Photonuclear Data-Abstract Sheets
1955-1982

I. Introduction

As used in connection with this collection of data-abstract sheets, the term photonuclear data is taken to mean any data leading to information on the electromagnetic matrix element between the ground state and excited states of a given nuclide. The most common types of reactions included in this compilation are: (e,e'), (γ,γ), (γ,γ'), (γ,n), (γ,p), etc. as well as ground-state particle capture reactions, e.g. (α,γ_0). Two reactions which fit the matrix element criterion are not included in the compilation because of their rather special nature. These are heavy particle Coulomb excitation and the thermal neutron capture reaction (n,γ_0). While the energy region of particular interest extends from 0 to 150 MeV, papers are indexed which report measurements in the region from 150 MeV to 4 GeV. Most of the experiments listed are concerned with the excitation energy range from 8 to 30 MeV, the region of the photonuclear giant resonance.

The hierarchical grouping of the photonuclear data-abstract sheets within the file is by: 1. Target Element, 2. Target Isotope, and 3. by the Bibliographic Reference Code assigned to the paper from which the data on the sheet were abstracted. In this file, colored pages are used to mark the beginning and end of the sheets for each chemical element. A brief historical sketch of the element is given on the divider sheet marking the start of each section; the information for this sketch was derived from references such as the Encyclopaedia Britannica. In those cases where the sheets for a given element make up a major part of a volume, colored pages are also used to delineate sections pertaining to the individual isotopes of the element. Each of the sections of the file, as delineated by two colored divider sheets, represents a 27 year history of the study of electromagnetic interactions in either a specific nuclide or a specifc element.

The data-abstract sheets are filed under the element and/or isotope in which the ground-state electromagnetic transition takes place. For example, the abstract sheet for a total neutron yield measurement for a naturally occurring copper sample would appear in the elemental section of the copper file. On the other hand, a measurement of the ^{62}Cu 9.73 minute positron activity produced in the same sample by photons with energies below the three-neutron separation energy for ^{65}Cu (28.68 MeV) would be filed with the sheets for ^{63}Cu. Similarly a measurement of the ground-state neutron capture cross section in ^{12}C would be filed under ^{13}C while the corresponding ground-state alpha-particle capture cross section would be filed under ^{16}O.

At the end of this volume there is a master list of the abbreviations that have been used in the index section of the abstract sheets. The listings are those used in the final published index, Photonuclear Data Index, 1973-1981, NBSIR 82-2543, issued in August 1982 by the U. S. Department of Commerce, National Bureau of Standards, Washington, DC 20234. In some cases two notations are entered for the same quantity. The second entry is the abbreviation that was used in one or more of the earlier published editions of the index.

NITROGEN
Z=7

Nitrogen was first recognized by C. W. Scheele (1742-1786), a Swedish chemist of great importance. It was discovered independently by Joseph Priestley and Daniel Rutherford, but there is little doubt that Scheele's discovery precludes them by two years. Antoine Lavoisier named the gas "azote" (from the Greek *azotos* "ungirt" taken to mean lifeless) because of its inability to support life; he recognized it as an element. The name nitrogen was introduced in 1790 by J. A. Chaptal to indicate that the element is a constituent of niter (potassium nitrate).

N
A=13

Scheele was a proprietor of a small pharmacy. Pharmacies were then considered quiet centers of original research. He was offered many academic positions, including the chair of chemistry at Berlin, but never exchanged the practice of pharmacy for an academic career. Scheele performed an extraordinary amount of original research and published many papers, most of which contain some major discovery or important observation. His work touched on every area in chemistry of his time. It is said that his unremitting work, particularly at night, in a poorly ventilated laboratory, and his handling of the most toxic materials (with the habit of tasting and smelling them indiscriminately) induced the illness which caused his death at the age of 43 in 1786.

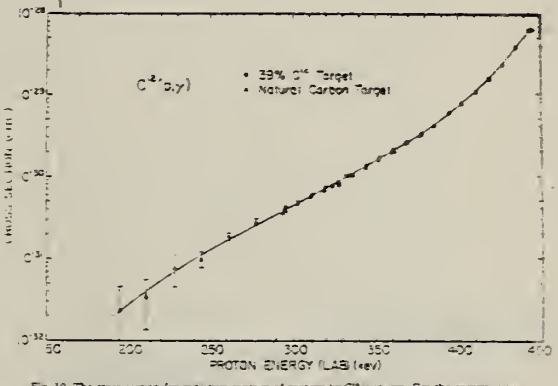

Fig. 10. The cross section for radiative capture of protons by C^{12} is shown. For the energy range from 296 keV to 444 keV a target of 39 %, C^{13} with a thickness of 8.9 keV for 448-keV protons was used. For the energy range from 194 keV to 378 keV, a natural carbon target, approximately 20 keV thick was used. The results from the latter target were normalized in the overlapping range to agree with the results from the target of known thickness, taken at higher energies. The experimental points have been corrected for the effect of the carbon contamination on the surface of the 39 % C^{13} target. Typical errors are shown at intervals in the energy range, and the origin of the solid curve is described in fig. 11.

TABLE 6

Resonance parameters for $C^{12}(p,\gamma)N^{13}$

Resonance energy (defined by $E_\lambda+\Delta_\lambda-\Sigma=0$)	462 keV
Reduced proton width γ_p^2	1.266 keV
Radiative width $\omega\Gamma_\gamma$	1.52 eV
Number ratios (for calculation of Δ_λ and $2\gamma/(F_c^2+G_c^2)$)	4.64×10^{-10} cm

*) A single-level Breit-Wigner formula is used, with all energy dependences included. The energies quoted are in the laboratory system. These parameters lead to a peak cross section of 137 μb at an energy of 440.5 keV.

			9.6 ± 3.5	170 ± 30	76 ± 28[c]
14.5 ± 0.2	15.3 ± 0.2	3/2+ (?)	0.21 ± 0.08	380 ± 150	≥0.5
			33 ± 13	310 ± 110	≥100

[a] Assuming no interfering background.
[b] A value of 0.30 ± 0.05 is assumed for Γ_{p_0}/Γ (Meyer and Plattner 1973).
[c] A value of 126 keV is taken for Γ_{p_0} (LeVine and Parker 1969).

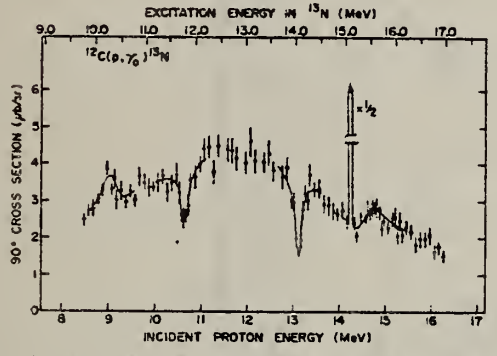

FIG. 4. The 90° yield curve for the reaction $^{12}C(p, \gamma_0)^{13}N$. The solid lines are fits to the data as described in the text. The narrow peak at $E_x = 15.1$ MeV is due to the first $T = 3/2$ level in ^{13}N. The errors shown are purely statistical and do not include a ±25% uncertainty in the absolute normalization.

(a) The Capture Reaction

The yield curve for the reaction $^{12}C(p, \gamma_0)^{13}N$ is presented in Fig. 4. The errors shown are purely statistical and do not include the error on the absolute normalization (±25%) nor the error for the energy dependence of the window efficiency (≃10% between the extremes of the yield curve). The yield for the γ rays leaving ^{13}N in excited states cannot be extracted from the data in a reliable way, although one can state that the cross section for γ_1 is always less than a half that for γ_0, whilst γ_2 and γ_3 have a summed cross section which is typically twice that for γ_0.

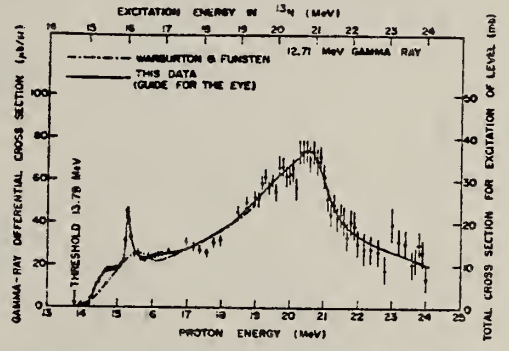

FIG. 5. The 90° yield curve for the 12.71 MeV γ ray in proton–carbon collisions. The errors shown are statistical and do not include a ±25% uncertainty in the absolute normalization.

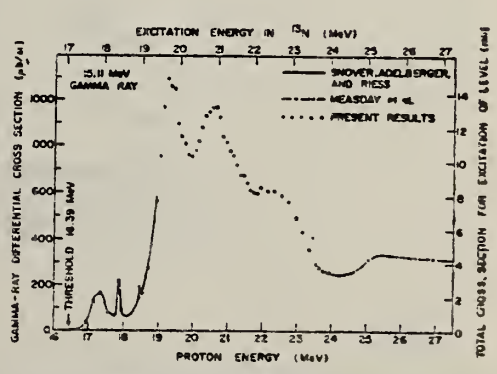

FIG. 6. The 90° yield curve for the 15.11 MeV γ ray in proton–carbon collisions. The errors shown are purely statistical and do not include a ±25% uncertainty in the absolute normalization.

LEVEL AT 15.07 MEV

We have measured the γ-ray branching ratios of the lowest $T = \frac{3}{2}$ levels in ^{13}C and ^{13}N, and the absolute strength of the γ_0 transition in ^{13}N. The mirror electromagnetic selection rule is obeyed by the $M1$ (γ_0 and γ_2) transitions. However the $E1$ (γ_1) transitions exhibit a surprisingly large charge asymmetry. Charge-dependent differences in the radial wave functions do not account for a similar asymmetry in strong $T = \frac{1}{2} \rightarrow T = \frac{1}{2}$ $E1$ transitions in mass 13.

Abstract: The reaction $^{12}C(p,\gamma)^{13}N$ has been studied over the energy range $9 < E_p < 14$ MeV. New structure is established around $E_x = 20$ MeV in the giant dipole resonance of ^{13}N. The interference dips at $E_x = 11.74$ MeV and at 14.04 MeV are confirmed as $\frac{3}{2}^+$ levels interfering with a pygmy resonance which has a predominantly $\frac{1}{2}^+$ strength. Total cross-section yield curves for the 12.71 and 15.11 MeV inelastic γ-rays have been obtained up to $E_p = 24$ MeV, and new structure is observed.

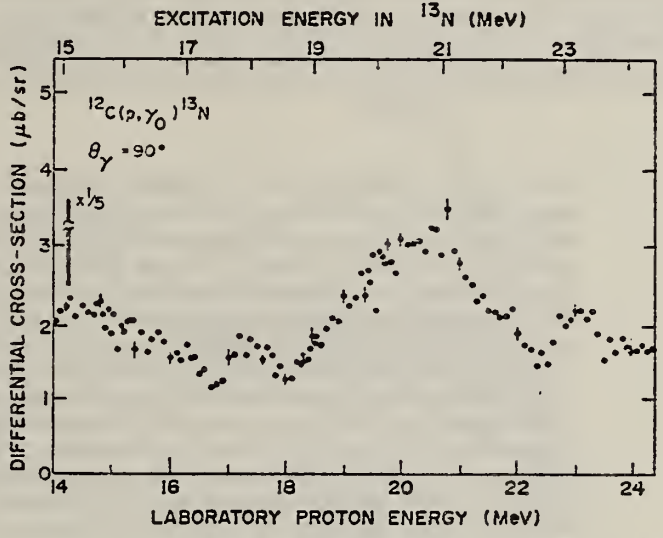

Fig. 3. Differential cross section for the 90° yield of capture γ-rays leading to the ground state of ^{13}N. In addition to the relative errors shown, there is an uncertainty in the absolute normalization of ±20%.

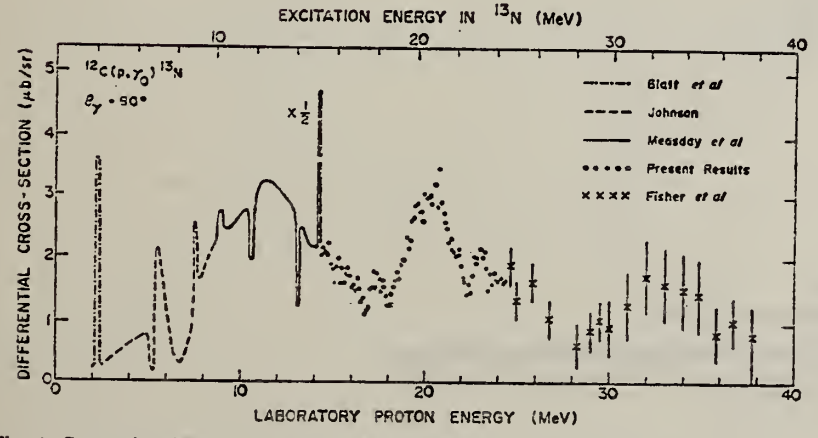

Fig. 4. Composite yield curve for capture γ-rays leading to the ground state of ^{13}N. There has been some slight adjustment of absolute normalizations between the various data (there were always overlapping regions which are not illustrated).

Summary. — Excitation functions for the reactions $^{12}C(p, \gamma_0)$ and $^{12}C(p, \gamma_{3+2})$ at proton energies in the range 16 to 40 MeV have been measured by means of a scintillation pair spectrometer. In the course of the same experiment, the yields of 4.43, 12.7 and 15.1 MeV γ-rays following inelastic proton scattering have been determined as a function of the incident-proton energy. Resonances are observed at proton energies of 20 and ~32 MeV; the former appears in all reaction channels except (p, γ_{3+2}), while the latter shows up in the capture cross-sections and in the yield of the 4.43 MeV γ-ray. The information collected in the present experiment, complemented by data on proton elastic and inelastic scatterings obtained by other authors, has been interpreted in the framework of the doorway-state-picture. The intermediate state in ^{13}N at an excitation energy of 20.4 MeV has been identified with the giant-dipole resonance, while the presence of *E*1 and *E*2 strength is suggested around 32 MeV.

over

Abstract: Cross sections for the $^{12}C(\vec{p},\gamma_0)^{13}N$ reaction have been measured from $E_{\vec{p}}$ = 10 MeV to 17 MeV in the laboratory system by bombarding an enriched carbon-12 target with a beam of polarized protons. A 25 cm diameter × 25 cm NaI(Tl) detector with a plastic anti-coincidence shield was used to detect the gamma rays. The total E2 capture cross sections were of the order of 0.2 μb and no resonance effects were observed. The amount of the E2 energy-weighted sum rule depleted in this energy range is $(8.5 \pm 3.3)\%$. Calculations based on a direct semi-direct capture model provide a good description of the experimental results by including only direct E2 capture and direct plus collective E1 capture.

POLARIZED PROTONS

E NUCLEAR REACTIONS $^{12}C(\vec{p},\gamma_0)^{13}N$, E = 10-17 MeV; measured differential cross-section $\sigma_-(E_{\vec{p}};\theta_\gamma)$, and differential asymmetry $\sigma_-(E_{\vec{p}},\theta_\gamma)$. ^{13}N deduced E1 and E2 cross sections. Enriched target.

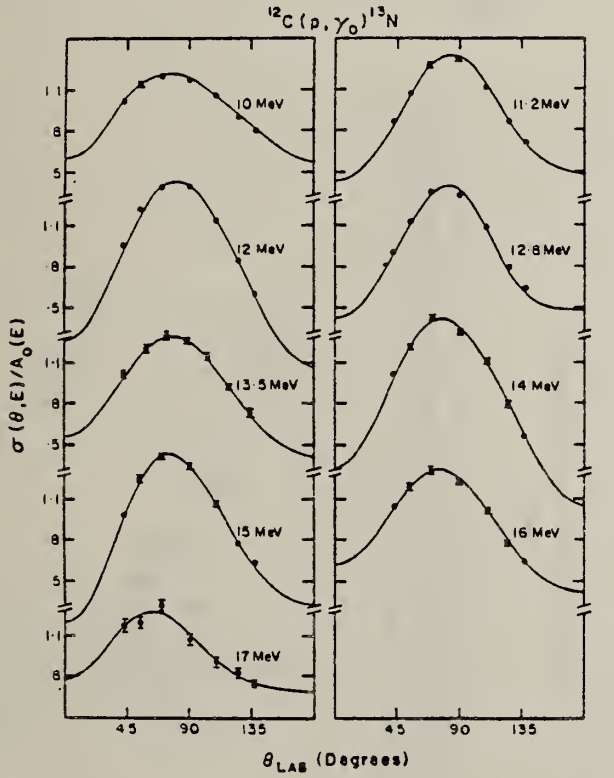

Fig. 4. $^{12}C(\vec{p},\gamma_0)^{13}N$ fractional differential cross sections $\sigma(\theta, E)/A_0(E)$. The solid lines are from a least squares fit to the data (see text). Statistical errors are shown where they are larger than the spot size.

Fig. 6. $^{12}C(\vec{p},\gamma_0)^{13}N$ normalized angular distribution coefficients. The solid points refer to the present data; the open circles refer to the data of ref. [16]. The solid curves are from a calculation which includes direct and collective E1 capture; the dotted curves include, in addition, a compact isoscalar E2 resonance (sect. 4).

(OVER)

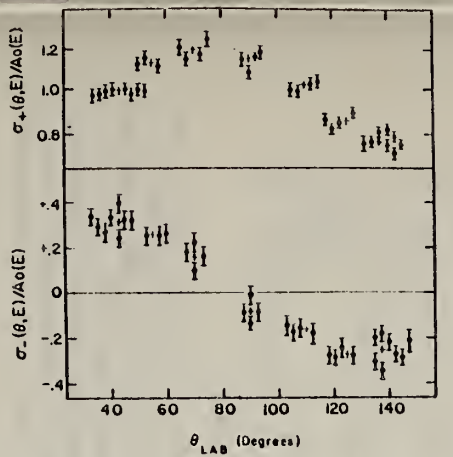

Fig. 3. The complete angular distribution measurements at $E_{\vec{p}} = 10$ MeV. The ordinate of the upper plot is the sum of the spin up and spin down yields. The ordinate of the lower plot is the difference of these yields divided by $2PA_0$ (see text). The plus signs are the averages of the measurements at a given angle; the surrounding points with error bars are the actual measurements at the angle indicated by the + sign.

POL PROTONS

The interference between the E_p = 14.23 MeV $M1(E2)$ $T = \frac{3}{2}$ resonance and the $E1$ giant-dipole-resonance "background" in the reaction $^{12}C(p_{pol},\gamma_0)^{13}N$ is used to determine uniquely the $E1$ reaction amplitudes. The $E1$ capture is found to be predominantly d wave, in agreement with the basic shell-model description of the nuclear giant dipole resonance.

PACS numbers: 24.30.Cz, 25.40.Lw, 27.20.+n

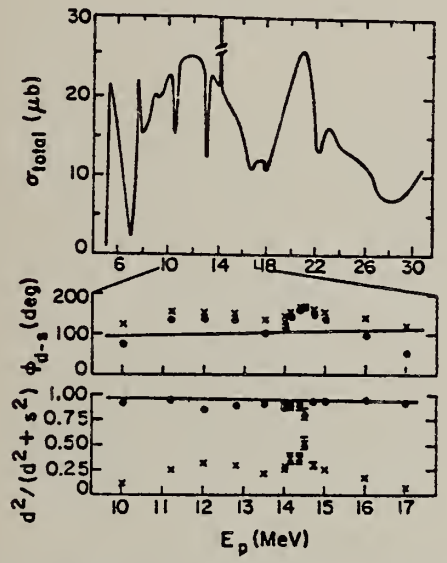

FIG. 1. Upper part: σ_{total} for $^{12}C(p_{pol},\gamma_0)$ for E_p = 5–30 MeV (Refs. 4 and 5). Lower part: The d–s phase difference and the relative d-wave intensity for E_p = 10–17 MeV (Ref. 5 plus the present work for 14 < E_p < 15 MeV). The points and crosses correspond to the two different solutions. The solid lines are DSD calculations described in Ref. 5.

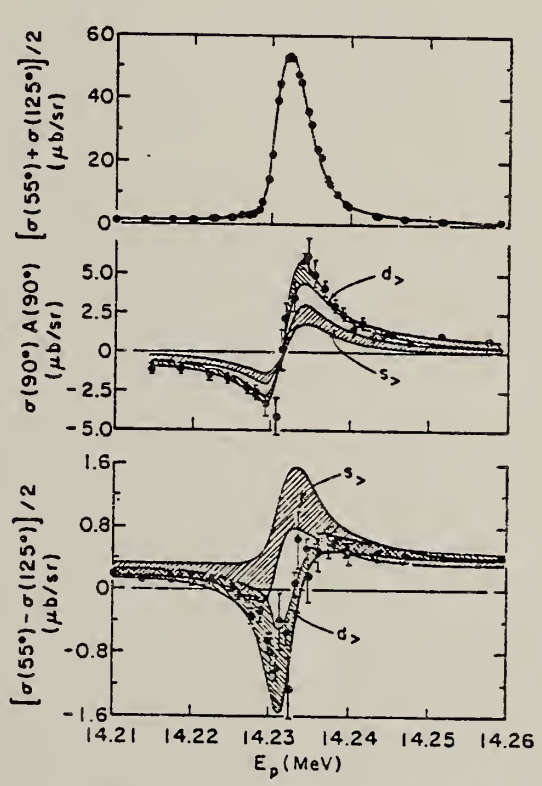

FIG. 3. Excitation curves taken near the lowest $T = \frac{3}{2}$ resonance in $^{12}C(p,\gamma_0)^{13}N$. The solid curve in the top part is a calculated fit. The bands in the lower two parts represent the spread of calculated curves for the $d_>$ and $s_>$ solutions, consistent with the off-resonance angular distributions.

The direct detection of neutrons from (γ,n) reactions induced by betatron bremsstrahlung has been applied to cross-section determinations using gaseous targets at approximately 100 atmospheres pressure. Results from oxygen are consistent with other determinations. The remaining elements represent new results and show the familiar giant dipole resonance for the photoneutron process. Parameters of the resonances are determined and related to the systematic behavior previously reported for other elements.

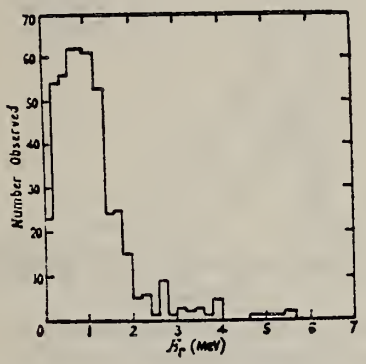

Figure 2. The energy distribution of the recoil nuclei from the reaction $^{14}N(\gamma, p)^{13}C$.

§ 6. Conclusion

From the experimental results, we conclude that:

(i) The cross sections for the reactions $^{14}N(\gamma, p)^{13}C$ and $^{14}N(\gamma, n)^{13}N$ are comparable, the relative values at any energy being shown in figure 13.

(ii) In the giant resonance, the emission of a single nucleon proceeds partly by a direct channel, and partly by the statistical evaporation of a nucleon. At energies greater than 30 Mev the emission proceeds mainly by a direct channel, and at all energies the results are consistent with the ratio of the two processes predicted by Wilkinson (1956).

(iii) The integrated cross section for the reaction $^{14}N(\gamma, pn)^{12}C$ is about 50% greater than that for the emission of either a single neutron or a single proton, for a spectrum of peak energy 200 Mev.

(iv) The (γ, pn) reaction appears to proceed either by a statistical or a knock-on process. The results for protons stopping within the sensitive volume of the chamber favour the statistical model and suggest that most of the observed events result from the absorption of a low energy ($\sim$20 Mev) photon.

(v) No evidence was found to suggest that many of the observed events could be satisfactorily explained by the quasi-deuteron model.

Relative Integrated Cross Section

Group	Reaction	Number	Relative number
(ii)	$^{14}N(\gamma, n)^{13}N$	627	1·18
(iii) (*a*)	$^{14}N(\gamma, p)^{13}C$	528	1·00
(iii) (*b*)	$^{14}N(\gamma, pn)^{12}C$	786	1·49
(iii) (*c*)	$^{14}N(\gamma, \alpha)^{10}B$ $(\gamma, \alpha n)$ etc.	28	0·05

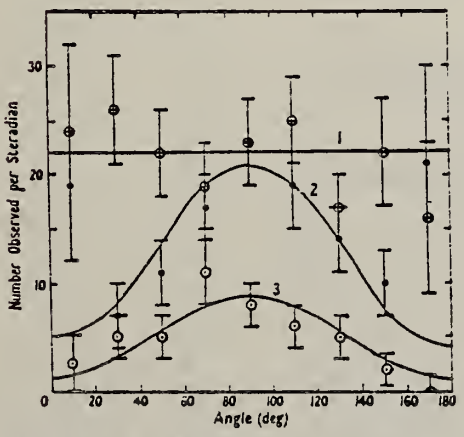

Figure 5. Angular distributions of protons from the (γ, p) reaction: 1, protons of energy less than 12 Mev—the distribution is fitted with the line $f(\theta) = 22$, and the experimental points are plotted as a cross within a circle; 2, protons of energy between 12 Mev and 20 Mev—the distribution is fitted with the curve $4 + 17 \sin^2\theta$, and the experimental points are plotted with a large spot; 3, protons of energy greater than 20 Mev—the distribution is fitted with the curve $1{\cdot}25 + 7{\cdot}4 \sin^2\theta$ and the experimental points are plotted with a small point within a circle.

Ref. No.: 60 He 2 JHH

Reaction	E or ΔE	E_o	Γ	∫σdE	Jπ	Notes
$C^{13}(p,\gamma)N^{14}$	130-450 kev	448.5±.5 kev	< 400 ev		2^-	E_γ (level in N^{14}) = 7.966 MeV Resonant γ ray yield, width and angular distribution data in Tables 1 and 2.

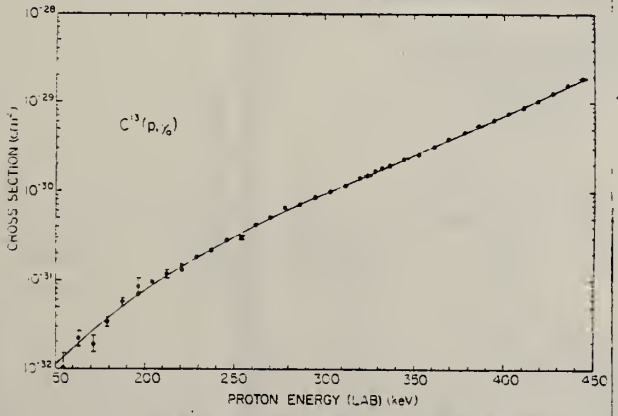

Fig. 8. The cross section for radiative capture of protons by C^{13}, with emission of the ground-state gamma ray, is shown. The target was 9.0 keV thick for 448-keV protons, and was enriched to 61 % C^{13}. Typical errors, due to counting statistics, are shown at intervals along the curve. The solid curve of this figure is derived from the solid curve in fig. 9 where an explanation will be found

TABLE 1
Resonant gamma ray yields and widths

	Transition from the 7.97-MeV level to the		
	ground state	3.95-MeV state	other states [a]
Yield 10^{-13} γ/p (61 % C^{13})	9.7 ±0.5	7.9 ±0.5	≲ 0.5
$\frac{\omega\Gamma_p\Gamma_\gamma}{\Gamma}$ (eV)	0.012	0.010	≲ 0.0005

[a] The cascades to the 2.31-MeV state, 5.10-MeV state and 5.68-MeV state may all be weakly resonant at 448-keV proton energy. Only an upper limit to the strength of this cascade radiation can be given.

TABLE 2
Resonant gamma-ray angular distributions [a]

7.97-MeV level to	Angular distribution
ground state	$P_0 - (0.570 \pm 0.020) P_2 - (0.004 \pm 0.03) P_4$
3.95-MeV state [b]	$P_0 - (0.33 \pm 0.03) P_2$

[a] The non-resonant distributions from the close neighbourhood of the 448-keV resonance were found to be isotropic, within experimental errors. Neither for resonant nor for non-resonant radiations were any odd-order Legendre polynomial coefficients observed. The tabulated distributions have been corrected for the finite solid angle of the detector.

[b] The angular distribution of gamma rays to the 3.95-MeV state was analyzed only for P_0 and P_2 terms. The subtractions necessary to eliminate the ground state radiation make the calculation of a $P_4(\cos\theta)$ term of doubtful value

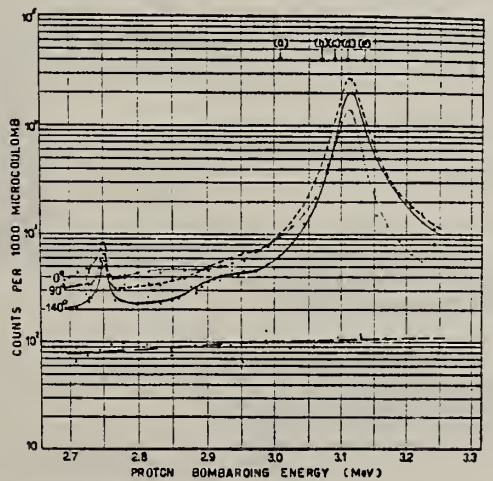

Fig. 1. The $C^{13}(p,\gamma)$ excitation functions as obtained with a 5 keV thick, 60 % enriched C^{13} target. A detailed explanation of this figure is given in sect. 3.

TABLE 2

The coefficients a_1 and a_2 of the angular distribution $W(\theta) = 1 + a_1 \cos\theta + a_2 \cos^2\theta$ of the 10.43-MeV gamma rays at different proton bombarding energies.

Measurement [a])	Bombarding energy (MeV)	a_1	a_2
(a)	3.01	$+(0.32 \pm 0.10)$	$-(0.29 \pm 0.10)$
(b)	3.07	$+(0.15 \pm 0.03)$	$-(0.41 \pm 0.03)$
(c)	3.09	$+(0.08 \pm 0.06)$	$-(0.40 \pm 0.10)$
(d)	3.11	$+(0.03 \pm 0.03)$ [b])	$-(0.50 \pm 0.03)$ [b])
		$+(0.02 \pm 0.02)$ [c])	$-(0.47 \pm 0.03)$ [c])
		$+(0.03 \pm 0.03)$ [d])	$-(0.47 \pm 0.03)$ [d])
(e)	3.135	$-(0.10 \pm 0.04)$	$-(0.46 \pm 0.08)$

With the exception of measurement (d) the errors quoted are due mainly to counting statistics and were evaluated using three standard deviations as uncertainty in a single determination. In measurement (d) the errors are least squares errors.

[a]) Compare fig. 1.
[b]) The values have been re-evaluated from the data displayed in ref. [4]) in order to check on a possible cos θ term.
[c]) Obtained with 45 keV thick target.
[d]) Obtained with a 5 keV thick target from measurements at 0° 90° and 140°.

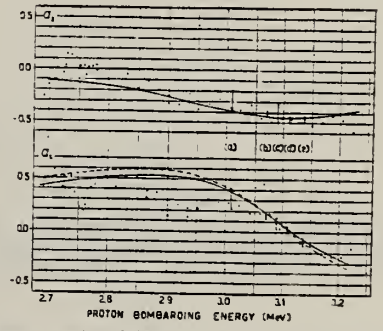

Fig. 2. The coefficients a_1 and a_2 of the angular distribution $W(\theta) = 1 + a_1 \cos\theta + a_2 \cos^2\theta$ as determined from the experiments described in sect. 3. The solid line gives the theoretical fit assuming interference between the 10.43-MeV state and background due to the 8.00-MeV level. The curve was calculated using the formulae of the appendix. The values of the parameters chosen for this calculation are given in the text. The broken line is obtained using a s-wave phase shift 18° larger than the one calculated with $R = 4.7 \times 10^{-13}$ cm from the hard sphere scattering condition. This slight increase of the s-wave phase shift is suggested by comparison of the hard sphere phases with the phases used by Zipoy *et al.* to fit the $C^{12}(p,p)C^{12}$ data.

The Yields of Radioactivities Induced by (γ, n) Reactions with Bremsstrahlung up to 68 MeV

by Tatsuya SAITO

The (γ, n) yields of 12 target nuclides have been measured at 10, 13, 16, 30, 45 and 68 MeV bremsstrahlung by observing the induced activities.

The energy dependence of the yields has been investigated extensively in the same way as in the previous work at 20 MeV bremsstrahlung.

In the case of heavy nuclides, the yields rise greatly as a function of maximum bombarding energy up to 20 MeV, and rise gradually from 20 MeV up to 68 MeV. However, in the case of light nuclides, the yields rise greatly up to 30 MeV, because the neutron separation energies of light ones are larger than those of heavy ones, and the bremsstrahlung spectrum covers the giant resonance and so the yields rise gradually from 30 MeV up to 68 MeV.

The yields have approximately been estimated from the parameter of the giant resonance, that is the peak cross section and the half width, in order to compare with the experimental data. As a result, the experimental data of light nuclides and heavy ones are nearly in agreement with the estimated data of Nathans et al., Johns et al. and Montalbetti et al., but those of medium weight ones are relatively lower values.

LEVEL AT 2.31 MEV

By observation of the resonant scattering of bremsstrahlung, the width of the 2.31-MeV level of ^{14}N has been measured as 6.2 ± 0.6 meV. This is somewhat smaller than previous values and in disagreement with inelastic electron scattering results and the prediction of the conserved vector current theory from the shape of the $^{14}O \rightarrow {}^{14}N$ β^+ spectrum.

Measurements were made of quasielastic scattering of electrons in the (e, e') reaction by the nuclei ^{9}Be, ^{12}C, ^{14}N, ^{16}O, and ^{27}Al. An experimental estimate is obtained of the effective mass of an intranuclear nucleon. At excitation energies up to 80 MeV, a ratio $M^*/M = 0.6$ is obtained, corresponding to a linear potential $V(E) = V_0 + 0.4E$ and in good agreement with the data on proton scattering by nuclei [C. M. and F. G. Perey, Atomic Data and Nuclear Tables 13, 294 (1974)]. At excitation energies above 120 MeV the nucleon effective mass turned out to be close to that of the free nucleon, $M^*/M = 0.9$.

Abstract—Mean cross sections for the photoproduction of ^{7}Be and ^{11}C from ^{19}F, ^{27}Al, ^{28}Si and ^{32}S targets, ^{7}Be from ^{10,11}B, and ^{11}C from ^{14}N and ^{16}O targets have been measured using bremsstrahlung beams in the energy range 0.3–1.0 GeV. The results have been compared with previous measurements and an excellent agreement has been found. In most cases, the values obtained turned out to be much larger than those expected from a simple spallation mechanism. A fragmentation and/or a fission-like process has been suggested in explaining the mechanism of such reactions.

999=1 GEV

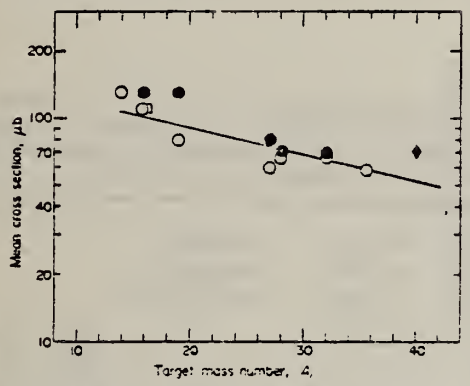

Fig. 1. Mean cross sections per photon, $\bar{\sigma}_A$, of ^{11}C photoproduction vs the target mass number A_t. Experimental data are taken from: ●, Ref. [9]; □, Ref. [13]; ◆, Ref. [2]; ○, present work. The straight line is a least squares fit of the experimental points.

The structure of the midget $E_p = 1701$ keV resonance in the $^{13}C(p,\gamma)^{14}N$ reaction was restudied with a high-volume Ge(Li) detector. The $(82 \pm 3)\%$ ground state ($J^\pi = 1^+$, $T = 0$) transition with the angular distribution $W(\theta) = 1 + (0.48 \pm 0.03) P_2(\cos\theta) - (0.16 \pm 0.03) P_4(\cos\theta)$ and the new $(9 \pm 3)\%$ branches to the 6.444-($J^\pi = 3^+$, $T = 0$) and 5.832-MeV ($J^\pi = 3^-$, $T = 0$) levels along with the deduced transition strengths lead to the new assignment of $J^\pi = 3^+$, $T = 0$ for the 9.130-MeV state.

9.13

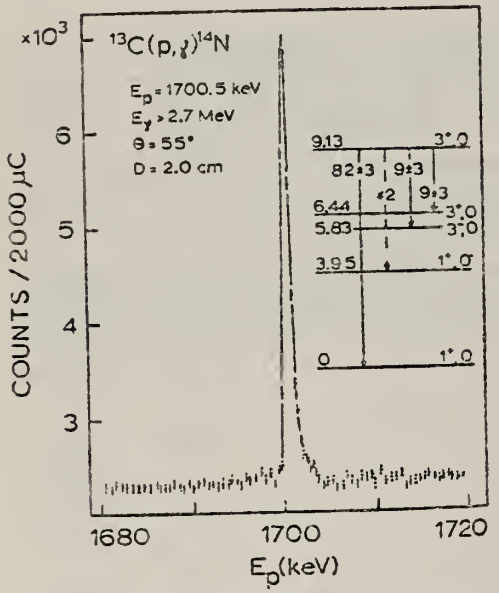

FIG. 1. The excitation function measured in the vicinity of the 1701 keV resonance in $^{13}C(p,\gamma)^{14}N$. The insert shows the γ-decay scheme of the resonance.

TABLE I. Summary of the angular distribution analysis performed for the different spin and parity alternatives for the (9.130→0) MeV transition. The experimental a_2 and a_4 values are 0.48 ± 0.03 and −0.16 ± 0.03, respectively. In the cases where the χ^2 value exceeded the 0.1% confidence limit, the error limits of the mixing ratio δ are not given.

7 LEVELS, J-PI, LFT

Inelastic electron scattering from ^{14}N at 180° has been studied at incident energies of 40.6, 50.6, and 60.2 MeV. Transitions to levels at 2.31, 9.17, and 10.43 MeV excitation energy were observed to be predominantly $M1$. The transition to the level at 16.11 MeV probably contains some $M2$ strength, and transitions to levels at 12.54, 13.27, and 13.76 appear to exhibit some $M1$ strength. Data on the 2.313 MeV transition, combined with earlier experiments, bring the observed reduced transition width into agreement with resonance fluorescence techniques. Transition widths for the other levels with reasonably certain multipolarities are also given.

[NUCLEAR REACTIONS $^{14}N(e,e')$, $\theta=180°$, $E=40.6$, 50.6, 60.2 MeV; measured $\sigma(E)$; deduced Γ_0, multipolarities for transitions excited.]

Abstract: Photoneutron angular distributions were measured for the reaction $^{14}N(\gamma, n_0)^{13}N$ using neutron time-of-flight techniques over the region of excitation energy from 17 to 26 MeV. Coefficients of a Legendre polynomial fitted to the data are interpreted in terms of a simple single-particle nuclear model. For reactions to the ground state in ^{13}N, it appears that most of the photon absorption in the giant resonance region studied forms $J^\pi = 2^-$ states in ^{14}N which decay by d-wave neutron emission. Some evidence was found for the existence of $J^\pi = 0^-$ strength at about 22.5 MeV (the peak of the cross section). The results are in general consistent with an identification of the (γ, n_0) process with the promotion of a $p_{1/2}$ neutron to the s-d shell. Little or no E2 or M1 absorption was observed. Comparison with photoproton measurements shows some evidence for a small amount of isospin $T = 0$ mixing also near 22.5 MeV. Comparison with calculations of the ground-state cross section shows reasonable agreement if the theoretical results are displaced upwards in energy by about 1 MeV.

E NUCLEAR REACTIONS $^{14}N(\gamma, n_0)$, $E = 17$–26 MeV; measured $\sigma(\theta_n)$ with time-of-flight; deduced $\sigma(E_\gamma)$, $T = 1$ purity.

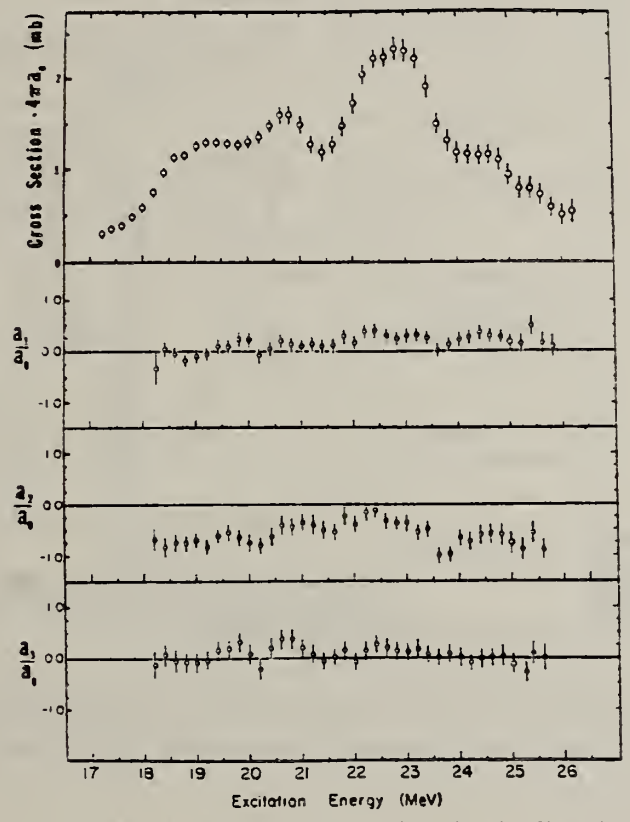

Fig. 5. The energy dependence of the angular distribution coefficients of a series of Legendre polynomials fitted to the eight neutron spectra for each end-point measurement. The a_n coefficient has been corrected by division by the photon distribution shape and has been plotted as the total ground-state cross section, $4\pi a_0$.

The gamma decay of E_p = 3.77 MeV resonance in $^{13}C(p,\gamma)^{14}N$ has been measured. From the measured excitation functions, the natural width of the resonance was deduced to be 1.2 ± 0.4 keV. The resonance is found to strongly populate the 3.945 MeV level, in addition to the gs transition. Gamma angular distribution measurements determined the resonance spin as 3^+. The reduced proton width is found to be 0.5% of the single particle unit. The transition strengths are measured to be $B(E2)$ = 0.45 ± 0.07 and 3.0 ± 0.8 Wu for transitions to ground state and the level at 3.945 MeV, respectively.

Abstract: Cross sections have been measured for the reaction $^{14}N(e, d_0)^{12}C$ over the incident electron energy range of 18 to 29 MeV together with the angular distributions of emitted deuterons. Analysis of these data has been performed by using a cluster model. The giant quadrupole resonance is deduced around 20 MeV. The dipole strength has two peaks which correspond to the pigmy and the giant resonances of the (γ, p_0) reaction, respectively. A monopole component is found to be necessary to reproduce the experimental results.

