TABLE OF CONTENTS

Photonuclear Data-Abstract Sheets
1955-1982

I. Introduction

As used in connection with this collection of data-abstract sheets, the term photonuclear data is taken to mean any data leading to information on the electromagnetic matrix element between the ground state and excited states of a given nuclide. The most common types of reactions included in this compilation are: (e,e'), (γ,γ), (γ,γ'), (γ,n), (γ,p), etc. as well as ground-state particle capture reactions, e.g. (α,γ_0). Two reactions which fit the matrix element criterion are not included in the compilation because of their rather special nature. These are heavy particle Coulomb excitation and the thermal neutron capture reaction (n,γ_0). While the energy region of particular interest extends from 0 to 150 MeV, papers are indexed which report measurements in the region from 150 MeV to 4 GeV. Most of the experiments listed are concerned with the excitation energy range from 8 to 30 MeV, the region of the photonuclear giant resonance.

The hierarchical grouping of the photonuclear data-abstract sheets within the file is by: 1. Target Element, 2. Target Isotope, and 3. by the Bibliographic Reference Code assigned to the paper from which the data on the sheet were abstracted. In this file, colored pages are used to mark the beginning and end of the sheets for each chemical element. A brief historical sketch of the element is given on the divider sheet marking the start of each section; the information for this sketch was derived from references such as the Encyclopaedia Britannica. In those cases where the sheets for a given element make up a major part of a volume, colored pages are also used to delineate sections pertaining to the individual isotopes of the element. Each of the sections of the file, as delineated by two colored divider sheets, represents a 27 year history of the study of electromagnetic interactions in either a specific nuclide or a specifc element.

The data-abstract sheets are filed under the element and/or isotope in which the ground-state electromagnetic transition takes place. For example, the abstract sheet for a total neutron yield measurement for a naturally occurring copper sample would appear in the elemental section of the copper file. On the other hand, a measurement of the ^{62}Cu 9.73 minute positron activity produced in the same sample by photons with energies below the three-neutron separation energy for ^{65}Cu (28.68 MeV) would be filed with the sheets for ^{63}Cu. Similarly a measurement of the ground-state neutron capture cross section in ^{12}C would be filed under ^{13}C while the corresponding ground-state alpha-particle capture cross section would be filed under ^{16}O.

At the end of this volume there is a master list of the abbreviations that have been used in the index section of the abstract sheets. The listings are those used in the final published index, Photonuclear Data Index, 1973-1981, NBSIR 82-2543, issued in August 1982 by the U. S. Department of Commerce, National Bureau of Standards, Washington, DC 20234. In some cases two notations are entered for the same quantity. The second entry is the abbreviation that was used in one or more of the earlier published editions of the index.

# LITHIUM
Z=3

Lithium was discovered in 1817 by J. A. Arfredson in Sweden while analyzing the mineral petalite. The name lithium (from the Greek, *lithos*, "stone") was proposed by Jons Jacob Berzelius, a Swedish chemist and one of the founders of modern chemistry.

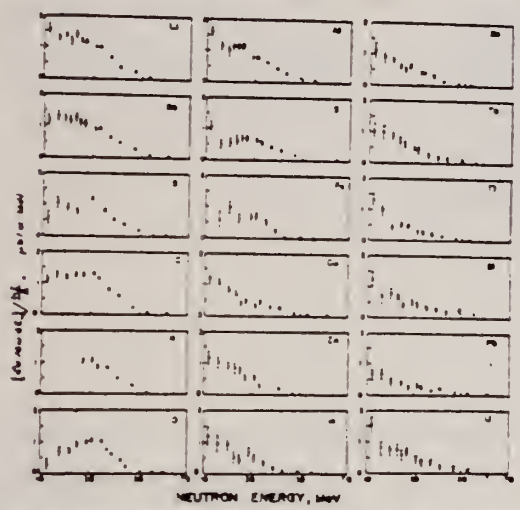

FIG. 6. Observed neutron spectra due to 55–85-MeV difference photon spectra. The effective cross sections have been divided by NZ/A.

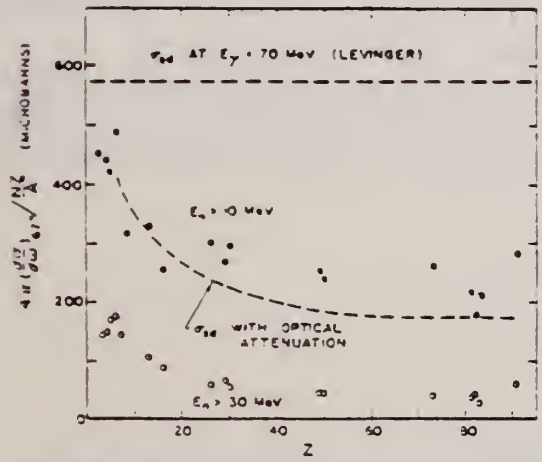

FIG. 7. Effective cross sections for production of fast neutrons with energies greater than 10 MeV (solid circles) and 30 MeV (open circles) by the 55–85-MeV photon difference spectrum. The dashed curves are modified quasideuteron model predictions as discussed in the text.

TABLE I. Comparison of present cross-section values in mb for production of high-energy photoneutrons by 55–85-MeV photons with measured cross sections $\sigma(\gamma,Tn)$, also in mb, for total photoneutron production. The present cross-section values are uncertain by 8 to 10% because of counting statistics and normalization errors; in addition all values depend on an absolute normalization in terms of the deuteron photodisintegration cross section, which is known to about 10% at these energies.

Target	$4\pi(d\sigma/d\omega)_{90°}$ (E_n > 10 MeV) [Present experiment]	$\sigma(\gamma,Tn)$ Jones and Terwilliger[a]	$\sigma(\gamma,Tn)$ Costa *et al.*[b]	Other results

The differential cross-sections of (γ, p), (γ, d) and (γ, t) reactions on carbon for 700 and 1200 MeV maximum energies of photons and energy distributions of the secondary particles were measured at 30, 60 and 120° of particle emission angles. Excitation function for protons with the energy of 97 MeV is given for the maximum incident photon energy from 400 to 1300 MeV. Deuteron to proton and triton to deuteron yield ratios for various nuclei are also shown.

Experiment was carried out at the Kharkov linear accelerator. The particles were detected by scintillation counters after a magnetic spectrometer.

Possible mechanisms of the high energy photon-nuclei interactions are discussed. (3 Figs).

Yield of protons 30-400 MeV, deuterons 30-200 MeV.

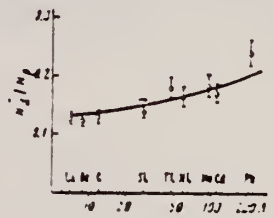

FIG. 4. The ratios N_d/N_p as a function of target-nucleus mass number A at an angle $\theta = 60°$ for E_0 = 1200 MeV. Solid curve – $A^{0.13}$.

The measured secondary-particle spectra for kinetic energies $T > 30$ MeV are well described by the expression

$$d^2\sigma / d\Omega dTQ = \text{const}\, T \exp(-T/\tau). \qquad (1)$$

which is identical to the formula for the evaporation process.[4] In Table I we have given the values of the parameter τ for the nuclei studied, at various angles. The accuracy in determination of τ is about 10%.

Tritons resulting from the electrodisintegration of ^{7}Li have been measured at 90° for an incident electron energy of 23.8 MeV over an energy range which ensured that only tritons emitted in the two-body channel were detected. The electrodisintegration cross sections were converted to equivalent photodisintegration data and compared to earlier results. Large discrepancies are observed. It is found that the (γ,^{3}H) channel contributes appreciably to the electric dipole sum rule for ^{7}Li.

Differential and total cross sections for the $^7Li(\gamma,t)^4He$ reaction were measured. Both real and virtual photons were used in the experiment and gave self-consistent results. The data show a broad resonance indicating the presence of positive parity states near 8 MeV excitation in ^7Li. A calculation using an α-^3H cluster model of ^7Li was also performed. Poor agreement is found between the calculation and experimental results.

VIRT PHOT ANALYSIS

(1) Measured ^4He particles above 14.5 MeV

(2) $\int_{THR}^{50} \sigma(\gamma,t)dE = 8.1$ MeV mb

(3) $\int \sigma(\gamma,t)dE$ for low energy resonance is 6.2 MeV mb and Breit-Wigner fit gives Γ=7.2 MeV centered at E_r=7.7 MeV

(4) Target 92.4% ^7Li, 7.6% ^6Li

[NUCLEAR REACTIONS $^7Li(\gamma,t)^4He$, measured $\sigma(E;E_\alpha,\theta_\alpha)$ and $(E;E_t,\theta_t)$ calculated ^3H-α cluster model cross section.]

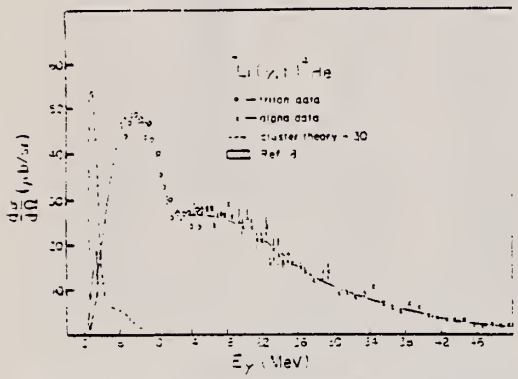

FIG. 2. The 90° cross section for the (γ,t) and (γ,α) reactions. The $^7Li(\gamma,t)^4He$ measurement is indicated by the open circles, while the $^7Li(\gamma,\alpha)^3H$ measurement is indicated by the crosses. The dashed line is the result of the theory described in the text. The solid line is only meant to guide the eye.

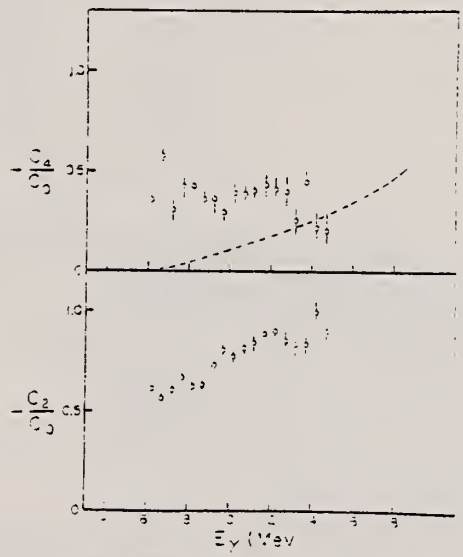

FIG. 3. Even Legendre coefficients found by least-squares fitting the data to Eq. (4). The dashed line indicates the $E2$ strength in our α-^3H cluster model.

(continued)

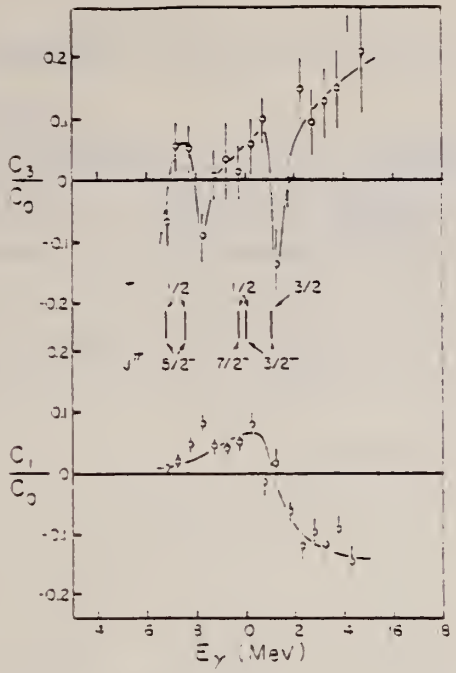

FIG. 4. Odd Legendre coefficients. The location of the known negative parity states in ^{7}Li are indicated

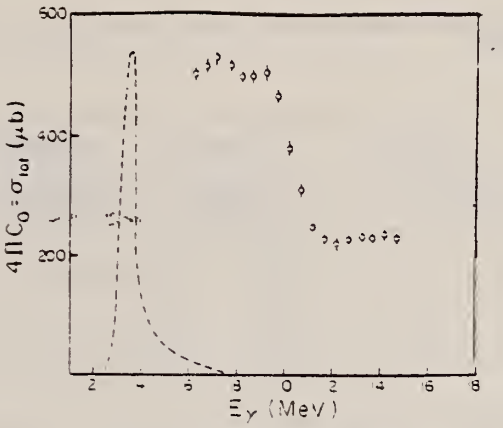

FIG. 5. The total cross section determined from the angular distribution data. The dashed line is the theory divided by 30.

YIELD DATA TABLE:

It should be noted that the yield of photoprotons of the energy considered rises smoothly with Z for the elements plotted in Fig. 3. and that starting already with Al, no direct proportionality to Z is observed on account of the effect of the Coulomb barrier. For illustration, we give the yields of photoprotons $Y(\gamma, p)$ per proton in the nucleus for several elements in relative units (the error in these measurements was estimated to be ±10%):

	Li^6	Li^7	Be	C	Al	Cu
$Y(\gamma,p)$ =	1.00	1.07	1.5	1.31	1.00	58

Reaction	E or ΔE	E_o	Γ	$\int \sigma dE$	Jπ	Notes
$Li^6(\gamma,\gamma)$	Bremss; 17	3.56				According to Cohen and Tobin [Nuclear Phys. 14, 243 (1959)], this γ-ray is resonant-scattered from Li^6 second excited state.

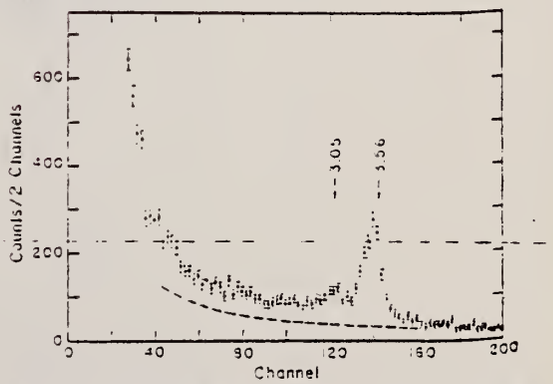

FIG. 2. Pulse-height spectrum for γ rays scattered from a Li^6H sample. The dashed line is the sample-out background. The rest of the counts are from resonant scattering from the 3.56-Mev level of Li^6 and from a sample-associated background. The horizontal energy scale was expanded compared to the other spectra to determine the spectrometer response to this γ ray.

On the Photo Nuclear Reactions of Li^6

T. ODA, H. HIRABAYASI,* and K. FUJIOKA

Faculty of Science, Tokyo Institute of Technology,

Megro Ookayama 1, Tokyo, Japan

The photo-nuclear reactions of Li^6 were studied at seven angles from 15^0 to 150^0 with respect to the incident Bremsstrahlung of the maximum energy $E_{\gamma m}$=15.7 MeV. In this energy region the $Li^6(\gamma,H^3)He^3$ reactions do not occur energetically. The foil of 5.5mg/cm^2 rolled from 99.8% Li^6 metal was used as the target. The product protons of energies larger than 800KeV were detected with the method of nuclear emulsion. As the proton energies are rather low, the effects of the target thickness to the energy spectrum were considered first analytically and were studied further by observing the elastic scattering on Al foil of 1.8 MeV protons accelerated by a Van de Graaff machine. Reasonable agreement with the analytical expectation was obtained.

The energy spectra of the protons emitted from Li^6 target show an eminent group at the proton energy E_p=1.85 MeV. This feature seems to be the same as the results shown by Bazhanov et al with Bremsstrahlung of $E_{\gamma m}$=25 MeV.(1) This proton group would be produced by one of the following two processes,

(1) $Li^6(\gamma,p)He^5$ (Q=-4.655 MeV) at E_x=6.38 MeV or

(2) $Li^6(\gamma,pn)He^4$ (Q=-3.697 MeV) at E_x=9.25 MeV.

Here E_x is the excitation energy in Li^6.
The former kind of interpretation was found in the literature.(2)

In the latter interpretation,(1)(3) the reaction would proceed following the scheme: $Li^6+\gamma \rightarrow He^4+H^2+\gamma \rightarrow He^4+p+n$(4).
In this case, some explanation must be, however, presented for the appearance of the eminent proton group. Further studies are now in progress both experimentally and theoretically.

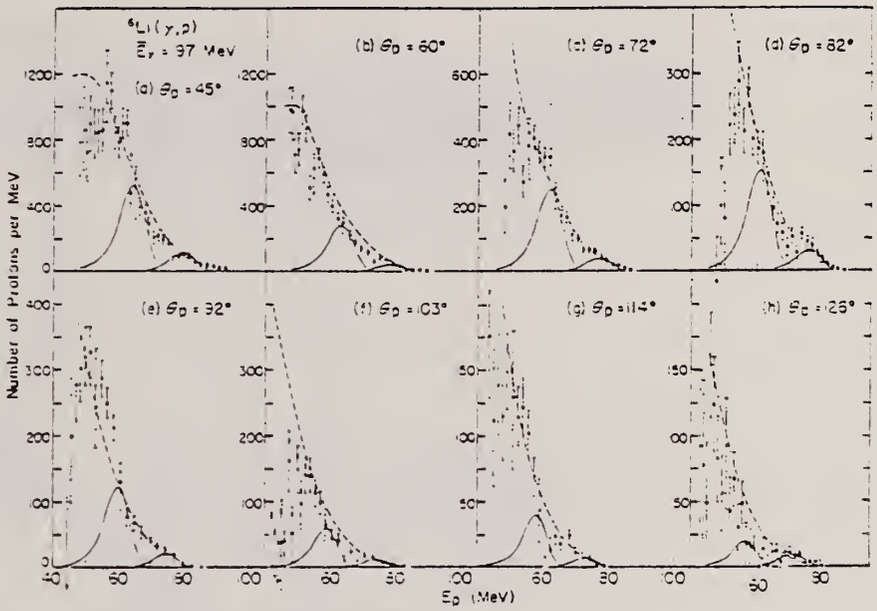

Fig. 14. The ^{6}Li photoproton spectra from "monochromatic" photons ($\bar{E}_\gamma$ = 97 MeV) formed by taking the difference of the 102 and the 95 MeV bremsstrahlung data. Multiplying the given numbers of counts per MeV by 1.80×10^{-3} converts the ordinate scales to μb/MeV · sr per photon of our assumed line width. The shape of the photon difference spectrum is similar to that of the solid curves, whose origin is explained in the text. The dashed curves represent the prediction of the quasi-deuteron model. The extended error bars and the crosses in fig. 14(f) refer to possible systematic uncertainties as discussed in the text.

The absolute cross-section was obtained by measuring the $^{12}C(\gamma, 3\alpha)$ yield and by normalizing the observed $^{12}C(\gamma, 3\alpha)$ yield to that measured by MAIKOV (*). A bremsstrahlung spectrum $I(E_\gamma) \propto 1/E_\gamma$ was assumed in the cross-section calculation.

The phototriton cross section of Li^6 has been measured between 24- and 35-MeV photon energy. This work complements an earlier experiment which established the production of the $Li^6(\gamma,t)$ reaction by giant-resonance photons and measured the cross section between 19 and 24 MeV. The phototriton cross section of Li^6 falls monotonically from 0.46±0.24 mb at 19 MeV to 0.11±0.06 mb at 35 MeV. The integrated (γ,t) cross section over this energy interval is 4.9±2.5 MeV mb. The measured bremsstrahlung-weighted cross section is 0.18±0.09 mb. Implications concerning the nuclear size are discussed.

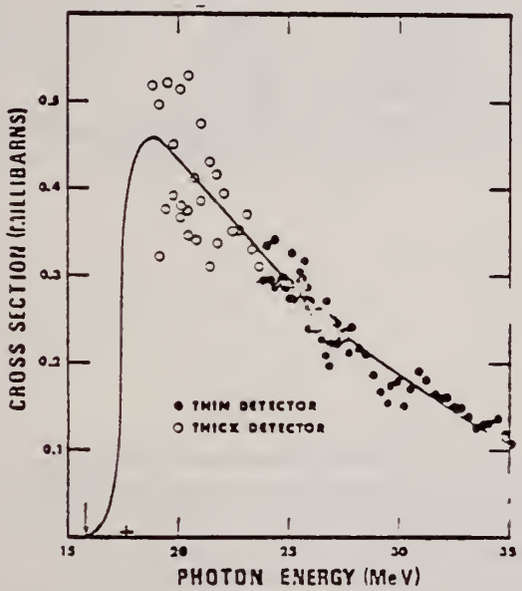

FIG. 5. Phototriton cross section of Li^6. The arrow indicates the reaction threshold. The cross represents the result of Ref. 1, the open circles that of Ref. 6, the solid circles that of the present work. The solid line, above 19 MeV, is an average of the experimental points.

—— results of the present work
⊼ results of Bazhanov *et al.*[7]
× results of Manuzio *et al.*[10]
—— results of Sherman *et al.*[11]
Only statistical errors are included.

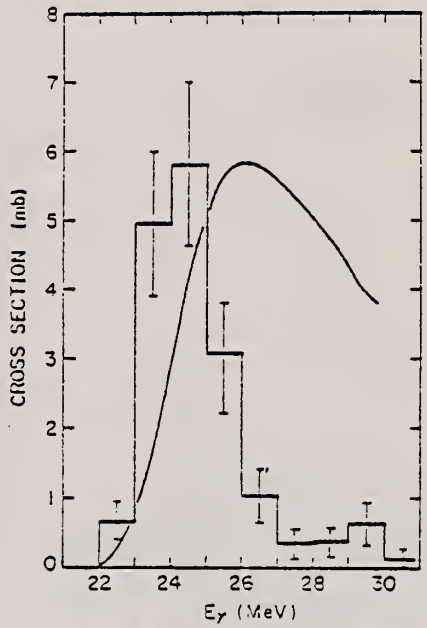

Fig. 7. The cross section obtained for the reaction $^6Li(\gamma, pd)^3H$. The theoretical cross section curve was calculated in terms of the $\alpha-d$ peripheral model. Only statistical errors are included.

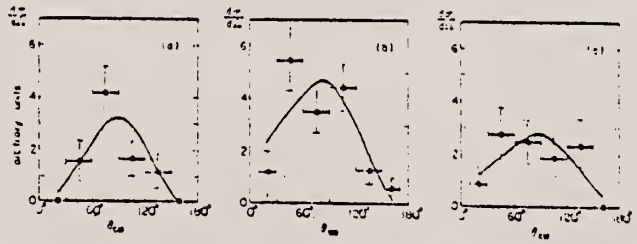

Fig. 6. The angular distributions of phototritons in the reaction $^6Li(\gamma, t)^3He$ are shown in the center of mass system. Figures (a), (b), (c) correspond to photon energies ranging from the threshold up to 20 MeV, from 20 MeV up to 22 MeV and from 22 MeV up to 28 MeV, respectively. Only statistical errors are included. The curves were obtained by a least squares fit of the data to $f(\theta)=a+b\cos\theta-c\cos^2\theta$.

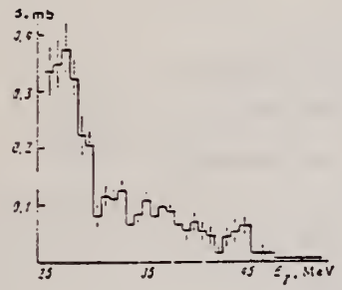

Fig. 5. The $^6Li(\gamma t)^3He$ cross section.

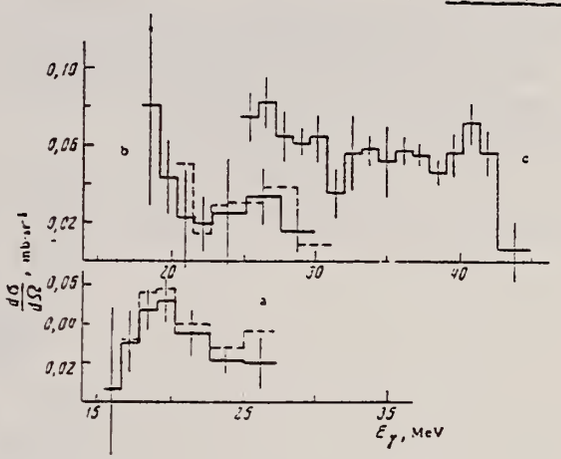

Fig. 2. Differential cross section for photoemission of protons at 90° to the photon beam in the following reactions: a) (γp_0) (^{5}He formed in its $I^\pi = 3/2^-$ ground state), b) (γp_1) (in the $1/2^-$ first excited state at 2.6 MeV), c) (γp_2) (in the $3/2^+$ second excited state at 16.7 MeV). The dashed histogram was drawn with allowance for the width of the first excited level.

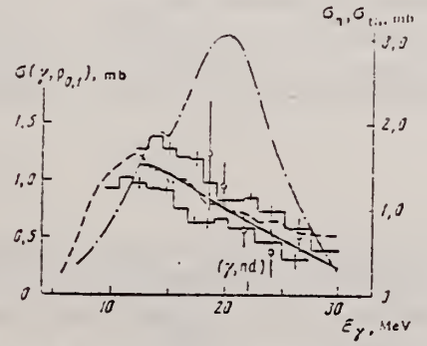

Fig. 3. Cross sections derived for protons from reactions with thresholds below the (γp_2) threshold. The lower (upper) histogram corresponds to the assumption that all the protons come from the (γp_0) ((γp_1)) reaction. The points represent the sum of the cross sections for these two reactions from the data of Fig. 2; the full curve is the average of the two histograms; the dashed curve gives the neutron photoproduction cross section σ_n [18]; and the dash-dot curve gives the theoretical value of the sum of the (γp_0), (γp_1), (γn_0), and (γn_1) cross sections [21].

(continued)

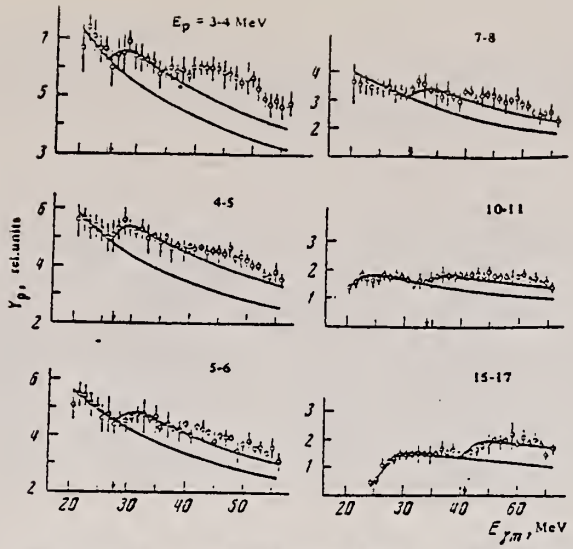

Fig. 1. The yields of protons in certain energy intervals as functions of $E_{\gamma m}$. The curves are isochromats for the (γp) reaction with the ^{5}He formed in its ground and first excited states (lower curves) and in its 16.7 MeV state (upper curves). The arrow marks the kinematic threshold for the (γp) reaction with the ^{5}He left in its 16.7 MeV state.

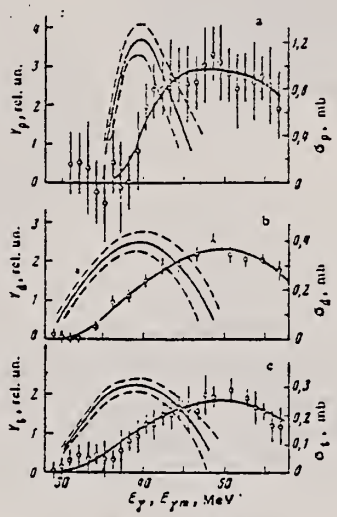

Fig. 4. $E_{\gamma m}$ dependence of particle yields from multiparticle photodisintegrations, and the corresponding cross sections: a) protons, $E_p \geq 3$ MeV; b) deuterons, $E_d \geq 4$ MeV; c) tritons, $E_t \geq 4$ MeV. The curve through the experimental points is an approximation to the yield curve derived from the measured cross section. The dashed curves mark the limits of statistical errors in the cross sections.

			TYPE	RANGE	TYPE	RANGE	

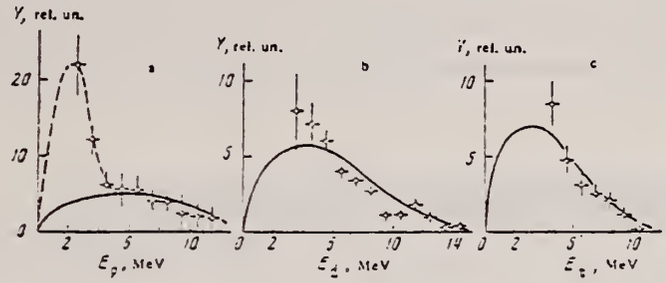

Fig. 7. Energy distributions of protons (a), deuterons (b), and tritons (c) from multiparticle photodisintegration of ^{6}Li. The curves are theoretical distributions from three-particle breakup [17] with allowance for the multiparticle photodisintegration cross-section curves (Fig. 4). The dashed curve is a rather arbitrary extrapolation of the part of the proton distribution that presumably contains a large contribution from disintegrations into more than three particles.

