphabetical order; capitalize only proper names; and separate key words by semicolons)*

Building drainage; supercritical flow; transition length; vertical stack drain
entry.