E NUCLEAR REACTIONS $^{14}N(e, d)$, $E = 18$–29 MeV; measured $\sigma(E_d, \theta_d)$. ^{14}N deduced resonances. Cluster model analysis. Natural BN target.

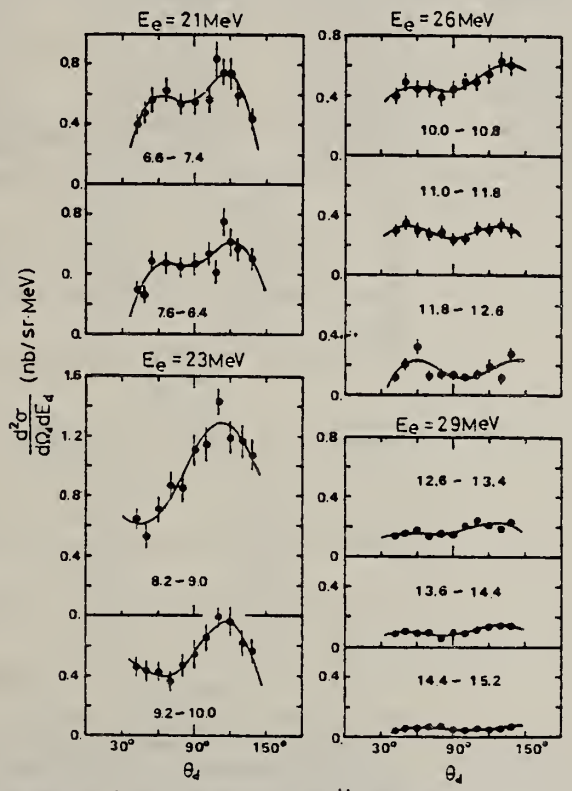

Fig. 3. Angular distributions of deuterons emitted by the $^{14}N(e, d_n)$ reaction. Solid curves are the best-fitted results with a Legendre polynomial series. The deuteron energy ranges (in MeV) used to get the average values of the cross sections under each experimental condition are shown in the figure.

(OVER)

The 90° yield curves for the $^{13}C(\vec{p},\gamma_0)^{14}N$ and $^{13}C(\vec{p},\gamma_1)^{14}N$ reactions have been measured in 200 keV steps for $E_p = 6.25$ to 13.6 MeV and in 100 keV steps for $E_p = 13.6$ to 17.0 MeV. In addition, 50 keV step data were obtained for E_p of 12.6 to 14.55 MeV. Angular distributions of both the cross section and the analyzing power were also obtained for these two reactions at twelve energies which span the giant dipole energy region. The cross section was measured at nine angles between 30° and 154° while the analyzing power was measured at seven angles between 42° and 142°. These data were used to obtain the complex $E1$ and $E2$ transition matrix elements in the case of $^{13}C(\vec{p},\gamma_1)^{14}N$. The results are compared to a direct-semidirect calculation. It is found that there is little justification in introducing $E2$ amplitudes other than a pure direct $E2$ term.

POLARIZED PROTONS

[NUCLEAR REACTIONS $^{13}C(\vec{p},\gamma_0)$, $^{13}C(\vec{p},\gamma_1)$ measured $\sigma(\theta)$ and $A(\theta)$, E_p=8.05–15.5 MeV. $^{13}C(p,\gamma_0)$, $^{13}C(p,\gamma_1)$ measured $\sigma(90°)$, E_p=6.24–17.0 MeV. Deduced $E1$ and $E2$ T-matrix amplitudes and phases. Compared to model calculations.]

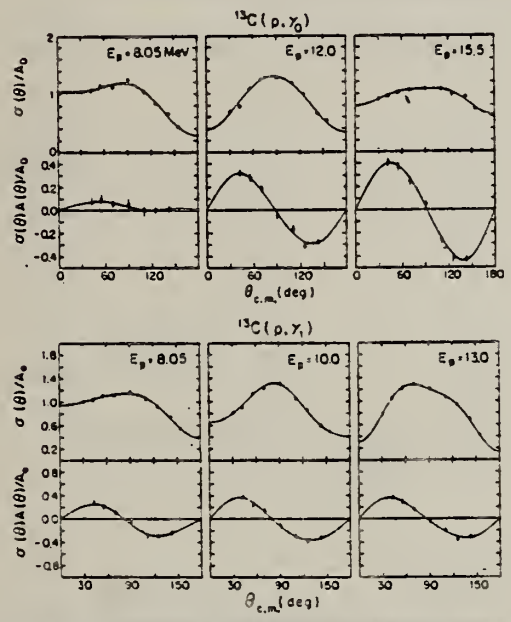

FIG. 5. (a) Typical cross section and analyzing power data for the $^{13}C(p,\gamma_0)^{14}N$ reaction. The error bars represent the statistical errors associated with the data points. The solid curves were generated by fitting the data through fourth order in the Legendre and associated Legendre polynomials as described in the text. (b) Same as for Fig. 5(a), but for $^{13}C(p,\gamma_1)^{14}N$.

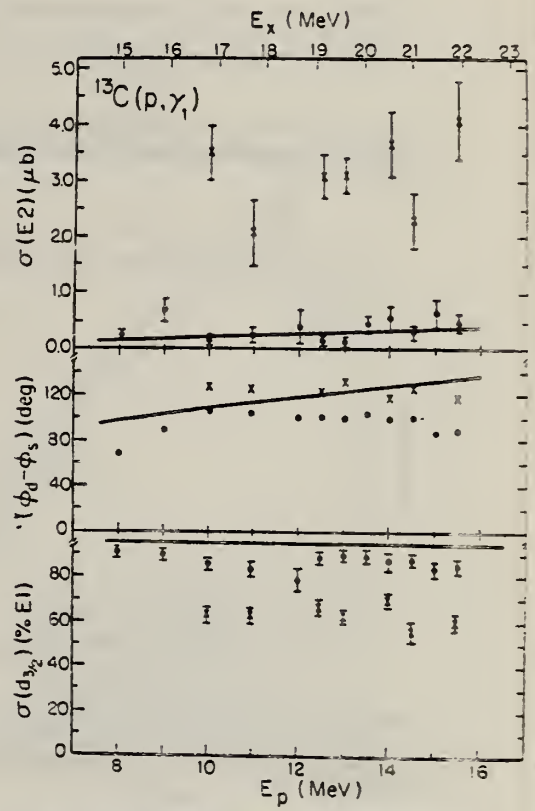

FIG. 8. The results of the $E1$-$E2$ analysis for the $^{13}C(p,\gamma_1)^{14}N$ reaction for dominant $d_{3/2}(E1)$ capture. The bottom plot shows the percentage of the $E1$ cross section due to the $d_{3/2}(E1)$ term. The middle plot shows the relative phase between the two $E1$ terms. The upper plot gives the angle integrated $E2$ cross section. The error bars represent the statistical uncertainties associated with these quantities (the errors associated with the relative phases are ≤4°). The ●'s and ×'s correspond to the two solutions corresponding to "small" and "large" $E2$, respectively. The curves are the result of the calculation described in the text.

(OVER)

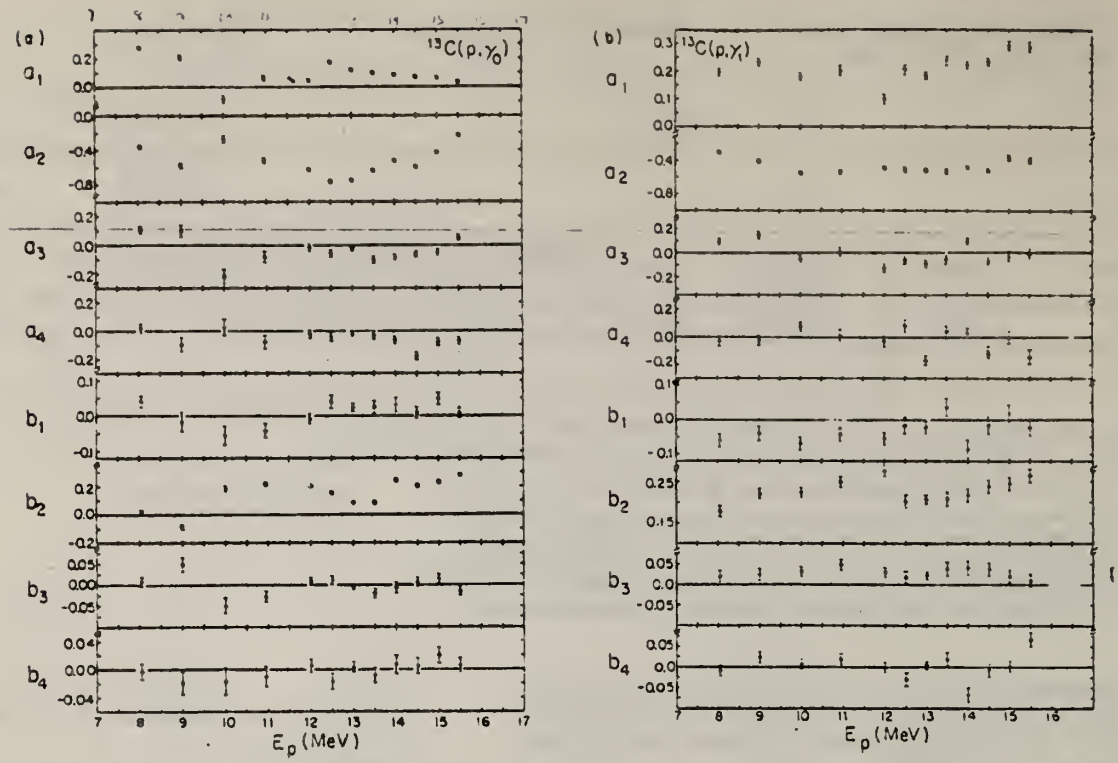

FIG. 6. (a) The a_k and b_k coefficients for the $^{13}C(p,\gamma_0)^{14}N$ reaction obtained from the fits through fourth order. The error bars represent the statistical errors associated with these coefficients. (b) Same as Fig. 6(a), but for $^{13}C(p,\gamma_1)^{14}N$.

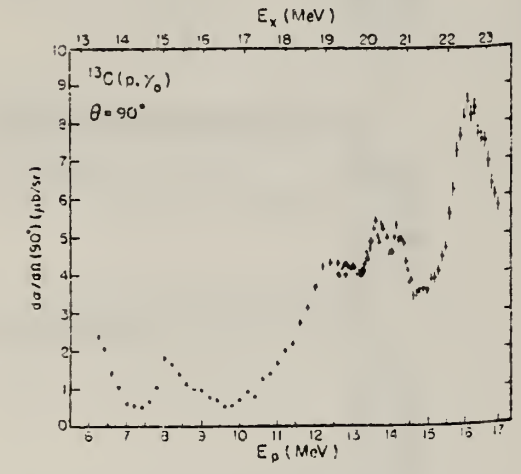

FIG. 2. The differential cross section measured at $\theta_{lab} = 90°$ for the $^{13}C(p,\gamma_0)^{14}N$ reaction. The error bars represent the statistical errors associated with the data points.

TABLE I. Summary of the percent of the $E2$ isoscalar EWSR obtained from experiment and from the direct calculation. The integrated energy weighted strengths are also given. Note: The value of $\langle r_3^2 \rangle$ required to evaluate the sum rule was taken both from electron data (Ref. 23) $\langle r_0^2 \rangle_1$ and from a uniform charged sphere model $\langle r_0^2 \rangle_2$.

	$\int \frac{\sigma dE}{E^2}$ (μb/MeV)	% $(\langle r_3^2 \rangle_1)$	% $(\langle r_0^2 \rangle_2)$

Mutually consistent measurements of elastic proton scattering and resonance absorption show that the width of the 9.17 MeV level in ^{14}N ($\Gamma = 135 \pm 8$ eV) is almost twice as large as the accepted literature value. The positive parity is unambiguously confirmed. The excitation energy is determined to be 9172.5±0.3 keV, based upon a cascade-crossover technique with a ^{56}Co source for calibration. The expected azimuthal asymmetry of the resonance fluorescence of the plane-polarized photons at this resonance is demonstrated quantitatively.

Experimental results for the 6.32 MeV level in ^{15}N. Transition strenghts are expressed in Weisskopf units as defined by Wilkinson [5].

	M1	E2
Γ_γ^0(eV)	3.4 ± 0.7	0.06 ± 0.02
Transition strength	0.64 ± 0.14	3 ± 1
$\lvert\delta(E2/M1)\rvert$	0.13 ± 0.03	

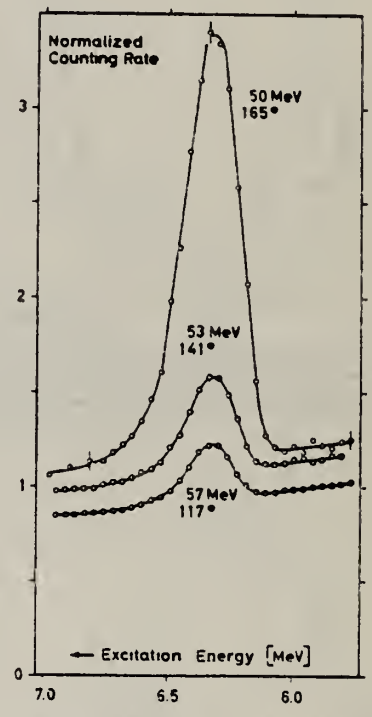

Fig. 1. Spectra of electrons scattered inelastically from a melamine ($C_3N_6H_6$) target enriched to 99% in ^{15}N. The scattering angles and primary energies, shown on the figure, were chosen to give a constant inelastic momentum transfer of 0.47 fm^{-1}. The peak results from the excitation of the 6.32 MeV level in ^{15}N. For convenience the three spectra are normalized to a constant elastic peak area. In such a plot, a pure longitudinal excitation would show a peak area independent of scattering angle. The strong enhancement of the observed peak area at backward angles demonstrates the predominantly transverse (magnetic) character of this transition. Only statistical errors are given: for the 117° spectrum they are smaller than the points.

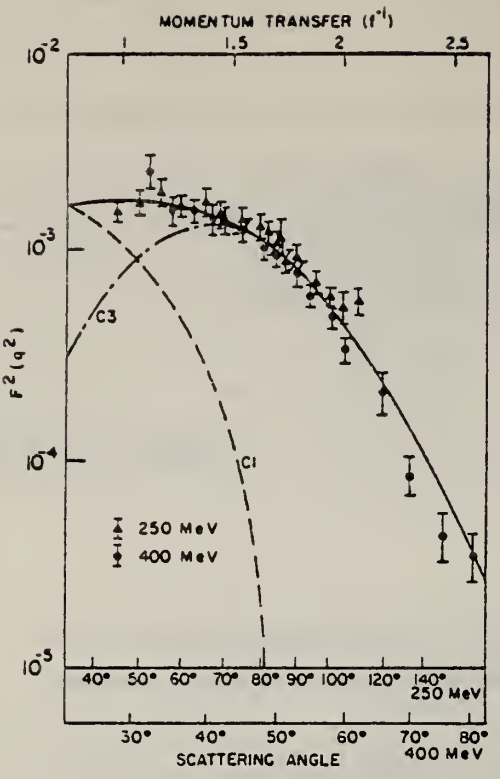

FIG. 6. The form factor versus momentum transfer for the inelastic electron scattering to the 5.3-MeV doulet in N^{15}. The curves labeled $C1$ and $C3$ are the separate contributions to the form factor of these transitions. The magnitude of each is found from a fit to the data as described in the text. The solid curve is the sum of the two transitions.

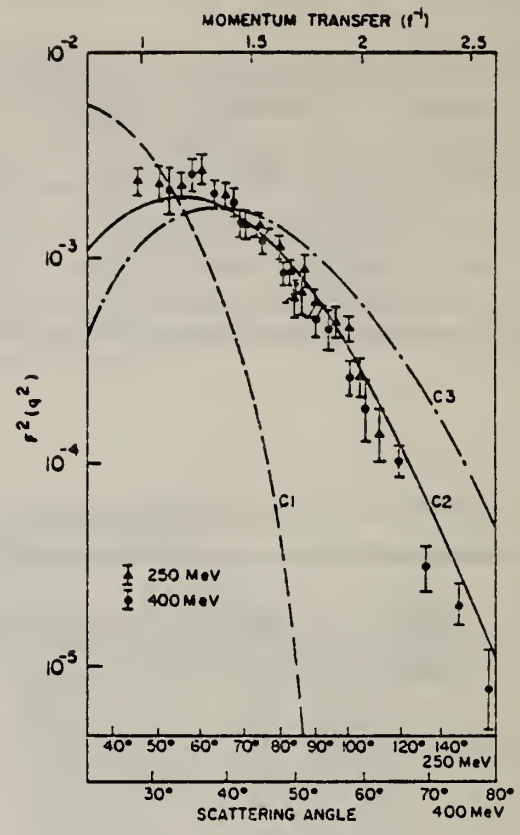

FIG. 7. The same as Fig. 5, for the excitation to the 6.3-MeV level in N^{15}. The curves $C1$, $C2$, and $C3$ are fitted to the data to find which multipole transition is involved in the excitation.

REACTION	RESULT	EXCITATION ENERGY	SOURCE		DETECTOR		ANGLE
			TYPE	RANGE	TYPE	RANGE	

TABLE VII. Summary of the experimental results on the inelastic scattering from N^{15}. Column 1 is the level energy. The 250- and 400-MeV data were separately fitted to the 6.3-MeV transition when $M1$ was included in the fit. The 250- and 400-MeV data were combined for the fits to the other levels and for the fit to the 6.3-MeV level when $C2$ was used alone. Column 2 gives the possible transitions. These transitions in parentheses were not considered for the fits. Column 3 identifies the fitting parameters defined in the text, and column 4 gives their values. Column 5 is the χ^2/degree of freedom for the fits. Column 6 contains the values of $B(M\lambda, J_i, J_f)\downarrow$ found in this experiment. Column 7 has values of $B\downarrow$ found from other experiments, and lifetimes found in this experiment in column 8 can be compared with other experimental values in column 9 and the values obtained using an independent particle model (column 10). The errors are standard deviations weighted by the χ^2 of the fit.

The analyzing power $A(\theta)$ was obtained at a given energy and angle from the expression[2]

$$A(\theta) = -1(N_u - N_d)/P(N_u + N_d), \quad (1)$$

where N_u and N_d are the γ-ray yields for spin up and spin down, respectively. In addition to the analyzing power, data were taken with an unpolarized beam to extend previous cross-section measurements[5,6] from $E_p = 12$ to 16.2 MeV and to obtain angular distributions needed for the present analysis. The angular distributions of cross section were expanded in terms of Legendre polynomials as

$$\sigma_u(\theta) = a_0[1 + \sum_{k=1} a_k P_k(\cos\theta)] \quad (2)$$

and the analyzing power was expanded as

$$A(\theta)\sigma_u(\theta) = \sum_{k=1} b_k P_k^1(\theta), \quad (3)$$

where a_0 in $\sigma_u(\theta)$ of Eq. (3) was set equal to 1.0.

REACTION	RESULT	EXCITATION ENERGY	SOURCE		DETECTOR		ANGLE
			TYPE	RANGE	TYPE	RANGE	
P,G	ABX	13- 38	D	2- 30	NAI-D		DST

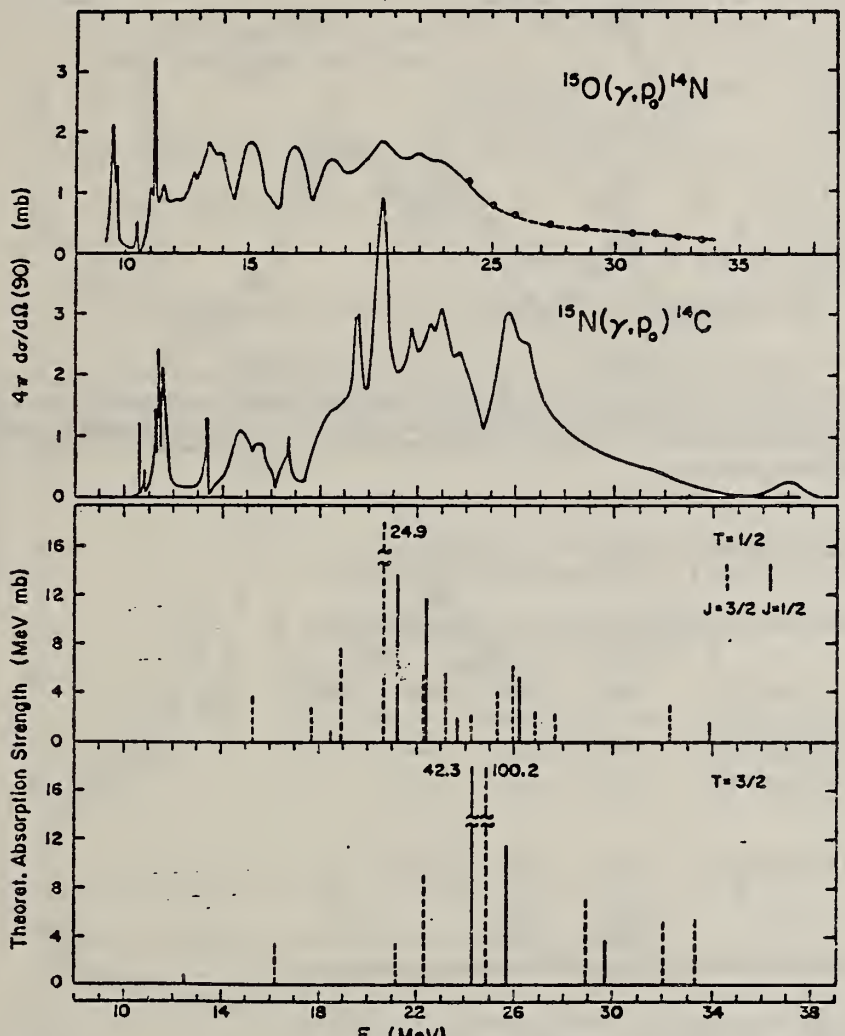

FIG. 6. Comparison of the experimental results from the $^{15}O(\gamma,p_0)^{14}N$ and $^{15}N(\gamma,p_0)^{14}C$ reactions and the theoretical predictions from the 2h-1p model (case B). The data below 25 MeV in the top curve are from Ref. 4, the data points at higher energies stem from the present work. The theoretical plots give the $T=\frac{1}{2}$ and $\frac{3}{2}$ components of the computed integrated photoabsorption cross section proportional to $E_\gamma[B(E1\uparrow)]$. Dashed and solid lines indicate $J=\frac{3}{2}$ and $\frac{1}{2}$, respectively. The top experimental curve should relate to the $T=\frac{1}{2}$ part while the $^{15}N(\gamma,p_0)^{14}C$ curve contains both T components.

Comment on "E1 excitations in $A = 15$ nuclei"

H. R. Weller
University of Florida and Triangle Universities Nuclear Laboratory,† Durham, North Carolina 27706*

N. R. Roberson, D. G. Rickel, C. P. Cameron, and R. D. Ledford

(Received 8 December 1975)

It is shown that the recent $J^\pi = \frac{1}{2}^+$ assignment for the level observed in the $^{14}C(p,\gamma_0)^{15}N$ reaction at $E_p = 6.925$ MeV is not unique.

Phys. Rev. C13, 2062 (1976)

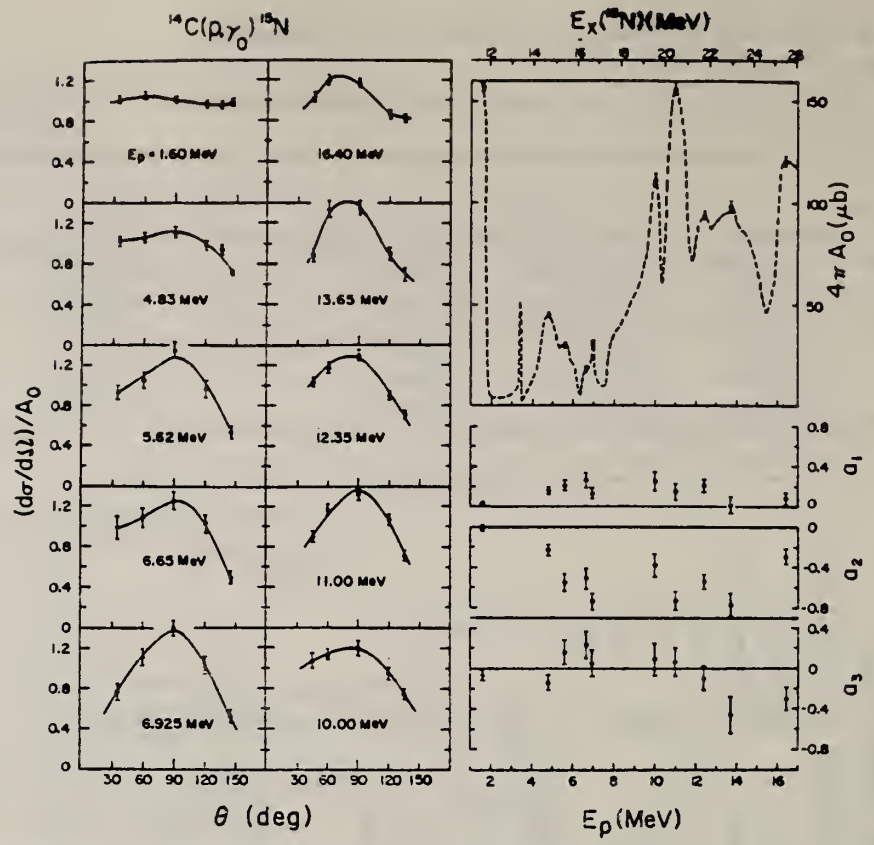

FIG. 4. Normalized angular distributions of the γ_0 yield at several bombarding energies corresponding to peaks in the excitation function. The curve at $E_p = 1.6$ MeV should be isotropic. Solid curves are fits with Legendre polynomials up to P_3. The total cross section $4\pi A_0$ and the normalized Legendre coefficients a_1, a_2, a_3 obtained from the fits are plotted on the right hand side of the figure.

TABLE II. Abstract: The 6.324 MeV level of ^{15}N was photoexcited by a chance energy overlap with a γ-line obtained from the Cr(n, γ) reaction using thermal neutrons. By measuring the angular distribution of the scattered radiation and its polarization, the spin and parity of the level was determined to be $J^{\pi} = \frac{3}{2}^-$. The E2/M1 mixing ratio of the $\frac{3}{2}^- \rightarrow \frac{1}{2}^-$ ground-state transition was unambiguously determined to be x(E2/M1) = 0.137±0.005. An upper limit to the branching ratio of the decay of the level to lower lying levels in ^{15}N was obtained. The radiative width of the level was also measured and found to be $\Gamma = 3.1 \pm 0.3$ eV. The result is compared with theoretical predictions.

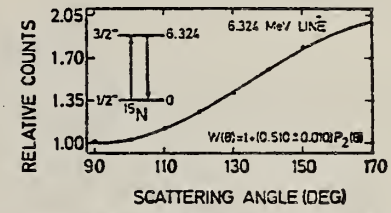

Fig. 3. Angular distribution of the 6.324 MeV scattered line from ^{15}N as measured using a 40 cm^3 Ge(Li) detector. The solid line has the form $W(\theta) = 1 + A_2 P_2(\cos\theta)$ and is a least square fit to the experimental distribution.

Abstract: The 90 differential cross section of the $^{13}C(d, \gamma_0)^{15}N$ reaction has been measured at deuteron energies from E_d = 2.90 to 9.95 MeV in steps of 200 keV. Angular distributions have been obtained at E_d = 3.28, 3.96, 4.30, 4.76, 5.32, 5.92, 6.23, 6.63 and 7.94 MeV. The γ-rays have been detected with a 23 cm long by 23 cm diameter NaI(Tl) crystal spectrometer enclosed in a plastic scintillator anticoincidence shield. The γ-ray yield curve decreases monotonically with energy and shows a resonant behaviour at E_d = 6.65 MeV (E_x = 21.9 MeV) and a wide structure at E_d = 8.8 MeV ($E_x \approx$ 23.8 MeV). The angular distributions are consistent with the hypothesis that states with quantum numbers $J^\pi = \frac{1}{2}^+$ and $\frac{3}{2}^+$ are excited in the capture process followed by emission of E1 radiation. There is also evidence of M1/E2 transitions over the whole energy region investigated.

Abstract: The temperature effect of nuclear resonance scattering from the 6.324 MeV level in ^{15}N was studied as a function of temperature using a gaseous $^{15}N_2$ target and a solid $Li^{15}NO_3$ target. The γ-source was produced by the Cr(n, γ) reaction using thermal neutrons. In order to reproduce the experimental variation of the scattering cross section versus temperature, the Lamb treatment for metallic elements was generalised to the case of diatomic and more complicated molecules. In $^{15}N_2$ an effective temperature was defined in which the zero-point energy of vibration of the diatomic molecule was included. In $LiNO_3$, an effective temperature was also defined by introducing a modified Debye temperature and accounting for the normal modes of vibration of ^{15}N in the $^{15}NO_3^-$ molecule. An excellent agreement between measured and calculated values was obtained. In a way, the present measurement may be viewed as detecting the zero-point vibrations in molecules.

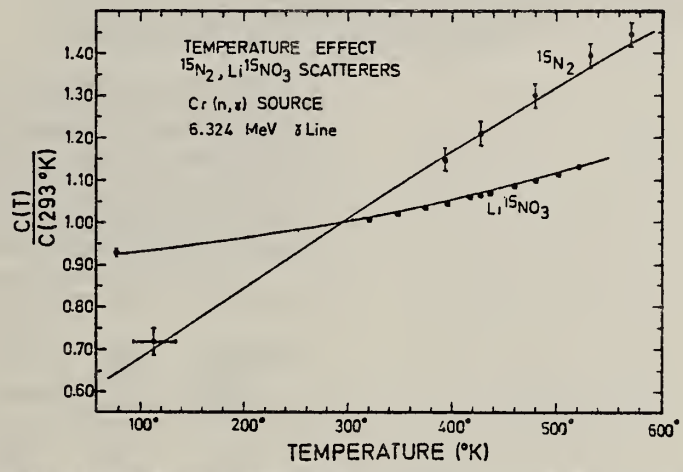

Fig. 2. Relative scattering yield (normalised to $T = 293°$ K) from gaseous $^{15}N_2$ and solid $Li^{15}NO_3$ targets as a function of temperature. The solid lines are the theoretical curves obtained using eq. (1) with $\Gamma_0 = \Gamma = 2.9$ eV and $\delta = 29.5$ eV. For $Li^{15}NO_3$, the value of θ was 160° K.

Absolute yields based on normalization to $^{59}Co(\gamma,n)$ cross section of Fultz (62Ful). If newer $^{59}Co(\gamma,1n)$ data from Alvarez (73Al7) is used, yields should be increased by a factor of 1.41.

Abstract. The photodisintegration of ^{15}N through excited states of the residual nuclei has been studied by measuring the yields of de-excitation γ rays in a Ge(Li) detector. Cross sections for all observed transitions were deduced from measurements with bremsstrahlung end-point energies ranging from 15 to 35 MeV and account for an integrated cross section of 44 MeV mb. Bound states in ^{14}N and ^{14}C with a dominant $(1p_{1/2})^{-1}$ or $(1p_{3/2})^{-1}$ configuration are found to be strongly populated. On the whole the results do not agree well with the meagre existing experimental information or with published theoretical calculations, with the possible exception of those of Zhusupov and Eramzhyan. The nature of the states in the ^{15}N giant resonance is discussed. The $^{15}N(\gamma,t)^{12}C^*$ (4·44 MeV) reaction was also observed and its integrated cross section is ~5% of the expected value of the E1 sum rule. Integrated cross sections for $^{16}O(\gamma,n_{p_{1/2}})$ transitions measured at the same time are given. Resonance fluorescence is observed from the ^{15}N 10·07 MeV level, for which $\Gamma_{\gamma_0} = 4{\cdot}2 \pm 1{\cdot}5$ eV is deduced.

Table 1. Cross sections, integrated up to 35 MeV, for neutron, proton and triton transitions to specific states of the residual nuclei. In the ^{15}N (γ, n) and (γ, p) cases, all final states lying below particle break-up energies are included. The dominant configurations for ^{14}N were taken from table V in True (1963) and those for ^{14}C from the work of Kaschl *et al* (1971). For the states with configurations given in square brackets, pick-up studies find no evidence for direct transitions and the configurations have been taken from ^{14}N states with the same J^π, T. The last two columns compare the measured integrated cross sections, divided by 150 MeV mb, with the theoretical predictions of Goncharova (1972). Errors on the integrated cross-sections are ~ ±30%.

POLARIZED PROTONS

Direct-semidirect radiative-capture calculations are compared to new detailed $^{14}C(p_{pol},\gamma_0)^{15}N$ measurements in the giant-dipole-resonance region. The calculations provide a good description of the data by including only direct $E2$ and direct plus collective $E1$. The experimentally determined $E2$ cross section exhausts (6.8±1.4)% of the isoscalar sum rule and shows no sign of a resonance.

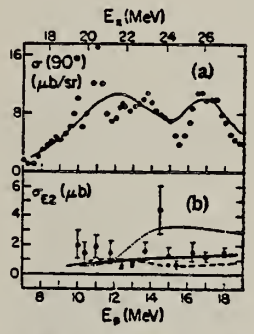

FIG. 2. (a) The 90° cross section (Ref. 6). (b) σ_{E2} derived from the data of Fig. 1 and (a) (see Fig. 1 caption).

The 90° differential cross section of the $^{11}B(\alpha,\gamma_0)^{15}N$ reaction has been measured at α-particle energies from 5.74 to 17.80 MeV. The γ rays have been detected by a 23 cm long × 23 cm diameter NaI(Tl) crystal spectrometer enclosed in a plastic scintillator anticoincidence shield. The yield curve shows three well separated resonances at E_{exc} = 16.29 ± 0.15, 18.88 ± 0.20, and 21.26 ± 0.20 MeV.

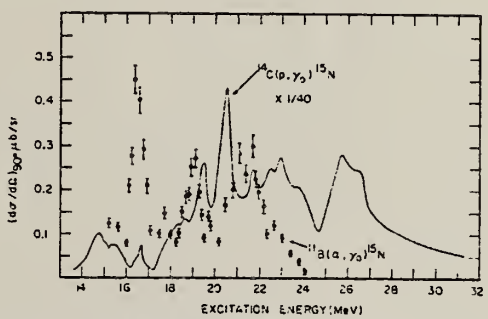

FIG. 1. Experimental differential cross sections at $\theta_L = 90°$ of the $^{14}C(p,\gamma_0)^{15}N$ and $^{11}B(\alpha,\gamma_0)^{15}N$ reactions. The solid line represents the results of Harakeh *et al.* (1975); the solid symbols are the results of this experiment. In the latter instance only statistical errors are shown in the figure.

5.3,6.32 MeV

Abstract. Form factors for the inelastic scattering of electrons from ^{15}N were measured for the excitation of the 6·32 MeV $\frac{3}{2}^-$ state and of the 5·3 MeV $\frac{5}{2}^+$ $\frac{1}{2}^+$ doublet. The experimental data obtained resolve apparent discrepancies between the results deduced from the previous studies of ^{15}N by electron scattering, and demonstrate that even large-basis shell-model calculations using the Kuo interaction do not produce realistic wave-functions for these states.

Abstract: The reaction $^{12}C(t, \gamma_0)^{15}N$ was studied for E_t = 1–3.4 MeV (E_x = 15.7–17.6 MeV). The excitation curve displays a strong resonance with a peak cross section of 4.4±0.5 μb/sr at E_t = 2.3 MeV (E_x = 16.60 MeV, Γ = 0.13 MeV) and evidence for additional structure. The excitation curve and the angular distributions were analysed using the complex eigenvalue theory. The parameters of three $J^\pi = \frac{1}{2}^+$ states and two $J^\pi = \frac{1}{2}^-$ states resulting from this analysis are given. Our results show the importance of complex configurations in this energy region of the ^{15}N giant resonance.

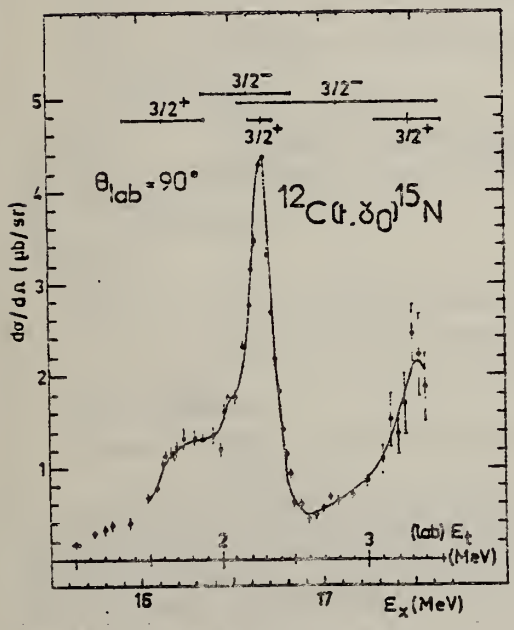

Fig. 3. Excitation function at 90° for the $^{12}C(t, \gamma_0)^{15}N$ reaction. The vertical error bars represent only errors of statistical origin. The solid line corresponds to the *S*-matrix fit. The horizontal bars at the top of the figure indicate the positions and the widths of the levels used in this fit (see also table 1).

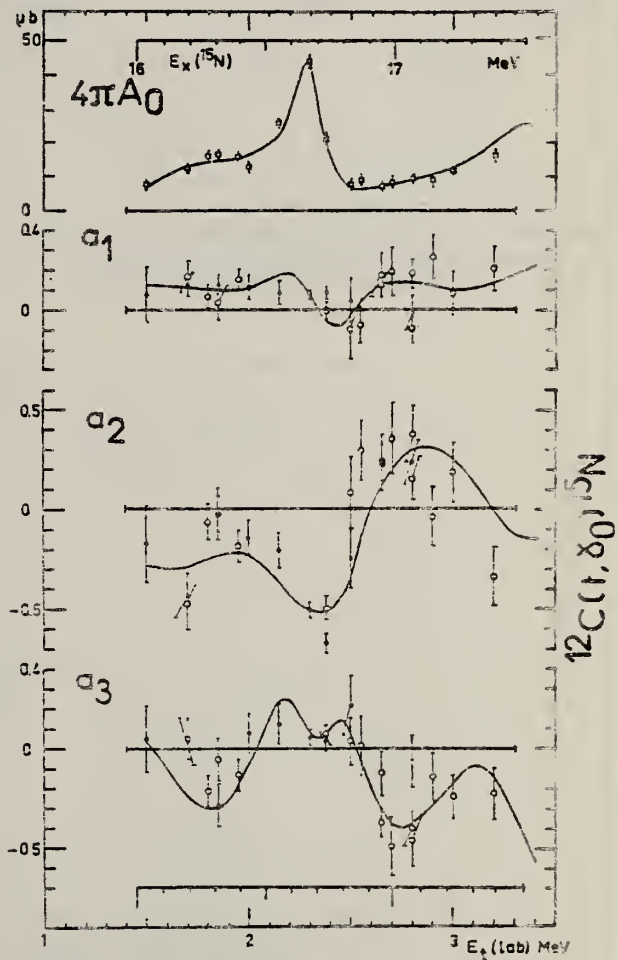

Fig. 5. Total cross section and coefficients of the expansion $d\sigma/d\Omega = A_0[1 + \sum_{n=1}^{3} a_n P_n(\cos\theta)]$ for the $^{12}C(t, \gamma_0)^{15}N$ reaction as a function of energy. The solid lines correspond to the *S*-matrix fit, involving the same parameters as those given in fig. 3 (see also table 1).

The giant resonance region of ^{15}N has been investigated by means of inelastic electron scattering in a momentum transfer range 0.36–1.25 fm^{-1}. The data show a splitting of the dipole resonance into two main peaks at 22 and 25.5 MeV, with some structure around 20 MeV and strength extending down to 13 MeV. The structure from 19 to 30 MeV correlates well with radiative capture and photodisintegration data and is in qualitative agreement with shell model predictions of the isospin splitting of the giant dipole resonance. The data show considerable spin-flip $E1$ strength, which agrees well with the predictions of the generalized Goldhaber-Teller model. Additional structure found in the energy region from ~ 14 to ~ 19 MeV has been analyzed as a $C2$-$C1$ superposition. The $C2$ strength in the 14–18.5 MeV region exhausts up to 22% of the isoscalar energy-weighted sum rule (Helm model, $J = 3/2$ assumed). The amount of $C2$ strength in the region from 18.5 to 30 MeV is negligible.

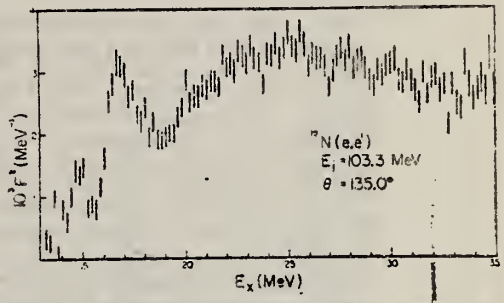

FIG. 3. Differential form factor at 135°. Other backward angle data were obtained at 141° and also show no evidence for strong transverse peaks.

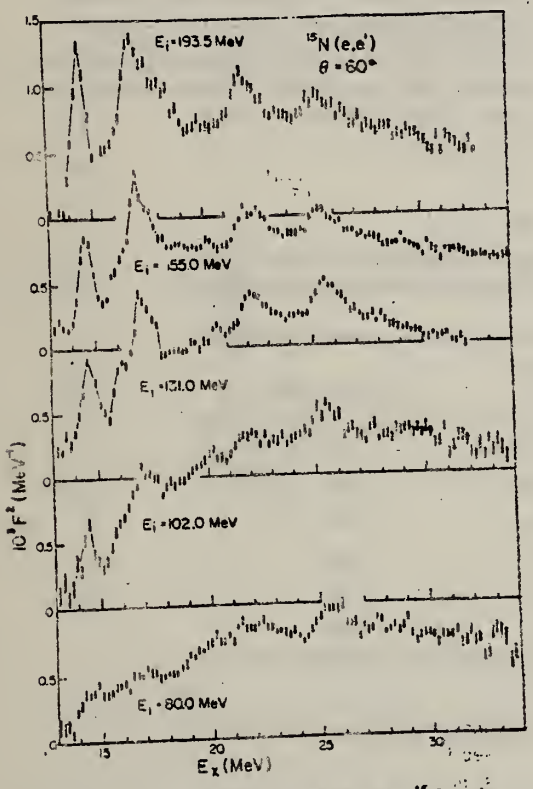

FIG. 2. Electron scattering spectra from ^{15}N in the giant resonance region, presented as differential form factors. All the data taken at 60° are presented here to show qualitatively the evolution of the structure in the GR with increasing momentum transfer.