Table 2

^{6}Li Photodisintegration Channels

Reaction	E_γ interval, MeV	Integral cross section, MeV·mb	Contribution to the total absorption in the $E_\gamma \leq 50$ MeV interval, %

Self-absorption measurements 3=3.56 MEV

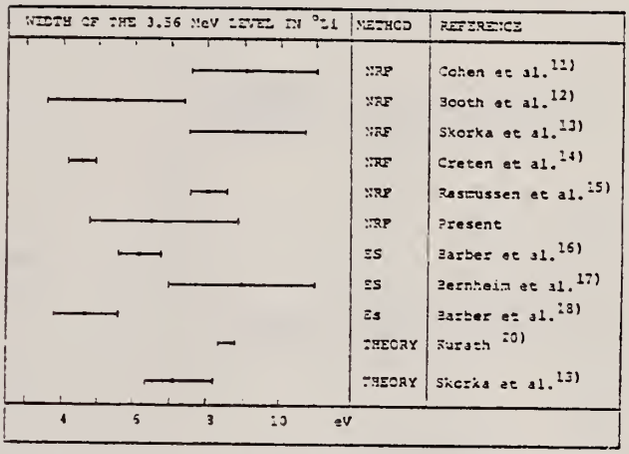

Fig. 4. Results of the width of the 3.56 MeV level in ^{6}Li measured by different authors. NRF denotes nuclear resonance fluorescence and ES denotes electron scattering. Lower two rows represent the theoretical results.

The bremsstrahlung beam from a 5 MeV electron linear accelerator was used to excite and study low-lying levels in ^{6}Li, ^{11}B and ^{27}Al. A self-absorption method was used to find the widths Γ of these levels. The following level widths are obtained: $\Gamma=(6.5^{+1.5}_{-1.2})$ eV for the 3.56 MeV level in ^{6}Li; $\Gamma=(0.23\pm0.09)$ eV for the 2.12 MeV level, and $\Gamma=(0.53\pm0.21)$ eV for the 4.44 MeV level in ^{11}B. For the 2.98 MeV level in ^{27}Al, the level width is found to be $\Gamma=(0.10\pm0.04)$ eV assuming that the lower energy member of the doublet at 3 MeV is excited.

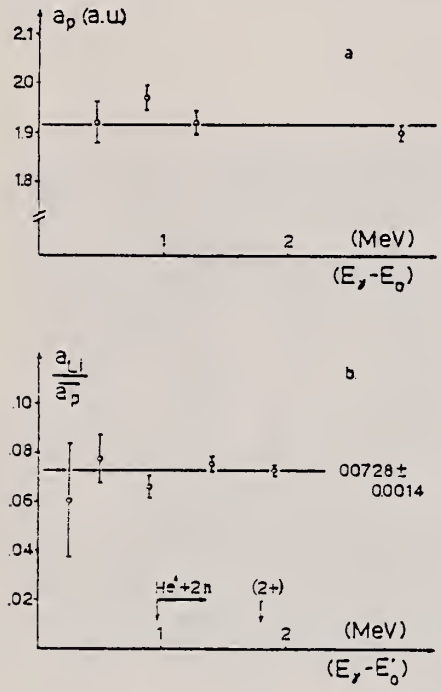

FIG. 1. (a) Coefficient a_p of the photoproduction on proton as a function of the lab photon energy above threshold. The line indicates the best-fit value $\overline{a_p}$. (b) Coefficient a_{Li} of the photoproduction on ^{6}Li normalized to the average a_p as a function of the lab photon energy above threshold. The position of the continuum and the 2^- level in ^{5}He are also shown.

TABLE I. Photoproduction yield as a function of the energy of the electron beam.

The reactions ^{6}Li(e,e'α) and ^{6}Li(e,e'd) have been studied at $T_0 \approx 520$ MeV and $q \approx 1.4$ fm^{-1}, by coincidence measurements. The angular dependence of the cross sections is interpreted in the plane wave impulse approximation to obtain the momentum distribution of α-particle and deuteron clusters in ^{6}Li. The amount of clustering of ^{6}Li is also discussed.

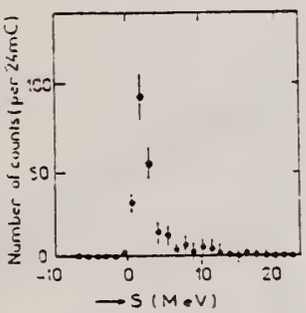

Fig. 1. Missing-energy spectrum for the (e,e'α) reaction on ^{6}Li at $k_3 = 0$ MeV/c, $T_0 = 525$ MeV, $\theta_1 = 33°$; $q = 1.79$ fm^{-1}, target thickness = 4.5 mg/cm^2 (the angle between target plane and incident beam is 50°). No corrections have been applied.

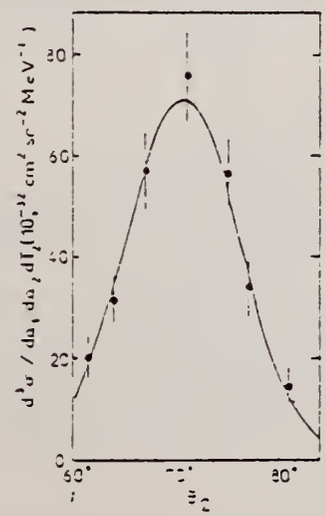

Fig. 2. The (e,e'α) coincidence cross section as a function of θ_2. The kinematical conditions are $T_0 = 525$ MeV, $\theta_1 = 33°$, $q = 1.49$ fm^{-1}, $T_2 = 11.5$ MeV. The curve is the best fit in PWIA for $Q_0 = 78.1$ MeV/c, $P_\alpha = 0.19$ and $\Delta\theta_2 = -0.21°$.

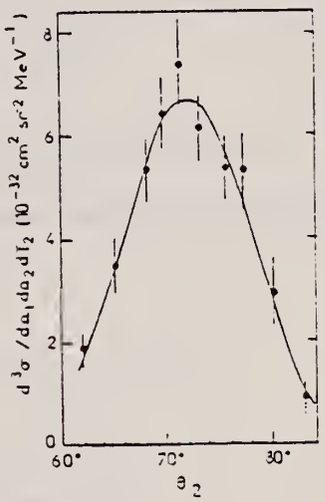

Fig. 3. The (e,e'd) coincidence cross section as a function of θ_2. The kinematical conditions are $T_0 = 515$ MeV, $\theta_1 = 30°$, $q = 1.33$ fm^{-1}, $T_2 = 18.2$ MeV. The curve is the best fit in PWIA for $Q_0 = 74$ MeV/c, $P_d = 0.073$ and $\Delta\theta_2 = -0.58°$.

QUASIELASTIC SCAT

See further analysis of this data in reference 79Zil

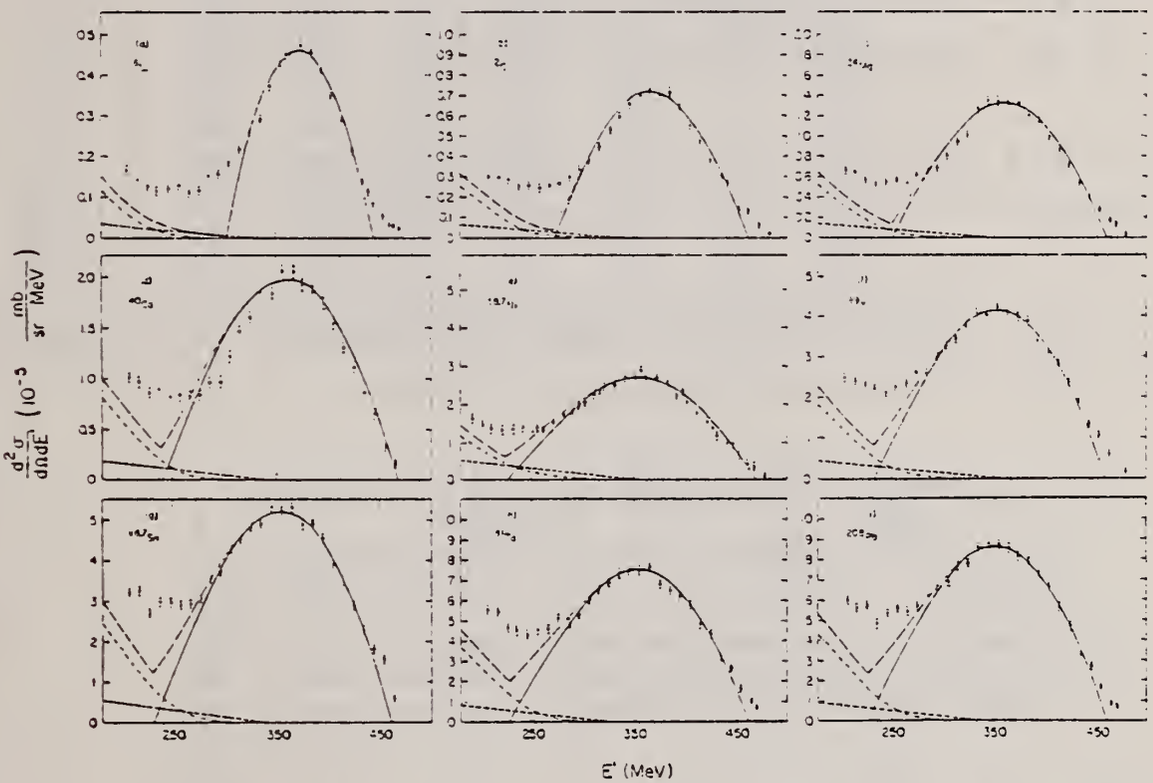

FIG. 1. The measured quasielastic peaks; the errors on the data points do not include an over-all 3% normalization uncertainty. The solid curve is a fit by the Fermi-gas model which yielded k_F (in MeV/c) and $\bar{\epsilon}$ (in MeV) as follows: (a) ^{6}Li (169, 17); (b) ^{12}C (221, 25); (c) ^{24}Mg (235, 32); (d) ^{40}Ca (249, 33); (e) ^{58,7}Ni (260, 36); (f) ^{89}Y (254, 39); (g) ^{118,124}Sn (260, 42); (h) ^{181}Ta (265, 42); (i) ^{208}Pb (265, 44). The fitting uncertainty in k_F is ±5 MeV/c and in $\bar{\epsilon}$ it is ±3 MeV. The small-amplitude dashed curve is the s-wave π-production contribution, the dot-dashed curve is the isobar excitation, and the large-amplitude dashed curve is the total result.

3=3.562,LIMIT ON LFT

Summary. — An experiment is reported on the parity-violating reaction $d(\alpha, \gamma)^6Li$, leading to the $J^P = 0^-$, $I = 1$, $E_x = 3.562$ MeV state, which, being a $\Delta I = 1$ transition, could be strongly enhanced by the presence of neutral currents in hadronic weak interactions in nuclei. The experiment has been carried out by exposing a deuterium target to a beam of α-particles reaching the resonant energy in the region in the middle of the tube containing the gas. Gamma-rays from this region are detected by a 90 cm^3 Ge(Li) counter connected to a 4096 channel analyser through an amplifying and analysing chain. The various sources of the background of spurious counting in the Ge(Li) and the procedure adopted to reduce their effect are discussed. We find no evidence for a nonzero parity-violating width of the 3.562 MeV state of ^6Li and can set an upper limit for this width of $8 \cdot 10^{-4}$ eV, which is an order of magnitude or more lower than that obtained in the previous experiments on this reaction.

Abstract: The form factor for the alpha-deuteron continuum in ^{6}Li has been measured in the excitation region within 2 MeV of threshold, for momentum transfers $q < 1.2$ fm^{-1}. The results are interpreted in terms of an α-d cluster model. The monopole breakup appears to be predominant near threshold, but the influence of the $J = 2^+$ (4.31 MeV) quadrupole resonance becomes important a few MeV above threshold. The form factor for the C2 transition to the 3^- (2.185 MeV) state is also presented.

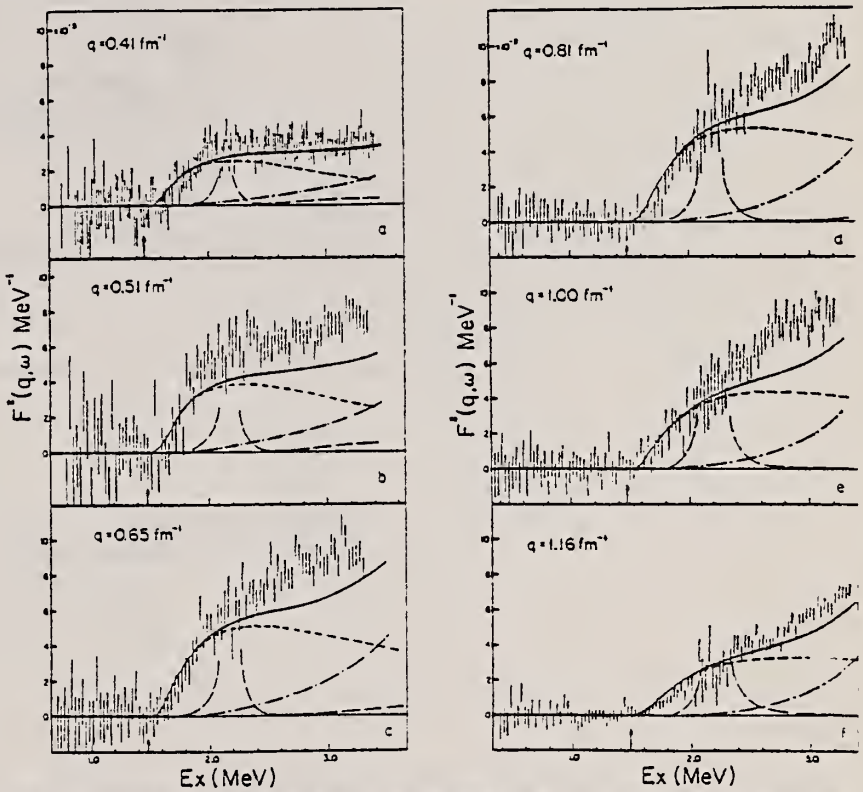

Fig. 2. Momentum transfer dependence of the continuum form factor near the α-d threshold. The theoretical monopole excitation is shown by the small dash curve, the $J = 3$ quadrupole by the large dash curve, and the tail of the $J = 2$ quadrupole resonance by the dot-dash curve. The main part of the 3^+ (2.185 MeV) resonance is not shown, as discussed in the text. The error bars are statistical and do not reflect the uncertainty in the elastic peak radiation tail.

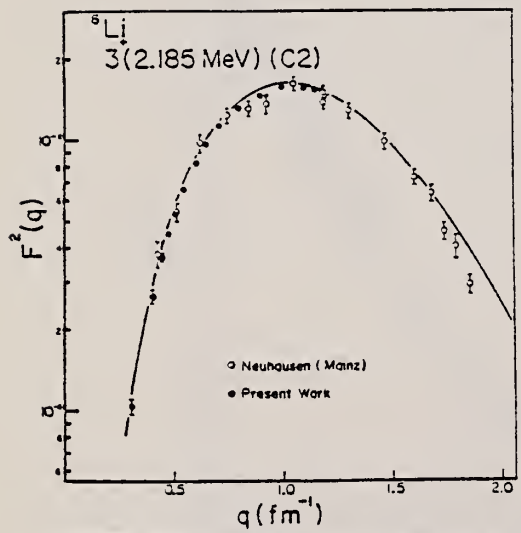

Fig. 3. Form factor of the $J = 3^+$ quadrupole excitation. The data from Mainz has been recalculated using the elastic parameters of Li *et al.*

We remeasured with improved techniques the positive-pion photoproduction yield on ^{6}Li near threshold and up to 7.2 MeV above it. If the total cross section of the reaction $\gamma+p\rightarrow\pi^++n$ is expressed as $\sigma_p=aq/k$, our result for the reaction $\gamma+{}^6\mathrm{Li}\rightarrow\pi^++{}^5\mathrm{He}_{g.s.}$ near threshold is

$$\sigma_{Li}=(0.098\pm0.004)(aq/k)\{(12.5/q)/[\exp(12.5/q)-1]\},$$

where q is the pion and k the photon c.m. momenta expressed in units of MeV/c. Deviations from this expression above threshold and the contribution of $\gamma+{}^5\mathrm{Li}\rightarrow\pi^-+{}^5\mathrm{He}$ (1.8 MeV) were also observed. The full understanding of this result requires further theoretical work and complementary experiments on the $A=6$ nuclear system.

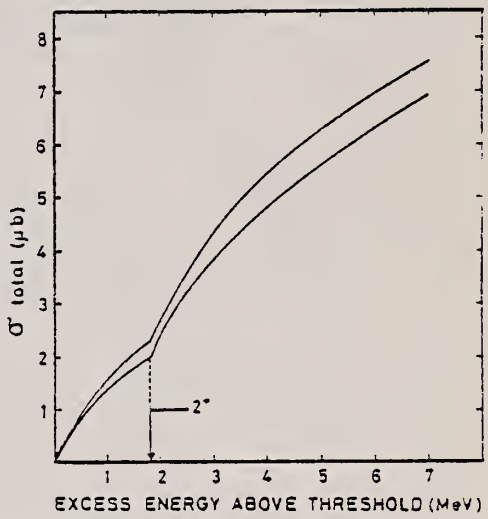

FIG. 10. Cross section of the (γ,π^+) reaction on ^{6}Li deduced from this experiment.

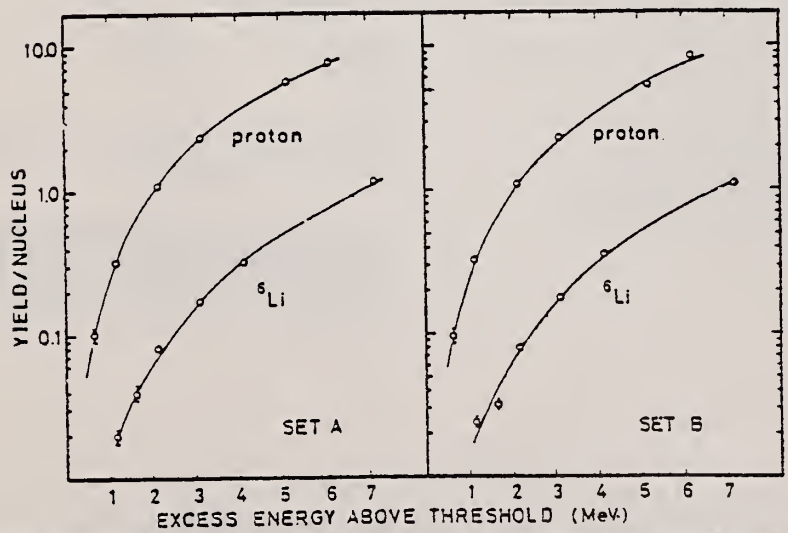

FIG. 9. Measured photoproduction yield per nucleus as a function of the excess energy above threshold for ^{6}Li and hydrogen. The curves indicate the best fit of Eq. (2) to our data.

This experiment ($0<\omega<2$ MeV)				$a(^6\mathrm{Li}\rightarrow{}^6\mathrm{He})/a(p\rightarrow\pi)=0.098\pm0.004$[c]	

[a] Strong $L=1$ admixture.

[b] Weak $L=1$ admixture.

[c] Comparing this result with the theoretical predictions, one should recall that it was deduced assuming $a(^6\mathrm{Li}\rightarrow{}^6\mathrm{He})/a(p\rightarrow\pi)=cte$ in the energy region of interest ($0<\omega<2$ MeV). As discussed in Sec. III C, this approximation has a negligible influence for reasonable variations of $a(^6\mathrm{Li}\rightarrow{}^3\mathrm{He})$ and $a(p\rightarrow\pi)$.

Abstract: The proton spectral functions of ^{6}Li, ^{7}Li, ^{9}Be and ^{10}B obtained from the (e, e'p) reactions at 700 MeV are presented. The results were analyzed in the distorted-wave impulse approximation, using the shell-model single-particle wave functions consistent with the elastic electron scattering results. The observed 1p proton momentum distributions for the nuclei ^{6}Li, ^{7}Li and ^{9}Be show significant disagreement with the shell-model momentum distributions. The occupation probabilities of the proton single-particle states are around 0.7, with a few exceptions.

*SEPARATION ENERGY

E NUCLEAR REACTIONS ^{6,7}Li, ^{9}Be, ^{10}B(e, e'p), E = 700 MeV; measured $\sigma(E_p, \theta_p)$; deduced proton spectral functions. DWIA calculations. Enriched ^{6,7}Li, ^{10}B and natural ^{9}Be targets.

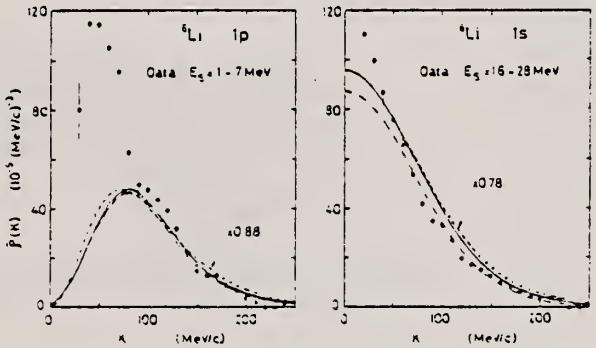

Fig. 5. The distorted momentum distributions corresponding to the optical potentials A (the solid curves) and B (the dot-dashed curves), and the undistorted momentum distributions (the dashed curves), calculated from the shell-model single-particle wave functions used in the DWIA analysis. (a) ^{6}Li, (b) ^{7}Li, (c) ^{9}Be and (d) ^{10}B. For comparison, data points in the appropriate separation energy ranges are shown. They are arbitrarily normalized to the calculated distorted momentum distributions.

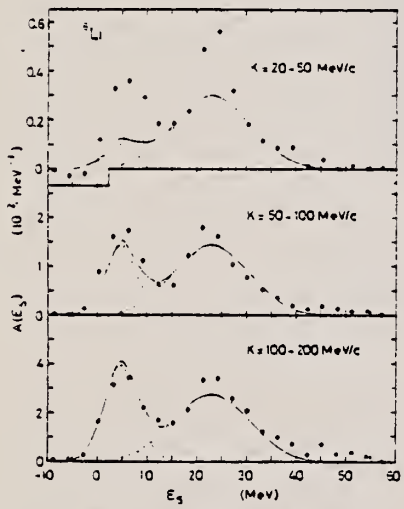

Fig. 1a. Proton separation energy spectra for ^{6}Li. The solid curves are the result of the DWIA fit using the shell-model momentum distributions. The contributions from the individual peaks are shown by the dashed curves. (The curves corresponding to the different optical potentials A and B are essentially indistinguishable.)

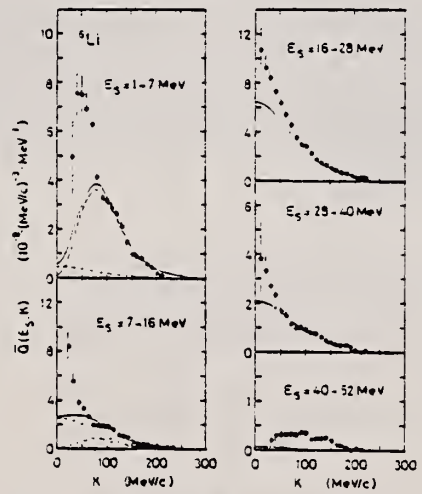

Fig. 1b. Recoil momentum distributions for ^{6}Li. The solid curves are the result of the DWIA fit using the shell-model momentum distributions. The contributions from the individual peaks in the separation energy spectra are shown by the dashed curves. (The curves corresponding to the different optical potentials A and B are essentially indistinguishable.)

Results are presented of an experimental study of reactions of the type ^{6,7}Li (γ, ab)X with emission of charged particles a and b detected in coincidence. It is established that the major part of such reactions are reactions of the type ^{6,7}Li (γ,pt)X. The results of measurement of the correlations of the directions of emission and energy distributions of protons and tritons are explained on the basis of the assumption of photodisintegration of α clusters in the ground state of the nuclei ^{6,7}Li into a proton and triton and of formation of the residues X in the form of two $(d+n)$ particles in reactions ^{6}Li (γ, pt)X, and two $(d+n)$ particles and possibly three $(n+p+n)$ particles in reactions ^{7}Li (γ, pt)X. The value of the average differential cross section of the reaction ^{6}Li (γ, pt) ^{1}Hn in the γ-ray energy interval 35–55 MeV amounts to 0.7±0.2 of the value of the cross section for the reaction ^{4}He (γ, p) ^{3}H. It is shown that in addition, three-particle reactions of the type ^{6}Li (γ,td) ^{1}H and ^{7}Li (γ, π) ^{1}H occur, but with a kinematics differing from that of the photodisintegration of α clusters, and also two-particle reactions of the type ^{6}Li (γ, t) ^{3}He and ^{7}Li (γ, t) ^{4}He.

Abstract: The form factor of the 3.56 MeV (0^+, $T = 1$) state of ^{6}Li has been measured for momentum transfers $q = 1.0$–3.0 fm^{-1}, and the 2.18 MeV (3^+, $T = 0$) and 5.37 MeV (2^+, $T = 1$) states have been measured up to $q = 2.5$ fm^{-1}. The 3.56 MeV form factor is analysed in terms of a phenomenological shell model with $l = 1$ valence nucleons. The radial wave functions are found to have a greater radial distribution than given by the harmonic oscillator, more closely resembling Woods-Saxon functions. The M1 form factor is found to decrease at high momentum transfer somewhat more slowly than the models predict. A technique for determining the M1 transition current density based on the Fourier-Bessel analysis is developed and applied to the M1 transition. The M1 transition current density is obtained within a moderate error band and compared with the harmonic oscillator and Woods-Saxon densities. The M1 radiative width is 8.18 ± 0.25 eV, in agreement with previous measurements.

E NUCLEAR REACTIONS ^{6}Li(e, e'), $E = 140$–330 MeV, $\sigma(E; E_x, \theta)$. ^{6}Li deduced form factors, transition current density and Γ_{γ_0}.

The 5.37 MeV results represent the strength within ±0.55 MeV of the peak centre (see text). The q-values are for the 3.56 MeV level.

*) The upper limit corresponds to two standard deviations of the measured counting rate at the expected location of the 3.56 MeV peak.

(continued

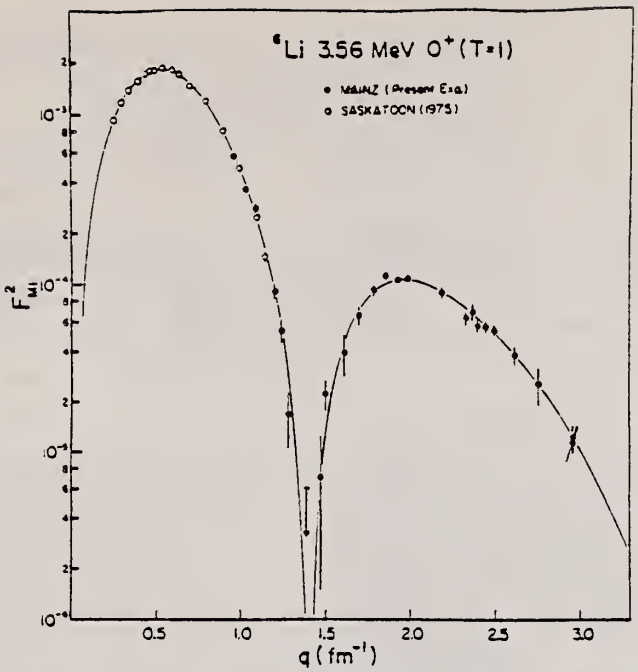

Fig. 2. The 3.56 MeV M1 form factor and the phenomenological shell model fit with the Sask-A amplitudes. The radial density is derived from the present analysis of the combined Mainz and Saskatoon [4]) data.

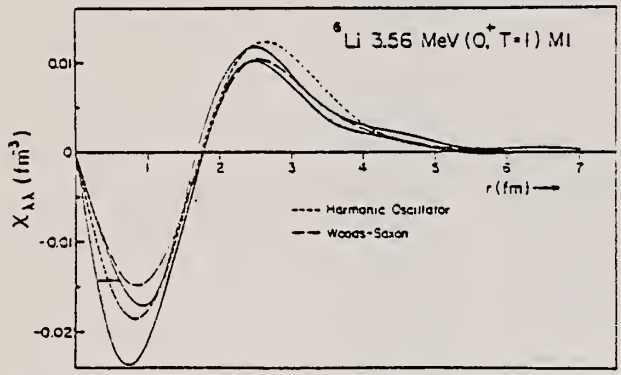

Fig. 5. The M1 transition current density for the 3.56 MeV level from the Fourier-Bessel analysis of the experimental form factor. The shaded region represents a ± 1 standard deviation error band and contains the statistical and model dependent errors. The wiggles at r = 4.5 and 6.5 fm are probably a consequence of the truncated series, although the rapid change in slope near r = 3.5 is believed genuine. The curves are predictions based on the harmonic oscillator and Woods-Saxon potentials with Sask-A amplitudes.

