TABLE OF CONTENTS

Photonuclear Data-Abstract Sheets
1955-1982

I. Introduction

As used in connection with this collection of data-abstract sheets, the term photonuclear data is taken to mean any data leading to information on the electromagnetic matrix element between the ground state and excited states of a given nuclide. The most common types of reactions included in this compilation are: (e,e'), (γ,γ), (γ,γ'), (γ,n), (γ,p), etc. as well as ground-state particle capture reactions, e.g. (α,γ_0). Two reactions which fit the matrix element criterion are not included in the compilation because of their rather special nature. These are heavy particle Coulomb excitation and the thermal neutron capture reaction (n,γ_0). While the energy region of particular interest extends from 0 to 150 MeV, papers are indexed which report measurements in the region from 150 MeV to 4 GeV. Most of the experiments listed are concerned with the excitation energy range from 8 to 30 MeV, the region of the photonuclear giant resonance.

The hierarchical grouping of the photonuclear data-abstract sheets within the file is by: 1. Target Element, 2. Target Isotope, and 3. by the Bibliographic Reference Code assigned to the paper from which the data on the sheet were abstracted. In this file, colored pages are used to mark the beginning and end of the sheets for each chemical element. A brief historical sketch of the element is given on the divider sheet marking the start of each section; the information for this sketch was derived from references such as the Encyclopaedia Britannica. In those cases where the sheets for a given element make up a major part of a volume, colored pages are also used to delineate sections pertaining to the individual isotopes of the element. Each of the sections of the file, as delineated by two colored divider sheets, represents a 27 year history of the study of electromagnetic interactions in either a specific nuclide or a specifc element.

The data-abstract sheets are filed under the element and/or isotope in which the ground-state electromagnetic transition takes place. For example, the abstract sheet for a total neutron yield measurement for a naturally occurring copper sample would appear in the elemental section of the copper file. On the other hand, a measurement of the ^{62}Cu 9.73 minute positron activity produced in the same sample by photons with energies below the three-neutron separation energy for ^{65}Cu (28.68 MeV) would be filed with the sheets for ^{63}Cu. Similarly a measurement of the ground-state neutron capture cross section in ^{12}C would be filed under ^{13}C while the corresponding ground-state alpha-particle capture cross section would be filed under ^{16}O.

At the end of this volume there is a master list of the abbreviations that have been used in the index section of the abstract sheets. The listings are those used in the final published index, Photonuclear Data Index, 1973-1981, NBSIR 82-2543, issued in August 1982 by the U. S. Department of Commerce, National Bureau of Standards, Washington, DC 20234. In some cases two notations are entered for the same quantity. The second entry is the abbreviation that was used in one or more of the earlier published editions of the index.

ALUMINUM
Z=13

Aluminum derives its name from the Latin *alumen* -, a naturally occurring aluminous sulfate that was used as an astringent and mordant at least as early as the 5th century B.C. Hans Christian Oersted is credited with having been the first to prepare the metallic aluminum. This he did in 1825 by chemically creating an aluminum amalgam and distilling off the mercury. Oersted's results were published in an obscure Danish journal and made little impact on the scientific community. Friedrich Wohler (1800-1882) improved upon the process and in 1845 he was able to make large droplets of the metal and determine some of its physical properties. The first pure sample was not made until 1854; the French chemist Henri Sainte-Claire Deville (1818-1881) improved Wohler's method and developed it into a successful commercial process until the advent of the cheaper electrolytic method. This process was introduced by Charles Hall of Oberlin College, Ohio, and Paul-Louis-Toussaint Heroult (1803-1914) of France. Both were 22 years old at the time; both independently and almost simultaneously discovered and patented the process. It remains to this day the only method by which aluminum is produced in commercial quantities.

G-WIDTH

TABLE I. Partial widths for the various γ-ray transitions from $T=\frac{3}{2}$ to $T=\frac{1}{2}$ states that were observed in the present work. The ratio of the observed width to the single-particle estimate[a] is given under the heading $|M|^2$. Where the $E2$ admixture is not determined, there are three dots in place of the appropriate entry and the transition was assumed to be pure $M1$.

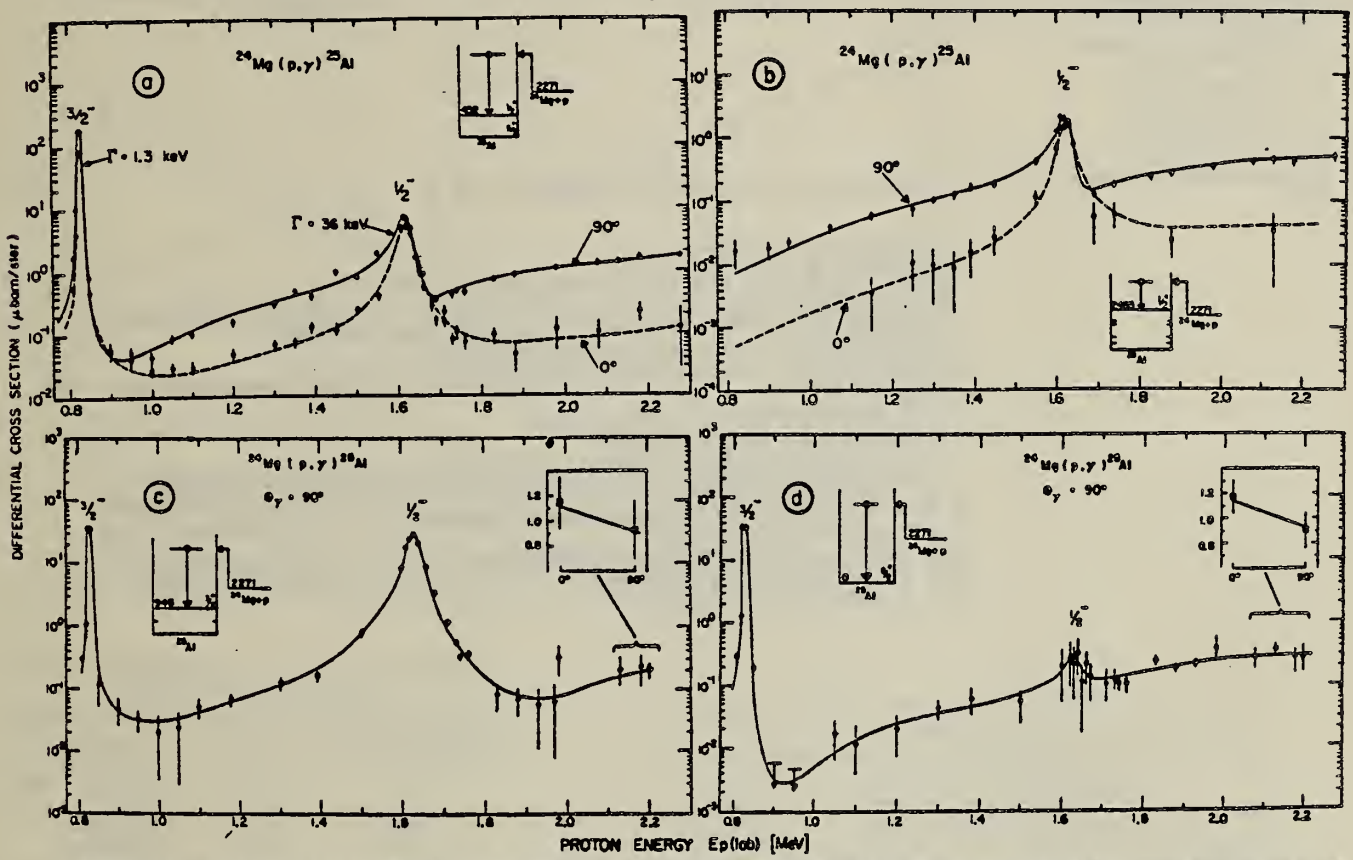

Fig. 4. Excitation functions at $\theta_\gamma = 0°$ and 90° for the transitions to the 452 keV state (a) and 2485 keV state (b). The solid and dashed lines represent best fits to the data (subsects. 3.2 and 3.3). Excitation functions at $\theta_\gamma = 90°$ for the transitions to the ground state and to the 945 keV state are shown in (d) and (c). The solid lines represent the best fits to the data (subsects. 3.4 and 3.5). The insets show the anisotropy of these transitions as observed at $E_p = 2.1$–2.3 MeV and the model predictions for $l_f = 2$ (solid line).

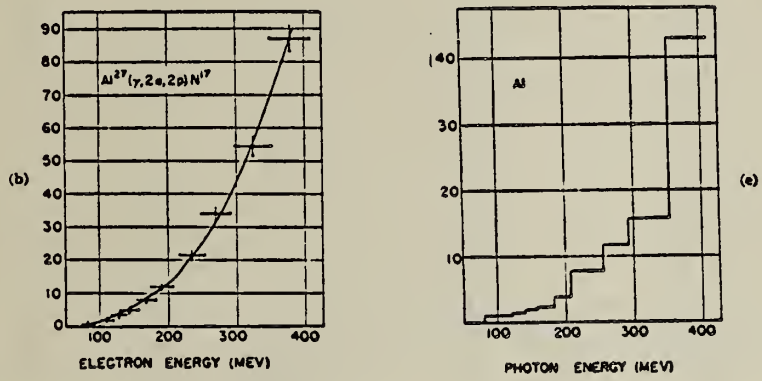

FIG. 5. Graphs a, b, and c show activation points for N^{17} yields in magnesium and aluminum. Graphs d, e, and f are the calculated photon cross sections, from which the solid lines in a, b, and c have been reconstructed. The third cross-section curve is actually the slightly modified result of an early aluminum run, and is included to illustrate the effects of moderate errors in data upon the photon cross section results.

$Al^{27}(\gamma,\gamma)$	Bremss. 4-40					Detector at 120°. Cross sections given here are 13% too high due to erroneous cos β factor in denominator of Eq. 5. [See Footnote 8 in Phys. Rev. 106, 993 (1957)].

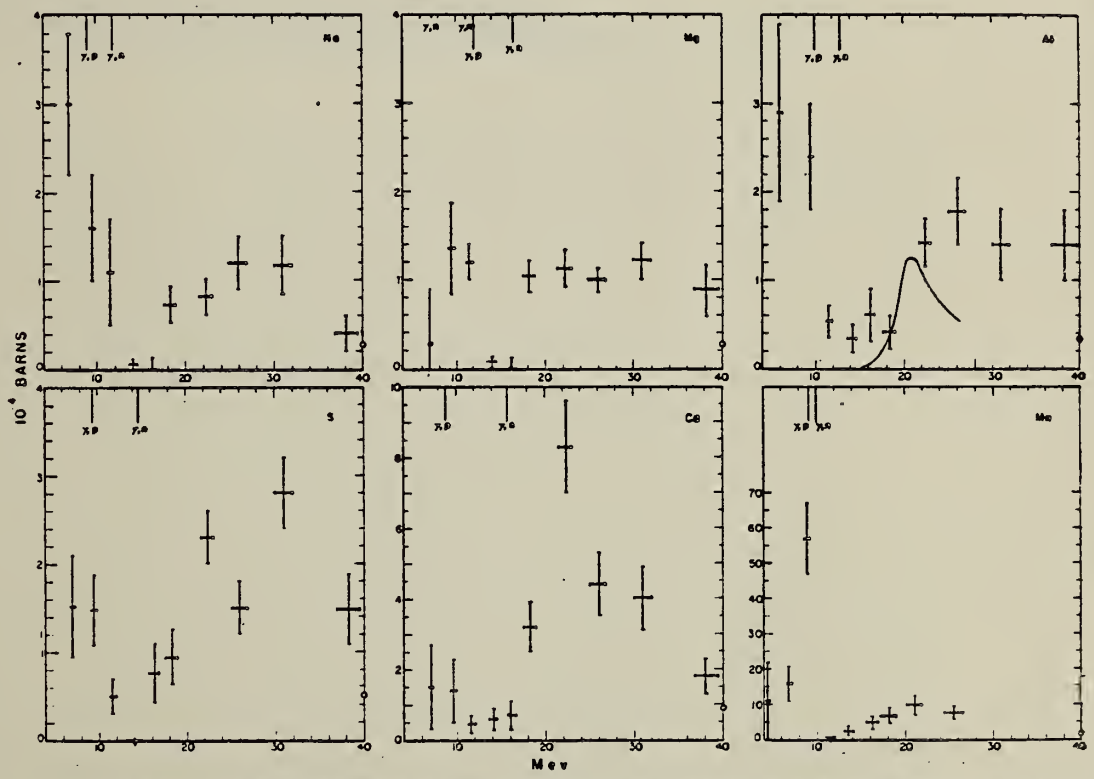

FIG. 4. The elastic scattering cross sections for Na, Mg, Al, S, Ca, and Mn. The indicated spread in energy is the width of the differential discriminator channel, and the standard deviations are based only on the number of counts. The vertical lines at the top represent the particle thresholds for the most important isotopes. The open circles at the extreme right indicate the magnitude of the Thomson cross section for Z free protons scattering coherently. The solid curve superimposed on the Al data is the scattering cross section calculated from the dispersion relation by substituting for $\sigma_a(E)$ in Eq. (6) the sum of the neutron and proton yield[1,18] cross sections.

Source Li(p,γ) with E_p = 500 keV.

Tabelle 1

Die gemessenen totalen Streuquerschnitte in cm² unter Annahme von E1- und E2-Streuung

Element	eigene Werte	Fuller und Hayward [13])	Stearns [6])
Pb	$(5.6\pm1)\times10^{-27}$	$(4-8)\times10^{-27}$	$(5-9)\times10^{-27}$
Al	$(2\ \pm1)\times10^{-29}$	$(2-6)\times10^{-29}$	
O	$(1\ -5)\times10^{-30}$		
C	$(5.8\pm2)\times10^{-30}$		

Durch die Wahl der Meßgeometrie ergibt sich für eine E1- wie eine E2-Winkelverteilung innerhalb der Fehlergrenzen der numerischen Rechnung der gleiche Wert für den totalen Streuquerschnitt. Die angegebenen Fehler enthalten nur den Fehler in der Bestimmung des primären γ-Flusses und die statistischen Fehler der Streuraten. Zum Vergleich sind die entsprechenden Ergebnisse von Fuller und Hayward [13]) und Stearns [6]) gegenübergestellt. Die angegebenen Werte gehören jeweils zu den Fehlergrenzen.

$Al^{27}(\gamma,d)$						Energy range of particles detected: E_p, E_d: 15.5-30 MeV

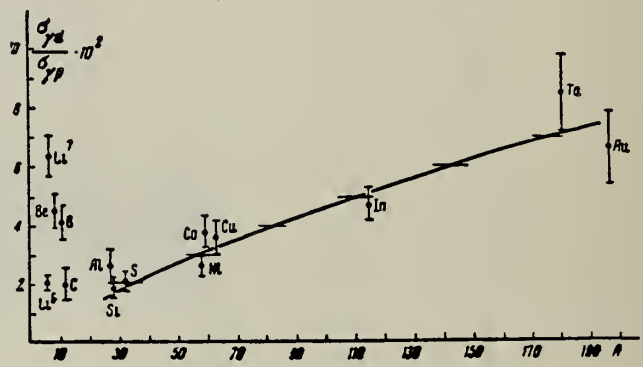

FIG. 3. Ratio of (γ, d) to (γ, p) cross sections for protons and deuterons of energies 15.5–30 Mev as function of atomic weight A. The solid curve shows the dependence given by Eq. (2), arbitrarily normalized.

YIELD DATA TABLE:

It should be noted that the yield of photoprotons of the energy considered rises smoothly with Z for the elements plotted in Fig. 3, and that starting already with Al, no direct proportionality to Z is observed on account of the effect of the Coulomb barrier. For illustration, we give the yields of photoprotons Y(γ, p) per proton in the nucleus for several elements in relative units (the error in these measurements was estimated to be ±10%):

	Li^6	Li^7	Be	C	Al	Cu
$Y(\gamma,p)$ =	1.49	1.57	1.5	1.31	1.00	0.56

Van de Graaff; $Al^{27}(p,p')Al^{27*}(2.98)$ source

REF. NO. 65 Kh 1 NVB

REACTION	RESULT	EXCITATION ENERGY	SOURCE TYPE	SOURCE RANGE	DETECTOR TYPE	DETECTOR RANGE	ANGLE
G,G	LFT	2, 3	D	2,3	NAI-D		DST
		(2.21, 2.98)	(2.21, 2.98)				

2.98 MeV level:

mean life $\tau = (6.6 \pm 0.7) \times 10^{-15}$ sec.
angular distribution $W(\theta) = 1 + (0.06 \pm 0.04)P_2(\cos\theta)$
E2/M1 mixing ratio δ: $-0.36 < \delta < +0.20$

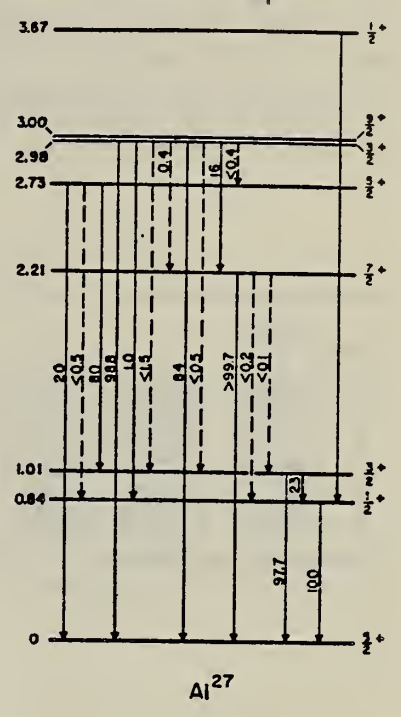

FIG. 1. Decay scheme of the low-lying levels of Al^{27}. The spin assignments and branching ratios up to 2.73 MeV are from Ophel and Lawergren, Ref. 11. For the 2.98- and 3.00-MeV levels they are from Lawergren, Ref. 5. The mode of decay of the 3.68-MeV level shown has been reported only in Ref. 3.

2.21 MeV level:

At $E_p = 5.00$ MeV, $W(\theta) = 1 + (0.37 \pm 0.02)P_2(\cos\theta)$

At $E_p = 4.155$ MeV, $W(\theta) = 1 + (0.21 \pm 0.04)P_2(\cos\theta)$

Difference may be due to a partial linear polarization of the x-ray source.

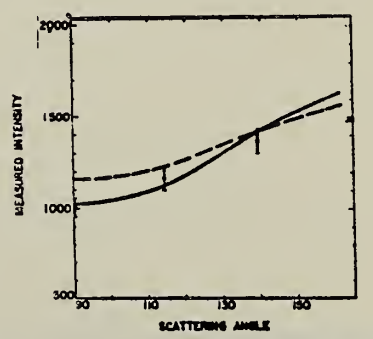

FIG. 6. The angular distribution for resonant scattering of 2.21-MeV radiation at $E_p = 5.00$ MeV. The solid curve is the function $W(\theta) = 1 + 0.37\ P_2(\cos\theta)$, the least-squares fit to the experimental points. This is indistinguishable from $W(\theta) = 1 + 0.23\ P_2(\cos\theta) - 0.053 P_2^3(\cos\theta)$, which includes a polarization term. The broken curve is the distribution $W(\theta) = 1 + 0.23 P_2(\cos\theta)$ obtained at $E_p = 4.115$ MeV by Metzger *et al.* (Ref. 8) and in the present work. The normalization of the two curves at 140° is arbitrary.

DETECTOR TYPE	DETECTOR RANGE	ANGLE

TABLE II. – *In this table the data from Table I are treated, as discussed in the text to give cross-sections corresponding to photoneutrons in the approximate energy ranges* (0÷15) MeV *and above* 15 MeV. Thus the result *a*) corresponds to the relation $a = I - 0.4E$, and *b*) corresponds to $b = 1.4 \cdot E$.

		^{12}C	^{27}Al	S
Thres.÷ 40 MeV	*a*)	3.13	9.03	6.17
	b)	0.53	1.12	0.98
(40÷ 80) MeV	*a*)	1.20	5.91	4.71
	b)	1.32	1.89	2.07
(80÷120) MeV	*a*)	0.97	5.08	3.35
	b)	1.58	2.62	3.35
(120÷160) MeV	*a*)	0.90	4.98	1.46
	b)	1.90	4.20	5.12
(160÷200) MeV	*a*)	1.11	6.05	6.95
	b)	2.07	7.35	5.05

a) $= I - 0.4E$. I = int. counter.
b) $= E \cdot 1.4$, E = ext. counter.

TABLE IV. – *The total absorption cross-section for γ-rays is calculated by dividing the total neutron production cross-section by the neutron multiplicity.* The result is given in the first column under each element and, for comparison, in the second column the value of *b* is inserted from Table II.

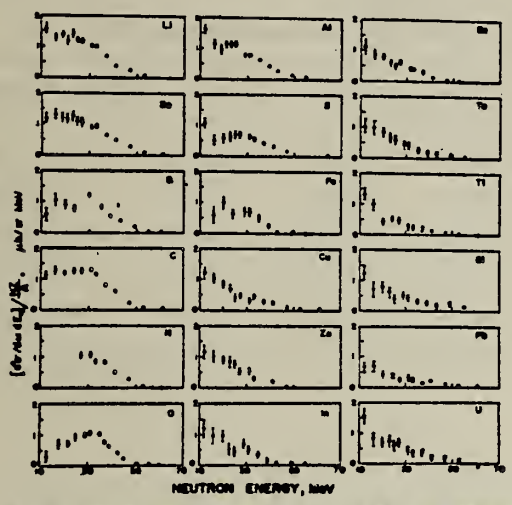

FIG. 6. Observed neutron spectra due to 55–85-MeV difference photon spectra. The effective cross sections have been divided by NZ/A.

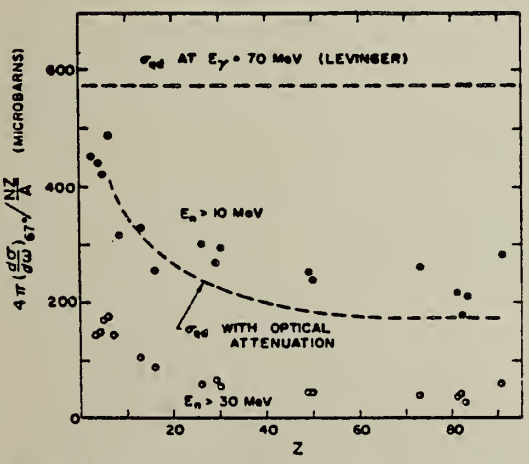

FIG. 7. Effective cross sections for production of fast neutrons with energies greater than 10 MeV (solid circles) and 30 MeV (open circles) by the 55–85-MeV photon difference spectrum. The dashed curves are modified quasideuteron model predictions as discussed in the text.

TABLE I. Comparison of present cross-section values in mb for production of high-energy photoneutrons by 55–85-MeV photons with measured cross sections $\sigma(\gamma,Tn)$, also in mb, for total photoneutron production. The present cross-section values are uncertain by 8 to 10% because of counting statistics and normalization errors; in addition all values depend on an absolute normalization in terms of the deuteron photodisintegration cross section, which is known to about 10% at these energies.

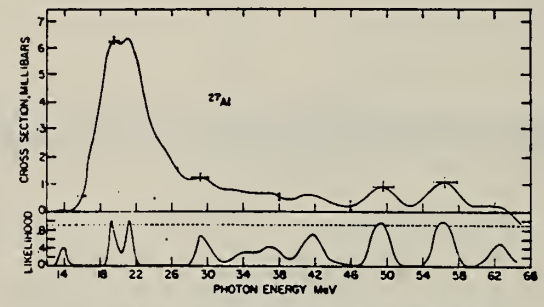

FIG. 4. The least-structure cross-section solution, $\sigma=\sigma_n+0.9\sigma_{2n}$, for aluminum. Vertical bars indicate errors in cross section. The experimental timing was such that the contribution due to the reaction $Al^{27}(\gamma, 2n)Al^{25}$ was depressed relative to the contribution due to the $Al^{27}(\gamma, n)Al^{26g}$ reaction. A likelihood estimate of the statistical certainty of the indicated structure is also shown.

$S^{32} \rightarrow Na^{24}$	52±6		

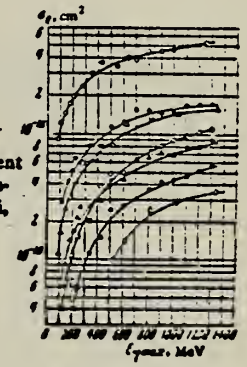

FIG. 1. Cross section σ_0 per equivalent photon as a function of maximum bremsstrahlung energy. Points: O – Al, ● – Si, Δ – P, ▲ – S, □ – Cl, ■ – K, ◇ – Ca.

According to the photomesonic mechanism, the cross section for the reaction can be written in the form

$$\sigma = \sigma_0 AP. \quad (1)$$

Here σ_0 is the total cross section for interaction of the photon with a free nucleon with inclusion of the nucleon motion in the nucleus (σ_0, as has been shown by Roos and Peterson,[6] depends only weakly on photon energy for $E_\gamma > 300$ MeV); A is the number of nucleons in the nucleus, and P is the probability that the reaction will proceed by a given channel.

* From plot of $\ln[\phi(E)/\sigma_c E^{3/2}]$ versus E.

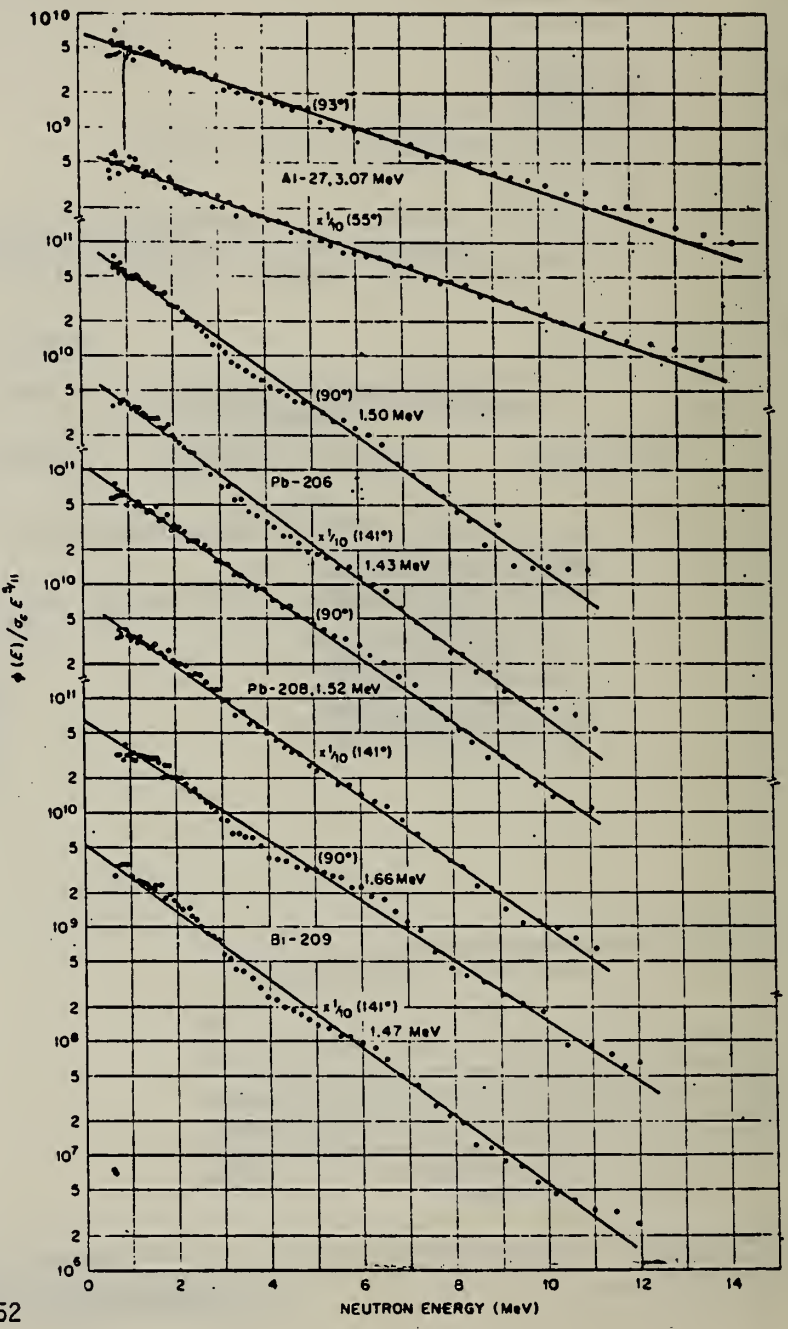

FIG. 7. Evaporation-analysis plots of neutron spectra from (γ,n) reactions. The logarithmic plots of $\phi(E)/(\sigma_c E^{3/2})$ show moderately good straight-line fits. Values of T, the magnitude of the reciprocal slope, are shown. In some cases, T is slightly higher at 90° than at 141°, indicating that a weak component of direct emissions is present. These are preferentially emitted at 90°, the direction of the electromagnetic field.