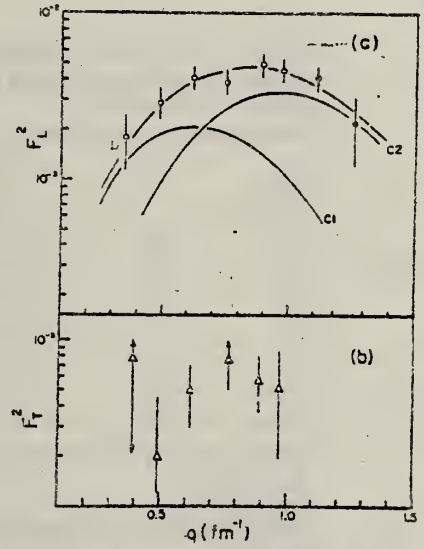

FIG. 4. Integrated longitudinal (a) and transverse (b) form factors for Region I (14–18.5 MeV) as a function of momentum transfer. The solid lines show the average fit and the Helm model $C1$-$C2$ components that yielded the radiative widths quoted in the text. The two points at higher q (dark circles) were obtained from fixed angle spectra by assuming a transverse component extrapolated from Fig. (b). They were not used in the $C1$-$C2$ analysis. The transverse form factor (b) is assigned to the spin-flip $E1$ transitions and as such is considered part of the GDR form factor.

over

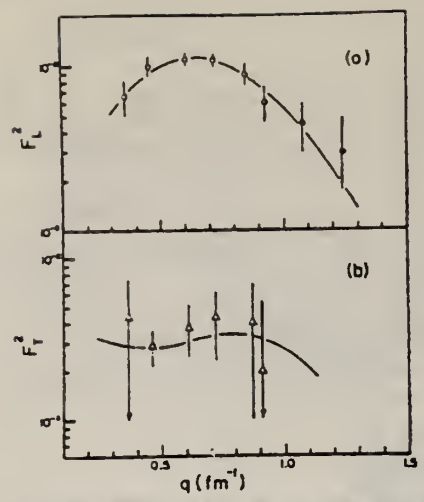

FIG. 5. Integrated form factors for region II plus region III (18.5–30 MeV) as a function of momentum transfer. (a) Longitudinal component. The solid line shows the Helm model fit for a $C1$–$C2$ multipolarity mixture. As discussed in the text, the $C2$ component is negligibly small. Only the data in open circles were used in the fitting. The two points at higher q (dark circles) were obtained from fixed angle spectra by assuming a transverse component extrapolated from (b). They are shown in the plot to demonstrate the consistency of the data at high q with the assumptions made in the analysis. (b) Transverse component. The solid line is the result of using Uberall's generalization of the Goldhaber-Teller model. This calculation is based on the elastic form factor, not a fit to the data points.

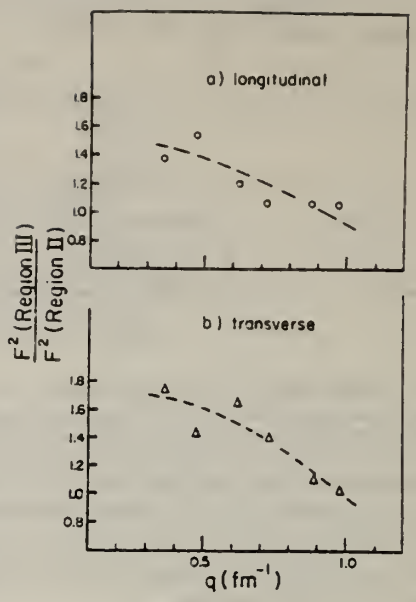

FIG. 6. Ratio of intergrated form factors for region III (24–30 MeV) to region II (18.5–24 MeV) as a function of momentum transfer. The dashed lines were drawn only to guide the eye. The errors were not drawn for the sake of clarity. Statistical errors are about the size of the points, but relative errors due to background subtraction and to longitudinal-transverse decomposition procedure amount typically to 20–25%.

TABLE I. Ground state $C2$ radiative widths, and fractions of the energy-weighted sum rule (isoscalar) from this and previous (e,e') work. The $J^\pi = \frac{1}{2}^-$ values in parentheses were assigned arbitrarily to evaluate Γ_{γ_0}.

J-PI FOR 4 LEVELS

Abstract: The reaction $^{11}B(\alpha, \gamma_0)^{15}N$ is studied for $6 \leqq E_\alpha \leqq 11.5$ MeV ($15.5 \leqq E_x \leqq 19.5$ MeV). The excitation function measured at $\theta_{lab} = 90°$ displays four strongly excited resonances at $E_x = 16.35 \pm 0.02$, 16.73 ± 0.02, 17.67 ± 0.05, and 19.05 ± 0.05 MeV, and a probable one at $E_x = 17.15 \pm 0.05$ MeV. These data and 14 angular distributions ($0 \leqq \theta_{lab} \leqq 135°$ for $16 \leqq E_x \leqq 18$ MeV) have been fitted with the *S*-matrix "many-levels" formalism. We propose J^π assignments for the first four resonances. The cross section is about four times smaller than in $^{12}C(t, \gamma_0)^{15}N$. We will discuss possible correlations with resonances observed in other reactions leading to ^{15}N.

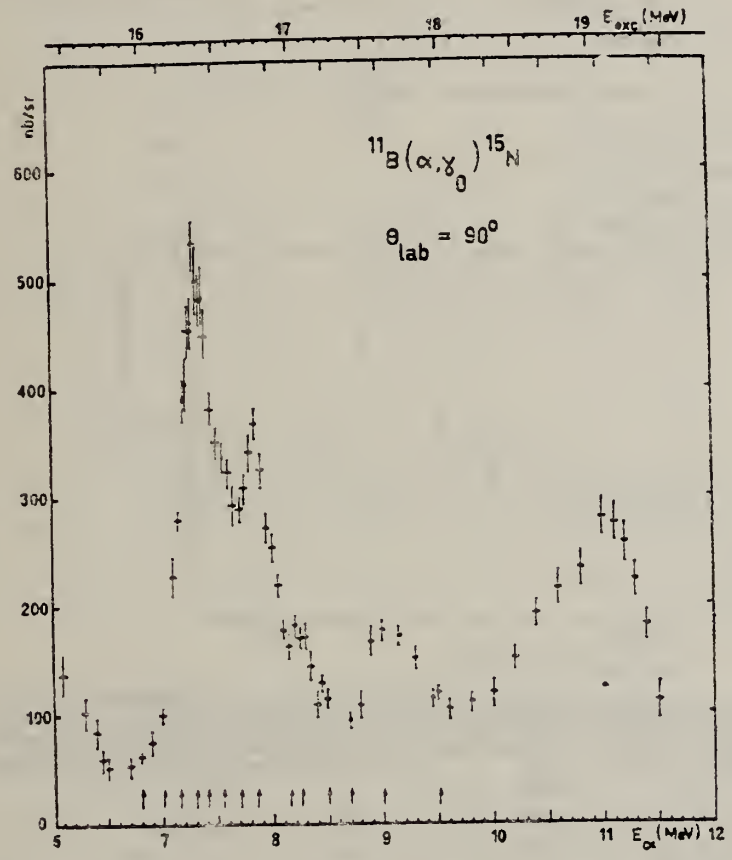

Fig. 2. Differential cross section of $^{11}B(\alpha, \gamma_0)^{15}N$ as a function of ^4He energy. Vertical bars represent only statistical errors and horizontal bars represent energy spread. Fourteen arrows locate energies at which angular distributions have been measured.

The 95° differential cross section of the $^{13}C(d,\gamma_0)^{15}N$ reaction has been measured at deuteron energies from 1.1 to 4.2 MeV. The γ rays have been detected by a 25.4 cm long by 25.4 cm diameter NaI(Tl) crystal spectrometer. The yield curve reveals a single resonance structure at E_d = 1.74 ± 0.04 MeV (E_{exc} = 17.7 MeV).

La section efficace différentielle à 95° de la réaction $^{13}C(d,\gamma_0)^{15}N$ a été mesurée pour des énergies des deuterons allant de 1.1 à 4.2 MeV. Les rayons gamma ont été détectés par un crystal de NaI(Tl). La courbe d'excitation montre une résonance à E_d = 1.74 ± 0.04 MeV (E_{exc} = 17.7 MeV).

Can. J. Phys., 56, 3 (1978)

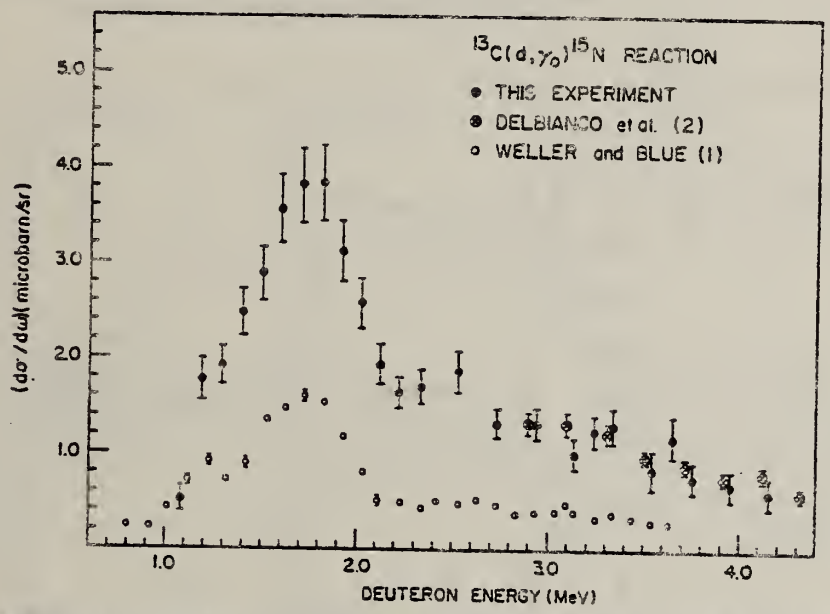

FIG. 1. Differential cross section of the $^{13}C(d,\gamma_0)^{15}N$ reaction as a function of deuteron energy at θ_L = 90°: ●, the results of this experiment; ○, the data of Weller and Blue (1); ⊗, the results of Del Bianco *et al.* (2). The error bars of Weller and Blue represent the statistical errors, whereas the errors of the other two experiments contain also the uncertainties resulting from unfolding the γ-ray spectra.

POLARIZED PROTONS

Measurements of cross sections and analyzing powers are examined for polarized proton capture on ^{14}C, ^{28}Si, ^{54}Fe, ^{56}Fe, ^{58}Fe, ^{59}Co, and ^{88}Sr at energies which cover the giant dipole resonance region. These data are used to extract the relative amplitudes and phases of the contributing $E1$ T-matrix elements. A typical result exhibits two solutions. Calculations using the direct (or a direct-semidirect) capture model appear to provide a means for choosing the physical solution.

[NUCLEAR REACTIONS: $^{14}C(\vec{p},\gamma_0)$, $^{30}Si(\vec{p},\gamma_0)$, $^{54}Fe(\vec{p},\gamma_0)$, $^{56}Fe(\vec{p},\gamma_0)$, $^{58}Fe(\vec{p},\gamma_0)$, $^{59}Co(\vec{p},\gamma_0)$, $^{88}Sr(\vec{p},\gamma_0)$; measured $\sigma(\theta)$ and $A(\theta)$ over energy region of the giant dipole resonance. Deduced T-matrix amplitudes and phases. Compare results to direct-semidirect model calculations.]

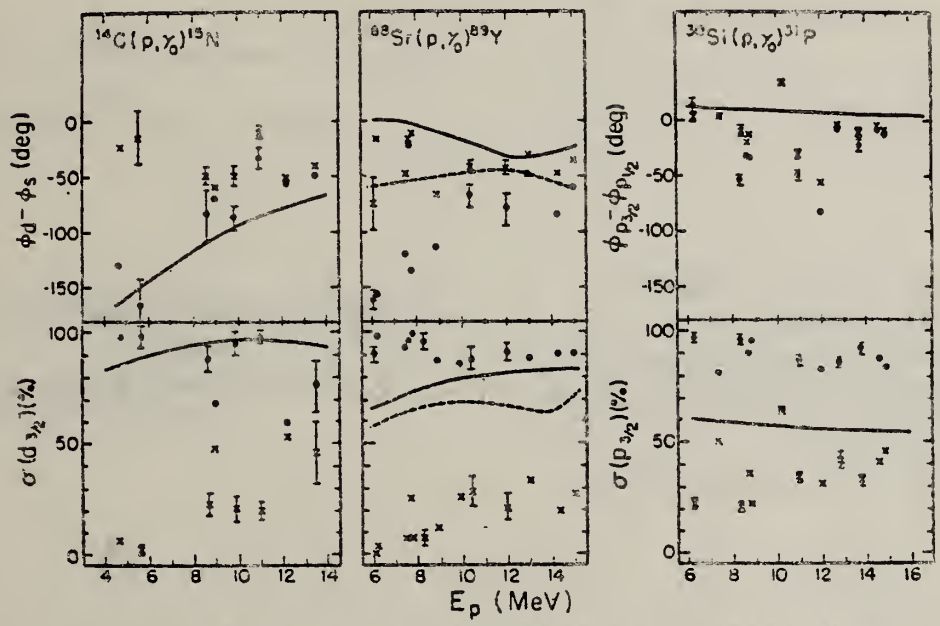

FIG. 1. The two solutions (dots and x's) resulting from a pure $E1$ analysis of the data are shown along with the results of the calculation for target nuclei of ^{14}C, ^{88}Sr, and ^{30}Si. The remaining cross section in the case of ^{14}C and ^{88}Sr is due to the $s_{1/2}$ matrix element. In the case of ^{30}Si it arises from the $p_{1/2}$ matrix element. The error bars represent typical statistical errors associated with the data points. The amplitudes are presented in terms of the percentage of the total cross section for which they are responsible. The curves represent DSD calculations as described in the text. The dashed curves in the case of ^{88}Sr were obtained using the optical model parameters of Ref. 16 while the solid lines were obtained from the parameters of Ref. 18.

The cross sections of $^{13}N(\gamma,d_0)^{13}C$ and $^{13}C(d,\gamma_0)^{15}N$ have been measured. A resonance was observed at $E_x \simeq 21.9$ MeV in the (γ,d_0) channel. Vector polarized deuterons were used to measure the angular distribution of gamma rays at this resonance and the results were analyzed assuming the two $S = 1/2$ $E1$ transition matrix elements are dominant.

The differential cross section for the reaction $^{15}N(\gamma,t_0)$ at $\theta_{lab} = 90°$ has been obtained for excitation energies between 20 and 25 MeV by the measurement of a triton energy spectrum from the reaction $^{15}N(e,t_0)e'^{12}C$. A virtual photon analysis was used to extract the photodisintegration cross section from the electrodisintegration data. Comparison of this cross section to the cross section at lower excitation energies shows that the $^{15}N(\gamma,t_0)$ strength is concentrated in the region between 16 and 21 MeV. Comparison of the (γ,t_0) cross section with those of other photodisintegration channels suggests an isospin separation energy of 6 MeV.

VIRTUAL PHOTON ANAL.

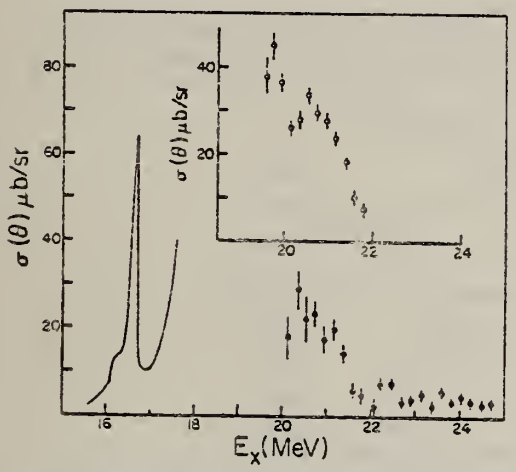

FIG. 2. The 90° cross section for the reaction $^{15}N(\gamma,t_0)^{12}C$. The solid curve is obtained from ref. 11 using detailed balance. The ground state cross section is given by the closed circles. The inset shows the non-ground state cross section in which transitions to the first two excited states in ^{12}C are kinematically allowed.

Abstract: The temperature dependence of the resonance scattering cross section σ_s of the 6.324 MeV photons from ^{15}N in the form of BN and NH_4Cl was measured in the range 78K–640K. Using these data the effective temperatures T_e of the *N-atom* in the two compounds as a function of the temperature T was deduced. At T = 293K we obtained $T_e = 561 \pm 28$K, and 521 ± 57K for BN and NH_4Cl respectively. The values of T_e and the variation versus T were reproduced theoretically by considering the Doppler broadening of the nuclear level, caused by the motion of the N-atom, and described by the frequency distribution function of the lattice in the two compounds. The effect of the values of T_e on the determination of the radiative width of nuclear levels is discussed.

FUNCT. OF TEMP., 6.324

E NUCLEAR REACTION $^{15}N(\gamma, \gamma)$, E = 6.324 MeV; measured temperature dependence of σ. Deduced effective temperatures. Natural BN, enriched NH_4Cl targets.

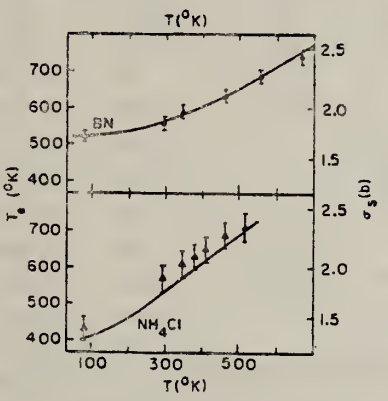

Fig. 3. Absolute scattering cross sections σ_s of the 6.324 MeV photons from ^{15}N in the form of BN and NH_4Cl. The scale of T_e is also given. The solid lines represent theoretical values of T_e (and hence of σ_s) obtained using the function $q(\nu)$ given in figs. 1 and 2 respectively.

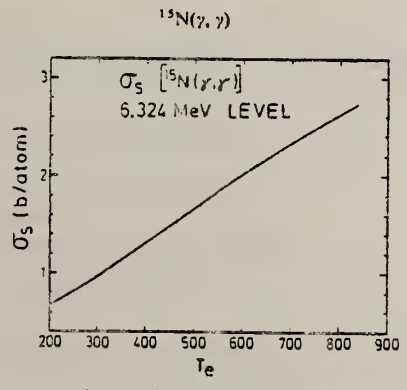

Fig. 4. Calculated scattering cross section σ_s of the 6.324 MeV photons from ^{15}N as a function of T_e as obtained using eq. (2) with the parameters: δ = 29.5 eV, $\Gamma = \Gamma_0$ = 2.9 eV, Δ_i = 9.6 eV, taken from ref. [7]).

The ground-state radiative widths of nine levels below 10.2 MeV in ^{15}N were measured using resonance fluorescence. The results are compared with various theoretical predictions and are found to best agree with very recent unpublished calculations in which the full $1\hbar\omega$ configurational basis is included in constructing the wave functions of the ^{15}N levels.

Photoneutron cross sections involving the emission of one and two neutrons from ^{15}N have been measured over the excitation energy interval from threshold (10.8 MeV) to 38 MeV using monoenergetic photons from the annihilation in flight of fast positrons. A very broad giant dipole resonance extending from about 16 to 30 MeV was observed, with a maximum (γ,n_{tot}) cross section of about 11 mb at 23.5 MeV. The magnitude of the measured average photoneutron energies shows that most of the strength below 15 MeV decays to the ground state of ^{14}N, whereas most of the strength in the giant resonance decays to excited states. Comparison with particle-capture cross-section data indicates that multiparticle-multihole interference effects probably account for some of the pronounced intermediate structure observed above 16 MeV in the (γ,n) cross section. Comparison with a recent shell-model calculation favors the use of a Tabakin potential over a δ-function force with a Soper exchange mixture, in marked contrast with recent corresponding results for ^{13}C and ^{17}O. Features of recently measured photoreaction cross sections for the ^{12}C, ^{13}C, ^{14}N, ^{15}N, ^{16}O, ^{17}O, and ^{18}O nuclei are compared as well.

[NUCLEAR REACTIONS $^{15}N(\gamma,n)$, E_γ=10.8–38.0 MeV; measured 4π neutron yield for monoenergetic photons; $(E_\gamma,1n)$, $(E_\gamma,2n)$, integrated cross sections; comparisons of results with other reaction channels and with cross sections for neighboring nuclei; comparison with shell-model theory.]

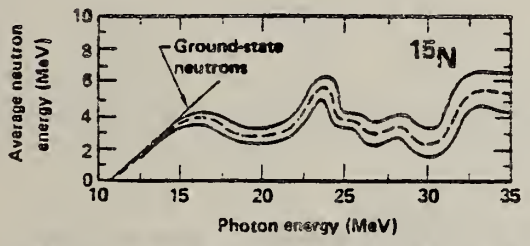

FIG. 2. The average energy of the emitted photoneutrons is plotted as a function of excitation energy in ^{15}N. These average energies were determined from the ring ratios. The light solid lines represent the statistical uncertainty associated with the ring-ratio measurement. The dark line represents the neutron energies expected if all transitions were to the ground state of ^{14}N.

TABLE II. Integrated cross sections for ^{15}N.[a]

Reaction	$\sigma_{int}=\int\sigma dE_\gamma$ (MeV mb)	$\sigma_{-1}=\int\sigma E_\gamma^{-1}dE_\gamma$ (mb)	$\sigma_{-2}=\int\sigma E_\gamma^{-2}dE_\gamma$ (mb MeV^{-1})
$(\gamma,1n)$	98.4	4.38	0.208
$(\gamma,2n)$	7.6	0.26	0.009
(γ,n_{tot})	105.9	4.63	0.216

[a]From threshold to 38.0 MeV.

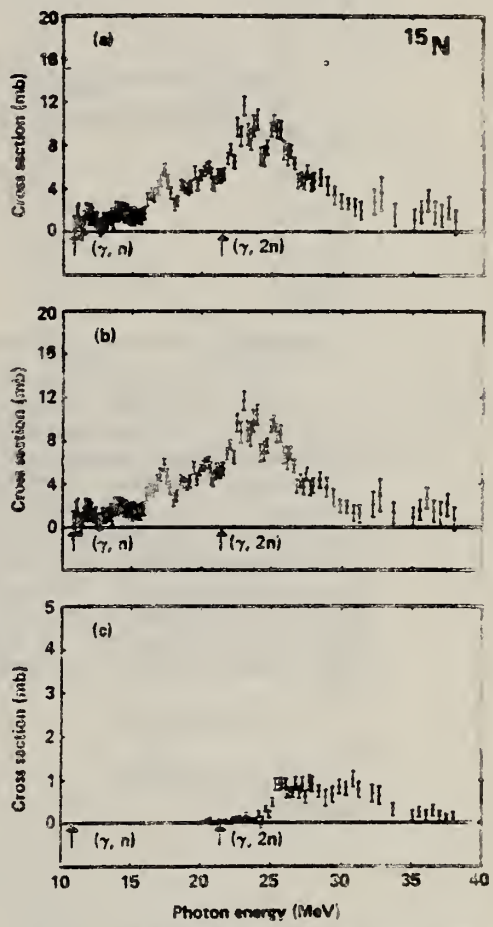

FIG. 1. Photoneutron cross sections for ^{15}N. Part (a) shows the total photoneutron cross section

$$\sigma(\gamma,n_{tot})=\sigma[(\gamma,n)+(\gamma,pn)+(\gamma,\alpha n)+(\gamma,2n)];$$

part (b) shows the single photoneutron cross section

$$\sigma(\gamma,1n)=\sigma[(\gamma,n)+(\gamma,pn)+(\gamma,\alpha n)];$$

part (c) shows $\sigma(\gamma,2n)$. The plotted error flags indicate the statistical uncertainties only. The threshold energies for the (γ,n) and $(\gamma,2n)$ reactions are indicated by arrows. Other photoreaction threshold energies are given in Table I.

(OVER)

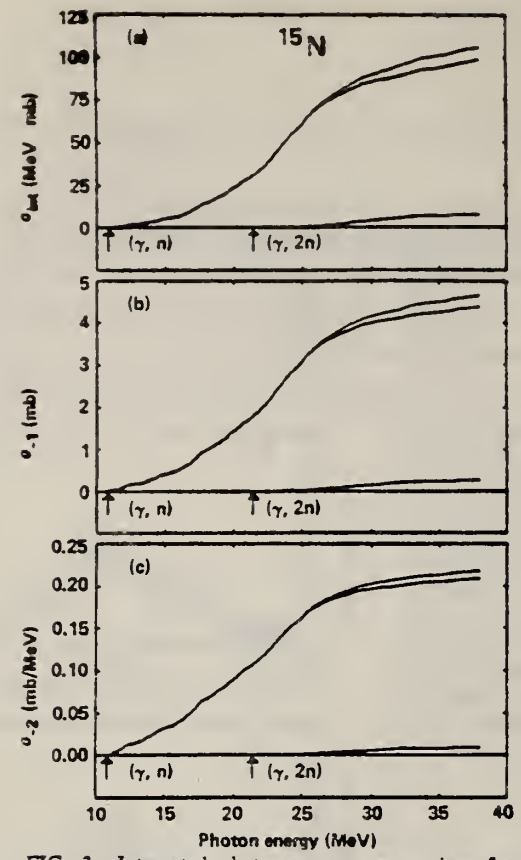

FIG. 3. Integrated photoneutron cross sections for ^{15}N are plotted as functions of the upper limit of integration. Part (a) shows the integrated cross sections $\sigma_{int} = \int \sigma(E_\gamma) dE_\gamma$ for the $(\gamma,2n)$ reaction (bottom curve), the $(\gamma,1n)$ reaction (middle curve), and their sum, the (γ,n_{tot}) reaction (top curve). Integrated cross sections over any desired limits can be obtained from these curves by subtraction. Parts (b) and (c) show the energy-weighted moments of the integrated cross sections

$$\sigma_{-1} = \int \sigma(E_\gamma) E_\gamma^{-1} dE_\gamma$$

and

$$\sigma_{-2} = \int \sigma(E_\gamma) E_\gamma^{-2} dE_\gamma ,$$

respectively.

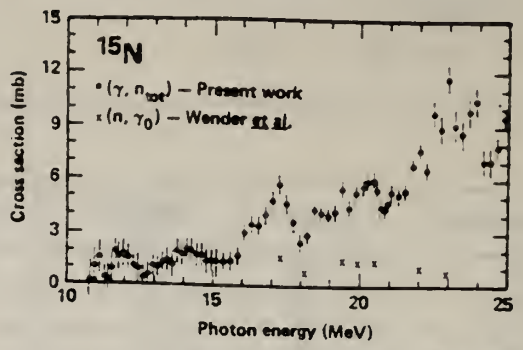

FIG. 4. The present total photoneutron cross section of Fig. 1(a) is shown with expanded scales and compared with the recent ground-state data of Wender *et al.*[12] This shows that $\sigma(\gamma,n_0)$ constitutes only a small part of $\sigma(\gamma,n_{tot})$ above ~17 MeV. [Only those points from Ref. 12 for which angular distributions were measured are plotted here; their 90° excitation function shows more detailed structure (see Table III).]

The photon spectra from the reaction $^{16}O(\pi^-,\gamma)^{16}N$ and $^{18}O(\pi^-,\gamma)^{18}N$ were measured with a high-resolution pair spectrometer. Transitions to 2^- states having $T = 1$ in ^{16}N and $T = 2$ in ^{18}N appear to dominate. Excitation of 1^- states in the giant dipole resonance region, which are the analogs of the levels excited in photoabsorption and inelastic electron scattering on ^{16}O and ^{18}O, respectively, were also observed. The total and partial branching ratios for bound states and giant-resonance transitions are compared with shell-model predictions. Higher admixtures to the predominantly 1p-1h wave functions are found to be necessary to obtain agreement with the measured branching ratios. A new treatment of the continuum and resonance excitation, based on calculations of Ohtsubo *et al.*, is compared with the data.

*MEV/C, PI=PI-

The photon spectra from the reaction $^{16}O(\pi^-,\gamma)^{16}N$ and $^{18}O(\pi^-,\gamma)^{18}N$ were measured with a high-resolution pair spectrometer. Transitions to 2^- states having $T = 1$ in ^{16}N and $T = 2$ in ^{18}N appear to dominate. Excitation of 1^- states in the giant dipole resonance region, which are the analogs of the levels excited in photoabsorption and inelastic electron scattering on ^{16}O and ^{18}O, respectively, were also observed. The total and partial branching ratios for bound states and giant-resonance transitions are compared with shell-model predictions. Higher admixtures to the predominantly 1p-1h wave functions are found to be necessary to obtain agreement with the measured branching ratios. A new treatment of the continuum and resonance excitation, based on calculations of Ohtsubo *et al.*, is compared with the data.

[NUCLEAR REACTIONS Radiative pion capture; measured photon spectra for $^{16}O(\pi^-,\gamma)^{16}N$ and $^{18}O(\pi^-,\gamma)^{18}N$; deduced transitions and transition strength with $J^\pi = 1^-$, 2^- and $T=1$ and $T=2$ respectively; comparison with shell-model calculations.]

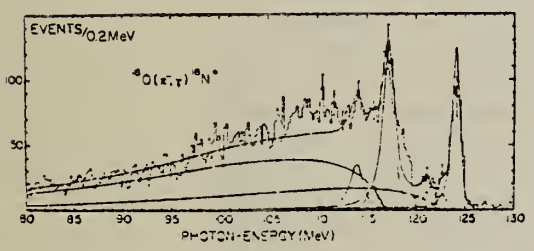

FIG. 4. Photon spectrum of π^- capture in ^{18}O. Solid curve is derived by folding the contributions of the pole models, four Breit-Wigner resonances and two lines with the response function of the apparatus.

TABLE III. Experimental parameters for radiative pion capture $^{18}O(\pi^-,\gamma)^{18}N$; all energies in MeV. The first column gives the photon energy, the second and the third columns give the excitation energies in ^{18}N and for the analog levels in ^{18}O. The third and the fourth columns list the transitions seen in other experiments, while the last column gives the radiative capture branching ratios.

OXYGEN
Z=8

Oxygen eluded early investigators although it is the most abundant of the elements. A reference to oxygen (*ȳne*), is found in a Chinese book written by Mao-Kho'a in the eighth century A.D. The topics of combustion and the release of oxygen by heating saltpeter is discussed. The authenticity of the manuscript, however, is in question.

O
A=15

The first European to recognize that air contains at least two constituents was Leonardo da Vinci (1452-1519) who noticed that air is consumed, but not completely, in respiration and combustion. The discovery of oxygen is generally attributed to C. W. Scheele who, in 1772, obtained it by heating metal oxides. It was discovered independently in 1774 by Joseph Priestly (1733-1804) in England. Priestly's results were published before those of Scheele because Scheele's publisher had been inexcusably negligent. Antoine-Laurent Lavoisier (1743-1774) was the first to recognize oxygen as a chemical element. He called it oxygène from the Greek (*oxýs+gen*) "for acid maker."

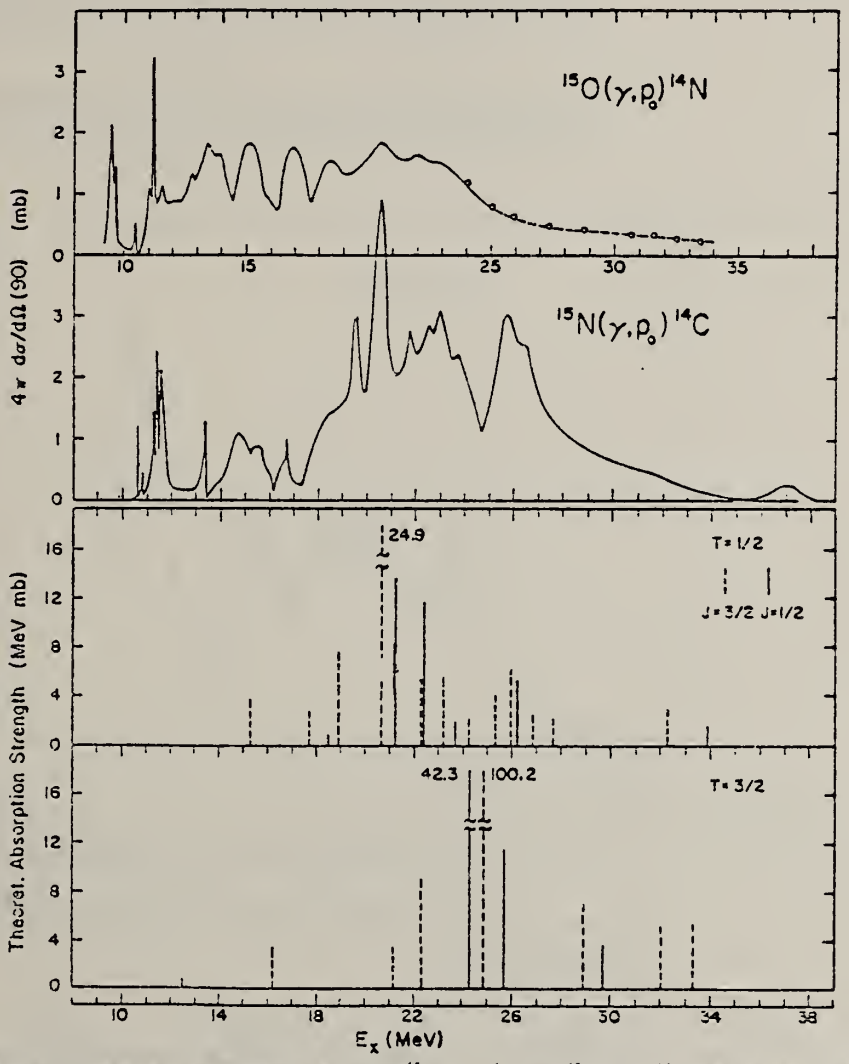

FIG. 6. Comparison of the experimental results from the $^{15}O(\gamma,p_0)^{14}N$ and $^{15}N(\gamma,p_0)^{14}C$ reactions and the theoretical predictions from the 2h-1p model (case B). The data below 25 MeV in the top curve are from Ref. 4, the data points at higher energies stem from the present work. The theoretical plots give the $T=\frac{1}{2}$ and $\frac{3}{2}$ components of the computed integrated photoabsorption cross section proportional to $E_\gamma[B(E1\uparrow)]$. Dashed and solid lines indicate $J=\frac{3}{2}$ and $\frac{1}{2}$, respectively. The top experimental curve should relate to the $T=\frac{1}{2}$ part while the $^{15}N(\gamma,p_0)^{14}C$ curve contains both T components.

Comment on "E1 excitations in A = 15 nuclei"

Phys. Rev. C13, 2062 (1976)

It is shown that the recent $J^\pi = \frac{3}{2}^+$ assignment for the level observed in the $^{14}C(p,\gamma_0)^{15}N$ reaction at E_p 6.925 MeV is not unique.

The 90° differential cross section of the $^{12}C(^3He,\gamma_0)^{15}O$ reaction has been measured at ^{3}He-particle energies from 5.24 to 13.95 MeV in steps varying from 100 to 300 keV. The γ rays have been detected by a 23 cm long × 23 cm diameter NaI(Tl) crystal spectrometer enclosed in an anticoincidence shield. The yield curve shows a resonant structure at the energies E_{exc} = 17.04 ± 0.06, 18.65 ± 0.06, 19.55 ± 0.08, 20.40 ± 0.07, and 21.61 ± 0.07 MeV.

La section efficace différentielle de la réaction $^{12}C(^3He,\gamma_0)^{15}O$ a été mesurée pour des énergies des particules-^{3}He allant de 5.24 à 13.95 MeV. Les rayons gamma ont été détectés par un crystal de NaI(Tl) entouré d'un scintillateur plastique en anticoincidence. La courbe d'excitation montre de la structure aux énergies E_{exc} = 17.04 ± 0.06, 18.65 ± 0.06, 19.55 ± 0.08, 20.40 ± 0.07 et 21.61 ± 0.07 MeV.

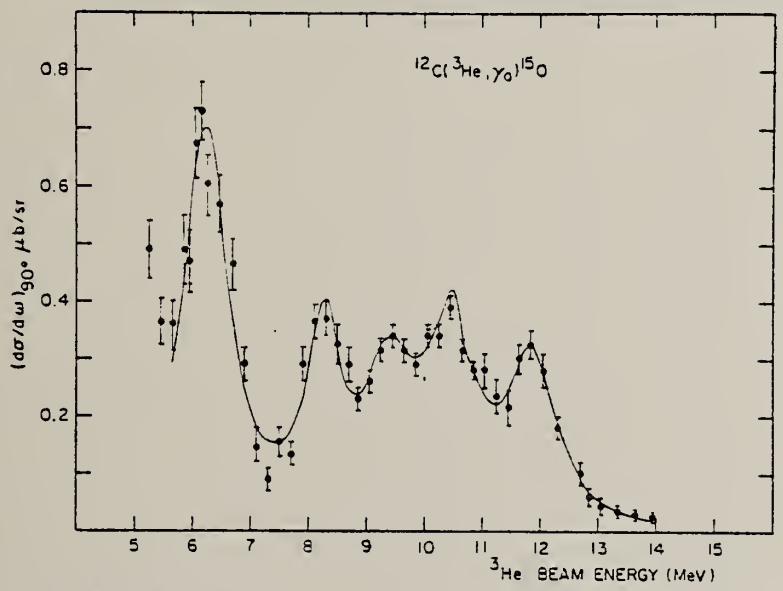

FIG. 1. Experimental differential cross section at $\theta_L = 90°$ of $^{12}C(^3He,\gamma_0)^{15}O$ reaction. The solid symbols are the experimental points; the solid line represents a least-squares-fit to the data with five Breit–Wigner lines. Only the statistical errors are shown in the figure. The ^{3}He beam energies are the average energies in the carbon target.

The direct detection of neutrons from (γ,n) reactions induced by betatron bremsstrahlung has been applied to cross-section determinations using gaseous targets at approximately 100 atmospheres pressure. Results from oxygen are consistent with other determinations. The remaining elements represent new results and show the familiar giant dipole resonance for the photoneutron process. Parameters of the resonances are determined and related to the systematic behavior previously reported for other elements.

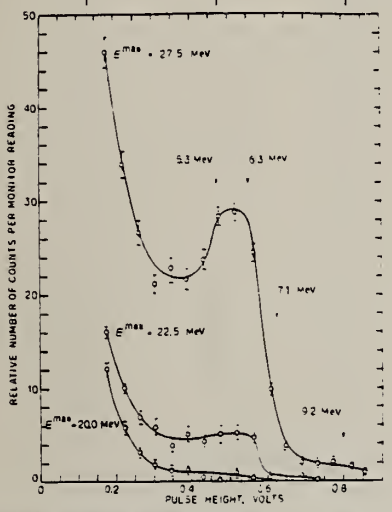

Fig. 3. Pulse height distributions measured when irradiating a 2" water target with 20.0, 22.6, and 27.5 MeV bremsstrahlung spectra. The background distributions are subtracted.

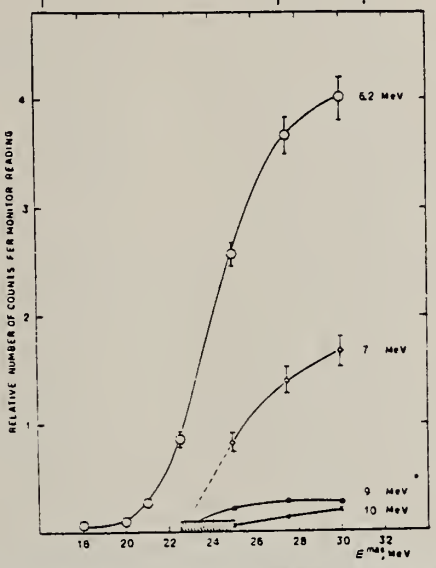

Fig. 9. The yield curves observed for the different daughter photon energies. The shaded area shows the energy interval in which the 7, 9 and 10 MeV photons are predominantly produced. When the statistical errors are not shown, they are within the symbols.

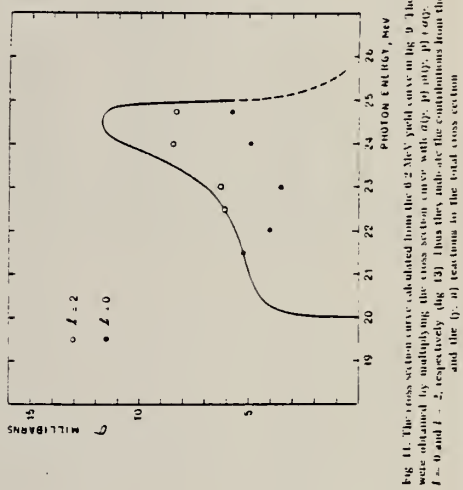

Fig. 11. The cross section curve calculated from the 6.2 MeV yield curve in fig. 9. The points were obtained by multiplying the cross section curve with $d(p,p_0)/d(p,p_0+p_1)$ for $I = 0$ and $I = 2$, respectively (fig. 13). Thus they indicate the contributions from the (γ,p_0) and the (γ,n_0) reactions to the total cross section.

TABLE 2

The integrated cross section (MeV·mb), together with the relative numbers, for the $O^{16}(\gamma,p)N^{15}$ and $O^{16}(\gamma,n)O^{15}$ reactions. The cross section for ground state transitions in the (γ,p) reactions was taken from Stephens *et al.*[3]. The same cross section was also used for ground state transitions in the (γ,n) reaction. In splitting the cross section for 6.2 MeV and 7 MeV photons into cross section for the two different reactions the photonucleons were assumed to have $I = 0$ and $I = 1$, respectively.

Excitation energy in O^{16} (MeV)	Reaction	Photodisintegration to ground state		excited state (MeV) 6.2		7		9		10		Total σ_{int}
		(MeV·mb)	%	(MeV·mb)	%	(MeV·mb)	%	(MeV·mb)	%	(MeV·mb)	%	(MeV·mb)

$N^{15}(p,\gamma)$	4.0-9.0					Ground state transitions measured at 90°.

Fig. 1. Excitation function for $^{15}N(p,\gamma)^{16}O$. The points are the experimental results for this reaction. The histogram is the excitation function for $^{15}N(p,\gamma)^{16}O$ considered by detailed balance from the excitation function for $^{16}O(\gamma,p)^{15}N$. The dotted lines indicate the position of resonances that might be expected in $^{15}N(p,\gamma)^{16}O$ from the fine structure in $^{16}O(\gamma,p)^{15}N$.

Reaction	E or ΔE	E_o	Γ	$\int \sigma dE$	Jπ	Notes
$N^{15}(p,\gamma_0)O^{16}$	200-627 kev	338 kev				This resonance observed for 12 MeV γ's corresponding to the 12.43 MeV level in O^{16}.

