#### ABSTRACT

Calcium aluminate hydrates and calcium aluminate hydrates containing other ions were investigated to determine the feasibility of their utilization as energy storage media. A series of these compounds were fabricated and analyzed for purity. The energy liberated on hydration of each compound was measured using conduction calorimetry and the dehydration temperature was measured using differential scanning calorimetry. Of the compounds investigated, 3CaO Al<sub>2</sub>O<sub>3</sub> 3CaSO<sub>4</sub> 32H<sub>2</sub>O liberated the largest amount of energy upon rehydration. Initially, this value was about 100 cal/g. However, after 18 cycles of hydration and dehydration this value drops to about 70 cal/g.

Key Words: Calcium-aluminum hydrates; calorimetry; dehydrating; energy storage; rehydration; solar energy.

#### 1. INTRODUCTION

Calcium aluminate hydrates and calcium aluminate hydrates modified by other ions were investigated to assess the feasibility of their utilization as phase change storage materials (PCM's). This was based on literature citations of low temperature reversible hydration-dehydration reactions involving only small changes in crystal structure rather than melting and freezing as is typical in salt hydrate PCM's.

Compounds were selected for further study if the literature indicated a dehydration reaction in the temperature range of 30 to 80 °C and excluded if the hydration reactions were known to be irreversible. However, the hydration data in the literature were only valid for a preliminary screening of potential compounds for phase change storage media. This is due to the fact that the thermal decomposition behavior of these materials depends on the partial pressure of water vapor during dehydration. Almost all of the thermal dehydration measurements cited in the literature are for ambient air of unspecified water vapor pressure. Since compounds chosen for solar energy storage applications may be used as slurries or under conditions of high relative humidity, the literature values for the thermal dehydration could only be used as a guide for selecting potential cement compounds for further investigation. In addition, little or no data on the kinetics of the hydration-dehydration reactions are available from the literature. These data were ascertained experimentally.

Based on the data from the literature the following components were selected for further study:

 $4Ca0 \cdot A1_{2}0_{3} \cdot 13H_{2}0$ 

Ca0 • A1203 • 10H20

2Ca0 • A1203 • 8H20

3Ca0 • A1203 • 3CaS04 • 32H20

3Ca0 • A1203 • CaS04 • 12H20

3Ca0 • Fe 203 • 3CaS04 • 32H 20

 $3Ca0 \cdot A1_{2}0_{3} \cdot 3CaC0_{3} \cdot 32H_{2}0$ 

 $3Ca0 \cdot Al_20_3 \cdot CaC0_3 \cdot 11H_20$ 

 $3Ca0 \cdot A1_20_3 \cdot 3CaC1_2 \cdot 32H_20$ 

 $3Ca0 \cdot A1_20_3 \cdot CaC1_2 \cdot 8H_20$ 

#### 2. CRYSTAL STRUCTURE AND MORPHOLOGY CHARACTERIZATION

. The methods used to prepare the various compounds are described subsequently. After preparation, the compounds were characterized for purity and completeness of reaction. Those not suitably pure were reformulated until a suitable purity was obtained. X-ray diffraction (XRD), and to a limited extent, scanning electron microscopy (SEM) were used for the characterization.

Prior to x-ray diffraction analysis of the compounds, a procedure was developed to prepare them for examination without changing their crystal structure as a result of drying, and for confirming that the XRD identification obtained for a dry powder was valid for the damp paste.

It was found that hydrated pastes could be prepared for x-ray diffraction analysis without altering their crystal structure by the following procedure: The slurry was filter pressed to form a filter cake of low water content (10 percent), followed by grinding the cake in absolute ethanol to form an alcohol-water-compound slurry. This was then vacuum dried at 30 °C and a pressure of 91 kilopascals. The powder was then x-rayed and the patterns compared to those obtained by the original original investigators.

To ensure that the vacuum drying procedure had not altered the crystal structure of the compounds x-ray diffraction patterns were also obtained for undried samples. This was done by intergrinding the filter cakes with a small amount of glycerin and analyzing the damp paste. The glycerin acts as a viscous thickener to prevent preferred orientation often found when performing x-ray analyses on dry powders which have a platelet morphology. Although the peak to background ratios of the damp patterns were smaller than those of the dry patterns, it was confirmed that the drying procedure did not alter the crystal structure or cause excessive preferred orientation.