The cross sections of reaction $(\gamma,\pi^{\circ}p)$ on Li^{5} C^{12} nuclei were measured in the 0–600 MeV/c range of momentum transfer to the residual nucleus. For large values of momenta, cross section values disagree with calculations carried out within the framework of a shell model and a model of quasi-free meson photoproduction on nuclei.

The photodisintegration of the stable Lithium isotopes has been investigated by spectroscopy of the emitted charged particles using the Giessen bremsstrahlung facility. Protons, deuterons, tritons, ^{3}He and alpha particles were detected and identified up to 20 MeV particle energy. Angular distributions were measured using γ-ray energies up to $E_\gamma = 50$ MeV. They are compared with theoretical predictions and with other experiments. A remarkable low (γ, t)-cross section was found for both isotopes in disagreement to previous measurements using virtual photons. Coincidence measurements between the emitted particles were performed in order to study the manybody-breakups of ^{7}Li.

		(5.37)					

The transverse form factor for the 5.37 MeV(2^+,$T=1$) level of ^{6}Li is analyzed in terms of a phenomenological model to give the configuration amplitudes and transition density. Radiative pion capture rates for the 1s atomic orbital of ^{6}Li leading to the two lowest states of ^{6}He are estimated using the phenomenological functions. The radiative pion capture rate to ^{6}He(g.s.) agrees with experiment, but the rate to ^{6}He(2^+,1.8 MeV) is larger than the measured value. It is shown that if the longitudinal form factor is small at $q \simeq m_\pi$, the transverse 5.37 MeV form factor gives the radiative pion capture matrix elements directly. As part of this study, the C2 form factor was measured near $q = m_\pi$, and its implications on the wave functions are considered.

[NUCLEAR REACTIONS ^{6}Li(e,e'), E=76–141 MeV; $\sigma(E;E_{e'},\theta)$. ^{6}Li deduced form factors, wave functions, radiative capture.]

6=5.37 MEV

TABLE I. Summary of the present experimental results for the 5.37 MeV (2^+, $T=1$) state of ^{6}Li. Radiative corrections and the elastic form factor were calculated as in Ref. 3. The total form factor is defined within ±0.55 MeV of the peak center. Errors do not reflect uncertainties in the position and width of the state.

E_0 (MeV)	ϑ (deg)	$\sigma(5.37)/\sigma(\text{el})$ ($\times10^{-3}$)	$F_{el}^2(q)$ (calc.)	$F_{tot}^2(q,\vartheta)$ ($\times10^{-4}$)

Photoreaction mechanisms of ^{6}Li were studied using bremsstrahlung below the $(\gamma,^3H)$ threshold. It was confirmed by the present work that only the $^6Li(\gamma,p)^5He$ and $^6Li(\gamma,n)^5Li$ reactions actually occur in the energy range of incident γ ray lower than the $(\gamma,^3H)$ threshold, and the $^6Li(\gamma,np)^4He$ reaction in various types does not occur in practice although this reaction is energetically possible. The assignment of the reactions $^6Li(\gamma,p)^5He$ and $^6Li(\gamma,n)^5Li$ to the measured photoproton spectrum for 15.4 MeV irradiation is presented.

[NUCLEAR REACTIONS ^{6}Li, checked photoreaction mechanisms, bremsstrahlung E=15.4 and 10.2 MeV, measured proton spectra, peak energies and widths, $\sigma(\theta)$, confirmed only $^6Li(\gamma,p)^5He$ and $^6Li(\gamma,n)^5Li$ actually occur below the $^6Li(\gamma,^3H)^3He$ threshold.]

TABLE II. The peak energy and half-width for each peak of the first three peaks in the range $K \geq 2$ MeV of observed proton spectra of ^{6}Li.

15.4 MeV irradiation		10.2 MeV irradiation	
peak energy (MeV)	half-width (MeV)	peak energy (MeV)	half-width (MeV)
2.29 ± 0.19	0.691 ± 0.066	2.30 ± 0.20	0.693 ± 0.062
3.14 ± 0.18	0.606 ± 0.052	3.17 ± 0.17	0.601 ± 0.066
3.93 ± 0.18	0.605 ± 0.066	4.08 ± 0.16	0.600 ± 0.064

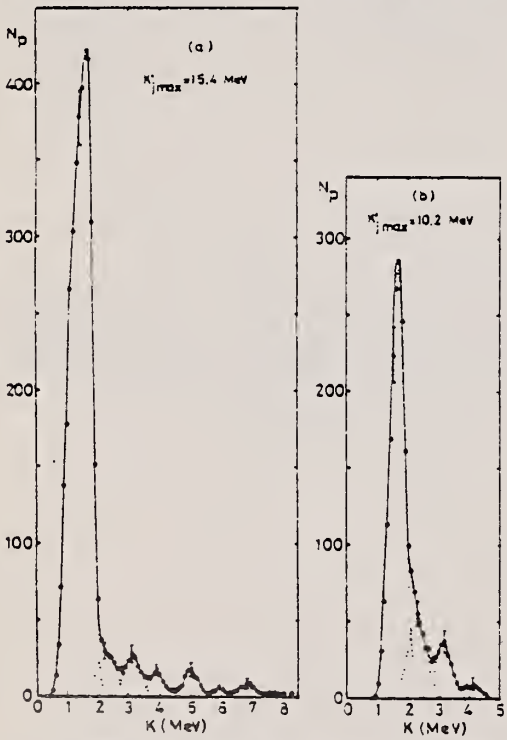

FIG. 2. Photoproton energy spectra of the ^{6}Li nucleus. The errors represent statistical errors.

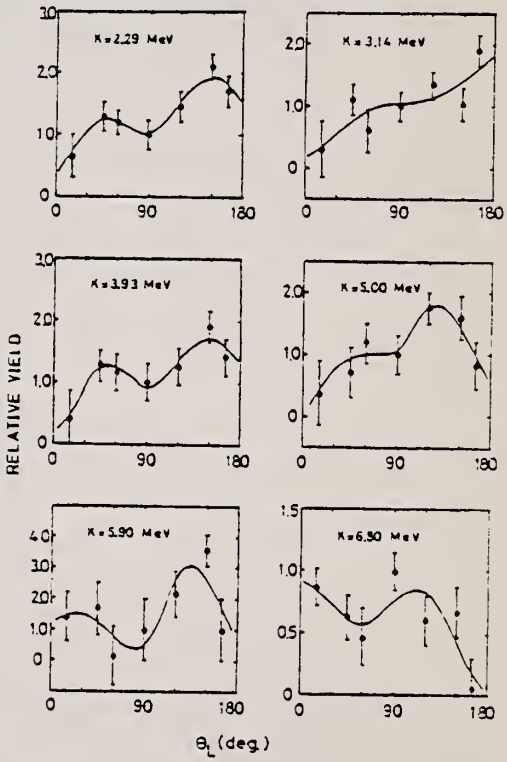

FIG. 3. Angular distributions for the proton groups in the 15.4 MeV irradiation. The errors represent $\pm[\sqrt{Y_p(\theta_L)}/Y_p(90°)]$ where $Y_p(\theta_L)$ is the proton yield for each group at θ_L. The solid curves are the least squares fit in terms of the Legendre polynomials up to order 4 for the groups of 2.29, 3.93, 5.00, and 5.90 MeV, and up to order 3 for the 3.14 and 6.80 MeV groups.

detected recoil ^{6}Li in forward direction

The capture of α particles by deuterium has been observed by using a magnetic analysis technique to detect the recoiling ^{6}Li ions. Measurements of the cross section down to 1 MeV in the center-of-mass system can be interpreted accurately in terms of a direct-capture model, and it is found that production of ^{6}Li in the big bang is 3 times smaller than has been assumed

PACS numbers: 25.60.+t, 25.10.+s, 98.80.Ft

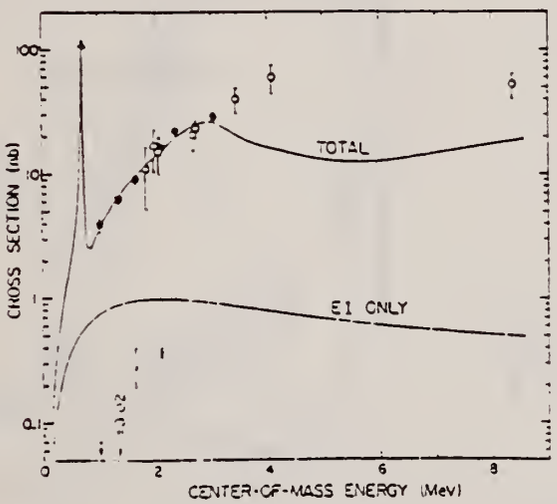

FIG. 1. Cross section for the reaction ^{2}H(α,γ)^{6}Li. Open circles, MSU data; closed circles, CRNL data; triangles, ^{6}Li($e,e'\alpha$) (Ref. 7); crosses, CRNL data for $E1$ component. The curves are a direct-capture calculation.

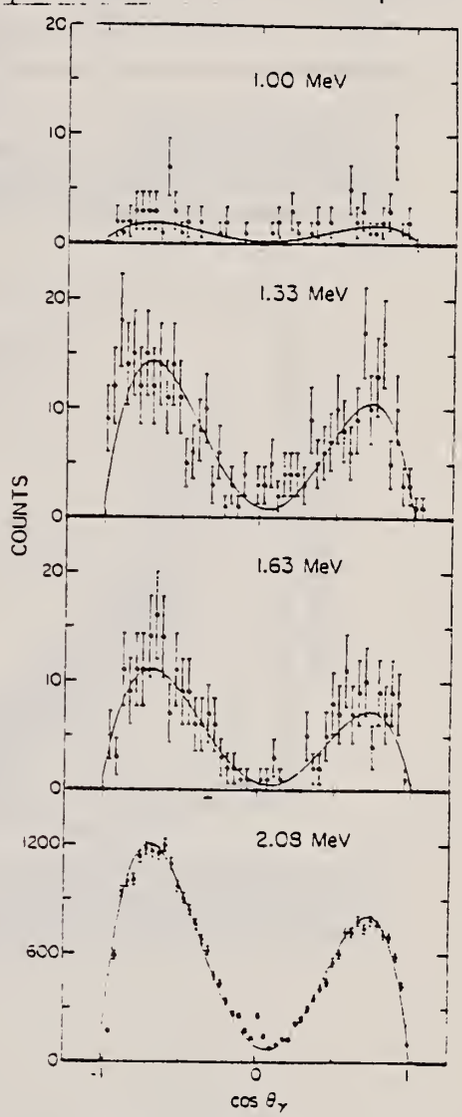

FIG. 2. Measured ^{6}Li momentum distributions for ^{2}H(α,γ)^{6}Li at four center-of-mass energies. The momentum varies linearly as the cosine of the angle between the incident beam and the outgoing photon, θ_γ. The curves are a direct-capture calculation in which the $E1$ operator has been renormalized. The small peak in the center of the lowest distribution is due to a weak ^{6}Li component in the beam, which was removed by means of a velocity filter in the other, more recent, data. The peak width is roughly the instrumental resolution.

Differential cross sections of ^{6}Li(γ, π^+)^{6}He leading to the ground and first excited residual states have been deduced in the range of momentum transfer $0.7\ m_\pi < q < 2\ m_\pi$ from the measured pion energy distributions of ^{6}Li(e, π^+)^{6}He. The results are compared with the shell-model estimates. In the case of the ground-state transition (M1), the experimental results show an enhancement in the region of $q > 1.6\ m_\pi$. It is not similar to the case of the first excited state transition (M1 + E2 + M3).

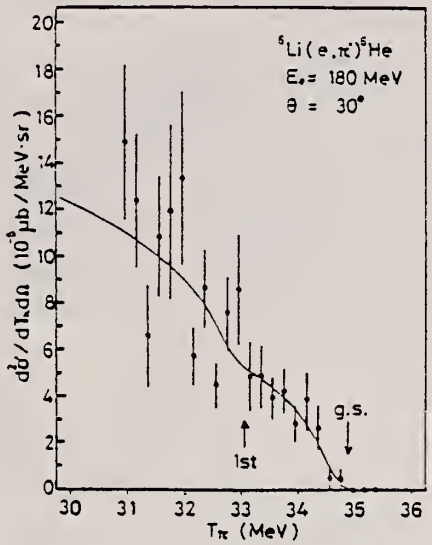

Fig. 1. An example of the energy distribution of pions emitted in the ^{6}Li(e, π^+)^{6}He reaction. Arrows show the end-point pion energies corresponding to the ground and first excited residual state. The best fitted curve is also shown.

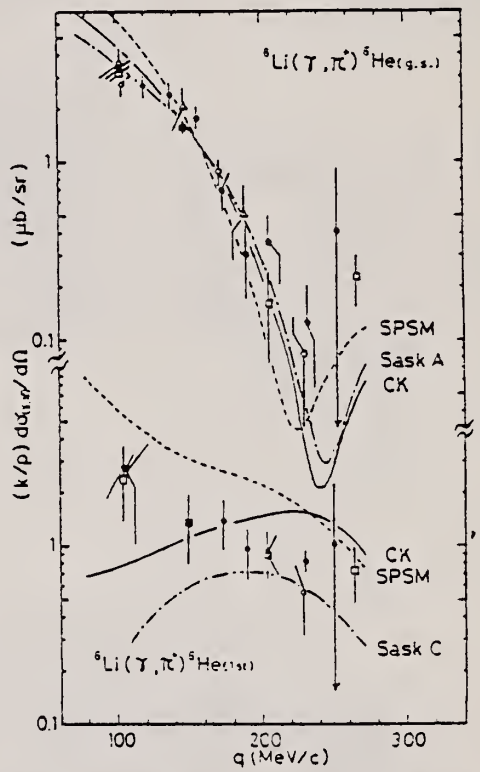

Fig. 2. Experimental results of $(k/p)\ d\sigma_{(\gamma,\pi^+)}/d\Omega$ leaving the ground and first excited residual state. Present results are given by open circles for E_e = 195 MeV (θ = 30°, 60°, 90°), open squares for E_e = 180 MeV (θ = 30°, 90°, 150°), open triangles for E_e = 170 MeV (θ = 30°, 60°, 90°). Closed circles are the previous results of angular distribution measurements (ref. [9]); closed squares are the previous results in the threshold region (ref. [8]). Theoretical curves with SPSM, CK (ref. [12]) and Sask A and C for E_e = 180 MeV are also given.

Photoproduction of π^0 mesons off targets of ^{6}Li, ^{12}C, ^{28}Si, ^{40}Ca, natural Cd, and natural Pb was studied using a bremsstrahlung beam with endpoint energies of 140, 145, 150, and 155 MeV. Photoproduction from a liquid hydrogen target was employed as a normalization. The measured yields were found to be in disagreement with published theoretical cross sections for ^{6}Li$(\gamma,\pi^0)^6$Li and also in disagreement with a simple schematic model which assumed only coherent contributions from the M_{1+} multipole. The schematic model, however, did approximately predict the relative magnitudes of the yield curves for the energy range 14—20 MeV over threshold.

*MEV ABOVE THR

[NUCLEAR REACTIONS ^{6}Li, ^{12}C, ^{28}Si, ^{40}Ca, Cd, Pb, (γ,π^0); E_γ = 140—155 MeV; measured σ; test of reaction model.]

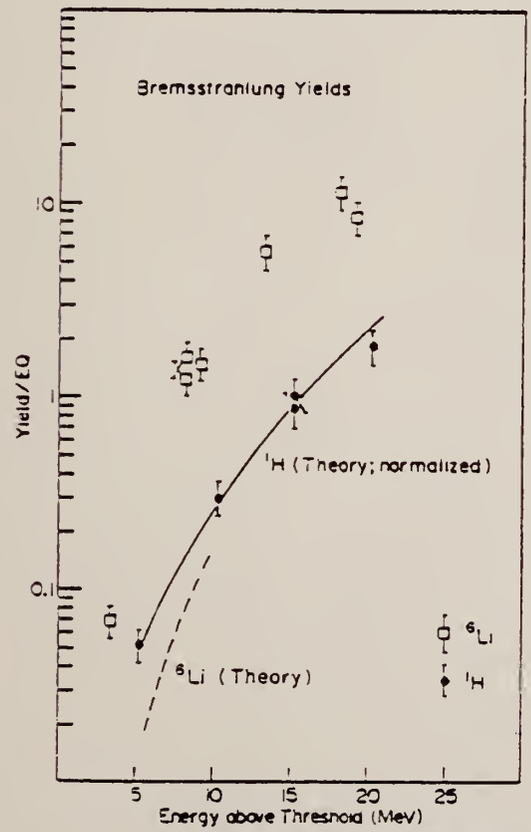

FIG. 5. The experimental and calculated yields for ^{6}Li(γ,π^0) and ^{1}H(γ,π^0). The calculated yield for ^{1}H(γ,π^0) was required to go through the data points at 15.33 MeV above threshold (see text).

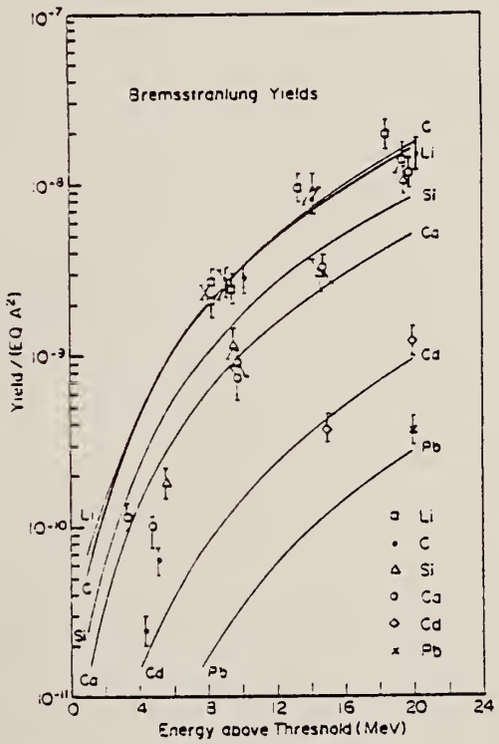

FIG. 6. The experimental and calculated yields for (γ,π^0) off a range of complex nuclei. The data were scaled so that the ^{12}C$(\gamma,\pi^0)^{12}$C experimental yield fit the calculated yield at 9.7 MeV over threshold (see text).

YIELD DATA TABLE:

It should be noted that the yield of photoprotons of the energy considered rises smoothly with Z for the elements plotted in Fig. 3, and that starting already with Al, no direct proportionality to Z is observed on account of the effect of the Coulomb barrier. For illustration, we give the yields of photoprotons $Y(\gamma, p)$ per proton in the nucleus for several elements in relative units (the error in these measurements was estimated to be ± 10 %):

	Li^6	Li^7	Be	C	Al	Cu
$Y(\gamma,p) =$	1.49	1.37	1.3	1.31	1.00	0.56

The dotted portions of the histogram indicate the magnitudes of the standard deviations. The two points with error bars in (a) represent the results of Titterton and Brinkley [5] obtained for γ radiations of energy 14.8 and 17.8 MeV.

Ref 5: Titterton & Brinkley - Proc. Phys. Soc. 67, 469 (1954)

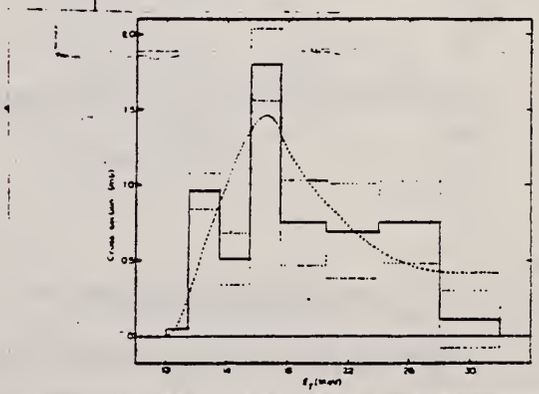

Fig. 6(b). The only difference with fig. 6(a) is that the histogram was obtained by averaging the cross-section over different ranges.

Table 2

The values of $B(E2\uparrow)$ are determined by extrapolation to $q^2 = 0$ of a fit to the relation $\frac{3}{2}\langle 1p|J_2(qr)|1p\rangle^2 = \frac{3}{2}x^2 \exp(-2x)$, where $x \equiv \frac{1}{4}q^2a_o^2$ and the oscillator parameter $a_o^2 = 2.95$ fm^2, as determined from the elastic form factor of Li^7. The values of $B(M1\uparrow)$ are determined from the peak cross sections [9] of the reactions $Li^7(\gamma,t)He^4$.

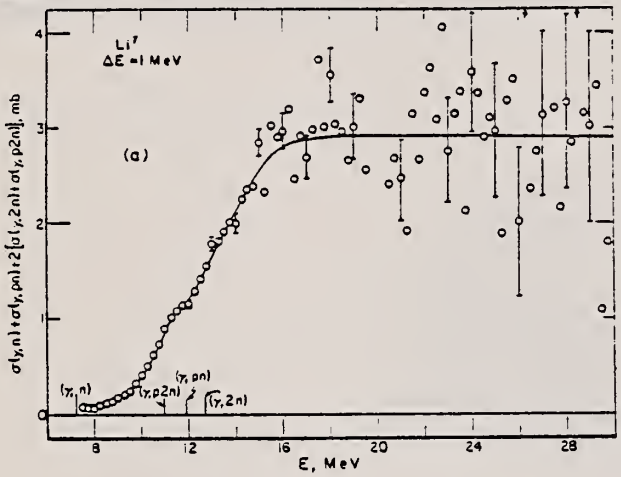

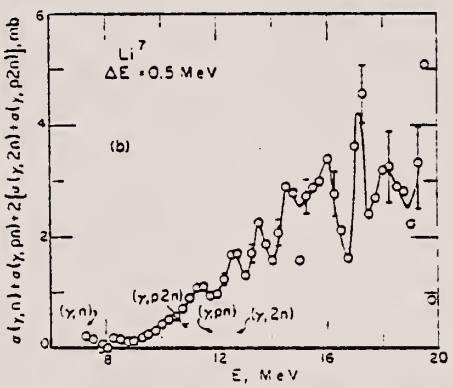

Fig. 4. The neutron production cross section for Li^7 where the analysis has been made using a 1 MeV grid (a) and a 0.5 MeV grid (b). Thresholds for the neutron producing cross sections are indicated by vertical lines at the bottom (a) and by dotted vertical lines at the bottom (b). The indicated errors are standard deviations based only on the number of counts. The arrows at the top represent points that exceed the dimensions of the graph, and the horizontal line is the average value of the cross section above 20 MeV.

Table II
Integrated cross sections

Reaction	σ_{int}, MeV-mb, Interval of energy E_γ, MeV: 0–23	23–33	33–52
(γ, p) *	14.0 ± 1.5	4.6 ± 0.5	Not determined
$(\gamma, p2n)$ *	13.3^{+3}_{-2}	12.0 ± 2.0	Not determined
(γ, pt) **	—	13.8 ± 2.5	22 ± 3
(γ, n) ***	$3.5^{+5}_{-3.5}$ $(2.5^{+5}_{-2.5})$	3^{+4}_{-3} (0^{+4}_{-3})	Not determined
(γ, nd) ***	—		33 ± 4 (32 ± 4)
(γ, nt) ***	Not determined		
(γ, nd) *	—	1.6 ± 0.4	4.2 ± 1
(γ, npd)	—		
$(\gamma, 2d)$	—		
(γ, t)	2.6 ± 0.3	1.2 ± 0.1	Not determined

*The cross section for the (γ, p) reaction was determined from curve 5, and for the $(\gamma, p2n)$ reaction from histogram 2 in Fig. 2; the cross sections for the (γ, nd), (γ, npd), and $(\gamma, 2d)$ reactions were determined from the curve for σ_4 in Fig. 5b.

**In the interval 23–33 from histogram 3, and in the interval 33–52 MeV from curve 4 in Fig. 2.

***The cross sections of the reactions indicated in the intervals 0–23 and 23–33 MeV were determined as $\sigma_n - 2\sigma(\gamma, p2n)$. The values without parentheses were computed from the data on σ_n from [1] and the values in parentheses were computed from [2]. In the interval 33–52 MeV the cross section was obtained on the assumption (see text) that $\sigma(\gamma, nt) \approx \sigma_n - \sigma_{4n}$.

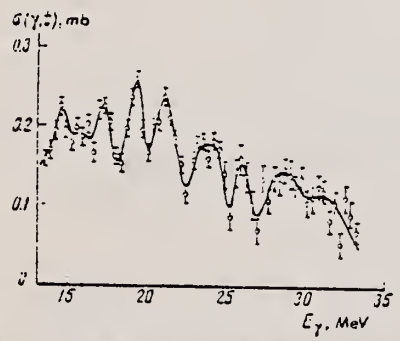

Fig. 4. Cross-section curve for the (γ, t) reaction.
From Brems spectrum

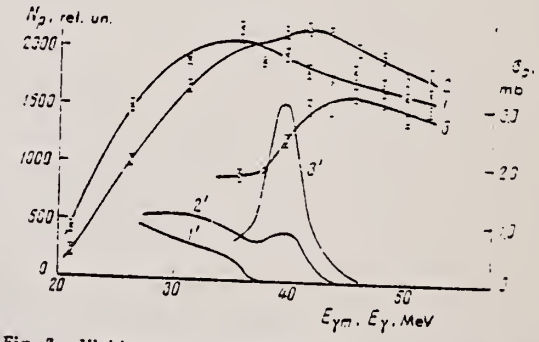

Fig. 3. Yield curves for protons (curves 1, 2, 3 with experimental points) and the corresponding curves 1', 2', 3' of the cross section for the following proton energy intervals: curve 1 – 4–7 MeV; curve 2 – 7–10.5 MeV; curve 3 – 10.5–17 MeV. The abscissa represents the value of $E_{\gamma m}$ for curves 1, 2, 3 and E_γ for curves 1', 2', 3'.

Protons presumably associated with mesons produced from individual nucleons. Amorphous part is yield of 340 MeV protons.

COHERENT BREMS.

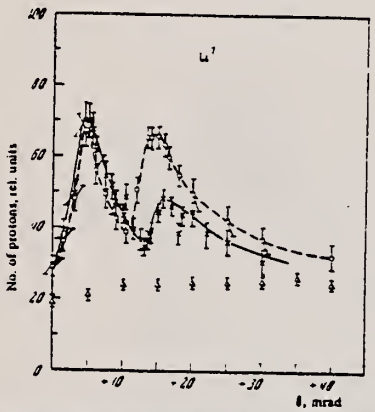

FIG. 3. Proton yield in the (γ, p) reaction in Li^7 as a function of crystal orientation angle θ for plane of polarization directions perpendicular (dashed curve and $O - N_\perp/N_0, \phi_1 = 90°$) and parallel (solid curve and $x - N_\parallel/N_0, \phi_1 = 0°$) to the plane of the reaction; Δ – amorphous part.

In Fig. 3 we have shown in relative units the experimentally measured proton yield from Li^7 for 68-MeV protons at an angle of 33°, as a function of the angle θ between the primary electron beam direction and the ⟨110⟩ axis. Here the ⟨001⟩ axis lies in the plane determined by the beam and the ⟨110⟩ axis of the crystal. The primary electron beam energy is 1120 MeV.

Summary

The cross-sections of the (γ, p) (γ, d) reactions were investigated. Li^7, Be^9, C^{12}, Si^{28}, Cu^{63}, Mo^{94} and Ta^{181} targets were irradiated with the bremsstrahlung of 700 and 1200 MeV maximum energy from the Kharkov PhTI Ac. Sci. UkrSSR linear accelerator. The photoprotons and deuterons were detected by the scintillation telescope at 30°, 60°, and 120° with the beam. Possible mechanisms of the proton and deuteron photoproduction are discussed. The qualitative agreement of *A* dependence of the cross-sections is observed with a suggestion on the meson mechanism for these reactions.

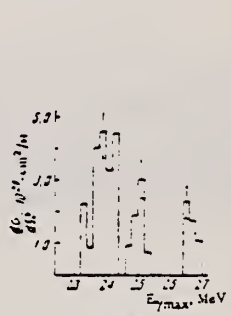

FIG. 2

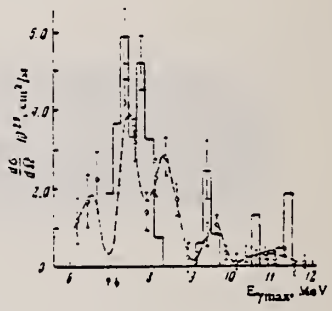

FIG. 3

FIG. 2. Dependence of the cross section for $Li^7(\gamma, \gamma' t)$ He^4 on the energy of scattered γ rays.

FIG. 3. The histogram represents the cross section for $Li^7(\gamma, \gamma' t)$ He^4 as a function of scattered γ – ray energy, as derived from the phototriton spectra. The dashed curve through the experimental points is the same function, as derived from the scattered γ – ray spectra.