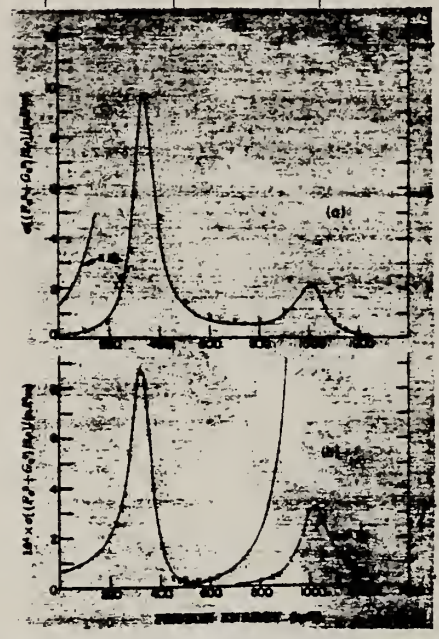

Fig. 6.

(a). The $N^{15}(p,\alpha_0)$ integrated cross section, with the calculated energy dependence included. The full curve represents the calculated cross section for constructive interference between two 1^- resonances at 338 kev and 1010 kev. The points are either experimental, (open circles) or are selected at intervals from the smooth curve of fig. 1. The ordinates at the resonance have been suppressed. The ordinate at high energies is directly proportional to the correction being allowed by multiplication of this ordinate by 4.57×10⁻³ to give S in kev-barns.

(b). The $N^{15}(p,\gamma_0)$ integrated cross section, with the calculated energy dependence included. The full curve represents the calculated cross section for constructive interference between two 1^- resonances at 338 kev and 1010 kev. The points are experimental, the ordinates at the 1010-kev resonance being obtained from the smooth curve of fig. 1, by multiplication by 0.142.

Ref 9: Hagedorn - Phys. Rev. 108, 735 (1957)

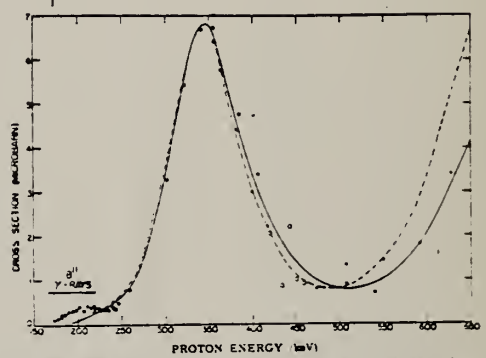

Fig. 4. The cross section for the $N^{15}(p,\gamma_0)O^{16}$ reaction, as a function of proton energy. The open circles are measurements that required correction for the simultaneous detection of both members of a cascade from the 429-keV resonance through the 6 and 7-MeV states in O^{16}. The dashed curve is the theoretical curve for destructive interference between two 1^- resonances at 338 kev and 1010 keV with the 1010-keV resonance having a peak cross section of 1000 μb. The full curve shows the improved agreement when the 1010-keV resonance peak cross section is reduced by the factor 1.42. Both theoretical curves are normalized to match the peak height of the 338-keV resonance. More weight should be attached to the points at 393 keV and 627 keV than to the scattered points between 425 keV and 560 keV.

TABLE 3

Single-level parameters for the 338 and 429 keV resonances

O^{16*} (MeV)	E_R (keV)	Γ_p (keV)	Γ_{α_0} (keV)	Γ_{α_1} (keV)	Γ_{γ_0} (eV)	$\Gamma_{\gamma\text{cascade}}$ (eV)

	215(80)				(1^-)	E1

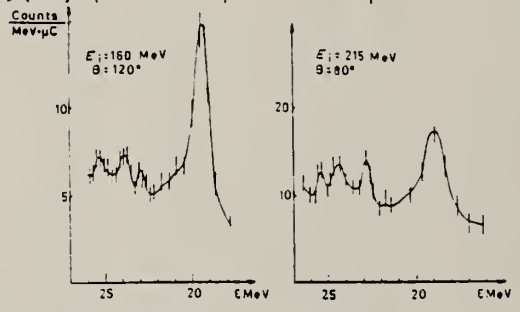

Fig. 5. Spectra of scattered electrons obtained with high resolution in the region of the giant resonance. The momentum transfer is the same, $q = 1.33$ fm^{-1}, but incident energy and scattering angle are varied. It is clear that the three peaks near $\varepsilon = 25$ MeV are independent of scattering angle, whilst the peak at 19.3 MeV shows a strong angular dependence.

Electric character established by performing experiment at constant momentum transfer and various scattering angles.

Details given on radiative tail calculations and corrections to data.

Data given for $\frac{d\sigma}{d\Omega}_{exp}$ and $F^2(q)$, the inelastic form factor (ratio of experimental cross section to Mott cross section)

TABLE 7

Comparison between the experimental values of the radiative transition probability calculated using the folded charge distribution model (F.C.D.) and the independent particle model (I.P.M.) with the theoretical value for the single particle model (S.P.M.)

Level	$B(E1)_{exp}$ F.C.D.	$B(E1)_{exp}$ I.P.M.	$B(E1)_{th}$ S.P.M.
22.6 MeV	9.7×10^{-27} cm^4	8.7×10^{-27} cm^4	8.6×10^{-27} cm^4
25.7 MeV	6.4×10^{-27} cm^4	5.8×10^{-27} cm^4	8.6×10^{-27} cm^4

144.4	135°	0.41±0.06	1.29	0.20±0.03	0.65	0.29±0.06	1.44	2.36±0.3	7.50	0.36±0.07	1.83
160.1	120°	0.48±0.07	0.85	0.23±0.03	0.41	0.24±0.05	1.23	1.99 0.30	3.5	0.31±0.06	1.57
218.5	80°	2.98±0.5	1.27	1.26±0.25	0.54	0.45±0.15	1.59	4.5 ±0.8	1.9	0.40±0.15	1.40

For electric transitions the form factors F_{in}^2 are obtained by dividing the experiment cross section by $\sigma_M = (Ze^2/2E)^2 \cos^2 \frac{1}{2}\theta / \sin^4 \frac{1}{2}\theta$. For magnetic transitions the form factors F_M^2 are obtained by dividing the experimental cross section by $\sigma_{point} = (Ze^2/2E)^2 (1+\sin^2 \frac{1}{2}\theta)/2 \sin^4 \frac{1}{2}\theta$.

EXCITATION LEVELS OF O^{16}

TABLE 3

The inelastic form factor of the peak at 13.2 MeV is compared with the form factors calculated by Willey from the wave functions of Gillet

Energy (MeV)	Angle	F_{in}^2(13.25 MeV) ($\times 10^3$)	F_x^2 (Willey) ($\times 10^3$)
101.6	60°	1.10±0.13	0.43
143.2	60	1.00±0.16	0.67
160.6	80°	2.92±0.27	
153.0	115°	2.90±0.38	3.92
144.4	135°	7.50±1.0	8.83
160.1	120°	3.5 ±0.55	5.01
218.5	80°	1.9 ±0.35	2.37

These calculated values correspond to the sum of transitions to $T = 1$ states with spins and parities 1^-, 2^- and 3^-. For the separate components see ref. [6]).

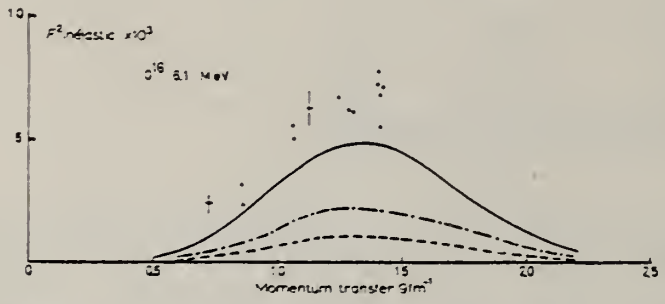

Fig. 1(a). The inelastic form factor of the 6.1 MeV peak taken from table 1. The full line is calculated for approximation II, the dot-dash line for approximation I and the dashed line for the I.P.M.

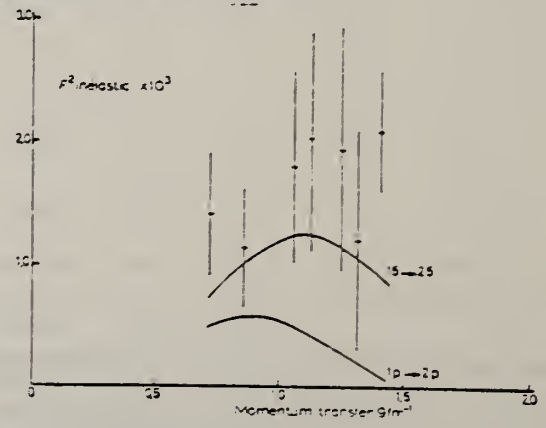

Fig. 1(b). The inelastic form factor which remains after subtraction of the full line curve of fig. 1(a) from the experimental points. For comparison the monopole form factor curves obtained as described in the text are also plotted.

REACTION	RESULT	EXCITATION ENERGY	SOURCE TYPE	SOURCE RANGE	DETECTOR TYPE	DETECTOR RANGE	ANGLE

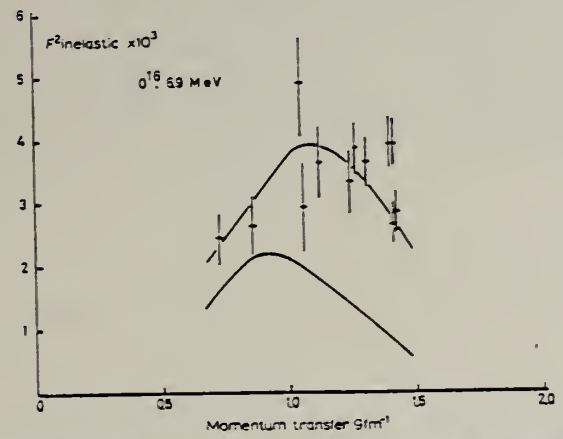

Fig. 2. The inelastic form factor of the 6.9 MeV peak. The upper curve represents the form factor $\langle 1s|j_3(qr)|1d\rangle^2$ and the lower curve the form factor $\langle 1p|j_3(qr)|1f\rangle^2$ each normalized to the radiative width as described in the text.

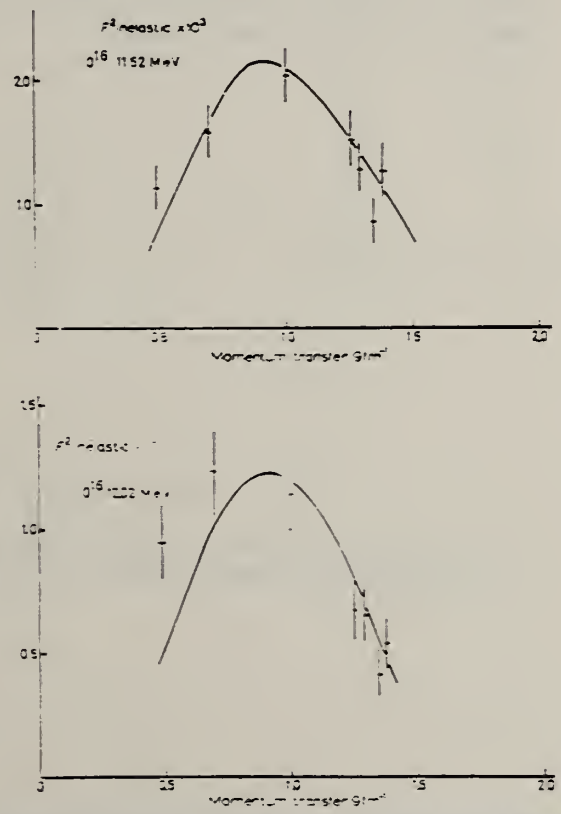

Fig. 3. The inelastic form factors of the 11.5 MeV and 12.0 MeV peaks. The fitted curve corresponds to the expression $F_{in}^2 = \langle p|j_3(qr)|1f\rangle^2$ normalized to give the radiative widths reported in the text.

REACTION	RESULT	EXCITATION ENERGY	SOURCE		DETECTOR		ANGLE
			TYPE	RANGE	TYPE	RANGE	

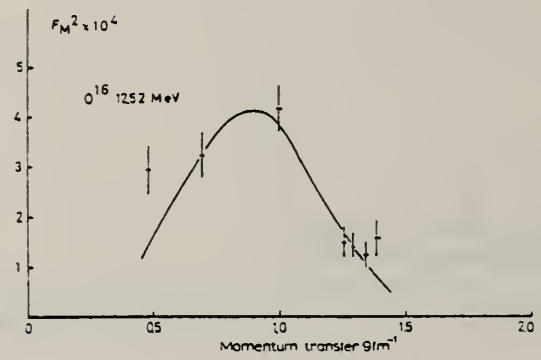

Fig. 4. The inelastic form factor of the 12.5 MeV peak. For this magnetic transition the form factor is obtained by dividing the experimental cross section by $\sigma_{point} = (Ze^2/2E)^2(1+\sin^2\frac{1}{2}\theta)/2\sin^4\frac{1}{2}\theta$. The full curve corresponds to the form factor discussed in the text.

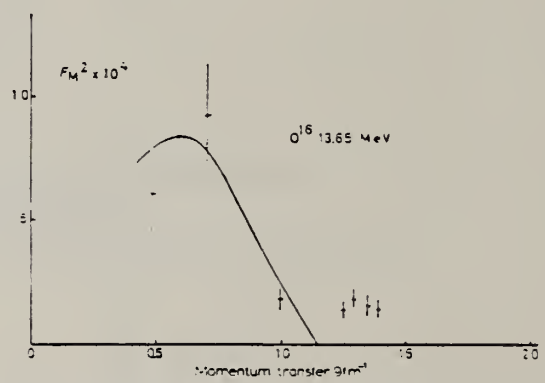

Fig. 5. The inelastic form factor of the 13.65 MeV peak considered as entirely transverse. The full line is the form factor calculated as described in the text. It has a zero value for $q = 1.35$ fm^{-1}.

INTERPRETATION

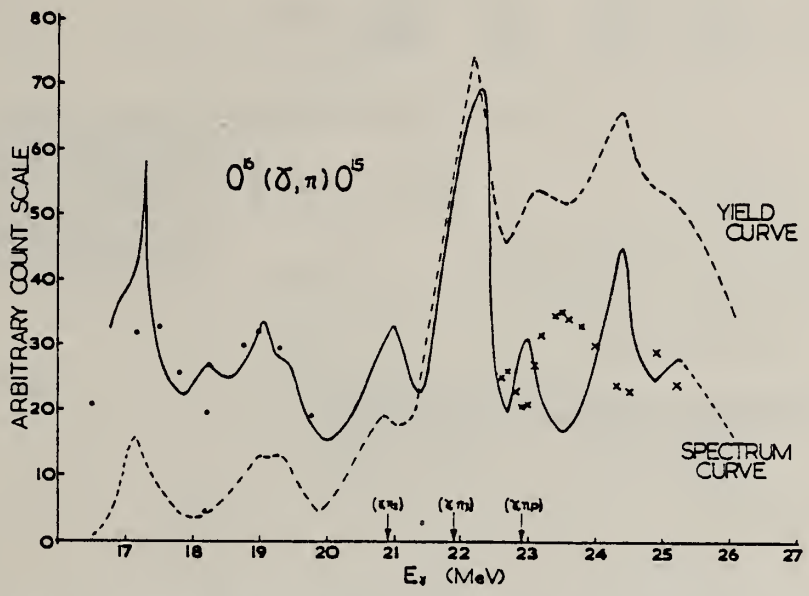

FIG. 1. Comparison of the neutron yield curve[4] of $O^{16}(\gamma,n)O^{15}$ with the neutron spectrum from bremsstrahlung irradiation.[1] The crosses show the difference between these two curves and indicate the yield of neutrons to excited states of O^{15}. The dots show the spectrum implied by the yield curve and the crosses, assuming neutron transitions only to the ground and 6.2-MeV states of O^{15}.

BRANCHING RATIØS

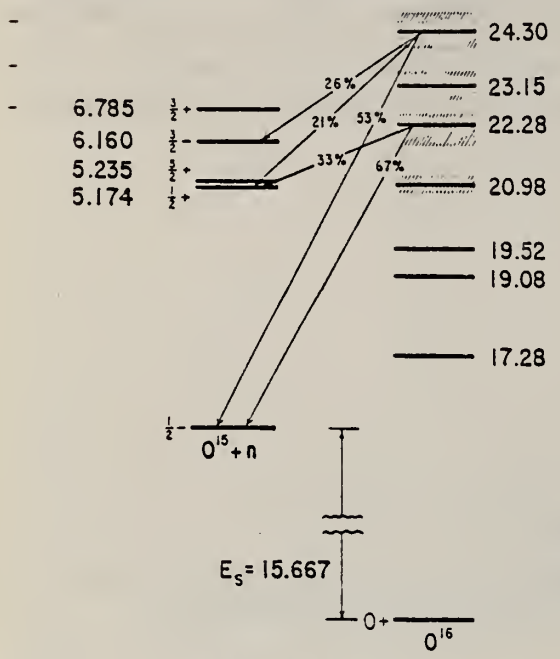

FIG. 1. Some energy levels of O^{16} and O^{15}. Only those levels of O^{16} which appear prominently in the photoneutron spectrum are shown. The energies are those measured in this experiment. All known levels of O^{15} up to the highest shown are included. The branching ratios for the neutron decays at 90° from the 22.2- and 24.3-MeV levels are those deduced from the measurements reported here. Ground-state decays only are observed for the other levels.

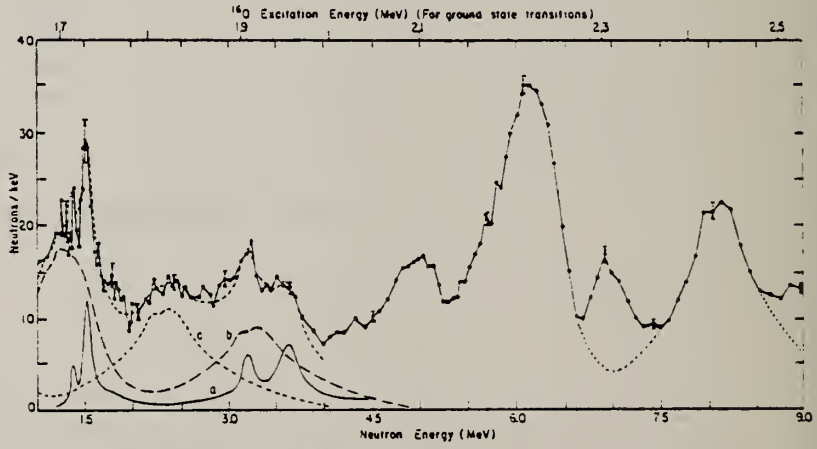

FIG. 2. Neutron spectrum from O^{16} photodisintegration by 35-MeV bremsstrahlung. The points connected by the solid lines, with typical error bars shown, are the experimental results corrected for the detector efficiency. From 1.0 to 1.2 MeV twelve channels of the time analyzer were averaged, from 1.2 to 4.9 MeV four channels, and above 4.9 MeV two channels. The upper dashed curve from 1.0 to 4.0 MeV is the composite fit to the data and is the sum of the lower three curves. (a) is derived from the cross-section curve of reference 14, (b) represents neutrons which leave O^{15} in the $\frac{1}{2}^-$ first excited state, and (c) represents neutrons which leave O^{15} in the $\frac{3}{2}^-$ third excited state. See the text for explanation of the dashed curve sections above 5 MeV. The scale at the top gives the excitation energy in O^{16} for the case of neutrons which leave O^{15} in its ground state. The ordinate is in arbitrary units, and represents the number of neutrons per unit energy interval.

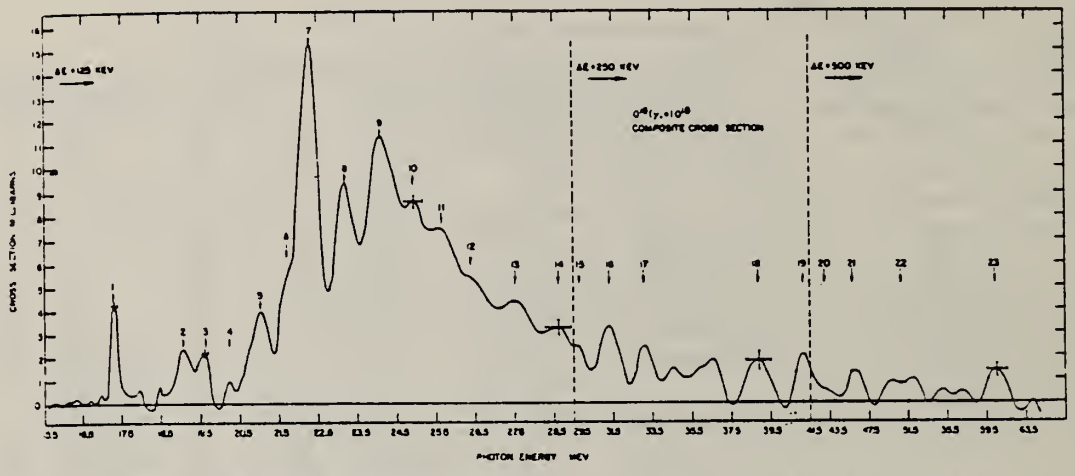

FIG. 3. The $O^{16}(\gamma,n)O^{15}$ cross section for energy to 65 MeV. This curve represents a fully converged least-structure solution for the yield function obtained using the average of six independent measurements. From 15.5 to 29.5 MeV data were taken in 125-keV intervals, from 29.5 to 41.5 MeV in 250-keV intervals, and above 41.5 MeV in 500-keV intervals. The vertical bars represent the standard deviation for the solution at representative energies. However, as adjacent cross-section points are strongly correlated, the interpretation of this bar as a random error is erroneous. The horizontal bar is the full width at half-maximum of the least-structure resolution function at representative energies. The numbered peaks occurred consistently in all cross sections derived from individual yield functions.

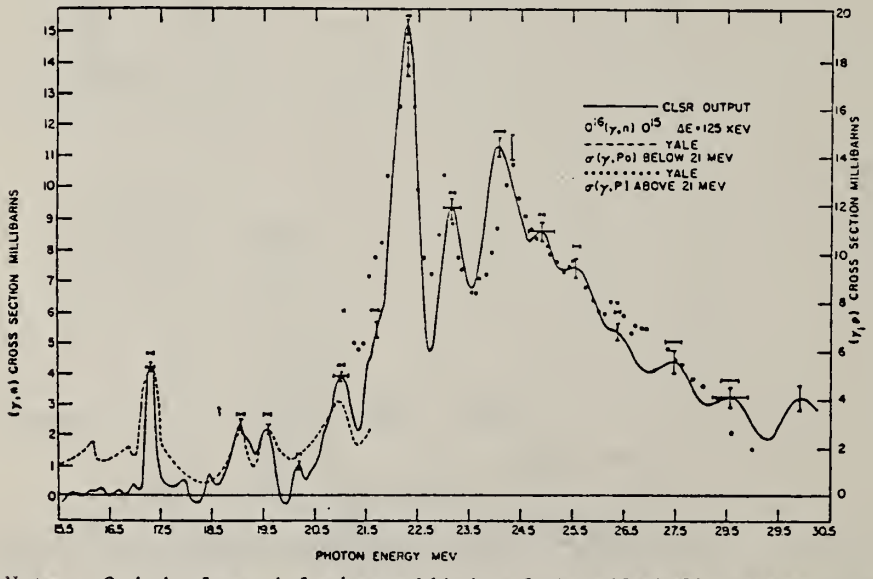

FIG. 6. A comparison between the (γ,p) and (γ,n) reaction in O^{16}. A recent measurement at Yale of the (γ,p) cross section obtained from the proton energy distribution is compared with results reported here. The scale on the left refers to the $O^{16}(\gamma,n)O^{15}$ cross section, while the scale on the right refers to the $O^{16}(\gamma,p)N^{16}$ cross section. The agreement between the cross sections for these differing processes is excellent.

Note: Original article has additional detailed figures and comparisons.

G-SPECTRUM

Decay Modes of O^{16} Giant Resonance States

J. E. E. Baglin and M. N. Thompson*

Electron Accelerator Laboratory, Yale University
New Haven, Connecticut USA

A study has been made of the spectrum of γ-rays produced in the decay of excited levels of O^{15} and N^{15} which result from the $O^{16}(\gamma,n)$ and $O^{16}(\gamma,p)$ processes. Examination to find which residual configurations are produced by specific regions of the giant resonance can indicate the nature of the parent excited states in O^{16}.

The figure shows a spectrum obtained from a water target with a 6 cc Ge(Li) detector placed at 135° to an incident bremsstrahlung beam of maximum energy 26.5 MeV. Most of the O^{16} giant resonance can thus contribute to this spectrum. The spectral peaks shown are double-escape peaks which rise over the corresponding compton and bremsstrahlung components of their line profiles.

The 30 keV resolution used is sufficient to show comparable population of all four positive parity states at 5.18 MeV ($1/2^+$) 5.24 MeV ($5/2^+$)[O^{15}] and 5.27 MeV ($5/2^+$), 5.30 MeV ($1/2^+$)[N^{15}], as well as the two $(p_{3/2})^{-1}$, $3/2^-$ states at 6.18 MeV [O^{15}]and 6.33 MeV [N^{15}], and the $3/2^+$ state of O^{15} and 6.79 MeV. The 6 MeV peaks exhibit their expected Doppler broadening.

In other spectra, taken also with 26.5 MeV bremsstrahlung, evidence has appeared for a weak line whose likely origin is the positive parity state at 8.3 MeV.

In a previous measurement (1) it was established that some or all of the 5 MeV lines make up about 24% of the total excited-state cross section. It is now evident that both $1/2^+$ and $5/2^+$ states are produced in this process. Their production occurs strongly between 22 and 25 MeV and it implies an appreciable non-single-particle excitation in this part of the O^{16} giant resonance.

The $(p_{3/2})^{-1}$ 6 MeV states are populated readily by single-particle processes, and their dominance is to be expected. The suppression of the cross section for the 6.18 MeV (O^{15}) line at energies below 24 MeV, as reported in reference (1), remains to be explained.

Giant Dipole Resonances in p-Shell Nuclei.*

J. L. Black, F. Riess, P. Paul,# W. J. O'Connell, G. A. Fisher, and S. S. Hanna

Department of Physics, Stanford University, Stanford, California, U.S.A.

The giant dipole resonances in p-shell nuclei have been studied by means of the (p,γ) capture reaction. The capture gamma rays are detected with good resolution with a 24 x 24 cm NaI detector encased in an anticoincidence plastic shield and employing pulse pile up suppression. The region of the giant resonance can be covered with good energy resolution with protons from an FN tandem accelerator up to proton energies of 18 MeV. Fine structure and gamma ray angular distributions for giant resonances observed in ^{8}Be, ^{14}N, and ^{16}O have been studied. For ^{8}Be and ^{14}N the giant resonances based on the first excited state can also be studied. The resonances observed in $^{7}Li(p,\gamma)^{8}Be$ are shown in Fig. 1. The γ_0 giant resonance shows little structure. The γ_1 resonance exhibits some structure at E_x = 22 MeV. The center of the γ_1 resonance lies about 2.5 MeV above the center of the γ_0 resonance. Thus, the excitation energy for both resonances is about the same, 21.5 MeV. The dipole strengths of the resonances are about equal i.e., the integrated yields are roughly proportional to $2J + 1$, where J is the spin of the final state. In ^{14}N the first excited state has T = 1, so that resonances based on a T = 1 level are observed. Previous measurements[1] on $^{15}N(p,\gamma_0)^{16}O$ have been extended to E_p = 17.5 MeV. Above E_x = 25.5 MeV, no pronounced structure was revealed. In addition, the main peak of the giant resonance at E_x = 22.2 MeV has been studied in detail with high resolution to search for possible fine structure. Results at θ = 45°, shown in Fig. 2, indicate the existence of structure in this peak. A measurement at θ = 90° displays similar structure. The results are compared with recent $^{16}O(\gamma,p)^{15}N$ data.[2]

G-SPECTRUM

γ,pγ and γ,nγ Reactions on ^{16}O

K. M. Murray and J. C. Ritter

U. S. Naval Research Laboratory

Washington, D. C. 20390

The absorption of electromagnetic photons in the energy range from approximately 10 MeV to 25 or 30 MeV is commonly referred to as the "photonuclear giant resonance". This absorption of energy generally results in particle emission and frequently the residual nucleus is left in an excited state. This excited state decays to its ground state thru the emission of one or more gamma rays. These deexcitation gamma rays from an ^{16}O target bombarded by bremsstrahlung from the US NRL Linac were observed using a large (30 cc) Li drifted Ge crystal.

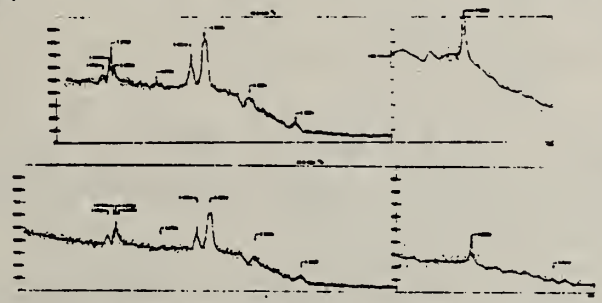

Fig. 1. A portion of the 4096 channel spectra for ^{16}O. The energies are in MeV. The letters indicate, d - double escape peak, s - single escape peak, and f - full energy peak.

Fig. 1 shows a portion of the spectra obtained with 28.0 and 30.0 MeV end-point-energy bremsstrahlung. Gamma rays from ^{15}N appear with energies of 3.924, 5.270, 5.299, 6.323, and 9.223 MeV while gamma rays from the corresponding isobaric analog levels in ^{15}O appear with energies of 5.188, 5.240, and 6.180 MeV. The lines are doppler broadened by recoil from particle emission. The two lines at 5.240 and 5.270 appear sharp because their life times are so long ($> 10^{-12}$sec.), that the recoil has been thermalized (thermalizing time $\sim 10^{-13}$ sec.). The level at 9.223 MeV has been seen in a recent run at 24.0 MeV. This indicates that it is probably coming from a level in ^{16}O at 22.5 MeV and this would imply a proton of approximately 1 MeV energy. Such a low energy proton would not produce very much recoil-doppler-broadening. This is consistent with the observed width of < 30 keV fwhm for this level.

The ^{15}O ground state decays thru a 124 sec. $^{+}\beta$ transition of ^{15}N. By observing this activity we measure the total number of ^{15}O ground states produced. Thereby the fractions of excited state transitions to ground state transitions can be calculated for the ^{15}O nucleus only.

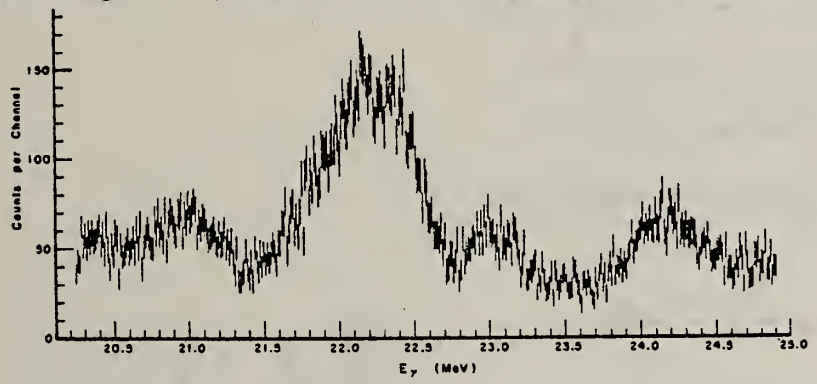
Photoprotons from O^{16}

M. N. Thompson and J. E. E. Baglin*

Electron Accelerator Laboratory, Yale University
New Haven, Connecticut USA

Spectra of photoprotons emitted from O^{16} to the ground state of N^{15} have been observed at lab angles of 45°, 90°, 120° and 135° with an experimental resolution of 40 keV. The gaseous oxygen target was irradiated with 26 MeV bremsstrahlung and the protons were detected using cooled Si(Li) detectors.



The figure shows an early 135° spectrum. Recent spectra at all four angles are statistically better and contain quantitative features similar to those shown. It is important to note that the former simplicity of the O^{16} ground state photoproton cross section is destroyed according to the above figure. Evidence from all the measured spectra suggests that the peaks previously considered to be the basic cross section entities, consist of narrower components. The "22 MeV peak" consists of at least three components (21.8, 22.1, 22.3 MeV) the "21MeV peak" has two (20.7, 21.0 MeV), as do both the "23 MeV peak" (23.0, 23.2 MeV), and the "24.5 MeV peak" (24.2, 25.1 MeV). In addition, much finer structure with a width of 50-70 keV is found over the whole energy region studied. Peaks of this nature appear repeatably in spectra at each angle, although with different relative intensities.

Although it is hoped to carry out a complete analysis of the angular distribution data, several observations can be made at this time. The two components of the "23 MeV peak" have different angular dependence. The one at 23.2 MeV is less strongly peaked at 90° than the 23.0 MeV component. Similarly for the peaks at 24.2 MeV and 25.1 MeV, the upper one is less dependent on angle than the other which is strongly peaked at 90°. It is also interesting to note that at 90° the valleys at 22.8 MeV and 23.5 MeV are of equal height as distinct from the situation shown here, indicating a cross section contribution at 23.5 MeV peaked at 90°.

The consistency of the fine (50 keV) structure at all angles implies that they are not statistical in nature. A paper by Duke et al. suggests that such fine structure may be accounted for by coupling between single particle and collective states of the O^{16} nucleus.

TABLE I. Comparison of present cross-section values in mb for production of high-energy photoneutrons by 55–85-MeV photons with measured cross sections $\sigma(\gamma,Tn)$, also in mb, for total photoneutron production. The present cross-section values are uncertain by 8 to 10% because of counting statistics and normalization errors; in addition all values depend on an absolute normalization in terms of the deuteron photodisintegration cross section, which is known to about 10% at these energies.

Using electrons with up to 60 MeV energy, ten transitions in ^{16}O have been studied: two $E0$ (6.05 and 12.05 MeV), one $E1$ (13.10 MeV), four $E2$ (6.92, 9.85, 11.52 and 13.1 MeV), two $M2$ (12.53 and 12.96 MeV) and one $E3$ (6.13 MeV). The cross sections measured as a function of momentum transfer have been analyzed to yield transition probabilities to the ground state and transition radii. The results are compared with the theory of BROWN and GREEN, and with the particle-hole calculations of LEWIS and DEFOREST. For levels at 11.08 and 13.67 MeV, upper limits for the transition probabilities are given.

10 LEVELS 6.05-13.1 MEV

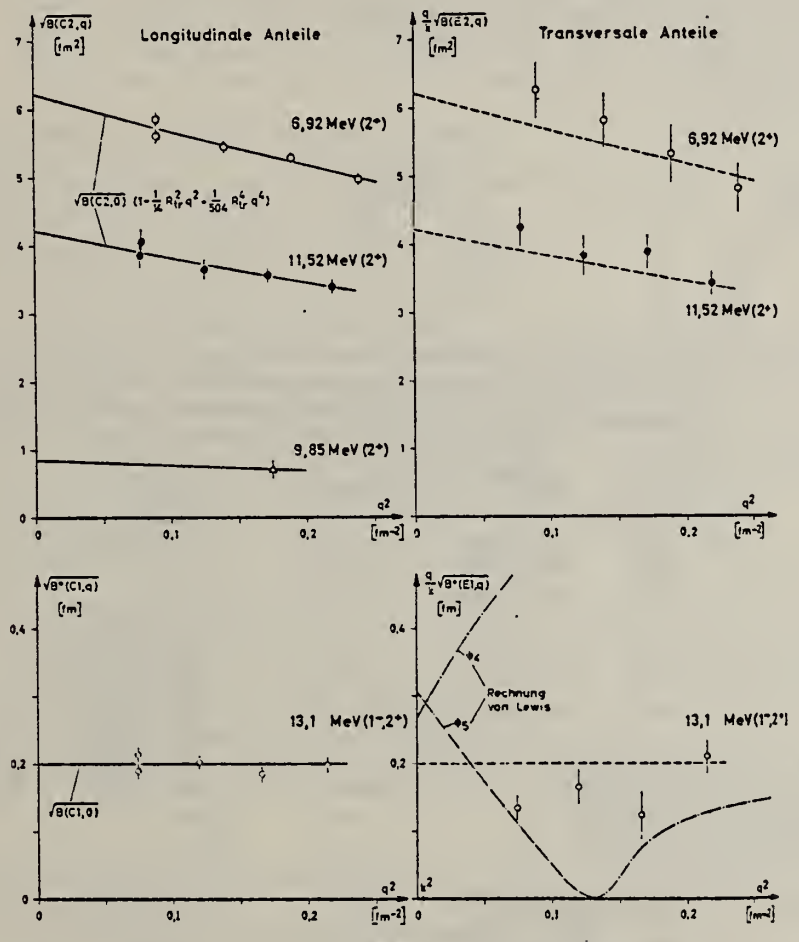

Fig. 2a

Fig. 2a und b. Longitudinale und transversale Übergangsmatrixelemente (nur statistische Fehler) aufgetragen über dem Quadrat der Impulsübertragung (BA-Auswertung). Eine Anpassung der angegebenen Funktionen an die Meßpunkte nach der Methode der kleinsten Fehlerquadrate liefert die durchgezogenen Kurven und die Parameter in Tabelle 2. Die gestrichelten Kurvenzüge für die transversal elektrischen Anteile wurden aus den zugehörigen longitudinalen Anteilen unter Annahme der Gültigkeit des Gleichheitszeichens in Formel (1) berechnet. Durch die gute Übereinstimmung mit den Meßpunkten wird diese Annahme für die hier betrachteten $E2$-Übergänge bewiesen. Die Ergebnisse von Teilchen-Loch-Rechnungen (strichpunktierte Kurven) werden im Text erläutert

21=21.71, 22=22.16

Nuclear emulsions placed in H_2O and monoenergetic γ rays from the reaction $T(p, \gamma)He^4$ have been used to measure the angular distributions of photoprotons from the reaction $O^{16}(\gamma, p)N^{15}$. The numbers of photoproton tracks observed at dip angles $\beta \leq 30°$ for emission-angle intervals θ = 0—15°, 15—30°, 30—45°, 45—60°, 60—75°, and 75—90° are respectively 305, 172, 89, 40, 25, and 33 (E_γ = 21.71 MeV) and 4, 18, 25, 33, 51, and 69 (E_γ = 22.16 MeV). The angular distributions obtained do not correspond to the angular distribution of γ rays for the inverse reaction $N^{15}(p, \gamma)O^{16}$ [$W_\gamma = 1 + 0.1P_1 - 0.6P_2$].[3]

We have studied the angular distribution of photoprotons from the reaction $O^{16}(\gamma, p)N^{15}$; nuclear emulsions and monoenergetic γ rays (E_γ = 22.16 MeV) were employed. As in our earlier work[1] the plates, in a cassette with H_2O, were placed in the plane of the incident protons and the γ rays emitted at 90°. The source of γ rays was the reaction $T(p, \gamma)He^4$. The track lengths were converted to photoproton energy by means of an experimentally determined range-energy relation: $\log E_{ph.pr.}(MeV) = -0.7147 + 0.5847 \log L(\mu)$.[2] The photoproton energy spectra obtained are shown in the figure. In the upper part are the results for E_γ = 22.16 MeV (E_p = 3.228 MeV, dip angle β_m = 30°), and in the lower part, the results for E_γ = 21.71 MeV (E_p = 2.622 MeV, β_m = 15°). The cross-hatched peaks correspond to photoprotons produced in the decay of O^{16*} to the ground state of N^{15}. The angular distributions of these photoprotons are shown by the solid curves in the upper corner of each part of the figure. The dashed curves are the angular distributions of γ rays from the inverse reaction $N^{15}(p, \gamma)O^{16}$ [3] ($F(\theta)$ is the yield of p or γ in relative units per unit solid angle).

It can be seen from the figure that the angular distributions differ strongly. For E_γ = 22.16 MeV the angular distribution is characterized by preferential emission of photoprotons at angles θ near 90°, and for E_γ = 21.71 MeV it has a sharply expressed directivity forward and backward.

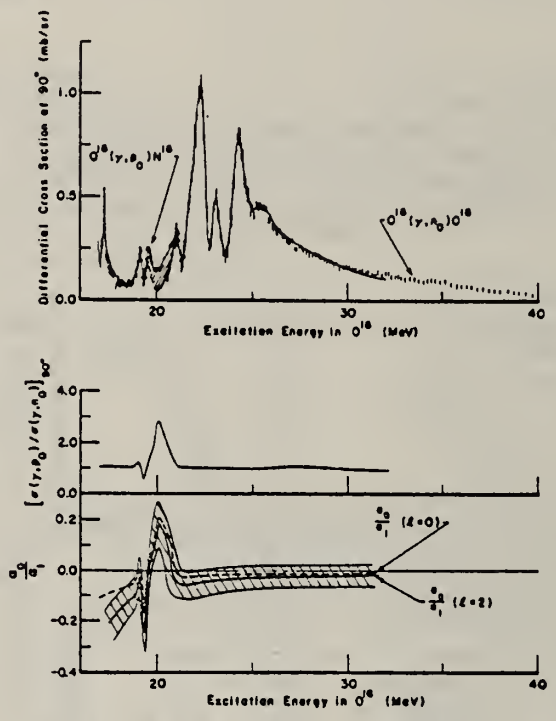

FIG. 2. The observed $O^{16}(\gamma, n_0)O^{15}$ differential cross section at 90° compared with the $O^{16}(\gamma, p_0)N^{15}$ data. The (γ, p_0) results are indicated by solid dots between 19 and 21 MeV and by a thin line elsewhere; Morrison's data (Ref. 15) are used between 17 and 22 MeV and between 25 and 32 MeV. In the region 22-25 MeV the (γ, p_0) data deduced from the $N^{15}(p, \gamma_0)O^{16}$ work of Tanner, Thomas, and Earle (Ref. 13) are used. The cross-hatched region indicates the error on a_0/a_1 due to statistics: The absolute $O^{16}(\gamma, n_0)O^{15}$ cross section has a systematic uncertainty of 10 % which is not included in the above diagrams.

GAMMA SPECTRUM

γ rays resulting from the decay of excited states in O^{15} and N^{15} have been observed when these states were produced from (γ, n) and (γ, p) reactions on O^{16}. Bremsstrahlung from the Naval Research Laboratory's 60-MeV Electron Linac was used as a source of x rays to produce the photonuclear reactions leading to N^{15*} and O^{15*}. The 5-MeV positive-parity quadruplet resulting from the above-described reactions was resolved into its four separate components and the width of each component was observed. Limits on lifetimes for all of the observed transitions were determined from the Doppler broadening of these lines. The $\frac{1}{2}^+$ states at 5.240 MeV in O^{15} and at 5.270 MeV in N^{15} were observed to have lifetimes considerably greater than 10^{-13} sec. All other observed transitions showed lifetimes short compared to 10^{-13} sec. It was also observed that the branching ratio of the 9.223-MeV level in N^{15} to the $\frac{1}{2}^+$ state at 5.299 MeV could not be greater than ~50%.