The use of the $^{19}F(\gamma,n)^{18}F$, $^{27}Al(\gamma,x)^{24}Na$, $^{197}Au(\gamma,n)^{196}Au$, and $^{12}C(\gamma,x)^{7}Be$ reactions as absolute monitors for high-energy, high-intensity bremsstrahlung beams is discussed. The cross sections per equivalent quantum and the absolute cross sections, in the energy range 300-1000 MeV, are reported for these reactions. $^{19}F(\gamma,n)^{18}F$, $^{27}Al(\gamma,x)^{24}Na$, and $^{12}C(\gamma,x)^{7}Be$ reactions are proposed as very simple and suitable systems for monitoring purposes.

[a] The branchings are obtained from the relative intensities observed at the scattering angle of 87°. The effect of the angular distribution of the γ-rays is not taken into account.

[b] The error for $(2J+1)\Gamma_{\gamma 0}$ only includes the statistical error. An estimate of the uncertainty associated with the shape of the incident bremsstrahlung is not included.

[c] Ref. [8]).

[d] Ref. [54]).

[e] Ref. [8]); this value was used for the normalization of $^{27}Al(\gamma,\gamma')^{27}Al$ intensities in the present work.

[f] Ref. [55]).

[g] The value given is not the $(2J+1)\Gamma_{\gamma 0}$ but the $(2J+1)\Gamma_{\gamma 0}\Gamma_\gamma/\Gamma$ value.

[h] The value of $(2J+1)\Gamma_\gamma\Gamma_p/\Gamma$ from ref. [8]) has been used to estimate the value of $(2J+1)\Gamma_{\gamma 0}$.

NEUTS E ABV 12 MEV

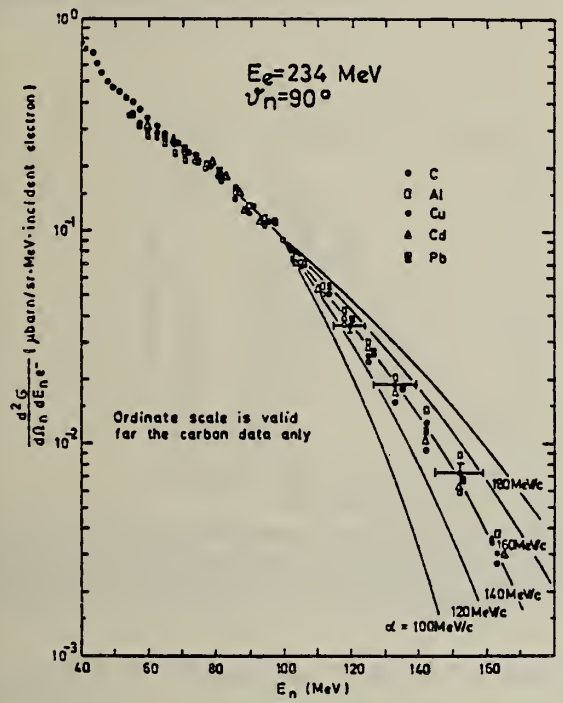

Fig. 8. Comparison of the shape of the high-energy part of the photoneutron spectra from C, Al, Cu, Cd and Pb. These measurements were performed with the same γ-shower spectrum, produced in a 0.3 cm thick lead sheet (see Fig. 2b). All spectra were fitted to the value for carbon at E_n=100 MeV. The values predicted by a quasi-deuteron model (solid lines), which are also fitted at E_n=100 MeV, were calculated with the parameters (defined in the text): E_b=−10 MeV, E_{well}=30 MeV and $C'L$=19.0 for different impulse parameters α=100, 120, 140, 160 and 180 MeV/c

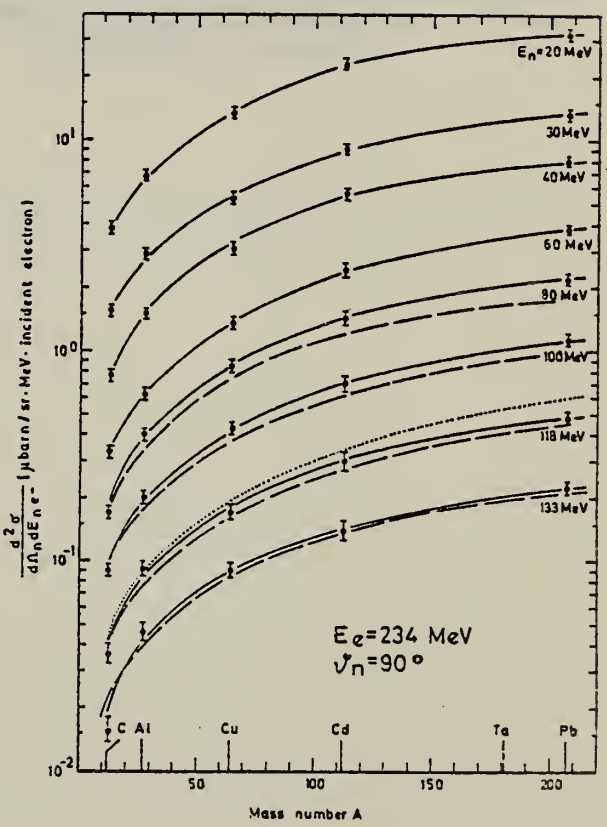

Fig. 9. Dependence of the production cross section on the mass number A with the neutron energy as parameter, measured at E_e=234 MeV. The γ-quanta were produced in a 0.3 cm thick lead sheet (see Fig. 2b) in front of the target of mass number A. The solid lines are fit curves through the measured values. The dashed lines are values calculated using a quasi-deuteron model with the parameters (defined in the text): E_b=−10 MeV, E_{well}=30 MeV, α=140 MeV/c and $C'L$=19.0. The dotted curve represents the dependence NZ/A, fitted at A=12. The error bars correspond to the statistical error

(over)

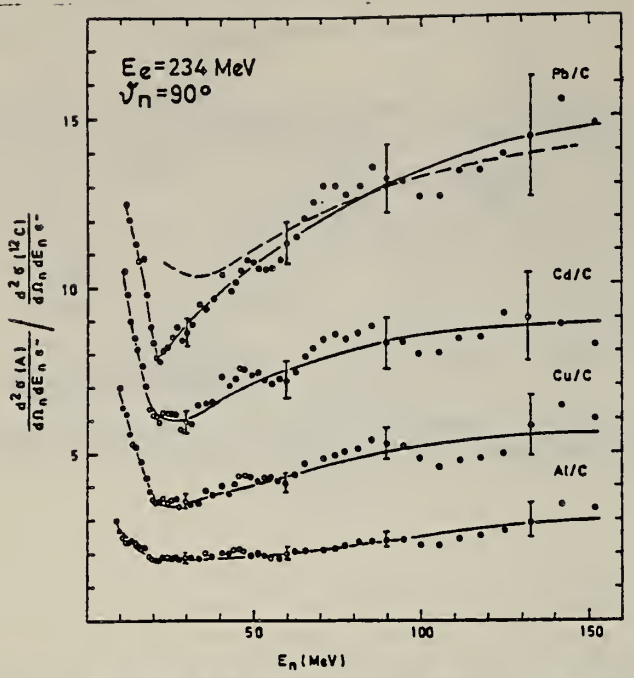

Fig. 10. Neutron yield from targets of mass number A relative to carbon, measured at $E_e = 234$ MeV. The target arrangement is that of Fig. 2b. The solid lines are fit curves through the experimental values. The dashed curve shows the energy dependence of the ratio of the nuclear absorption factors $f_a(\mathrm{Pb})/f_a(\mathrm{C})$, taken from Fig. 6. The error bars correspond to the statistical error

Self-absorption measurements 3=2.98

The bremsstrahlung beam from a 5 MeV electron linear accelerator was used to excite and study low-lying levels in ^{6}Li, ^{11}B and ^{27}Al. A self-absorption method was used to find the widths Γ of these levels. The following level widths are obtained: $\Gamma=(6.5^{+2.4}_{-1.7})$ eV for the 3.56 MeV level in ^{6}Li; $\Gamma=(0.23\pm0.09)$ eV for the 2.12 MeV level, and $\Gamma=(0.53\pm0.21)$ eV for the 4.44 MeV level in ^{11}B. For the 2.98 MeV level in ^{27}Al, the level width is found to be $\Gamma=(0.10\pm0.04)$ eV assuming that the lower energy member of the doublet at 3 MeV is excited.

The induced-activity method has been used to study the ratio of the cross sections for photo- and electrodisintegration of nuclei for the reactions $^{27}Al \rightarrow {}^{24}Na$ and $^{63,65}Cu \rightarrow {}^{58}Co$ in the energy interval 300–1200 MeV. The results of the measurements are compared with calculations with various assumptions regarding the spectra of virtual and real photons.

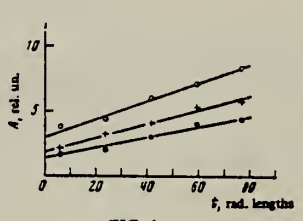

FIG. 1

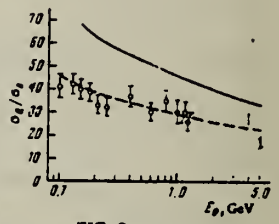

FIG. 2

FIG. 1. Target activity as a function of radiator thickness. Points: ○–E_0 = 800 Mev, +–1170 MeV, ●–600 MeV.

FIG. 2. The ratio σ_Q/σ_e as a function of electron energy E_0. Points: ○–$^{27}Al \rightarrow {}^{24}Na$; ●–$^{63,65}Cu \rightarrow {}^{58}Co$. The thin vertical line shows the data of ref. 4, and the heavy vertical line with end bars shows the data of ref. 5. The curves are theoretical.

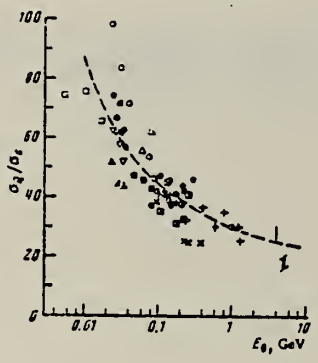

FIG. 4. The ratio σ_Q/σ_e as a function of E_0 for various reactions. Points: +–$^{27}Al \rightarrow {}^{24}Na$; ●–$^{63,65}Cu \rightarrow {}^{58}Co$. These points represent the data of the present work and of ref. 3. The other designations are given in ref. 9.

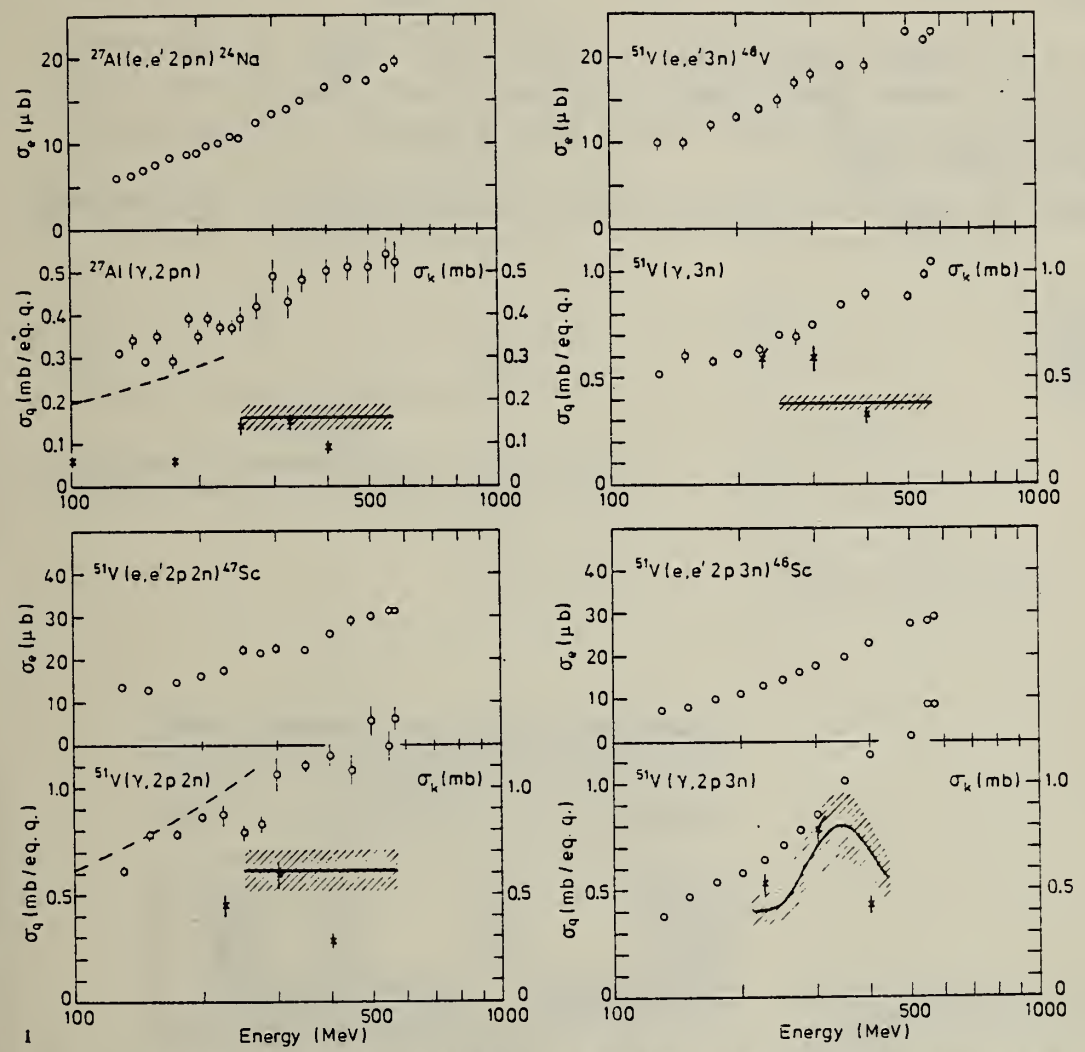
Cross sections for some electro- and photoinduced spallation reactions on ^{27}Al and ^{51}V have been measured in the energy region 130-580 MeV with the activation method. The cross sections per photon are compared to Monte-Carlo calculations based on a cascade-evaporation model. The electrodisintegration cross sections are compared to calculations based on the Dalitz formalism for virtual photon spectra.

GIVES YLD RATIO G/E



Figs. 1 and 2. Experimental cross sections σ_q and σ_e versus energy for different reactions on ^{27}Al and ^{51}V. The cross sections σ_k deduced from σ_q are given by the solid drawn curves, the hatched areas showing the uncertainty. Dashed curves show σ_q calculated from the low-energy data in Reference 11. Crosses give σ_k calculated with Monte-Carlo method

Abstract: Information on proton hole states has been obtained for ^{27}Al, ^{40}Ca and ^{51}V through the (e, e'p) reaction. Lower-lying hole states have been identified. For ^{40}Ca an extensive analysis has been performed to study the structure of the 1s hole state. For ^{27}Al and ^{51}V, the properties of the 1s hole states have also been determined. The separation energies of the 1p and 1s states seem to be constant (40 and 60 MeV, respectively) for $A > 30$.

*SEPARATION ENERGY

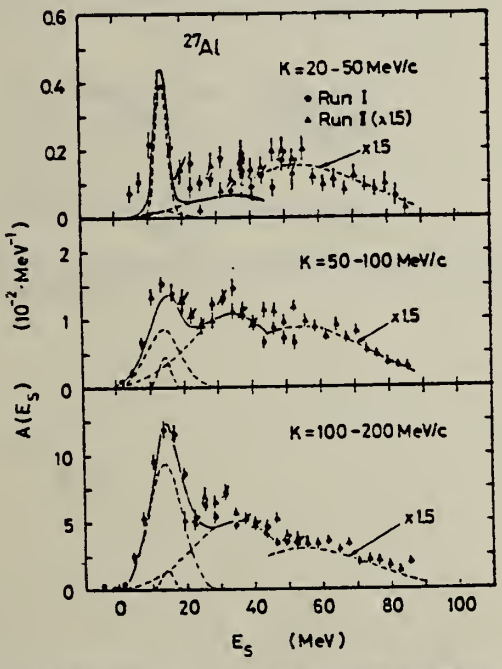

Fig 4a. Proton separation energy spectra for ^{27}Al. The solid curves are the result of the PWIA fit. The contributions from each proton state are shown by the dashed curves.

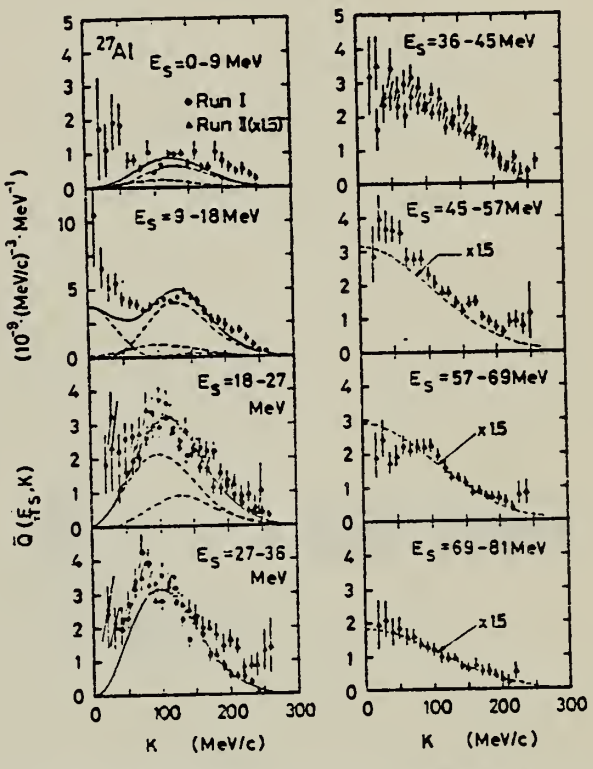

Fig. 4b. Recoil momentum distributions for ^{27}Al. The curves are as in fig. 4a.

Inelastic electron scattering has been used to measure the total hadronic cross sections for absorption of photons with energy 150-500 MeV by nuclei of C, Al, Ni, Mo, and W. The results obtained are compared with calculations carried out in the impulse approximation.

COMMENTS: $f \sim \exp(-Bp^2)$

$$B = \frac{E}{p^4(d^2\sigma/d\Omega dpQ)}$$

*E,GEV, 999=4.5 GEV

The A^n-dependence and momentum spectra of photoprotons in the nuclei ^{12}C, ^{27}Al, ^{63}Cu, ^{118}Sn, and ^{208}Pb have been studied experimentally for maximum bremsstrahlung energies of 2.0, 3.0, and 4.5 GeV. The A-dependence shows that the proton photoproduction mechanism for $E_\gamma > 400$ MeV is identical for the entire kinetic-energy region 65–280 MeV and the angle region 45–150° for the secondary protons studied. The dependence of the exponent n on the transverse momentum $p_\perp$ is in good agreement with the same dependence for protons produced in nuclei by primary protons. In the momentum spectra of the invariant cross section $f = (E/p^2)(d^3\sigma/d\Omega dpQ) \sim \exp(-Bp^2)$ it is observed that the parameter B does not depend on the incident-photon energy and on the target nucleus, but depends on the proton-detection angle.

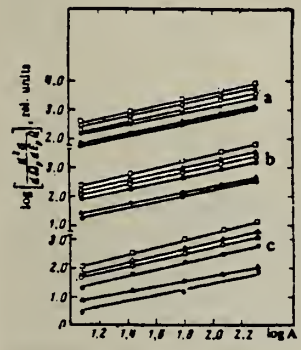

FIG. 1. Differential cross section for proton photoproduction as a function of atomic number A of the nucleus at E_0 = 2 GeV. The lines a correspond to ϑ_p = 60°, b to 90; and c to 150°. Points: □—E_p = 64, Δ—80, ○—101, ■—137, ▲—209, and ●—280 MeV.

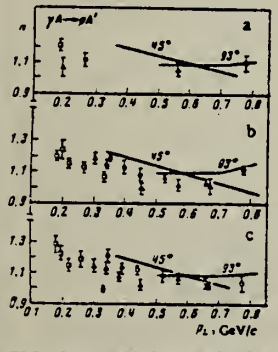

FIG. 2. Dependence of the exponent n in the A^n dependence of the cross section for the reaction $\gamma A \to pA'$ as a function of proton transverse momentum: a—E_0 = 2.0 GeV, b—E_0 = 3.0 GeV, c—E_0 = 4.5 GeV. The points for a and b: Δ—ϑ_p = 60°, ○—90°, □—150°; for c: Δ—ϑ_p = 46°, ○—86°, □—136°. The curves show the dependence of n on $p_\perp$ for the reaction $A(p,p')A'$ taken from Ref. 9.

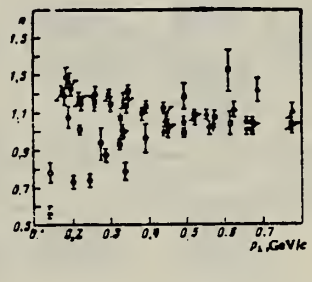

FIG. 3. The same as Fig. 2. Experimental points: ▲—E_0 = 0.13, ○—0.25, ▲—0.4, □—1.2, □—2.0, ×—3.0, and ●—4.5 GeV.

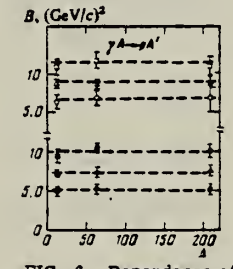

FIG. 6. Dependence of the parameter B from the relation $f \sim \exp(-Bp^2)$ on the atomic number of the target nucleus. The solid points refer to E_0 = 2.0 GeV, and the hollow points to E_0 = 3.0 GeV; the points ● and ○ are for ϑ_p = 60°, ▲ and Δ are for 90°, and ■ and □ are for 150°.

Photonuclear reactions in the targets ^{27}Al, ^{28}Si, ^{31}P, ^{32}S, and ^{40}Ca have been studied for maximum bremsstrahlung energies of 2, 2.4, 3, and 4.5 GeV. The yields of the residual nuclei ^{7}Be, ^{11}C, ^{13}N, ^{18}F, ^{22}Na, and ^{24}Na were measured by means of a germanium-lithium semiconductor detector with a sensitive volume of 30 cm^3. In discussion of the results we took into account the contribution of the low energy part of the bremsstrahlung spectrum. Comparison of the measured yields with estimates calculated by Rudstam's formula permitted us to conclude that there is a difference in the mechanism of formation of the light fragments ^{7}Be, ^{11}C, and ^{13}N from that of the other residual nuclei ^{18}F, ^{22}Na, and ^{24}Na.

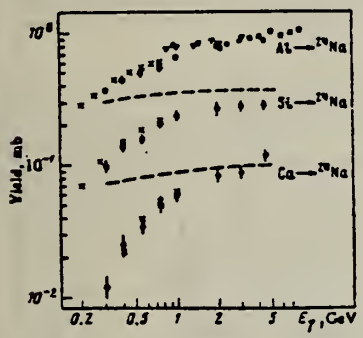

FIG. 1. Yields of the isotope ^{24}Na from targets of Al, Si, and Ca. ×—Data of Ref. 4, ○—data of Ref. 2, ▽—data of Ref. 6, □—data of Ref. 10, ●—data of the present work. The dashed lines show the contributions of the low energy part of the bremsstrahlung spectrum to the yields of the reactions Al—^{24}Na, Si—^{24}Na according to the data of Ref. 4 and the results of the calculations of the present work.

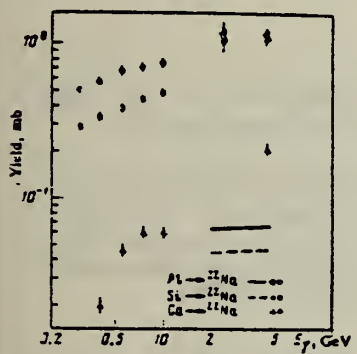

FIG. 2. Yields of ^{22}Na from targets of Al, Si, and Ca. The hollow symbols show the data of Ref. 2, and the solid symbols the data of the present work. The lines indicate the results of the calculations of the present work, which determine the contribution of the low-energy part of the bremsstrahlung spectrum to the yields of the reactions Al—^{22}Na and Si—^{22}Na for 2 GeV $\leq E_{\gamma_{max}} \leq$ 4.5 GeV.

Cross sections for electroproduction and photoproduction of charged pions on ^{27}Al and ^{51}V have been measured in the energy region 130–580 MeV by use of the activation method. Special care has been taken to subtract out background yields. Photoproduction cross sections have been calculated from the region just above threshold to the tail of the (3,3) resonance. π-nucleus final state interactions are taken into account through optical potentials. Calculated photoproduction cross sections are decomposed into multipoles which are used to derive relative bremsstrahlung-induced to electron-induced yields. The pronounced effect of final state interactions is pointed out and discussed.

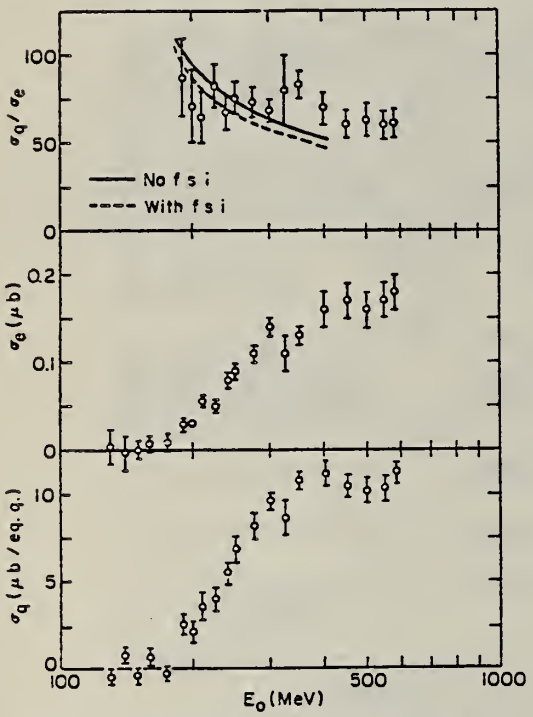

FIG. 3. Bremsstrahlung cross section per equivalent quantum σ_q and electron cross section σ_e and ratio σ_q/σ_e as a function of electron energy for the reactions ^{27}Al$(\gamma,\pi^+)^{27}$Mg and ^{27}Al$(e,e'\pi^+)^{27}$Mg. See text for theoretical curves.

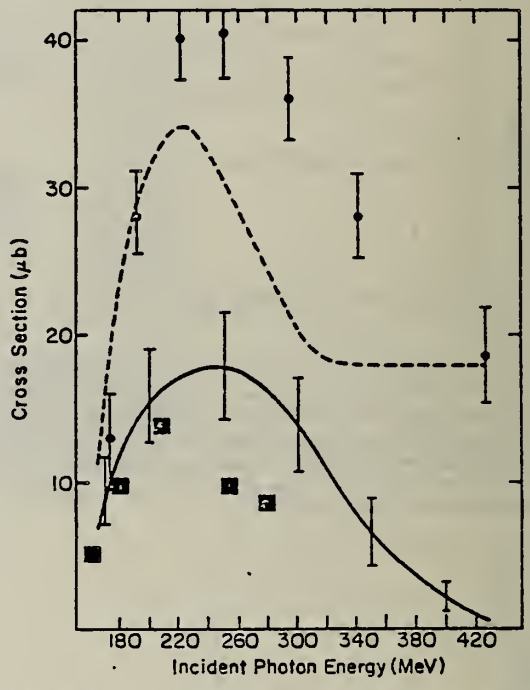

FIG. 6. Experimental cross sections per photon for the reaction ^{27}Al$(\gamma,\pi^+)^{27}$Mg. The solid curve with error bars is the result of the present work. Circles with error bars are the data of Ref. 17. The dashed curve is the work of Ref. 13. The full squares are the work of Ref. 12. Reaction threshold is 142 MeV.

A survey of electromagnetic transitions excited in ^{27}Al by 180° inelastic electron scattering has been made at incident energies of 37, 51, and 61 MeV. Transitions to levels at 2.23, 2.98, 4.42, 8.74, and 11.69 MeV are dominantly $M1$ with some possible $E2$ contributions. Tentative $M1$ assignments are given transitions at 7.57 and 8.05 MeV, but the possibility of their being $E1$ cannot be excluded. Transitions to levels at 10.68 and 12.30 MeV are probably $M1$ but with considerable $E2$ admixture. A transition at 6.50 MeV is also probably $M1$, but both $E1$ and $E2$ are possible alternative assignments. Model-dependent radiative widths $\Gamma_0(M1)$ for the $M1$ transitions are given based on an analysis of the data using simple but representative harmonic-oscillator wave functions to calculate cross sections.