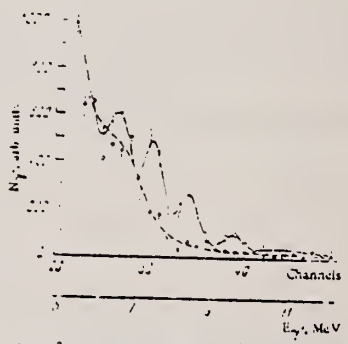

FIG. 4. Spectra of γ rays scattered in Li^7 and Li^6 targets for identical bremsstrahlung doses. For Li^7 – open circles and the solid curve; for Li^6 – filled circles and the dashed curve.

Inelastic scattering of γ rays, which is one of the inadequately investigated processes of nuclear physics, is studied in the reaction $Li^7(\gamma, \gamma')Li^{7*} \rightarrow He^4 + H^3$. When investigating phototritons from the Li^7 nucleus by analyzing triton yield curves for narrow energy intervals a triton group was found having its production threshold between the thresholds of the (γ, t) and (γ, pt) reactions (2.46 and 22.28 MeV, respectively). These tritons can be attributed only to a (γ, γ't) reaction. The integral cross section for the (γ, γ't) reaction was found to be 1.1 ± 0.3 MeV-mb for 3.5–10 MeV tritons. The (γ, γ') cross section was also investigated by direct registration of scattered γ rays. The spectrum of the scattered γ rays shows peaks at 7.5, 8.4, and 9.5 MeV.

999 = 1115 MEV

The angular distributions of photoprotons in the reaction $\gamma + Li^7 \rightarrow p + X$ have been measured for maximum γ-ray energies of 620 and 1115 MeV for proton energies of 80, 160, and 285 MeV in the angular range 25–140°. The experimental results agree satisfactorily with a calculation assuming two elementary processes: single meson production from free nucleons and disintegration of quasideuterons, in the region where the contribution of double meson photoproduction is small.

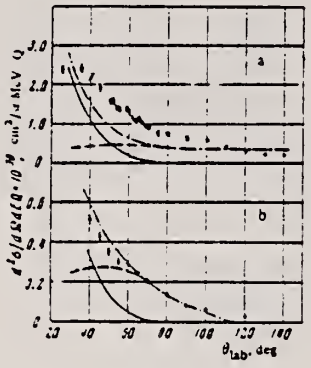

FIG. 1

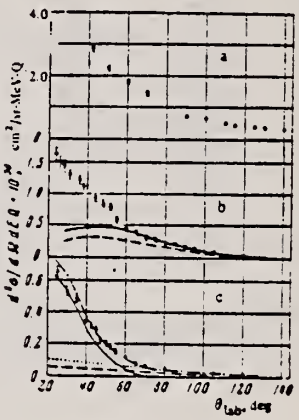

FIG. 2

FIG. 1. Angular distributions of protons from the nucleus Li^7 for a bremsstrahlung energy E_0 = 620 MeV: a–E = 80 MeV. Dashed line–calculation according to Levinger's quasideuteron model. [7] Solid line–calculation with inclusion of reactions (3) and (4) in the impulse approximation; dot-dash line–sum; b–the same for E = 160 MeV.

FIG. 2. Angular distribution of protons from the nucleus Li^7 for E_0 = 1115 MeV; a–E = 80 MeV, b–E - 106 MeV, c–E = 285 MeV. The designations are the same as in Fig. 1. The dotted curves indicates extrapolation of the quasideuteron yield to the small-angle region.

PI-/PI+ YIELD RATIO

Measurements are reported of the relative yield of π^+ mesons and the π^-/π^+ yield ratio for mesons with energy 40 ± 10 MeV emitted in the angular range θ_{lab} = 50—160° in photon-induced reactions with E_γ^{max} = 500 MeV with light and medium nuclei. The charged π-meson detector was a 34-cm Freon bubble chamber with a tube for the beam. The π^-/π^+ yield ratio for He^4, Li^7, C^{12}, Si^{28}, S^{32}, Ca^{40}, and Nb^{93} was found to be respectively 0.94 ± 0.14, 2.15 ± 0.31, 1.22 ± 0.21, 1.25 ± 0.15, 1.0 ± 0.13, 1.11 ± 0.13, and 1.53 ± 0.25. It was established that the π^+-meson yield follows a $ZA^{-1/3}$ law.

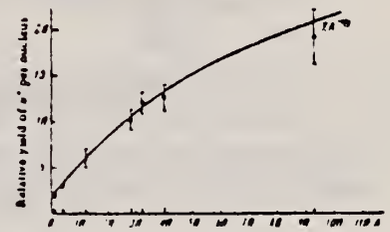

FIG. 2. Relative yield of π^+ mesons per nucleus as a function of mass number A.

SEP ISOTOPES

2.4 MeV $\leq E_p \leq$ 23 MeV

The energy distributions of photoprotons from ^{7}Li have been measured for 40 values of the maximum bremsstrahlung energy $E_{\gamma m}$ ranging upwards from $E_{\gamma m} = 15.5$ MeV in $\Delta E_{\gamma m} \approx 1$ MeV steps. Analysis of these distributions shows that the ^{6}He final nucleus can be formed with excitations up to ~17 MeV. Transitions to the ^{6}He ground state and first excited state (1.8 MeV) were detected and indications were found of transitions to previously unknown levels (or groups of levels) at 2.5 and 8.5 MeV. Partial cross sections for the (γ, p) reaction with the formation of ^{6}He were found by the isochromat method.

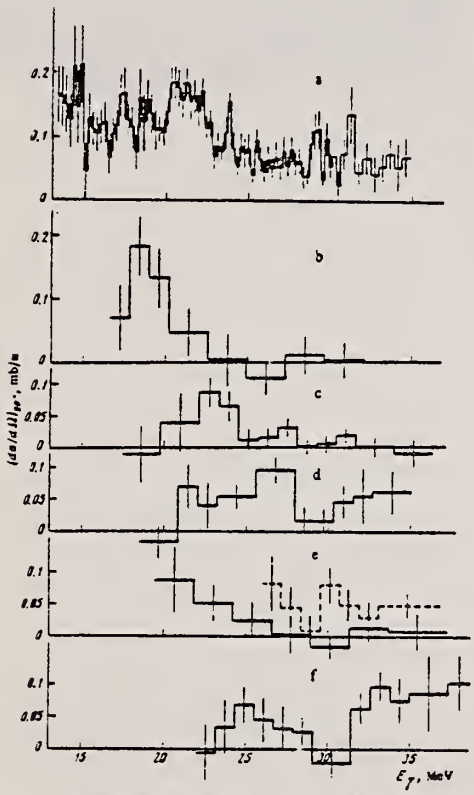

FIG. 3. Cross sections for individual ^{7}Li(γ, p) ^{6}He reaction channels corresponding to the formation of ^{6}He in the ground state (a), the first excited state at 1.8 MeV (b), and with excitation energies in the following intervals (MeV): 2.1–3.6 (c), 3.6–5.7 (d), 5.7–7.7 (e, full histogram), 7.7–11.0 (f), and 11.0–14.5 (e, dashed histogram).

TABLE II. Integral cross sections σ_{int} for individual channels of the ^{7}Li(γ, p)^{6}He reaction corresponding to the formation of ^{6}He with different excitation energies E(E_γ = 18–35 MeV)

E, MeV	σ_{int}, MeV·mb	E, MeV	σ_{int}, MeV·mb
0	14.4±0.6	5.7÷7.7	3.2±1.8
1.8	4.0±1.6	7.7÷11.0	5.3±1.7
2.1÷3.6	5.4±1.4	11.0÷14.5	6.2±1.5

Energy distributions of photodeuterons from ^{7}Li have been measured for various bremsstrahlung maximum energies. From difference spectra of the deuterons it has been established that in the region of the ^{7}Li giant resonance the (γ, d_0) reaction occurs intensely with formation of the ^{5}He nucleus in the ground state, and a group of deuterons has been observed which can be due to the reaction (γ, d_1) with formation of the final nucleus in the first excited state. The integrated cross sections of these reactions, on the assumption that the (γ, d_1) reaction actually occurs, are respectively 4.0±0.5 and 3.2±0.7 MeV-mb in the range $E_\gamma = 16.5$–30 MeV. In addition we have observed the emission of deuterons, which must be due to decay of ^{7}Li states with energies 25–30 MeV into $n + d + {}^4$He (5±2 MeV-mb), and also to some kind of complex disintegration of ^{7}Li (~5 MeV-mb) by γ rays with energy $E_\gamma = 37$–50 MeV.

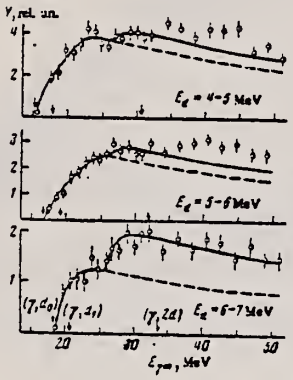

FIG. 3. Some deuteron yield curves and their approximation by isochromats. The arrows indicate the kinematic thresholds of the reactions shown.

Reaction	$E_{\gamma_1} \div E_{\gamma_2}$, MeV	σ^*_{int}, MeV-mb	$\frac{[\sigma(\gamma, d_0)]_{int}}{\sigma_{int}}$

			TYPE	RANGE	TYPE	RANGE	
G,N	ABX	8- 23	C	13- 25	TOF-D		90

Photoneutron energy spectra from ^{7}Li have been measured by time-of-flight methods, for bremsstrahlung end-point energies increasing in 2 MeV steps from 13 to 25 MeV. The ground-state and approximate first-excited-state differential cross sections at 90° have been obtained from 8.5 to 23 MeV. No pronounced fine structure has been observed. The measured branching ratio to the first excited state falls from an average value of 0.70 between 10.3 and 14.5 MeV to an average of 0.29 between 14.5 and 18 MeV, and rises again to an average of 0.38 between 18 and 23 MeV. This behaviour can be explained by a crude theoretical model in which $1p \rightarrow 2s$ and $1p \rightarrow 1d$ single particle transitions dominate below 18 MeV. The calculation predicts a branching ratio of 0.50 near threshold, falling to 0.23 at higher energies, in reasonable agreement with the experiment. The integrated value of the ground-state cross section up to 23 MeV is about (38.7 ± 3.9) MeV mb, while that for the first excited state is about (17.2 ± 3.4) MeV mb. Together they account for 39% of the exchange-augmented dipole sum of ^{7}Li.

Abstract: The proton spectral functions of ^{6}Li, ^{7}Li, ^{9}Be and ^{10}B obtained from the (e, e'p) reactions at 700 MeV are presented. The results were analyzed in the distorted-wave impulse approximation, using the shell-model single-particle wave functions consistent with the elastic electron scattering results. The observed 1p proton momentum distributions for the nuclei ^{6}Li, ^{7}Li and ^{9}Be show significant disagreement with the shell-model momentum distributions. The occupation probabilities of the proton single-particle states are around 0.7, with a few exceptions.

*SEPARATION ENERGY

Results are presented of an experimental study of reactions of the type ^{6,7}Li (γ, ab)X with emission of charged particles a and b detected in coincidence. It is established that the major part of such reactions are reactions of the type ^{6,7}Li (γ,pt)X. The results of measurement of the correlations of the directions of emission and energy distributions of protons and tritons are explained on the basis of the assumption of photodisintegration of α clusters in the ground state of the nuclei ^{6,7}Li into a proton and triton and of formation of the residues X in the form of two ($d+n$) particles in reactions ^{6}Li (γ, pt)X, and two ($d+n$) particles and possibly three ($n+p+n$) particles in reactions ^{7}Li (γ, pt)X. The value of the average differential cross section of the reaction ^{6}Li (γ, pt) ^{1}Hn in the γ-ray energy interval 35–55 MeV amounts to 0.7±0.2 of the value of the cross section for the reaction ^{4}He (γ, p) ^{3}H. It is shown that in addition, three-particle reactions of the type ^{6}Li (γ,td) ^{1}H and ^{7}Li (γ, π) ^{1}H occur, but with a kinematics differing from that of the photodisintegration of α clusters, and also two-particle reactions of the type ^{6}Li (γ, t) ^{3}He and ^{7}Li (γ, t) ^{4}He.

Total cross sections for $^{12}C(\gamma,\pi^-)^{12}N$ and $^7Li(\gamma,\pi^-)^7Be$ have been measured from threshold to 360 MeV photon energy by detecting the radioactivity of the residual nuclei, thereby singling out the ground state of ^{12}N and the ground and first excited states of ^7Be. The cross sections are found to peak at about 40 MeV pion energy and then to fall gradually. In contrast to pion charge exchange and other photopion experiments, these results are well reproduced both in shape and in magnitude by distorted-wave impulse-approximation calculations.

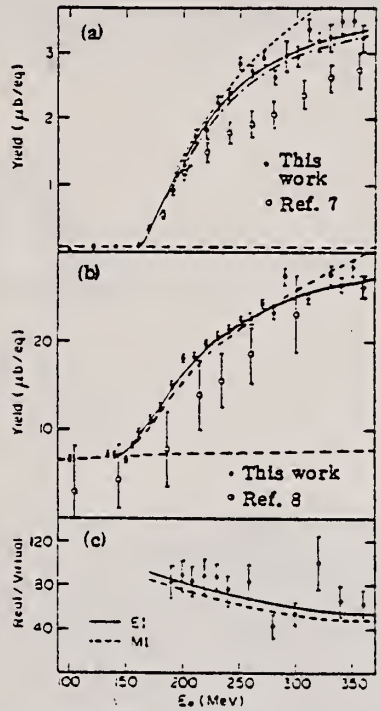

FIG. 2. Yields for (a) ^{12}C and (b) ^7Li as a function of incident electron energy. The theoretical curves are those calculated from the corresponding cross sections shown in Fig. 3 with the two-step background added back in. (c) Real-to-virual ratios per equivalent quantum (i.e., photoproduction-to-electroproduction ratios) for ^{12}C vs endpoint energy compared with Dalitz-Yennie predictions.

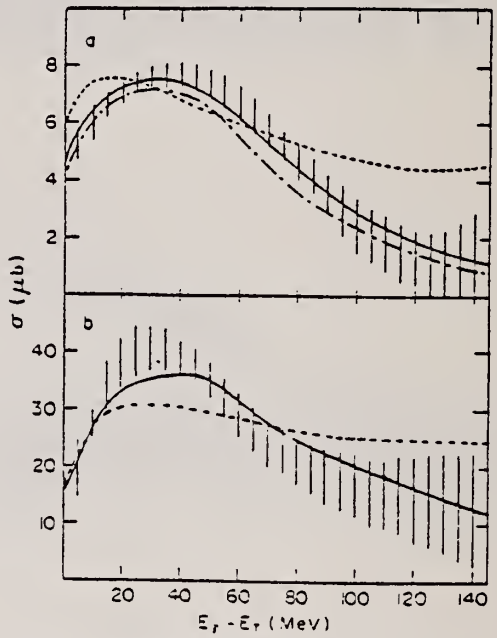

FIG. 3. Extracted cross sections for (a) ^{12}C and (b) ^7Li vs photon energy above threshold (shaded regions). Calculation of EST (see Ref. 13) shown as solid lines (full interaction) and dotted line (Coulomb only). Calculation of NU (see Ref. 15) shown as dash-dotted line.

The photodisintegration of the stable Lithium isotopes has been investigated by spectroscopy of the emitted charged particles using the Giessen bremsstrahlung facility. Protons, deuterons, tritons, ^{3}He and alpha particles were detected and identified up to 20 MeV particle energy. Angular distributions were measured using γ-ray energies up to $E_\gamma = 50$ MeV. They are compared with theoretical predictions and with other experiments. A remarkable low (γ, t)-cross section was found for both isotopes in disagreement to previous measurements using virtual photons. Coincidence measurements between the emitted particles were performed in order to study the manybody-breakups of ^{7}Li.

Measurements have been made for the first time of the contributions of the longitudinal and transverse components to the cross section for inelastic scattering of electrons by the ^{7}Li nucleus in the region of the pion-production threshold and the (33) resonance. The violation of the impulse approximation in the region of the minimum between the quasielastic scattering peak and the (33) resonance peak is associated with the contribution of meson-exchange currents.

The α-t interaction potential model, which takes into account forbidden states in ^{7}Li, was used to calculate cross sections for the ^{7}Li(γ, t)^{4}He reaction. In addition, the energy and angular dependence of the reaction cross section was also measured. Comparison of experiment and calculation shows that the model describes $E1$ absorption well. However, there are discrepancies in the coefficients which determine the contribution of $E2$ absorption to the angular distribution.

BERYLLIUM
Z=4

Berylia (beryllium oxide) was first isolated in 1797 by L. N. Vauquelin from beryl, a silicate of beryllium and aluminum, from which came the name beryllium. The word has its origin from the German word Brille "eye glasses" for the reason that Nero had a kind of monocle made from optically clear polished beryl. The alternate name, glucinum, reluctantly adopted by Vauquelin, was suggested by the editors of Annales de Chimie, publishers of Vauquelin's article, because of the pronounced sweetish taste of its salts.

Giant Dipole Resonances in p-Shell Nuclei.*

J. L. Black, F. Riess, P. Paul,# W. J. O'Connell, G. A. Fisher, and S. S. Hanna

Department of Physics, Stanford University, Stanford, California, U.S.A.

The giant dipole resonances in p-shell nuclei have been studied by means of the (p,γ) capture reaction. The capture gamma rays are detected with good resolution with a 24 x 24 cm NaI detector encased in an anticoincidence plastic shield and employing pulse pile up suppression. The region of the giant resonance can be covered with good energy resolution with protons from an FN tandem accelerator up to proton energies of 18 MeV. Fine structure and gamma ray angular distributions for giant resonances observed in ^{8}Be, ^{14}N, and ^{16}O have been studied. For ^{8}Be and ^{14}N the giant resonances based on the first excited state can also be studied. The resonances observed in $^{7}Li(p,\gamma)^{8}Be$ are shown in Fig. 1. The γ_0 giant resonance shows little structure. The γ_1 resonance exhibits some structure at E_x = 22 MeV. The center of the γ_1 resonance lies about 2.5 MeV above the center of the γ_0 resonance. Thus, the excitation energy for both resonances is about the same, 21.5 MeV. The dipole strengths of the resonances are about equal i.e., the integrated yields are roughly proportional to 2J + 1, where J is the spin of the final state. In ^{14}N the first excited state has T = 1, so that resonances based on a T = 1 level are observed. Previous measurements[1] on $^{15}N(p,\gamma_0)^{16}O$ have been extended to E_p = 17.5 MeV. Above E_x = 25.5 MeV, no pronounced structure was revealed. In addition, the main peak of the giant resonance at E_x = 22.2 MeV has been studied in detail with high resolution to search for possible fine structure. Results at θ = 45°, shown in Fig. 2, indicate the existence of structure in this peak. A measurement at θ = 90° displays similar structure. The results are compared with recent $^{16}O(\gamma,p)^{15}N$ data.[2]

Abstract: The polarized proton capture in ^{7}Li was used to study the reaction mechanism and to obtain spectroscopic information on the ^{8}Be nucleus. Gamma-ray angular distributions of the analyzing power were measured as a function of proton energy from E_p = 330–960 keV with three Ge(Li) detectors simultaneously. The excitation functions of the cross section and the analyzing power are strongly energy dependent. The data were analyzed unambiguously and represented by three R-matrix elements, two M1 and one E1. The energy dependence of the two M1 matrix elements agrees with the well-known two 1^+ resonances at E_x = 17.642 and 18.157 MeV. The energy dependence of the E1 matrix element shows a smooth background presumably caused by a direct-capture mechanism, and furthermore, a resonant contribution, which is a significant suggestion of a new 1^- state in the ^{8}Be system at E_x = 17.70 MeV with a width of Γ_p = 180 keV.

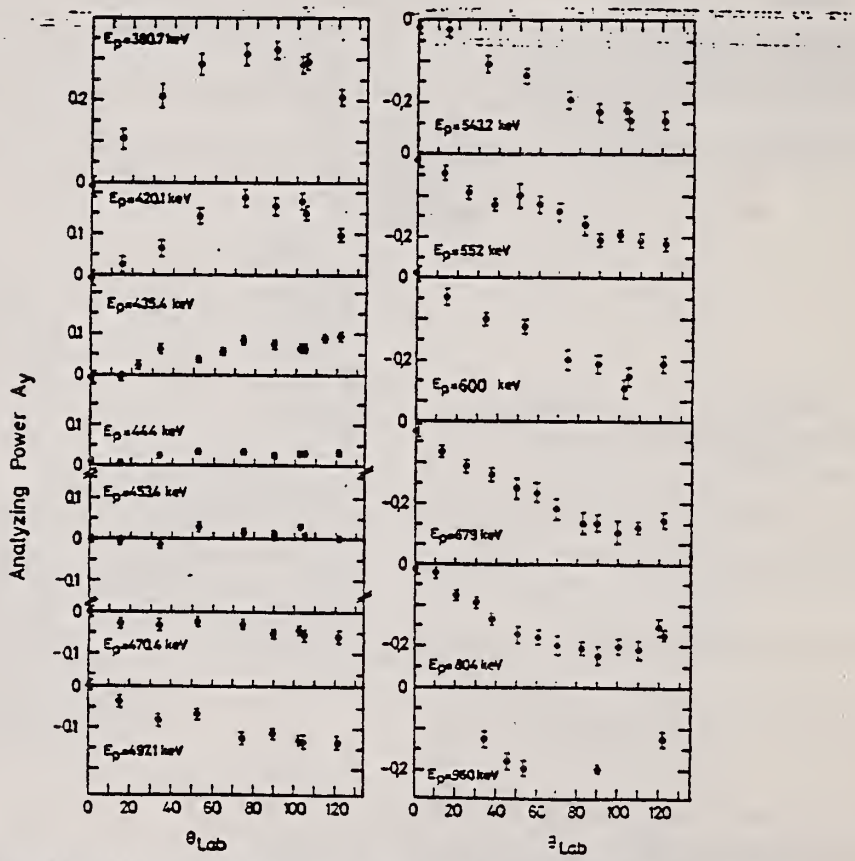

Fig. 4. Analyzing power angular distributions $A_y(E, \theta)$ of the ^{7}Li(p, γ)^{8}Be reaction for proton energies between 380 and 960 keV. All proton energies refer to the center of the target. Error bars are from statistics only.

(continued)

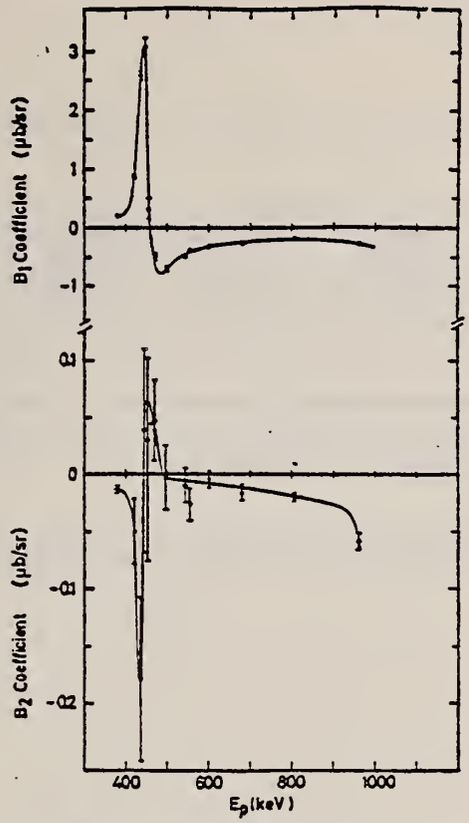

Fig. 6. The B_1 and B_2 coefficients obtained from the fits (eq. (3)) of the data. The solid lines are only to guide the eye. The assigned errors result from the fitting procedure of the complete angular distribution.

						$\sigma(\gamma,t)/\sigma(\gamma,d)$ summed over angles 35°-145°

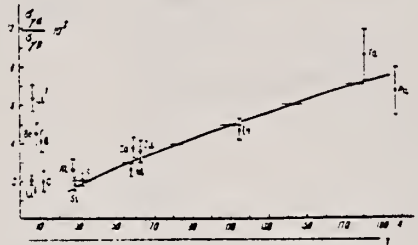

FIG. 3. Ratio of (γ, d) to (γ, p) cross sections for protons and deuterons of energies 15.5–30 Mev as function of atomic weight A. The solid curve shows the dependence given by Eq. (2), arbitrarily normalized.

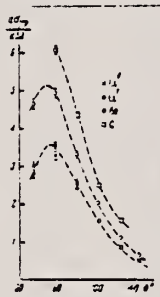

FIG. 6. Angular distributions of photoprotons of energies 15.5–30 Mev for Li^6, Li^7, Be, and C. The errors are statistical.

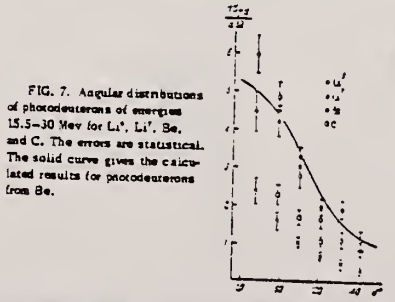

FIG. 7. Angular distributions of photodeuterons of energies 15.5–30 Mev for Li^6, Li^7, Be, and C. The errors are statistical. The solid curve gives the calculated results for photodeuterons from Be.

YIELD DATA TABLE:

It should be noted that the yield of photoprotons of the energy considered rises smoothly with Z for the elements plotted in Fig. 3, and that starting already with Al, no direct proportionality to Z is observed on account of the effect of the Coulomb barrier. For illustration, we give the yields of photoprotons $Y(\gamma, p)$ per proton in the nucleus for several elements in relative units (the error in these measurements was estimated to be ±10%):

	Li^6	Li^7	Be	C	Al	Cu
$Y(\gamma,p)$ =	1.10	1.07	1.0	1.01	1.00	0.56

POL OF NEUTS

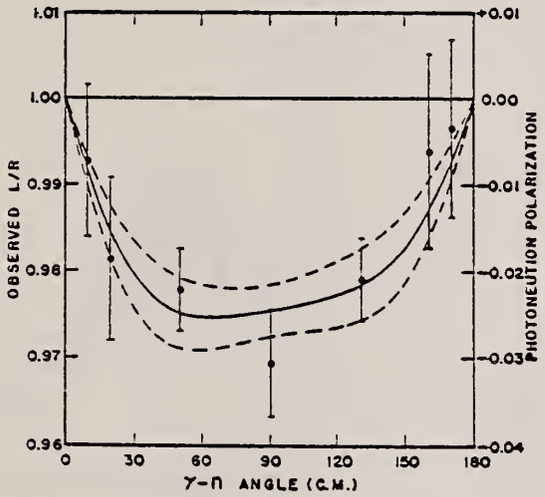

Fig. 1. Plot of the polarization of photoneutrons from $Be^9(\gamma,n)$. The abscissa is the γ-n angle, the left ordinate the observed left-right ratio of the neutrons scattered from a helium analyzer. The right ordinate is the polarization of the neutrons calculated from the data (Basel sign convention). The errors on the measured points are statistical only. The solid curve is a least-squares fit of eq. (1) to the data, the dotted curves being one standard deviation from the best fit.

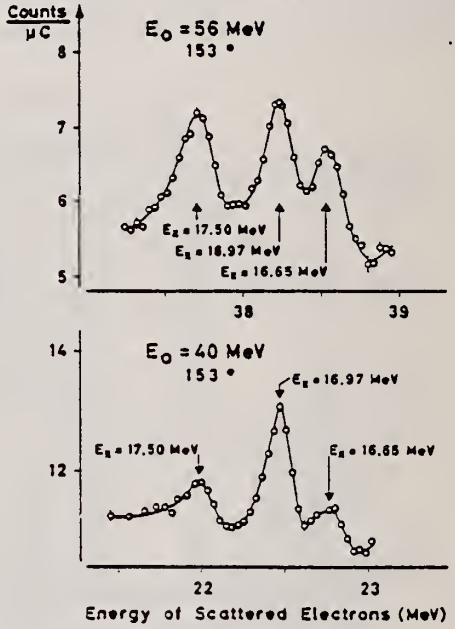

Fig. 2. Spectrum of inelastically scattered electrons from ^{9}Be. The inelastic momentum transfer if q = 0.467 fm^{-1} in the upper and q = 0.310 fm^{-1} in the lower part of the figure. Note the suppressed zero of the ordinate scales.

Table 1: Summary of experimental results
The first and second columns give the excitation energies in ^{9}Be and the multipolarities as determined in this experiment. For the type of transition indicated in column 2, the ground state radiation widths Γ_γ^0 and the transition strengths in Weisskopf units Γ_W are given in column 3 and 4. respectively; the statistical factor g is defined by $g = (2I_f + 1)/(2I_i + 1)$ with $I_i = \frac{3}{2}$. The last column lists the transition radii R_{tr} as defined in refs. 15 or 14.