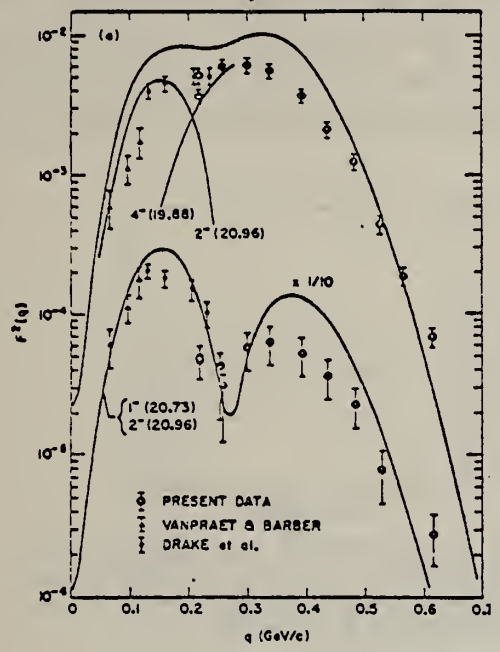

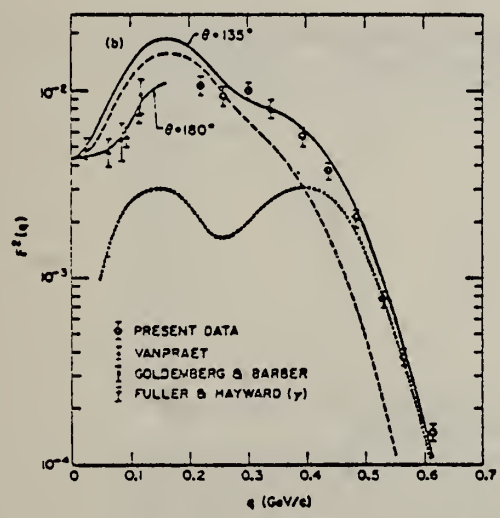

FIG. 3. Form factors as for Fig. 2. (a) 20-MeV region for $\theta = 135°$ (the longitudinal contributions are, in fact, small). Only the lower curve for the 1^- and 2^- states has been reduced in amplitude (by 1.4). The comparison there is for data at about 20.4 MeV. (b) Giant resonance region. The dotted curve is the quasielastic contribution and the dashed curve is the form factor for the discrete levels, both curves for $\theta = 135°$. The solid curves are the total. Data below 120 MeV/c are at $\theta = 180°$; the rest are at 135° except for the point at 219 MeV/c which, having $\theta = 145°$, lies relatively lower.

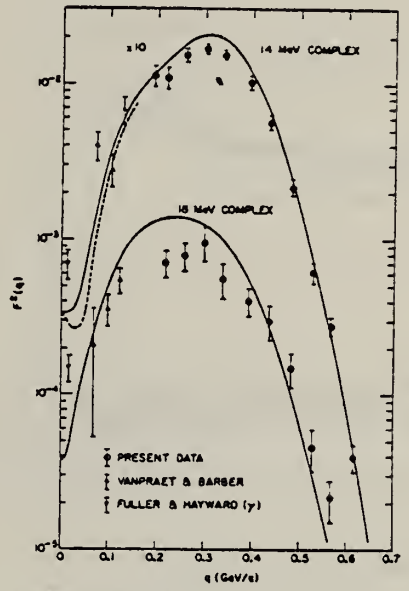

FIG. 2. Form factors

$$F^2(q) = \frac{d\sigma/d\Omega}{[4\pi\sigma_{Mott}(\frac{1}{2} + \tan^2\frac{1}{2}\theta)]}$$

for the 14- and 18-MeV complexes. The solid curves are for $\theta = 135°$, the scattering angle in the present experiment except at 191 and 219 MeV/c where $\theta = 145°$. The dashed curve is for $\theta = 180°$ to compare with the data below 120 MeV/c. Longitudinal contributions are relatively small for both complexes. The calculated curves for the 14-MeV complex have been reduced in amplitude by 1.7, the 18-MeV complex by 1.4.

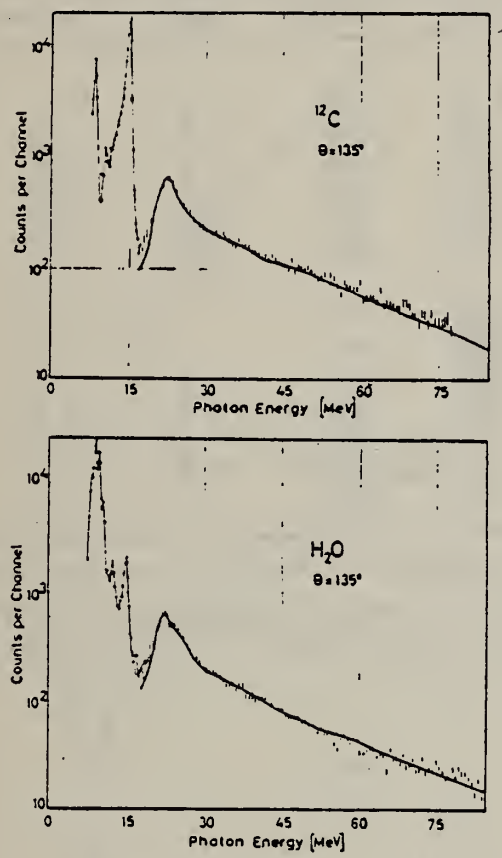

Fig. 1. Pulse height distribution for ^{12}C and ^{16}O. The simultaneously measured neutron background distribution is subtracted. The 15.11 MeV line in the oxygen distribution is the deexcitation of the 15.11 MeV level in ^{12}C, populated by ^{16}O(γ, α)^{12}C [7]. Lines below 10 MeV are γ-transitions in the daughter nuclei following (γ,n) or (γ,p) reactions. The heavy is calculated with the assumptions given in the text and with resonance parameters adjusted to give a good fit to the measured distribution.

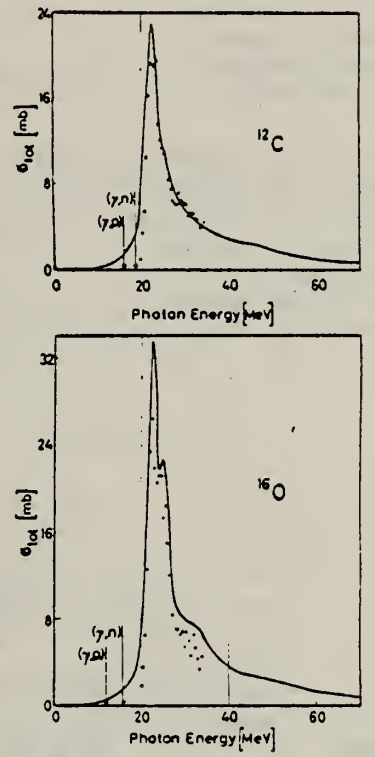

Fig. 2. The full line is the total absorption cross section σ_{tot} calculated from the imaginary part of the scattering amplitude. The points are taken from total absorption measurements [8]. Since particle threshold effects are not built into the scattering amplitude, agreement between the calculated and measured cross section cannot be expected in the threshold regions.

Photonuclear Reactions in Oxygen and their Use for the Control of Energy and Photon Spectrum at Electron Accelerators

The yields of the photonuclear reactions $^{16}O(\gamma, n)$ and $^{16}O(\gamma, 2n)$ are measured with a newly constructed device for fluid samples. The well known structures of the (γ, n) cross section are used for the energy calibration of our accelerator. Though the yield should be strongly dependent on small changes of the bremsspectrum no difference was found, using a thin or a thick target. The conclusion is, that also the thick target is in its effect a thin target under the accelerator conditions. The $(\gamma, 2n)$ cross section is measured for the first time between threshold and 120 MeV. It is unusually small compared to the (γ, n) cross section.

The $^{12}C(\alpha,\gamma)^{16}O$ capture cross section was measured for α-particle energies between 1.86 MeV ($\sigma = 1.1 \pm 0.4$ nb) and 3.11 MeV ($\sigma = 29 \pm 4$ nb) using a pulsed $^4He^+$ beam from the ORNL 6-MV Van de Graaff accelerator and a 23- by 30-cm NaI(Tl) crystal viewed by six matched, bialkali photomultiplier tubes. An upper limit was obtained for the capture cross section at $E_\alpha = 1.6$ MeV. The over-all time resolution (full width at half maximum) of the system for 8–10-MeV pulses due to γ rays is 2.7 nsec. Enriched (99.94%) ^{12}C targets ranging in thickness from 98 to 178 $\mu g/cm^2$ were used. Pulses resulting from fast neutrons [from the $^{13}C(\alpha,n)^{16}O$ reaction] interacting with the NaI(Tl) crystal were further separated from true γ pulses through the use of a new technique based on rise-time distribution differences of the respective neutron- and γ-ray-produced pulses. The face of the crystal (shielded with a 10.2 cm thickness of ^6LiH) was 12.2 cm from the target. The astrophysical significance of this reaction in the helium-burning sequence of stellar nucleosynthesis is also discussed.

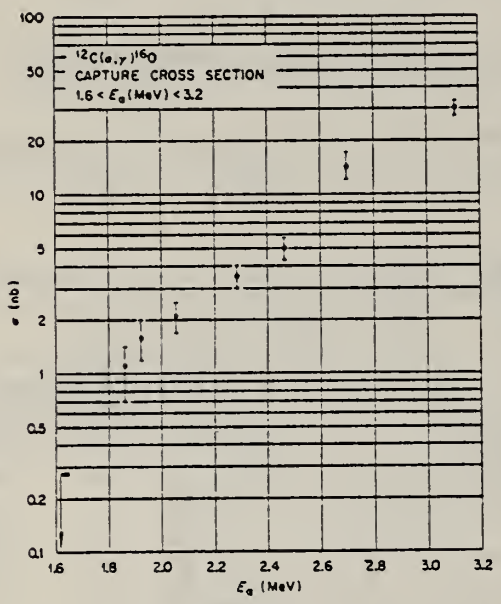

FIG. 9. The $^{12}C(\alpha,\gamma)^{16}O$ capture cross section measured in the present experiment. The errors include the effects due to target-thickness uncertainty, detector-efficiency uncertainty, current integration, statistics, and background subtraction. Refer to text for comparison of data with previous results.

				(1.6 - 4.1)			

The possibility of 1^- states above the 9.58- and 7.12-MeV states in ^{16}O interfering with these lower states would strongly affect the $^{12}C(\alpha,\gamma)^{16}O$ capture cross sections near $E_\alpha = 3.2$ MeV and the inferred stellar-reaction rate. Cross sections below 3.2 MeV reported earlier have been extended to 4.1 MeV using similar techniques and overlap the previous measurement from ~2.9 to ~3.2 MeV.

In an earlier paper[1] the $^{12}C(\alpha,\gamma)^{16}O$ capture cross section below $E_\alpha = 3.2$ MeV was reported. A recent report[2] indicates that the rate of the $^{12}C(\alpha,\gamma)^{16}O$ reaction at stellar energies may be predicted with a precision that is limited only by the precision of the experimental data obtained at higher energies. This analysis is now in the stage of preparation for publication.[3] The cross section above the 3.2-MeV resonance is strongly affected through interferences with the tail from the region of the giant dipole resonance in ^{16}O.[4] Thus, further measurements of the $^{12}C(\alpha,\gamma)^{16}O$ capture cross sections were made at Oak Ridge National Laboratory (ORNL) for α-particle energies extending to 4.08 MeV using the terminally pulsed ^4He beam from the ORNL 5.5-MV Van de Graaff accelerator. The experimental methods (time-of-flight techniques, etc.) used have been described in detail earlier.[1] The results of these measurements are shown in Fig. 1. These values again consider only the ground-state transition γ ray and do not include any contribution from cascade γ rays, although ~7-MeV γ rays are observed in the pulse-height (time and energy) spectra. The α-particle energies reported are those at the center of the target. Data were taken such that resonances other than the tails of the 1^- levels did not contribute significantly to the γ-ray yield at the datum points shown. Particularly, the datum point at $E_\alpha = 3.39$ MeV was below the narrow resonance at $E_\alpha = 3.58$ MeV (the 2^+ 9.85-MeV state in ^{16}O with $\Gamma_{c.m.} = 0.75$ keV), while the datum point at 3.80 MeV was above this resonance. Furthermore, the angular distribution of the 2^+ ground-state radiation is a minimum at 90°.

The measurement at 4.08 MeV may contain a contribution to the yield from the resonance at $E_\alpha = 4.26$ MeV (the 4^+ level in ^{16}O at 10.36 MeV with $\Gamma_{c.m.} = 27$ keV), although the ground-state transition rate should be small compared with the rate of the 2^+ state.

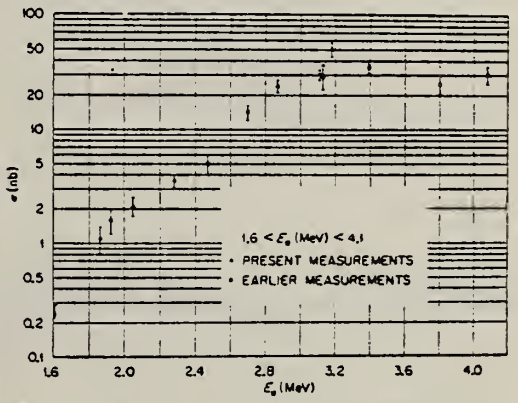

FIG. 1. The $^{12}C(\alpha,\gamma)^{16}O$ capture cross section below 4.1 MeV. This figure assumes a 1^- distribution of γ radiation and includes only the ground-state transition. The earlier data were taken from Ref. 1.

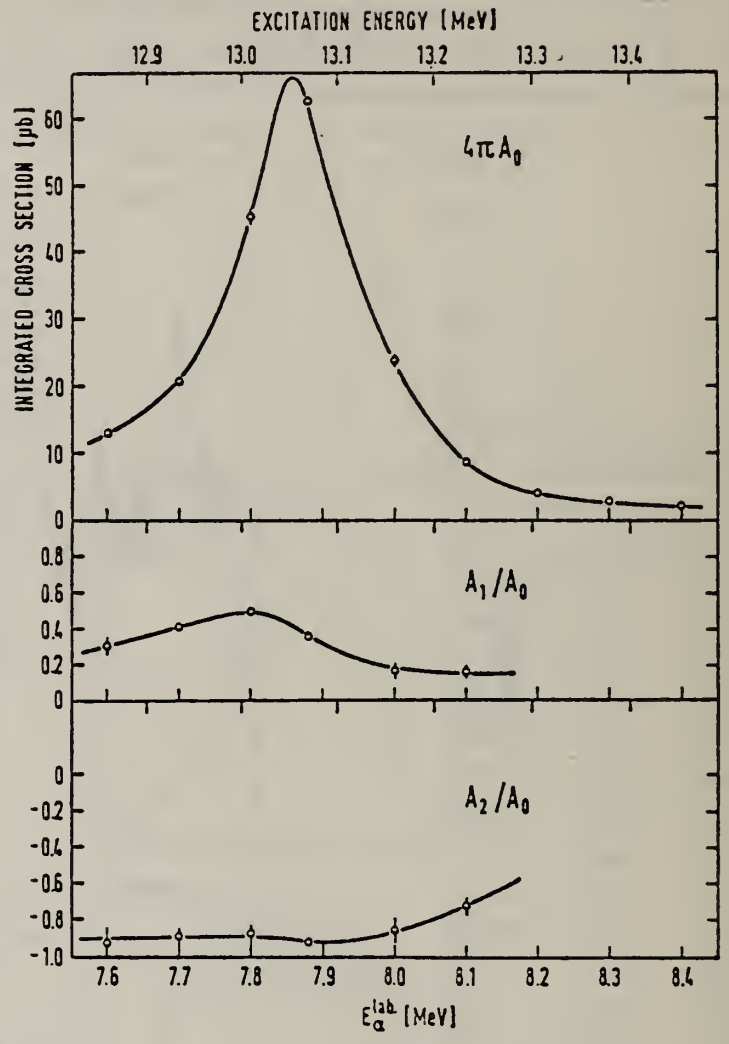

Fig. 8. Legendre polynomial coefficients. The upper diagram represents the integrated cross section. Values for A_1/A_0 and A_2/A_0 at energies higher than $E_\alpha = 8.1$ MeV are not shown due to large errors. The errors due to the normalization of A_0 values to each other are not given in the upper diagram; they amount to about 4%. Where the errors for A_1/A_0 and A_2/A_0 are not shown they are smaller than the radius of data circles. The upper scales for excitation energies were obtained using a Q-value of −7.161 MeV from ref. [7]).

The Yields of Radioactivities Induced by (γ, n) Reactions with Bremsstrahlung up to 68 MeV

by Tatsuya SAITO

The (γ, n) yields of 12 target nuclides have been measured at 10, 13, 16, 30, 45 and 68 MeV bremsstrahlung by observing the induced activities.

The energy dependence of the yields has been investigated extensively in the same way as in the previous work at 20 MeV bremsstrahlung.

In the case of heavy nuclides, the yields rise greatly as a function of maximum bombarding energy up to 20 MeV, and rise gradually from 20 MeV up to 68 MeV. However, in the case of light nuclides, the yields rise greatly up to 30 MeV, because the neutron separation energies of light ones are larger than those of heavy ones, and the bremsstrahlung spectrum covers the giant resonance and so the yields rise gradually from 30 MeV up to 68 MeV.

The yields have approximately been estimated from the parameter of the giant resonance, that is the peak cross section and the half width, in order to compare with the experimental data. As a result, the experimental data of light nuclides and heavy ones are nearly in agreement with the estimated data of Nathans et al., Johns et al. and Montalbetti et al., but those of medium weight ones are relatively lower values.

				(2.2-2.9)			

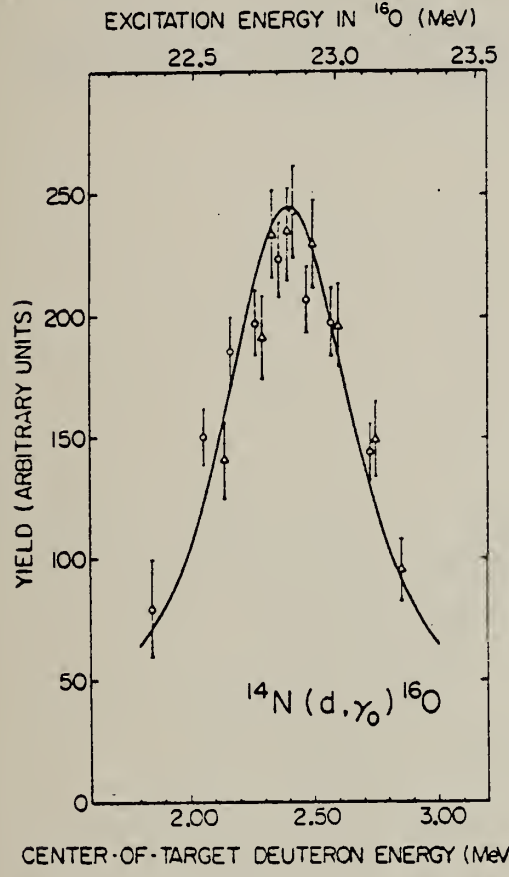

FIG. 2. Relative yield at 90° for the reaction $^{14}N(d,\gamma_0)^{16}O$. The triangles are data obtained with the tantalum nitride target, while the circles are data obtained with the nitrogen gas target. The deuteron energies have been corrected to correspond to center-of-target energies. The error bars represent the statistical uncertainties for the data points. The curve is a Breit-Wigner shape with $\Gamma(\text{lab}) = 700$ keV and $E_0 = 2.40$ MeV.

The 90° yield from the reaction $^{14}N(d,\gamma_0)^{16}O$ has been measured between 2.1 and 2.9 MeV to accurately determine the location of the strong resonance previously observed in this region. Two separate measurements were made. It is found that the resonance occurs at $E_d = 2.40 \pm 0.05$ MeV, moving it with respect to the dip $^{15}N(p,\gamma_0)^{16}O$ and $^{16}O(\gamma,n_0)^{15}O$. This result brings into question interpretations of the fine structure of the ^{16}O giant dipole resonance made on the basis of earlier experimental work.

12.44, 13.09

Abstract. — Desexcitations of the 1⁻ levels situated at 12.44 and 13.09 MeV in ^{16}O have been studied and two new transitions were observed. A new determination of the parameters of the two 1⁻ levels was made.

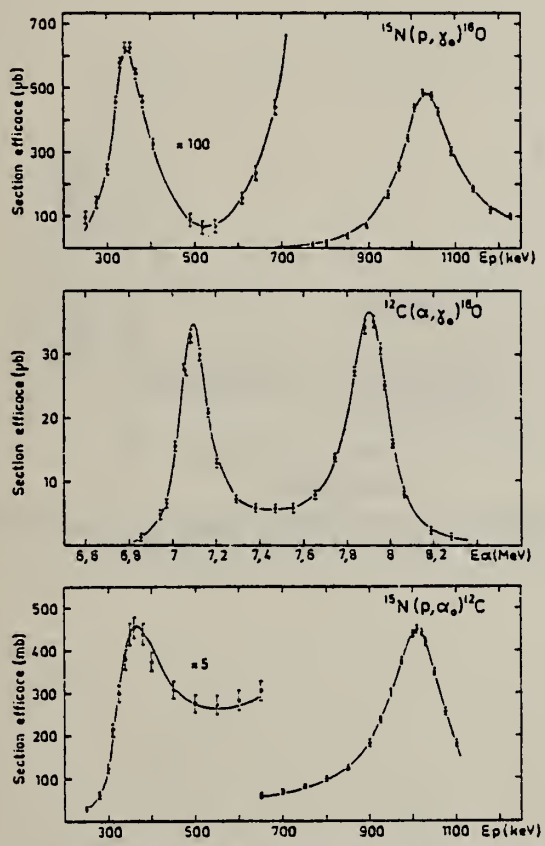

FIG. 3. — Comparaison des fonctions d'excitations théoriques obtenues à l'aide d'une formule à deux niveaux avec les valeurs expérimentales correspondantes.

TABLEAU III

Paramètres des niveaux situés à 12,44 *et* 13,09 MeV *déduits dans le formalisme de la matrice S en utilisant une formule à deux niveaux*

Niveaux (MeV)	Γ_p (keV)	Γ_{α_0} (keV)	Γ_{γ_0} (eV)	Γ (keV)	q_n (a)
12,44	1,25	95,3	9,5	96,5	0,988
13,09	95,5	39,5	44	135	1,2

(a) q_n représente le facteur défini par J. Humblet et L. Rosenfeld [15].

Nucl. Phys. 26 (1961) 529.

Data on $^{13}C(^3He,\gamma_{1+2})$ and $^{13}C(^3He,\gamma_{3+4})$ also given.

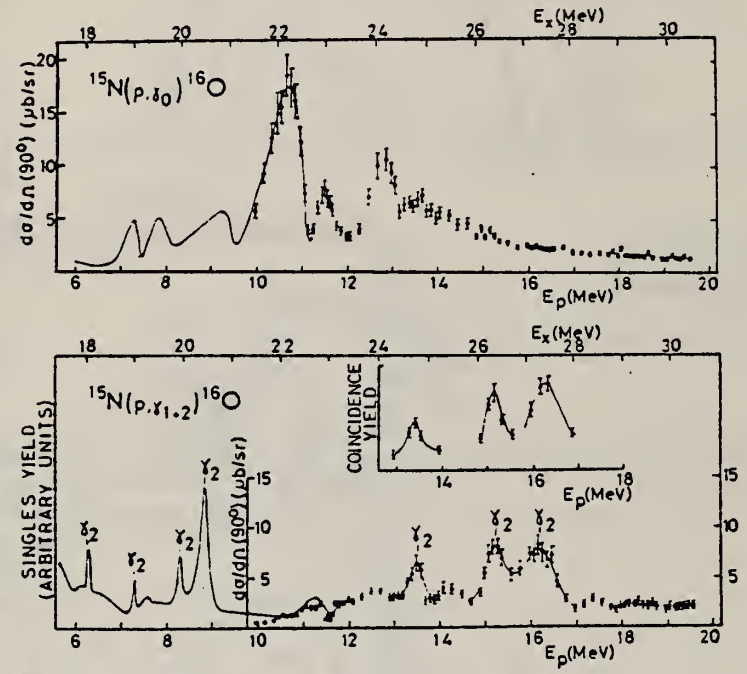

Fig. 3. Excitation functions from the present work for $^{15}N(p,\gamma_0)^{16}O$ and $^{15}N(p,\gamma_1+\gamma_2)^{16}O$ ($E_p > 10$ MeV). For $E_p < 12$ MeV, the yield curve from ref. [1]) is shown. The peaks denoted γ_2 have been found by coincidence measurements to decay through the 6.13 MeV, $J^\pi = 3^-$ state. The coincidence yield curve for $^{15}N(p,\gamma_2\gamma_{6.13})^{16}O$ is also shown.

1
A.R. Barnett and N.W. Tanner, Nucl. Phys. A152 (1970) 257

Abstract: Measurements are reported of the excitation function for $^{15}N(p,\gamma_1+\gamma_2)^{16}O$. Together with earlier data, the range $E_p = 6$–19.6 MeV is covered and is found to contain seven resonances. Coincidence measurements are described which, together with other data, establish that all seven decay to the $J^\pi = 3^-$ state at 6.13 MeV. One of these states is tentatively identified as the giant M2 state observed in inelastic electron scattering. Three higher states are attributed to the $(1p_{\frac{1}{2}}^{-1}\,1f_{\frac{7}{2}})$ excitation. The excitation function for $^{13}C(^3He,\gamma_1+\gamma_2)^{16}O$ is also given for $E_{^3He} = 4$–12 MeV. One resonance is found, which probably decays to the $J^\pi = 0^+$ state at 6.05 MeV, and, if so, is part of the deformed giant resonance in ^{16}O.

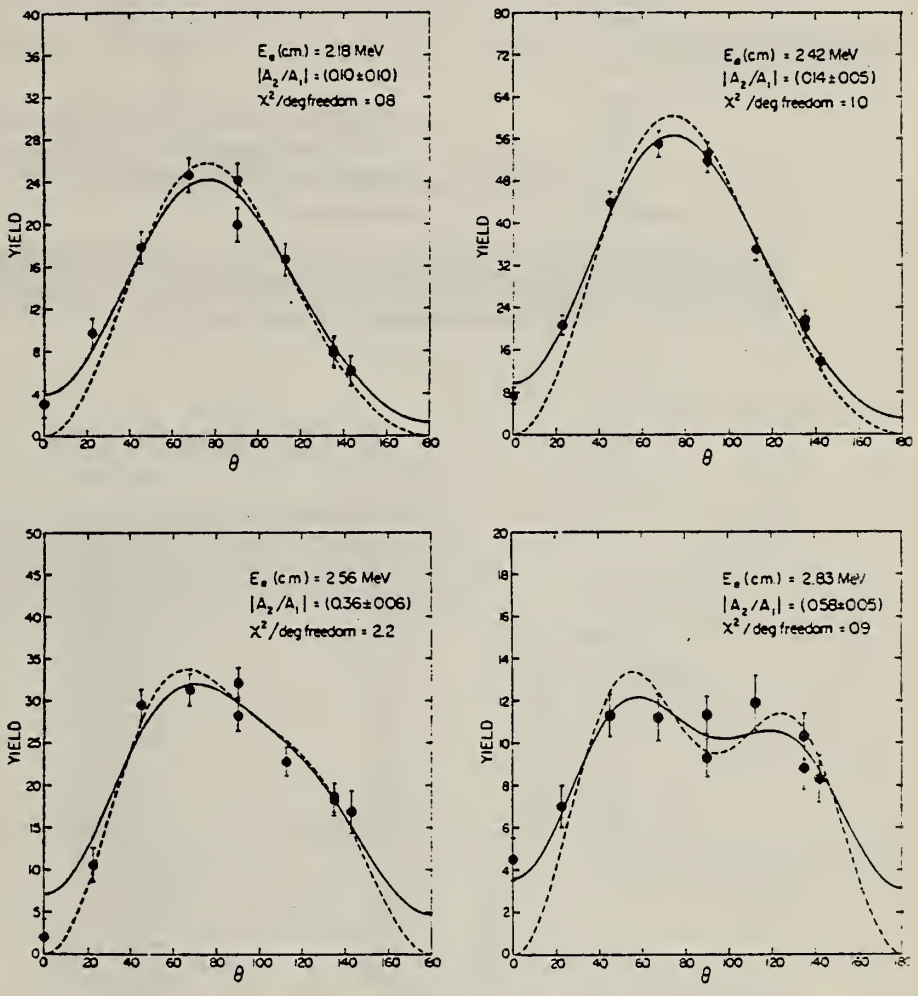

Fig. 6. $^{12}C(\alpha,\gamma)^{16}O$ angular distributions. The solid curves are fits to the data obtained by assuming interference between 1^- and 2^+ capture amplitudes, taking into account the finite size of the detectors. The dashed curves indicate the same angular distributions as they would be measured by a point detector. Yield is in arbitrary units.

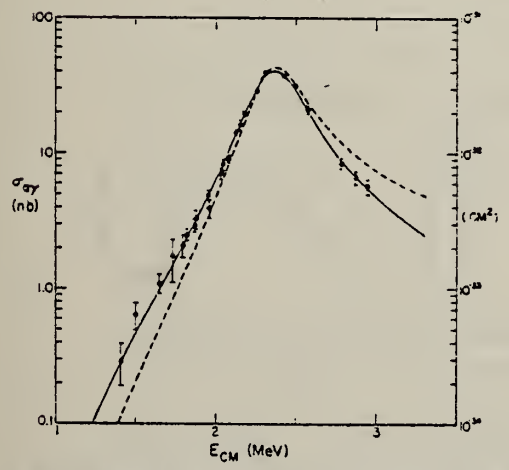

Fig. 8. Measured electric dipole contributions to the $^{12}C(\alpha,\gamma)^{16}O$ total cross sections and the "hybrid" R-matrix optical-model fits. The data are indicated by circles. The solid curve is the best fit to the data, with χ^2 per degree of freedom = 1.0. The dashed curve is a fit in which the reduced α-width of the bound 7.12 MeV state is constrained to zero, and the remaining parameter is free to vary; χ^2 per degree of freedom is 8.5. The theoretical curves for the three-level R-matrix fits are qualitatively similar.

(over)

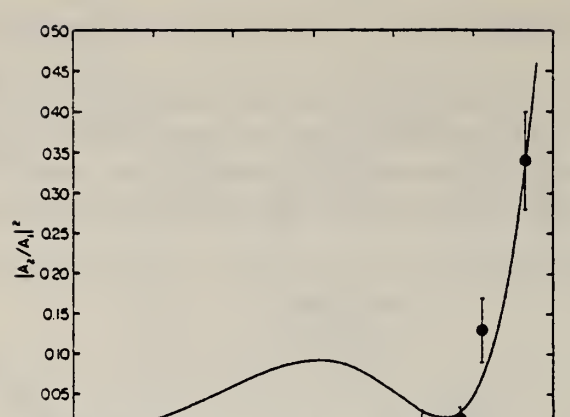

Fig. 7. Variation of the ratio $|A_2|^2/|A_1|^2$ with c.m. α-energy. The circles indicate the values derived from the angular distribution measurements. The solid curve shows the values calculated from the E2 direct capture formulation of Tombrello and Phillips [25], with θ_α^2(g.s., ^{16}O) = 0.04±0.01, and the three-level R-matrix fit to the E1 contributions.

POLARIZED PROTONS

Measurements on the polarized-proton capture reaction $^{15}N(p,\gamma_0)^{16}O$ indicate a broad $E2$ resonance which lies above the giant $E1$ resonance of ^{16}O. The measurements show that the $E2$ radiation for the (γ,p_0) channel of ^{16}O exhausts approximately 30% of the quadrupole sum rule.

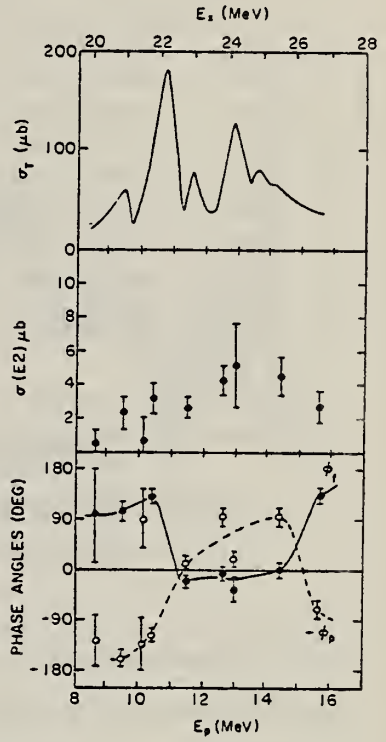

FIG. 2. Top: total cross section curve of $^{15}N(p,\gamma)^{16}O$ (Ref. 8). Middle: plot of total $E2$ cross sections derived from the analyses in Table I. Bottom: plot of the phases of the partial-wave amplitudes for proton capture leading to $E2$ radiation.

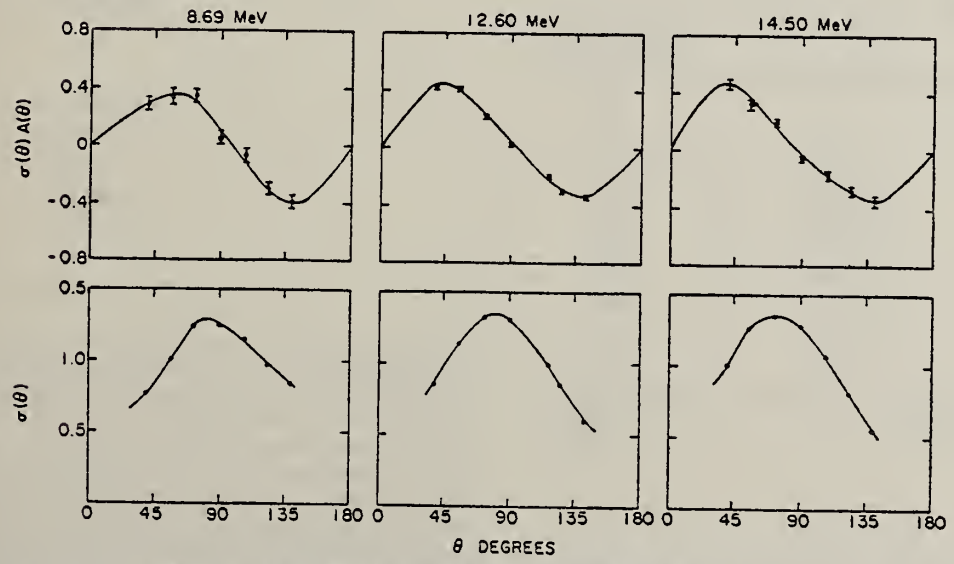

FIG. 1. Plots of $\sigma(\theta)$ and $\sigma(\theta)A(\theta)$ measured at three bombarding energies (listed at top) in the polarized-proton capture reaction $^{15}N(p,\gamma)^{16}O$. Where error bars are not shown the errors are of the same order as or smaller than the dot size. The analysis of these and all the data is given in Table I.

Abstract: Excitation functions of the $^{15}N(p,\gamma)^{16}O$ proton capture reaction have been obtained at $\theta_\gamma = 45°$ and $E_p = 150$–2500 keV. Below $E_p = 400$ keV, the reaction is dominated by capture into the ground state of ^{16}O. The observed excitation function for the latter process can be explained if, in addition to the two well-known $J^\pi = 1^-$ resonances at $E_p = 338$ and 1028 keV, a direct radiative capture process (DC → 0) is included in the analysis. The direct capture component in the capture reaction is enhanced through interference effects on the tails of the two resonances. From the observed direct capture cross section, a single-particle spectroscopic factor of $C^2S(1p) = 1.8 \pm 0.4$ has been deduced for the ground state in ^{16}O. The extrapolated astrophysical S-factor of $S(0) = 64 \pm 6$ keV · b for the $^{15}N(p,\gamma_0)^{16}O$ reaction is a factor of 2.5 larger than previously reported. This result amplifies the role of the oxygen side cycle in the CNO hydrogen burning process.

The observed excitation function of the $^{15}N(p,\alpha_1\gamma_1)^{12}C$ reaction at $E_p = 150$–2500 keV shows that this reaction makes a negligible contribution to hydrogen burning at stellar energies [$S(0) \approx 0.1$ keV · b] compared to $^{15}N(p,\gamma_0)^{16}O$ and $^{15}N(p,\alpha_0)^{12}C$.

1053

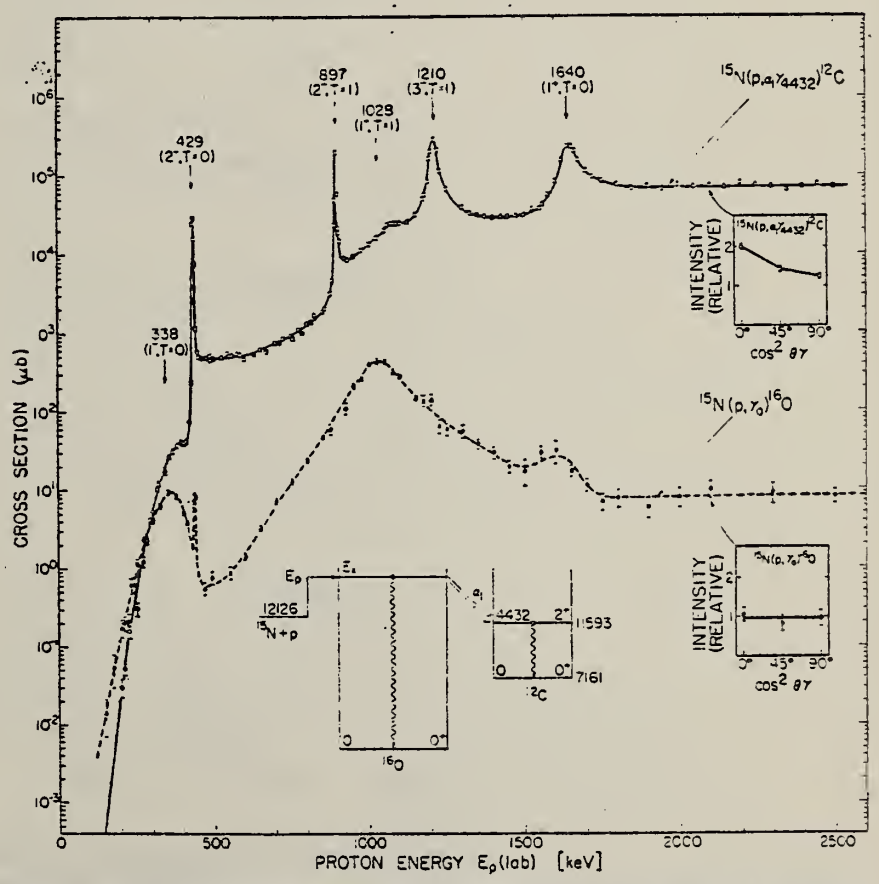

Fig. 2. Total cross sections for the $^{15}N(p,\alpha_1\gamma_1)^{12}C$ and $^{15}N(p,\gamma_0)^{16}O$ reactions are shown as a function of beam energy. The solid and dashed lines through the data points are placed to guide the eye. The insets show the γ-ray angular distributions observed at $E_p = 2.10$ MeV.

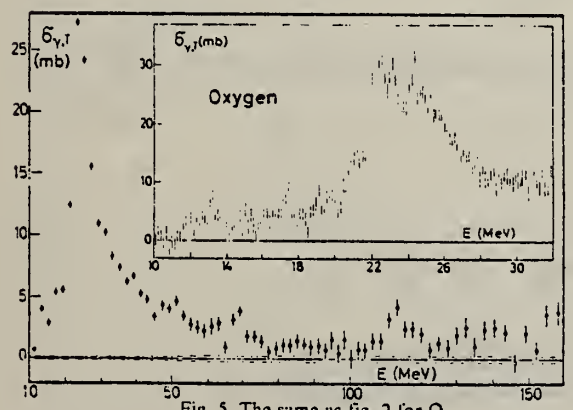

Fig. 5. The same as fig. 2 for O.

Fig. 2. Total photonuclear cross section for natural Li. The error bars indicate one standard deviation of counting statistics from the main spectrometer. The dashed lines along the abscissa indicate the uncertainty due to counting statistics in the normalizing spectrometer. Oscillations of the base line within this area are possible, the period of these oscillations, however, must not be smaller than 10% in photon energy. The dashed and dotted lines through the cross section values have been drawn to guide the eye.

7=7.12

The isospin-forbidden electroexcitation of the 1^-, $T = 0$ state at 7.12 MeV in ^{16}O has been studied for momentum transfers $q = 0.22 - 0.49$ fm^{-1}. The form factor at these momentum transfers is determined by the sum of the isospin $T = 0$ part and a $T = 1$ contribution. A single particle-hole harmonic oscillator shell model calculation reproduces the q-dependence of the measured form factor which shows that the isovector contribution interferes destructively with the isoscalar part and has a strength of about 2% of the $T = 0$ amplitude.

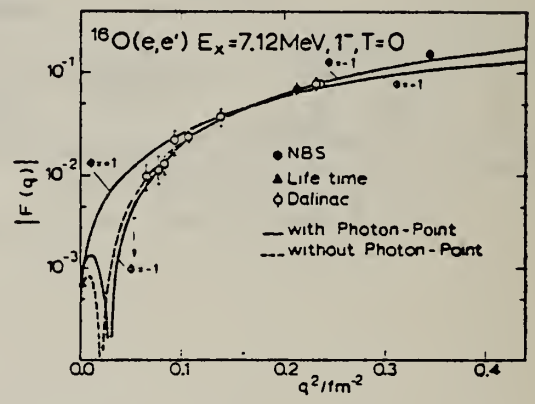

Fig. 2. Form factor $F(q)$ as a function of q^2. In addition to the present measurements at the DALINAC, data from NBS (see ref. [7] and $F(q)$ at the photon point from the lifetime of ref. [2] are also shown. The full line is a fit of the harmonic oscillator model [eq. (1)] to the present data and the photon point; for the dashed line the photon point is not included.

3.5. THE $^{12}C(\alpha, \gamma_0)$ ABSOLUTE CROSS SECTION AND TOTAL CROSS SECTION

It was not possible to obtain a measurement of the absolute cross section from the above data because of the emphasis placed on cosmic ray rejection to minimize background at off-resonance energies. It is difficult to determine accurately how many of the total interactions within the detector by the γ-rays of interest are rejected due to detection of escape radiation by the surrounding anticoincidence annulus.