10 LEVELS

TABLE I. Values of cross sections for excitation of the nuclear transitions studied at the three incident energies of 37.3, 50.9, and 60.5 MeV.

Excitation energy (MeV)	Cross section (nb/sr) 37.3 MeV	50.9 MeV	60.5 MeV
2.23	3.40±0.95	2.19±0.44	1.74±0.42
2.98	2.97±1.01	1.79±0.39	1.06±0.29

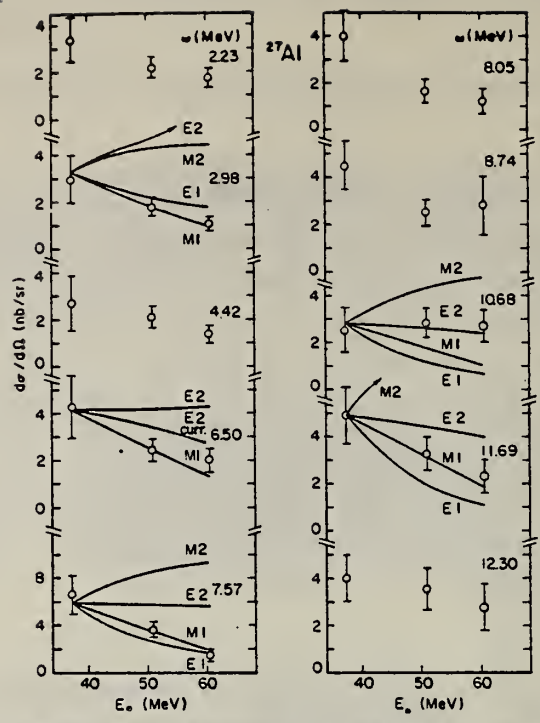

FIG. 2. Plots of experimental cross section vs incident energy for the transitions observed. In selected cases comparison has been made with cross section curves calculated from the generalized Helm model for four different multipolarities. Shown with the 6.5-MeV plot is a comparison with only the $E2$, $E2$ current, and $M1$ Helm curves. The model parameters used were: $\rho_1 = \bar{\rho}_1 = 1.16$ fm^{-3}, $\gamma_1 = 1$, $g = \bar{g} = 0.77$, with $\beta_1 = 1$ for the electric transitions and $\beta_1 = 0$ for the magnetic transitions (see Ref. 7).

Cross sections for photoproduction and electroproduction of π^+ on ^{27}Al and ^{51}V leading to bound states in the daughter nuclei have been measured at Kharkov in the energy range 600–1200 MeV by use of the activation method. Careful comparison is made to other recent results obtained at intermediate and high energies. Agreement is found between the present data and results of earlier work carried out at Lund and DESY. Discrepancies between photoproduction data taken at different laboratories are attributed to differences between methods of background subtraction. Relative bremsstrahlung-induced to electron-induced yield ratios are compared with predictions based on the Dalitz-Yennie formalism for virtual-photon spectra.

Measurements were made of quasielastic scattering of electrons in the (e, e') reaction by the nuclei ^{9}Be, ^{12}C, ^{14}N, ^{16}O, and ^{27}Al. An experimental estimate is obtained of the effective mass of an intranuclear nucleon. At excitation energies up to 80 MeV, a ratio $M^*/M \approx 0.6$ is obtained, corresponding to a linear potential $V(E) = V_0 + 0.4E$ and in good agreement with the data on proton scattering by nuclei [C. M. and F. G. Perey, Atomic Data and Nuclear Tables 13, 294 (1974)]. At excitation energies above 120 MeV the nucleon effective mass turned out to be close to that of the free nucleon, $M^*/M = 0.9$.

Abstract: The disintegration of aluminium nuclei by 800 MeV electrons is studied using plastic detectors. Angular and energy distributions of emitted Li, Be and B isotopes are presented. The compatibility of the results with a two-stage process (cascade and evaporation) is studied with the aid of a Monte Carlo calculation.

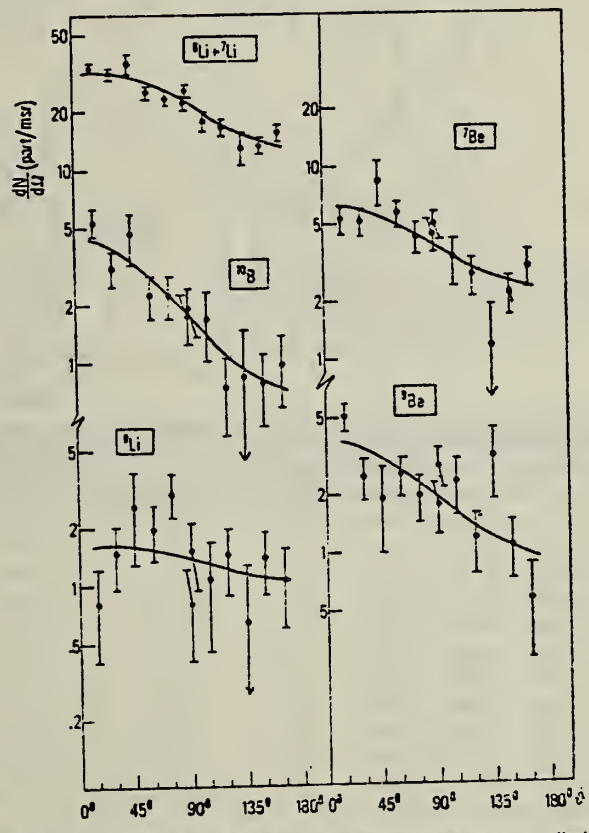

Fig. 4. Angular distributions of most of the detected fragments within the energy limits quoted in table 1. The lines, normalized to the experimental data, are the results of a Monte Carlo calculation (see text).

over

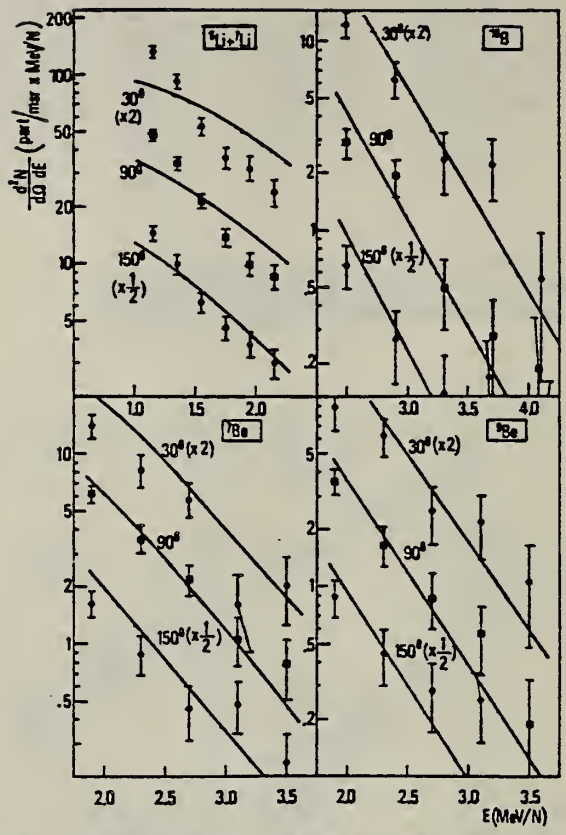

Fig. 5. Energy spectra of the fragments $^{6}Li + ^{7}Li$, ^{7}Be, ^{9}Be and ^{10}B at mean emission angles of 30°, 90° and 150° to the beam in the lab system. The lines are the result of a Monte Carlo calculation (see text) and are normalized to the experimental data at 90° only. The data and curves at 30° have been raised by a factor of two, those at 150° have been lowered by a factor of two.

Abstract—Mean cross sections for the photoproduction of ^{7}Be and ^{11}C from ^{19}F, ^{27}Al, ^{28}Si and ^{32}S targets, ^{7}Be from ^{10,11}B, and ^{11}C from ^{14}N and ^{16}O targets have been measured using bremsstrahlung beams in the energy range 0.3–1.0 GeV. The results have been compared with previous measurements and an excellent agreement has been found. In most cases, the values obtained turned out to be much larger than those expected from a simple spallation mechanism. A fragmentation and/or a fission-like process has been suggested in explaining the mechanism of such reactions.

999= 1 GEV

Experimental data on the (γ, p) reaction at $E_\gamma = 60-100$ MeV for targets in the range $A = 7-93$ are compared with predictions based on a single-particle knock-out mechanism using shell model wavefunctions. The results show that this mechanism is more important than has generally been believed

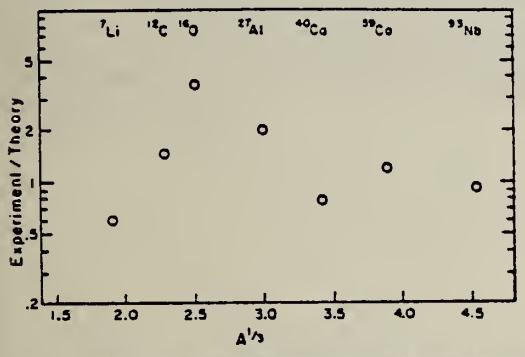

Fig. 2. The ratio of the measured photoproton emission populating low-lying states to the single-particle direct knock-out predictions is shown as a function of nuclear mass A for 80 MeV bremsstrahlung. Errors in the ratio, due to uncertainties in our calculations, are estimated to be a factor of ≈ 1.5. Errors in the experimental data are negligible.

Analysis is made of reactions interfering with photon activation analysis procedures.

The activation yield curves have been presented for a number of photonuclear reactions in the energy range from 30 to 68 MeV, in order to evaluate quantitatively the interferences due to competing reactions in multielement photon activation analysis. The general features of the yields as functions of both target mass number and excitation energy were elucidated from the data obtained, discussion being given on the results in terms of the reaction mechanism.

Simultaneous neutron activation due to appreciable neutron production from the converter and surrounding materials has also been studied, and, finally, the magnitudes of interferences in real multielement analysis were given in the form of their energy dependences.

Abstract: Measurements of the γ-ray decay and angular distributions at eight low-energy (E_p < 1 MeV) ^{26}Mg(p, γ)^{27}Al resonances lead to the spin and parity assignments $J^\pi = \frac{1}{2}^+, \frac{1}{2}^-, \frac{3}{2}^-, \frac{3}{2}^+, \frac{5}{2}^+, \frac{5}{2}^-, \frac{7}{2}^-$ and $\frac{9}{2}^-$ for the bound states at E_x = 3.96, 4.05, 5.16, 5.25, 5.44, 6.16, 6.99, 7.23 and 7.48 MeV, respectively. For other levels, spin and parity limitations are set. Also reported are precise excitation energies, branching and mixing ratios, and lifetime limits. For the resonances additional information is given on energies, strengths and widths. The reaction Q-value is Q = 8271.0±0.5 keV. The level scheme of ^{27}Al, complemented with these new data, is compared with the results from recent shell-model calculations.

This paper presents energy spectra of α particles emitted following the bombardment of ^{27}Al, ^{nat}Ni, ^{92}Mo, ^{94}Mo, and ^{197}Au with 120-MeV electrons, together with α-particle angular distributions from ^{197}Au and ^{nat}Ni for $E_\alpha = 30$ and 50 MeV. The data are compared with preequilibrium exciton-model and statistical-model calculations. It is concluded that few-step processes are dominant in the production of α particles with energies above 20 MeV.

PREEQUILIB A EMISS

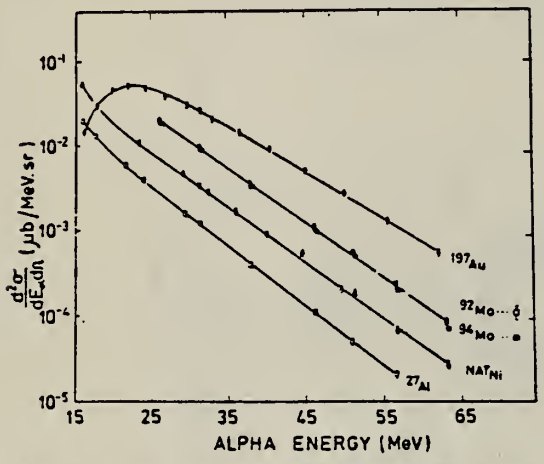

FIG. 1. α-particle energy spectra at $\theta_\alpha = 30°$, for $E_e = 120$ MeV. Errors shown are the sum of statistical and systematic contributions. The solid lines are a guide to the eye.

TABLE I. Temperatures corresponding to the preequilibrium component of the (e,α) reaction, derived from energy spectra at $\theta_\alpha = 30°$ for $E_e = 120$ MeV.

Target	Temperature[a] (MeV)
^{27}Al	5.3
^{nat}Ni	5.5
^{68}Zn	5.4
^{92}Mo	5.6
^{94}Mo	5.4
^{197}Au	6.1

The ratio $R = \sigma^+/\sigma^-$ of the cross sections for inelastic positron and electron scattering on ^{12}C and ^{27}Al has been measured for four momentum transfers 0.08 $(GeV/c)^2 \leq q^2 \leq 0.45$ $(GeV/c)^2$ of the virtual photon and invariant masses 0.95 GeV $\leq W \leq$ 3.3 GeV of the hadronic system. The mean value of the ratio is $R = (1.005 \pm 0.027)$. No q^2, respectively, W dependence of the ratio is observed.

Table 2
Ratio $R = \sigma_+/\sigma_-$ for inelastic lepton scattering on ^{27}Al. The variables are defined in table 1. All errors include the systematic error contributions given in the text.

Inelastic electron scattering form factors were measured for the low-lying odd-parity states of ^{27}Al over a momentum transfer range of 0.57 to 2.41 fm^{-1}. Reduced ground-state transition probabilities were deduced for states at 4.055 MeV(1/2$^-$), 5.156 MeV(3/2$^-$), 6.159 MeV(3/2$^-$), 6.477 MeV(7/2$^-$), 6.605 MeV(1/2$^-$ or 3/2$^-$), 6.651 MeV(5/2$^-$), 6.993 MeV(3/2$^-$), and 7.228 MeV(9/2$^-$). In addition, the results support odd-parity assignments for the 5.827 MeV(3/2$^-$ or 5/2$^+$) and 7.477 MeV(7/2) levels. Attempts have been made to interpret the results in terms of the weak-coupling and strong-coupling models. The measurements confirm the apparent high concentration of 1*p*-shell proton hole strength in the 4.055 MeV,1/2$^-$ and 5.156 MeV,3/2$^-$ states. To satisfactorily account for the observed properties of these two levels using the weak-coupling model requires an anomalously small value of 1.35 MeV for the spin-orbit splitting of the 1*p* shell. The structure of levels in the 6 to 7.5 MeV region is shown to be based on the excitation of 1*d*-shell nucleons into the 1*f* shell.

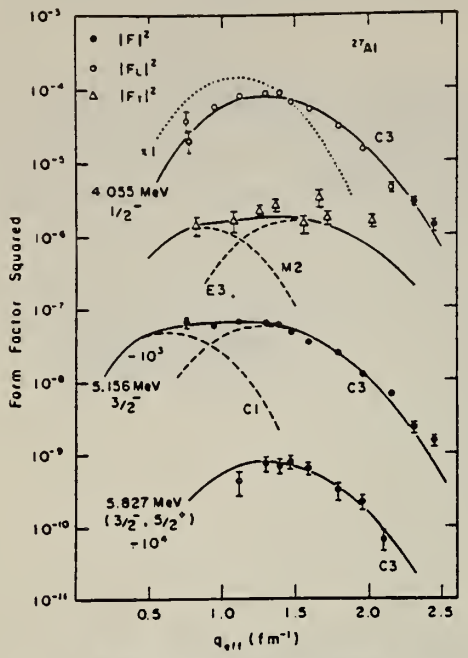

FIG. 5. Inelastic form factors measured for $1p$-hole states in ^{27}Al, and comparison with best-fit theoretical curves. The calculated longitudinal form factors were obtained in the distorted-wave Born approximation using the single-particle, harmonic oscillator model with b = 1.85 fm. The q dependence of the data differs markedly from that expected for the $C3$ multipole of a $1d \rightarrow 1f$ transition, which is represented by a dotted curve at the top of the figure.

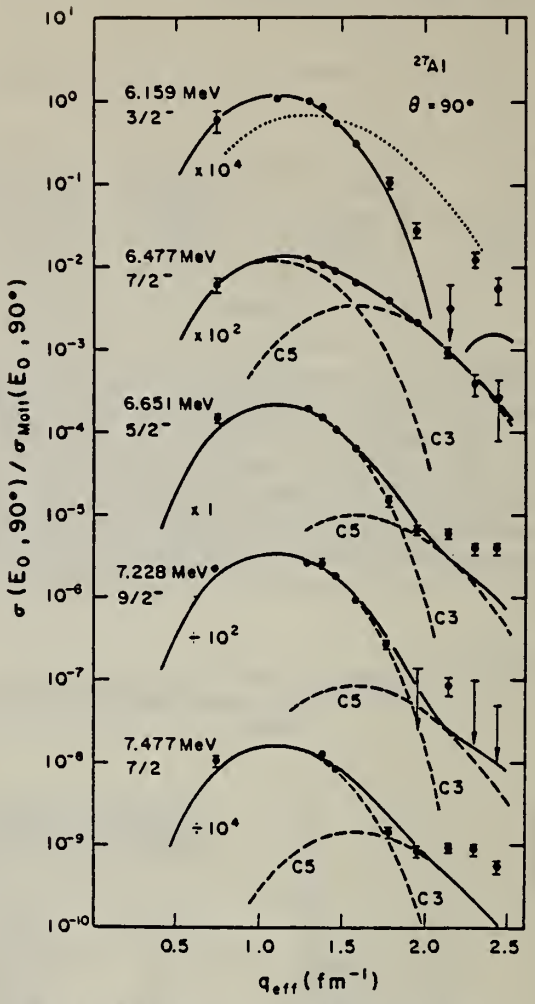

FIG. 6. Measured (e, e') form factors for ^{27}Al odd-parity states characterized, in large part, by the excitation of a $1d$-shell nucleon into the $1f$ shell. For comparison, the q dependence expected for a $C3$ excitation to a $1p$-hole state is shown by the dotted line at the top of the figure. The best-fit DWBA curves were calculated using the single-particle harmonic oscillator model with b = 1.94 fm. Transverse components were assumed to be small and are excluded from the calculated curves.

Measurements of the charged-particle yield in the electrodisintegration of ^{27}Al have been carried out in the linear electron accelerator at our institute. Positively charged particles emitted from the target were analyzed in momentum by a magnetic spectrometer in the focal plane of which were located 10 surface-barrier silicon detectors. This arrangement permitted separation of particles according to the value of Z^2/A, where Z and A are the charge and atomic weight of the particle, respectively. The technique permitted simultaneous detection of five groups of particles: p, d, t, ^{3}He, and ^{4}He. Protons and α-particles, which have identical Z^2/A, were separated by appropriate choice of the bias voltages on the detectors.[1] An example of this separation is shown in Fig. 1 for particles emitted at an angle $\theta = 20°$.

Yield measurements were made at four angles $\theta = 20$, 55, 90, and 110° for an initial electron energy 100 MeV. The differential cross sections obtained for protons, deuterons, tritons, and α particles as a function of the

[1])Khar'kov State University.

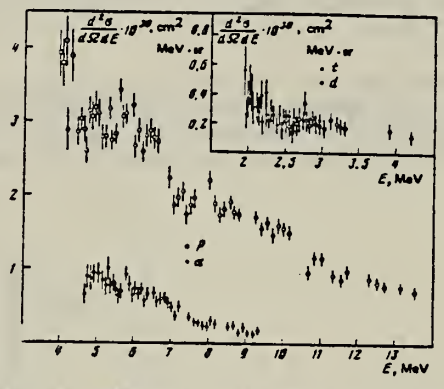

FIG. 2. Differential cross sections for production of p, d, t, and α in electrodisintegration of ^{27}Al. $E_0 = 100$ MeV, $\theta = 55°$. The errors are only statistical.

kinetic energy of the detected particles (Fig. 2) show that the α-particle yield is comparable with the proton yield. In the kinetic-energy region 7–8 MeV the ratio of the cross sections for protons and α particles as a function of angle is isotropic and amounts to 4.8 ± 0.5. The ratio of the triton and α-particle cross sections at 55° is 0.3 ± 0.1. This value agrees with the data of Adler *et al.*,[2] who reported the yield ratio ($t/^4$He) obtained with γ rays at an initial energy 500 MeV.

Photon absorption by Al, Ta, and Bi between 3 and 30 MeV was measured using as a photon spectrometer a photoneutron time-of-flight detector and a liquid deuterium target. The atomic cross sections of Ta and Bi at the lowest energies (and of Al at higher energies) agree with calculated values appearing in published tabulations but exceed them at 25 MeV by about 2% in Ta and 3% in Bi. Calculations by others using empirical Coulomb corrections and improved screening corrections to the cross section for pair production by the nucleus agree with experiment to within $(0.5 \pm 0.4)\%$. Best experimental values of the combined correction for Bi are given.

[NUCLEAR REACTIONS ^{27}Al, ^{181}Ta, ^{209}Bi; measured total photon absorption $\sigma_\gamma(E)$; observed GDR; deduced electron pair production $\sigma_K(E)$; $E = 3.0$ to 30.0 MeV; resolution 500 keV; deduced experimental values for Bi of the combined Coulomb and screening correction; ^{2}H(γ,n) LD$_2$/TOF spectrometer.]

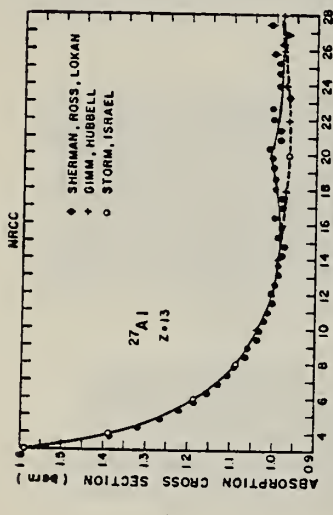

FIG. 3. The measured Al absorption cross section (solid circles) compared to the new (Ref. 6) (crosses) and old (Ref. 5) (open circles) theory. The excess above 15 MeV is photonuclear.

TABLE V. Values σ_A and σ_B of the Al absorption cross section obtained from different data sets A and B for photon energies ω below the photonuclear giant resonance. Data set A was accumulated in about one-quarter the time required for data set B, at an average counting rate about 4% higher. The difference $\delta_{AB}\sigma$ between the two measurements is listed, as are σ_{AB}(Al) obtained by statistically weighting both data sets, σ_{calc} interpolated from a table[a] of calculated values, and $\delta\sigma$ the difference between σ_{calc} and the experimental values σ_{exp}(Al) obtained from σ_{AB}(Al) by correcting for in-scattering and air displacement.

DATA ALSO IN 81AR3

Double differential cross sections for the photo-emission of protons and charged pion production were investigated for a number of target nuclei (He, Be, C, O, Al, Ti, Cu, Sn, Pb) in the photon energy range k = (215–386) MeV. On the basis of these experimental results the total hadronic cross section was determined.

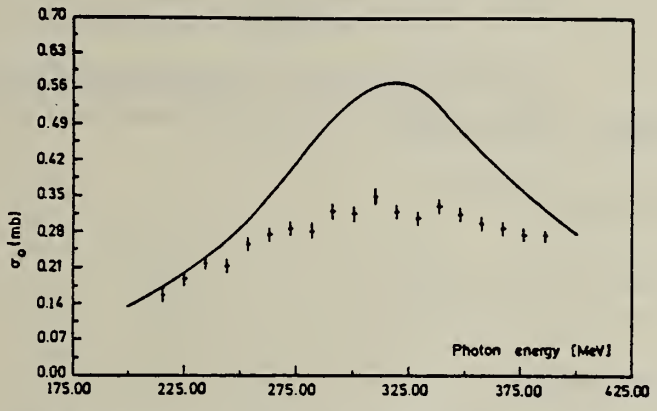

Fig. 7. Parameter σ_0 as a function of photon energy (data points) compared to the mean cross section for a free nucleon (solid line).

The total hadronic cross sections for all measured elements can be parametrized in the form

$$\sigma(k, A) = \sigma_0(k) \cdot A^x ,$$

A being the atomic number, with a constant exponent $x = 1.1$. The photon energy dependence of σ_0 is shown in fig. 7. Compared to the mean cross section for a free nucleon (the solid line in fig. 7) the excitation of the Δ-resonance is suppressed. Such a suppression is expected in the Δ-hole model [11].

Abstract: Double differential cross sections for the photoemission of protons and charged pion photoproduction were investigated for a number of target nuclei (He, Be, C, O, Al, Ti, Cu, Sn, Pb) using the tagged bremsstrahlung beam at the Bonn 500 MeV-Synchrotron in the photon range k = (215-386)MeV. On the basis of these experimental results the total hadronic cross section was determined.

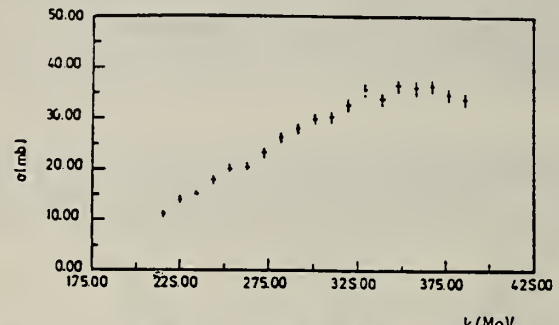

Fig. 2. Cross section for the process: $\gamma + Pb \rightarrow p + X$. The proton threshold is 58 MeV.

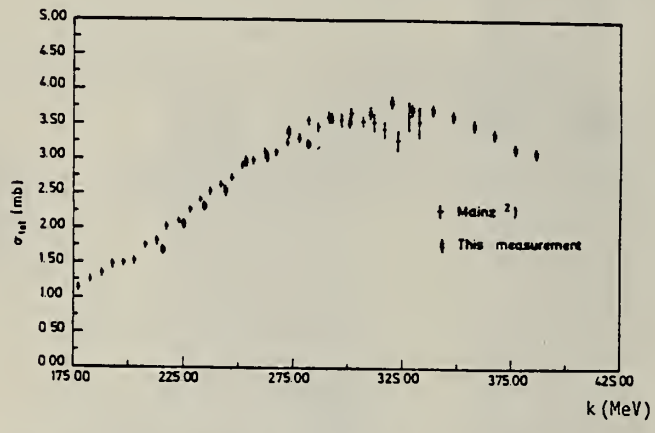

Fig. 3. Total hadronic cross section for Be. The data are compared to the cross section taken from ref.[2]).

The photon energy dependence of the total cross sections for heavier nuclei are similar to the Be results. The complete data set can be parametrized in the form

$$\sigma(k,A) = \sigma_0(k) \cdot A^x.$$

The exponent is constant x = 1.1. The photon energy dependence of σ_0 is shown in fig. 4. Compared to the mean cross section for a free nucleon, the excitation of the Δ-resonance is suppressed.

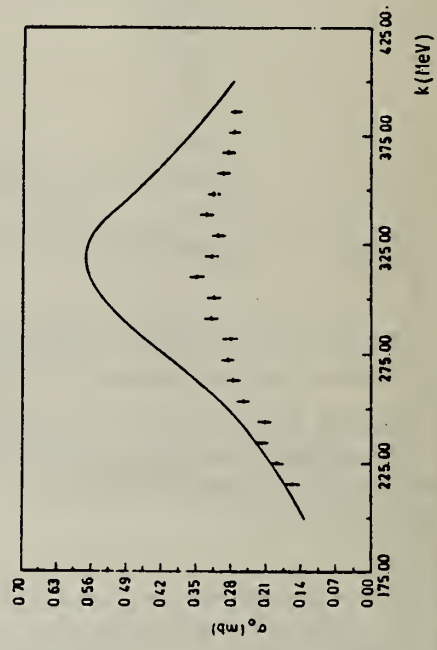

Fig. 4. Parameter σ_0 compared to the cross section for a free nucleon (full line).

Abstract. Lifetimes of 49 excited states below 1.65 MeV have been measured in ^{24}Mg, ^{27}Al, ^{48}Ti, ^{58}Ni, ^{59}Co, ^{61,62}Ni, ^{63,65}Cu, ^{64,66,68}Zn, ^{75}As, ^{103}Rh, ^{113,115}In, ^{116,118,120}Sn and ^{121,123}Sb by means of nuclear resonance fluorescence experiments. The levels are excited by bremsstrahlung x-ray photons. The self-absorption technique applied to suitable cases provides nuclear absorption cross sections, widths and lifetimes from which the x-ray spectral distributions are also obtained. Scattering experiments are performed for all other cases in order to obtain widths and lifetimes from these x-ray photon curves. The Compton effect in the sample is taken into account. Self-absorption provides $g\Gamma_0$ from which Γ is deduced using adopted J^π and Γ_0/Γ values; scattering provides $u = g(\Gamma_0^2/\Gamma)W(\theta)$ from which Γ is also deduced with J, Γ_0/Γ and mixing ratios taken from the literature. Thanks to simultaneous determination of the x-ray spectra all the lifetimes as given by our programs with their statistical errors form an unusually coherent set of values.