#### COMPOUND PREPARATION

#### 3.1 4Ca0•Al<sub>2</sub>O<sub>3</sub>•13H<sub>2</sub>O

This compound was reported to reversibly dehydrate to  $4Ca0 \cdot Al_{2}O_{3} \cdot 11H_{2}O$ at about 50 °C at a partial pressure of water vapor of 6 mm [1, 2]. On dehydration a slight change in crystal structure occurs due to the simplification and deterioration of the order of stacking of the layers. This results in a decrease in the basal spacings as the compound goes from the 13 hydrate to the 11 hydrate and to the 7 hydrate at 120 °C [3].  $4Ca0 \cdot Al_{2}O_{3} \cdot 13H_{2}O$ was prepared by the stochiometric addition of freshly ignited CaO to a metastable monocalcium aluminate solution and shaking the mixture for several days at 25 °C. Care was taken to exclude CO<sub>2</sub> during preparation. The compound fabricated was a mixture of  $\alpha$  and  $\beta$  polymorphic forms of  $4Ca0 \cdot Al_{2}O_{3} \cdot 13H_{2}O$  and contained a few percent of unreacted Ca(OH)<sub>2</sub>. The two polymorphic forms differ only by a slight difference in the packing of the crystal lattice. There is little difference in stability between the two forms. As Ca(OH)<sub>2</sub> does not dehydrate in the temperature range under investigation, the presence of a small amount was not deemed detrimental.

#### 3.2 CaO·Al<sub>2</sub>O<sub>3</sub>·10H<sub>2</sub>O

The compound CaO+Al<sub>2</sub>O<sub>3</sub>+10H<sub>2</sub>O was reported to decompose to an amorphous calcium aluminate if heated between 50 and 75 °C in air [4]. If heated to 110°C in the presence of water vapor CaO+Al<sub>2</sub>O<sub>3</sub>+10H<sub>2</sub>O irreversibly converts to a mixture of  $3Ca+Al_2O_3+6H_2O$  and  $Al_2O_3+3H_2O$  [4]. The reversibility of the the reaction of CaO+Al<sub>2</sub>O<sub>3</sub>+0H<sub>2</sub>O to amorphous reaction product was not cited. CaO+Al<sub>2</sub>O<sub>3</sub>+10H<sub>2</sub>O is the main reaction product of hydrated calcium aluminate cement and was prepared by hydrating a commercially available calcium aluminate cement to completion.

X-ray diffraction analysis of the compound  $Ca0 \cdot Al_2O_3 \cdot 10H_2O$ , revealed the presence of minor amounts of  $4Ca0 \cdot Al_2O_3 \cdot 13H_2O$  due to the relatively impure commercial calcium cement used as a reactant. It was, however, possible to account for the  $4Ca0 \cdot Al_2O_3 \cdot 13H_2O$  contribution to the total heats of transition measured [5].

#### 3.3 2Ca0 • A1 203 • 8H20

The compound  $2Ca0 \cdot Al_2O_3 \cdot 8H_2O$  was reported to reversibly dehydrate to  $2Ca0 \cdot Al_2O_3 \cdot 7.5H_2O$ at room temperature when dried in air having 34 percent RH and to further dehydrate to  $2Ca0 \cdot Al_2O_3 \cdot 5H_2O$  when heated to  $102^\circ C$  [2]. Both the 7.5 and 5 hydrate compounds will readily convert to the 8 hydrate when exposed to a damp atmosphere. A corresponding change in the x-ray diffraction pattern for the longest basal spacing of 10.7 Å or 10.4 Å depending on the polymorphic form of the 8 hydrate, to 10.6 Å for the 7.5 hydrate resulted, indicating some structural rearrangement had occurred. The compound was prepared using a method similar to that used to prepare  $4Ca0 \cdot Al_2O_3 \cdot 13H_2O$ . However,  $2Ca0 \cdot Al_2O_3 \cdot 8H_2O$  was found to be unstable with respect to  $4Ca0 \cdot Al_2O_3 \cdot 13H_2O$  and work on this compound was discontinued.