Accordingly, a 12.6 cm × 10.2 cm NaI detector, was used to determine the cross section independently at 90°. The detector was surrounded by lead shielding 10 cm thick, except for the front face which was 27 cm from the target. The cross section obtained at 7.05 MeV was 2.1 ± 0.5 μb/sr and, at 7.90 MeV, 1.7 ± 0.5 μb/sr. Both measurements have been corrected for angular distribution effects. The stated errors arise mainly from the uncertainty in the target thickness and in the extrapolation of the spectrometer response to low energy in order to determine the total number of γ-ray interactions. The result at 7.90 MeV corresponds to a total cross section of 22 ± 7 μb, confirming the results of Larson and Spear and Brochard *et al.* It is tempting to speculate that the use of a singly ionized helium beam by Kernel *et al.* led to incorrect interpretation of the integrated charge by a factor of two.

Absolute yields based on normalization to $^{59}Co(\gamma,n)$ cross section of Fultz (62Ful). If newer $^{59}Co(\gamma,1n)$ data from Alvarez (73Al7) is used, yields should be increased by a factor of 1.41.

Abstract. The photodisintegration of ^{15}N through excited states of the residual nuclei has been studied by measuring the yields of de-excitation γ rays in a Ge(Li) detector. Cross sections for all observed transitions were deduced from measurements with bremsstrahlung end-point energies ranging from 15 to 35 MeV and account for an integrated cross section of 44 MeV mb. Bound states in ^{14}N and ^{14}C with a dominant $(1p_{1/2})^{-1}$ or $(1p_{3/2})^{-1}$ configuration are found to be strongly populated. On the whole the results do not agree well with the meagre existing experimental information or with published theoretical calculations, with the possible exception of those of Zhusupov and Eramzhyan. The nature of the states in the ^{15}N giant resonance is discussed. The $^{15}N(\gamma,t)^{12}C^*$ (4·44 MeV) reaction was also observed and its integrated cross section is ~5% of the expected value of the E1 sum rule. Integrated cross sections for $^{16}O(\gamma,p_0\gamma_1)$ transitions measured at the same time are given. Resonance fluorescence is observed from the ^{15}N 10·07 MeV level, for which $\Gamma_{\gamma_0} = 4{\cdot}2 \pm 1{\cdot}5$ eV is deduced.

Table 2. A comparison of cross sections for neutron and proton emission from ^{16}O to specific final states, integrated up to 29 MeV, as measured in the present experiment with errors of ~ ±30%, with those of Caldwell *et al* (1967).

Double-differential cross sections for the electroproduction of pions of both charges have been measured. We compare the data obtained for production near threshold from ^{12}C and ^{16}O with theoretical treatments employing both shell-model and sum-rule nuclear descriptions with full inclusion of the final-state interaction.

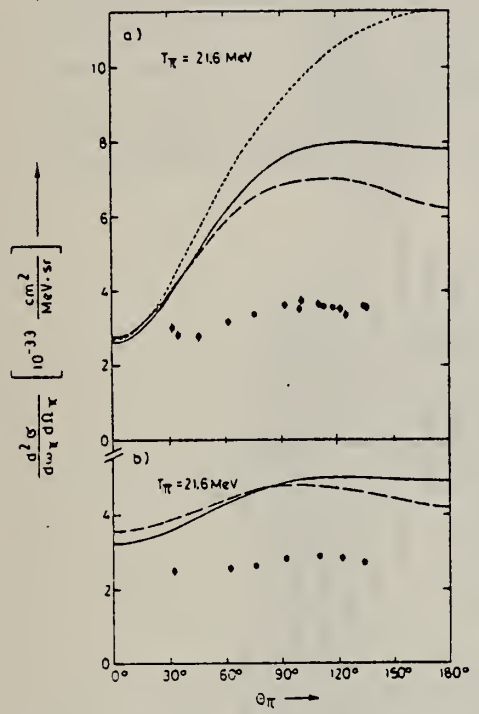

FIG. 1. Double-differential cross sections for production of negative pions by 280-MeV electrons from (a) ^{16}O and (b) ^{12}C as a function of the pion angle. The shell-model results (solid line) are compared with the predictions of the sum-rule results when evaluated with (dashed line) and without (dotted line) the effective two-body Skyrme II (Ref. 14) interaction.

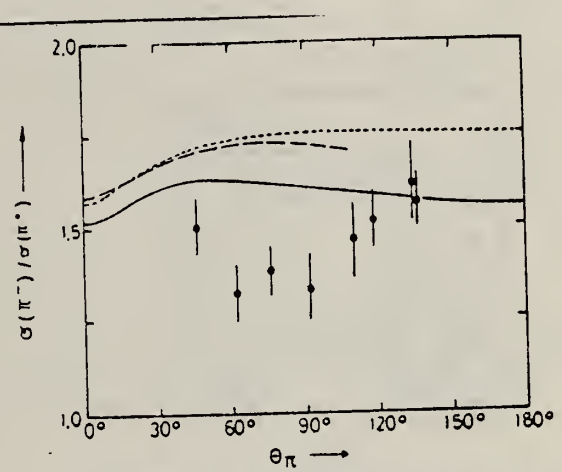

FIG. 3. Same in Fig. 2, but for production of 30.25-MeV pions from ^{16}O. The theoretical curves are as in Fig. 1. The sum-rule calculation with the Skyrme II interaction breaks down for angles above 110°, as discussed in Ref. 15.

[14] M. Beiner, H. Flocard, N. van Giai and P. Quentin, Nucl. Phys. A283, 29 (1975)

[15] The discrepancy between theory and experiment also shows up in weak and electromagnetic excitations of giant dipole states. This is probably due to complicated many-particle-many-hole states and can be taken into account by an overall reduction factor, at least at low momentum transfer. [See, e.g., T.W. Donnelly and J.D. Walecka, Annu. Rev. Nucl. Sci. 25, 329 (1975)]. Note, however, that in our calculations we have to include states well above the giant resonances, particularly in backward direction.

Sharp fluctuations in the coefficients describing the angular distribution and analyzing power in the reaction $^{15}N(p_{pol},\gamma_0)^{16}O$ are observed near $E_\gamma = 21$ MeV. These correspond to structure in the total cross section. All these structures can be fitted by introducing a narrow secondary doorway state interfering with the primary giant dipole resonance of ^{16}O.

Pol P, Doorway States

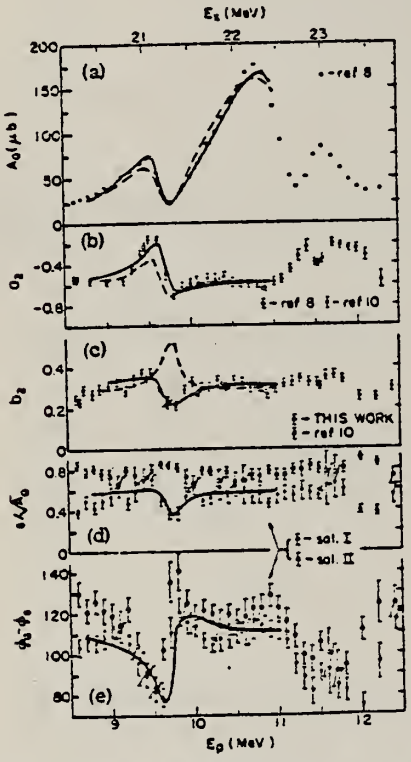

FIG. 1. (a) The cross section from Ref. 8 along with the fits from Ref. 9 (dashed curve) and the present work (solid curve); (b) the coefficient a_2 from Refs. 8 and 10 (which agree quite well) along with the fits corresponding to those in (a); (c) the observed b_2 from the present work and Ref. 10 along with the prediction of Ref. 9 (dashed line) and our fit (solid curve); (d) the normalized s-wave amplitude and fit; and (e) the relative phase $\phi_d - \phi_s$ and fit. All solid lines correspond to the same fit and represent the best χ^2.

TABLE I. The best-fit values of the resonance parameters.

Doorway[a]		E_i (MeV)	Γ_i (MeV)	$g_i^d g_0^\gamma$ (keV)	$g_i^s g_0^\gamma$ (keV)	φ_s (deg)	φ_d (deg)
	A	21.26[a]	0.1[a]	7.6 ± 0.4	1.2 ± 0.4	52 ± 14	163 ± 2
		(21.3–21.22)	(0.0–0.2)	(10.8–3.5)	[4.3–(–3.2)]	(44–75)	(158–162)
	B	22.15[b]	1.6 ± 0.6	37.6 ± 0.5	27.5 ± 0.7	0[c]	109 ± 1
				(36.8–39.6)	(26.8–28.9)		(111–107)

[a]The energy and width of resonance A, which do not include the shift and damping, respectively, were fixed and stepped; equally good χ^2 were obtained for Γ_A ranging from 0.0 to 0.2 MeV. The corresponding value of V is from 0.54 to 0.39 MeV. Corresponding excursions of the best-fit parameters are shown in parentheses.
[b]The energy of resonance B was fixed to the value in Ref. 9.
[c]φ_s for resonance B was arbitrarily chosen to be zero.

Abstract: Previous data on excitation functions for $^{15}N(p, \gamma_1+\gamma_2)^{16}O$ have been extended to cover the energy range E_p = 6–22 MeV (E_x = 18–33 MeV). In addition, angular distribution measurements have been made throughout this range, and γ-γ angular correlation measurements made over the region of a resonance at E_p = 8.86 MeV. From the data, and from comparison with other work, spin assignments are made for resonances as follows: E_x = 18.02 MeV, J = 3; E_x = 18.98 MeV, J = 2, 4; E_x = 19.90 MeV, J = 3; E_x = 20.43 MeV, $J^\pi = 2^-$; E_x = 24.77 MeV, $J^\pi = 2^+, 4^+$; E_x = 26.42 MeV, $J^\pi = 2^+, 4^+$ and E_x = 27.36 MeV, $J^\pi = 2^-, 4^-$. Radiative widths are also deduced. The region E_x = 23–32 MeV is identified as a giant dipole resonance on the 6.13 MeV, $J^\pi = 3^-$, T = 0 state of ^{16}O from angular distribution measurements. The nature of this giant resonance is discussed and it is compared with the ground-state giant dipole resonance; it is shown that the main part of the excited-state giant resonance can be accounted for by broad states with $J^\pi = 2^+$ and 4^+ with configuration $(1p_{1/2}^{-1}(2p, 1f))$ in this region.

Abstract: The strengths of the isospin forbidden E1 ground-state transitions from the 1^-, 6.95 MeV state of ^{40}Ca and the 1^-, 7.12 MeV state of ^{16}O were determined in a γ-ray resonance scattering experiment; the partial widths are $\Gamma_0 = 0.41 \pm 0.03$ eV and 0.06 ± 0.01 eV, respectively. The results are in good agreement with previous determinations, confirming the unusually large strengths of these E1 transitions. In addition, the widths of the 2^+, 6.91 MeV state of ^{40}Ca and the 2^+, 6.92 MeV state of ^{16}O were measured as $\Gamma_0 = 0.13 \pm 0.06$ eV and 0.094 ± 0.010 eV, respectively.

GROUND STATE PROTONS

The $^{16}O(\gamma,p_0)$ cross section has been measured for a series of photon energies between 100 and 300 MeV at proton angles of 45°, 90°, and 135°. Above 250 MeV, the results exceed simple shell-model predictions by several orders of magnitude. The data are compared with a calculation which involves Δ excitation in an intermediate state.

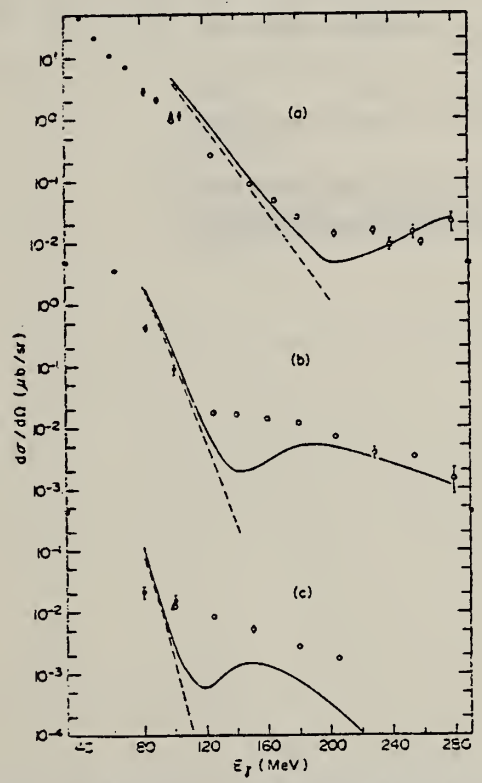

FIG. 1. Differential cross section in the laboratory system for the reaction $^{16}O(\gamma,p_0)^{15}N$ as a function of photon energy at proton angles (a) 45°, (b) 90°, and (c) 135°. Solid circles are used for the data of Ref. 2, open circles for the present results. Only statistical errors are shown. The curves represent the theoretical predictions of Ref. 5, as discussed in the text: dashed curve, single-step process only; solid curve, one-step plus two-step process (see Fig. 2).

Measurements were made of quasielastic scattering of electrons in the (e, e') reaction by the nuclei ^{9}Be, ^{12}C, ^{14}N, ^{16}O, and ^{27}Al. An experimental estimate is obtained of the effective mass of an intranuclear nucleon. At excitation energies up to 80 MeV, a ratio $M^*/M = 0.6$ is obtained, corresponding to a linear potential $V(E) = V_0 + 0.4E$ and in good agreement with the data on proton scattering by nuclei [C. M. and F. G. Perey, Atomic Data and Nuclear Tables 13, 294 (1974)]. At excitation energies above 120 MeV the nucleon effective mass turned out to be close to that of the free nucleon, $M^*/M = 0.9$.

Abstract—Mean cross sections for the photoproduction of ^{7}Be and ^{11}C from ^{19}F, ^{27}Al, ^{28}Si and ^{32}S targets, ^{7}Be from ^{10,11}B, and ^{11}C from ^{14}N and ^{16}O targets have been measured using bremsstrahlung beams in the energy range 0.3–1.0 GeV. The results have been compared with previous measurements and an excellent agreement has been found. In most cases, the values obtained turned out to be much larger than those expected from a simple spallation mechanism. A fragmentation and/or a fission-like process has been suggested in explaining the mechanism of such reactions.

999=1 GEV

The angular distribution for the $^{17}O(\gamma,n_0)^{16}O$ reaction was observed throughout the excitation energy region 4.3–7 MeV and at angles of 90° and 135°. The ground-state radiation widths for resonances in this energy region were extracted from the data. The value of the radiation width for the $d_{5/2} \rightarrow d_{3/2}$ spin-flip transition at 5.08 MeV was found to be approximately 1/3 of the value expected for a pure single-particle transition. The implications that this result has for the nuclear structure of ^{17}O is discussed. The effects of potential radiative capture were observed directly in a photoneutron reaction for the first time. At the location of the 5.38-MeV, 3/2⁻ resonance in ^{17}O, an anomalous symmetric dip was observed in the cross section at both reaction angles. The data were interpreted in terms of a general R-matrix reaction theory which includes the effects of internal, channel, and potential radiative capture in a self-consistent manner. The neutron channel was defined by incorporating an R-matrix analysis of the $^{16}O(n,n)^{16}O$ reaction into the present interpretation. The anomalous minimum at 5.38 MeV was found to be due to a unique feature of channel capture. The R-matrix prediction for the total cross section was extrapolated into the keV region and the significance that this cross section has for stellar nucleosynthesis is discussed.

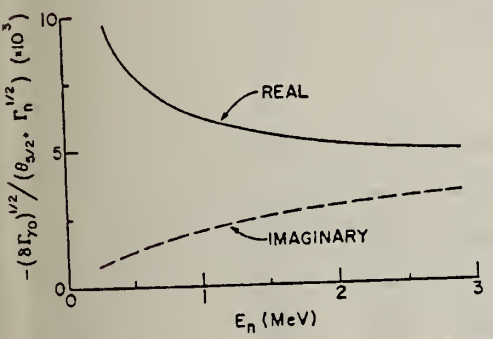

FIG. 3. Real and imaginary components of the $E1$ radiative channel capture for $p_{3/2}$ neutrons. In the MeV region the imaginary part is not negligible in comparison with the real component.

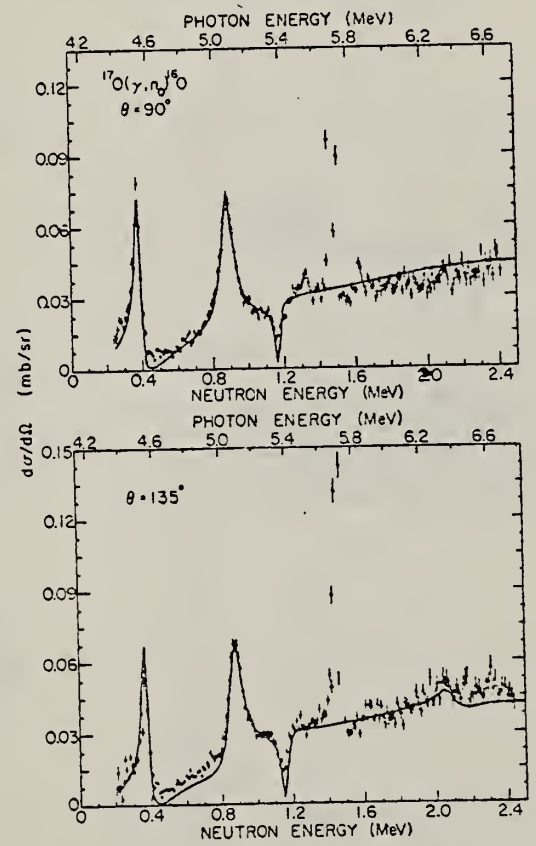

FIG. 4. R-matrix interpretation of the differential cross section for the $^{17}O(\gamma,n_0)^{16}O$ reaction. The points represent the observations while the curves represent the results of a "hard-sphere" external capture model.

over

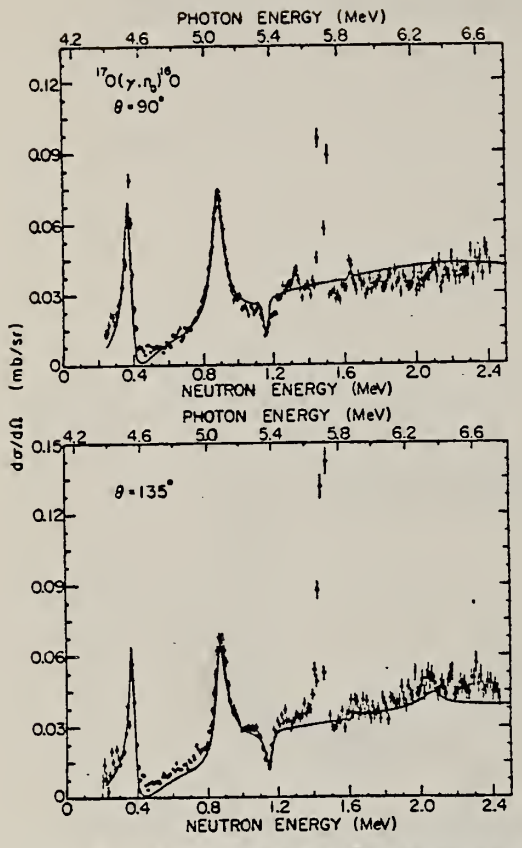

FIG. 5. Final R-matrix analysis of the observations of the $^{17}O(\gamma,n_0)^{16}O$ reaction. The parameters used in this analysis, Tables III and IV, also describe the $^{16}O(n,n)^{16}O$ reaction. The interference minimum at 5.38 MeV is not as deep as that given by the simple hard-sphere model.

The giant electric dipole resonance based on the ground state (0^+) of ^{16}O has been studied with the reaction $^{15}N(p,\gamma_0)^{16}O$ from E_p=8.6 to 18.0 MeV (E_γ=20.2 to 29.0 MeV). The $E1$ strength in (γ,p_0) is concentrated between E_γ=20 and 29 MeV where it exhausts about 15% of the $E1$ sum rule. Major peaks are displayed at 22.2 and 25.0 MeV and secondary structure at 21.0, 22.9, and in the 24 MeV region. The angular distributions indicate predominantly dipole radiation and are fairly constant over the entire range, except in the region of the secondary peaks where the coefficient of $P_2(\cos\theta)$ displays striking interference effects. This behavior supports the suggestion that these structures are due to interference between more complex states and the simple particle-hole configurations of the $E1$ resonance. The value of the coefficient of $P_2(\cos\theta)$ can be used to restrict greatly the allowed configurations of the p_0 channel—the solution is predominantly either $d_{3/2}$ wave or $s_{1/2}$ wave. The presence of terms in $P_1(\cos\theta)$ and $P_3(\cos\theta)$ indicates significant $E2$ strength which increases above the $E1$ resonance. Data are also presented on the reactions $^{15}N(p,\gamma_1-\gamma_4)^{16}O$ and $^{15}N(p,\alpha\gamma_{15.1})^{12}C$.

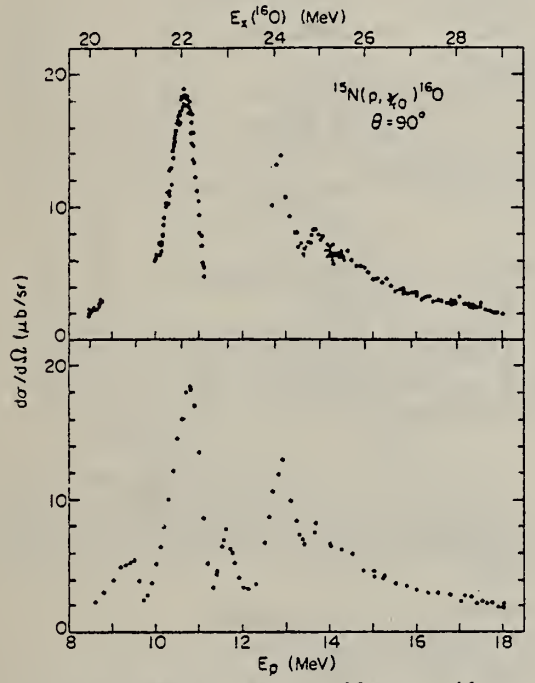

FIG. 2. The 90° yield of $^{15}N(p,\gamma_0)^{16}O$. Top: Measurements taken over selected areas to search for intermediate and fine structure. Bottom: Yields extracted from the angular distribution measurements. The proton energy scale here and in subsequent figures is corrected for the energy loss in the entrance foil of the cell.

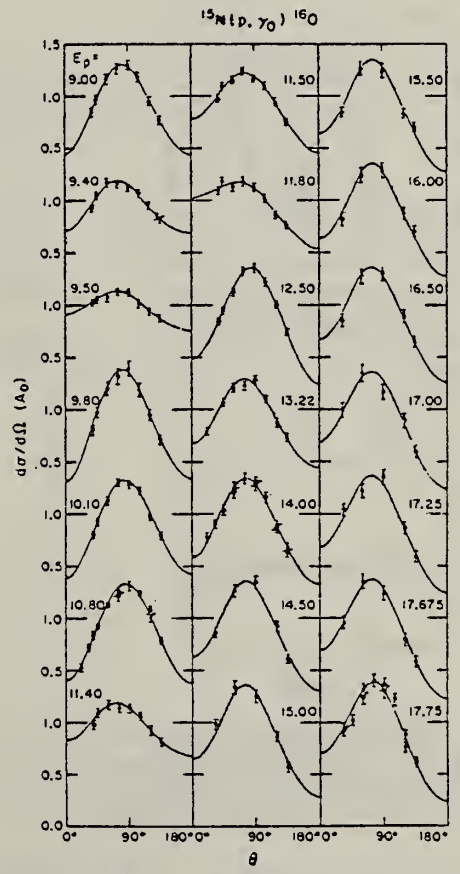

FIG. 3. Selected angular distribution measurements from $^{15}N(p,\gamma_0)^{16}O$, plotted in units of A_0.

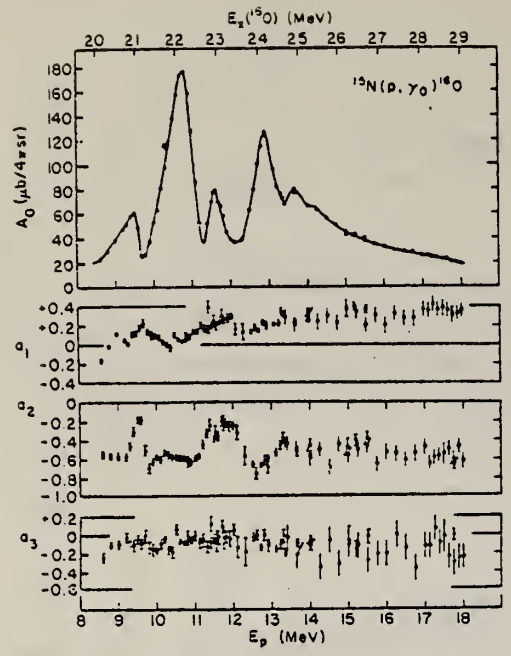

FIG. 4. Plot of A_0, a_1, a_2, and a_3 obtained from Legendre polynomial fits (k = 3) to the measured angular distributions of $^{15}N(p,\gamma_0)^{16}O$.

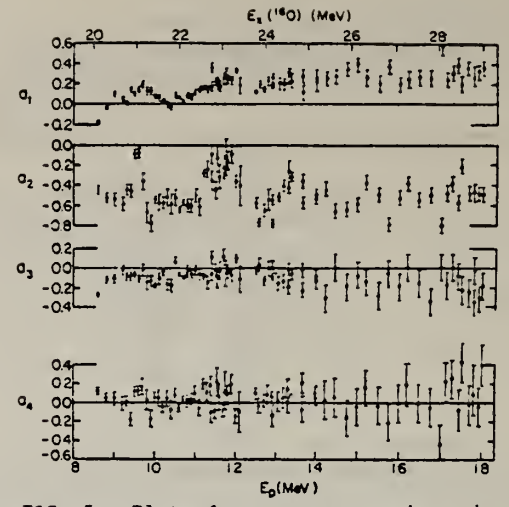

FIG. 5. Plot of a_1, a_2, a_3, and a_4 obtained from Legendre polynomial fits (k = 4) to the measured angular distributions of $^{15}N(p,\gamma_0)^{16}O$.

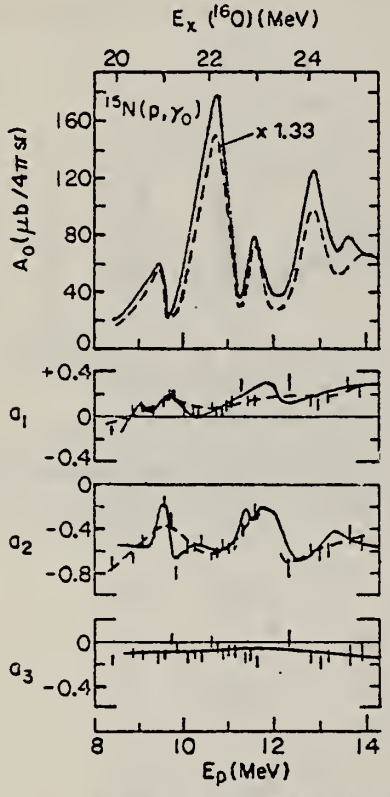

FIG. 6. The results of this experiment on $^{15}N(p,\gamma_0)^{16}O$ (solid curves) compared with those of Earle and Tanner[24] (data points and dashed curves). To facilitate comparison the A_0 curve of Ref. 24 has been multiplied by 1.33.

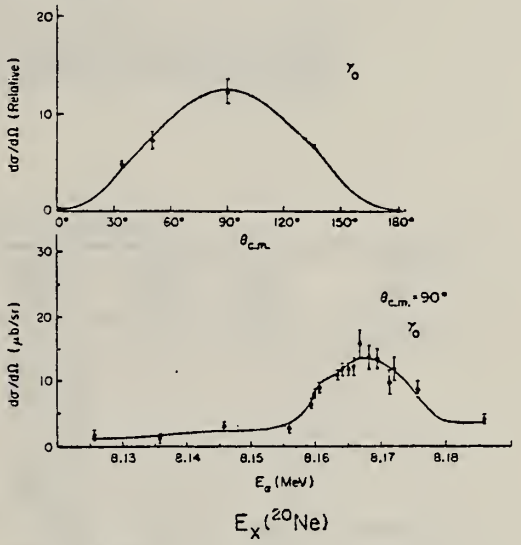
Six ^{20}Ne levels have been investigated in detail via the $^{16}O + \alpha$ channel between $6.9 \lesssim E_\alpha \lesssim 10.2$ MeV. Level parameters for states at $E_x(^{20}Ne) = 10.264 \pm 0.008$, 11.077 ± 0.008, 11.259 ± 0.008, 11.552 ± 0.008, 12.237 ± 0.008, and 12.390 ± 0.008 MeV have been extracted from γ decay properties and phase shift analysis of the elastic scattering. With the exception of the 11.552 and 12.39 MeV states, these levels display primarily $T = 1$ characteristics. In addition to some previously reported $T = 0$ states, several other weak γ decaying resonances were observed at 11.97 ± 0.04, 12.05 ± 0.04, and 12.49 ± 0.02 MeV but were not studied in detail. Charge dependent matrix elements (4–120 keV) for isospin mixing of $T = 1$ states with nearby $T = 0$ states were estimated from the measured level parameters.

LIFETIME



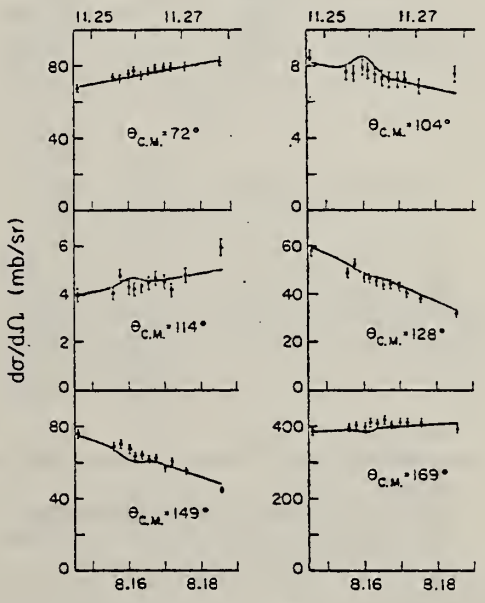


FIG. 4. The $E_\alpha = 8.16$ MeV resonance ($E_x = 11.26$ MeV). Same format as Fig. 2. The angular distribution fit is typical of a $1^- \rightarrow 0^+$, $E1$ transition. The γ_0 excitation function fit has a CL of 0.9. The ES fit includes the contributions from a 300 eV, $L = 1$ resonance.

The total cross sections relative to photoproduction off the proton have been measured for the reactions $^{16}O(\gamma,\pi^+)^{16}N$ and $^{9}Be(\gamma,\pi^-)^{9}Li$ over the energy region from the production threshold up to 12 MeV over threshold. A distorted wave impulse approximation calculation has been performed for the $^{16}O(\gamma,\pi^+)^{16}N$ reaction and is seen to be $\simeq$30% higher than the observed cross section from threshold to 10 MeV. The $^{9}Be(\gamma,\pi^-)^{9}Li$ reaction represents the first (γ,π^-) measurement near threshold in which the cross section is not dominated by the $\vec{\sigma}\cdot\vec{\epsilon}$ term in the production Hamiltonian.

[NUCLEAR REACTIONS $^{16}O(\gamma,\pi^+)^{16}N$, $^{9}Be(\gamma,\pi^-)^{9}Li$, bremsstrahlung end point energies to 175 MeV, measured $\sigma(E)$; calculated $\sigma(E)$, DWIA.]

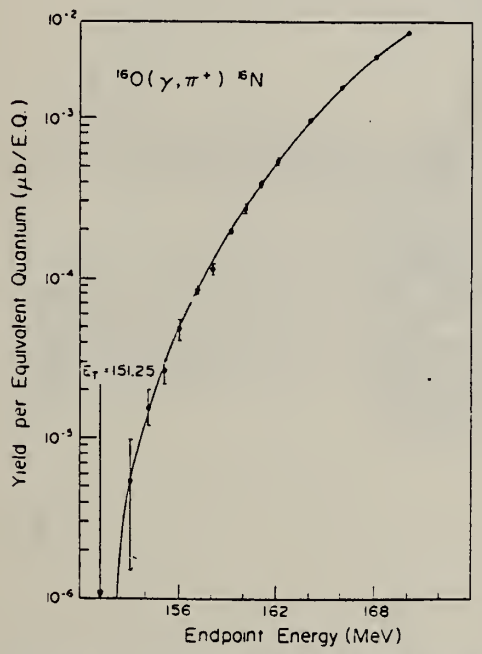

FIG. 1. The $^{16}O(\gamma,\pi^+)^{16}N$ yield per equivalent quantum. The solid curve is the result of a fit as described in the text.

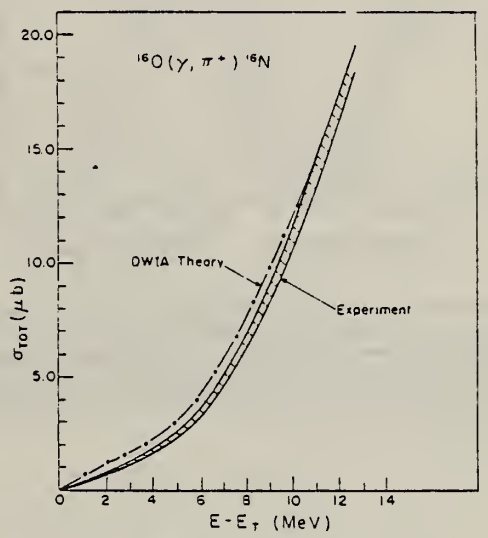

FIG. 3. The measured and calculated total cross sections for $^{16}O(\gamma,\pi^+)^{16}N$. E_T is the pion threshold energy and E is the bremsstrahlung end point energy. The shaded region represents the statistical uncertainty on the cross section. The systematic error is an additional 5%.

The cross sections of reaction $(\gamma,\pi^{+}p)$ on Li^{6} C^{12} nuclei were measured in the 0–600 MeV/c range of momentum transfer to the residual nucleus. For large values of momenta, cross section values disagree with calculations carried out within the framework of a shell model and a model of quasi-free meson photoproduction on nuclei.

PACS numbers: 25.20. + y

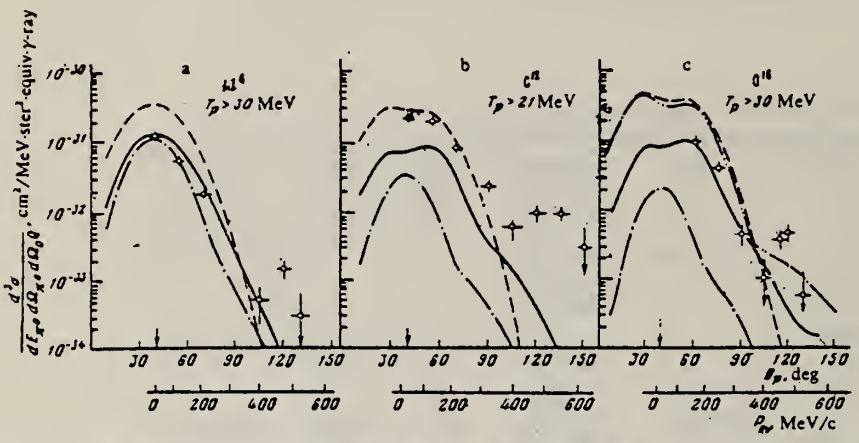

FIG. 1. Dependence of reaction cross section on the proton angle of emission: O—experiment, with total measurement errors; — —calculations using plane waves; —— final state interactions taken into account; ————effect of S-shell shown separately; ————calculations with momentum distribution from Ref. 3 with allowance for correlation by the Jastrow model. Oscillator parameters $\alpha_1 = \alpha_2 = 115$ MeV/sec for Li^6 nucleus,[12] 120 MeV/sec for C^{12} and 113 MeV/sec for O^{16}.[13] Arrow indicates angle of proton emission in the case of reaction $\gamma + p \rightarrow \pi^0 + p$.

The cross section and angular distribution for the reaction $^{16}O(\gamma,n_0)^{15}O$ have been measured over an excitation energy range of 25–45 MeV. Neutron time-of-flight spectra were recorded at six angles (22.5°, 45°, 67.5°, 90°, 112.5°, and 135°) and at four bremsstrahlung end-point energies (30, 35, 40, and 45 MeV). Differential cross sections deduced from these spectra were fitted by a fourth-order Legendre-polynomial expansion. The cross section obtained from this expansion decreases smoothly from 3.95 mb at 25.5 MeV to 0.22 mb at 43.8 MeV. The appearance in this analysis of large first-, third-, and especially fourth-order coefficients, is strong evidence for significant $E2$ cross section. An $E2$ cross section extracted from the data exhausts approximately 68% of the isovector $E2$ energy-weighted sum rule. The present data are compared to previous related measurements and excellent agreement is seen. In comparisons with theoretical studies on ^{16}O, there is good general agreement but relatively poor detailed agreement.

[NUCLEAR REACTIONS $^{16}O(\gamma,n_0)^{15}O$, $E_x = 25–45$ MeV; measured $\sigma(E_x,\theta)$; deduced $E2$ strength.]

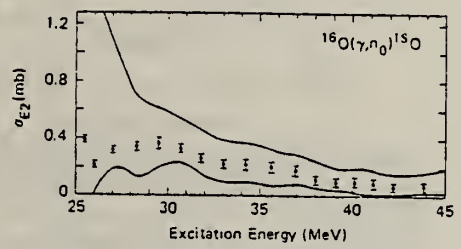

FIG. 6. Electric-quadrupole cross section vs excitation energy for the $^{16}O(\gamma,n_0)^{15}O$ reaction. The solid lines are upper and lower limits on this cross section based on the present data alone. The data points were obtained by including information from polarization measurements (see text).

We demonstrate that polarized-proton radiative capture may be used to unambiguously identify concentrations of magnetic dipole strength. Three $M1$ resonances are observed in the doubly magic ^{16}O nucleus between $E_x = 16$ and 20 MeV, with a relatively large total γ_0-transition strength $B(M1)\uparrow \geq 0.24\mu_0^2$.

POLARIZED PROTONS

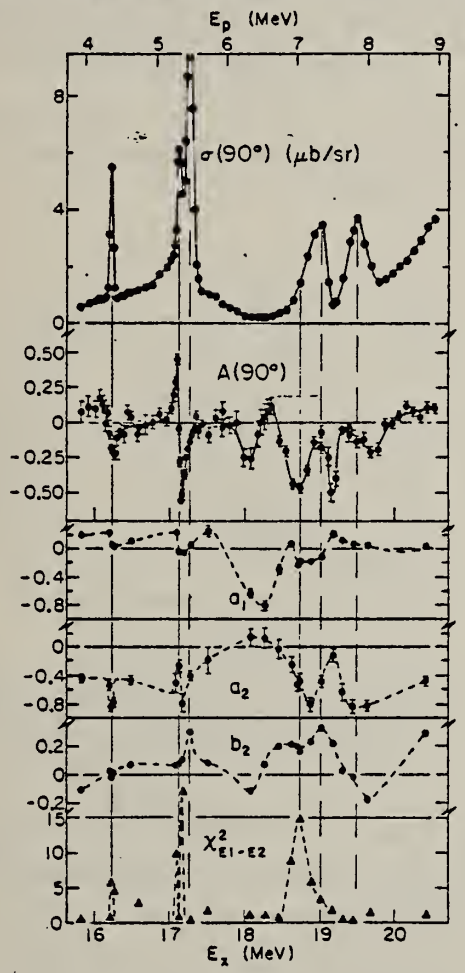

FIG. 1. Excitation curves for $^{15}N(p_{pol},\gamma_0)^{16}O$. From top to bottom: $\sigma(90°)$, $A(90°)$, and the a_1, a_2, and b_2 coefficients (third- and fourth-order coefficients not shown); reduced χ^2 for the angular distribution fits assuming only $E1$ and $E2$ radiation. The curves are to guide the eye. The vertical solid and dashed lines indicate $M1$ and $E1$ resonances, respectively.

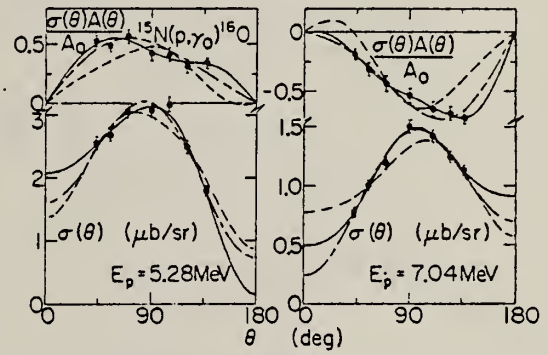

FIG. 2. Representative angular distributions which require $M1$ radiation. Solid curve, $E1+E2+M1$; dashed curve, $E1+E2$; long-short dashed curve, $E1+M1$ calculated fits.

The capture reaction $^{13}C(^3He,\gamma)^{16}O$ has been studied over an excitation energy range of 25 to 30 MeV in ^{16}O. The 90° differential yield curve for the ground state transition shows resonances at E_x = 25.1, 26.0 and 27.3 MeV. The measured angular distributions are consistent with a spin and parity assignment of $J^\pi = 1-$ to these states. The relation between this structure and that observed in the $^{15}N(p,\gamma_0)^{16}O$ reaction is discussed. The 90° differential yield curves for the doublet transitions $\gamma_1 + \gamma_2$ and $\gamma_3 + \gamma_4$ were also measured. The former shows resonances at E_x = 26.0, 26.6, 27.2, 27.7, and 28.6 MeV, while the latter shows a broad resonance centered at $E_x \simeq 27.5$ MeV with mild structure. Both curves suggest the existence of giant resonance strength built on the excited states of ^{16}O.

HE=HE3

[NUCLEAR REACTIONS $^{13}C(^3He,\gamma)^{16}O$, $E_{^3He}$ = 3.0-8.5 MeV, measured $\sigma(E_{^3He},E_\gamma,\theta)$. ^{16}O deduced resonances and structure in giant resonance region. Enriched ^{13}C target.]

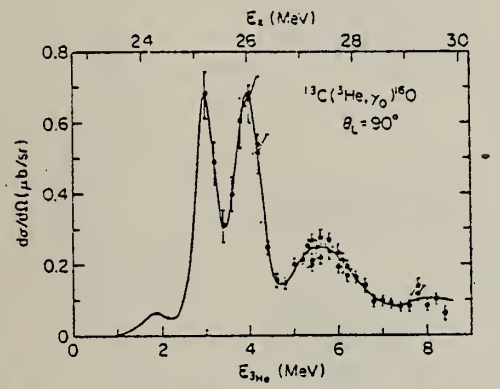

FIG. 2. Excitation function of the differential cross section for $^{13}C(^3He,\gamma_0)^{16}O$ at θ_{lab} = 90°. The data up to $E(^3He)$ = 3.0 MeV are taken from Ref. 5 and normalized to the present work at $E(^3He)$ = 3.0 MeV.