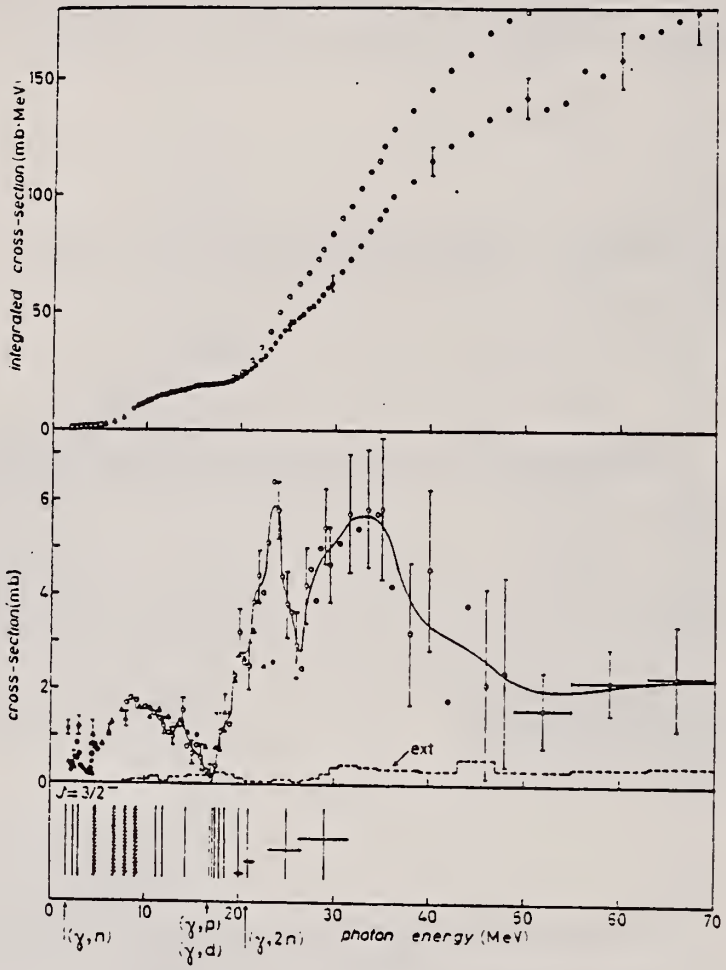

Fig. 2. – Upper part: the integrated cross-section of process ^{9}Be(γ, Tn) is shown (points). The open circles represent the sum of the (γ, Tn) and (γ, p) integrated cross-sections; ▫ $\int\sigma(\gamma, \mathrm{Tn})$, JAKOBSON; ▲ $\int\sigma(\gamma, \mathrm{Tn})$, NATHANS and HALPERN. Middle part: cross-section of the process ^{9}Be(γ, Tn). An average curve (solid line) is drawn through the experimental values (open circles). In the high-energy tail these values have been averaged over the indicated intervals. Previous measurements up to 23 MeV are also reported: • JAKOBSON; ▲ EDGE; ▲ NATHANS and HALPERN. The dashed histogram shows the contribution to the (γ, Tn) cross-section arising from the EXTernal counters. Lower part: energy-level diagram of ^{9}Be [ref. (10)]. Vertical lines with horizontal arrows indicate the levels at (20 ± 0.5), (21 ± 0.6), (25 ± 2) and (29 ± 3) MeV suggested in ref. (4).

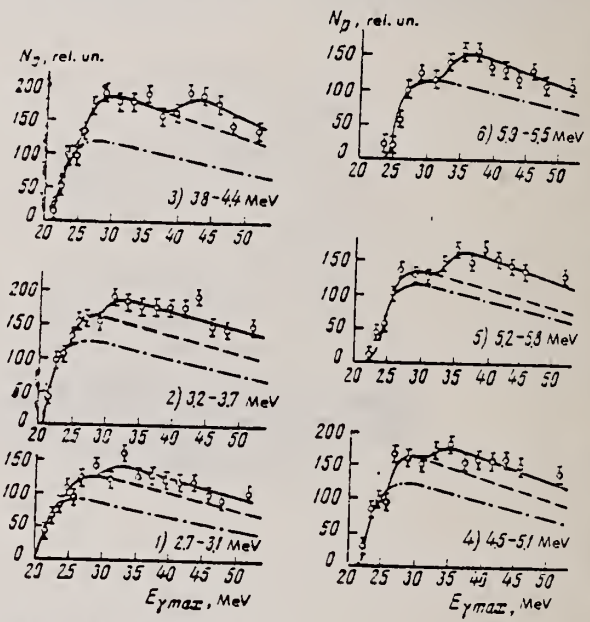

Fig. 2. Proton yield curves for individual sections of the proton spectra, as a function of $E_{\gamma max}$. The points denote the experimental values. The solid curve is a superposition of bremsstrahlung isochromats normalized to the total energy, chosen so as to best approximate the experimental points; the dot-dash curves are isochromats of transitions to the ground and first excited states; the dashed curves are with the isochromats of transitions to the second and third excited states added to the first. N_p is the relative number of protons.

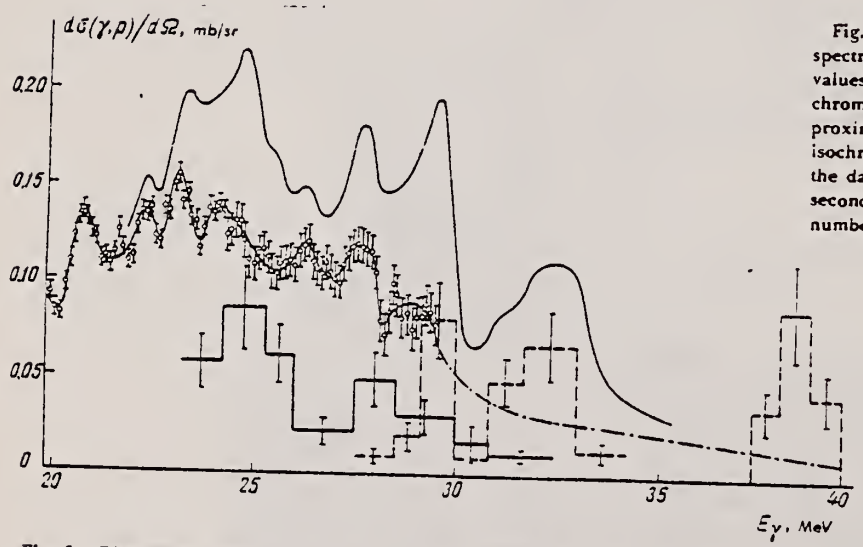

Fig. 3. Differential cross-section curves for the reaction $Be^9(\gamma,p)Li^8$, obtained from photoproton spectra for an angle of 90°. The curve with the experimental points is the sum of the cross sections for transitions to the ground state and first excited state (0.98 MeV); its extension (the dot-dash curve) is the cross section obtained from the proton spectra of Chuvilo and Shevchenko[13] on the assumption of transitions only to the ground state, normalized to our data; the solid histogram is the sum of cross sections for transitions to the second and third excited states; the dashed histograms are the cross sections for transitions to the states ~9 MeV and ~17 MeV; the solid curve represents the smoothed combined cross sections for the reaction, $d\sigma/d\Omega$.

2.44±0.02	< 30	M1	2.7±0.5	$8.9 \cdot 10^{-3}$	$89 \cdot 10^{-3}$±11 %	0.30
		C2	3.1±0.4	41.6	$1.89 \cdot 10^{-3}$±7 %	24.4
3.04±0.03 [b])	450±150	C1	(2.46)	$1.5 \cdot 10^{-2}$	0.45/g±83 %	0.054/g
		M1	2.9±0.9	$3.0 \cdot 10^{-2}$	$3.8 \cdot 10^{-2}$/g±51 %	0.15/g
4.7 ±0.2	700±300	C(1)	(2.46)	$2.3 \cdot 10^{-2}$	2.4/g±47 %	0.079/g
6.4 ±0.2	1100±300	(C2)	(3.1)	15	$8.2 \cdot 10^{-2}$±42 %	8.3

Column 3 gives the character and multipolarity of the transitions as determined in this experiment; Cλ denotes a longitudinal electric, Mλ a magnetic transition of multipolarity λ. Values in parenthesis have been used but not determined by this experiment; the M1 assignment for E_x = 3.04 MeV is tentative. The M1 and C2 reduced photon transition probabilities and ground state widths Γ_γ^0 have been decreased by 4 % to account for the error of the Born approximation. To calculate Γ_γ^0 the excitation energies given in column 1 were used (without errors); only for the 2.44 MeV level was the value 2.429 MeV from ref. [1]) used. The statistical factor is $g = (2I+1)/4$, with I the spin of the excited state. For the spins of the levels at 1.78, 2.44 and 6.4 MeV, $I = \frac{1}{2}, \frac{4}{2}$ and $\frac{7}{2}$, respectively, were assumed. The last column gives the transition strengths in Weisskopf units Γ_W defined in ref. [47]).

[a]) Units are fm² for C1 and M1, and fm⁴ for C2; $k = E_x/\hbar c$.

[b]) Energy of the centre of the peak.

Summary

The cross-sections of the (γ, p) (γ, d) reactions were investigated. Li^7, Be^9, C^{12}, Si^{28}, Cu^{63}, Mo^{96} and Ta^{181} targets were irradiated with the bremsstrahlung of 700 and 1200 MeV maximum energy from the Kharkov PhTI Ac. Sci. UkrSSR linear accelerator. The photoprotons and deuterons were detected by the scintillation telescope at 30°, 60°, and 120° with the beam. Possible mechanisms of the proton and deuteron photoproduction are discussed. The qualitative agreement of A dependence of the cross-sections is observed with a suggestion on the meson mechanism for these reactions.

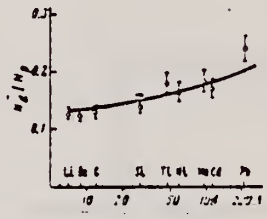

FIG. 4. The ratios N_d/N_p as a function of target-nucleus mass number A at an angle $\theta = 60°$ for E_0 = 1200 MeV. Solid curve—$A^{0.13}$.

The measured secondary-particle spectra for kinetic energies T > 80 MeV are well described by the expression

$$d^2\sigma / d\Omega dTQ = \text{const}\, T \exp(-T/\tau), \qquad (1)$$

which is identical to the formula for the evaporation process.[4] In Table I we have given the values of the parameter τ for the nuclei studied, at various angles. The accuracy in determination of τ is about 10%.

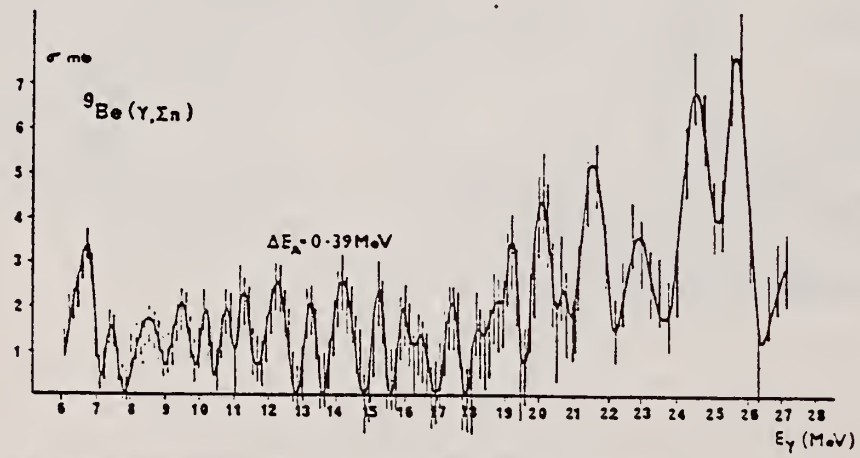

Fig. 2. Photoneutron production cross section in ^{9}Be, deduced from bremsstrahlung yield data on ^{9}Be(γ, Σn) using a Leiss-Penfold analysis [12]). Analysis bin width ΔE_A = 0.39 MeV; 3 sets of data interlaced. Cross sections were smoothed by treating unsmoothed Leiss-Penfold data using as resolution-function formula: $\sigma(E_i) = 0.15\,\sigma(E_{i-1}) + 0.70\,\sigma(E_i) + 0.15\,\sigma(E_{i+1})$.

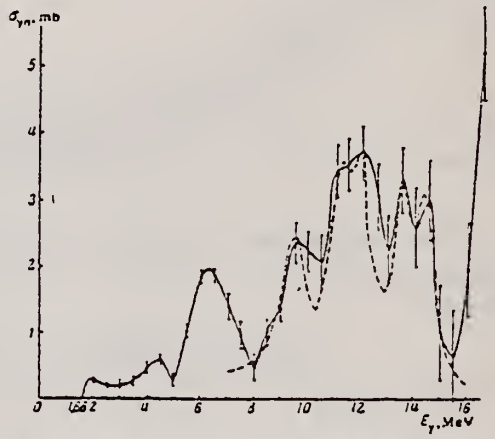
The cross section of the ^{9}Be photoneutron reaction has been measured from the threshold to 15.5 MeV in the bremsstrahlung beam of a betatron. The energy dependence of the cross section has a complicated resonance structure. Possible values of the spin and parity of the ^{9}Be levels are discussed.



Cross section for the (γn) reaction of ^{9}Be. The dashed curve is calculated (see the text).

5 LEVELS

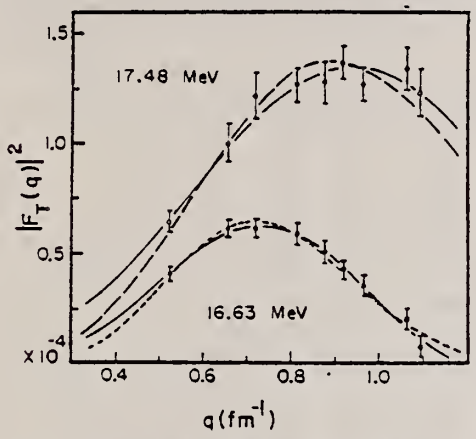

FIG. 4. Transverse form factors for the 16.63- and 17.48-MeV levels. The solid curve through the 16.63-MeV data represents the generalized Helm model fit for an $M1$ transition, and the short-dashed curve is the $E2$ (spin-flip) fit, which is slightly poorer. The $E1$ and $M2$ fits to the 16.63-MeV data are nearly indistinguishable from the solid curve. The solid curve through the 17.48-MeV data represents an $M1$ fit, while the long-dashed curve represents $E1$ and $M2$ fits, which are nearly identical.

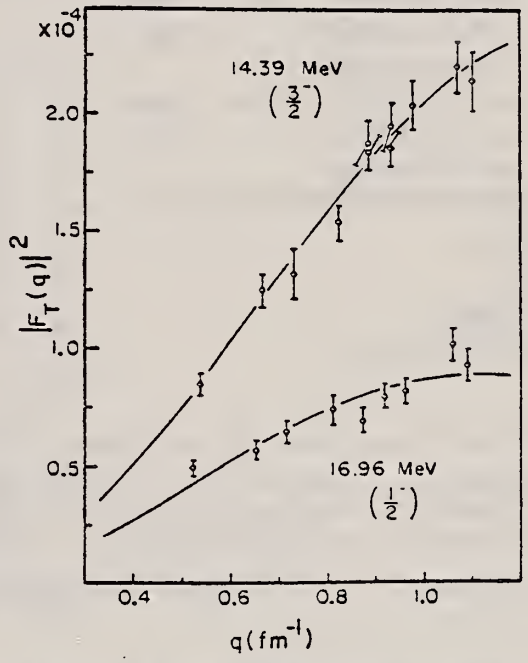

FIG. 3. Transverse form factors for the $T=\frac{3}{2}$ levels in ^{9}Be. The solid lines represent generalized Helm model fits for $M1$ transitions.

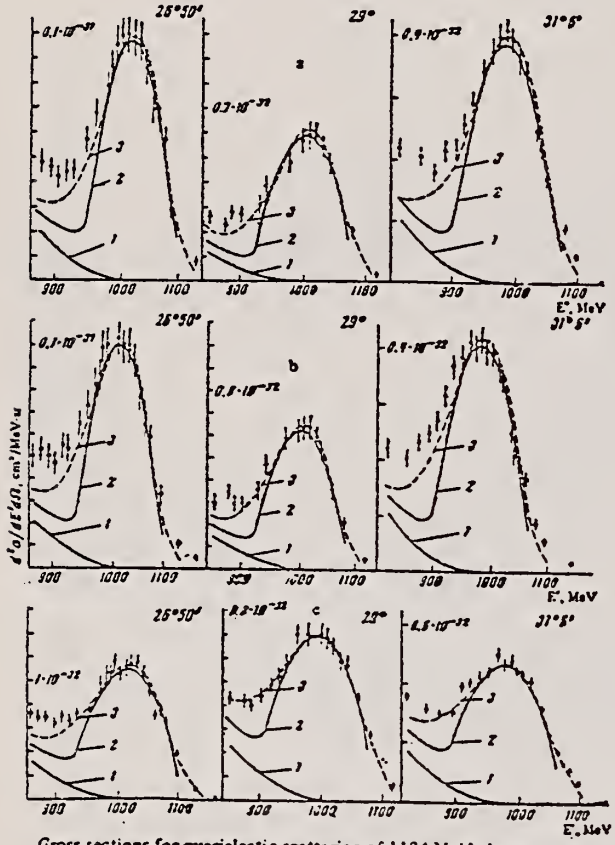
H. Überall, Electron Scattering from Complex Nuclei, Academic Press, New York, 1971.



Cross sections for quasielastic scattering of 1184-MeV electrons on Li^6 (a), Li^7 (b), and Be^9 (c) vs energy E' of electrons scattered at 26°50', 29°, and 31°6'. The curves 1, 2, 3 represent calculations based, respectively, on allowance for the pion contribution, on the Fermi gas model, and on the single-particle shell model.

Nucleus	P_0, MeV/c	$\langle r^2\rangle^{1/2}_{qu.elast}$, F	$\langle r^2\rangle^{1/2}_{elast}$, F	P_F, MeV/c	$\bar{\varepsilon}$, MeV
Li^6	115±4	2.46±0.09	2.54±0.05	157±6	13±3
Li^7	116±4	2.43±0.09	2.37±0.03	160±6	14±3
Be^9	126±5	2.35±0.09	2.43±0.08	180±8	18±3

Remark. P is the oscillator parameter, $\langle r^2\rangle^{1/2}_{qu.elast}$ is the rms charge radius of the nucleus, P_F is the Fermi momentum, $\bar{\varepsilon}$ is the mean nucleon binding energy for $q \gtrsim 300$ MeV/c; all these experimental values were obtained for quasielastic electron scattering on the light nuclei Li^6, Li^7, and Be^9; $\langle r^2\rangle^{1/2}_{elast}$ is the experiment rms radius derived from elastic electron scattering on the same nuclei. We measured the ^{9}Be photoneutron production cross section $\sigma(\gamma, T.n) = \sigma(\gamma, n) + 2\,\sigma(\gamma, 2n) + \sigma(\gamma, pn)$ in the energy range from 17–25 MeV with quasimonoenergetic photons from positron annihilation in flight. In contrast to experiments of Thomas, Crawford and Thies (1972) and Hughes (1973), performed with bremsstrahlung photon sources we found no pronounced structure in this energy range.

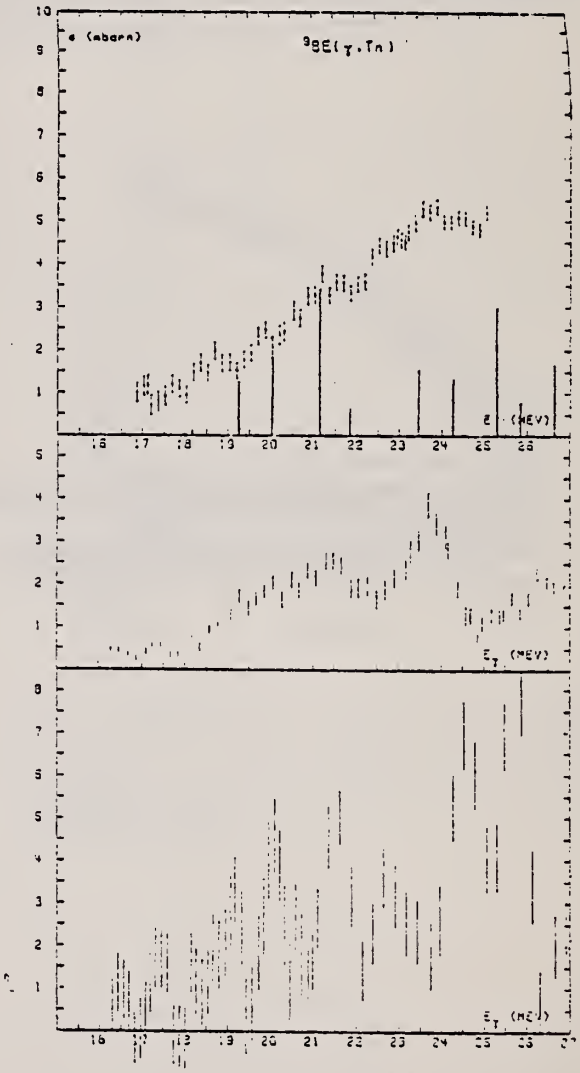

Fig. 1. Upper part: Present experiment with dipole strengths according to Majling [7]. Second curve: Results of the bremsstrahlung experiment of Hughes [4]. Below: Data given by Thomas et al. [1].

Abstract: The absolute total cross section for photoneutron production from ^{9}Be has been deduced from bremsstrahlung yield curves measured from threshold to 28 MeV. Neutron yields were measured using direct neutron counting and were analysed using the variable-bin Penfold-Leiss method. The integrated cross section to 17.8 MeV is 13 ± 1 MeV · mb; and to 27.5 MeV is 28.3 ± 3 MeV · mb. Detailed comparison between experiment and various shell model calculations show some points of agreement either at lower energies or in the GDR but there is no one overall satisfactory detailed version. More refined and detailed calculations are required.

E NUCLEAR REACTIONS ^{9}Be(γ, xn), $E < 28$ MeV; measured neutron yields; deduced total and integrated σ. ^{9}Be deduced resonances.

The $^{9}Be(\gamma,n_0)^{8}Be$ and $^{9}Be(\gamma,n_1)^{8}Be$ reactions were studied in the photon energy region 18 to 26 MeV. The integrated cross section of the (γ,n_0) reaction was found to be less than 0.1 MeV mb in this energy region. The integrated cross section for the (γ,n_1) reaction in the energy region is 2.4 ± 0.4 MeV mb, which is 10 to 15% of the total photoneutron cross section. The measured angular distributions for the (γ,n_1) reaction are consistent with the population of $3/2^+$ and $5/2^+$ states of ^{9}Be. These results are consistent with slightly re-interpreted predictions of Majling, Kukulin, and Smirnov.

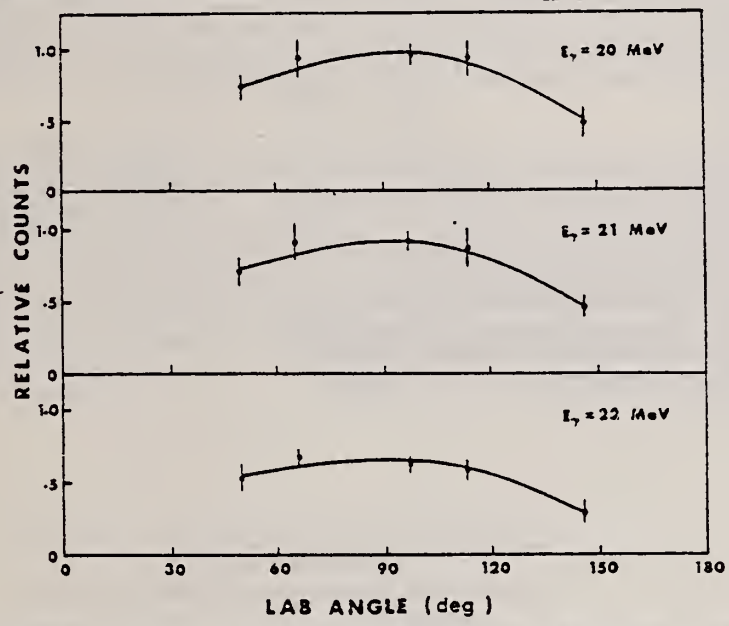

FIG. 2. Angular distributions of photoneutrons from the reaction $^{9}Be(\gamma,n_1)^{8}Be$ at an endpoint energy of 22.5 MeV and at the indicated photon energies.

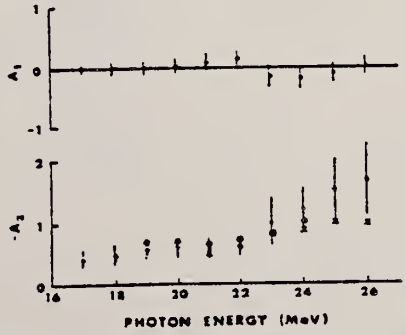

FIG. 3. Angular distribution coefficients for the reaction $^{9}Be(\gamma,n_1)^{8}Be$ from the expression, $W(0) = A_0(1 + A_1P_1(\cos\theta) + A_2P_2(\cos\theta))$. Data are as follows: + 22.5 MeV endpoint; ○ 24.5 MeV endpoint; × 26.5 MeV endpoint; and ● 28.5 MeV endpoint.

G,N to 8Be(16.6)

Alpha particles from the $^{9}Be(\gamma,n)^{8}Be(16.6)$ and $^{9}Be(\gamma,\alpha_0)^{5}He$ reactions were studied in the photon energy region 18 to 26 MeV; the results yielded a combined integrated cross section of 13.1 ± 2 MeV mb and an upper limit on the integrated (γ,α_0) cross section of 4.0 MeV mb. This agrees within error with the integrated cross section of Becchi, Meneghetti, Sanzone, and Vitale, 10 ± 2 MeV mb, which would contain about 50% of any contribution from the (γ,α_0) reaction. These reactions together with the $^{9}Be(\gamma,n_1)^{8}Be$ reaction (which has an integrated cross section of 2.4 ± 0.4 MeV mb) are the major reaction channels contributing to the total photoneutron cross section in this energy region. Their sum, 15.5 MeV mb, agrees well with the results of Nathans and Halpern and Hughes, Sambell, Muirhead, and Spicer but disagrees with that of Costa, Pasqualini, Piragino, and Roasio.

Les particules α émises lors des réactions $^{9}Be(\gamma,n)^{8}Be(16.6)$ et $^{9}Be(\gamma,\alpha_0)^{5}He$ ont été étudiées dans la gamme d'énergie 18 à 26 MeV pour les photons; les résultats ont fourni une section efficace totale combinée de 13.1 ± 2 MeV mb et une limite supérieure de la section efficace totale (γ,α_0) de 4.0 MeV mb. Ceci est en accord, compte tenu de l'erreur experimentale, avec la section efficace totale de Becchi, Meneghetti, Sanzone et Vitale, 10 ± 2 MeV mb, dans laquelle interviendrait une contribution d'environ 50% de la réaction (γ,α_0). Ces réactions, avec la réaction $^{9}Be(\gamma,n_1)$ ^{8}Be, (qui a une section efficace totale de 2.4 ± 0.4 MeV mb) sont les principaux canaux de réaction qui contribuent à la section efficace totale photon-neutron dans cette région d'énergie. Leur somme, 15.5 MeV mb, est en bon accord avec les résultats de Nathans et Halpern et Hughes, Sambell, Muirhead et Spicer mais sont en désaccord avec ceux de Costa, Pasqualini, Piragino et Roasio.

*GEV, QUASIELASTIC

Measurements were made of quasielastic scattering of electrons in the (e, e') reaction by the nuclei ^{9}Be, ^{12}C, ^{14}N, ^{16}O, and ^{27}Al. An experimental estimate is obtained of the effective mass of an intranuclear nucleon. At excitation energies up to 80 MeV, a ratio $M^*/M = 0.6$ is obtained, corresponding to a linear potential $V(E) = V_0 + 0.4E$ and in good agreement with the data on proton scattering by nuclei [C. M. and F. G. Perey, Atomic Data and Nuclear Tables 13, 294 (1974)]. At excitation energies above 120 MeV the nucleon effective mass turned out to be close to that of the free nucleon, $M^*/M = 0.9$.

PROTONS OVER 50 MeV

Data on the differential cross-sections for the emission of photo-protons from beryllium irradiated with bremsstrahlung of various end-point energies up to a maximum of 600 MeV are presented and discussed. Particular attention has been paid to the photon energy-region around 150 MeV, where a dip in the total cross-sections for photon absorption has been reported. No evidence of anomalous structure is observed.
The data are compared with the predictions of the intra-nuclear cascade model PICA. Good fits can be obtained with a value of 7.2 ± 1.0 for the quasi-deuteron constant.