#### 3.4 3Ca0.Al<sub>2</sub>O<sub>3</sub>.3CaSO<sub>4</sub>.32H<sub>2</sub>O

The compound  $3Ca0 \cdot Al_2O_3 \cdot 3CaSO_4 \cdot 32H_2O$  (ettringite) was reported to dehydrate to  $3Ca0 \cdot Al_2O_3 \cdot 3CaSO_4 \cdot 32OH_2O$  at 60 °C at an unspecified partial pressure of water vapor [5]. X-ray diffraction has shown that very little change occurs in the crystal structure during this dehydration. The dehydration reactions were found to be reversible down to the 7 hydrate form [7]. Ettringite forms as the result of slow reaction of  $3CaO \cdot Al_2O_3$  with  $CaSO_4 \cdot 2H_2O$  (gypsum) in solution. No secondary phases were detected in the  $3CaO \cdot Al_2O_3 \cdot 3CaSO_4 \cdot 32H_2O$  fabricated in this manner. SEM analysis revealed well formed needles about 1  $\mu$ m in length.

#### 3.5 3Ca0•A1203•CaS04•12H20

 $3Ca0 \cdot Al_{2}O_{3} \cdot CaSO_{4} \cdot 12H_{2}O$  gradually loses water on heating transforming to  $3Ca0 \cdot Al_{2}O_{3} \cdot CaSO_{4} \cdot 7H_{2}O$  by 110 °C [7, 8]. No information was available on the reversibility of the reactions.  $3Ca0 \cdot Al_{2}O_{3} \cdot CaSO_{4} \cdot 12H_{2}O$  was prepared by adding a saturated  $Ca(OH)_{2}$  solution containing sufficient  $CaSO_{4} \cdot 2H_{2}O$  to obtain a  $CaSO_{4}/Al_{2}O_{3}$  ratio of unity to a metastable calcium aluminate solution. 3Ca0·Al<sub>2</sub>O<sub>3</sub>·CaSO<sub>4</sub>·12H<sub>2</sub>O prepared in this manner was found to contain a small amount of ettringite. However, since a pure ettringite sample was available, the contribution of ettringite on the total heat of transition could be measured.

3.6 3Ca0 • Fe<sub>2</sub>O<sub>3</sub> • 3CaSO<sub>4</sub> • 32H<sub>2</sub>O

The thermal dehydration behavior of  $3Ca0 \cdot Fe_2O_3 \cdot 3CaSO_4 \cdot 32H_2O$  has been shown to be similar to that of ettringite [7], as would be expected due to the similiarity of their crystal structures.  $3CaO \cdot Fe_2O_3 \cdot 3CaSO_4 \cdot 32H_2O$  was prepared by mixing a solution of iron alum with  $Ca(OH)_2$  in suitable proportions [11]. SEM analysis revealed well formed crystals which exhibited a blocky habit.

#### 3.7 3Ca0.Al203.3CaC03.32H20

The dehydration of this compound initiates at about 75 °C and is essentially complete at 135 °C [9].  $3CaO \cdot Al_2O_3 \cdot 3CaCO_3 \cdot 32H_2O$  was prepared by dissolving CaO in an aqueous solution of sucrose. After the solution clarified by settling it was decanted into a calcium aluminate solution followed by the addition of an ammonium bicarbonate solution.  $3CaO \cdot Al_2O_3 \cdot 3CaCO_3 \cdot 32H_2O$  formed as a flocculant precipitate.

3.8 3Ca0•Al<sub>2</sub>0<sub>3</sub>•CaCO<sub>3</sub>•11H<sub>2</sub>0

This compound was reported to dehydrate over a temperature range from 75 to 150 °C [10]. It was produced by the slow reaction of calcium aluminate cement with  $Ca(OH)_2$  and  $CaCO_3$  in aqueous solution. SEM analysis revealed the  $3CaO \cdot Al_2O_3 \cdot CaCO_3 \cdot 11H_2O$  to form as thin hexagonal plates, approximately 2 µm in width.