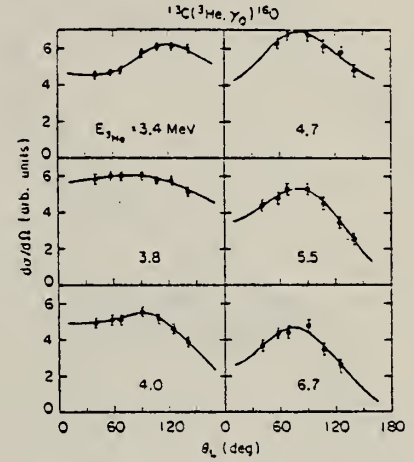

FIG. 3. Angular distributions for the $^{13}C(^3He,\gamma_0)^{16}O$ reaction. The curves are least squares fits of Eq. (1) with k = 1 → 3.

TABLE I. Angular distributions in $^{13}C(^3He,\gamma_0)^{16}O$ as determined from the data of Fig. 3 and a measurement at 2.9 MeV.

$E_{^3He}$ (MeV)	E_x (MeV)	W(θ) a_1	a_2	a_3

Differential cross sections for $^{10}B(\gamma,\pi^+)^{10}Be$ to the ground and first excited states of ^{10}Be separately and $^{16}O(\gamma,\pi^+)^{16}N$ to the sum of the four lowest-lying states in ^{16}N have been measured at laboratory angles of 45° and 90° for pions with kinetic energies from 80 and 210 MeV. The results, which are the first to discrete nuclear final states in the $\Delta(1236)$ region, are in qualitative agreement with several distorted-wave impulse-approximation calculations.

PACS numbers: 25.20.+y

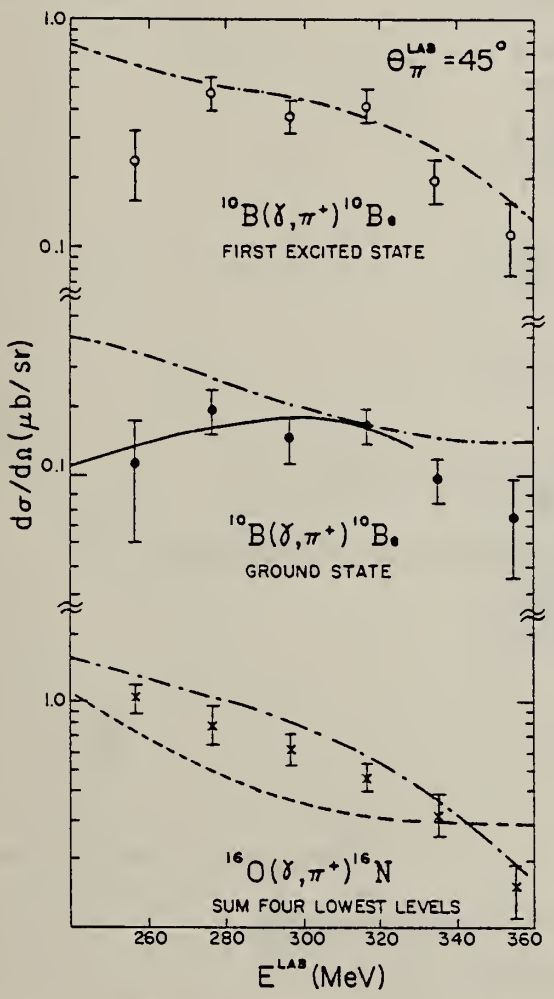

FIG. 3. Same as for Fig. 2, but at a pion laboratory angle of 45°.

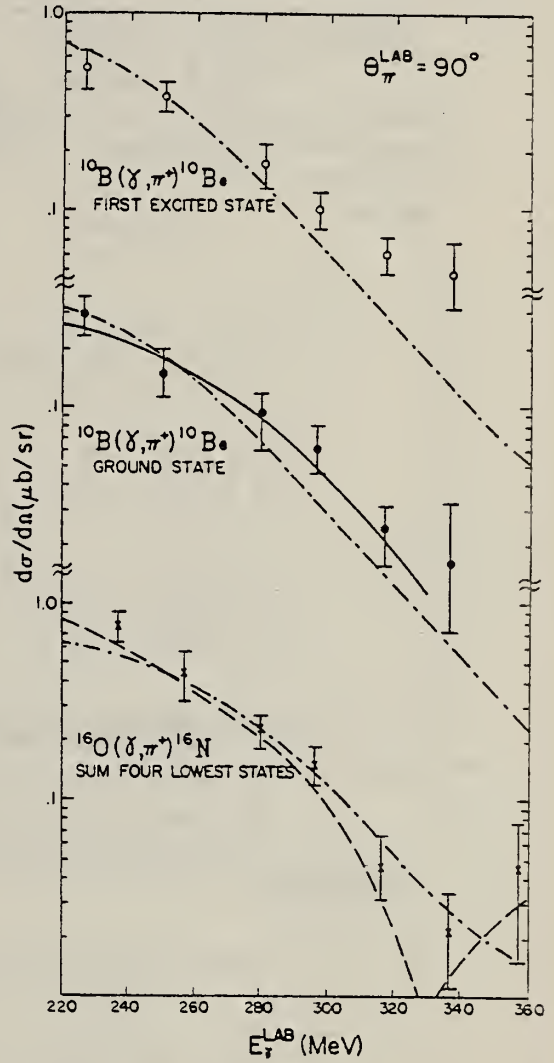

FIG. 2. Differential cross sections for $^{16}O(\gamma,\pi^+)^{10}Be$ at 90°. The solid circles represent the contributions from the ground state of ^{10}Be, the open circles are for the first excited state of ^{10}Be, and the crosses are for the sum of the four lowest-lying levels in ^{16}N. The solid line is the calculation of Singham and Tabakin (Ref. 8), the dashed line that of Devanathan *et al.* (Ref. 9), and the dot-dashed lines are from Nagl and Uberall (Ref. 10). Pion energies can approximately be found by subtracting 140 MeV from the photon energies.

BREMS. TIP

Differential (γ, n_0) cross sections on ^{12}C and ^{16}O have been measured for photon energies 60 MeV $\leq E_\gamma \leq$ 160 MeV. These results combined with the corresponding (γ, p_0) cross sections support an absorption mechanism of the photon by neutron–proton pairs.

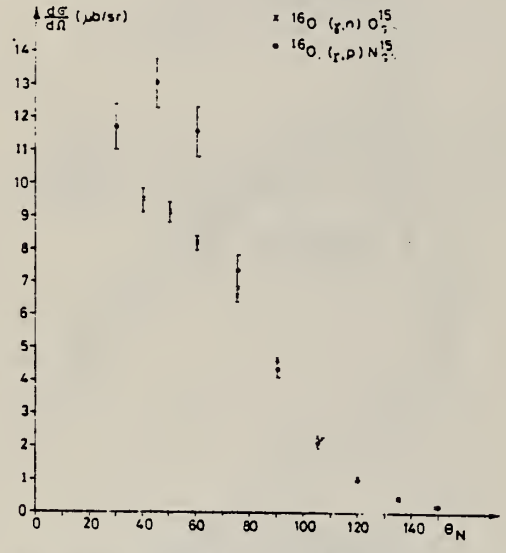

Fig. 2. Angular distribution at E_γ = 60 MeV. Proton data: ref. [11].

Cross sections have been measured for elastic scattering of photons by the nuclei ^{12}C and ^{16}O in the region of the giant resonance. The energy resolution achieved in the experiment is comensurate with the energy resolution in the total photoabsorption cross section. It is shown that study of the cross sections for total absorption and elastic scattering of photons permits spectroscopic information to be obtained on the high-lying states of nuclei.

TEST VIRTUAL PHOTONS

The virtual photon spectrum shape and intensity within several MeV of the kinematic limit was measured for $^{9}Be(e,\pi^{+})^{9}Li,e'$ and $^{16}O(e,\pi^{+})^{16}N,e'$ ($T_{\pi}=28$ MeV, $\theta_{\pi}=90°$). The intensity over this interval is 1.25 ± 0.10 times plane-wave virtual photon theory predictions; the shape agrees with theory within errors. Measurements on the proton 30 to 55 MeV below the end point agree with the intensity predictions of virtual photon theory within the errors ($\pm 8\%$).

[NUCLEAR REACTIONS $^{16}O(e,\pi^{+})$, $E=180.4$ MeV; $^{9}Be(e,\pi^{+})$, $E=184.8$ MeV; measured $\sigma(E_{\gamma},90°_{lab})$ relative to (γ,π^{+}), near $E_{\gamma}=28$ MeV. $^{1}H(e,\pi^{+})$, $E=230$ MeV; measured $\sigma(E_{\gamma},90°_{lab})$ relative to (γ,π^{+}), near $E_{\gamma}=18$, 30 MeV. Compared to PWBA virtual photon theory.]

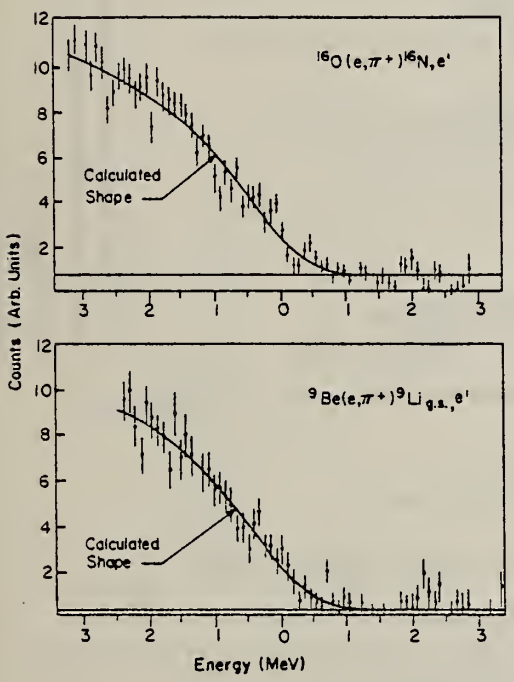

FIG. 1. Number of pions as a function of virtual photon energy. The zero on the abscissa corresponds to the virtual photon spectrum end point, 179.9 MeV for ^{16}O and 184.3 MeV for ^{9}Be. The solid curves were obtained as described in the text and normalized to the experimental data.

TABLE I. Results for R/V, the real-to-virtual ratio as defined in the text. The quantity E_0 is the incident electron total energy, T_{π} the pion kinetic energy, k the virtual photon energy, and ΔT_{π} the averaging interval over pion energy in the experiment (corresponding to the range of k). Note that k is close to the end point for ^{16}O and ^{9}Be but 30 to 55 MeV below for ^{1}H.

	$^{16}O(e,\pi^{+})$	$^{9}Be(e,\pi^{+})$	$^{1}H(e,\pi^{+})$

DATA ALSO IN 81AR3

Double differential cross sections for the photo-emission of protons and charged pion production were investigated for a number of target nuclei (He, Be, C, O, Al, Ti, Cu, Sn, Pb) in the photon energy range k = (215–386) MeV. On the basis of these experimental results the total hadronic cross section was determined.

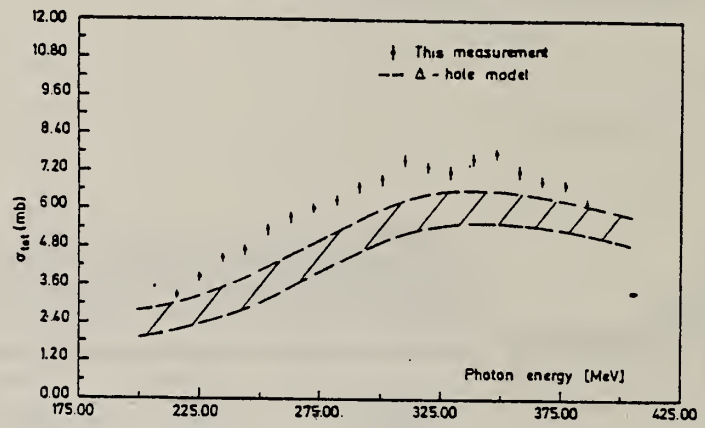

Fig. 6. Total hadronic cross section for ^{16}O (statistical errors only). Data are compared to a calculation in the Δ-hole formalism [11].

The total hadronic cross sections for all measured elements can be parametrized in the form

$\sigma(k,A) = \sigma_0(k) \cdot A^x$,

A being the atomic number, with a constant exponent $x = 1.1$. The photon energy dependence of σ_0 is shown in fig. 7. Compared to the mean cross section for a free nucleon (the solid line in fig. 7) the excitation of the Δ-resonance is suppressed. Such a suppression is expected in the Δ-hole model [11].

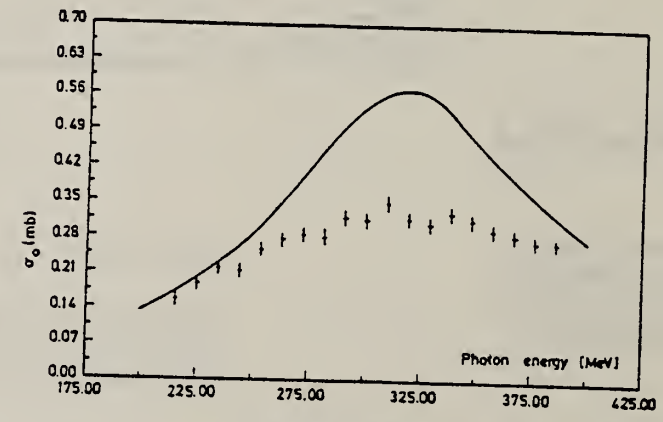

Fig. 7. Parameter σ_0 as a function of photon energy (data points) compared to the mean cross section for a free nucleon (solid line).

Abstract: Double differential cross sections for the photoemission of protons and charged pion photoproduction were investigated for a number of target nuclei (He, Be, C, O, Al, Ti, Cu, Sn, Pb) using the tagged bremsstrahlung beam at the Bonn 500 MeV-Synchrotron in the photon range k = (215-386)MeV. On the basis of these experimental results the total hadronic cross section was determined.

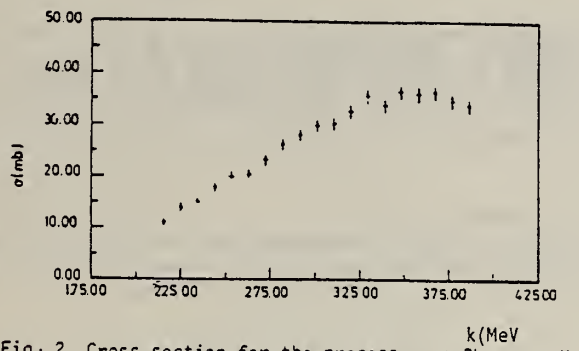

Fig. 2. Cross section for the process: $\gamma + Pb \rightarrow p + X$. The proton threshold is 58 MeV.

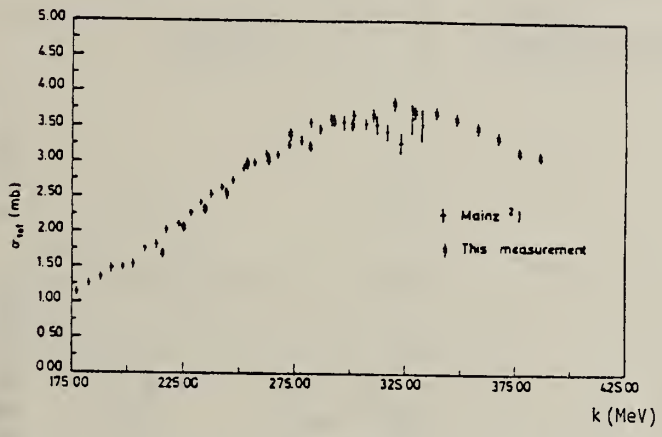

Fig. 3. Total hadronic cross section for Be. The data are compared to the cross section taken from ref.[2]).

The photon energy dependence of the total cross sections for heavier nuclei are similar to the Be results. The complete data set can be parametrized in the form

$$\sigma(k,A) = \sigma_0(k) \cdot A^x.$$

The exponent is constant x = 1.1. The photon energy dependence of σ_0 is shown in fig. 4. Compared to the mean cross section for a free nucleon, the excitation of the Δ-resonance is suppressed.

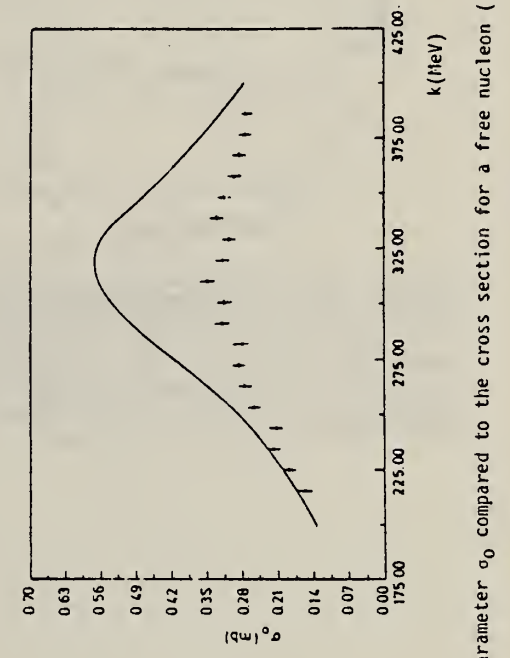

Fig. 4. Parameter σ_0 compared to the cross section for a free nucleon (full line).

Angular distribution coefficient a_2 for the $^{16}O(\gamma,p_3)$ reaction is $-0.14\ ^{+0.19}_{-0.23}$

POLARIZED PHOTONS

The $^{16}O(\gamma,p_0)$ reaction has been studied with linearly polarized bremsstrahlung photons in and below the giant $E1$ resonance. The parity of the absorbed radiation was determined from the observed azimuthal asymmetry of the emitted protons. Combined with unpolarized measurements the polarized results determine the proton decay amplitudes of the $M1$ resonance at $E_x = 16.2$ MeV in ^{16}O. The shape of the unpolarized $^{16}O(\gamma,p_3)$ angular distribution in the giant $E1$ resonance was derived from the measured analyzing power.

[NUCLEAR REACTIONS $^{16}O(\gamma,p)$, $E = 15-25$ MeV; measured analyzing power $\theta = 90°$ linearly polarized bremsstrahlung; ^{16}O dipole levels deduced π; 16.2 MeV 1^+ resonance deduced p_0 decay amplitudes; ^{16}O GEDR deduced p_3 angular distribution.]

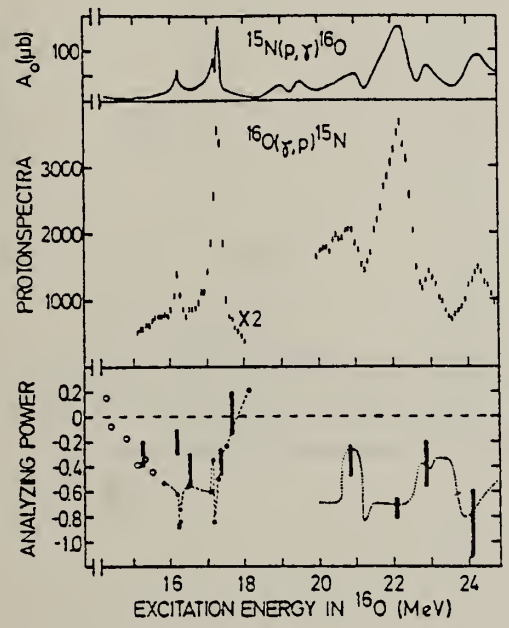

FIG. 2. The upper part shows the total $^{15}N(p,\gamma)^{16}O$ cross section from Ref. 8. The middle part gives the original proton energy spectra from this measurement. In the lower part the measured analyzing power at 90° is presented as error bars together with calculated values taking a_2 coefficients from the literature and assuming only $E1$ excitation.

Abstract: The measurement of recoiling nucleus momentum distributions in (e,e'p) reactions has been performed for p-hole states in ^{12}C and ^{16}O under extended kinematical conditions. The analysis of the experimental data has been performed without requiring the usual factorization of the cross section. The sensitivity of the data and of the analysis for deducing bound and scattering proton states is discussed.

DLTQ MEV/C

DATA ANALYSIS

A large discrepancy is found between the value for the integrated total photonuclear cross section for ^{16}O determined from the sum of the partial cross sections and that obtained from a total photon absorption measurement.

[NUCLEAR REACTIONS $^{16}O(\gamma, \text{tot}:E_\gamma)$, $(\gamma, \text{partial}: E_\gamma)$: integrated cross sections; sum rule; meson-exchange factor K, A dependence.]

Abstract: The inclusive partial photoneutron cross section $\sigma(\gamma, 1n\ldots)$ and $\sigma(\gamma, 2n\ldots)$ and the total photoneutron cross section $\sigma^{(1)}(E_\gamma) = \sum_{i=1}\sigma(\gamma, in\ldots)$ for ^{16}O have been measured with monoenergetic photons in the energy region above the giant resonance and below the meson thresholds. Comparison with other data shows the dominance of the (γ, pn) process in this energy region and thus underscores the importance of the mechanism of photon absorption by a correlated proton-neutron pair in the nucleus; thus, satisfactory agreement of modern versions of the quasideuteron theory with the data has been obtained. The measured integrated total photoneutron cross section up to 140 MeV is 0.67 ± 0.07 TRK sum-rule units.

E NUCLEAR REACTIONS $^{16}O(\gamma, xn)$, $E = 24$–133 MeV; integrated σ for $x = 1, 2$, moments; deduced interaction mechanisms. Monoenergetic beam.

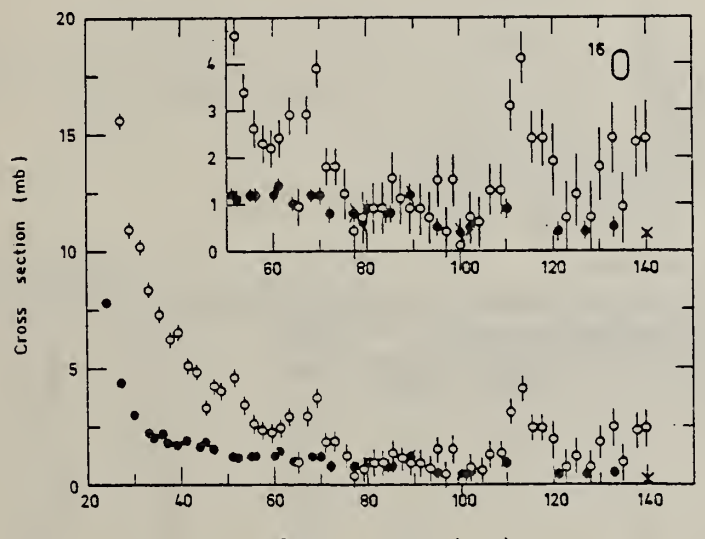

Fig. 7. Comparison of the present results for $\sigma^{(1)}(E_\gamma)$ (solid data points) with the $\sigma(\gamma, \text{tot}: E_\gamma)$ data from Mainz [43] (open data points) and the $\sigma(\gamma, pn)$ datum at $E_\gamma = 140$ MeV from Bonn [44] (cross; converted to a total cross section by multiplication by 4π).

Abstract: A new TOF facility has been built for measurements of differential (γ, n) cross sections to discrete final states of light nuclei in the photon energy range between giant resonance and pion threshold. The observed neutron angle θ_n can continuously be varied between 0° and 150°, and additionally measurements at 175° and 180° are possible. Differential cross sections for the reaction $^{16}O(\gamma, n_0)^{15}O$ are presented for $E_\gamma = 60$ MeV ($40° \leq \theta_n \leq 149°$) and for $\theta_n = 90°$ (60 MeV $\leq E_\gamma \leq$ 160 MeV). The results, combined with the corresponding (γ, p_0) cross sections, indicate an absorption mechanism of high energy photons by neutron–proton pairs.

E NUCLEAR REACTION $^{16}O(\gamma, n_0)$, $E = 60$–160 MeV, $\theta_n = 40°$–149°, measured $\sigma(E_\gamma, \theta_n)$. Targets D_2O and H_2O.

16885 MEASUREMENT OF THE OUTFLOW OF PHOTONEUTRONS AND CALCULATION OF THE CROSS SECTION OF THE $^{17}O(\gamma,n)^{16}O$ REACTION AT LOW ENERGIES. Berzin, A. K.; Gryaznov, A. L.; Meshcheryakov, R. P.; Startsev, A. A.; Khimenkov, Yu. V. Tr., Vses. Nauch.-Issled. Inst. Yadern. Geofiz. Geokhim.; No. 9, 113-115(1971). (In Russian).

Yields from the reaction $^{17}O(\gamma,n)^{16}O$ were measured from 4 to 8.5 MeV, and the cross section for the reaction was calculated. It exceeded 0.3 mb at the highest energy. Errors in the determination of photoneutron yield were estimated to be 10 to 15%. Application of these data and the photoneutron method to the estimation of the water-to-oil contact position in oil wells was explored. (2 figures) (RWR)

Abstract: The giant resonance region of ^{17}O has been investigated by means of inelastic electron scattering in a momentum transfer range 0.34–0.98 fm^{-1}. The data reveal a broad dipole resonance centred at 22–23 MeV excitation, with strength extending down to 10–12 MeV. A smaller resonance found between 17.5 and 19.6 MeV excitation has a form factor consistent with a C2 transition. Levels at 16.5 and 17.1 MeV excitation are also reported for the first time. Fine structure is observed between 11 and 15 MeV which correlates well with the positions of previously known levels. A particle-hole model with the Kuo-Brown residual interaction gives a satisfactory description of the strength distribution and q-dependence of the giant dipole resonance, although a scale factor of 1.85 is required to achieve agreement in magnitude.

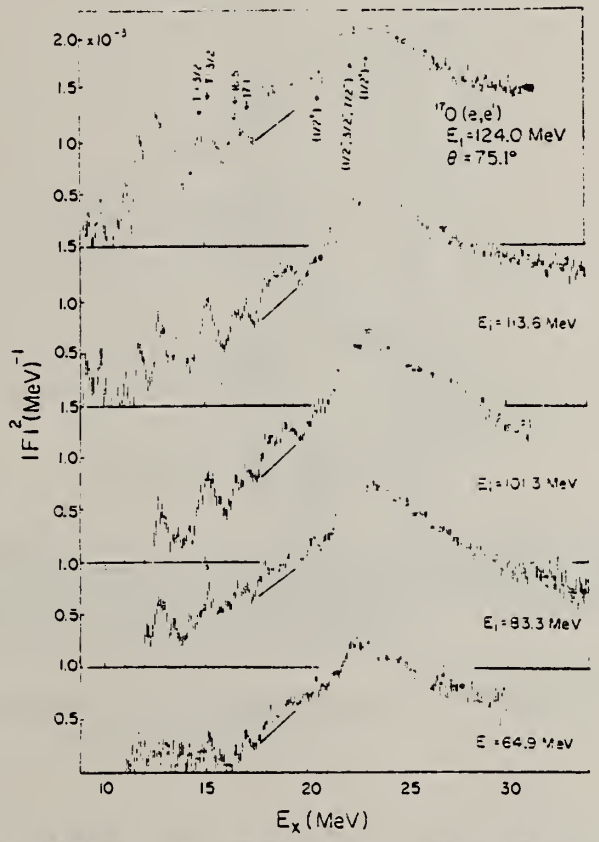

Fig. 3. Electron scattering spectra from ^{17}O in the giant resonance region, presented as differential form factors. The radiation and background tails have been removed. The straight lines approximately delineate the 17.5–19.6 MeV structure.

over

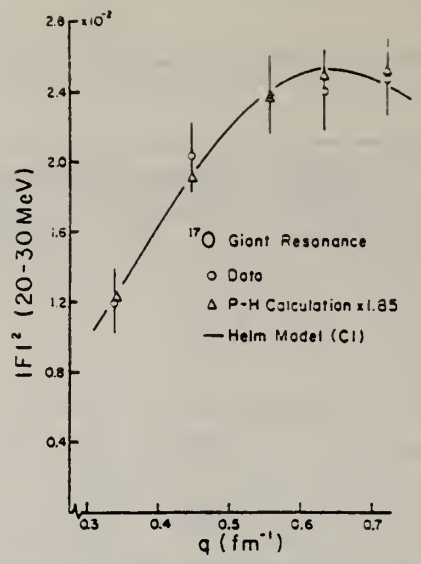

Fig. 4. The total form factor in the 20–30 MeV region of ^{17}O. The triangles represent the particle-hole calculations, scaled upward by 1.85, based on the Kuo-Brown matrix elements. The solid line is a Helm model fit assuming a C1 transition.

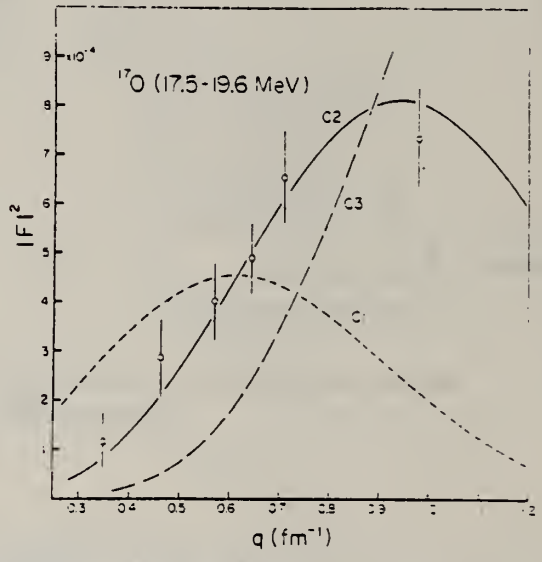

Fig. 5. The total form factor for the 17.5–19.6 MeV region of ^{17}O. The Helm model fits are based on R and q determined from the C1 fit in fig. 4.

Photoneutron spectra from ^{17}O have been obtained at bremsstrahlung end-point energies of 13.7, 16, 22, 28, and 34 MeV using the neutron time-of-flight technique. The angle between the incident photon beam and the 49.2-m flight path was 98°. From the measured spectra the differential cross section for the $^{17}O(\gamma,n_0)^{16}O$ reaction between 5 and 33 MeV was obtained. The considerable structure in the cross section is compared with the known spectrum of levels for this nucleus compiled from previous studies using various reactions. In the region below 19 MeV, 18 resonances correspond to levels previously identified. In addition at least 12 other resonances which have not been seen previously have been observed. In the giant-dipole resonance region (above 19 MeV) the present results delineate the $T = 1/2$ strength. The measurement is compared to the $^{16}O(p,\gamma_0 + \gamma_1)^{17}F$ reaction with the expected similarities observed. The measurement also is compared to 1p,2p-1h shell-model calculations.

[NUCLEAR REACTIONS $^{17}O(\gamma,n_0)^{16}O$, $E_x = 5.0-33.0$ MeV; measured photoneutron time-of-flight spectra; deduced $(d\sigma/d\Omega)$ $(E_x, 98°)$, resonant structure; $T=\frac{1}{2}$ strength of the GDR.]

Photoneutron cross sections involving the emission of one and two neutrons from ^{17}O have been measured over the energy interval 8.5 to 39.7 MeV using monoenergetic photons from positron in-flight annihilation. The 6-MeV wide giant dipole resonance is observed to be centered at 23 MeV and a pygmy resonance is seen at about 13 MeV. Such structure as is apparent in the cross sections is not as pronounced as for the cases of ^{16}O and ^{18}O. Comparison of the total photoneutron cross section with recent ground-state data indicates that much of the pygmy resonance decays to the ground or first excited state of ^{16}O, but that the giant dipole resonance decays mainly to highly excited states in the daughter. Excellent agreement is observed between the present results and a recent two-particle, one-hole shell-model calculation of the isospin-split giant dipole resonance states for this nucleus. New photoneutron cross-section results for ^{16}O up to 39.7 MeV are reported as well.

[NUCLEAR REACTIONS $^{17}O(\gamma,n)$, E_γ=8.5–39.7 MeV and $^{16}O(\gamma,n)$, E_γ=15.9–39.7 MeV; measured 4π neutron yield for monenergetic photons; $\sigma(E_\gamma,1n)$, $\sigma(E_\gamma,2n)$, integrated cross sections, isospin splitting of the giant resonance for ^{17}O.]

[a] From A. H. Wapstra and K. Bos, At. Data Nucl. Data Tables 19, 215 (1977).

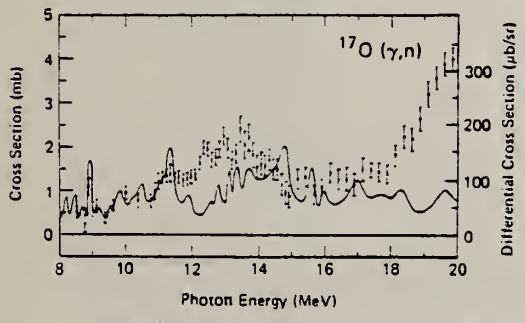

FIG. 5. The present results for the $^{17}O(\gamma,n)$ cross section at low energies (data points) are compared with the ground-state differential cross section of Ref. 2 (solid line). The vertical scale has been chosen to reflect a factor of 4π between the two cross-section scales. Below 10.2 MeV (the threshold for photoneutron emission to the first excited state of ^{16}O), the two results should be identical except for (a) angular-distribution effects in the differential measurement and (b) resolution differences.

(over)

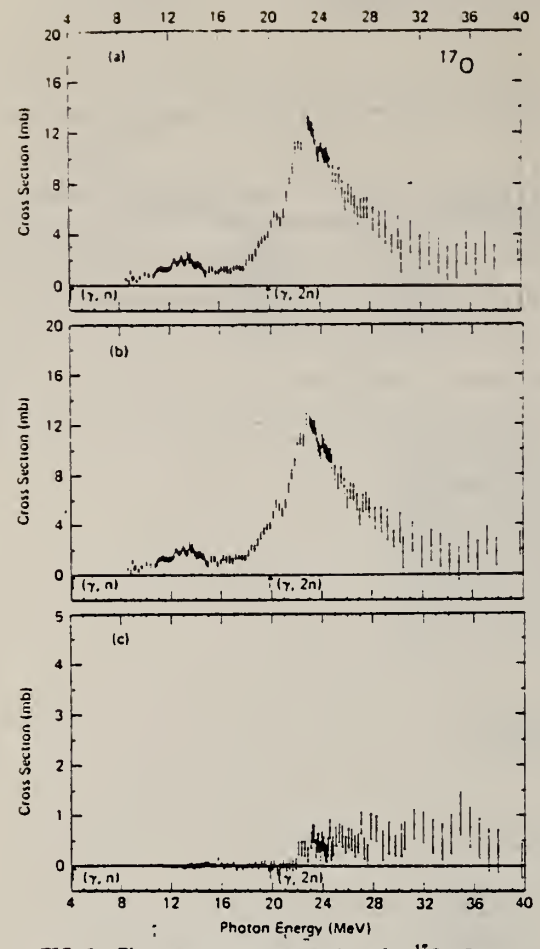

FIG. 3. Photoneutron cross sections for ^{17}O: Part (a) shows the total photoneutron cross section $\sigma(\gamma, n_{tot}) = \sigma[(\gamma, n) + (\gamma, pn) + (\gamma, \alpha n) + (\gamma, 2n)]$; part (b) shows the single photoneutron cross section $\sigma(\gamma, 1n) = \sigma[(\gamma, n) + (\gamma, pn) + (\gamma, \alpha n)]$; part (c) shows $\sigma(\gamma, 2n)$. The plotted error bars indicate the statistical uncertainties. The threshold energies are indicated by arrows in this and other plots.

J-PI, LFT

Cross sections for the radiative capture of tritons by ^{14}N have been measured in the incident energy range 0.8 to 3.3 MeV and found to be of order 200–300 nb/sr. The 90° excitation functions exhibit resonant structures for the transitions to the $5/2^+$ ground state of ^{17}O and the $1/2^+$ (0.87-MeV) first excited state. Multilevel S-matrix fits of both excitation functions and angular distributions, on the assumption that dipole transitions dominate, permit J^π assignments for the observed resonances to be limited to a very few possibilities; the best fit results, which are also most consistent with other relevant arguments, give the most likely assignments $3/2^-$, $5/2^-$, $1/2^+$, and $3/2^-$ for states at 19.76, 20.39, 20.58, and 21.05 MeV, respectively, although the parities cannot be individually ascertained. The lower limit for the radiative widths Γ_γ ranges from 1 to 6 eV. An additional level also appears to be present at ~19.3 MeV.

[NUCLEAR REACTION $^{14}N(t,\gamma)^{17}O$, $E=0.8-3.3$ MeV; measured $\sigma(\theta,E)$, ^{17}O deduced levels, J^π, Γ, $\Gamma_t \cdot \Gamma_{\gamma_0}$, $\Gamma_t \cdot \Gamma_{\gamma_1}$. Natural nitrogen target.]

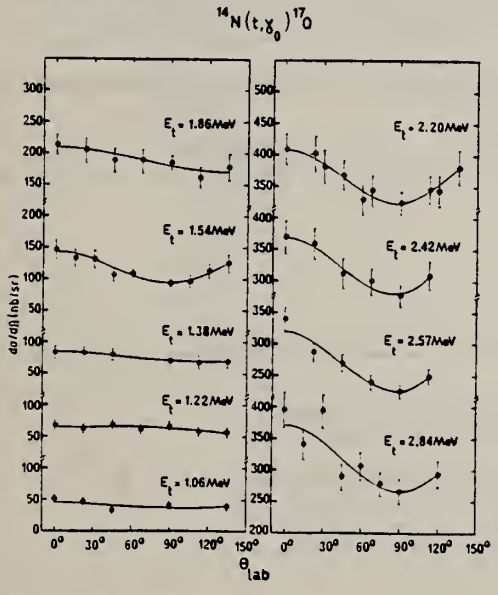

FIG. 3. Experimental angular distributions of t-capture γ rays to the ^{17}O ground state. The incident energies are given at the gas target center as in Fig. 2. The solid curves are least squares fits to Legendre polynomials up to order 2. The resulting coefficients are shown in Fig. 5.

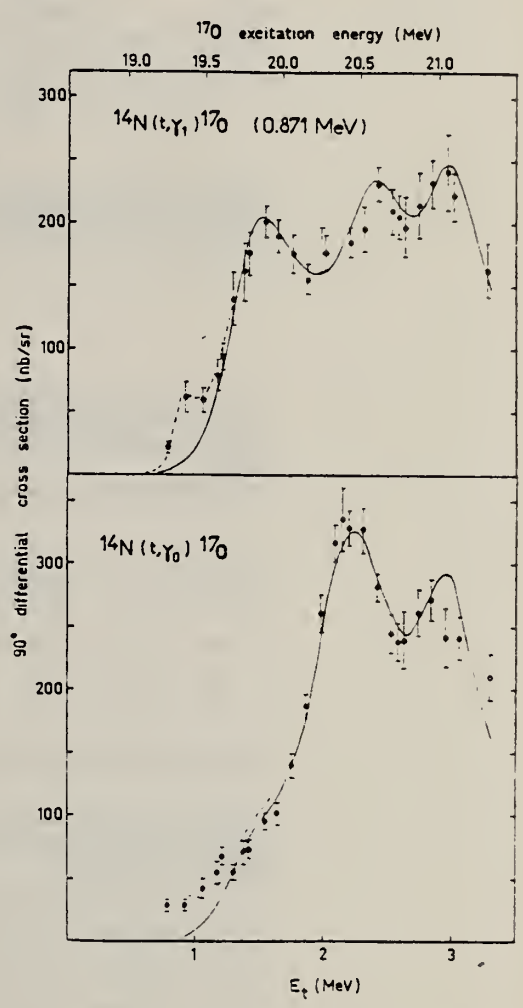

FIG. 2. Excitation functions at 90° for t-capture γ rays to the ^{17}O ground state and first excited state. The bombarding energies have been corrected for energy losses in the entrance Ni foil and target gas. The curves correspond to the "best" fit, as described in the text.

(OVER)

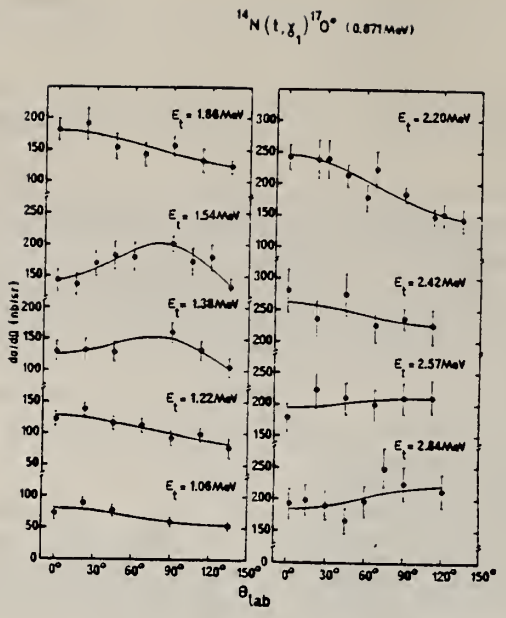

FIG. 4. Experimental angular distributions of t-capture γ rays to the ^{17}O first excited state. Also see comments of Fig. 3; the resulting Legendre coefficients are shown in Fig. 6.

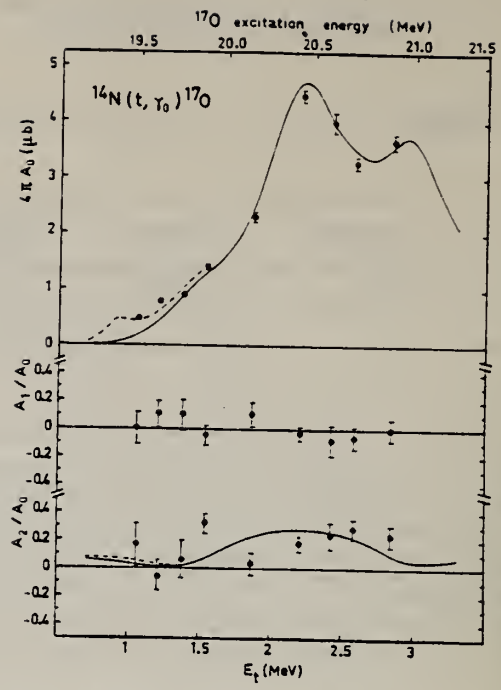

FIG. 5. Legendre polynomial fit coefficients of the γ_0 angular distributions. The curves correspond to the fit obtained with the sequence $(\frac{1}{2}^-, \frac{5}{2}^-, \frac{3}{2}^-)$ and the parameters of Table I. The dashed curve corresponds to the inclusion of a $\frac{3}{2}^-$ state at low energy.

TABLE I. Best fit resonance parameters resulting from the three-level fit of the 90° excitation functions and coefficients of the Legendre polynomial fit to the angular distributions, in the reactions $^{14}N(t,\gamma_0)^{17}O$ and $^{14}N(t,\gamma_1)^{17}O^*$. The corresponding calculated curve is drawn on Figs. 2, 5, and 6. The possibility of other spin sequences is discussed in the text.