NUCLEAR REACTIONS (γ, γ), bremsstrahlung excitation; natural isotopes; ^{24}Mg, ^{27}Al, ^{48}Ti, ^{58}Ni, ^{59}Co, ^{61,62}Ni, ^{63,65}Cu, ^{64,66,68}Zn, ^{75}As, ^{103}Rh, ^{113,115}In, ^{116,118,120}Sn and ^{121,123}Sb; $E \simeq 0.5$–1.65 MeV; measured $g\Gamma_0$ or $g(\Gamma_0^2/\Gamma)W(\theta)$; deduced $T_{1/2}$.

Remarque. Pour calculer δ^2 quand nous ne disposons que de $B(E2)$, pour un mélange (E2) + (M1), nous déduisons $g\Gamma_0(E2) \propto B(E2)E_\gamma^5$; en admettant $W(\theta)=1$ et connaissant Γ_0/Γ, notre détermination de u donne une première approximation de $g\Gamma_0$ d'où une valeur de $\delta^2=(g\Gamma_0(E2))/(g\Gamma_0-g\Gamma_0(E2))$ qui permet d'améliorer $W(\theta)$ et $g\Gamma_0$ de proche en proche.

Photoproton spectra have been obtained from the ^{27}Al nucleus at 14 bremsstrahlung maximum energies E_γ^{max} in the range 17.0–29.7 MeV. From the spectra we have calculated the partial cross sections for the photoproton reaction with formation of the final nucleus in the ground state, the first two excited states, and in groups of states with centers of gravity at 4.4, 6.6, 8.5, 11.0, and 13.0 MeV. The sum of the partial cross sections exhausts the total cross section of the (γ,p) reaction. Analysis of the experimental results was carried out simultaneously for the nuclei ^{27}Al, ^{26}Mg, and ^{28}Si with use of data on pickup reactions. The role of nucleons of different shells and the fraction of excitations of the $1p\,1h$ type in the ^{27}Al giant dipole resonance are estimated. The influence of the structure of the ground state of nuclei of the $1d$-$2s$ shell on the properties of the giant resonance is discussed.

VIRT PHOTON THEOR

Abstract: Photoproton spectra from ^{27}Al were measured from 14.8 to 27.6 MeV excitation energy in 400 keV steps. From these, high resolution photoproton cross sections to low-lying states of the residual ^{26}Mg nucleus were deduced. The large integrated cross sections to these states justify the interpretation of the de-excitation γ-ray measurements which consistently indicate strong population of low-lying residual states following photodisintegration. Further, the results are discussed with reference to the particle-hole model. By examination of the microscopic configurations of the possible GDR states an explanation is proposed for the differences in the cross sections to various residual states. Finally, the results are compared with spectroscopic factors determined from pickup reactions on ^{27}Al.

E NUCLEAR REACTIONS ^{27}Al(e, p), E = 14.8-27.6 MeV; measured proton energy spectra at θ = 90°. Deduced $\sigma(\gamma, p)$ to different ^{26}Mg states, mechanism. Magnetic spectrometer, isotopically pure target.

Abstract: The angular distributions of the $^{27}Al(\gamma, p_0)$ and $^{27}Al(\gamma, p_1)$ reactions were measured over the GDR energy region. Both reactions exhibit considerable anisotropy indicating the effects of multipole interference. From the behaviour of the fitted Legendre polynomial coefficients the principal 1p-1h configurations in the $^{27}Al(\gamma, p_0)$ reaction were investigated and an approximate cross section for the E2 component deduced using justifiable assumptions. The angular distribution of the $^{27}Al(\gamma, p_1)$ reaction is qualitatively similar to that of the $^{27}Al(\gamma, p_0)$ reaction. However if only a single intermediate configuration is involved it appears that the first excited state (2^+) of ^{26}Mg is likely to be populated by $p_{3/2}$ proton emission whereas the ground state (0^+) is populated predominantly by $f_{7/2}$ proton emission from the ^{27}Al GDR.

E NUCLEAR REACTIONS $^{27}Al(e,p)$, E = 16.8–25.6 MeV; measured $\sigma(E,\theta)$, derived $\sigma(\gamma, p_i, \theta)$. ^{27}Al deduced GDR configurations, E2 decay characteristics.

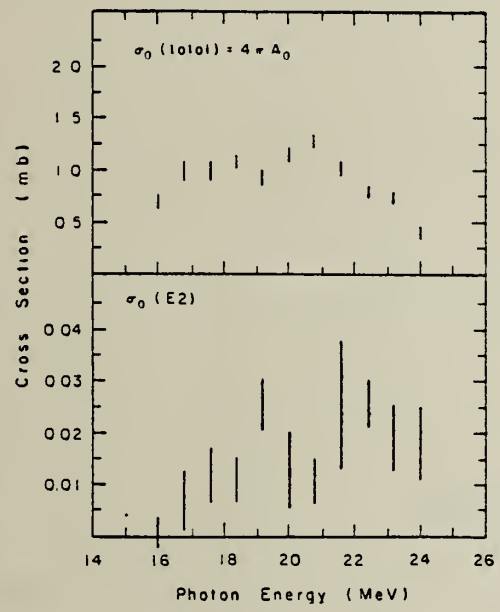

Fig. 7. The small E2 component of the $^{27}Al(\gamma, p_0)$ cross-section calculated from eq. (7) (see text) is plotted in the lower half of the diagram while the total cross section, given by $4\pi A_0$, is plotted in the upper half for comparison.

SILICON
Z=14

The name silicon was derived from *silic-*, the bare syllables of the Latin word silex meaning "flint". Before 1787 chemists thought that the compound of silicon, silica, was an element. It was then that Lavoisier speculated that silica was an oxide of an unknown element. In 1817 Berzelius decomposed iron silicite in such a way that the presence of another metal was indicated. Finally, in 1824, he showed that this metal was derived from silica and he succeeded in preparing the amorphous form of it. The crystalline form was first prepared by Sainte-Claire Deville in 1854 by electrolysis of impure sodium chloride containing about 10% silicon in the melt. Shiny platelets of silicon were obtained when he dissolved the aluminum.

Si²⁹	1.8—3.3	$1-(0.50\pm0.39)\sin^2\theta$
	3.3—4.7	$1-(0.09\pm0.44)\sin^2\theta$
	4.7—6.3	$1+(0.01\pm0.40)\sin^2\theta$
	6.3—7.7	$1+(0.06\pm0.49)\sin^2\theta$
	larger than 7.7	$1-(0.48\pm0.73)\sin^2\theta$
	Total	$1-(0.05\pm0.20)\sin^2\theta$
P³¹	2.7—4.5	$1+(0.85\pm0.42)\sin^2\theta$
	4.5—6.0	$1+(0.35\pm0.34)\sin^2\theta$
	6.0—8.5	$1-(1.31\pm0.59)\sin^2\theta$
	larger than 8.5	$-(0.08\pm0.18)-\sin^2\theta$
	Total	$1+(1.10\pm0.27)\sin^2\theta$

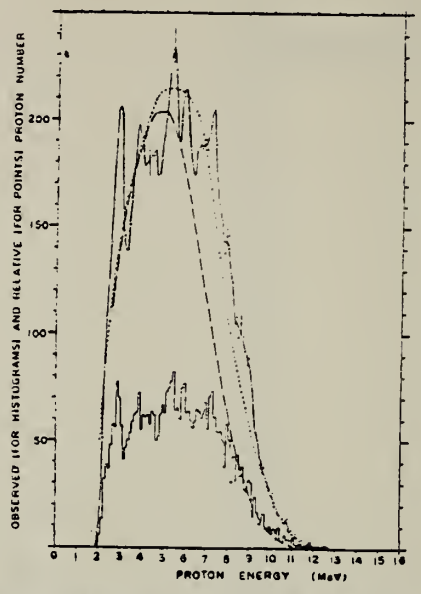

Fig. 3. Energy distribution of total observed protons and calculated distributions by the statistical theory from Si²⁸.
Full line: Observed spectrum smoothed out by the method of Ferreira and Valoshek.
Broken line: Calculated spectrum using $\omega = C\exp[2\sqrt{0.45E}]$ MeV⁻¹
Dotted line: Calculated spectrum using $\omega = C\exp[E/2.8]$ MeV⁻¹
Each curve is normalized to best fit to experimental points.

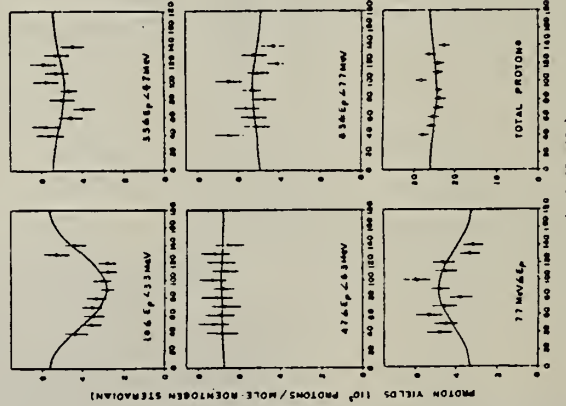

Fig. 4. Angular distributions of protons from Si²⁹. Full lines are obtained by least squares.

104° 30′	−0.25	−16.9	0.84 ± 0.04	0.38 ± 0.03	0.46 ± 0.03	0.06 ± 0.01
120°	−0.50	−33.9	0.84 ± 0.05	0.43 ± 0.03	0.41 ± 0.03	< 0.03

(*) Errors shown are only statistical errors; maximum uncertainties of other origin (background evaluation, separation of neighbouring peaks, wall effects, etc.) are estimated to range from 1% to 7% for lower and higher values respectively. In addition a possible uncertainty in the geometrical conditions (estimated to be less than 1°) may introduce a systematic error in the value of the energy shift which ranges from 1.5 keV at 0° to 3.5 keV at 90°. The energy-spread for every single point, however, is determined essentially by the width of the resonance as ±6 keV. The ratios shown were evaluated through an objective criterion suitable chosen for the best separation of the peaks; as a result, the values may be expected to differ somewhat from the cross-section ratios for transitions to the corresponding final levels. They are, however, proportional to them through a factor which is about 1 and does not depend on energy.

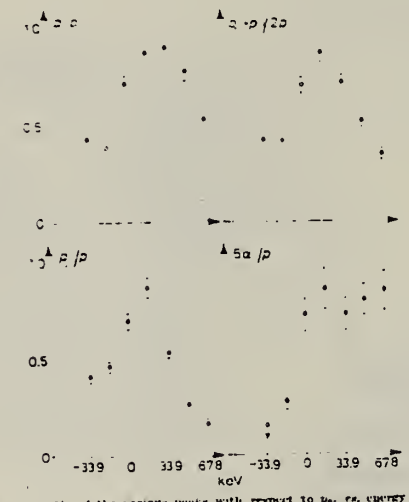

Fig. 2. – Intensity ratio of the various peaks with respect to p_0 vs. energy shift of incident γ radiation.

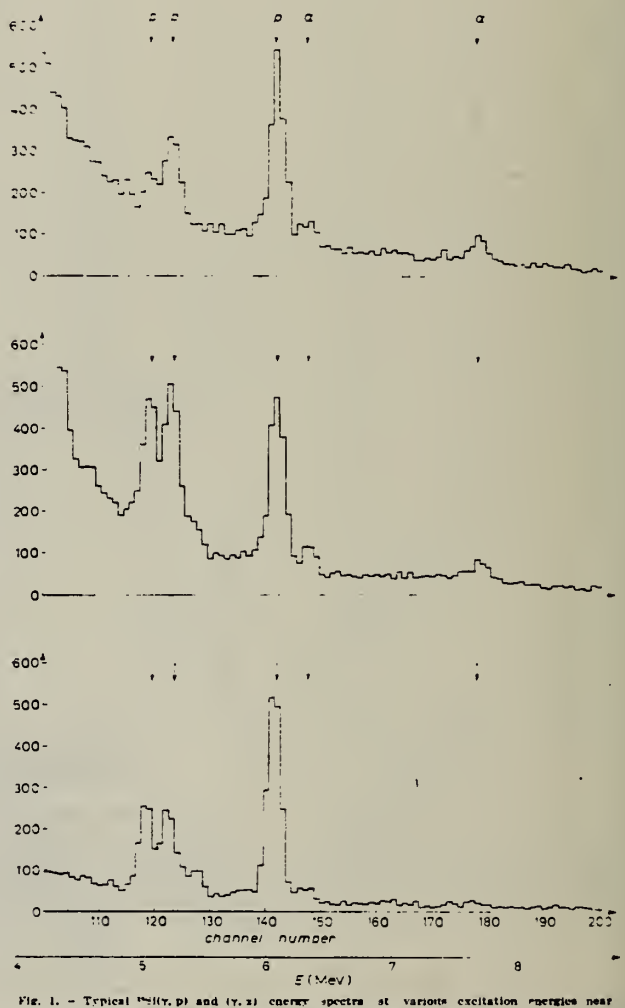

Fig. 1. – Typical $^{28}Si(\gamma,p)$ and (γ,α) energy spectra at various excitation energies near 17.64 MeV. The energy shifts ΔE of incident γ-rays are, from the top, +67.8, +16.9 and −33.9 keV, respectively. Note shifted energy-zero.

SCD TARGET

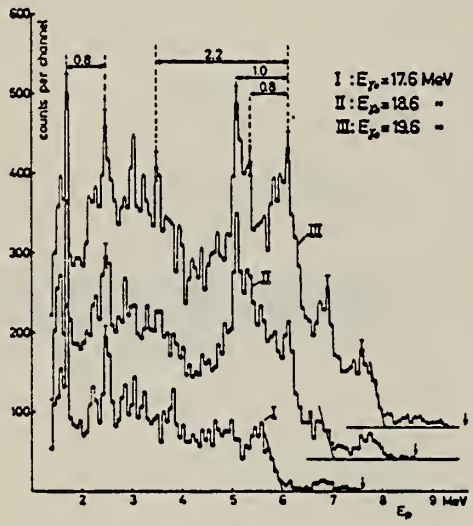

Fig. 1

Fig. 1 shows 3 measured spectra for different end point energies. For each spectrum the highest possible alpha energy is indicated by an arrow, the straight line 1.6 MeV below, indicates the end of the proton distribution. The measured points in the region in between must be attributed to alpha particles **. As the number of observed particles at the proton limits rises considerably, and since the alpha yields in general are small, below these limits the measured distributions should be mainly due to protons.

The observed proton peaks in the spectra clearly indicate the presence of narrow resonances in the excited silicon nucleus. As from each excited state proton transitions to several discrete state in the residual nucleus are possible, identification of the peaks is only possible from a series of measurements. As for instance the proton peaks at 6.2, 5.4, 5.2 and 4.0 MeV are present in curve III and II but not in curve I of fig. 1, they all must be attributed to a resonance between 18.6 and 17.6 MeV excitation energy. Thus the peak at 6.2 MeV must be due to ground state transitions since adding the Q-value of 11.6 MeV one obtains the right excitation energy. The other peaks are associated with transitions into excited states of the residual nucleus. Indeed, the distances between these peaks correspond well to the excitation energies of the first three excited states in Al^{27} with 0.8, 1.0 and 2.2 MeV.

Branching ratios for the transitions mentioned here are given in the table. These values have been derived from the difference of curve II and I. The errors are due to statistical uncertainties. At the high energy limit the proton (and alpha) spectra contain only contributions from ground state transitions. Thus together with the knowledge of the bremsstrahlung spectrum, cross section curves for reactions leading to the ground state can be derived within a certain energy range for each spectrum.

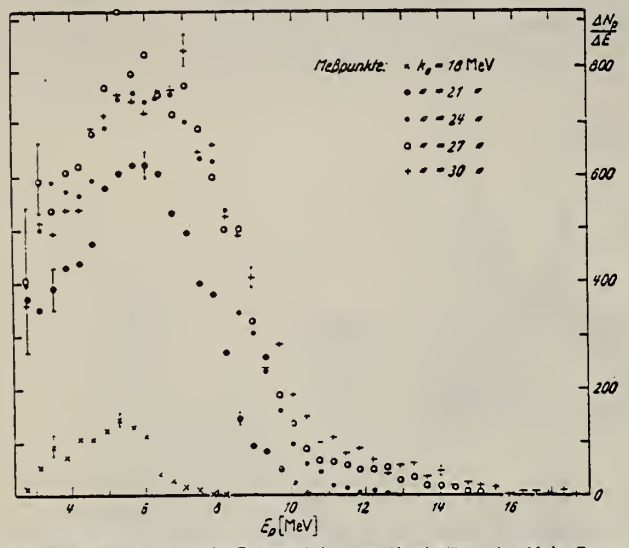

Fig. 3. Korrigierte Energieverteilung der Protonen bei 150 cm Absorberlänge. Anzahl der Protonen ΔN_p pro Energieintervall ΔE = 360 keV, aufgetragen über der Protonenenergie. Die verschieden bezeichneten Meßpunkte wurden bei Bestrahlungen mit verschiedenen Grenzenergien k_0 gewonnen

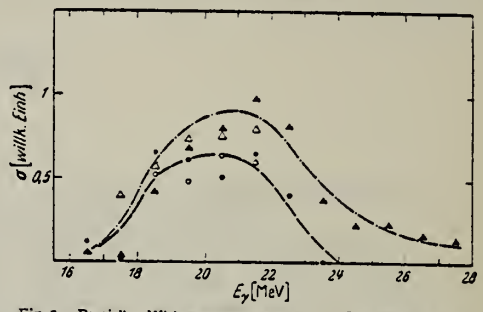

Fig. 7. Partielle Wirkungsquerschnitte für Übergänge in den Grundzustand (—·—·—) und Übergänge in die beiden ersten angeregten Niveaus (·····) des Folgekerns, aufgetragen über der Quantenenergie. (Die Meßpunkte beider Kurven wurden im gleichen Ordinatenmaßstab aufgetragen, der auch mit dem Ordinatenmaßstab der Fig. 5 übereinstimmt.) Meßpunkte: ▲ $\sigma(k, 0)$, aus der Tabelle; ● $\sigma(k, 1)$, aus der Tabelle; ▲ Grundzustandsübergänge, aus Differenzspektren (vgl. Fig. 6); ○ Übergänge in die beiden ersten angeregten Niveaus, aus Differenzspektren

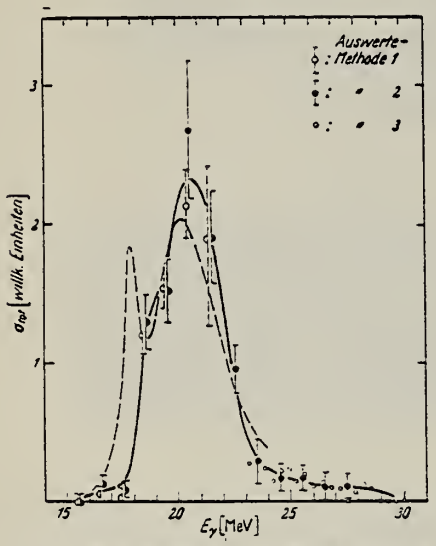

Fig. 5. Totaler Wirkungsquerschnitt der Reaktion $Si^{28}(\gamma, p)$ Al^{27} als Funktion der Quantenenergie. Die verschieden bezeichneten Punkte beziehen sich auf die im Text erläuterten verschiedenen Auswertemethoden. Die ausgezogene Kurve stellt den aufgrund der Meßpunkte wahrscheinlichsten Wirkungsquerschnittsverlauf dar. Die gestrichelte Kurve ist der nach der Methode des detaillierten Gleichgewichts aus Messungen der Umkehrreaktion $Al^{27}(p, \gamma_0)$ Si^{28} abgeleitete Wirkungsquerschnittsverlauf [10], wobei nur Übergänge in den Grundzustand von Si^{28} gemessen worden waren

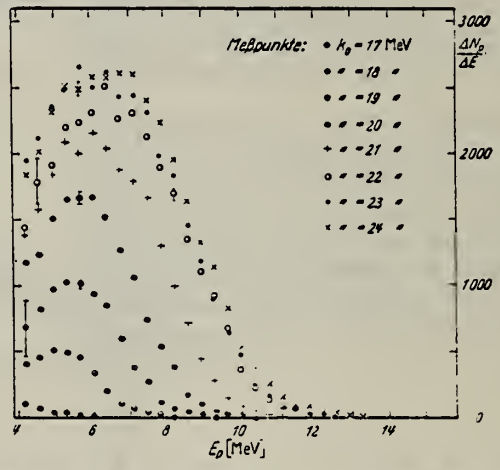

Fig. 4. Korrigierte Energieverteilung der Protonen bei 75 cm Absorberlänge. Anzahl der Protonen ΔN_p pro Energieintervall ΔE = 360 keV, aufgetragen über der Protonenenergie. Die verschieden bezeichneten Meßpunkte wurden bei Bestrahlungen mit verschiedenen Grenzenergien k_0 gewonnen

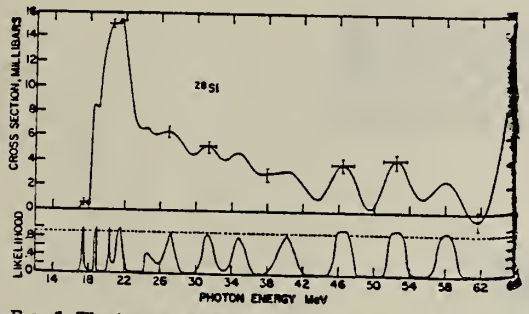

FIG. 5. The least-structure cross section, $\sigma=\sigma_a+2.0\sigma_{2a}+\sigma_{pn}$, for the silicon data. Vertical bars indicate errors in cross section. Horizontal bars indicate the resolution function width. The coefficient for σ_{2a} arises because of enhancement of the yield due to formation of Si^{28} as discussed in Sec. II. A likelihood estimate of the statistical certainty of the indicated structure is also shown.

TABLE I. Peak energies for the cross-section maxima of Figs. 4 and 5. All maxima with greater than 70% likelihood as computed from the cross-section errors[a] are shown. Maxima with less than 90% likelihood are doubtful.

Summary

The cross-sections of the (γ, p) (γ, d) reactions were investigated. Li^7, Be^9, C^{12}, Si^{28}, Cu^{63}, Mo^{96} and Ta^{181} targets were irradiated with the bremsstrahlung of 700 and 1200 MeV maximum energy from the Kharkov PhTI Ac. Sci. UkrSSR linear accelerator. The photoprotons and deuterons were detected by the scintillation telescope at 30°, 60°, and 120° with the beam. Possible mechanisms of the proton and deuteron photoproduction are discussed. The qualitative agreement of A dependence of the cross-sections is observed with a suggestion on the meson mechanism for these reactions.

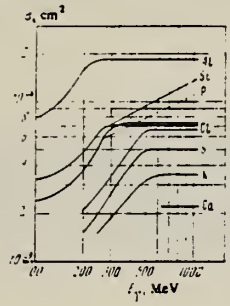

FIG. 2. Cross sections as a function of γ-ray energy.

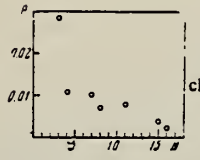

FIG. 3. Dependence of P on number of nucleons which have left the nucleus.

Table I

Reaction	Nucleons emitted	Threshold*, MeV	Target	Distribution of isotopes, %
$Al^{27} \rightarrow Na^{24}$	2p, n	31	Al	100
$Si^{28} \rightarrow Na^{24}$	3p, n	43	Si	92.27
$P^{31} \rightarrow Na^{24}$	4p, 3n	69	P	100
$S^{32} \rightarrow Na^{24}$	5p, 3n	78	S	95.02
$Cl^{35} \rightarrow Na^{24}$	6p, 5n	104	NH_4Cl	75.4
$K^{39} \rightarrow Na^{24}$	8p, 7n	140	K_2CO_3	93.08
$Ca^{40} \rightarrow Na^{24}$	9p, 7n	148	CaO	96.97

*The threshold was calculated as the binding energy of the emitted nucleons.

Table II. Cross sections for reactions in the saturation region

Reaction	σ_k, 10^{-28} cm²	Reaction	σ_k, 10^{-28} cm²
$Al^{27} \rightarrow Na^{24}$	185±20	$Cl^{35} \rightarrow Na^{24}$	68±7
$Si^{28} \rightarrow Na^{24}$	72±8	$K^{39} \rightarrow Na^{24}$	35±5
$P^{31} \rightarrow Na^{24}$	74±8	$Ca^{40} \rightarrow Na^{24}$	22±5
$S^{32} \rightarrow Na^{24}$	52±6		

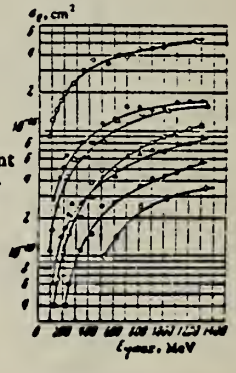

FIG. 1. Cross section σ_0 per equivalent photon as a function of maximum bremsstrahlung energy. Points: ○ – Al, ● – Si, △ – P, ▲ – S, □ – Cl, ■ – K, ◇ – Ca.

According to the photomesonic mechanism, the cross section for the reaction can be written in the form

$$\sigma = \sigma_0 AP. \qquad (1)$$

Here σ_0 is the total cross section for interaction of the photon with a free nucleon with inclusion of the nucleon motion in the nucleus (σ_0, as has been shown by Roos and Peterson,[8] depends only weakly on photon energy for $E_\gamma > 300$ MeV); A is the number of nucleons in the nucleus, and P is the probability that the reaction will proceed by a given channel.

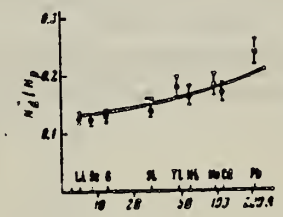

FIG. 4. The ratios N_d/N_p as a function of target-nucleus mass number A at an angle $\theta = 60°$ for $E_0 = 1200$ MeV. Solid curve—$A^{0.13}$.

The measured secondary-particle spectra for kinetic energies $T > 80$ MeV are well described by the expression

$$d^2\sigma / d\Omega dTQ = \text{const}\, T \exp(-T/\tau), \qquad (1)$$

which is identical to the formula for the evaporation process.[4] In Table I we have given the values of the parameter τ for the nuclei studied, at various angles. The accuracy in determination of τ is about 10%.

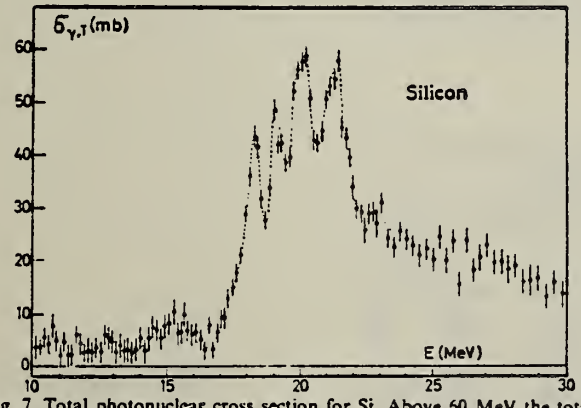

Fig. 7. Total photonuclear cross section for Si. Above 60 MeV the total attenuation cross section of Si displays a structure which can qualitatively be described by coherent pair production in the monocrystalline absorber rods (Überall effect) [11]). A more accurate measurement of this effect is in preparation. An unambiguous determination of the nuclear cross section above 50 MeV therefore turned out to be impossible.

(Submitted 21 February 1980)
Yad. Fiz. 32, 1465–1475 (December 1980)

The energy spectra of photons scattered at 90° by ^{28}Si and ^{52}Cr targets have been measured in the betatron bremsstrahlung beam at 16 values of the maximum bremsstrahlung energy from 13.1 to 31 MeV. The photon elastic scattering cross sections in the vicinity of the giant resonance, as well as the cross sections for photon inelastic scattering with excitation of the 1.75 and 4.98 MeV levels of ^{28}Si and the 1.43 and 2.98 MeV levels of ^{52}Cr, were calculated from the spectra. A dispersion-theory analysis of the results enabled us to identify the peaks in the cross sections for which $E1$ photoabsorption is dominant. The experimental data are compared with the results of shell-model and simple-rotator-model calculations. The nature of the peaks observed in the scattering cross sections is discussed.