#### 3.9 3Ca0•A1<sub>2</sub>0<sub>3</sub>•3CaC1<sub>2</sub>•32H<sub>2</sub>0

This compound was reported to initiate dehydration at about 0 °C and to decompose above 20°C [13].  $3Ca0 \cdot Al_2O_3 \cdot 3CaCl_2 \cdot 32H_2O$  was formed by the reaction of  $3Ca0 \cdot Al_2O_3$  with a CaCl<sub>2</sub> solution at -10 °C. On heating  $3Ca0 \cdot Al_2O_3 \cdot 3CaCO_3 \cdot 32H_2O$ to room temperature, it was confirmed that this compound decomposed to  $2Ca0 \cdot Al_2O_3 \cdot CaCl_2 \cdot 8H_2O$ . Further work on this compound was dropped due to its instability.

#### 3.10 3Ca0•A1<sub>2</sub>0<sub>3</sub>•CaC1<sub>2</sub>•8H<sub>2</sub>0

This compound was reported to initiate dehydration at about 120 °C [13]. 3Ca0·Al<sub>2</sub>O<sub>3</sub>·CaCl<sub>2</sub>·8H<sub>2</sub>O was produced by the slow reaction of a commercial calcium aluminate cement with Ca(OH)<sub>2</sub> and CaCl<sub>2</sub>. SEM analysis revealed this compound to form as 1  $\mu$ m plates in width

#### 4. THERMAL ANALYSIS

Two schemes were investigated for using hydrated calcium aluminate compounds to store energy. The first involved storing the compounds as wet pastes in sealed containers. As the containers are heated the compounds expel waters of hydration from their crystal structures and absorb energy as latent heat. Upon lowering the temperature of the containers, the compounds rehydrate and release the latent heat.

The compounds were tested using a differential scanning calorimeter to determine the temperature at which dehydration occurred and to determine the associated latent heats. The key feature of the differential scanning calorimetric (DSC) technique was the use of hermetically sealed sample pans which prevented the samples from dessicating during heating. All the compounds formulated for this study were tested using this method. Of these compounds only  $3Ca0 \cdot Fe_2O_3 \cdot 3CaSO_4 \cdot 32H_2O$ ,  $Ca0 \cdot Al_2O_3 \cdot 10H_2O$  and  $3Ca0 \cdot Al_2O_3 \cdot CaCO_3 \cdot 11H_2O$  exhibited reversible hydration reactions at temperatures below 140 °C.  $3Ca0 \cdot Fe_2O_3 \cdot 3CaSO_4 \cdot 32H_2O$ exhibited a reversible hydration reaction at 64 °C but the latent heat of transition was only 5 cal/g. Similarly,  $Ca0 \cdot Al_2O_3 \cdot 10H_2O$  and  $3Ca0 \cdot Al_2O_3 \cdot CaCO_3 \cdot 11H_2O$  had reversible reactions at 77 and 127 °C, respectively, with heats of transition of 6 and 24 cal/g. As a consequence of these results, it was concluded that this method of energy storage using cement compounds was not feasible.

A second method for using hydrated cement compounds to store energy involved removing the water of hydration by drying the compounds at a suitable temperature. Upon the subsequent addition of water, the compounds would rehydrate and release their latent heats of hydration. This methodology involved the determination of the temperature at which these compounds would dehydrate in dry air. This was accomplished by testing the hydrated compounds in a DSC utilizing a cell with a pinhole opening which allowed the escape of hydration water. The thermogram for 3CaO.Al<sub>2</sub>O<sub>3</sub>.3CaSO<sub>4</sub>.32H<sub>2</sub>O is shown in figure 1 while that for 3CaO.Fe<sub>2</sub>O<sub>3</sub>.3CaSO<sub>4</sub>.32H<sub>2</sub>O is shown in figure 2. Three endothermic dehydration peaks are observed for 3CaO·Al<sub>2</sub>O<sub>3</sub>·3CaSO<sub>4</sub>·32H<sub>2</sub>O. The first peak shows an onset near 67 °C and a small latent heat of dehydration. The onset of the second peak occurs near 90 °C and also shows as small heat of dehydration. The onset temperature of the third peak is about 100 °C and a relatively large heat of dehydration is observed. The thermogram for 3CaO.Fe2O3.3CaSO4.32H2O, figure 2, shows one endothermic dehydration peak with an onset near 95°C.