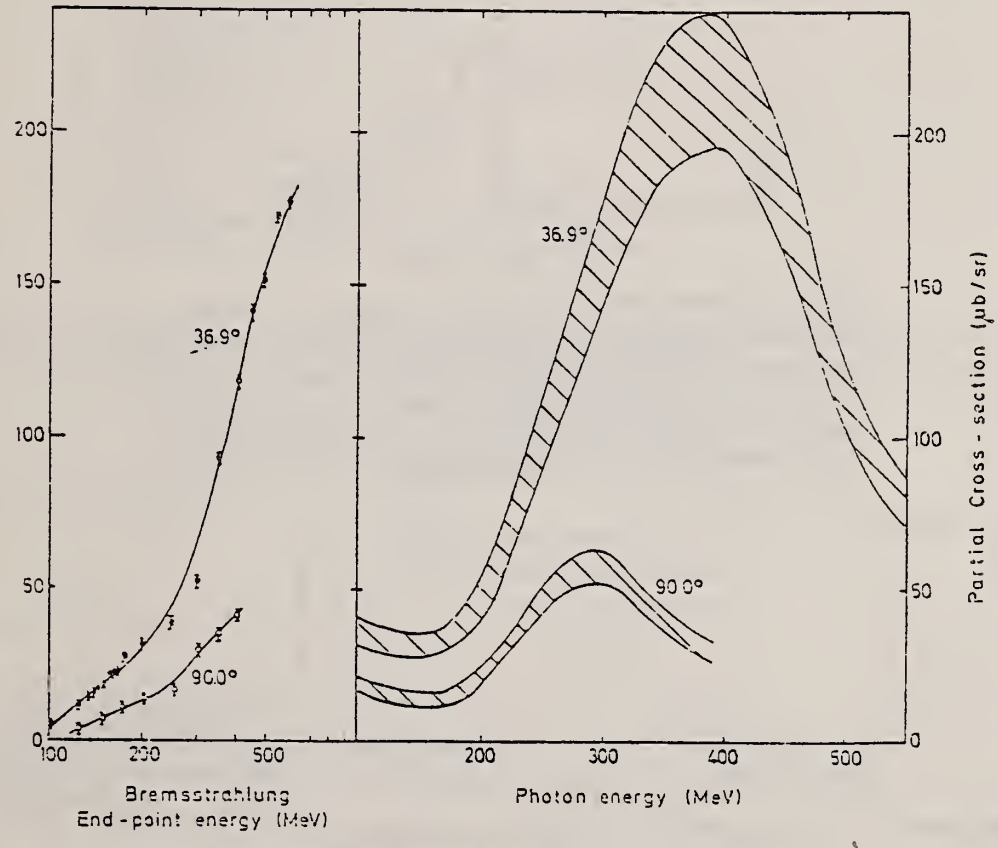

Fig. 1. The yields of photo-protons (integrated over energies from about 50 to about 100 MeV) observed at 36.9 and 90.0 degrees lab. and the values of partial cross-sections derived from them using the data-smoothing method. The solid curves in Figure 1a show the fifth-order polynomials fitted to the experimental data and which are unfolded to give the values shown in Figure 1b. The permissible ranges of variation of the (partial) cross-sections are as indicated. This is discussed in the text

over

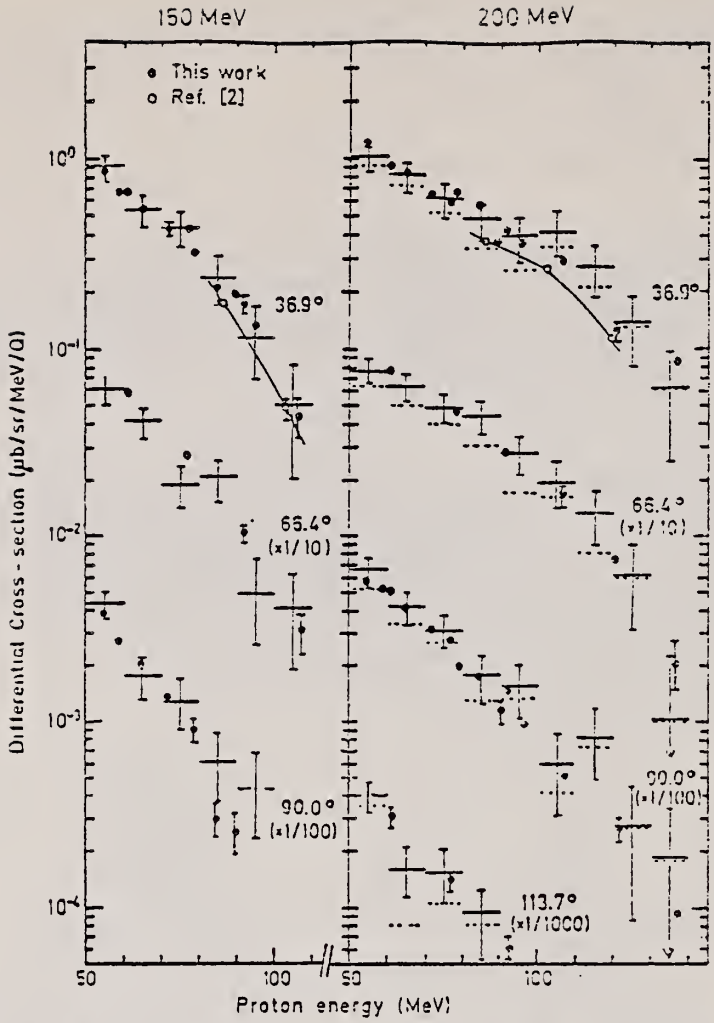

Fig. 2. Experimental values of the differential cross-sections for photo-proton production for beryllium irradiated with bremsstrahlung of maximum energy 150 and 200 MeV are compared with PICA predictions with $L = 7.2$. The energy-resolution of the experimental data varies from ≃25 MeV at 50 MeV to ≃15 MeV at 160 MeV. The PICA results are averaged over intervals of ten degrees on either side of the mean values. The experimental values at different angles have been shifted by the stated scale-factors to improve the legibility of the drawing. The dotted lines in the 200 MeV diagram show the effect of completely excluding photons of energies between 140 and 160 MeV in PICA

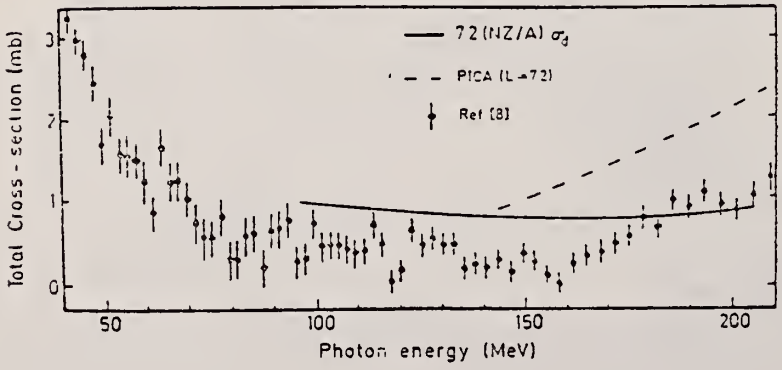

Fig. 4. Experimental values of the total cross-sections for the absorption of photons in beryllium nuclei as reported in [8] are compared with results calculated using PICA with $L = 7.2$ and with those given by $\sigma_{tot} = 7.2\,(NZ/A)\,\sigma_d$. As can be seen, the experimental values are considerably lower than expected

Abstract: The proton spectral functions of ^{6}Li, ^{7}Li, ^{9}Be and ^{10}B obtained from the (e, e'p) reactions at 700 MeV are presented. The results were analyzed in the distorted-wave impulse approximation, using the shell-model single-particle wave functions consistent with the elastic electron scattering results. The observed 1p proton momentum distributions for the nuclei ^{6}Li, ^{7}Li and ^{9}Be show significant disagreement with the shell-model momentum distributions. The occupation probabilities of the proton single-particle states are around 0.7, with a few exceptions.

*SEPARATION ENERGY

E NUCLEAR REACTIONS ^{6}, ^{7}Li, ^{9}Be, ^{10}B(e, e'p), E = 700 MeV; measured $\sigma(E_p, \theta_p)$; deduced proton spectral functions. DWIA calculations. Enriched ^{6}, ^{7}Li, ^{10}B and natural ^{9}Be targets.

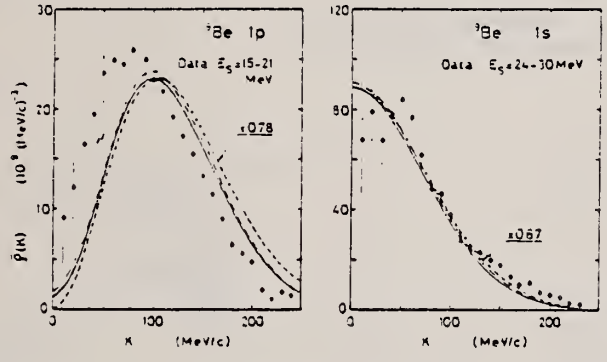

Fig. 5. The distorted momentum distributions corresponding to the optical potentials A (the solid curves) and B (the dot-dashed curves), and the undistorted momentum distributions (the dashed curves), calculated from the shell-model single-particle wave functions used in the DWIA analysis (a) ^{6}Li, (b) ^{7}Li, (c) ^{9}Be and (d) ^{10}B. For comparison, data points in the appropriate separation energy ranges are shown. They are arbitrarily normalized to the calculated distorted momentum distributions.

The total cross sections relative to photoproduction off the proton have been measured for the reactions $^{16}O(\gamma,\pi^-)^{16}N$ and $^{9}Be(\gamma,\pi^+)^{9}Li$ over the energy region from the production threshold up to 12 MeV over threshold. A distorted wave impulse approximation calculation has been performed for the $^{16}O(\gamma,\pi^-)^{16}N$ reaction and is seen to be $\simeq 30\%$ higher than the observed cross section from threshold to 10 MeV. The $^{9}Be(\gamma,\pi^-)^{9}Li$ reaction represents the first (γ,π^-) measurement near threshold in which the cross section is not dominated by the $\vec{\sigma}\cdot\vec{\epsilon}$ term in the production Hamiltonian.

[NUCLEAR REACTIONS $^{16}O(\gamma,\pi^+)^{16}N$, $^{9}Be(\gamma,\pi^+)^{9}Li$, bremsstrahlung end point energies to 175 MeV, measured $\sigma(E)$; calculated $\sigma(E)$, DWIA.]

As the result of measurements of the spectra of electrons scattered by ^{9}Be, the transverse and longitudinal form factors for electrodisintegration are obtained in the region of the quasielastic scattering peak. In both the longitudinal and transverse components of the form factor, giant-resonance peaks are observed up to an excitation energy 63 MeV. Hindrance coefficients are obtained for the quasielastic scattering cross section for the transverse and longitudinal form-factor components. The ratio of the transverse form factor for quasielastic scattering to the longitudinal form factor is measured.

QUASI-ELASTIC SCATT

PACS numbers: 25.30.Cq, 27.20. + n

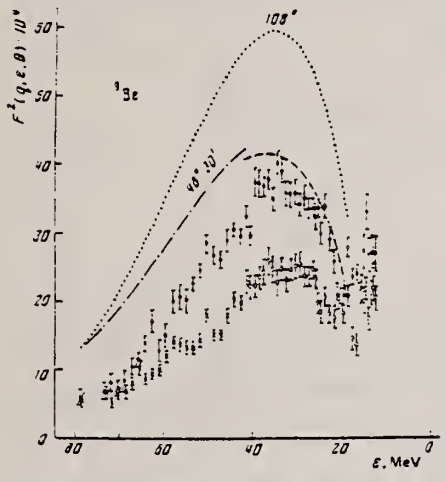

FIG. 2. Form factors for electrodisintegration of the ^{9}Be nucleus, measured at various scattering angles. The lines are the result of calculation of the form factors for quasielastic electron scattering[1] with values of θ and E_0 at which the measurements were made. The solid circles and the dotted line correspond to the experimental results and calculation at θ = 108°; the hollow circles and the dashed line are for θ = 52°30′; the crosses and the dot-dash line are for θ = 48°30′ (the measurements at θ = 48° are given for the portion of the spectrum 42 MeV < ε < 80 MeV).

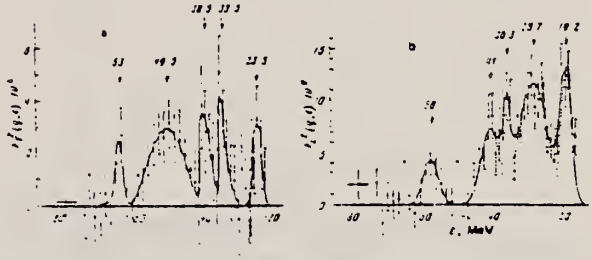

FIG. 4. Transverse and longitudinal spectra of the differential form factors of excited states of the ^{9}Be nucleus as the result of subtraction from the electrodisintegration spectra of the quasielastic electron-scattering continuum pedestal. The solid line in Fig. a has been drawn by eye through the points, and that in Fig. b is the result of variation by the method of least squares of the locations, heights, and half-widths of the sum of the Gaussian distributions shown by the dotted curves.

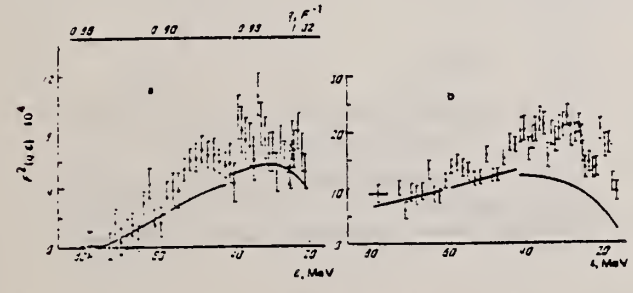

FIG. 3. Spectra of the transverse differential form factor $F_T^2(q, \varepsilon)$ (a) and of the longitudinal differential form factor $F_T^2(q, \varepsilon)$ (b) for electrodisintegration of ^{9}Be. Momentum spectra of protons in the reaction of γ + Be $\rightarrow p$ + anything in the incident energy range from 180 to 420 MeV were measured. The spectrum obtained shows two peaks which are interpreted to be due to the protons in reactions γ + "N" $\rightarrow p + \pi$ and γ + "d" $\rightarrow p + n$, where "N" and "d" are the quasifree nucleons and neutron-proton systems, respectively, in the beryllium nucleus.

The reaction $^{9}Be(\gamma,\pi^{+})^{9}Li$ has been studied with bremsstrahlung in the energy range 100-800 MeV employing the radioactivity method. The cross section curve deduced is compared with an impulse approximation calculation including a volume and a surface production model. In the energy region 200-300 MeV the experimental cross section, approximately 7 μb, is best reproduced by the surface production model with a cut-off parameter r_0 equal to 2.8 fm, i.e. somewhat larger than the r.m.s. radius of ^{9}Be.

TEST VIRTUAL PHOTONS

The virtual photon spectrum shape and intensity within several MeV of the kinematic limit was measured for $^{9}Be(e,\pi^{+})^{9}Li,e'$ and $^{16}O(e,\pi^{+})^{16}N,e'$ ($T_{\pi}=28$ MeV, $\theta_{\pi}=90°$). The intensity over this interval is 1.25 ± 0.10 times plane-wave virtual photon theory predictions; the shape agrees with theory within errors. Measurements on the proton 30 to 55 MeV below the end point agree with the intensity predictions of virtual photon theory within the errors ($\pm 8\%$).

[NUCLEAR REACTIONS $^{16}O(e,\pi^{+})$, $E=180.4$ MeV; $^{9}Be(e,\pi^{+})$, $E=184.3$ MeV; measured $\sigma(E_{\pi},90°_{lab})$ relative to (γ,π^{+}), near $E_{\pi}=28$ MeV. $^{1}H(e,\pi^{+})$, $E=230$ MeV; measured $\sigma(E_{\pi},90°_{lab})$ relative to (γ,π^{+}), near $E_{\pi}=18$, 30 MeV. Compared to PWBA virtual photon theory.]

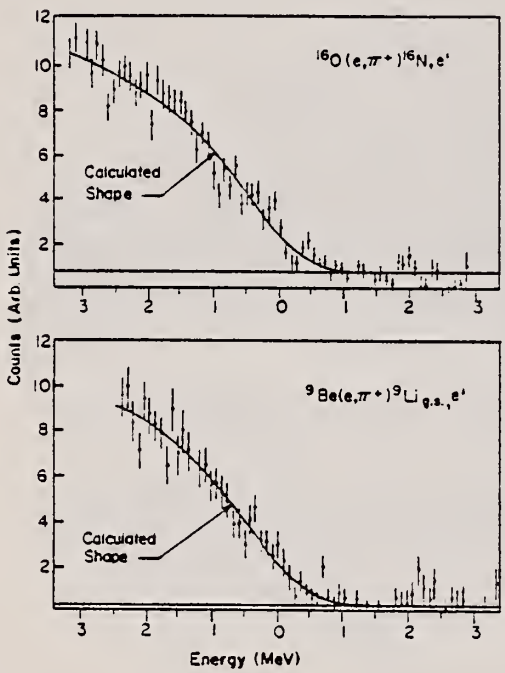

FIG. 1. Number of pions as a function of virtual photon energy. The zero on the abscissa corresponds to the virtual photon spectrum end point, 179.9 MeV for ^{16}O and 184.3 MeV for ^{9}Be. The solid curves were obtained as described in the text and normalized to the experimental data.

TABLE I. Results for R/V, the real-to-virtual ratio as defined in the text. The quantity E_0 is the incident electron total energy, T_{π} the pion kinetic energy, k the virtual photon energy, and ΔT_{π} the averaging interval over pion energy in the experiment (corresponding to the range of k). Note that k is close to the end point for ^{16}O and ^{9}Be but 30 to 55 MeV below for ^{1}H.

DATA ALSO IN 81AR3

Double differential cross sections for the photo-emission of protons and charged pion production were investigated for a number of target nuclei (He, Be, C, O, Al, Ti, Cu, Sn, Pb) in the photon energy range k = (215–386) MeV. On the basis of these experimental results the total hadronic cross section was determined.

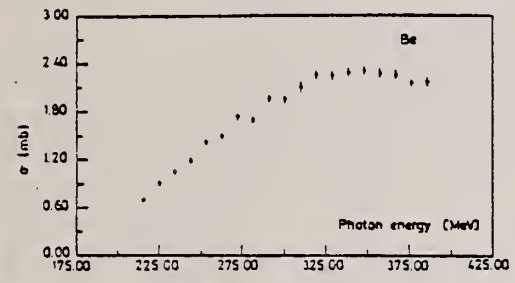

Fig. 4. Cross section for the photo emission of at least one charged particle of energy $T_p > T_p^{min}$ or $T_\pi > T_\pi^{min}$ off Be in a single hadronic process. (Statistical errors only.)

The total hadronic cross sections for all measured elements can be parametrized in the form

$$\sigma(k,A) = \sigma_0(k) \cdot A^x ,$$

A being the atomic number, with a constant exponent x = 1.1. The photon energy dependence of σ_0 is shown in fig. 7. Compared to the mean cross section for a free nucleon (the solid line in fig. 7) the excitation of the Δ-resonance is suppressed. Such a suppression is expected in the Δ-hole model [11].

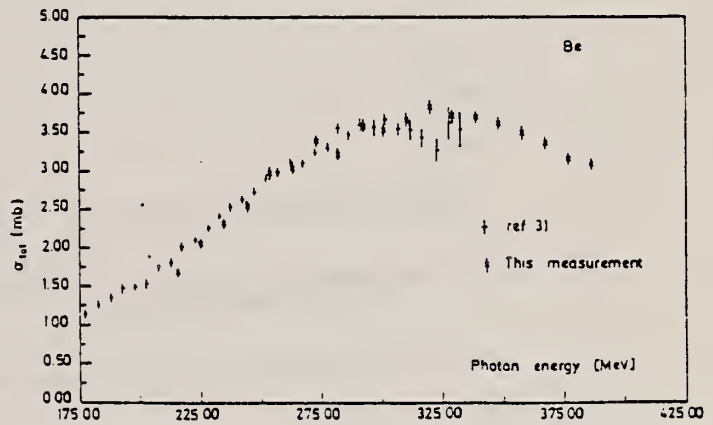

Fig. 5. Total hadronic cross section for Be. Our data are compared to ref. [3]. (Statistical errors only.)

Abstract: Double differential cross sections for the photoemission of protons and charged pion photoproduction were investigated for a number of target nuclei (He, Be, C, O, Al, Ti, Cu, Sn, Pb) using the tagged bremsstrahlung beam at the Bonn 500 MeV-Synchrotron in the photon range k = (215-386)MeV. On the basis of these experimental results the total hadronic cross section was determined.

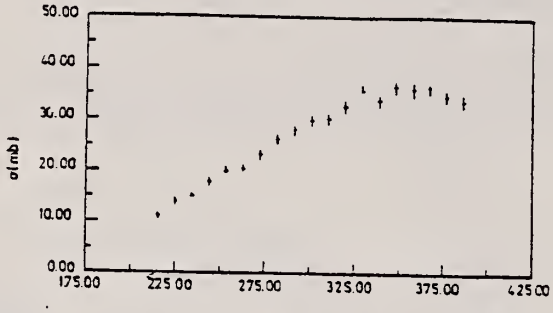

Fig. 2. Cross section for the process: $\gamma + Pb \rightarrow p + X$. The proton threshold is 58 MeV.

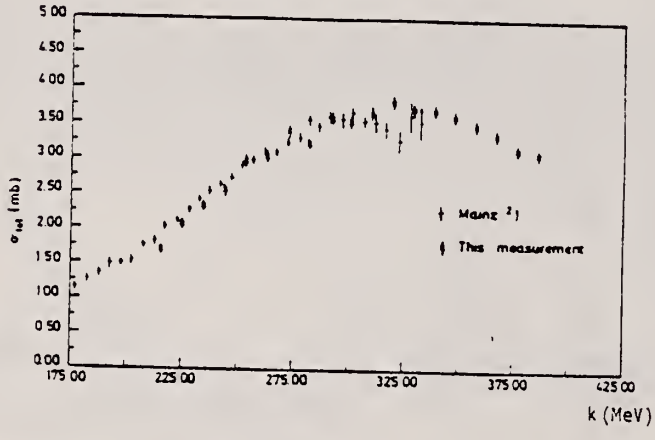

Fig. 3. Total hadronic cross section for Be. The data are compared to the cross section taken from ref.[2]).

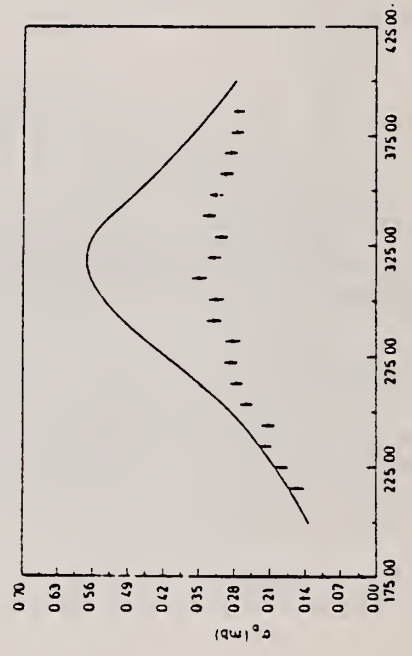

Fig. 4. Parameter σ_0 compared to the cross section for a free nucleon (full line).

The photon energy dependence of the total cross sections for heavier nuclei are similar to the Be results. The complete data set can be parametrized in the form

$$\sigma(k,A) = \sigma_0(k) \cdot A^x.$$

The exponent is constant $x = 1.1$. The photon energy dependence of σ_0 is shown in fig. 4. Compared to the mean cross section for a free nucleon, the excitation of the Δ-resonance is suppressed.

RADIOISOTPE SOURCES

Six kinds of radioisotopes were used to measure cross sections of the ^{9}Be(γ, n) reaction near its threshold. The results obtained were 0.88 ± 0.16, 1.33 ± 0.24, 1.10 ± 0.20, 0.73 ± 0.13, 0.47 ± 0.09, and 0.18 ± 0.04 mb at 1674.7, 1705.2, 1724.9, 1778.9, 1836.0, and 2167.6 keV, respectively. The cross sections measured show a sharp peak near the threshold, and its width is narrower than that observed by Jakobson with Bremsstrahlung X-rays. Comparison of the present results with theories based on the valence neutron model indicates that the agreement is only qualitative.

On a utilisé six sortes de radioisotopes pour mesurer les sections efficaces de la réaction ^{9}Be(γ, n) près de son seuil. Les résultats obtenus sont 0.88 ± 0.16, 1,33 ± 0,24, 1,10 ± 0,20, 0.73 ± 0.13, 0,47 ± 0.09 et 0,18 ± 0.04 mb, à 1674.7, 1705.2, 1724.9, 1778.9, 1836.0 et 2167.6 keV, respectivement. Les sections efficaces mesurées présentent un pic prononcé au voisinage du seuil, et la largeur de ce pic est plus étroite que celle qu'a observée Jakobson avec des rayons X de freinage. La comparaison de ces résultats avec les théories basées sur le modèle du neutron de valence indique que l'accord est seulement qualitatif.

Abstract: The ^{7}Li(^{3}H, γ)^{10}Be radiative capture reaction has been studied for ^{3}H energies of 0.4–1.1 MeV. Gamma transitions to the ground and first excited states are observed. Their excitation functions at 0° and 90° and angular distributions at 0.8 MeV and 1.1 MeV are measured. The excitation curves show a peak at E_t = 0.8 MeV corresponding to an excitation energy in ^{10}Be of 17.79 MeV. This peak is interpreted as a resonance and the assignment J^{π} = 2^{+} is determined. The resonance structure observed in the capture reactions at 0° is much more pronounced than at 90°, indicating sizeable contributions of the direct capture process to the radiative transition strength.

18=17.79
Jπ=2+

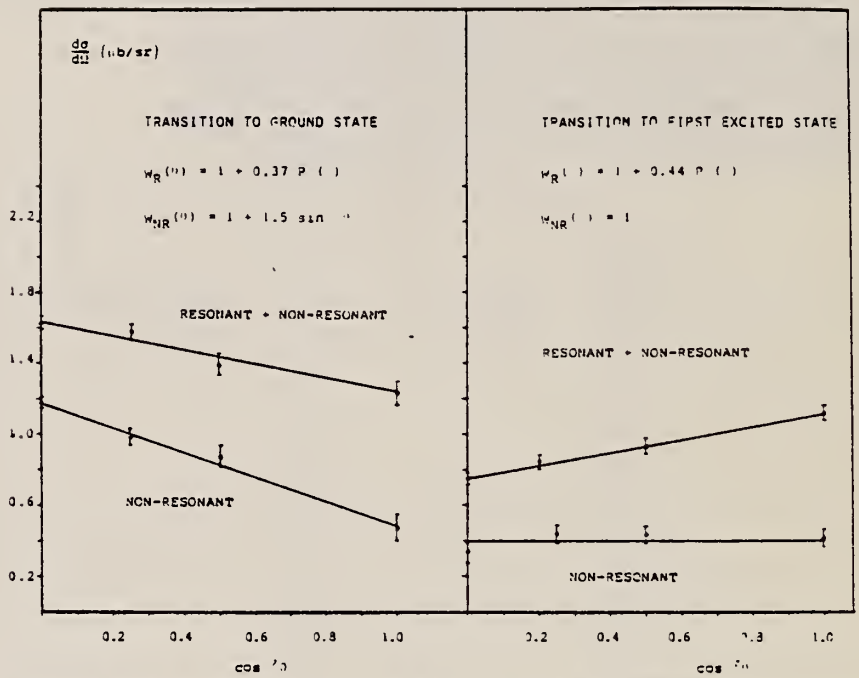

Fig. 5. The angular distributions of γ-rays from the 17.79 MeV level and non-resonant radiation from this energy region. The least-squares fits to the experimental points are shown.

BORON
Z=5

The name boron, analogous to carbon, was coined by Sir Humphry Davy. As borax, it was known to ancient peoples (Arabic, *buraq*; Persian, *borah*;) but was often confused by medieval writers. The boron hydrides (boranes) range from compounds so reactive as to be employed as rocket fuels, to materials so inert as to be promising in the field of heat-resistant plastics.

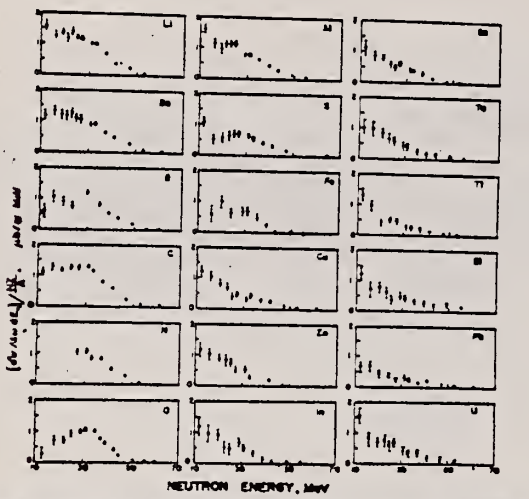

FIG. 6. Observed neutron spectra due to 55–85-MeV difference photon spectra. The effective cross sections have been divided by NZ/A.