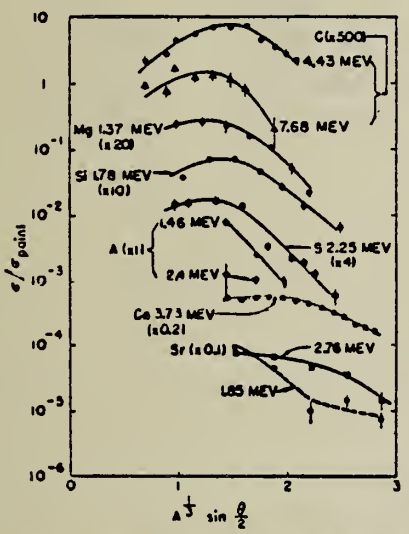

FIG. 3. Inelastic angular distributions (observed cross section divided by Feshbach point-charge cross sections). The results of Hahn *et al.* (reference 8) for Ca and of Fregeau and Hofstadter (reference 11) are included for comparison.

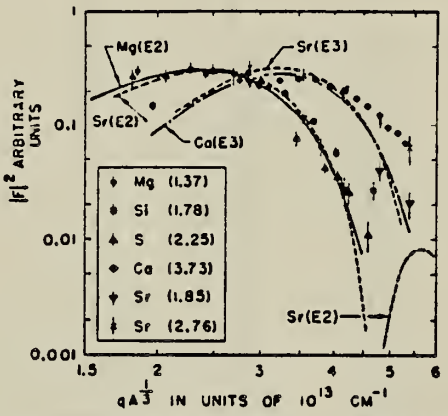

FIG. 7. Inelastic "universal curves." A composite plot of inelastic data from Mg, Si, S, Ca, and Sr against $qA^{\frac{1}{3}}$. The various form factors are arbitrarily normalized to minimize the spread of points. The point from sulfur and the point from silicon which seem to deviate from the "universal curve" are assumed to contain undetected experimental errors. The curves labeled Mg($E2$), Sr($E2$), Ca($E3$), and Sr($E3$) are calculated for electric-quadrupole and-octupole transitions using the "smeared δ-function" transition charge densities of Sec. V, and are arbitrarily normalized.

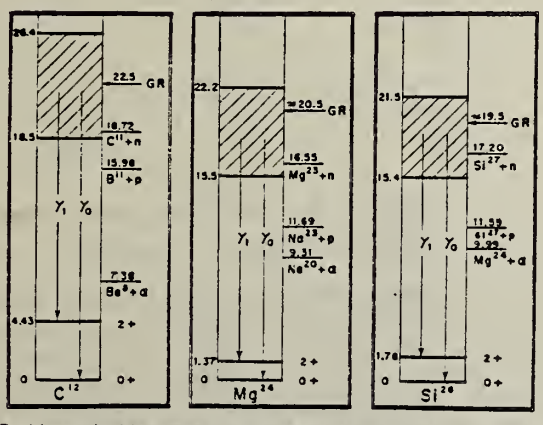

Fig. 1. Partial energy level diagrams for C^{12}, Mg^{24} and Na^{23} showing the region of excitation energy covered (shaded), the positions of the first excited states and the energies at which each nucleus becomes unstable against neutron, proton and alpha particle emission. The approximate position of the peak of the giant resonance (GR) is also indicated.

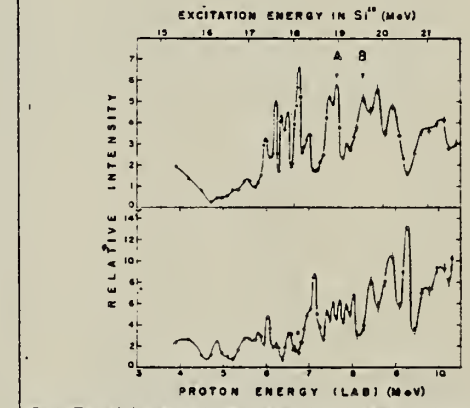

Fig. 16. The yield of gamma rays leading to the ground state (upper curve) and to the first excited state (lower curve) of Si^{28} resulting from proton capture in Al^{27} and measured at 90° to the incident beam. The ordinates of the two yield curves are correct relative to each other. The abscissae are marked both in terms of the incident laboratory proton energy and in excitation energy in the compound nucleus Si^{28}. A and B mark the energies at which angular distributions were measured.

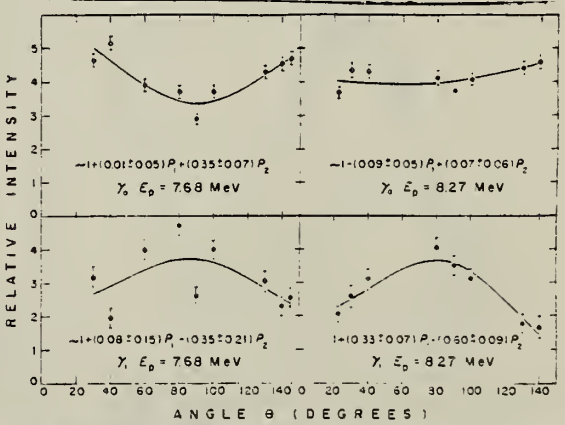

Fig. 17. Angular distributions of gamma rays leading to the ground state (γ_0) and to the first excited state (γ_1) of Si^{28} from the reaction Al^{27} (p, γ) measured at two proton energies of 7.68 and 8.27 MeV (corresponding to the positions A and B on the yield curve of fig. 14). The solid lines are least square Legendre polynomial fits and, in each case, values of the coefficients are given in the expressions $1+a_1P_1+a_2P_2$.

TABLE I.

Values of relative intensity of the various peaks with respect to p_0 (*)

θ	cos θ	Energy shift (keV)	$(p_1+p_2)/p_0$	p_1/p_0	p_2/p_0	α_0/p_0
0°	+1.00	+67.8	0.70±0.06	0.53±0.05	0.17±0.03	0.17±0.02
41° 30′	+0.75	+50.8	1.04±0.06	0.77±0.05	0.27±0.03	0.16±0.02
60°	+0.50	+33.9	1.44±0.08	0.90±0.05	0.54±0.03	0.15±0.02
75° 30′	+0.25	+16.9	1.73±0.10	0.87±0.06	0.86±0.06	0.17±0.02
90°	0	0	1.41±0.08	0.71±0.05	0.70±0.05	0.15±0.02
104° 30′	−0.25	−16.9	0.84±0.04	0.38±0.03	0.46±0.03	0.06±0.01
120°	−0.50	−33.9	0.84±0.05	0.43±0.03	0.41±0.03	< 0.03

(*) Errors shown are only statistical errors: maximum uncertainties of other origin (background evaluation, separation of neighbouring peaks, wall effects, etc.) are estimated to range from 15 to 7% for lower and higher values respectively. In addition a possible uncertainty in the geometrical conditions (estimated to be less than 2°) may introduce a systematic error in the value of the energy shift which ranges from 1.5 keV at 0° to 3.5 keV at 90°. The energy spread for every single point, however, is determined essentially by the width of the resonance as ±6 keV. The ratios shown were evaluated through an objective criterion suitably chosen for the best separation of the peaks: as a result, the values may be expected to differ somewhat from the cross-section ratios for transitions to the corresponding final levels. They are, however, proportional to them through a factor which is about 1 and does not depend on energy.

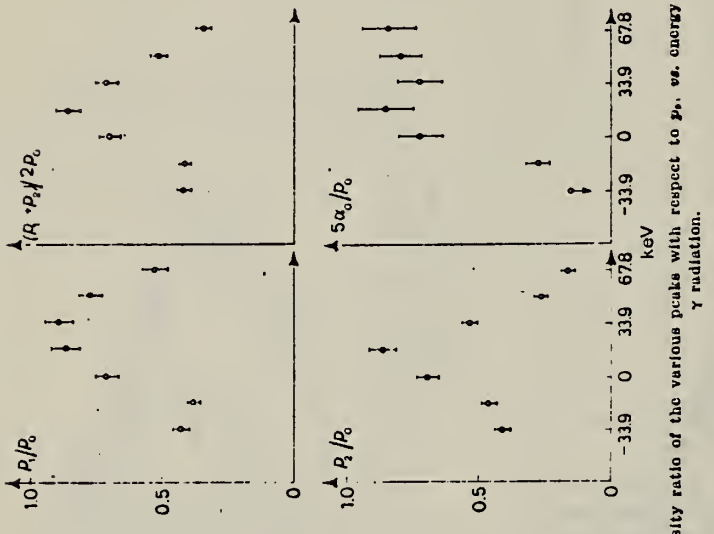

Fig. 2. – Intensity ratio of the various peaks with respect to p_0 vs. energy shift of incident γ radiation.

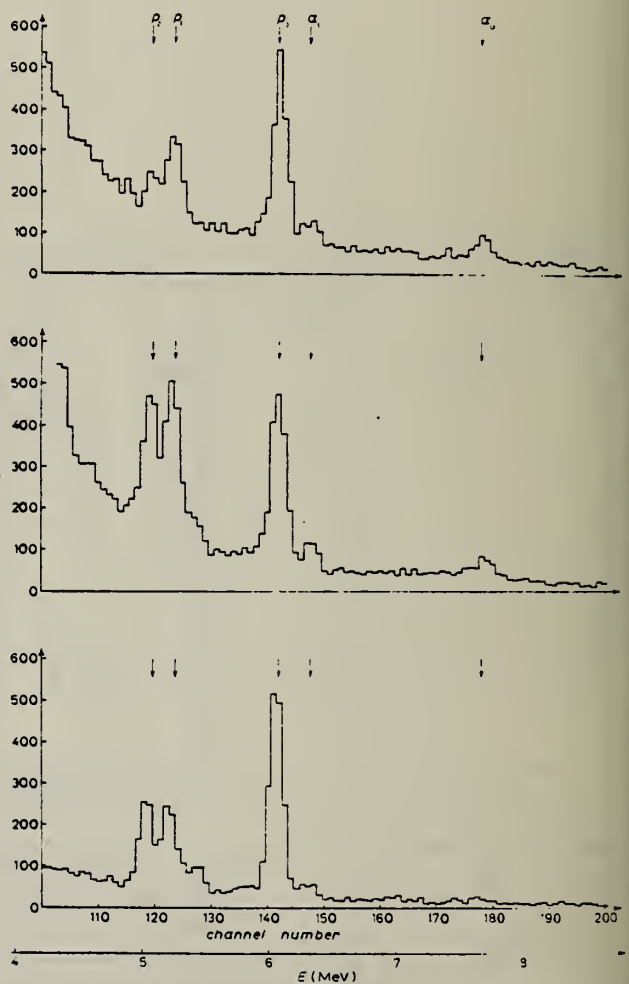

Fig. 1. – Typical $^{28}Si(\gamma,p)$ and (γ,α) energy spectra at various excitation energies near 17.64 MeV. The energy shifts ΔE of incident γ-rays are, from the top, +67.8, +16.9 and −33.9 keV, respectively. Note shifted energy-zero.

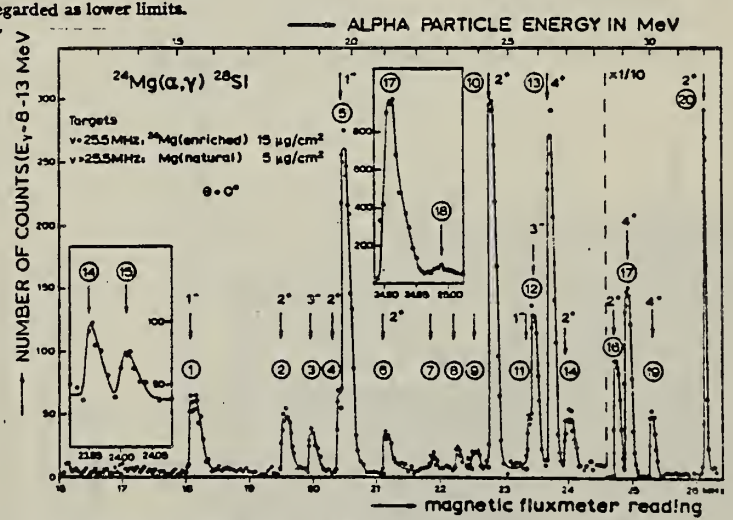

Fig. 2. Yield curve of the ^{24}Mg$(\alpha,\gamma)^{28}$Si reaction in the E_α = 1.2–3.2 MeV region. High-energy γ radiation ($E_\gamma \approx$ 8–13 MeV) is detected with a NaI scintillation crystal (10 cm long and 10 cm in diameter), as close to the target as possible at 0° to the beam. For $E_\alpha < 3.1$ MeV an enriched ^{24}Mg target was used of 15 μg/cm²; for $E_\alpha > 3.1$ MeV the target was natural Mg of 5 μg/cm² thickness; the parts of the yield curve shown in the two inserts were taken with a natural Mg target of about 3 μg/cm² thickness.

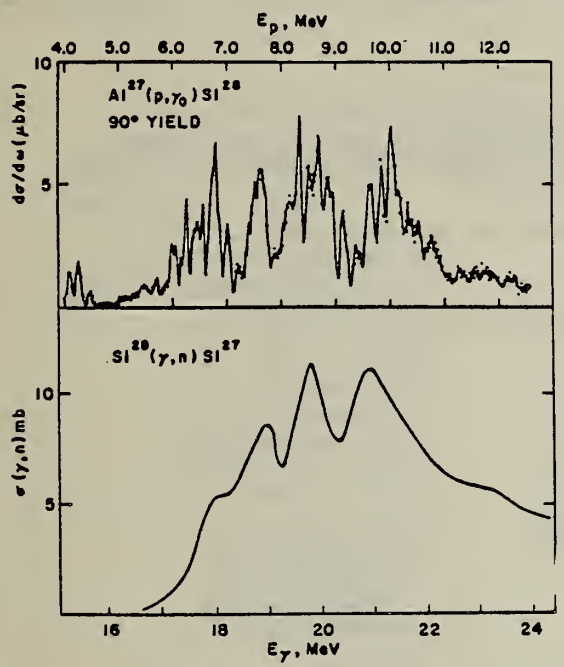

FIG. 1. Top curve: 90° yield of the ground-state gamma ray from the reactions $Al^{27}(p,\gamma)Si^{28}$. This yield curve was taken in 15-keV steps using a target about 10 keV thick. Bottom curve: yield of Si^{27} from the reaction $Si^{28}(\gamma,n)Si^{27}$ taken with a gamma-ray energy resolution of about 600 keV. The data are those of Caldwell et al. (reference 8). The two curves are plotted so as to be on the same gamma-ray energy scale.

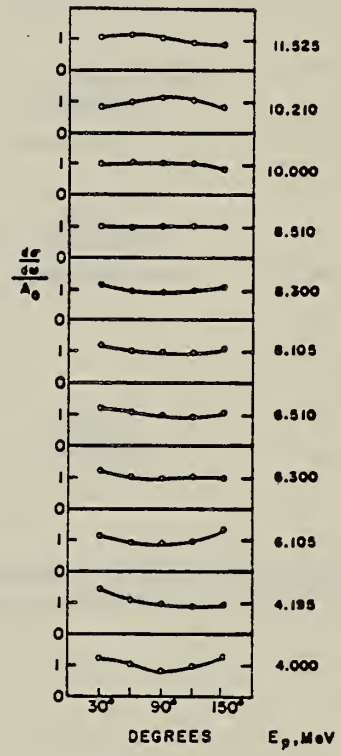

FIG. 2. Sample angular distributions of the ground state gamma ray from the reaction $Al^{27}(p,\gamma)Si^{28}$.

Table I. Summary of experimental results on the (p,γ) giant resonance (references 9-11). The angular distributions that are quoted generally characterize the data to within 15% throughout the giant-resonance region.

Nucleus	Type of observation	Energy interval and range	Result
C^{12}	90° yield curve	50-keV steps 4.0-14 MeV	Broad ($\Gamma \approx 1$ MeV) overlapping levels; no correlation between γ_0 and γ_1.
	Angular distribution[a]	50-keV steps 4.0-14 MeV	$W(\theta)_{\gamma_0} = 1 + 0.15P_1 - 0.6P_2$ $W(\theta)_{\gamma_1} = 1 + 0.15P_1$
Ne^{20}	90° yield curve	30-keV steps 4.3-9.1 MeV	Broad ($\Gamma \approx 400$ keV) levels usually well isolated, γ_0 and γ_1 well correlated.
	Angular distribution	100-keV steps 4.0-10.5 MeV	$W(\theta)_{\gamma_0} = 1 + 0.05P_1 - 0.7P_2$ $W(\theta)_{\gamma_1} = 1 + 0.05P_1 + 0.2P_2$
Si^{28}	90° yield curve	15-keV steps 4.0-12.5 MeV	Narrow ($\Gamma \approx 50$ keV) Ericson fluctuations, superimposed on intermediate structure; no correlation between γ_0 and γ_1.
	Angular distribution	15-keV steps 4.0-4.32 MeV 6.0-6.62 MeV 8.0-8.54 MeV 10.0-10.28 MeV 11.54-11.58 MeV	$W(\theta)_{\gamma_0} = 1 + 0.07P_1$ $W(\theta)_{\gamma_1} = 1 + 0.1P_1 - 0.45P_2 - 0.1P_3$

[a]The coefficients of P_1 are average values. They actually increase by about 0.03/MeV over the giant resonance.

1^-, 2^+ resonances have ground state transitions.

WIDTHS

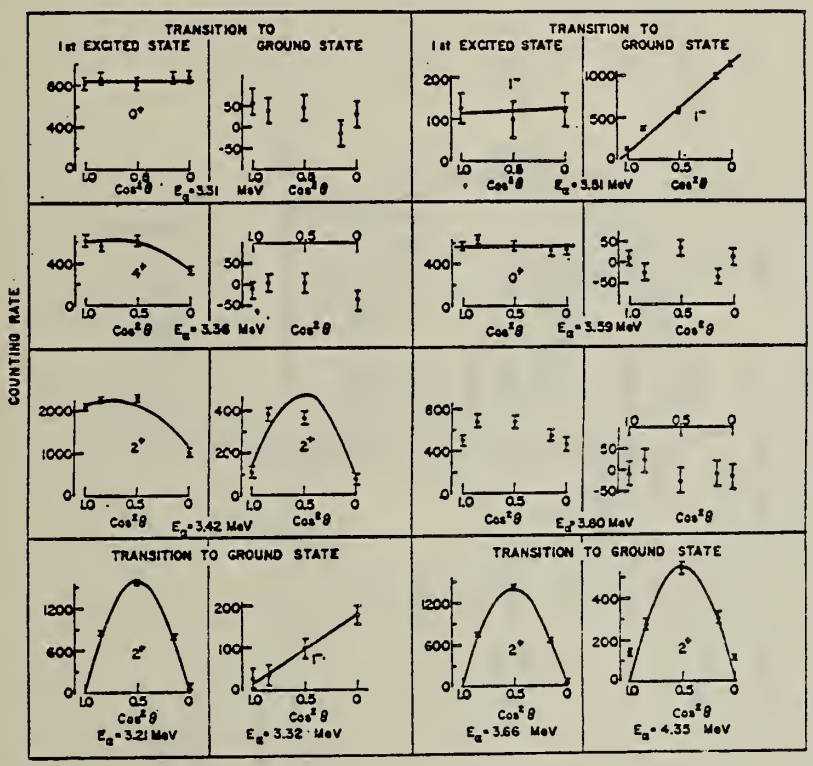

FIG. 5. Gamma-ray angular distributions measured on the peaks of the various resonances studied. Alpha-particle energies and observed transitions (to ground state or excited state) are indicated with each plot. The solid curves are theoretical curves calculated for a resonance having the spin and parity indicated and corrected for finite solid angle of the detector. At the resonance at $E_\alpha = 3.42$ MeV, the transition to the first excited state is of mixed multipolarity, the intensity ratio being $I(E2)/I(M1) = 4$.

C^{12}	8.1	0.20	30.7	(γ, p_0)	42)

Results for the (p, γ) reaction have been converted to the inverse (γ, p) process by means of the detailed-balance theorem. In general the (γ, p) measurements may include transitions to excited states in the final nucleus. Whenever appropriate, the results have been corrected for the observed angular distributions. The integrated cross sections are in units of the electric-dipole sum $(2\pi^2 e^2 \hbar/Mc)(NZ/A) = 0.42$ and 0.18 MeV · b for Si^{28} and C^{12}, respectively.

a) Present work.
b) By extrapolation of the yield curve.

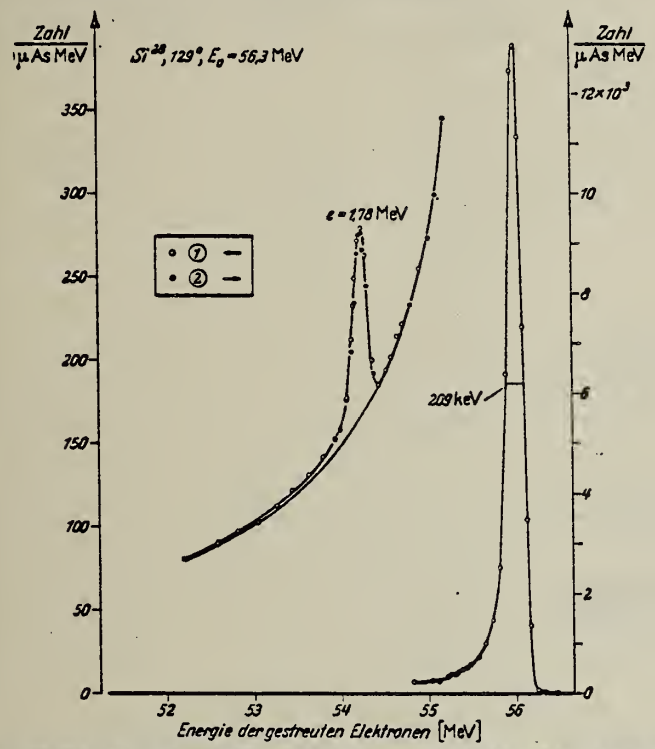

Fig. 1. Spektrum der gestreuten Elektronen mit 0 bis 3,5 MeV Energieverlust (q=0,510 fm^{-1} für ε=1,78 MeV). Die relative Energieunschärfe von Primärstrahl und Spektrometer betrug $(\Delta E/E)_A = (\Delta E/E)_S = 3‰$. Zur Prüfung der Reproduzierbarkeit wurde das Spektrum zweimal durchgemessen (offene Kreise von rechts, ausgefüllte von links kommend). Auf der Ordinate aufgetragen ist die Zahl der registrierten Elektronen pro Energieintervall bezogen auf die vom Strahlfänger aufgesammelte Ladung. Die linke Skala gilt für die unelastische, die rechte für die elastische Linie. Das Target stand in Transmissionsstellung

G,G	LFT	11-13	D	11-13	NAI-D	11-13	135

Photons, defined in energy to about 1% with the aid of a bremsstrahlung monochromator, were scattered by isolated energy levels in C, Mg, and Si. Parameters for the six observed levels are:

Isotope	Energy (MeV)	Γ_0^2/Γ (eV)	Γ_0/Γ	$B(M1)/(e\hbar/2M_pc)^2$
C^{13}	15.11	36	1	0.93
Mg^{24}	10.66±0.02	14	0.8	1.21
Si^{28}	11.42±0.02	23	1	1.33
Si^{28}	12.33±0.03			
Mg^{24}	9.92±0.03	3.0	0.5	0.49
Mg^{26}	10.07±0.05	4.2		≥0.36

The 15.11-MeV level in C^{13}, the 9.92- and 10.66-MeV levels in Mg^{24}, and the 11.42-MeV level in Si^{28} are $T=1$, $T_z=0$ analogs of low-lying 1+ states in the neighboring odd-odd nuclei. These levels exhaust most of of the magnetic dipole transition strength of the respective nuclei, and therefore give information about the expectation value of $l\cdot s$ in the ground state.

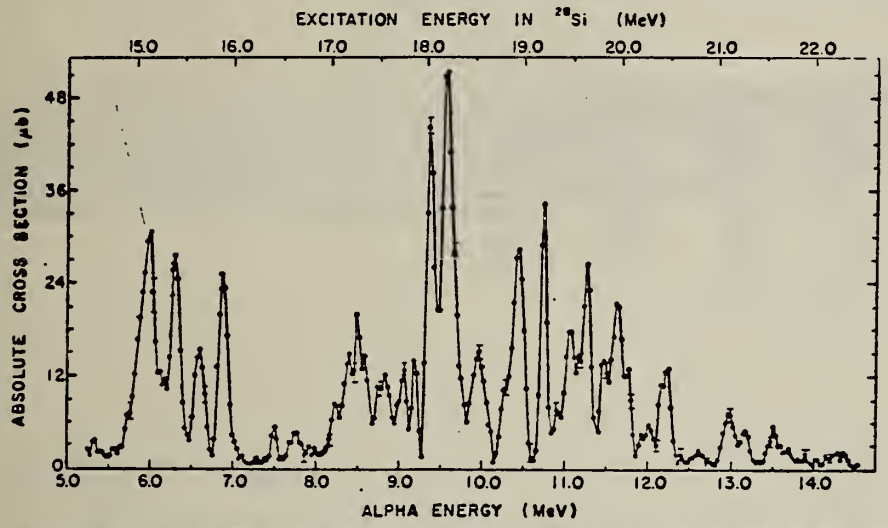

Fig. 3. The absolute cross section for the reaction $^{24}Mg(\alpha,\gamma_0)^{28}Si$, plotted as a function of the bombarding energy E_α. In integrating the γ_0 intensity over all angles to obtain these cross sections, the measured angular distribution of the $\sin^2\theta$ form – characteristic of pure electric-dipole transitions – has been used. A slight correction for the solid angle of the detector is included.

TABLE 1

The averaged absolute cross sections $\overline{\sigma(\alpha,\gamma_0)}$ and $\overline{\sigma(\alpha,\gamma_1)}$ for the reactions $^{24}Mg(\alpha,\gamma_0)$, $^{24}Mg(\alpha,\gamma_1)$, $^{26}Mg(\alpha,\gamma_0)$ and $^{28}Si(\alpha,\gamma_0)$

	$^{24}Mg(\alpha,\gamma)^{28}Si$		$^{26}Mg(\alpha,\gamma_0)^{30}Si$		$^{32}Si(\alpha,\gamma_0)^{32}S$	
ΔE_x (MeV)	$\overline{\sigma(\alpha,\gamma_0)}$ (μb)	$\overline{\sigma(\alpha,\gamma_1)}$ (μb)	ΔE_x (MeV)	$\overline{\sigma(\alpha,\gamma_0)}$ (μb)	ΔE_x (MeV)	$\overline{\sigma(\alpha,\gamma_0)}$ (μb)
14.65–16.65	8.5	5.0	14.1–16.1	6.1	13.1–15.5	1.7
16.65–18.65	12.9	6.1	16.1–18.1	9.7	15.5–17.5	2.2
18.65–20.65	11.0	8.6	18.1–20.1	4.6		
20.65–22.65	2.1	5.6	20.1–22.1	1.0		
14.65–22.65	8.6	6.3	14.1–22.1	5.3	13.1–17.5	1.9

The cross sections in the first four rows were obtained from the data in figs. 3–6 and 15 by averaging over the indicated ≈ 2 MeV ranges of excitation energy E_x in the product nucleus (^{28}Si, ^{30}Si or ^{32}S). The last line gives the average for the entire energy range that was studied.

TABLE 3

The cross sections $\overline{\sigma(\gamma, \alpha_0)}$ for the α-decay of the nuclei ^{28}Si, ^{29}Si and ^{32}S

Target nucleide	ΔE (MeV)	$\overline{\sigma(\gamma, \alpha_0)}$ (mb)	$\overline{\sigma(\gamma, p_0)}$ (mb)	$\frac{\overline{\sigma(\gamma, \alpha_0)}}{\overline{\sigma(\gamma, p_0)}}$	$\gamma^2(\alpha_0)/\gamma^2(p_0)$	
					$l = 1$	$l = 3$
^{28}Si	16.65–18.65	1.01	6.2	0.16	0.35	0.12
	18.65–20.65	0.94	11.7	0.080	0.095	0.041
	20.65–22.65	0.22	9.6	0.023	0.019	0.011
	16.65–22.65	0.72	9.2	0.08		
^{29}Si	14.1 –16.1	0.43				
	16.1 –18.1	0.69				
	18.1 –20.1	0.35				
	18.1 –20.1	0.35				
	20.1 –22.1	0.08				
	14.1 –22.1	0.38				
^{32}S	13.1 –15.5	0.20	1.7	0.12		
	15.5 –17.5	0.27	2.1	0.13		
	17.5 –19.5		3.0			
	13.1 –17.5	0.23	1.9	0.12		

The averages were taken over ≈ 2 MeV wide energy regions ΔE and over the total studied energy region of the giant dipole resonance. These cross sections were obtained by detailed balance from the α-capture in ^{24}Mg, ^{25}Mg and ^{26}Si. For comparison, the average cross sections $\overline{\sigma(\gamma, p_0)}$ over the same energy regions ΔE for the reactions ^{28}Si$(\gamma, p_0)^{27}$Al and ^{32}S$(\gamma, p_0)^{31}$P are also presented. These likewise were obtained by detailed balance from the inverse reactions as measured by Singh *et al.* [5]) and by Dearnaley *et al.* [4]). For the calculation, we assumed an isotropic angular distribution for the ^{28}Si(γ, p_0) reaction, a $\sin^2\theta$ distribution for ^{32}S(γ, p_0). In addition, the ratios $\overline{\sigma(\gamma, \alpha_0)}/\overline{\sigma(\gamma, p_0)}$ are given for both ^{28}Si and ^{32}S and also the calculated reduced width $\gamma^2(\alpha_0)/\gamma^2(p_0)$ for an orbital-angular-momentum transfer of $l = 1$ and of $l = 3$ in the decay of ^{28}Si.