Once the dehydration temperatures were determined using differential scanning calorimetry the compounds were heated to temperatures above their dehydration temperatures and their latent heats of hydration measured using a conduction calorimeter. In this technique, the dried cement compound was placed in the calorimeter, equilibrium established, and excess distilled water injected into the calorimeter to hydrate the compound. The heat released as the compound rehydrated was integrated to give the latent heat in cal/g. In addition, information on the rate of heat release was also obtained.

temperature of approximately 95°C.

Table 1 lists the onsets of the dehydration peaks as measured by differential scanning calorimetry and the latent heats as measured by conduction calorimetry for the compounds investigated. The temperatures at which the compounds were dehydrated are also listed. The dehydration temperature is the temperature at which the compounds were dried for 24 hours prior to rehydration. For most of the compounds the latent heats were either too low or the temperature required to dehydrate the compounds was too high for practical application. However, compounds with significant latent heats were studied further. These were  $3Ca0 \cdot Al_{2}O_{3} \cdot 3CaSO_{4} \cdot 32H_{2}O$  and  $3Ca0 \cdot Fe_{2}O_{3} \cdot 3CaSO_{4} \cdot 32H_{2}O$  with heats of rehydration of 97 and 43 cal/g respectively after drying at 100 °C.

These compounds were alternately dehydrated at 100 °C for 24 hours and rehydrated to measure the latent heat released on thermal cycling. Results are shown in figure 3. Both compounds were observed to undergo a slow decrease in total heat release with repeated cycling. An SEM examination of the morphology of  $3Ca0 \cdot Al_2O_3 \cdot 3CaSO_4 \cdot 32H_2O$  after repeated rehydration did not suggest a reason for the decrease in latent heat. Although the latent heats decreased with the number of drying cycles, the time required for complete heat release remained constant.  $3Ca0 \cdot Al_2O_3 \cdot 3CaSO_4 \cdot 32H_2O$  was readily wetted by water and its rate of heat release was faster than the time constant of the calorimeter. This compound rapidly heated to a temperature of up to 60 °C giving off the majority of its latent heat within 10 seconds.  $3Ca0 \cdot Fe_2O_3 \cdot 3CaSO_4 \cdot 32H_2O$  also readily wetted by water but its rate of heat release was noticeably slower requiring at least a minute to release the majority of its latent heat.

The time required to fully dehydrate  $3CaO \cdot Al_2O_3 \cdot 3CaSO_4 \cdot 32H_2O$  at 100 °C in order to to achieve the maximum heat release on rehydration was 3 days. Drying 24 hr at this temperature yielded about 95 percent of the maximum drying while for 3 hr yielded about 75 percent.

#### SUMMARY

Of the compounds investigated in this study 3CaO·Al<sub>2</sub>O<sub>3</sub>·3CaSO<sub>4</sub>·32H<sub>2</sub>O, appears to be the most promising phase change storage material.

The potential for the use of  $3Ca0 \cdot Al_2O_3 \cdot 3CaSO_4 \cdot 32H_2O$  as an energy storage medium results from several factors: 1) the ability to store energy at ambient temperature; 2) low corrosivity and toxicity; and 3) the low cost of the compound. Impure  $3CaO \cdot Al_2O_3 \cdot 3CaSO_4 \cdot 32H_2O$  may be made using waste products from coal combustion including lignitic fly ash and scrubber sludge [12]. The disadvantages to the use of this compound are: 1) relatively high temperatures required for dehydration; and 2) the observed decrease in latent heat on cyclic hydration and dehydration.

Compound	Peak Onset Temperature	Dehydration Temperature	Latent heat of Hydration cal/g
$3Ca0 \cdot Al_20_3 \cdot 3CaS0_4 \cdot 32H_20$	60000	30 °C	2
	67 °C	80	8