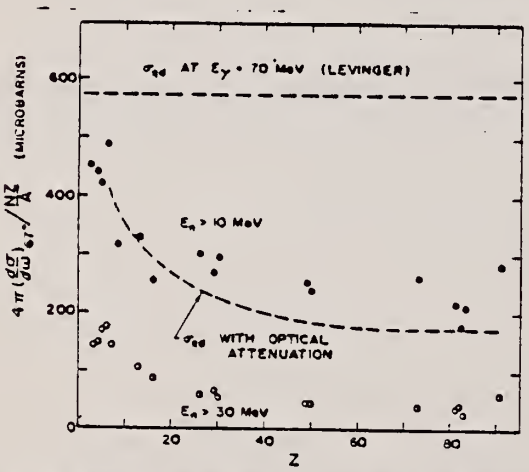

FIG. 7. Effective cross sections for production of fast neutrons with energies greater than 10 MeV (solid circles) and 30 MeV (open circles) by the 55–85-MeV photon difference spectrum. The dashed curves are modified quasideuteron model predictions as discussed in the text.

TABLE I. Comparison of present cross-section values in mb for production of high-energy photoneutrons by 55–85-MeV photons with measured cross sections $\sigma(\gamma,Tn)$, also in mb, for total photoneutron production. The present cross-section values are uncertain by 8 to 10% because of counting statistics and normalization errors; in addition all values depend on an absolute normalization in terms of the deuteron photodisintegration cross section, which is known to about 10% at these energies.

2.8	$\leqslant 3$			

[a] Differential cross section at 90° to proton beam from present work, normalized to 400 $\mu b/4\pi$ sterad, i.e., $\Gamma_\gamma = 23$ ev (see reference 5), for the ground-state gamma ray at $E_p = 0.99$ Mev (see reference 6).
[b] These yields include the nonresonant as well as the resonant contributions. For a comparison of our results with those of reference 4, see Figs. 5 to 8.
[c] See reference 7.
[d] See reference 11.
[e] See reference 3.
[f] Calculated from present work assuming the partial and total level widths given in reference 1.
[g] Ratio of gamma-ray width to Weisskopf estimate. See reference 13 for definitions. The assumed multipolarity of the gamma ray is given in parentheses.
[h] Normalized to this value.
[i] The intensity of the capture transition to the 4.77-Mev state of B^{10} is less than or equal to that to the 3.58-Mev state.
[j] The major part of this transition appears to go to the 5.16-Mev state; a small transition probability to the 5.11-Mev state is not excluded by our results.
[k] The existence of an additional 2^+ state near $E_p = 0.98$ Mev is postulated in reference 9 and appears to be indicated by the transition to the 1.74-Mev state. See text.
[l] See reference 5. We assumed that the relative errors in intensity are one-half of the absolute errors given for the yields in this reference.
[m] This value of $\lvert M\rvert^2$ does not take into account possible transitions from the 2^+ state at 7.5 Mev.
[n] Γ_γ and $\lvert M\rvert^2$ calculated for a transition from the 2^+ state, assuming the widths for this state given in reference 9, but neglecting a possible angular anisotropy (which would not affect the value within the stated error).

Tabelle 2. *Meßergebnisse für die untersuchten Kernniveaus*

Die in der vorliegenden Arbeit bestimmten Anregungsenergien stehen in der Spalte 2. Zum Vergleich sind in Klammern die Werte nach LANDOLT-BÖRNSTEIN (Neue Serie 1961) angegeben. Mit den in Spalte 3 gegebenen Spins wurden die Strahlungsbreiten Γ_γ^0 berechnet. Γ_ω in Spalte 8 sind die von WILKINSON — in F. AJZENBERG-SELOVE: Nuclear Spectroscopy, Part B. New York and London: Academic Press 1960 — benutzten Weisskopfeinheiten (mit $R = 1{,}2$ fm).

1. Isotop	2. Anregungsenergie (MeV)	3. I_f	4. Übergang	5. $B(\lambda, k, I_i \to I_f)$ (a)	6. R_{tr} (fm)	7. Γ_γ^0 (eV)	8. $\Gamma_\gamma^0/\Gamma_\omega$	9. Andere Autoren Γ_γ in eV

*) Assumes isotropy; angular distribution not determined in present experiment.

Abstract: Existing data on four resonances seen in $^7Li+\tau$ reactions have been re-examined, and additional measurements of the reaction $^7Li(\tau,\gamma)^{10}B$ have been made, in order to better establish the spins and parities of the ^{10}B compound states involved. The excitation energies of these states and their most likely assignments are: 18.4 MeV, 2^-; 18.8 MeV, $(1^+, 2^+)$; 19.3 MeV, 2^-; and 20.2 MeV, 1^-. All appear to be $T = 1$ states.

E NUCLEAR REACTIONS $^7Li(^3He,\gamma)$, $E = 1.1$, 1.4, 2.2 MeV; measured $\sigma(E_\gamma, \theta_\gamma)$. ^{10}B deduced levels, J, π. Enriched target.

6 LEVELS, 5.11-11.56

Peaks at excitations of 5.11, 6.02, 7.48, 8.90, 10.79, and 11.56 MeV were observed in spectra of ^{10}B produced by 180° inelastic scattering of electrons at 40.5, 50.6, and 60.6 MeV. The transitions at 6.02 and 8.90 MeV appear to be $E2$ and $M2$ or $E2$, respectively. There is evidence for $M1$ transition strength to at least one level in the 11 MeV excitation region. The model-dependent radiative widths of the levels at 5.11 and 7.48 MeV were determined to be: $\Gamma_0(M2) = (6.9 \pm 1.4) \times 10^{-4}$ eV and $\Gamma_0(M1) = 11.3 \pm 2.0$ eV, respectively. Subject to qualifications cited in the text, radiative widths for some of the other transitions are also given.

TABLE I. Values of cross sections for excitation of the nuclear states studied at the three incident energies of 40.5, 50.6, and 60.6 MeV.

Excitation energy (MeV)	Cross section (nb/sr) 40.5 MeV	50.6 MeV	60.6 MeV
5.11	0.52 ± 0.08	1.03 ± 0.15	1.24 ± 0.17
6.02	0.97 ± 0.15	1.08 ± 0.16	0.83 ± 0.12
7.48	15.99 ± 1.74	14.18 ± 1.55	9.72 ± 0.95
8.90	0.30 ± 0.08	0.39 ± 0.09	0.38 ± 0.08
10.79	2.62 ± 0.33	2.52 ± 0.33	2.02 ± 0.26
11.56	3.72 ± 0.46	3.70 ± 0.46	2.57 ± 0.33

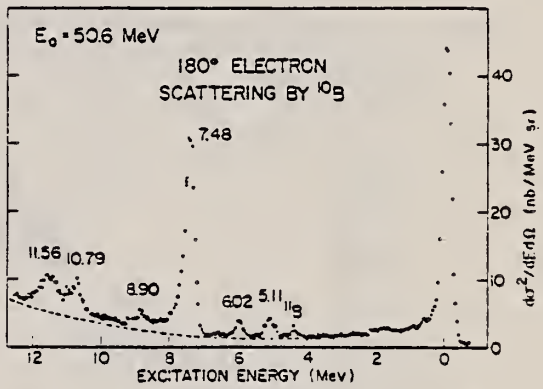

FIG. 1. Spectrum of 50.6-MeV electrons scattered at 180° from ^{10}B. The base line used is indicated by the dashed curve. An indication of the statistical errors involved is given by the error bars on the point on the left hand side of the 7.48-MeV peak.

TABLE II. Multipolarities, transition radii, and ground state transition widths for states in ^{10}B electroexcited at 180°.

Excitation energy (MeV)	J^π, T [a]	Multipolarity	R (fm)	Γ_0 (eV)
5.11	$2^-, 0$	$M2$		$(6.9 \pm 1.4) \times 10^{-4}$ [b]
			4.3 ± 1.1	$(10.2 \pm 2.2) \times 10^{-4}$ [c]
6.02	4^+	$E2$	(4.6 ± 1.0)	(0.3 ± 0.07) [c,d]
7.48	$2^+, 1$	$M1$		11.3 ± 2.0 [b]
			2.4 ± 0.4	10.1 ± 1.9 [c]
8.90	$(2^+, 1)$	$(E2)$		(0.5 ± 0.2) [c]
	$(3^-, 1)$	$(M2)$		$[(6 \pm 2) \times 10^{-3}]$ [c]
10.79		$M1$ or $E2$		
11.56		$(M1)$		(11.4 ± 2.3) [b]

[a] Spin assignments are taken from Ref. 17.
[b] Result obtained by direct comparison with DWBA oscillator model; oscillator parameter, 1.88.
[c] Result obtained using DWBA corrected PWBA generalized Helm model expressions.
[d] Due to other levels in this region there may be some question as to whether all of this strength is due to a transverse $E2$ transition to the 4^+ state. A DWBA oscillator model calculation was not available for electric transitions.

Abstract—Mean cross sections for the photoproduction of ^{7}Be and ^{11}C from ^{19}F, ^{27}Al, ^{28}Si and ^{32}S targets, ^{7}Be from ^{10,11}B, and ^{11}C from ^{14}N and ^{16}O targets have been measured using bremsstrahlung beams in the energy range 0.3–1.0 GeV. The results have been compared with previous measurements and an excellent agreement has been found. In most cases, the values obtained turned out to be much larger than those expected from a simple spallation mechanism. A fragmentation and/or a fission-like process has been suggested in explaining the mechanism of such reactions.

Abstract: The proton spectral functions of ^{6}Li, ^{7}Li, ^{9}Be and ^{10}B obtained from the (e, e'p) reactions at 700 MeV are presented. The results were analyzed in the distorted-wave impulse approximation, using the shell-model single-particle wave functions consistent with the elastic electron scattering results. The observed 1p proton momentum distributions for the nuclei ^{6}Li, ^{7}Li and ^{9}Be show significant disagreement with the shell-model momentum distributions. The occupation probabilities of the proton single-particle states are around 0.7, with a few exceptions.

*SEPARATION ENERGY

E NUCLEAR REACTIONS ^{6}, ^{7}Li, ^{9}Be, ^{10}B(e, e p), E = 700 MeV; measured $\sigma(E_p, \theta_p)$; deduced proton spectral functions. DWIA calculations. Enriched ^{6}, ^{7}Li, ^{10}B and natural ^{9}Be targets.

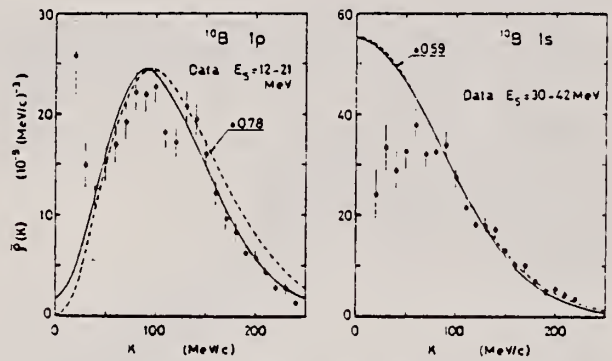

Fig. 5. The distorted momentum distributions corresponding to the optical potentials A (the solid curves) and B (the dot-dashed curves), and the undistorted momentum distributions (the dashed curves), calculated from the shell-model single-particle wave functions used in the DWIA analysis. (a) ^{6}Li, (b) ^{7}Li, (c) ^{9}Be and (d) ^{10}B. For comparison, data points in the appropriate separation energy ranges are shown. They are arbitrarily normalized to the calculated distorted momentum distributions.

Energy spectra of 140-MeV electrons are measured after scattering by ^{10}B and ^{12}C nuclei. Peaks above the nucleon emission threshold are observed in the ^{10}B spectra at energies 8.26, 9.0, and 9.7 MeV, and at 18.1 MeV in the ^{12}C spectra. The existence of these peaks and their energy location is predicted by calculations based on inclusion of the contribution of triangle Feynman diagrams to the reaction amplitude.

Abstract: Electron scattering form factors were measured for six transitions in ^{10}B in the momentum transfer range 0.61 to 1.81 fm^{-1}. Ground state radiative widths were extracted by means of the generalized Helm model for the levels at 1.74 MeV (M3), 5.17 MeV (M1+M3), 6.03 MeV (C2+C4), 7.48 MeV (M1), 8.07 MeV (C2) and 8.9 MeV (M1+M3 or M2). The transverse form factors for the 1.74 and 5.17 MeV levels agree well with predictions based on Cohen–Kurath wave functions. The longitudinal form factor for the 6.03 MeV state shows effects due to the deformation of ^{10}B and is in good agreement with the deformed Hartree–Fock shell model prediction of Bouten and Bouten. Estimates are presented for the ratios of radiative pion capture rates leading to analogue states in ^{10}Be.

6 LEVELS 1.74-8.9 MEV

E NUCLEAR REACTIONS ^{10}B(e, e'), E = 67–194 MeV; measured $\sigma(E; E_e; \theta)$. ^{10}B deduced form factors, reduced widths, multipolarities, (π^-, γ) rates. Helm model. Enriched targets.

REACTION	RESULT	EXCITATION ENERGY	SOURCE		DETECTOR		ANGLE
			TYPE	RANGE	TYPE	RANGE	
E,PI+	ABX	12*	D	159-165	TEL-D		DST

The electroproduction of 12.3±0.7 MeV positive pions from ^{10}B, leading to low-lying states in ^{10}Be, has been measured in the angular range $\theta_\pi = 30° - 140°$ for incident electron energies $E_e = 158.5 - 165.0$ MeV. The unique character of $M3$ transitions in the p shell permits a direct comparison of $d^2\sigma/dE_\pi d\Omega_\pi$ with the analog electron scattering form factors in ^{10}B, assuming the strong π-nucleus interaction can be neglected. For the two lowest $T=1$ states, the (e,π^+) angular distributions agree with the $M3$ form factors. The convective term in the $M1$ form factor for the third $T=1$ state is deduced from a comparison of the (e,π^+) and (e,e') data and is in good agreement with recent radiative pion capture results. The photoproduction cross section leading to the ^{10}Be ground state is estimated.

[NUCLEAR REACTIONS ^{10}B$(e,\pi^+)e'$ ^{10}Be; $E_e = 158.5 - 165.0$ MeV; $E_\pi = 12.3$ MeV; measured $\sigma(E_\pi,\theta_\pi)$; $\theta_\pi = 30° - 140°$; compare to electron scattering, radiative pion capture, and photoproduction.]

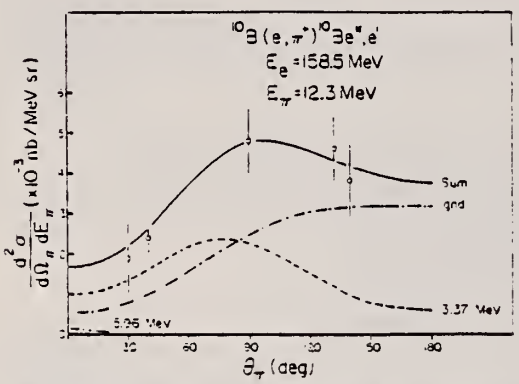

FIG. 2. Double differential cross sections for the (e,π^+) reaction leading to the ground plus first excited states of ^{10}Be, for an incident energy $E_e = 158.5$ MeV and detected pion energies of 12.3±0.7 MeV. The curves are predictions based directly on the experimental $M3$ form factors for the 1.74 MeV (0^+) and 5.17 MeV (2^+) states of ^{10}B as discussed in the text. The gradual decrease in the 3.37 MeV curve is due to the kinematic cutoff for excitation of this state which does not occur simultaneously in all detectors.

12*=12.3±.7 MEV PI+

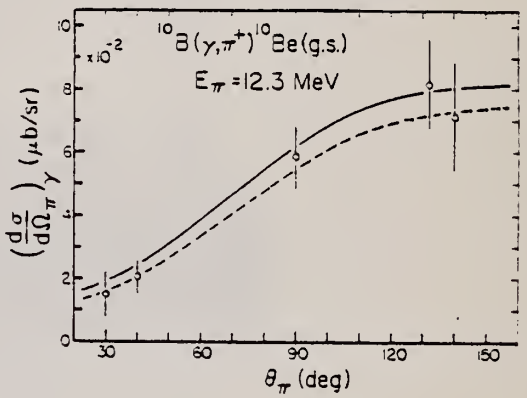

FIG. 6. Photopion angular distribution leading to the ^{10}Be ground state as deduced from the data in Fig. 2. The solid curve is based on the $M3$ form factor for the 1.74 MeV state of ^{10}B. For the dashed curve some allowance was made for Coulomb distortion of the (e,e') data by using the effective-q approximation.

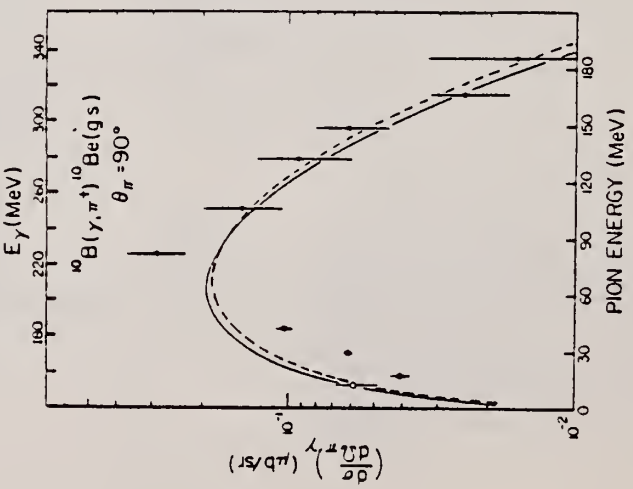

FIG. 7. The 90° photopion cross section leading to the ^{10}Be ground state, as a function of the pion kinetic energy. The open-circle point is from this work, the closed-circle points are from Rowley *et al.* (Ref. 11), and the triangle points are from Bosted *et al.* (Ref. 12). The curves are as in Fig. 6.

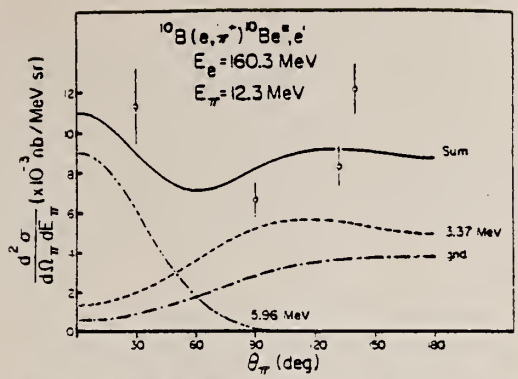

FIG. 3. Same as Fig. 2, but for $E_e = 160.3$ MeV. The threshold for population of the 5.96 MeV state has now been crossed causing an increase in the forward-angle cross section, consistent with the behavior expected for an $M1$ transition.

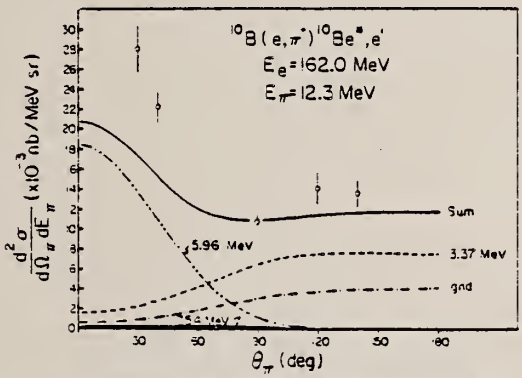

FIG. 4. Same as Fig. 2, but for $E_e = 162.0$ MeV. Excitation of the 7.54 MeV state is now possible. As in Fig. 3, the 5.96 MeV prediction is based directly on the 7.48 MeV $M1$ form factor in ^{10}B. The discrepancy with the forward-angle data is interpreted as a destructive interference between the spin and convection terms in the $M1$ form factor.

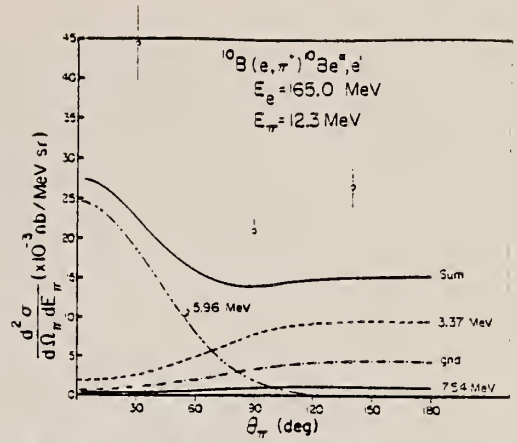

FIG. 5. Same as Fig. 2, but for $E_e = 165.0$ MeV. At this energy it is possible for ^{10}Be to be excited somewhat above 7.54 MeV.

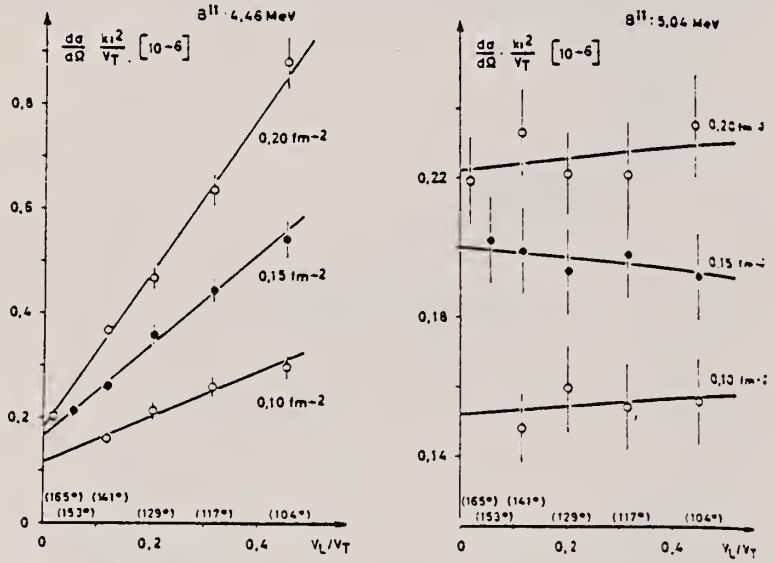

Fig. 2. Angular distributions at various constant inelastic momentum transfers q (indicated in the diagrams) for two transitions in ^{11}B. $d\sigma/d\Omega$ is the differential inelastic cross section, $k_i = E_x/\hbar c$, and V_L, V_T are functions of the scattering angle ϑ (see, e.g., Ref. 2 or 4). The slope of the straight lines gives the longitudinal part; the intersection with the ordinate scale the transverse part of the cross sections. The figure shows that the 4.46 MeV transition is mixed, whereas the 5.04 MeV transition is purely magnetic within experimental errors. The multipolarity, Γ_γ^0, and R_σ, are determined from the q dependence of the cross sections (see, e.g., Ref. 4).

Tabelle 2. *Meßergebnisse für die untersuchten Kernniveaus*

Die in der vorliegenden Arbeit bestimmten Anregungsenergien stehen in der Spalte 2. Zum Vergleich sind in Klammern die Werte nach LANDOLT-BÖRNSTEIN (Neue Serie 1961) angegeben. Mit den in Spalte 3 gegebenen Spins wurden die Strahlungsbreiten Γ_γ^0 berechnet. Γ_w in Spalte 8 sind die von WILKINSON — in F. AJZENBERG-SELOVE: Nuclear Spectroscopy, Part B. New York and London: Academic Press 1960 — benutzten Weisskopfeinheiten (mit $R = 1{,}2$ fm).

COMMENTS

Conclusions drawn in this paper were modified in a later paper. See Evans Hayward, Robert B. Schwartz, and Kenneth M. Murray, Phys. Rev. C2, 761 (1970).

GAMMA SPECTRUM

In summary: There is evidence for the (γ, n) reaction leaving B^{10} in an excited state (717 keV); there is no evidence of population of the $T = 1$ states in B^{10}; and the first excited state in Be^{10} at 3366 keV is seen clearly.

From these data it appears that the cross section integrated from threshold to 35 MeV for the $T = \frac{3}{2}$ giant resonance in B^{11} is considerably smaller than the cross section over the same range for the $T = \frac{1}{2}$ giant resonance.

PHYSICAL REVIEW C VOLUME 2, NUMBER 2 AUGUST 1970

Comments on "Isospin of the B^{11} Giant Resonance"

Evans Hayward and Robert B. Schwartz
National Bureau of Standards, Washington, D. C. 20234
and
Kenneth M. Murray
Linac Branch, Nuclear Physics Division, U. S. Naval Research Laboratory, Washington, D. C. 20390

(Received 4 February 1970)

It was recently shown that in the photodisintegration of B^{11} certain expected γ rays were missing. A partial explanation is offered here for the failure to observe these transitions. It is also pointed out that no conclusions about the strength of the $T=\frac{3}{2}$ giant resonance can be drawn from this experiment.

The differential cross section for the $^{10}Be(p,\gamma_0)^{11}B$ reaction has been measured at 90° for $0.6 \leq E_p \leq 6.3$ MeV. Compound resonances in ^{11}B have been located at (12.17±0.04)-, 12.55±0.03-, 12.91±0.02-, 14.33±0.02-, and 15.3±0.1-MeV excitation energy. The last four are probably analogs to the lowest four levels in ^{11}Be. Total widths and ground-state γ-ray widths of these levels are presented. The spins of the 12.55- and 14.33-MeV levels are shown to be $\frac{1}{2}^+(\frac{1}{2}^+)$ and $\frac{1}{2}^{(+)}(\frac{1}{2}^-)$, respectively.

TABLE I. Levels in ^{11}B from the $^{10}Be(p,\gamma_0)^{11}B$ reaction.

Excitation energy (MeV±keV)	Proton energy (MeV±keV)	$\Gamma_{c.m.}$ (keV)	$(J+\frac{1}{2})(\Gamma_p/\Gamma)\Gamma_{\gamma_0}$ (eV)	J^π	Γ_{γ_0} (eV)	$\Gamma_{\gamma_1}/\Gamma_{\gamma_0}$
(12.17±40)	(1.05±40)	230±90	$1.8_{-1.2}^{+1.2}$	...	...	
12.55±30	1.46±30	230±65	6_{-3}^{+4}	$\frac{1}{2}^+(\frac{1}{2}^+)$	6_{-3}^{+4}	0.25±0.08
12.91±20	1.85±20	235±27	17±5	$\frac{1}{2}^-$ [b]	17±5	≤0.06
14.33±20	3.41±20	255±36	17±5	$\frac{1}{2}^{(+)}(\frac{1}{2}^-)$	8.5±2.5	≤0.1
15.3±100	4.5±100	635±180	31_{-18}^{+28} [c]	...	...	

[a] These values assume that $J = \frac{1}{2}$. Γ_p/Γ has been estimated as described in the text.
[b] Reference 2.
[c] Assumes that $\sigma_{total} = 4\pi\, d\sigma/d\Omega\ (90°)$.

Cross sections and γ-ray widths should be increased by a factor of 1.7.

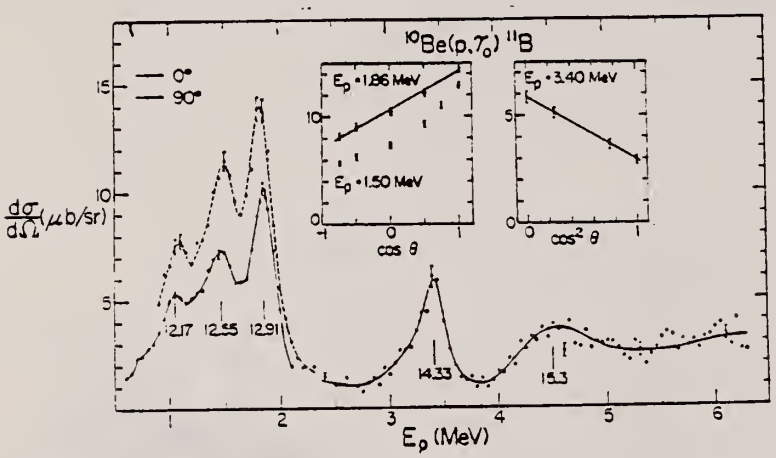

FIG. 5. Excitation function for $^{10}Be(p,\gamma_0)^{11}B$. Angular distributions at three beam energies are shown, and the fit for the distribution at $E_p = 3.4$ MeV is drawn for $J = \frac{1}{2}$. In addition to the relative error bars shown, there is a 30% uncertainty in the cross-section scale.

Cross sections and γ-ray widths should be increased by a factor of 1.7.