Summary

The cross-sections of the (γ, p) (γ, d) reactions were investigated. Li^7, Be^9, C^{12}, Si^{28}, Cu^{63}, Mo^{96} and Ta^{181} targets were irradiated with the bremsstrahlung of 700 and 1200 MeV maximum energy from the Kharkov PhTI Ac. Sci. UkrSSR linear accelerator. The photoprotons and deuterons were detected by the scintillation telescope at 30°, 60°, and 120° with the beam. Possible mechanisms of the proton and deuteron photoproduction are discussed. The qualitative agreement of A dependence of the cross-sections is observed with a suggestion on the meson mechanism for these reactions.

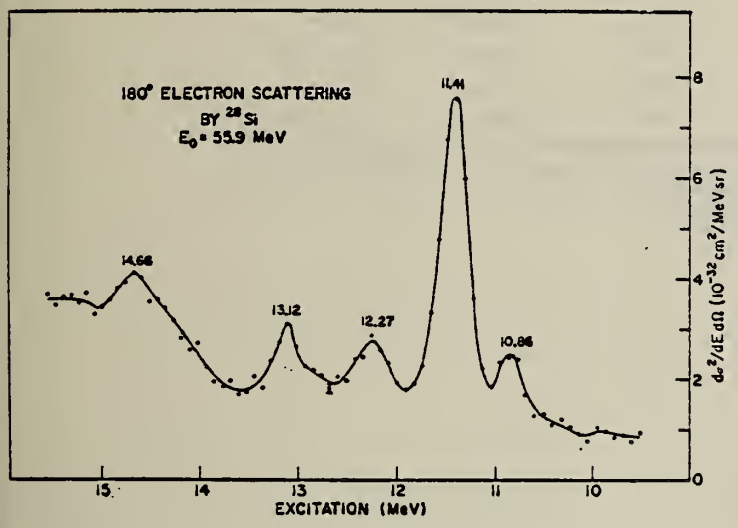

FIG. 2. Differential cross section for 180° electron scattering from ^{28}Si at E_0 = 55.9 MeV covering the excitation energy range 10–15 MeV.

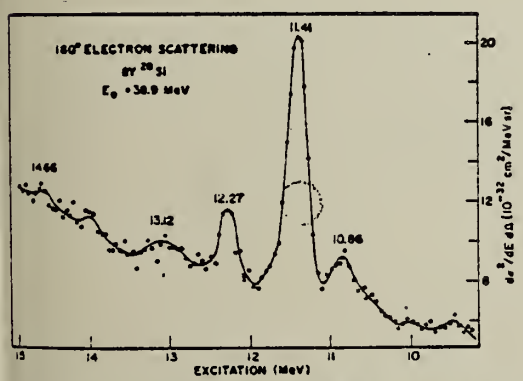

FIG. 3. Differential cross section for 180° electron scattering from ^{28}Si at E_0 = 38.9 MeV covering the excitation energy range 9-15 MeV.

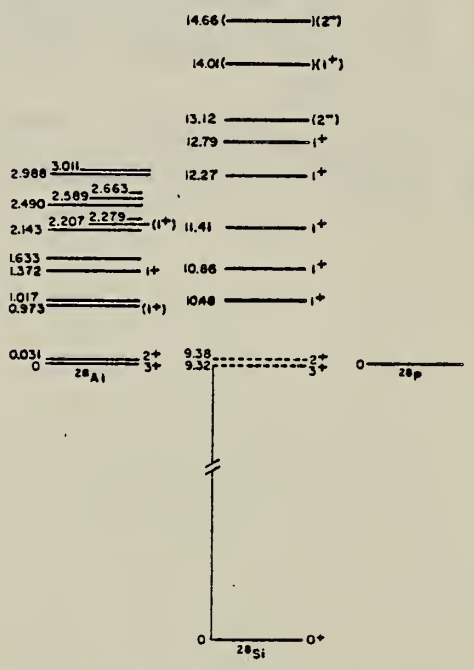

FIG. 4. Energy-level diagram adjusted for the Coulomb displacement so that the ^{28}Si and ^{28}Al analog states are approximately aligned. Only the ^{28}Si states denoted with a solid line were excited in this experiment. The energies given in the ^{28}Al-level scheme are those quoted from Endt and Van der Leun (Ref. 22). The parentheses around the states at 14.66 and 14.01 MeV indicate a considerable degree of uncertainty as to their existence and position.

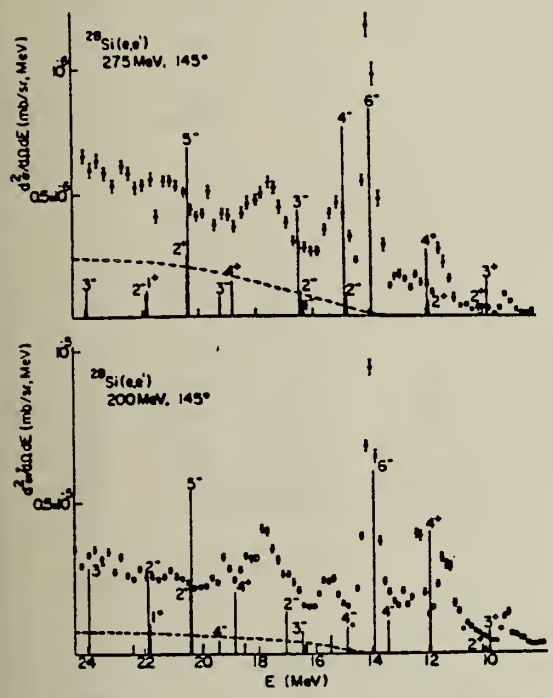

Fig. 1a. The cross section $d^2\sigma/d\Omega dE$ for inelastic electron scattering from ^{28}Si at E_e = 275 MeV, $\theta = 145^\circ$ unfolded for radiative processes. The non-negligible cross sections predicted by the p-h model for q = = 525 MeV/c are shown as spikes (arbitrary overall scale). The dashed line is the computed quasi-elastic spectrum; b) Same as (a), except E_e = 200 MeV and theoretical cross sections computed for q = 375 MeV/c.

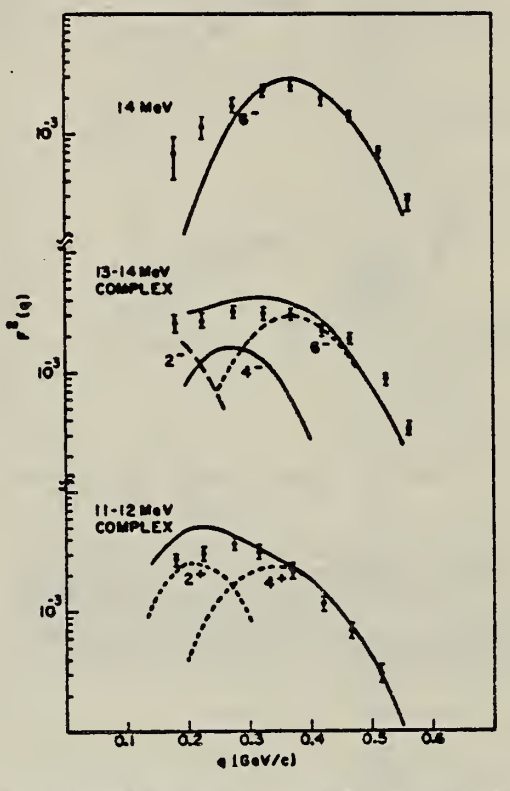

Fig. 2. Form factors for the 11-12 MeV, 13-14 MeV and 14 MeV complexes. The p-h states comprising each complex and the experimental energy intervals are given in the text. All theoretical T = 1 form factors have been reduced by $\frac{1}{2}$.

[over]

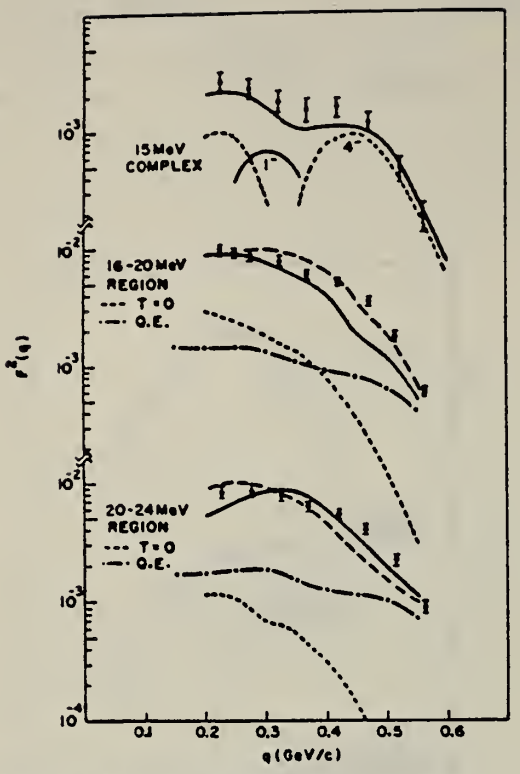

Fig. 3. Form factors for the 20-24 MeV, 16-20 MeV and 15 MeV complexes. For the first two complexes, the quasi-elastic (see text) and $T = 0$ p-h contributions are also shown. The $T = 1$ p-h contributions have been reduced by $\frac{1}{2}$. The results of moving the $1f_{5/2}$ configuration energy down by 1 MeV is indicated by the heavy dashed line.

PI-/PI+ YIELD RATIO

Measurements are reported of the relative yield of π^0 mesons and the π^-/π^0 yield ratio for mesons with energy 40 ± 10 MeV emitted in the angular range θ_{lab} = 50–160° in photon-induced reactions with E_γ^{max} = 500 MeV with light and medium nuclei. The charged π-meson detector was a 34-cm Freon bubble chamber with a tube for the beam. The π^-/π^+ yield ratio for He^4, Li^7, C^{12}, Si^{28}, S^{32}, Ca^{40}, and Nb^{93} was found to be respectively 0.94 ± 0.14, 2.15 ± 0.31, 1.22 ± 0.21, 1.25 ± 0.15, 1.0 ± 0.13, 1.11 ± 0.13, and 1.53 ± 0.25. It was established that the π^0-meson yield follows a $ZA^{-1/3}$ law.

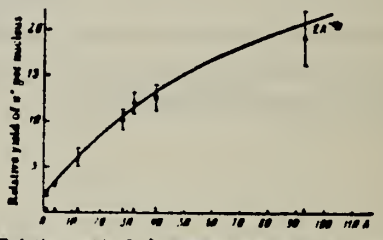

FIG. 2. Relative yield of π^0 mesons per nucleus as a function of mass number A.

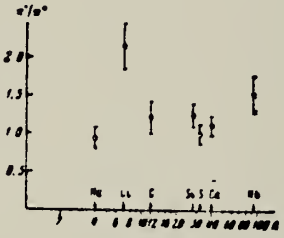

FIG. 3. π^-/π^0 yield ratio as a function of mass number A.

The activation method has been used to measure the yields of the reactions $^{28}Si(\gamma,\pi^-)^{28}P$ and $^{11}B(\gamma,\pi^-)^{11}C$ from the π-meson production threshold to 400 MeV. The results obtained are in satisfactory agreement with theoretical calculations based on the model of surface production of mesons.

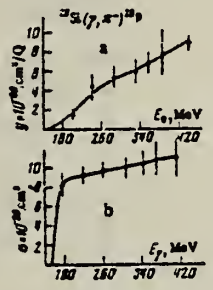

FIG. 1. Yield curve (a) and total cross sections (b) for the reaction $^{28}Si(\gamma,\pi^-)^{28}P$.

Photonuclear reactions in the targets ^{27}Al, ^{28}Si, ^{31}P, ^{32}S, and ^{40}Ca have been studied for maximum bremsstrahlung energies of 2, 2.4, 3, and 4.5 GeV. The yields of the residual nuclei ^{7}Be, ^{11}C, ^{13}N, ^{18}F, ^{22}Na, and ^{24}Na were measured by means of a germanium-lithium semiconductor detector with a sensitive volume of 30 cm^3. In discussion of the results we took into account the contribution of the low energy part of the bremsstrahlung spectrum. Comparison of the measured yields with estimates calculated by Rudstam's formula permitted us to conclude that there is a difference in the mechanism of formation of the light fragments ^{7}Be, ^{11}C, and ^{13}N from that of the other residual nuclei ^{18}F, ^{22}Na, and ^{24}Na.

*GEV 5=4.5 GEV

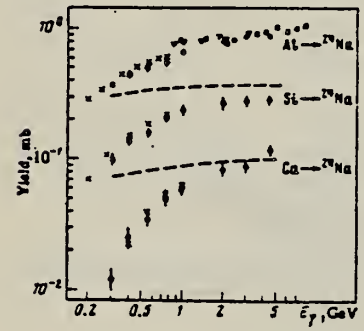

FIG. 1. Yields of the isotope ^{24}Na from targets of Al, Si, and Ca. ×—Data of Ref. 4, ○—data of Ref. 2, ▽—data of Ref. 6, □—data of Ref. 10, ●—data of the present work. The dashed lines show the contributions of the low energy part of the bremsstrahlung spectrum to the yields of the reactions Al—^{24}Na, Si—^{24}Na according to the data of Ref. 4 and the results of the calculations of the present work.

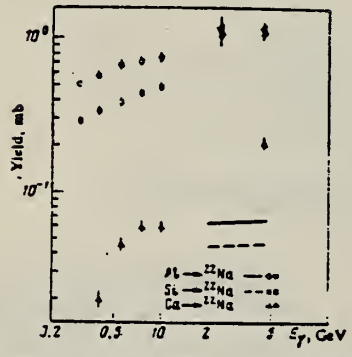

FIG. 2. Yields of ^{22}Na from targets of Al, Si, and Ca. The hollow symbols show the data of Ref. 2, and the solid symbols the data of the present work. The lines indicate the results of the calculations of the present work, which determine the contribution of the low-energy part of the bremsstrahlung spectrum to the yields of the reactions Al—^{22}Na and Si—^{22}Na for 2 GeV $\leq E_{\gamma_{max}} \leq$ 4.5 GeV.

Abstract—Mean cross sections for the photoproduction of ^{7}Be and ^{11}C from ^{19}F, ^{27}Al, ^{28}Si and ^{32}S targets, ^{7}Be from ^{10,11}B, and ^{11}C from ^{14}N and ^{16}O targets have been measured using bremsstrahlung beams in the energy range 0.3–1.0 GeV. The results have been compared with previous measurements and an excellent agreement has been found. In most cases, the values obtained turned out to be much larger than those expected from a simple spallation mechanism. A fragmentation and/or a fission-like process has been suggested in explaining the mechanism of such reactions.

999=1 GEV

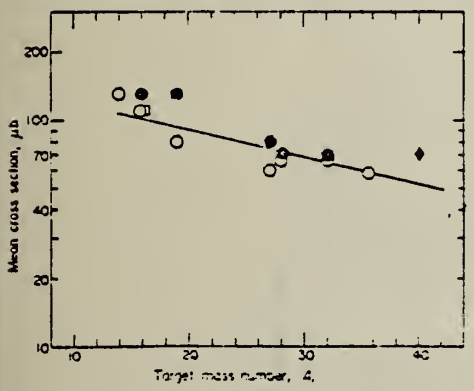

Fig. 1. Mean cross sections per photon, $\bar{\sigma}_A$, of ^{11}C photoproduction vs the target mass number A. Experimental data are taken from: ●, Ref. [9]; □, Ref. [13]; ◆, Ref. [2]; ○, present work. The straight line is a least squares fit of the experimental points.

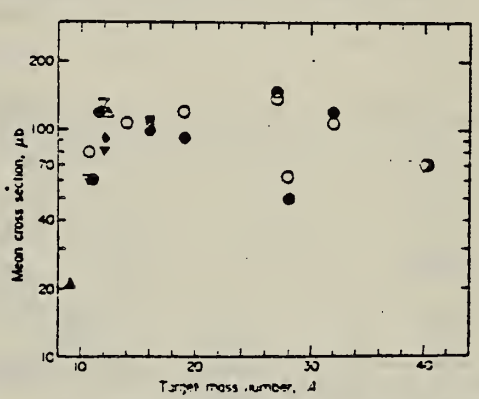

Fig. 2. The same as in Fig. 1 for ^{7}Be photoproduction. Experimental data are taken from: ▲, Refs. [6, 7]; ▽, Ref. [8]; ⊖, Ref. [9]; △, Ref. [10]; ◆, Ref. [11]; ▼, Ref. [12]; □, Ref. [13]; ■, Ref. [14]; ◇, Ref. [2]; ○, present work.

M2 LEVELS

The location of the M2 giant resonance in ^{28}Si, ^{90}Zr and ^{208}Pb, predicted within the framework of the MSI-RPA particle–hole model, has been confirmed by high-resolution inelastic electron scattering ($E_x \approx 44A^{-1/3}$ MeV). The fragmented M2 strength distribution can only be described assuming a mass-dependent quenching of the intrinsic g_s factor. This has the consequence that the long sought M1 strength is much reduced in heavy nuclei, an effect which is supported experimentally.

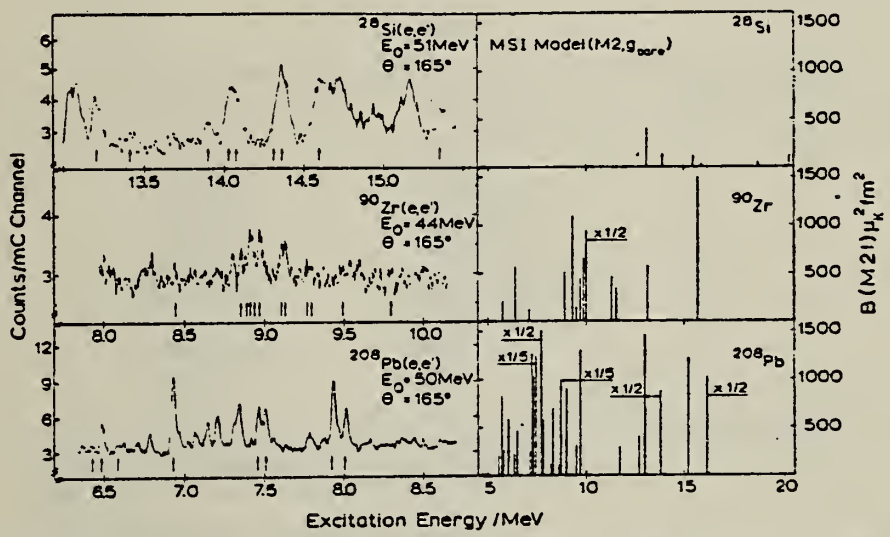

Fig. 1. The left part shows selected (e, e') spectra on ^{28}Si, ^{90}Zr and ^{208}Pb at various energies but all at $\theta = 165°$. The 2^- states are marked by arrows. The right part displays the model prediction for the M2 strength.

Observations are reported from the first systematic studies of proton radiative capture at intermediate energies. In addition to captures to the ground and first few excited states, the reactions $^{11}B(p,\gamma)^{12}C$ and $^{27}Al(p,\gamma)^{28}Si$ reveal unexpectedly strong transitions to isolated high-lying states. These latter transitions could take place via "second-harmonic" giant resonances. Protons on ^{12}C produce a rich spectrum of γ rays which may arise from captures to high-lying single-particle states.

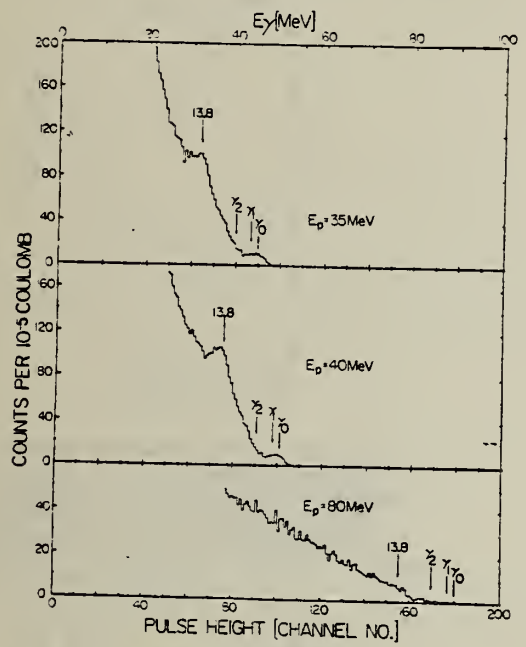

FIG. 2. γ-ray spectra from 35-, 40-, and 60-MeV protons on ^{27}Al observed at 60°. See Fig. 1 for notation.

				(91.2)			

Inelastic electron scattering in ^{28}Si between 4 and 50 MeV excitation energy reveals two concentrations of $E2$ strength in the continuum. One is between 15 and 20 MeV, with a peak at 17 MeV, and can be identified with the giant quadrupole resonance in the ground state oblate well. A broad distribution of $E2$ strength between 22 and 42 MeV is predominantly isovector in nature. In addition, a small but persistent $E2$ peak at 24 MeV was found, which may be interpreted as being the corresponding state in the prolate well to the 17 MeV resonance. It is shown that 50% or more of the photon cross section in excess of the classical dipole sum rule between 10 MeV and the pion threshold may be due to $E2$ absorption.

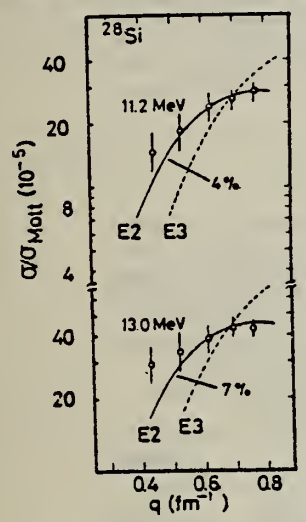

FIG. 2. The cross section divided by the Mott cross section for the states (or group of states) at 11.2 and 13.0 MeV. Comparison with a DWBA calculation based on the Tassie (identical with the Goldhaber-Teller) model and normalized to the percentage exhaustion of the isoscalar EWSR as indicated shows clearly that these states are quadrupole excitations.

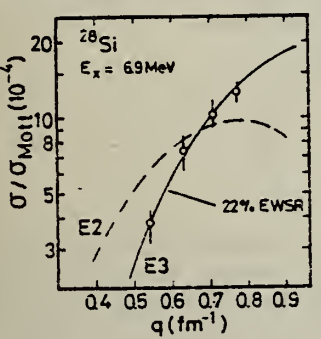

FIG. 3. Similar to Fig. 2 but for the level at 6.9 MeV. Comparison with DWBA calculations shows this state to be $E3$. This state agrees very well with the $1\hbar\omega$, isoscalar $E3$ state predicted by the shell model at $24A^{-1/3}$ MeV with a strength of 28% of the EWSR ($\Delta T = 0$) (see Ref. 22).

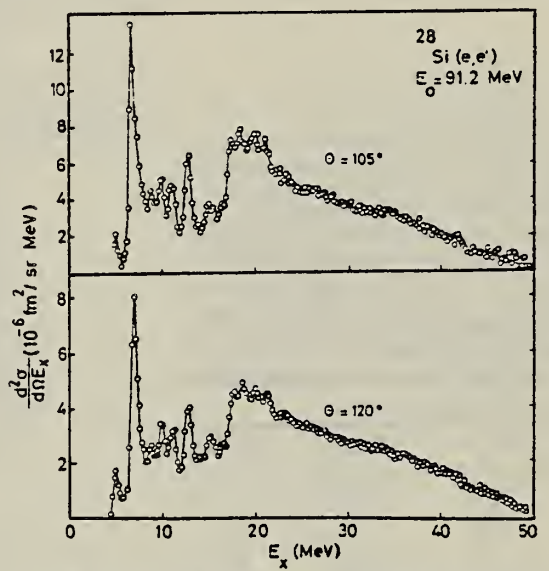

FIG. 5. Data of Fig. 1 after subtraction of a background described in the text and correction for the constant dispersion of the magnetic spectrometer. Some similarity to the photon data of Fig. 4 in the 17 to 22 MeV region can be recognized, especially the four characteristic peaks at 17.7, 18.8, 20.2, and 21.4 MeV. The ghost peak located at 92% of the elastic energy (E_x = 7.3 MeV) has been subtracted. The spectra were taken and fitted with 10 points per MeV, which have been reduced by a factor of 2 for graphical purposes. The statistical error is equal to the size of the circles in the 120° spectrum and slightly larger for 105°.

over

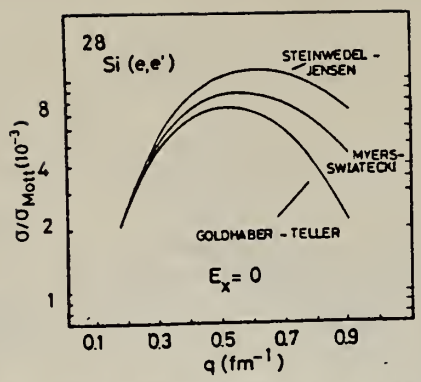

FIG. 7. Comparison of DWBA calculations based on the three models indicated. It is evident that, e.g., use of the Goldhaber-Teller model instead of the Myers-Swiatecki model would influence the quantitative results because the relative difference $[\sigma(MS)-\sigma(GT)]/\sigma(MS)$ changes from 8% for 60° to 28% for 120°, lowering the $E1$ strength subtracted by approximately 20%. However, measurements in other nuclei indicate that the MS model describes the GDR better, and, furthermore, the qualitative features do not change no matter what model is used.

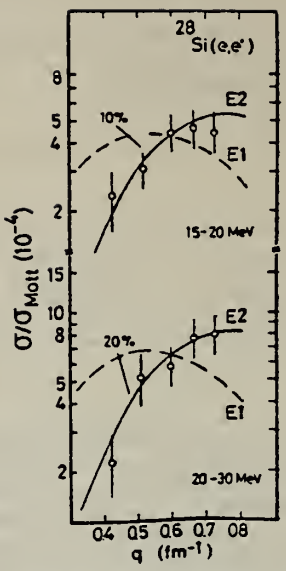

FIG. 8. Comparison of (e,e') strength between 15 to 20 and 20 to 30 MeV with DWBA calculations based on the MS model for the $E1$ and the GT model for the $E2$. The data correspond to the R_{min} values of Table I, but the 15 to 20 MeV data do not include half of the $E2$ strength found between 14 and 16 MeV.

TABLE I. Distribution of $E2$ strength in ^{28}Si into the various regions discussed in the text. Although isospin cannot be directly inferred from (e,e'), the strength below 20 MeV should be predominantly isoscalar and the one above isovector, based on macroscopic and microscopic considerations and comparison with heavier nuclei. The subscripts max and min refer to maximum and minimum values of the sum rule extracted under the background assumptions discussed in the text, ΔR shows the error (in %) if one does not take into account contributions to the error from the background assumptions.

E_x (MeV)	R_{max} [a]	R_{min} [a]	ΔR (%)
0–15	30 [b]	30 [b]	10
15–20	26 [b]	14 [b]	20
20–30	32	10	20
30–50	70	50	30
	50 [c]	30 [c]	

[a] $R = E_x B(E2)/\mathrm{EWSR}(E2,\Delta T = 0,1)\times 100$.
[b] Includes 3.5% EWSR from 14–16 MeV complex.
[c] Lower value derived by assuming 70% of isoscalar $3\hbar\omega_0 E3$ strength between 30 and 50 MeV (Ref. 22).

TABLE II. Comparison of the strength of the isoscalar $E2$ resonance around 17 to 20 MeV from various reactions. It is evident that the strength is grouped around two values, (12 to 14)% and (25 to 31)% of the isoscalar sum rule. As outlined in the text the higher value in hadronic experiments is from measurements where the $E1$ was not taken into consideration. If we use the equivalent background procedure as in (α,α'), the lower value of (14±3)% EWSR results.