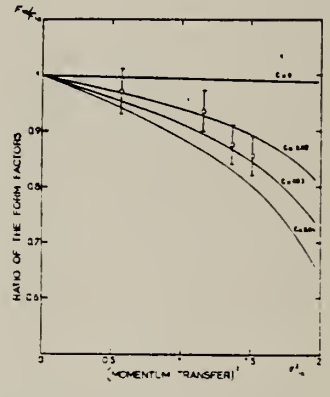

Fig. 7. Experimental ratios of the O^{18} and O^{16} elastic form factors versus x_0 (defined in sect. 3). The curves labelled $\varepsilon = 0$, $\varepsilon = 0.02$, $\varepsilon = 0.03$ and $\varepsilon = 0.04$ give the shell model predictions assuming a parabolic well potential with $x_{0n}(O^{18}) = 1 - \varepsilon x_{0n}(O^{16})$.
For $\varepsilon = 0$ the predicted ratio is different from unity because the masses of the two nuclei are different and therefore the recoil corrections are not identical.

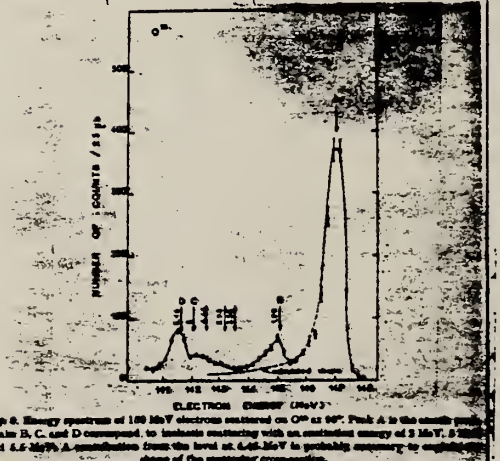

Fig. 8. Energy spectrum of 150 MeV electrons scattered on O^{16} at 90°. Peak A is the elastic peak. Peaks B, C and D correspond, to inelastic scattering with an excitation energy of 3 MeV, 6 MeV and 6.6 MeV. A contribution from the level at 6.46 MeV is probably responsible for asymmetric shape of the scattering cross-section.

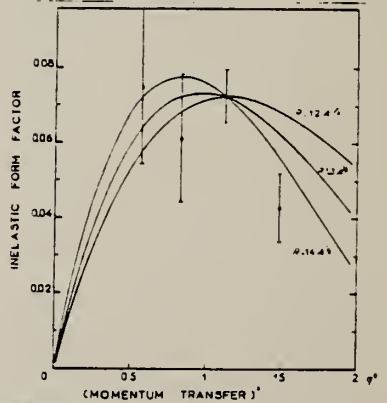

Fig. 10. Inelastic form factor F_1 corresponding to the first excited state of O^{16}. The solid curves are the values of $r_s\,(qR)\,Cl$, normalized at our best experimental point, with $R = r_0 A^{\frac{1}{3}}$ ($r_0 = 1.2$, $r_0 = 1.3$ and $r_0 = 1.4$).

5.33	0_3^+	0.0592	Longitudinal	(7.2)	—	—	0.3	—

[a]Model parameters were adjusted to reproduce the experimental value of Litherland *et al.* (1963).
[b]Allen and Lawson (1971).

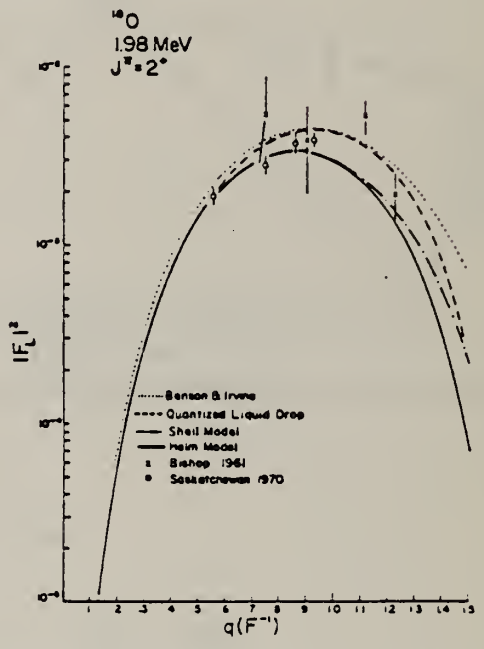

FIG. 5. Longitudinal form factor for the 1.98 MeV, 2^+ level in ^{18}O. The model curves are fitted to reproduce the transition probability to the ground state. An effective charge $e_n = 0.5$ is required for the deformed state model (Benson and Irvine 1966) and $e_n = 0.65$ for the shell model (Kanestroem and Koren 1969). In the notation of Walecka (1962) the liquid drop strength parameter is $(b_2c_2)^{1/2} = 7.33$. Harmonic oscillator wave functions have been assumed with an oscillator parameter $b = 1.869$ fm (Singhal *et al.* 1970) except for Benson and Irvine who use a value $b = 1.77$ fm.

21064 CROSS SECTION OF THE (γ,p) REACTION WITH THE ^{18}O NUCLEUS. Dorosh, M. M.; Mazyukevich, N. P.; Shkoda-Ul'yanov, V. A. (Uzhgorod State Univ., USSR). Ukr. Fiz. Zh. (Russ. Ed.); 17: No. 5, 847-9(May 1972). (In Russian).

The cross section of the reaction $^{18}O(\gamma,p)^{17}N$ was investigated as a possible basis for a novel analytical method for geology, metallurgy, and the chemical industry. The delayed neutron yield from O was measured by a betatron using two independent methods (thin and thick targets) within the limits from threshold (16.4 MeV) to 24.5 MeV. Averaged values for the maximum observed cross section (12 mb at 23.0 MeV), which is considerably smaller than the cross section published by other workers, are given. (KSW)

SELF-ABSORPTION

Abstract: The width of the 6.20 MeV, $J^\pi = 1^-$ state of ^{18}O has been measured using a resonance fluorescence self-absorption technique. For a ground state branching ratio, $\Gamma_0/\Gamma = 0.88$, one finds $\Gamma_0 = 180 \pm 30$ meV. The energy of this state was determined to be 6202.7 ± 0.8 keV.

E NUCLEAR REACTIONS $^{18}O(\gamma,\gamma')$, $E = 6.20$ MeV, measured self-absorption ratio, $\sigma(E_\gamma)$. ^{18}O deduced level, Γ. Resonance fluorescence.

The decay of the ^{18}O GDR to excited residual nuclear states has been examined by measuring spectra of prompt deexcitation γ-rays. The target was irradiated by bremsstrahlung with endpoint energies of 23.5 and 28 MeV. "Bremsstrahlung-weighted" integrated cross sections are given for the population of the residual nuclear states in ^{17}O, ^{17}N, ^{16}O and ^{14}C. Proton decay to excited states in ^{17}N is remarkably weak. It seems that $1p_{3/2}$ excitations play only a minor role in the ^{18}O GDR.

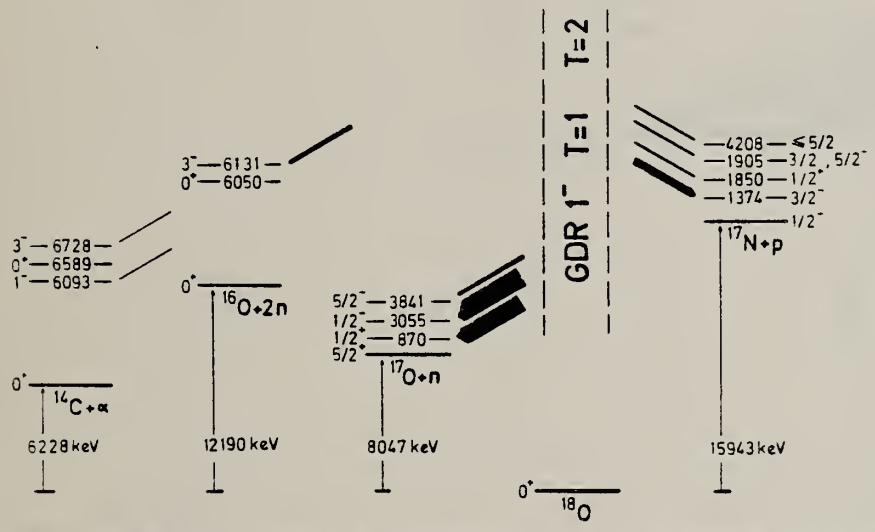

Fig. 1. Population of excited residual nuclear states measured with 28 MeV bremsstrahlung endpoint energy. The thickness of the arrows pointing to the states is proportional to the population strength. (Note that only the ground and first excited state of each nucleus are drawn in correct scale)

DELAYED N FROM N17

The $^{18}O(\gamma,p)^{17}N$ cross section has been measured with monoenergetic photons from threshold to 30 MeV. The results show striking similarities and differences with the $^{16}O(\gamma,p)^{15}N$ cross section.

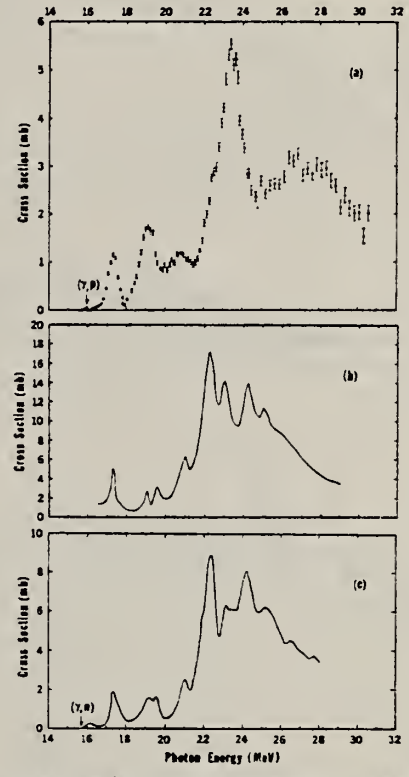

FIG. 1. (a) The $^{18}O(\gamma,p)^{17}N$ cross section measured in the present experiment compared with (b) the $^{16}O(\gamma,p)^{15}N$ and (c) the $^{16}O(\gamma,n)^{15}O$ cross sections taken from the literature (see text). Threshold energies (from Ref. 2) are indicated by the arrows. Solid lines are used to represent the ^{16}O cross sections because they have been synthesized from several experimental results; in any case, the relative precision of these results is good enough so that no important structure has been created or obscured by this procedure.

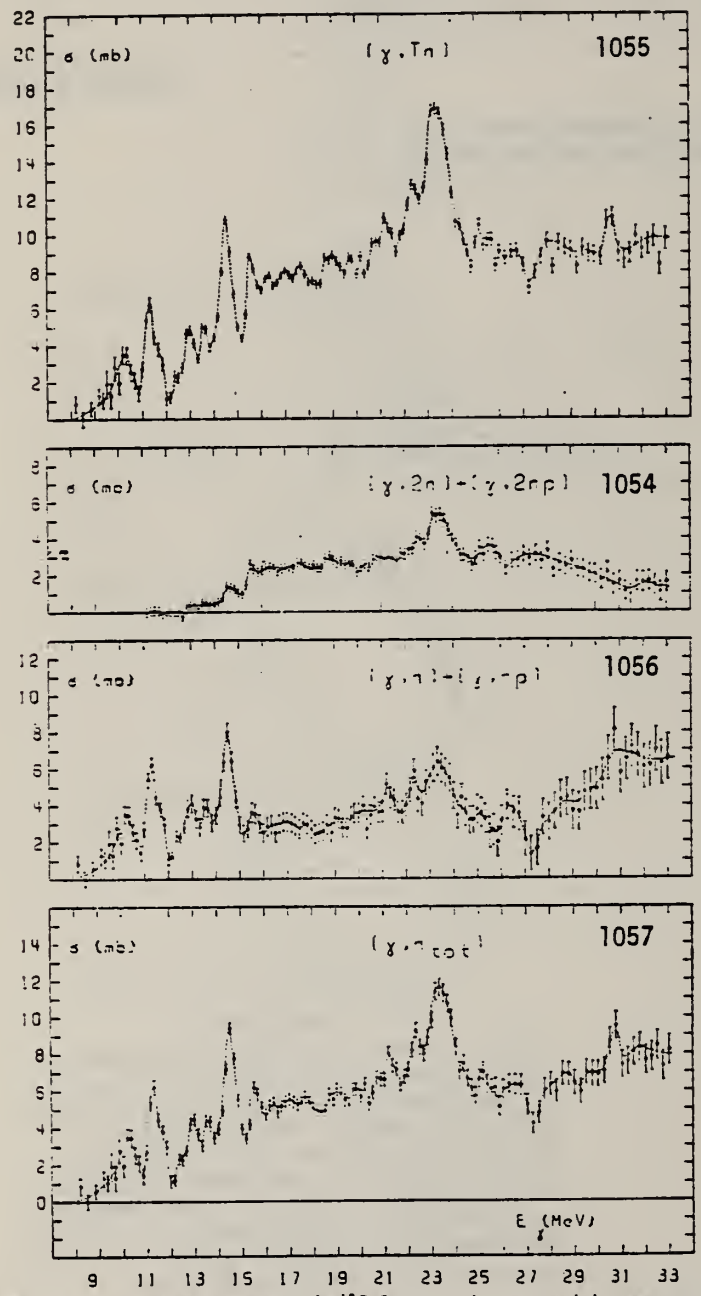

Fig. 1. Measured photoneutron cross sections for ^{18}O, from top to bottom: total photoneutron production cross section $\sigma(\gamma, Tn) = \sigma(\gamma, n)+\sigma(\gamma, pn)+2\sigma(\gamma, 2n)+2\sigma(\gamma, 2np)$; double neutron cross section $\sigma(\gamma, 2n)+\sigma(\gamma, 2np)$; single neutron cross section $\sigma(\gamma, n)+\sigma(\gamma, pn)$; total photoneutron cross section $\sigma(\gamma, n_{tot}) = \sigma(\gamma, n)+\sigma(\gamma, pn)+\sigma(\gamma, 2n)+\sigma(\gamma, 2np)$. The lines are drawn merely to guide the eye.

Abstract: Absolute (γ, xn) cross sections for ^{18}O were measured up to 33 MeV, using a quasimonoenergetic photon beam from positron annihilation in flight. The cross sections show pronounced structure in particular at energies below the main giant dipole resonance. The (γ, 2n) cross section is large in the whole energy region. The integrated total photoneutron cross section amounts to 0.53 in units of the classical dipole sum. No pronounced isospin splitting could be observed in the photoneutron decay channel.

All the major photonuclear cross sections for ^{18}O, including $\sigma(\gamma,p)$, $\sigma[(\gamma,n)+(\gamma,np)]$, and $\sigma(\gamma,2n)$, were measured as a function of photon energy from threshold to 42 MeV. The photon energy resolution was between 200 and 300 keV. The source of radiation was the monoenergetic photon beam obtained from the annihilation in flight of fast positrons. The partial photoneutron cross sections were determined by neutron multiplicity counting, and the average neutron energies for both single- and double-photoneutron events were determined simultaneously with the cross-section data by the ring-ratio technique. The photoproton cross section was determined by counting the delayed neutrons from the β-decay of the residual ^{17}N nuclei. Integrated cross sections were extracted from the data and compared with sum-rule predictions. Resonances in the pygmy-resonance region exhibit substantial decay branching to negative-parity states in ^{17}O. Significant differences in the branching of resonances in the giant-resonance region to the various partial cross sections, together with the photoneutron-energy data, allow isospin assignments to be made for all the resonances, with the consequent delineation of the isospin strength distribution for ^{18}O. Evidence was found for two weak but broad resonances above the giant-resonance region. Finally, comparison with the corresponding cross sections for ^{16}O shows considerable differences between the two nuclei.

The giant resonance region of ^{18}O has been investigated by means of inelastic electron scattering at three values of the momentum transfer. The main features of the giant dipole resonance correlate well with photonuclear reaction data. In addition, considerable contribution from quadrupole excitations is apparent in the excitation energy range from 10 to 23 MeV, with some additional strength from 30 to 45 MeV.

[NUCLEAR REACTIONS $^{18}O(e,e')$, $E=80.0-165.7$ MeV, $\theta=67.0-132.0°$—enriched gas target. Measured $\sigma(E',\theta)$. Deduced differential form factors.]

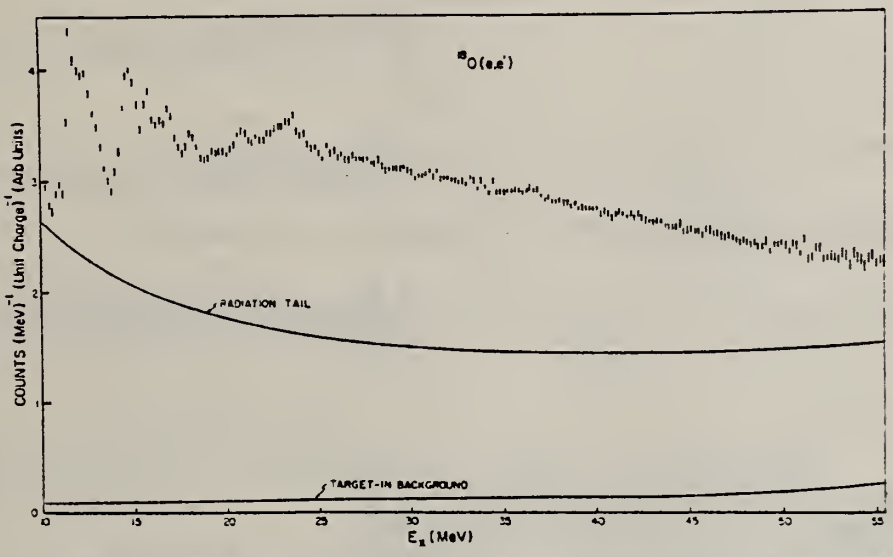

FIG. 1. Inelastic electron scattering spectrum at 165.7 MeV, 67°, showing the contributions due to the elastic peak radiation tail and background due to the target. The target-in background shown was obtained by fitting a smooth curve through the data obtained with an empty target and scaling that curve by a factor 1.12 that takes into account multiple scattering events in the target gas.

In a high-resolution $^{18}O(e, e')$ experiment sharp states at $E_X = 16.38 \pm 0.01$ MeV ($J^\pi = 2^-$, ground state analogue of ^{18}N) and at $E_X = 18.86 \pm 0.01$ MeV ($J^\pi = 1^+$) and clustering of strength (possibly with $J^\pi = 1^-, 2^-$) at $E_X \approx 23.7$ MeV have been observed and compared to theoretical predictions. The transition strengths for the narrow states are $B(M2) \uparrow = 58 \pm 8\ \mu_K^2$ fm^2 and $B(M1) \uparrow = 0.28 \pm 0.04\ \mu_K^2$, respectively. These results agree qualitatively with the results from the analogous $^{18}O(\pi^-, \gamma)\,^{18}N$ reaction.

J-PI, BEL, 16.4, 18.9

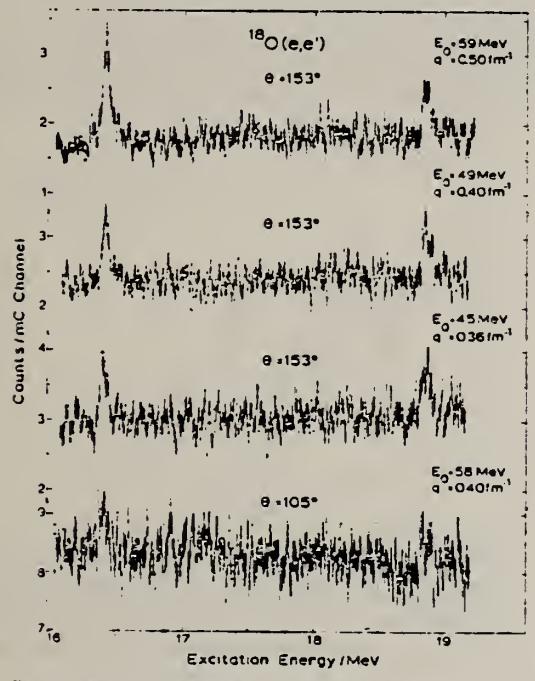

Fig. 1. Spectra of inelastically scattered electrons at three different momentum transfers. Notice the suppressed zero of the scales on both axes.

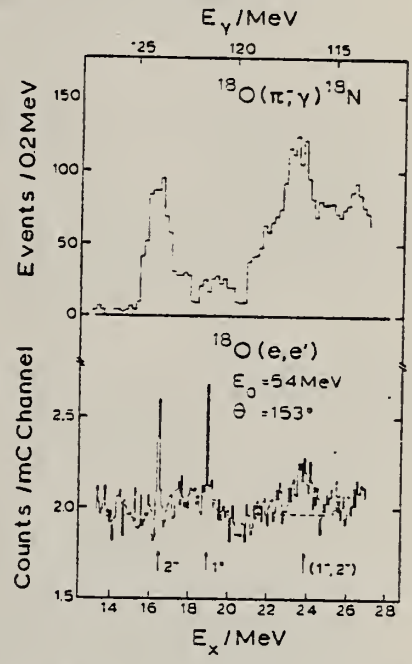

Fig. 2. A comparison of the photon spectrum from the (π^-, γ) experiment (top, adapted from ref. [1]) with the inelastic (e, e') spectrum at 54.3 MeV (153°) (bottom). The area above the dashed line has been used in the cross section estimates discussed in the text.

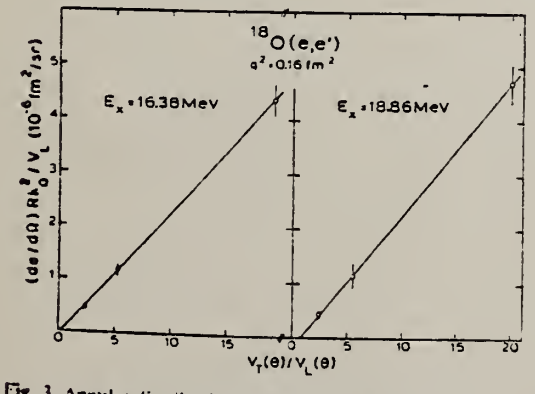

Fig. 3. Angular distributions at constant $q = 0.4$ fm^{-1} showing that both narrow peaks observed in this work are purely transverse. For procedural details and notation see main text and ref. [9].

The $^{18}O[(\gamma, n) + 2(\gamma, 2n)]$ and $^{18}O(\gamma, p)$ cross sections have been measured using the bremsstrahlung yield-curve technique. Unfolding of the yield curves to obtain the cross sections is carried out using the Variable-Bin-Penfold–Leiss technique. The results obtained agree very well with the results obtained using monoenergetic photons. The accuracy of the bremsstrahlung yield-curve technique and the resolution obtainable with this technique are thereby established.

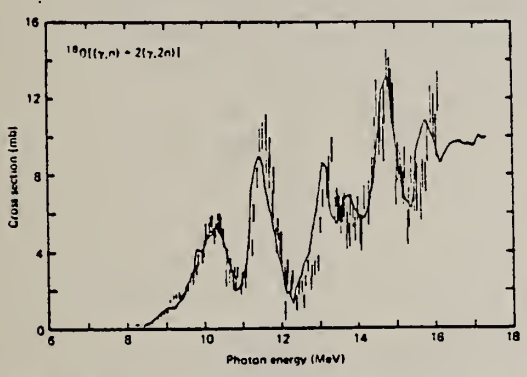

Fig. 3. The $^{18}O[(\gamma, n) + 2(\gamma, 2n)]$ cross section derived from the ^{18}O "fine-resolution" prompt-neutron yield curve, by analysis using the VBPL method using a smoothing factor $f = 1.75$. The solid line is drawn between the data points for the same cross section measured at Livermore.

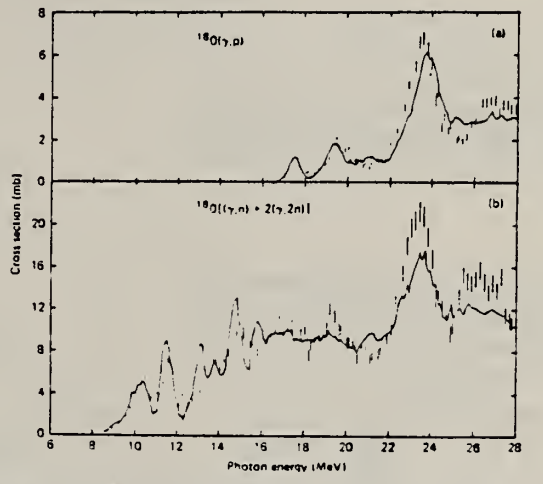

Fig. 4. (a) $^{18}O(\gamma, p)$ and (b) $^{18}O[(\gamma, n) + 2(\gamma, 2n)]$ cross sections derived from the "coarse-resolution" yield curves using the VBPL analysis method with the smoothing factor $f = 1.75$. The solid lines are drawn between the data points for the same cross sections measured at Livermore.

(OVER)

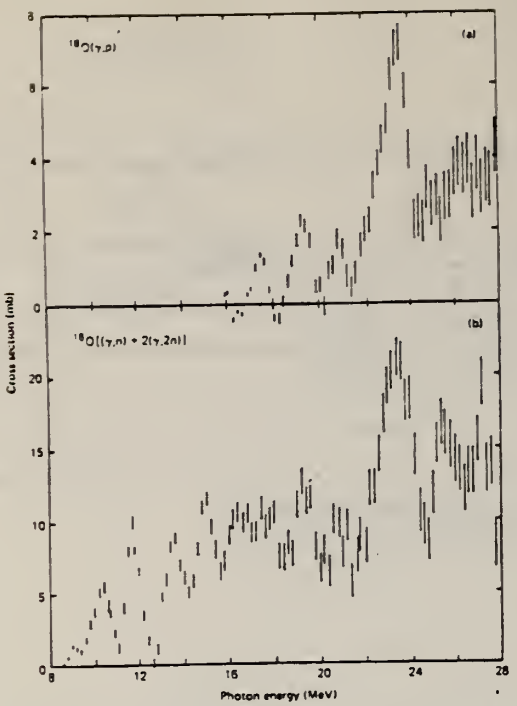

Fig. 5. (a) $^{18}O(\gamma, p)$ and (b) $^{18}O[(\gamma, n) + 2(\gamma, 2n)]$ cross sections derived from the "coarse-resolution" yield curves using analysis bin widths which varied smoothly with energy, and which follow the Thies-criterion optimum bin width as closely as possible.

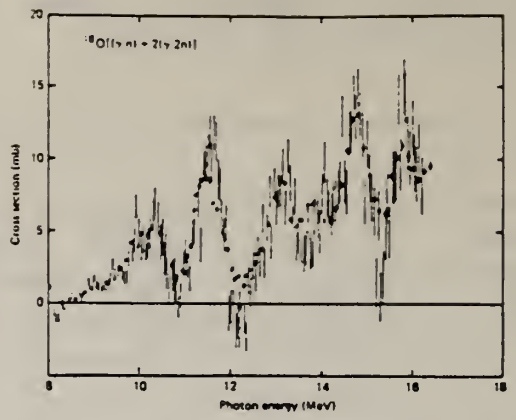

Fig. 6. The error bars show the $^{18}O[(\gamma, n) + 2(\gamma, 2n)]$ cross section obtained by analysis bin widths following the Thies criterion. The solid dots with error bars show the same cross section measured at Livermore.

Abstract: Emission of charged photoparticles from the ^{18}O giant E1 resonance region was investigated at the University of Giessen electron linac at bremsstrahlung endpoint energies of 24 and 32 MeV. Spectra of protons, deuterons, tritons and α-particles were measured at six angles. Proton decay shows strong transitions to excited states in ^{17}N. Deuterons and tritons have a nearly isotropic angular distribution. The $^{18}O(\gamma, t_0)^{15}N$ and the $^{18}O(\gamma, \alpha_0)^{14}C$ cross sections are determined in the giant E1 resonance region. E1 and E2 $^{18}O(\gamma, \alpha_0)^{14}C$ cross sections are derived from the angular distribution measurement.

E NUCLEAR REACTIONS $^{18}O(\gamma, p)$, (γ, d), (γ, t), (γ, α), $E_x < 32$ MeV, measured particle spectra, deduced $\sigma_{\gamma,t_0}(E_\gamma; \theta)$, $\sigma_{\gamma,\alpha_0}(E_\gamma; \theta)$. Enriched target.

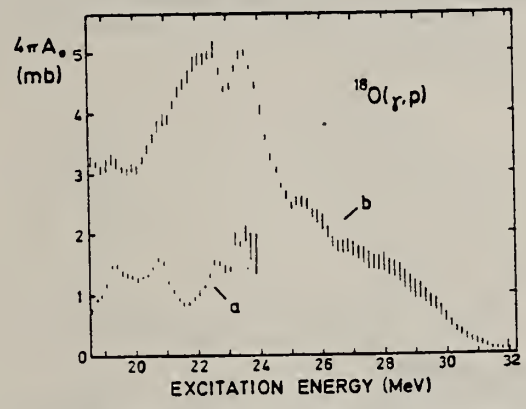

Fig. 1. Total (γ, p) cross section determined under the assumption of transitions to the ground state of ^{17}N (a) for the measurement with 24 MeV endpoint energy and (b) for the measurement with 32 MeV endpoint energy. The energy scale is valid only for transitions to the ground state of ^{17}N.

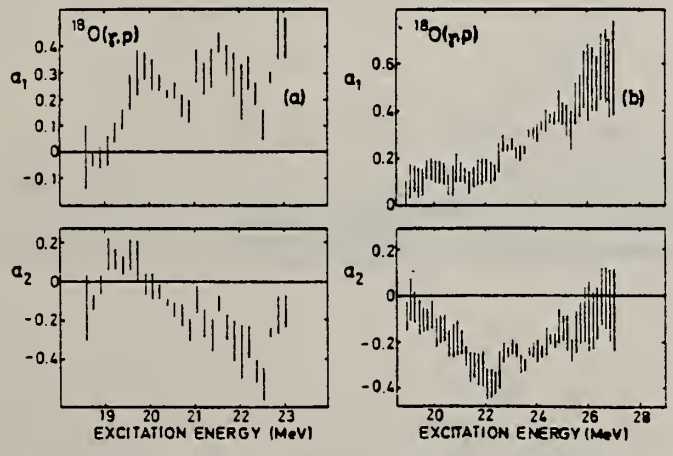

Fig. 2. The $a_1 = A_1/A_0$ and $a_2 = A_2/A_0$ coefficients for the angular distribution of protons derived from the measurement with (a) 24 MeV and (b) 32 MeV bremsstrahlung endpoint energy.

Inelastic electron scattering from the low-lying even-parity states of ^{18}O has been performed. The measurements span a range in momentum transfer from 0.6 to 2.7 fm^{-1}. Form factors have been determined for the two lowest 0^+ excitations, the three lowest 2^+ excitations, and the three lowest 4^+ excitations. Transition densities for the 2^+ and 4^+ excitations have been obtained from a Fourier-Bessel analysis of these data. Comparisons were made with the predictions of various theoretical calculations and the agreement was found generally to be poor. A coexistence model was used to decompose the measured form factors into their single-particle and collective components, which in turn were compared with their counterparts in ^{16}O and ^{17}O. The results indicate that this model provides a useful framework within which to understand the structure of the oxygen isotopes. Transition densities also were obtained within the context of this model.

[NUCLEAR REACTIONS $^{18}O(e,e')$ low-lying even-parity excited states; measured form factors at 90° and 160°, $0.6 \leq q \leq 2.7$ fm^{-1}; comparison to shell and coexistence models; transition densities extracted.]

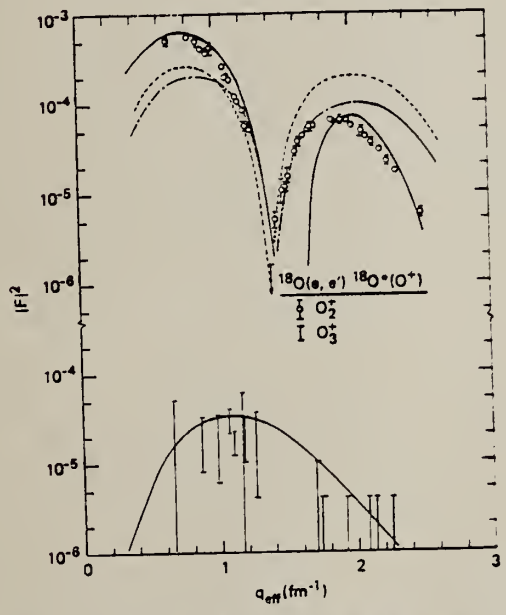

FIG. 4. Form factors for the lowest two 0^+ excitations in ^{18}O, measured at 90° (data points). The solid and dashed curves are from Refs. 33 and 34, respectively. The dotted-dashed curve was computed from wave functions given in Ref. 10.

0.6*2.7 FM-1 8 STATES

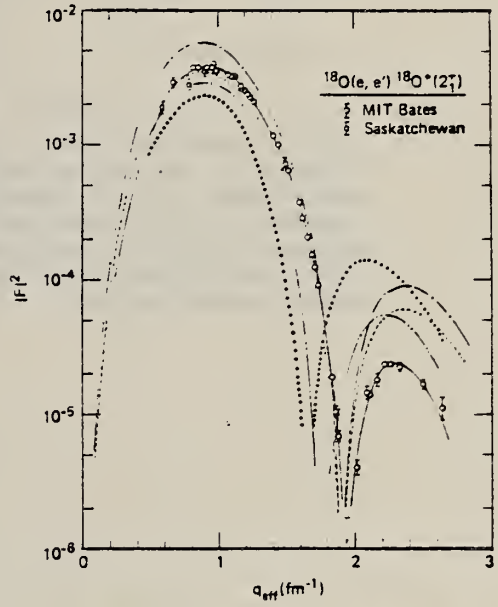

FIG. 5. Measured form factors for the lowest 2^+ excitation in ^{18}O. The circles represent our measurements made at 90°; the squares are taken from Ref. 17. The solid curve shows the result of an FBA fit to the data. The dashed (dashed-dotted) curve was computed using wave functions from Ref. 14 and $e_{pol}=0.33e$ ($e_{pol}=0.50e$). The dashed-dotted-dotted curve is taken from Ref. 34, while the dotted curve was computed using wave functions from Ref. 10.

TABLE II. Reduced transition probabilities.

State	$B(EL;\ 0_1^+ \rightarrow L^+)$ (e^2fm^{2L})
2_1^+ (1.982 MeV)	44.8±1.3
2_2^+ (3.919 MeV)	22.2±1.0
2_3^+ (5.250 MeV)	28.3±1.5
4_1^+ (3.553 MeV)	(9.04±0.90)×10^2
4_2^+ (7.114 MeV)	(1.31±0.06)×10^4

(OVER)

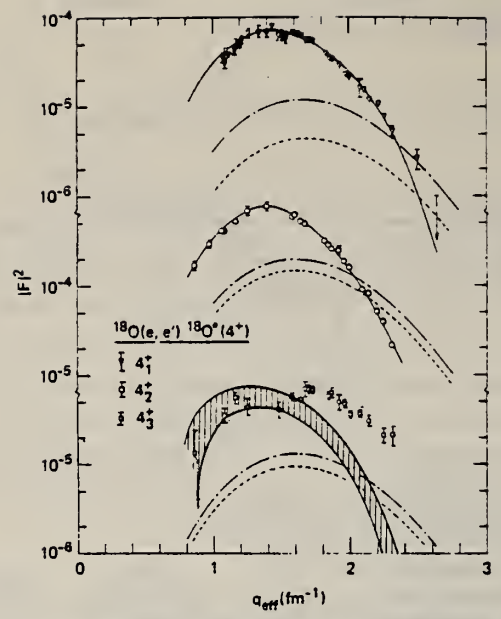

FIG. 8. Measured form factors for the lowest three 4^+ states in ^{18}O. The data points represent our measurements made at 90°. See caption for Fig. 5 for descriptions of curves. The shaded band represents the form factor for the third 4^+ state computed [within the context of the LSF (Ref. 11) model] from those measured for the lowest two 4^+ states.

DEFINITIONS OF ABBREVIATIONS AND SYMBOLS

Note: In this list definitions are given for various photoneutron reactions in which the following symbols are used: N, NL, nN, SN and XN. Corresponding definitions apply for reactions involving other nuclear particles where the symbols N (neutron) is replaced by, e.g. P, D, T, HE, A etc. Where unknown reactions result in the production of a specific radionuclide, the chemical symbol and mass number is listed as the reaction product, e.g. a G,NA22 reaction in ^{59}Co.

A	alpha particle
ANAL	analysis
ABI	absolute integrated cross-section data
ABX	absolute cross-section data
ABY	absolute yield data. Often means cross-section per equivalent quantum is listed.
ACT	measurement of induced radioactivity of the target
ASM	asymmetric, asymmetry
AVG	average
BBL	bubble chamber
BEL B(EL)	reduced electric radiative transition probability
BF3	BF_3 neutron counter with moderator e.g., Halpern detector, long counter
BML	reduced magnetic radiative transition probability, B(ML)
BREAKS	levels located by "breaks" in the yield curve
BRKUP	breakup
BRMS	bremsstrahlung
BTW	between
C	continuous. Used to describe a photon source or a detector response function. Contrast with D = discrete.
CCH	cloud chamber
CF	compared with
CHRGD	charged
CMPT	Compton
COIN COINC	coincidence, coincide
COH	coherent
CK	Cerenkov
D	deuteron or discrete. When discrete, it is used to describe a photon source or a detector response function. Contrast with C = continuous.
DLTE	energy loss
DLTQ	momentum transfer
DST	distribution
DT BAL	detailed balance
E	electron
E/	inelastically scattered electron
E+	positron
EDST	energy distribution or spectrum
E/N	used only to indicate a coincidence experiment as in (E,E/N).

	N stands for any outgoing particle measured in coincidence with an inelastically scattered electron. Distinguish from eg., (E,N) which is used to represent an electron induced reaction when only the outgoing particle N is detected.
EMU	emulsions (photographic plates)
EXCIT	excited
F	fission
FMF	form factor
FM-1	inverse femtometers
FRAG	fragment
G	photon
G/	inelastically scattered photon
G-WIDTH	gamma-ray transition width
HAD	hadrons, hadron production
HE He3	^{3}He particle
INT	interaction, integral, intensity
INC	includes
ION	ionization chamber
ISOB	isobaric
ISM	isomer
J	multiplicity of particle defined by following symbol e.g. (G,PJN) with remark J = 2,3,5,7
JPI J-PI	spin and parity of a nuclear state
K	second multiplicity index, e.g. (G,JPKN) with both J & K positive integers greater than 1
KE	kinetic energy
L	may be an integer or zero that always follows a reaction product symbol. This is used to indicate transitions to specific states in the residual nuclide. When the letter is used as in (G,NL) the cross section given is that for the sum of transitions to two or more specific final states.
LFT	excited state lifetime
LIM	limit
LV,LVS	level, levels
LQD	liquid
MAG	magnetic spectrometer
MEAS	measurement(s)
MGC	magnetic Compton spectrometer
MGP	magnetic pair spectrometer
MOD	moderated neutron detector not employing a BF_3 counter, e.g. rhodium foil, Szilard-Chalmers reaction, ^{3}He, ^{6}Li reactions, GD loaded liquid scintillator, etc.
MSP	mass spectrometer
MULT	multiple, multipole, multiplicity
MU-T	used only in combination with G to indicate a total photon absorption cross section measurement, i.e. (G,MU-T)
N	neutron (see also XN and SN). The notation (G,N) is used to indicate a reaction in which only a single neutron is emitted, i.e. the reaction that can, in many cases, be measured by observing the radioactive decay of the residual nuclide.

nN	where n is any integer. (G,nN) indicates the sum over all reaction cross sections in which n neutrons are emitted.
NAI	NaI(Tl) spectrometer
NEUT	neutron(s)
NOX	no cross-section data
P	proton (see also XP)
PART	particle(s)
PHOT	photon(s)
PI	pion, usually written as PI+, PI-, PIO to indicate charge
POL	polarized or polarization
Q-SQUAR	momentum transfer squared (q^2)
RCL	recoil
REL	relative
RLI	relative integrated cross-section data
RLX	relative cross-section data
RSP	reaction spectrometer
RLY	relative yield data
SCTD	scattered
SCD	semiconductor (solid state) detector
SCI	scintillator detector other than NaI, e.g., CsI, KI, organic (liquid or solid), stilbene, He
SEP	separation
SEP ISOTP	separated isotope used
SIG	SIGMA (cross section)
SN	sum of neutron producing reactions, $\sigma(\gamma,SN)=\sigma(\gamma,N) + \sigma(\gamma,NP) + \sigma(\gamma,2N) + \sigma(\gamma,3N)$ + etc.
SPC	photon or particle energy spectrum
SPK	spark chamber
SPL	spallation
STAT	statistical
SYM	symetric, symmetry
T	triton
TEL	counter telescope
THR	threshold for reaction or threshold detector, e.g., $^{29}Si(n,p)^{29}Al$.
TOF	time-of-flight detector
TRK	tracks of particles or fragments observed in solid materials (glass, mylar, etc.)
TRNS	transition
UKN UNK	unknown
VIB	vibrational
VIR PHOT	virtual photon(s)
XN	all neutrons, total neutron yield, $\sigma(\gamma,XN) = \sigma(\gamma,N) + 2\sigma(\gamma,2N) + 3\sigma(\gamma,3N) + \sigma(\gamma,NP)$ + etc.
XP	all protons, total proton yield $\sigma(\gamma,XP) = \sigma(\gamma,P) + \sigma(\gamma,NP) + 2\sigma(\gamma,2P)$ + etc.
XX XXX	reaction products defined in REMARKS
YLD	yield

4PI	a 4π geometry was used or a method like radioactivity or a total absorption measurement		products was determined. The polarized particle is indicated in REMARKS.
999	energy defined in REMARKS	* or @	symbols used to indicate that the units associated with the numerals on one or both sides of the symbol in a specific column are not MeV. The units are defined in REMARKS.
$	indicates the measurement involved beams or targets that were either polarized or aligned, or that the polarization of the reaction

☐ Document describes a computer program; SF-185, FIPS Software Summary, is attached.

11. ABSTRACT (A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here)

These abstract sheets cover most classes of experimental photonuclear data leading to information of the electromagnetic matrix element between the ground and excited states of a given nucleus. This fifteen volume work contains nearly 7200 abstract sheets and covers 89 chemical elements from hydrogen through americium. It represents a twenty-seven year history of the study of electromagnetic interactions. The sheets are ordered by target element, target isotope, and by an assigned bibliographic reference code. Information is given on the type of measurement, excitation energies studied, source type and energies, detector type, and angular ranges covered in the measurement. For a given reference, the relevant figures and tables are mounted on a separate sheet for each nuclide studied.

12. KEY WORDS (Six to twelve entries; alphabetical order; capitalize only proper names; and separate key words by semicolons)

data-abstract sheets, elements, experimental, isotopes, nuclear physics, photonuclear reactions