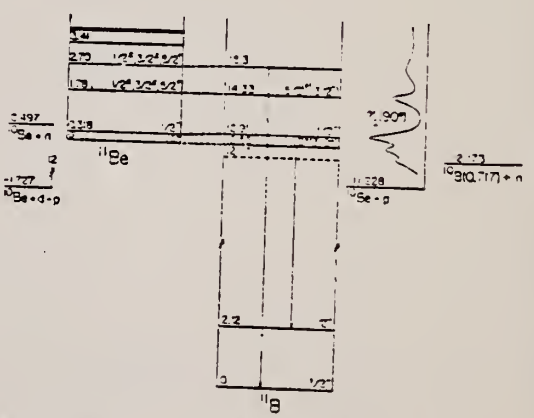

FIG. 6. Energy levels of ^{11}Be and ^{11}B that are relevant to the present work. The spins shown for the ground and first excited states of ^{11}Be are due to Auton *et al.* (Ref. 12) and Goosman and Kavanagh (Ref. 3), while the spins of higher levels are due to Pullen *et al.* (Ref. 5).

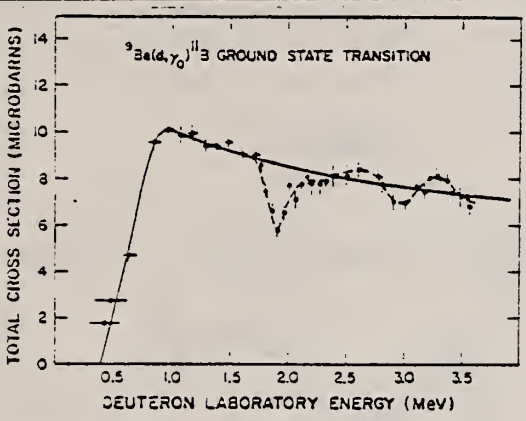

FIG. 4. Excitation function for the ground-state γ-ray transition in the reaction ^{9}Be(d,γ)^{11}B. Data points were obtained both from angular-distribution measurements and from runs at 55° to the incident beam as described in the text. Horizontal bars on the data points show the energy loss of the deuteron in passing through the target. The solid curve is meant to represent the over-all data behavior neglecting the resonance structure. The dashed curve is drawn through the actual data points.

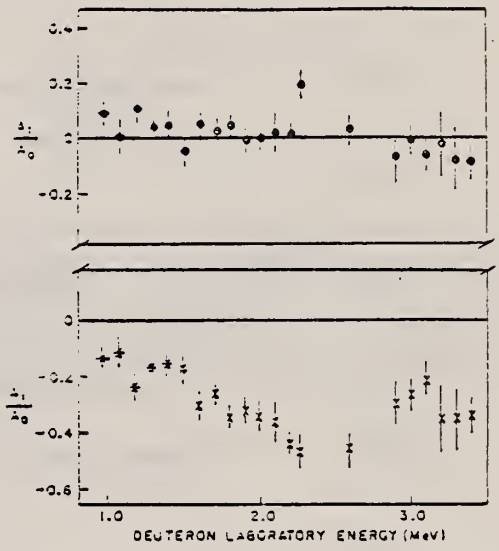

FIG. 5. Plots of the Legendre polynomial coefficients obtained from the angular-distribution measurements as a function of the incident deuteron energy for the γ-ray transition to the ground state of ^{11}B.

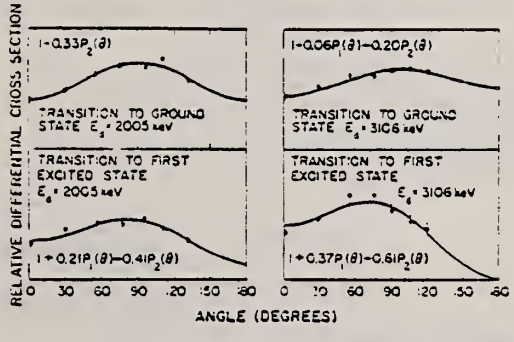

FIG. 7. Typical examples of angular-distribution data. The solid curve represents a least-squares fit to $A_0 + A_1P_1(\cos\theta) + A_2P_2(\cos\theta)$, with A_0 normalized to unity.

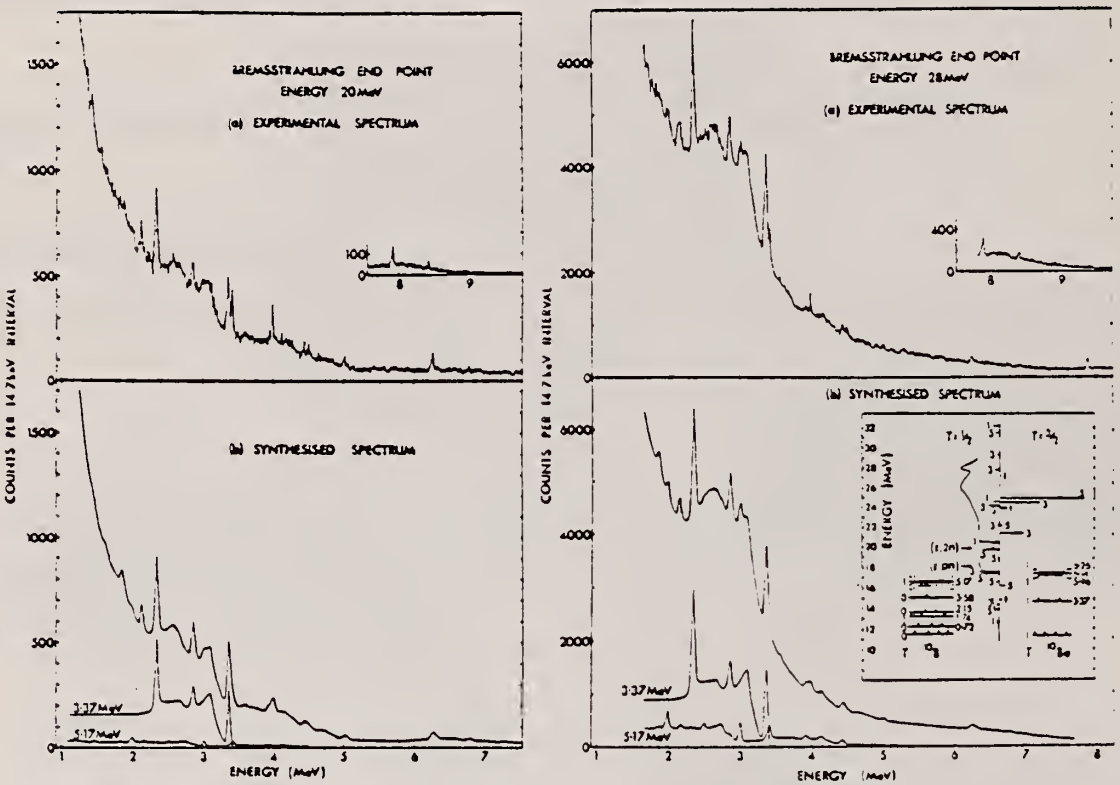

Fig. 1. Measured and computer-synthesized γ-ray spectra from the $(\gamma, \overset{n}{p}\gamma')$ reactions on ^{11}B with 20 and 28 MeV bremsstrahlung. The insert shows the results of the calculations by Fraser [4] in relation to the energy levels of ^{10}B and ^{10}Be. The lines emanating from the central vertical line represent the strength of the dipole states in ^{11}B calculated for a 50 MeV Gillet force, the $T = 1/2$ states to the left, the $T = 3/2$ states to the right. The spin (shown as $2J$ for clarity) of each state is also indicated. The curve shows the $(\gamma, n) + (\gamma, pn) + 2(\gamma, 2n)$ cross section as measured by Hayward and Stovall [13].

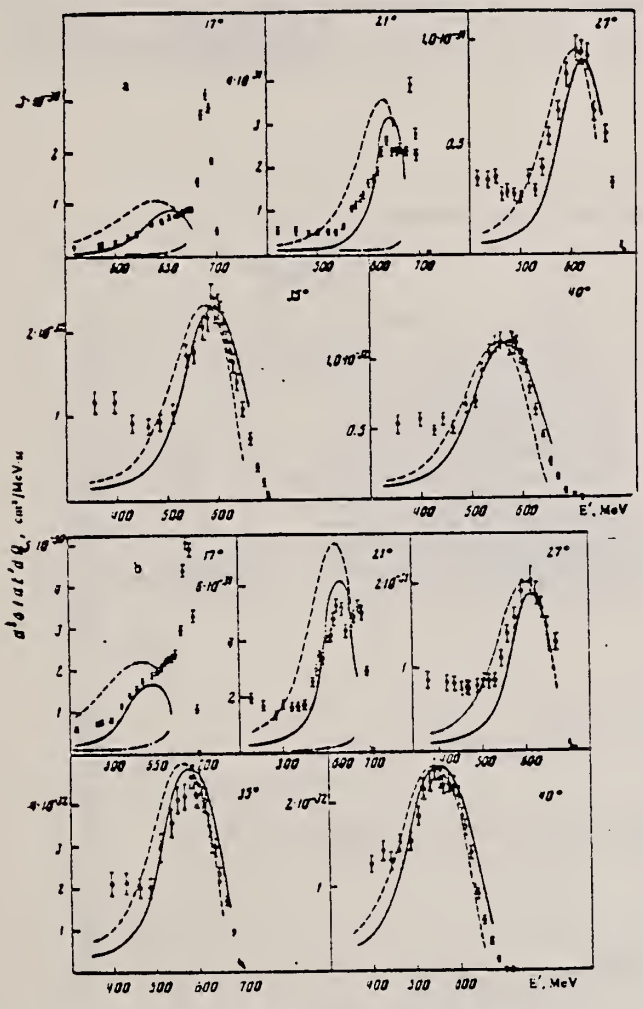

FIG. 1. Cross sections for scattering of 690-MeV electrons by B^{11} (a) and Al^{27} (b) at angles 17, 21, 27, 35, and 40°, as a function of scattered-electron energy. The dashed and solid curves have been calculated from Eqs. (1), (2), (4) and (1), (3), (4), respectively.

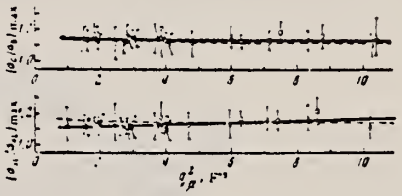

FIG. 2. Ratios of cross sections for scattering of electrons, $\sigma_{C^{12}}/\sigma_B$ and $\sigma_{Si^{28}}/\sigma_{Al^{27}}$ at the maximum of the continuum, as a function of squared momentum transfer. The solid lines are the result of fitting a linear function to the experimental points, and the dashed lines correspond to calculations using Eq. (5) for the cross section. The following designations are used for the experimental ratios at the various initial electron energies: ● – 592 MeV, ○ – 690 MeV, Δ – 802 MeV, □ – 969 MeV, X – 1143 Mev.

$$\left(\frac{d^2\sigma}{dE'\,d\Omega}\right)_{\max} = A\frac{M}{\sqrt{\pi}p_0 q}(z\sigma_p + n\sigma_n)\left(1+\frac{2E_0}{M}\sin^2\frac{\theta}{2}\right). \quad (5)$$

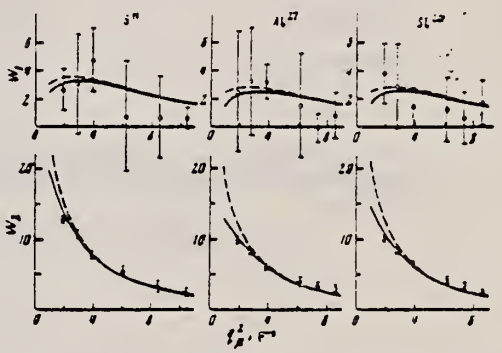

FIG. 3. Inelastic electromagnetic form factors of B^{11}, Al^{27}, and Si^{28}, measured in the region of the continuum. The dashed curves are the result of a calculation based on Eqs. (2), (7), and (8), and the solid curves based on Eqs. (3), (7), and (8).

Self-absorption measurements

2=2.12, 4=4.44

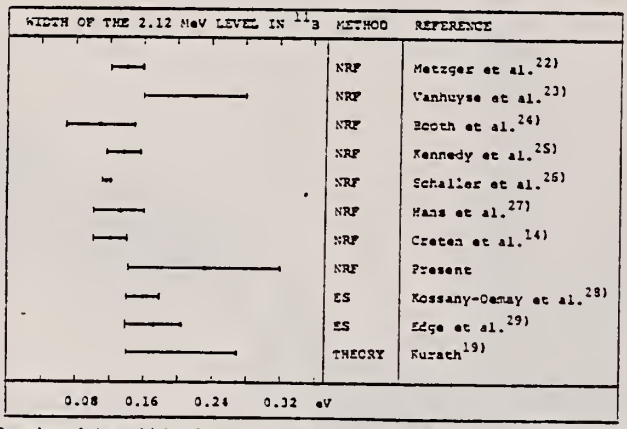

Fig. 7. Results of the width of the 2.12 MeV level in ^{11}B measured by different authors.

The bremsstrahlung beam from a 5 MeV electron linear accelerator was used to excite and study low-lying levels in ^{6}Li, ^{11}B and ^{27}Al. A self-absorption method was used to find the widths Γ of these levels. The following level widths are obtained: $\Gamma=(6.5^{+2.4}_{-1.7})$ eV for the 3.56 MeV level in ^{6}Li; $\Gamma=(0.23\pm0.09)$ eV for the 2.12 MeV level, and $\Gamma=(0.53\pm0.21)$ eV for the 4.44 MeV level in ^{11}B. For the 2.98 MeV level in ^{27}Al, the level width is found to be $\Gamma=(0.10\pm0.04)$ eV assuming that the lower energy member of the doublet at 3 MeV is excited.

		(25.5)					

Relative yields of capture photons have been observed for four nuclei at angles of 55°, 90°, and 125° in bombardments with 14-MeV neutrons. The yields from ^{10}B, ^{29}Si, and ^{40}Ca show smaller fore-aft anisotropies than those observed in corresponding proton captures. This suggests that the forward peaking in (p,γ) reactions is due mainly to direct rather than collective capture amplitudes. Photons from $^{12}C(n,\gamma_0)^{13}C$ peak backward, but this peaking cannot be straightforwardly accounted for in terms of the interference between the collective excitations dominant in this energy region.

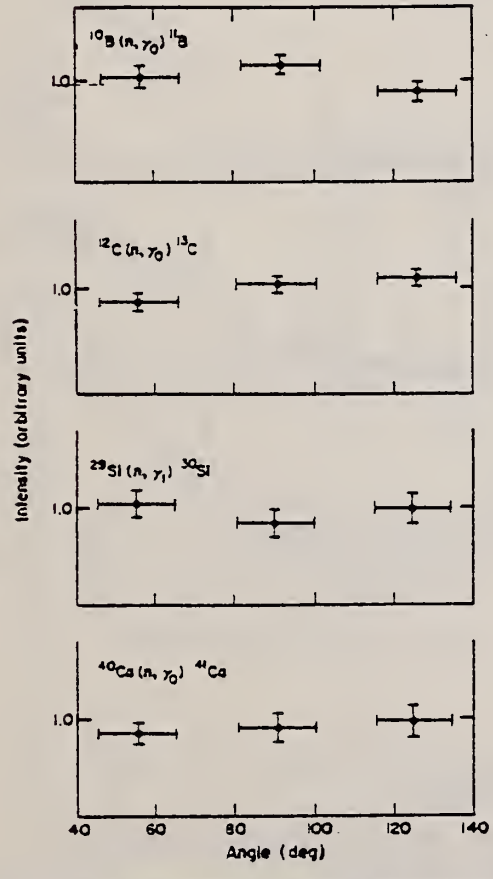

FIG. 3. Angular distributions obtained for 14-MeV neutron capture leading to the designated final states. The horizontal bars show the angular widths subtended by the capture targets.

The activation method has been used to measure the yields of the reactions $^{28}Si(\gamma,\pi^-)^{28}P$ and $^{11}B(\gamma,\pi^-)^{11}C$ from the π-meson production threshold to 400 MeV. The results obtained are in satisfactory agreement with theoretical calculations based on the model of surface production of mesons.

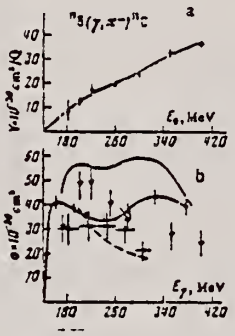

FIG. 2. Yield curve (a) and total cross sections (b) for the reaction $^{11}B(\gamma,\pi^-)^{11}C$. The dashed curve shows the theory of Ref. 10, and the solid curve that of Ref. 11; the solid circles are the data obtained by us (they are joined by a smooth curve), the hollow circles are the data of Ref. 2, and the triangles are data from the Ukrainian Physicotechnical Institute at Khar'kov.

Yields for the $^{11}B(\gamma,\pi^-)$ reaction have been measured between its threshold at 142.0 MeV and 169 MeV by observing the residual ^{11}C activity. The reaction was initiated by thin-radiator bremsstrahlung. Measurements were made in 1 MeV steps up to 150 MeV, and in larger steps above this. The present results are consistent with previous data for this reaction obtained at higher energies. The cross section values near threshold deduced from the data are compared to recent preliminary theoretical values.

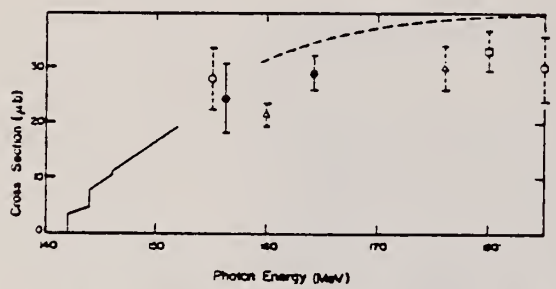

FIG. 9. The solid line and solid points are the present cross section results. The two open circle points are the results of Hughes and March (Ref. 3), the two open triangle points are the results of Dyal and Hummel (Ref. 4), the dashed curve is from the work of Nydahl and Forkman (Ref. 6), while the open square point is due to Noga *et al*. (Ref. 7).

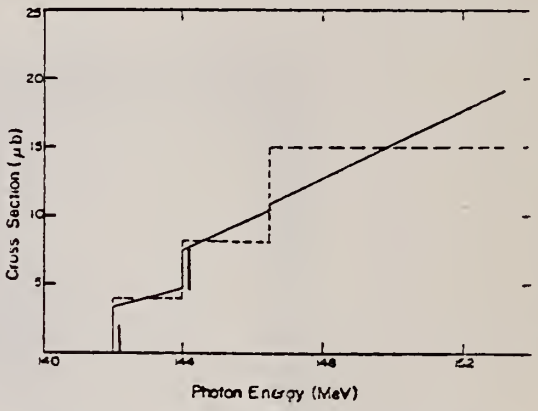

FIG. 8. The solid curve is the best-fit three-step cross section taking the same slope per unit height as that measured (Ref. 11) for the $^{12}C(\gamma,\pi^-)$ ground state transition. The vertical bars are the preliminary theoretical results of Koch and Donnelly (Ref. 21). The dashed curve is the best-fit three-step cross section with horizontal steps.

Abstract—Mean cross sections for the photoproduction of ^{7}Be and ^{11}C from ^{19}F, ^{27}Al, ^{28}Si and ^{32}S targets, ^{7}Be from ^{10,11}B, and ^{11}C from ^{14}N and ^{16}O targets have been measured using bremsstrahlung beams in the energy range 0.3–1.0 GeV. The results have been compared with previous measurements and an excellent agreement has been found. In most cases, the values obtained turned out to be much larger than those expected from a simple spallation mechanism. A fragmentation and/or a fission-like process has been suggested in explaining the mechanism of such reactions.

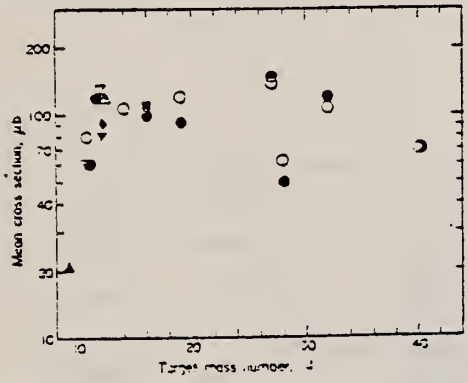

Fig. 2. The same as in Fig. 1 for ^{7}Be photoproduction. Experimental data are taken from: ▲, Refs. [6,7]; ▽, Ref. [8]; ●, Ref. [9]; △, Ref. [10]; ◆, Ref. [11]; ▼, Ref. [12]; □, Ref. [13]; ■, Ref. [14]; ◇, Ref. [2]; ○, present work.

RESONANCE SELF-ABSOR

The radiative widths of the 2.125, 4.445, 5.020, 7.285 and 8.920 MeV levels in ^{11}B were determined rather accurately by the resonance fluorescence self-absorption method using bremsstrahlung from a betatron. The results are very useful for the calibration of the bremsstrahlung spectrum multiplied by the detection efficiency $N(E_\gamma)\cdot\varepsilon(E_\gamma)$, which is necessary in the determination of level widths by the resonance fluorescence scattering method which is far more versatile than the self-absorption method. An example using such a procedure is given of determining the 8.091 MeV level of ^{52}Cr.

TABLE I
Level widths of ^{11}B determined by the present experiment[a].

DE-EXCIT GAMMA RAYS

The inelastic scattering of gamma rays by the ^{11}B nucleus is studied experimentally with a Ge(Li) detector, in order to investigate the wave function of highly excited states of a nucleus with an unfilled shell. The 1.02-MeV gamma line is observed for the first time in this reaction. It is suggested that states with isospin $T_<$ and $T_>$ can both contribute to the photoneutron cross section.

Inelastic electron scattering has been used to measure the Coulomb form factors of the excited states of the ^{11}B nucleus at excitation energies ω = 4.4, 6.7, 8.5, 8.9, and 13 MeV. The measurements were made at initial electron energies E_0 = 121, 186, and 250 MeV in the momentum-transfer region q' = 0.7–1.6 F^{-1}. The data obtained for discrete low-lying levels are discussed in terms of the excited-core model, and the resonances beyond threshold are discussed in terms of a diagram model of nuclear excitation.

DEFINITIONS OF ABBREVIATIONS AND SYMBOLS

Note: In this list definitions are given for various photoneutron reactions in which the following symbols are used: N, NL, nN, SN and XN. Corresponding definitions apply for reactions involving other nuclear particles where the symbols N (neutron) is replaced by, e.g. P, D, T, HE, A etc. Where unknown reactions result in the production of a specific radionuclide, the chemical symbol and mass number is listed as the reaction product, e.g. a G,NA22 reaction in ^{59}Co.

A	alpha particle
ANAL	analysis
ABI	absolute integrated cross-section data
ABX	absolute cross-section data
ABY	absolute yield data. Often means cross-section per equivalent quantum is listed.
ACT	measurement of induced radioactivity of the target
ASM	asymmetric, asymmetry
AVG	average
BBL	bubble chamber
BEL B(EL)	reduced electric radiative transition probability
BF3	BF_3 neutron counter with moderator e.g., Halpern detector, long counter
BML	reduced magnetic radiative transition probability, B(ML)
BREAKS	levels located by "breaks" in the yield curve
BRKUP	breakup
BRMS	bremsstrahlung
BTW	between
C	continuous. Used to describe a photon source or a detector response function. Contrast with D = discrete.
CCH	cloud chamber
CF	compared with
CHRGD	charged
CMPT	Compton
COIN COINC	coincidence, coincide
COH	coherent
CK	Cerenkov
D	deuteron or discrete. When discrete, it is used to describe a photon source or a detector response function. Contrast with C = continuous.
DLTE	energy loss
DLTQ	momentum transfer
DST	distribution
DT BAL	detailed balance
E	electron
E/	inelastically scattered electron
E+	positron
EDST	energy distribution or spectrum
E/N	used only to indicate a coincidence experiment as in (E,E/N).

	N stands for any outgoing particle measured in coincidence with an inelastically scattered electron. Distinguish from eg., (E,N) which is used to represent an electron induced reaction when only the outgoing particle N is detected.
EMU	emulsions (photographic plates)
EXCIT	excited
F	fission
FMF	form factor
FM-1	inverse femtometers
FRAG	fragment
G	photon
G/	inelastically scattered photon
G-WIDTH	gamma-ray transition width
HAD	hadrons, hadron production
HE He3	^{3}He particle
INT	interaction, integral, intensity
INC	includes
ION	ionization chamber
ISOB	isobaric
ISM	isomer
J	multiplicity of particle defined by following symbol e.g. (G,PJN) with remark J = 2,3,5,7
JPI J-PI	spin and parity of a nuclear state
K	second multiplicity index, e.g. (G,JPKN) with both J & K positive integers greater than 1
KE	kinetic energy
L	may be an integer or zero that always follows a reaction product symbol. This is used to indicate transitions to specific states in the residual nuclide. When the letter is used as in (G,NL) the cross section given is that for the sum of transitions to two or more specific final states.
LFT	excited state lifetime
LIM	limit
LV,LVS	level, levels
LQD	liquid
MAG	magnetic spectrometer
MEAS	measurement(s)
MGC	magnetic Compton spectrometer
MGP	magnetic pair spectrometer
MOD	moderated neutron detector not employing a BF_3 counter, e.g. rhodium foil, Szilard-Chalmers reaction, ^{3}He, ^{6}Li reactions, GD loaded liquid scintillator, etc.
MSP	mass spectrometer
MULT	multiple, multipole, multiplicity
MU-T	used only in combination with G to indicate a total photon absorption cross section measurement, i.e. (G,MU-T)
N	neutron (see also XN and SN). The notation (G,N) is used to indicate a reaction in which only a single neutron is emitted, i.e. the reaction that can, in many cases, be measured by observing the radioactive decay of the residual nuclide.

nN	where n is any integer. (G,nN) indicates the sum over all reaction cross sections in which n neutrons are emitted.
NAI	NaI(Tl) spectrometer
NEUT	neutron(s)
NOX	no cross-section data
P	proton (see also XP)
PART	particle(s)
PHOT	photon(s)
PI	pion, usually written as PI+, PI-, PI0 to indicate charge
POL	polarized or polarization
Q-SQUAR	momentum transfer squared (q^2)
RCL	recoil
REL	relative
RLI	relative integrated cross-section data
RLX	relative cross-section data
RSP	reaction spectrometer
RLY	relative yield data
SCTD	scattered
SCD	semiconductor (solid state) detector
SCI	scintillator detector other than NaI, e.g., CsI, KI, organic (liquid or solid), stilbene, He
SEP	separation
SEP ISOTP	separated isotope used
SIG	SIGMA (cross section)
SN	sum of neutron producing reactions, $\sigma(\gamma,SN)=\sigma(\gamma,N) + \sigma(\gamma,NP) + \sigma(\gamma,2N) + \sigma(\gamma,3N)$ + etc.
SPC	photon or particle energy spectrum
SPK	spark chamber
SPL	spallation
STAT	statistical
SYM	symetric, symmetry
T	triton
TEL	counter telescope
THR	threshold for reaction or threshold detector, e.g., $^{29}Si(n,p)^{29}Al$.
TOF	time-of-flight detector
TRK	tracks of particles or fragments observed in solid materials (glass, mylar, etc.)
TRNS	transition
UKN UNK	unknown
VIB	vibrational
VIR PHOT	virtual photon(s)
XN	all neutrons, total neutron yield, $\sigma(\gamma,XN) = \sigma(\gamma,N) + 2\sigma(\gamma,2N) + 3\sigma(\gamma,3N) + \sigma(\gamma,NP)$ + etc.
XP	all protons, total proton yield $\sigma(\gamma,XP) = \sigma(\gamma,P) + \sigma(\gamma,NP) + 2\sigma(\gamma,2P)$ + etc.
XX XXX	reaction products defined in REMARKS
YLD	yield

4PI	a 4π geometry was used or a method like radioactivity or a total absorption measurement		products was determined. The polarized particle is indicated in REMARKS.
999	energy defined in REMARKS	* or @	symbols used to indicate that the units associated with the numerals on one or both sides of the symbol in a specific column are not MeV. The units are defined in REMARKS.
$	indicates the measurement involved beams or targets that were either polarized or aligned, or that the polarization of the reaction

10. SUPPLEMENTARY NOTES

☐ Document describes a computer program; SF-185, FIPS Software Summary, is attached.

11. ABSTRACT (A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here)

These abstract sheets cover most classes of experimental photonuclear data leading to information of the electromagnetic matrix element between the ground and excited states of a given nucleus. This fifteen volume work contains nearly 7200 abstract sheets and covers 89 chemical elements from hydrogen through americium. It represents a twenty-seven year history of the study of electromagnetic interactions. The sheets are ordered by target element, target isotope, and by an assigned bibliographic reference code. Information is given on the type of measurement, excitation energies studied, source type and energies, detector type, and angular ranges covered in the measurement. For a given reference, the relevant figures and tables are mounted on a separate sheet for each nuclide studied.

12. KEY WORDS (Six to twelve entries; alphabetical order; capitalize only proper names; and separate key words by semicolons)

data-abstract sheets, elements, experimental, isotopes, nuclear physics, photonuclear reactions

13. AVAILABILITY

☐ Unlimited

☒ For Official Distribution. Do Not Release to NTIS

☐ Order From Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

☐ Order From National Technical Information Service (NTIS), Springfield, VA. 22161