E_x (MeV)	Reaction	R [a]	Reference
16.9–24.8	(α,α')	31±5	Knö76
15.5–23.0	(α,α')	27±6	VanB77
	(p,p')	12±4 [b]	
~19.4	(α,α')	~25	YouR77

Abstract: High resolution inelastic electron scattering at low momentum transfer yields the precise location of states with J^π, $T = 1^+$, 1 in ^{28}Si at excitation energies E_x = 10.594, 10.725, 10.901, 11.445 and 12.331 MeV with an overall energy uncertainty of about ±1 keV. An analysis of the inelastic cross sections to these states in terms of the DWBA with RPA wave functions from the model of separable interaction (MSI) yields a total isovector strength of $\sum\Gamma_\gamma^0$ = 34.40±1.37 eV. This result is compared to RPA and open-shell model calculations and it is shown that M1 spin-flip transitions seem to be a sensitive tool to investigate ground state correlations. A qualitative comparison of the M1 transitions with analogous charge exchange reactions involving hadrons and radiative pion and muon capture is also made.

LEVELS 5 J-PI, B(ML)

E NUCLEAR REACTIONS ^{28}Si(e, e'). E = 38.7–57.5 MeV; measured $\sigma(E_1, \theta)$. ^{28}Si deduced levels with $J^\pi = 1^+$, transition probability; performed shell-model calculations.

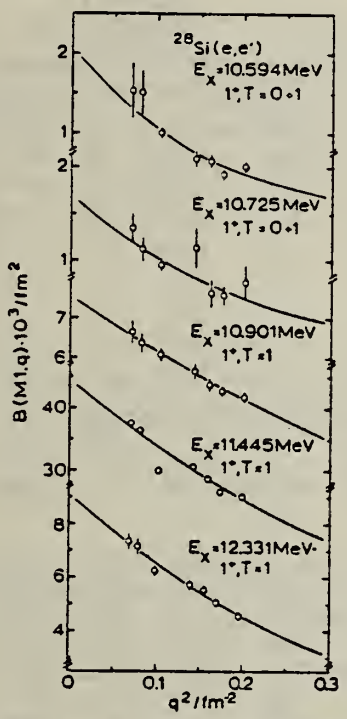

Fig. 4. The B(M1, q) values determined from experiment with the help of eq. (1) in the main text plotted as a function of q^2. In the momentum range $q^2 < 0.2$ fm^{-2} the influence of the higher moments $R_{tr}^4 = \langle r^5\rangle/\langle r\rangle$ and $R_{tr}^6 = \langle r^7\rangle/\langle r\rangle$ in eq. (2) is small. Therefore for the fit we have used the estimates $R_{tr}^4 = 1.32[R_{tr}^2]^2$ and $R_{tr}^6 = 2.25[R_{tr}^2]^3$ following from the prediction of a phenomenological model which reproduces the experimental value of $R_{tr}^2 = \langle r^3\rangle/\langle r\rangle$. Fitted to the experimental values is expression (2) which yields extrapolated to $q = k = E_x/\hbar c$ the B(M1, k) value at the photon point.

Natural Silicon Target

2=1.78, 5=4.62 MEV

Electron scattering from ^{28}Si and ^{29}Si has been performed at energies from 126 to 293 MeV and at angles of 45° and 90°. Form factors were extracted for levels below 5.0 MeV in ^{28}Si and ^{29}Si over an effective momentum transfer range of 0.6 to 2.1 fm^{-1}. A particle-phonon coupling calculation using harmonic-oscillator single-particle states and data from ^{28}Si give a reasonable description of the low-lying states of ^{29}Si.

[NUCLEAR REACTIONS ^{28}Si(e,e') first 2 excited states; ^{29}Si(e,e') first 5 excited states; measured form factors 45° and 90°, $0.6 \leq q \leq 2.1$ fm^{-1}; natural Si target; PWBA analysis, vibrating core and intermediate coupling for ^{29}Si.]

		(14.36)					

High-resolution (e,e') was used to measure the form factor of the 6^-, $T = 1$ resonance in ^{28}Si. The results disagree with previous experimental results and with theoretical calculations. The role of meson-exchange currents in producing the observed quenching of magnetic strength, and the relevance of (e, e') to other reactions are briefly discussed.

*Q IN FM-1

Photoproduction of π^0 mesons off targets of ^{6}Li, ^{12}C, ^{28}Si, ^{40}Ca, natural Cd, and natural Pb was studied using a bremsstrahlung beam with endpoint energies of 140, 145, 150, and 155 MeV. Photoproduction from a liquid hydrogen target was employed as a normalization. The measured yields were found to be in disagreement with published theoretical cross sections for ^{6}Li$(\gamma,\pi^0)^6$Li and also in disagreement with a simple schematic model which assumed only coherent contributions from the M_{1+} multipole. The schematic model, however, did approximately predict the relative magnitudes of the yield curves for the energy range 14—20 MeV over threshold.

A study of the reaction $^{29}Si(\gamma,n)$ near threshold suggests that a doorway state with $J^\pi = \frac{3}{2}^-$ common to the channels $^{28}Si + n$ and $^{29}Si + \gamma$ lies near 750 keV. We observe experimentally Lane's prediction of a significant nonresonant background cross section associated with strong partial-width correlations.

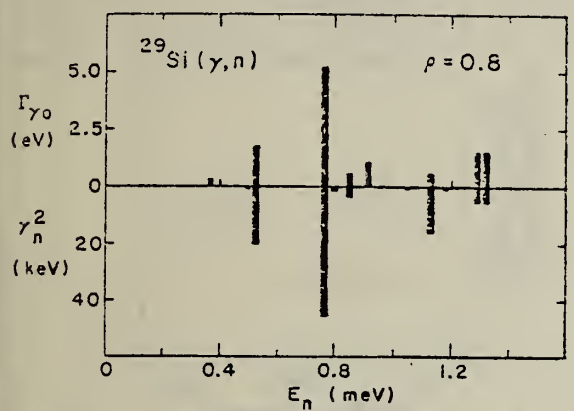

FIG. 2. Ground-state radiation widths Γ_{γ_0} and reduced neutron widths γ_n^2 for resonances in the ^{29}Si compound nucleus with $J^\pi = \frac{3}{2}^-$.

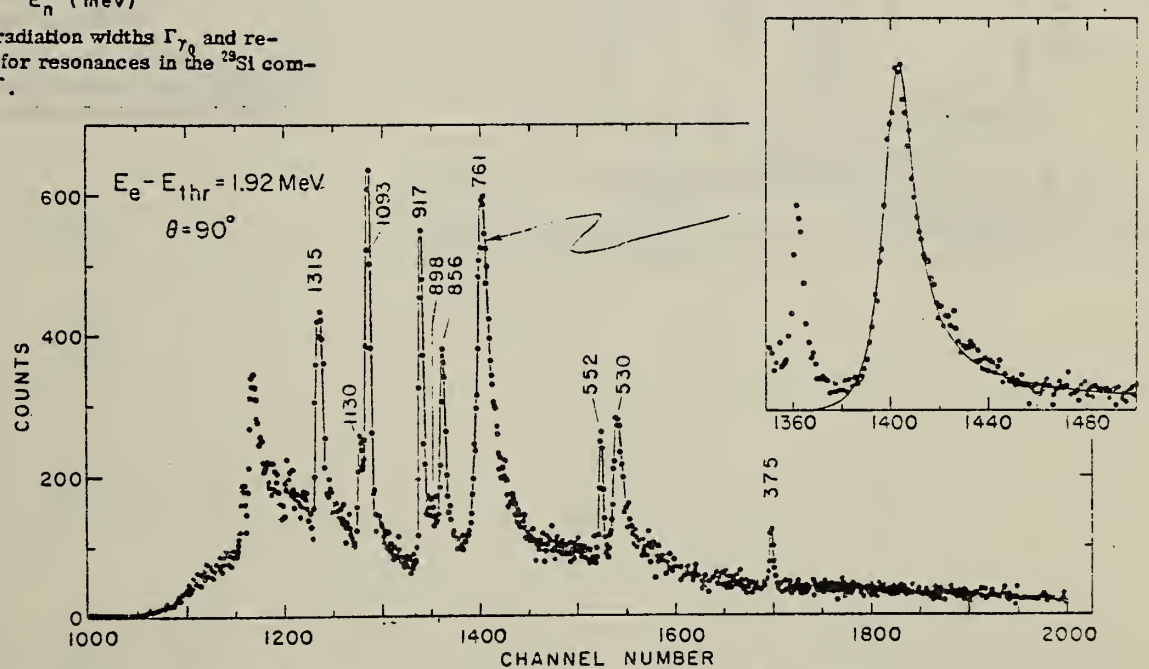

FIG. 1. Photoneutron time-of-flight spectrum for $^{29}Si(\gamma,n)$. Flight path, 9 m; bremsstrahlung pulse width, 6 nsec; pulse repetition rate, 800 pulses/sec; average linac current, ~25 μA. The spectrum was accumulated in a 24-h run. The data have not been corrected for variations in detector efficiency or for the energy dependence of the incident flux. Resonance energies are given in keV. Inset, expanded plot of the data in the region of the 761-keV resonance. The curve is the resonance shape resulting from the sum of a normal Breit-Wigner amplitude whose total width is $\Gamma = 26$ keV and a nonresonant amplitude corresponding to a background cross section of 0.32 mb.

Abstract. The excited states of ^{29}Si up to 8·3 MeV excitation energy have been studied by inelastic electron scattering in the momentum transfer range 0·4 to 1·05 fm^{-1}. Ground-state transition probabilities and transition radii were obtained for the levels excited. At lower excitation energies our transition probabilities agree with previous work. A number of high excitation and high-multipolarity levels are studied for the first time, and several previously tentative spin–parity assignments are confirmed. Transition probabilities for $L = 2$, 3 and 4 are compared with the predictions of the intermediate coupling model, and the Nilsson and shell models.

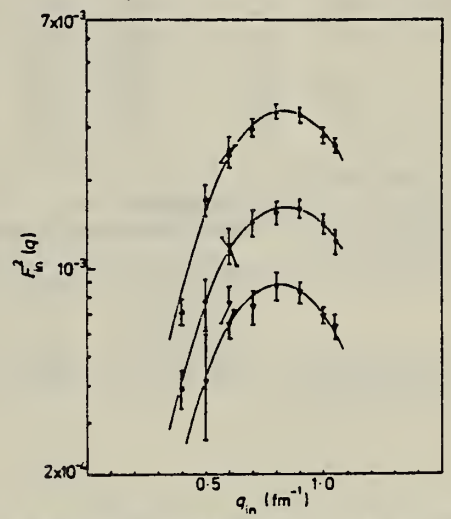

Figure 2. Inelastic form factors for the ^{29}Si E2 transitions at 1·27 MeV (▽), 2·03 MeV (△) and 2·43 MeV (○). The full curves are the best-fit DWBA form factors.

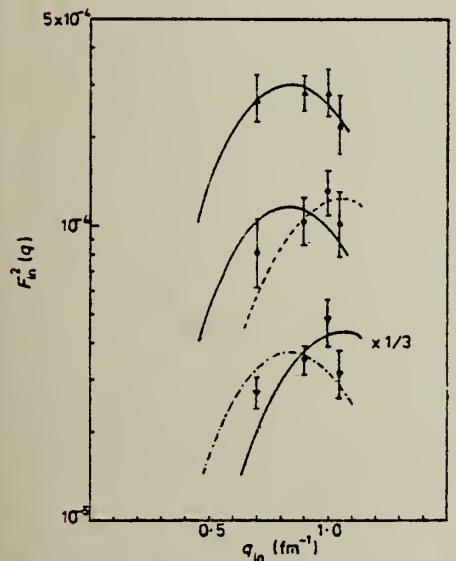

Figure 7. DWBA fits to the form factor data for the 7·91 MeV (——, E2; – – –, E3), 8·13 MeV (——, E2) and 8·27 MeV (——, E3; – – –, E2) levels.

Abstract: Gamma-ray spectra from the neutron capture by natural silicon have been measured with Ge(Li) and NaI detectors for neutron resonances at 565 and 813 keV. Absolute partial and total radiative widths have been obtained and compared with previous results and with recent valence and shell-model calculations.

E NUCLEAR REACTIONS ^{28}Si(n, γ), E = 565, 813 keV; measured $\sigma(E, E_\gamma)$. ^{29}Si deduced $\Gamma_{\gamma 0}$, Γ_γ. Natural target.

4 STATES 1.27-4.08

Electron scattering from ^{28}Si and ^{29}Si has been performed at energies from 126 to 293 MeV and at angles of 45° and 90°. Form factors were extracted for levels below 5.0 MeV in ^{28}Si and ^{29}Si over an effective momentum transfer range of 0.6 to 2.1 fm^{-1}. A particle-phonon coupling calculation using harmonic-oscillator single-particle states and data from ^{28}Si give a reasonable description of the low-lying states of ^{29}Si.

[NUCLEAR REACTIONS ^{28}Si(e,e') first 2 excited states; ^{29}Si(e,e') first 5 excited states; measured form factors 45° and 90°, $0.6 \leq q \leq 2.1$ fm^{-1}; natural Si target; PWBA analysis, vibrating core and intermediate coupling for ^{29}Si.]

Abstract: The photoneutron cross section of ^{29}Si has been measured over the energy range 8 to 28 MeV using the bremsstrahlung yield curve technique. The giant dipole resonance is observed to be centered at 21.2 MeV and is 5.5 MeV wide. In addition, a pygmy resonance containing much fine structure is observed below 17 MeV. An attempt is made to interpret these observations in terms of the weak coupling of the extra neutron to a ^{28}Si core. However, detailed comparisons of the structure and relative strengths of the ^{28}Si and ^{29}Si cross sections reveal that the coupling of the extra-core nucleon is large and significantly modifies the core wave function.

E NUCLEAR REACTIONS ^{29}Si(γ, xn), $E \approx$ 8-28 MeV, enriched sample; measured 4π neutron yield with bremsstrahlung. Deduced σ(E), observed GDR and pygmy resonance.

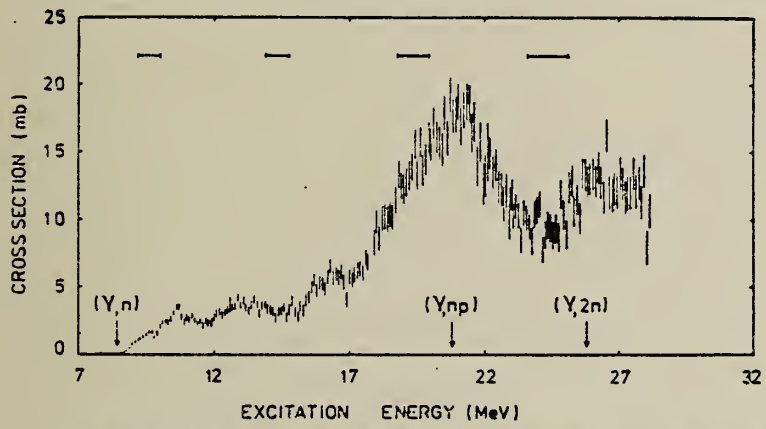

Fig. 1. The cross section ^{29}Si(γ, sn), obtained from the yield curve measured in 100 keV intervals. Error bars are statistical only. There is an uncertainty no greater than 10 % in the absolute magnitude of the cross section. Horizontal bars indicate the width of the interval used in data analysis.

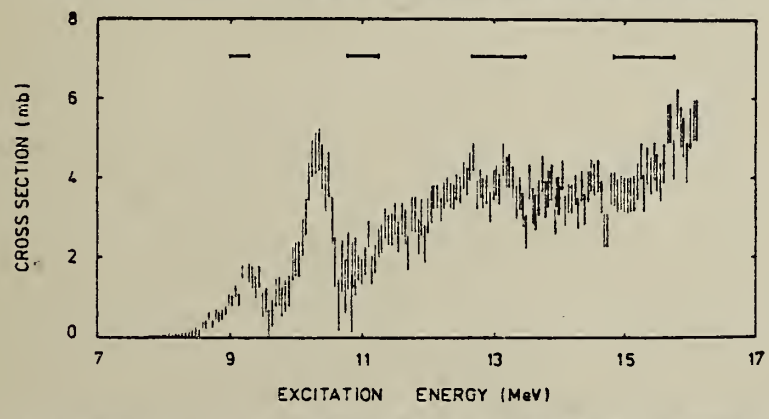

Fig. 2. The cross section for ^{29}Si(γ, n), obtained from the yield curve measured in 50 keV intervals. Error bars are statistical only. There is an uncertainty no greater than 10 %, in the absolute magnitude of the cross section. Horizontal bars indicate the width of the interval used in data analysis.

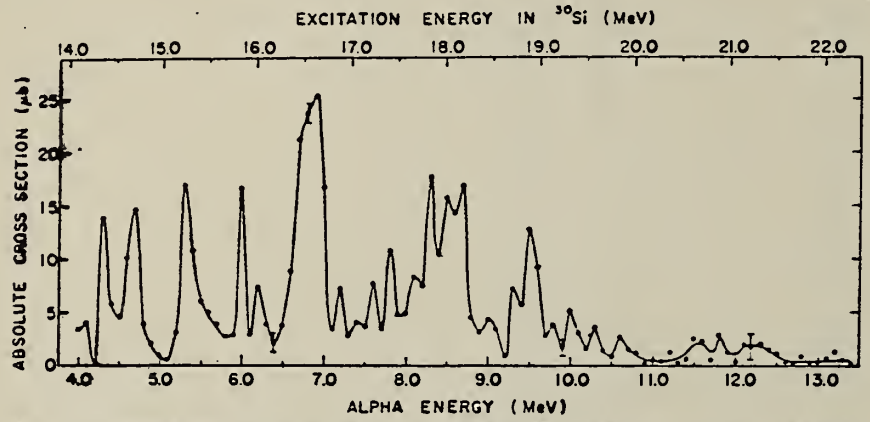

Fig. 5. The absolute cross section for the reaction ^{26}Mg$(\alpha,\gamma_0)^{30}$Si plotted as a function of the energy of the incident alpha. The data were taken in 100 keV steps. As in fig. 3, the angular distribution used was of the $\sin^2\theta$ form typical of an electric-dipole transition.

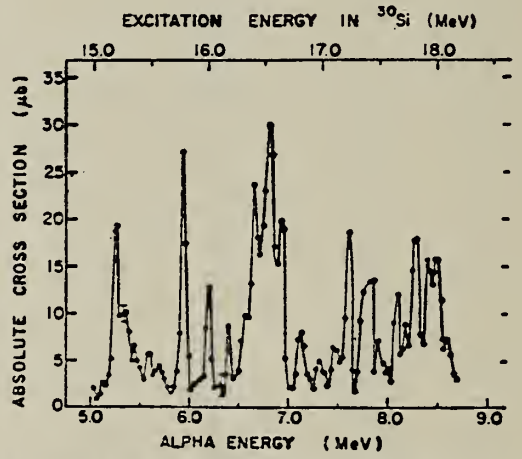

Fig. 6. Same as fig. 5 except that the measurements were taken in 30 keV steps instead of 100 keV and extend only from 5.0 to 8.7 MeV.

TABLE 1

The averaged absolute cross sections $\overline{\sigma(\alpha,\gamma_0)}$ and $\overline{\sigma(\alpha,\gamma_1)}$ for the reactions $^{24}Mg(\alpha,\gamma_0)$, $^{24}Mg(\alpha,\gamma_1)$, $^{26}Mg(\alpha,\gamma_0)$ and $^{28}Si(\alpha,\gamma_0)$

	$^{24}Mg(\alpha,\gamma)^{28}Si$		$^{26}Mg(\alpha,\gamma_0)^{30}Si$		$^{28}Si(\alpha,\gamma_0)^{32}S$	
ΔE_x (MeV)	$\overline{\sigma(\alpha,\gamma_0)}$ (μb)	$\overline{\sigma(\alpha,\gamma_1)}$ (μb)	ΔE_x (MeV)	$\overline{\sigma(\alpha,\gamma_0)}$ (μb)	ΔE_x (MeV)	$\overline{\sigma(\alpha,\gamma_0)}$ (μb)
14.65–16.65	8.5	5.0	14.1–16.1	6.1	13.1–15.5	1.7
16.65–18.65	12.9	6.1	16.1–18.1	9.7	15.5–17.5	2.2
18.65–20.65	11.0	8.6	18.1–20.1	4.6		
20.65–22.65	2.1	5.6	20.1–22.1	1.0		
14.65–22.65	8.6	6.3	14.1–22.1	5.3	13.1–17.5	1.9

The cross sections in the first four rows were obtained from the data in figs. 3–6 and 15 by averaging over the indicated ≈ 2 MeV ranges of excitation energy E_x in the product nucleus (^{28}Si, ^{30}Si or ^{32}S). The last line gives the average for the entire energy range that was studied.

TABLE 3

The cross sections $\overline{\sigma(\gamma,\alpha_0)}$ for the α-decay of the nuclei ^{28}Si, ^{30}Si and ^{32}S

Target nucleide	ΔE (MeV)	$\overline{\sigma(\gamma,\alpha_0)}$ (mb)	$\overline{\sigma(\gamma,p_0)}$ (mb)	$\dfrac{\overline{\sigma(\gamma,\alpha_0)}}{\overline{\sigma(\gamma,p_0)}}$	$\gamma^2(\alpha_0)/\gamma^2(p_0)$	
					$l=1$	$l=3$
^{28}Si	16.65–18.65	1.01	6.2	0.16	0.35	0.12
	18.65–20.65	0.94	11.7	0.080	0.095	0.041
	20.65–22.65	0.22	9.6	0.023	0.019	0.011
	16.65–22.65	0.72	9.2	0.08		
^{30}Si	14.1 –16.1	0.43				
	16.1 –18.1	0.69				
	18.1 –20.1	0.35				
	18.1 –20.1	0.35				
	20.1 –22.1	0.08				
	14.1 –22.1	0.38				
^{32}S	13.1 –15.5	0.20	1.7	0.12		
	15.5 –17.5	0.27	2.1	0.13		
	17.5 –19.5		3.0			
	13.1 –17.5	0.23	1.9	0.12		

The averages were taken over ≈ 2 MeV wide energy regions ΔE and over the total studied energy region of the giant dipole resonance. These cross sections were obtained by detailed balance from the α-capture in ^{24}Mg, ^{26}Mg and ^{28}Si. For comparison, the average cross sections $\overline{\sigma(\gamma,p_0)}$ over the same energy regions ΔE for the reactions $^{28}Si(\gamma,p_0)^{27}Al$ and $^{32}S(\gamma,p_0)^{31}P$ are also presented. These likewise were obtained by detailed balance from the inverse reactions as measured by Singh *et al.* [6]) and by Dearnaley *et al.* [6]). For the calculation, we assumed an isotropic angular distribution for the $^{28}Si(\gamma,p_0)$ reaction, a $\sin^2\vartheta$ distribution for $^{32}S(\gamma,p_0)$. In addition, the ratios $\overline{\sigma(\gamma,\alpha_0)}/\overline{\sigma(\gamma,p_0)}$ are given for both ^{28}Si and ^{32}S and also the calculated reduced width $\gamma^2(\alpha_0)/\gamma^2(p_0)$ for an orbital-angular-momentum transfer of $l=1$ and of $l=3$ in the decay of ^{28}Si.

The yields of the $(\gamma,2p)$ reaction on ^{30}Si and of the $(\gamma,2p)$, $(\gamma,2pn)$, $(\gamma,3p)$ and $(\gamma,3pn)$ reactions on ^{31}P have been measured as a function of the maximum bremsstrahlung energy in the range 75–640 MeV. The cross sections have been deduced and are compared to Monte-Carlo calculations. The magnitude of the cross sections in the energy range above the threshold for the photoproduction of mesons is also discussed using a simple analytical approach.

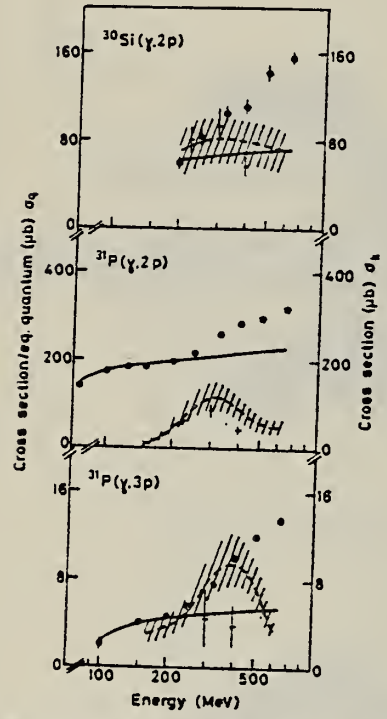

Fig. 1. The filled circles show measured yields as a function of the maximum bremsstrahlung energy. The meaning of the solid lines, the hatched areas and the plus signs is given in the text

Abstract: The photoneutron cross section for ^{30}Si has been measured over the energy range 10 to 28 MeV using the bremsstrahlung-yield-curve technique. The cross section is observed to be highly fragmented, consistent with systematic trends observed in other light nuclei consisting of two neutrons outside a self-conjugate core.

E NUCLEAR REACTIONS ^{30}Si(γ, xn), $E \sim 10$–28 MeV bremsstrahlung; measured neutron yield; deduced $\sigma(E)$. ^{30}Si deduced GDR fragmentation.

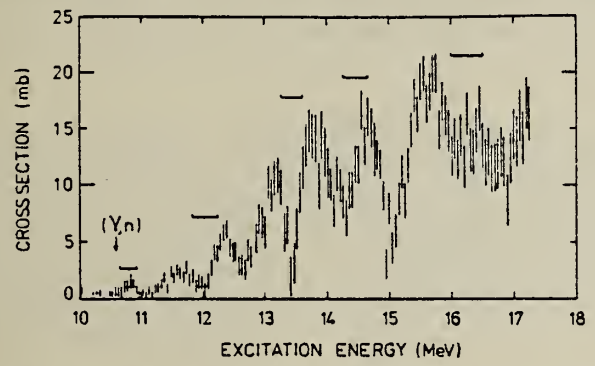

Fig. 1. Low-energy region of the ^{30}Si(γ, n) cross section determined from a yield measurement taken at 50 keV intervals. The vertical bars indicate statistical uncertainty and the horizontal lines give a measure of the resolution.

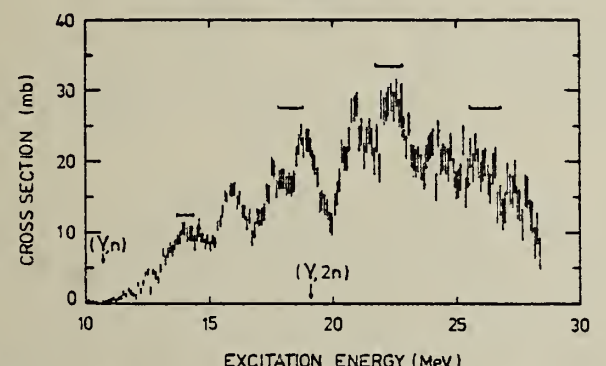

Fig. 2. The ^{30}Si(γ, xn) cross section. No correction has been made for double counting from the (γ, 2n) reaction. The vertical bars indicate statistical uncertainty and the horizontal lines give a measure of the resolution.

TABLE 1

Resonances observed in the reaction ^{30}Si(γ, xn)

Energy (MeV)	Peak height (mb)	FWHM (MeV)
10.8	1	0.15
11.6	2	0.4
12.4	4	0.3
13.1	8	0.4
13.8	12	0.5

[a]) Ref. [2]). [b]) Ref. [8]). [c]) Present work.

* Uncorrected for double counting above the (γ, 2n) reaction threshold at 19.1 MeV.

The values for ^{30}Si are obtained from the present work. The absolute uncertainty is ±10%. Column 2 lists the values below 17 MeV (essentially the ^{28}Si(γ, n) threshold). Column 3 lists the values up to the energy where the ^{30}Si(γ, 2n) contribution becomes significant. Column 5 allows comparison of the (γ, n) strengths over a specific region of the GDR for these nuclei.

PHOSPHOROUS
Z=15

The name phosphorous, derived from the Greek *phos* + *phoros* meaning "light bearing", indicates its properties of glowing in the dark when exposed to air.

Raimondo di Sangro (1710-1771) mentioned the "perpetual lamps" of Saint Augustine (354-430) which were found in the sepulchers of the early Christians. Di Sangro believed that these lamps contained phosphorous. Paracelsus (1493-1541) had a recipe for "the separation of the element from watery substances". He obtained "icicles which are the elements of fire" apparently from the distillation of urine. This probably was elemental phosphorous.

P
A=29

Most authorities attribute the discovery of phosphorous to Hennig Brand of Hamburg who used the residue from evaporated urine as the source of the element. No one knows what led this zealous alchemist to hope, that in human urine, he might find a liquid that might change silver into gold, but it is well known that his odd experiments, produced both startling and strangely beautiful results. News of the discovery spread across Germany but Brand kept his process secret —— at least for awhile.

Its history at this point is sprinkled with deceit and intrigue. Many alchemists sought the philosopher's stone and it was thought that such an unusual material as phosphorous might lead to this stone. Von Leibniz (1646-1716), the famous German mathematician and scientist, was personally acquainted with Brand and wrote a detailed account of the discovery of phosphorous as well as a biographical sketch of the people involved. It is interesting that an element so difficult to isolate should have been discovered through the unguided fumbling of an alchemist.

Abstract: The absolute resonance strengths of the $^{28-30}$Si(p, γ)$^{29-31}$P reactions have been studied. New values for the frequently used standard resonances at E_p = 370, 416 and 620 keV in the above reactions, respectively, have been determined. In addition, the strengths of the ^{28}Si(p, γ)^{29}P resonances at E_p = 1381, 1652 and 2088 keV and of the four dominant ^{30}Si(p, γ)^{31}P resonances at E_p = 499, 777, 942 and 983 keV have been determined. The branching ratios and angular distributions of the γ-rays used in the determinations were obtained in the same experimental set-up as the strength measurements. Using these revised resonance strengths, the astrophysical reaction rates of hydrogen burning of ^{29,30}Si in explosive carbon burning have been deduced. The reaction rates found for hydrogen burning of $^{28-30}$Si in the stellar temperature region of $T = (0.3–10) \times 10^9$ K are compared with Hauser-Feshbach calculations.

STELLAR REACTION RATE

E NUCLEAR REACTIONS ^{28}Si(p, γ), E = 0.37, 1.38, 1.65, 2.09 MeV; ^{29}Si(p, γ), MeV, ^{30}Si(p, γ), E = 0.50, 0.62, 0.78, 0.94, 0.98 MeV; measured $\sigma(E_p)$, $I_\gamma(\theta)$. ^{29,30,31}P resonances deduced γ-branchings, resonance strengths. Ge(Li) detector. Natural and enriched targets.

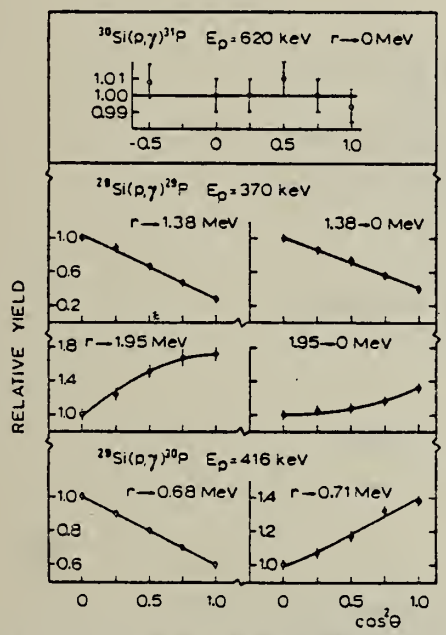

Fig. 1. The results of angular distribution measurements of the standard resonances at E_p = 370, 416 and 620 keV in the $^{28-30}$Si(p, γ)$^{29-31}$P reactions. In the case of the E_p = 620 keV resonance, the experimental points are shown without eccentricity or absorption corrections. In other cases these corrections have been made. The solid lines are the fitted curves of the form $W(\theta) = 1 + a_2 P_2(\cos\theta) + a_4 P_4(\cos\theta)$.

TABLE I. Resonances in the $Si^{29}(p,\gamma)P^{30}$ reaction for E_p = 300–1800 keV. The resonance strengths $S=(2J+1)\Gamma_\gamma\Gamma_p/\Gamma$ and the total widths Γ are given. For comparison, resonances reported in Refs. 22 and 23 for $Si^{29}(p,p)Si^{29}$ are also listed. The (p,p) data at 1505 keV is from recent work in this laboratory, to be published elsewhere (Ref. 17).

$Si^{29}(p,\gamma)P^{30}$				$Si^{29}(p,p)Si^{29}$		
E_p (keV)	$E_x(P^{30})$ (keV)	S (eV)	Γ (keV)	E_p (keV)	Γ (keV)	J^π
327	5.913	0.077±0.015	≤3			
416	5.999	0.70±0.10	≤5

Reaction	E or ΔE	E_o	Γ	$\int \sigma dE$	Jπ	Notes
$P^{31}(\gamma,n)$	Bremss. 30					Neutron spectrum for $E_n \geq 1.5$ MeV. 90° measurement. High-energy tail and wide peak around 5.5 MeV in E_n spectrum indicate that other processes besides evaporation must occur. 30% direct for $E_n > 1.5$; 60% direct for $E_n > 4$.

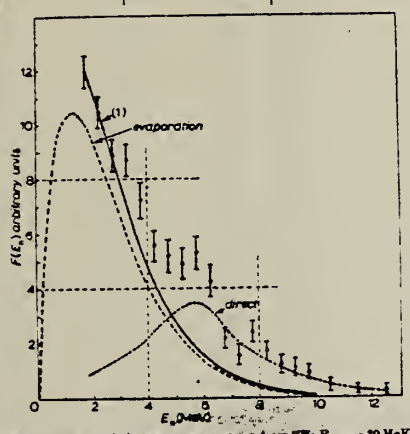

Fig. 1. – Points: experimental photoneutron spectrum from ^{31}P; $E_{\gamma\,max} = 30$ MeV. Curve (1) represents the function $F(E_n) = KE_n \exp[-E_n/1.3]$ which fits the experimental points for $E_n < 3$ MeV. The « evaporation » and « direct » curves represent the contribution of the evaporation and direct interaction to the experimental spectrum.

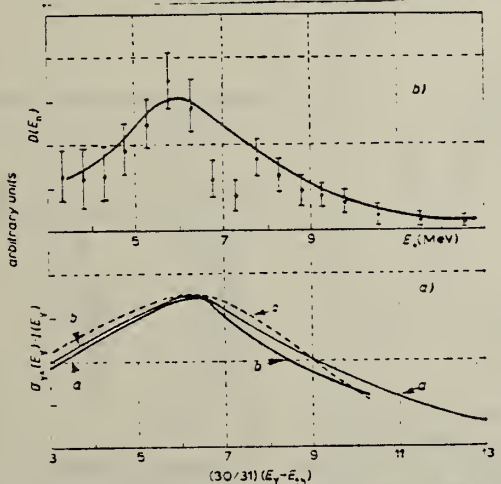

Fig. 3 a), b). – The curves *a*, *b*, *c*, represent the function $\sigma_{(\gamma,n)}(E_\gamma) \cdot D(E_n)$ assuming the $\sigma(\gamma, n)$ cross-section given in refs. [10,11,12] respectively; for the curve $D(E_n)$ see text.

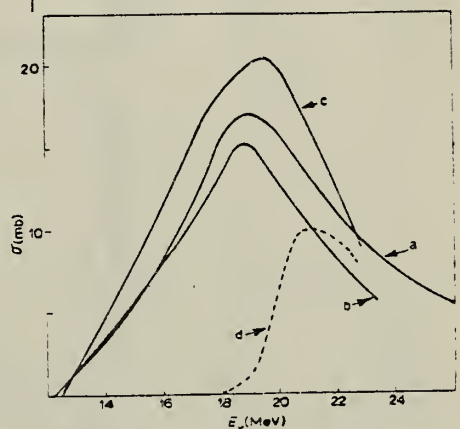

Fig. 2. – The curves *a*, *b*, and *c* represent the $^{31}P(\gamma, n)$ cross-section according to the refs. [10,11,12] respectively; the curve *d* represents the (γ, np) cross-section according to ref. [12].

Table III. Anisotropic factor B/A of angular distributions estimated for the groups of strong transitions.

	Assumed residual Energy (MeV)	E_γ (MeV)	B/A	Used data[a]
^{23}Na	1.27	18.8–20.5	0.5±0.4	20.5
	3.3	20.8–22.1	∞[b]	D
		22.1–24	∞[b]	24.0
	7.0	20.7–22.7	1.5±0.3	D
^{31}P	0	15.7–21	∞[b]	24.0,19.0
	7.0	17.4–20.2	0.5±0.6	D
		20.2–22.7	1.3±1.3	D
^{32}S	0	14–20	∞[b]	(p, γ_0)
		14–14.8	2.4±0.7	17.0
		14.8–16.2	∞[b]	17.0
		16.2–17.1	∞[b]	17.0
	5.0	19.2–20.1	0.5±0.2	D
		20.1–21.3	0.4±0.2	D
^{40}Ca	0	17.1–20.5	1.5±0.2	20.5
	2.8	17.4–19.9	2.6±0.3	20.5
	6.0	17.2–18.7	0.05±0.09	20.5
		18.7–20.5	0.6±0.1	20.5

a) The numerical number indicates the maximum energy of the bremsstrahlung irradiated for the data. D shows the difference between the two distributions. (p, γ_0) shows the inverse reaction data.
b) The notation ∞ indicates that the distribution is almost $\sin^2\theta$, *i.e.*, the result has stronger maximum than $1+10\sin^2\theta$.

Table II. Anisotropic factor B/A of angular distributions determined by least-squares fits with $A+B\sin^2\theta$.

^{31}P					
($E_{\gamma max}$=19.0 MeV)		($E_{\gamma max}$=24.0 MeV)[b]		(Curve D in Fig. 2)	
E_p(MeV)	B/A	E_p(MeV)	B/A	E_p(MeV)	B/A
3.9–5.5	0.6±0.1	3.0–4.6	0.9±0.4	3.0–5.7	0.5±0.6
5.5–7.9	1.3±0.3	4.6–6.0	0.4±0.3	5.7–8.1	1.3±1.3
7.9≦	∞[a]	6.0–8.2	1.3±0.6	8.1–11.3	∞[a]
3.9≦	1.7±0.2	8.2≦	∞[a]		
		3.0≦	1.1±0.3		

a) The notation ∞ indicates that the distribution is almost $\sin^2\theta$. It is used when the result has stronger maximum than that of $1+10\sin^2\theta$.
b) The data are used from ref. 4).

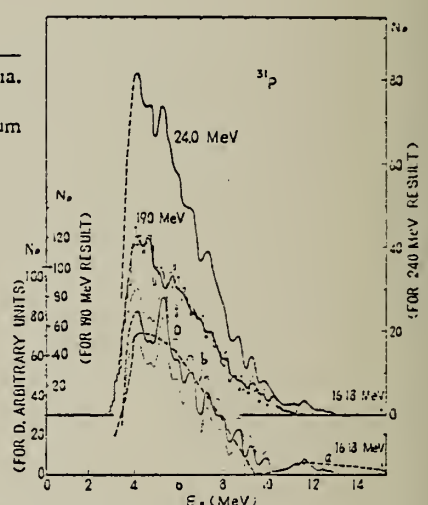

Fig. 2. Energy distributions of photoprotons from ^{31}P irradiated with 19.0 MeV bremsstrahlung. The early data on 24.0 MeV bremsstrahlung[4] is also shown. See also the caption of Fig. 1 for curves D, a and b. Here a and b correspond to the ground and 7.0 MeV state of residual nucleus respectively.

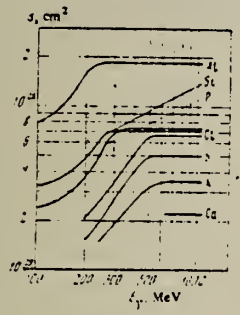

FIG. 2. Cross sections as a function of γ-ray energy.

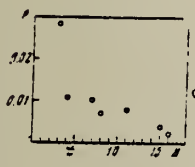

FIG. 3. Dependence of P on number of nucleons which have left the nucleus.

Table I

Reaction	Nucleons emitted	Threshold*, MeV	Target	Distribution of isotopes, %
$Al^{27} \rightarrow Na^{24}$	2p, α	31	Al	100
$Si^{29} \rightarrow Na^{24}$	3p, α	43	Si	92,27
$P^{31} \rightarrow Na^{24}$	4p, 3n	69	P	100
$S^{32} \rightarrow Na^{24}$	5p, 3n	78	S	95,02
$Cl^{35} \rightarrow Na^{24}$	6p, 5n	105	NH_4Cl	75,4
$K^{39} \rightarrow Na^{24}$	8p, 7n	140	K_2CO_3	93,08
$Ca^{40} \rightarrow Na^{24}$	9p, 7n	148	CaO	96,97

*The threshold was calculated as the binding energy of the emitted nucleons.

Table II. Cross sections for reactions in the saturation region

Reaction	σ_P, 10^{-28} cm²	Reaction	σ_P, 10^{-28} cm²
$Al^{27} \rightarrow Na^{24}$	185±20	$Cl^{35} \rightarrow Na^{24}$	69±7
$Si^{29} \rightarrow Na^{24}$	72±8	$K^{39} \rightarrow Na^{24}$	35±5
$P^{31} \rightarrow Na^{24}$	71±8	$Ca^{40} \rightarrow Na^{24}$	22±5
$S^{32} \rightarrow Na^{24}$	52±6		

FIG. 1. Cross section σ_Q per equivalent photon as a function of maximum bremsstrahlung energy. Points: ○ – Al, ● – Si, △ – P, ▲ – S, □ – Cl, ■ – K, ◇ – Ca.

According to the photomesonic mechanism, the cross section for the reaction can be written in the form

$$\sigma = \sigma_0 AP. \qquad (1)$$

Here σ_0 is the total cross section for interaction of the photon with a free nucleon with inclusion of the nucleon motion in the nucleus (σ_0, as has been shown by Roos and Peterson,[5] depends only weakly on photon energy for $E_\gamma > 300$ MeV); A is the number of nucleons in the nucleus, and P is the probability that the reaction will proceed by a given channel.

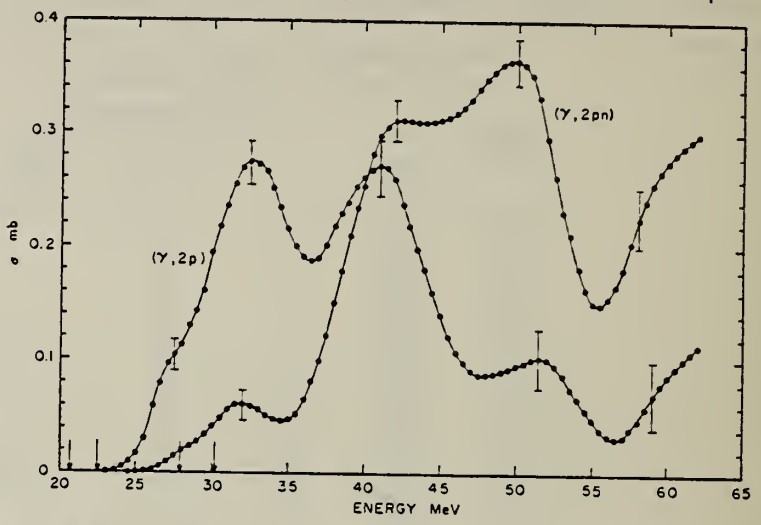

Fig. 3. The least structure cross-section solutions for the $^{31}P(\gamma, 2p)^{29}Al$ and $^{31}P(\gamma, 2pn)^{28}Al$ reactions. The flags on the points represent the estimated cross-section errors. The arrows on the energy axis indicate mass threshold energies for the $(\gamma, 2p)$, $(\gamma, {}^3He)$, (γ, dp) and $(\gamma, 2pn)$ reactions from left to right.

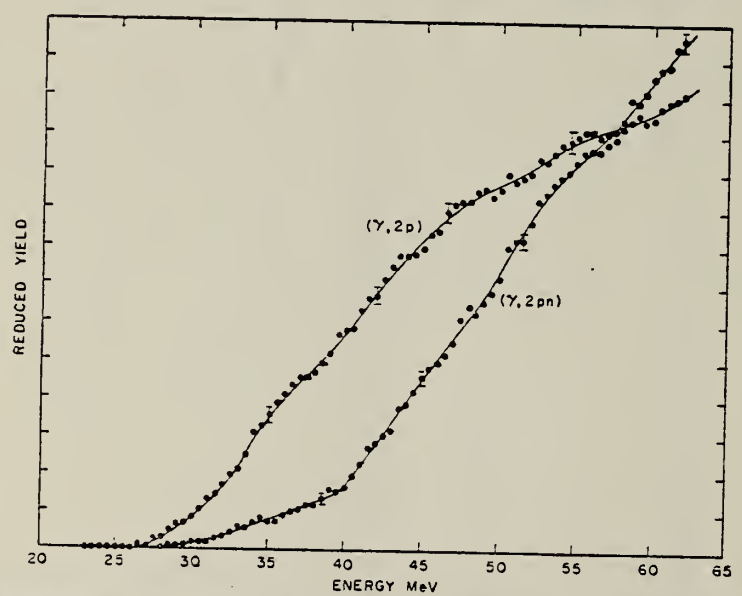

Fig. 2. The reduced yield points for the $(\gamma, 2p)$ and $(\gamma, 2pn)$ reactions in phosphorus are shown. The error bars indicate the standard deviations for the yield points. The smooth curves represent the polynomials fit to the yield points by the least structure procedure [9]).

[9] F.S. Goulding, D.A. Landis, J. Cerny and R.J. Pehl, Nucl. Instr. 31 (1964) 1.

Abstract: Bremsstrahlung activation curves were measured for the reactions $^{31}P(\gamma, 2p)^{29}Al$ and $^{31}P(\gamma, 2pn)^{28}Al$ in 0.5 MeV steps from 23.0 to 62.0 MeV. The cross sections obtained from these curves show peaks at 32.6±0.7 MeV, 41.2±0.8 MeV and 51.0±1.5 MeV for both reactions. The cross section integrated to 62 MeV for the $(\gamma, 2p)$ reaction is 5.6±0.6 MeV · mb and for the $(\gamma, 2pn)$ reaction is 7.6±0.8 MeV · mb.

[a]) The branchings are obtained from the relative intensities observed at the scattering angle of 87°. The effect of the angular distribution of the γ-rays is not taken into account.

[b]) The error for $(2J+1)\Gamma_{\gamma 0}$ only includes the statistical error. An estimate of the uncertainty associated with the shape of the incident bremsstrahlung is not included.

[c]) Ref. [21]).

[d]) Ref. [8]).

[e]) Ref. [56]).

[f]) Ref. [57]).

[g]) The value of $(2J+1)\Gamma_{\gamma 0}$ has been estimated by combining the value of $\Gamma_{\gamma 0}$ from ref. [23]) and the branching from the present work; this value has been used for normalization.

[h]) Ref. [22]).

[i]) The value given is not $(2J+1)\Gamma_{\gamma 0}$ but the $(2J+1)\Gamma_{\gamma 0}\Gamma_\gamma/\Gamma$ value.

[j]) The value of $(2J+1)\Gamma_\gamma\Gamma_0/\Gamma$ from ref. [8]) has been used to estimate the value of $(2J+1)\Gamma_{\gamma 0}$.

[k]) Ref. [24]).

[l]) This branching is not $\Gamma_{\gamma 0}/\Gamma_\gamma$ but $\Gamma_{\gamma 0}/\Gamma$ from ref. [24]).

[m]) Ref. [8]). The energy is corrected for the Q-value given in ref. [21]).

Abstract. The $^{31}P(\gamma, x\,n)$ cross section was measured from threshold up to 25 MeV, using the bremsstrahlung photon beam from the 35 MeV linac. Several analysis procedures were used to compute the photoneutron cross section from the experimental yield curve. Our results are compared with other bremsstrahlung measurements and with the quasimonoenergetic photon work by the Saclay group. The leading edge of the giant resonance shows an extremely rich fine structure which seems to be characteristic for nuclei in the $1d-2s$ shell.

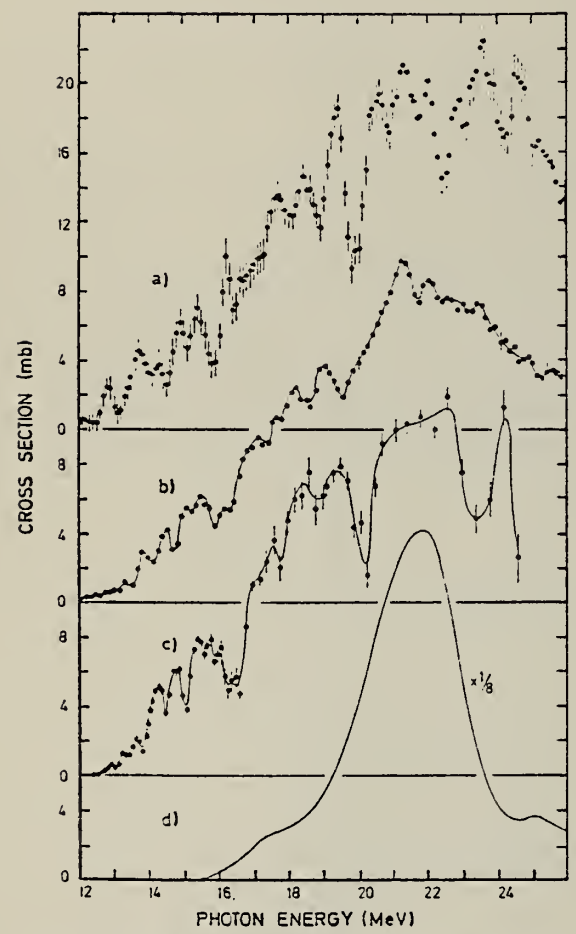

Fig. 2. Comparison of the present cross section results (c) with the data obtained by (a) Ishkhanov *et al.* [1] using bremsstrahlung, and (b) those measured by Bergère *et al.* [2] using a quasi-monoenergetic gamma-ray beam. At the bottom (d) we have plotted the total gamma absorption cross section for ^{32}S, as calculated by Wong *et al.* [14]

The yields of the $(\gamma,2p)$ reaction on ^{30}Si and of the $(\gamma,2p)$, $(\gamma,2pn)$, $(\gamma,3p)$ and $(\gamma,3pn)$ reactions on ^{31}P have been measured as a function of the maximum bremsstrahlung energy in the range 75–640 MeV. The cross sections have been deduced and are compared to Monte-Carlo calculations. The magnitude of the cross sections in the energy range above the threshold for the photoproduction of mesons is also discussed using a simple analytical approach.

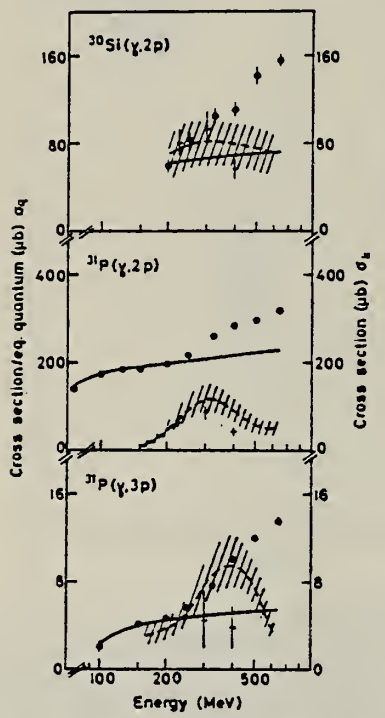

Fig. 1. The filled circles show measured yields as a function of the maximum bremsstrahlung energy. The meaning of the solid lines, the hatched areas and the plus signs is given in the text

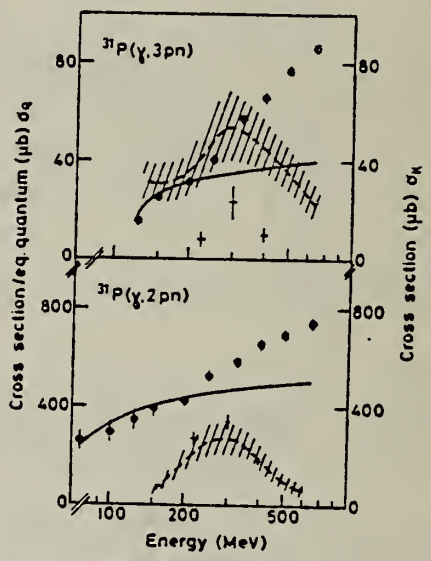

Fig. 2. The same as in Figure 1

Photonuclear reactions in the targets ^{27}Al, ^{28}Si, ^{31}P, ^{32}S, and ^{40}Ca have been studied for maximum bremsstrahlung energies of 2, 2.4, 3, and 4.5 GeV. The yields of the residual nuclei ^{7}Be, ^{11}C, ^{13}N, ^{18}F, ^{22}Na, and ^{24}Na were measured by means of a germanium-lithium semiconductor detector with a sensitive volume of 30 cm^3. In discussion of the results we took into account the contribution of the low energy part of the bremsstrahlung spectrum. Comparison of the measured yields with estimates calculated by Rudstam's formula permitted us to conclude that there is a difference in the mechanism of formation of the light fragments ^{7}Be, ^{11}C, and ^{13}N from that of the other residual nuclei ^{18}F, ^{22}Na, and ^{24}Na.

POLARIZED PROTONS

Measurements of cross sections and analyzing powers are examined for polarized proton capture on ^{14}C, ^{30}Si, ^{54}Fe, ^{56}Fe, ^{58}Fe, ^{59}Co, and ^{88}Sr at energies which cover the giant dipole resonance region. These data are used to extract the relative amplitudes and phases of the contributing $E1$ T-matrix elements. A typical result exhibits two solutions. Calculations using the direct (or a direct-semidirect) capture model appear to provide a means for choosing the physical solution.

[NUCLEAR REACTIONS: $^{14}C(\vec{p},\gamma_0)$, $^{30}Si(\vec{p},\gamma_0)$, $^{54}Fe(\vec{p},\gamma_0)$, $^{56}Fe(\vec{p},\gamma_0)$, $^{58}Fe(\vec{p},\gamma_0)$, $^{59}Co(\vec{p},\gamma_0)$, $^{88}Sr(\vec{p},\gamma_0)$; measured $\sigma(\theta)$ and $A(\theta)$ over energy region of the giant dipole resonance. Deduced T-matrix amplitudes and phases. Compare results to direct-semidirect model calculations.]

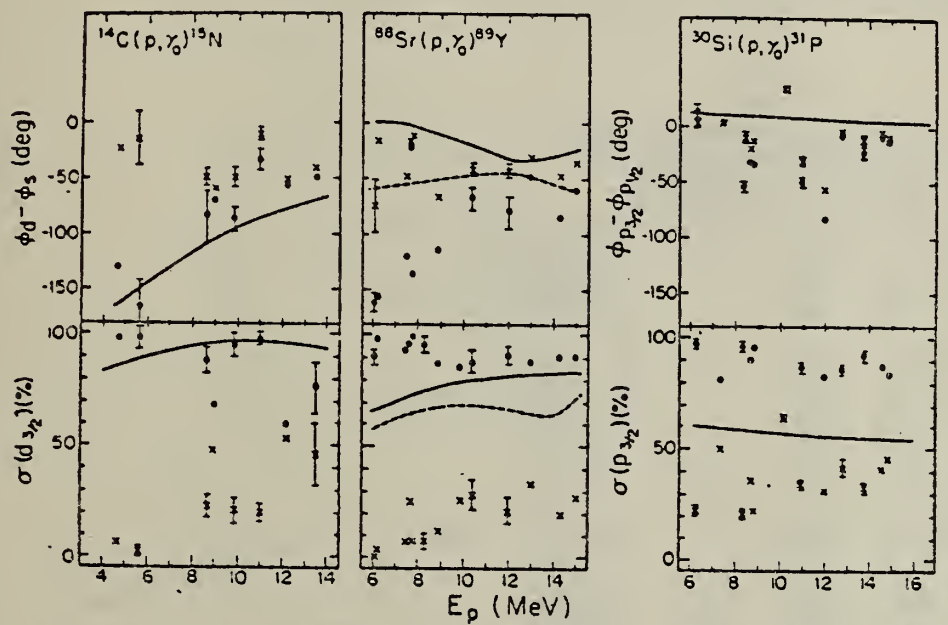

FIG. 1. The two solutions (dots and x's) resulting from a pure $E1$ analysis of the data are shown along with the results of the calculation for target nuclei of ^{14}C, ^{88}Sr, and ^{30}Si. The remaining cross section in the case of ^{14}C and ^{88}Sr is due to the $s_{1/2}$ matrix element. In the case of ^{30}Si it arises from the $p_{3/2}$ matrix element. The error bars represent typical statistical errors associated with the data points. The amplitudes are presented in terms of the percentage of the total cross section for which they are responsible. The curves represent DSD calculations as described in the text. The dashed curves in the case of ^{88}Sr were obtained using the optical model parameters of Ref. 16 while the solid lines were obtained from the parameters of Ref. 18.

Abstract: The absolute resonance strengths of the $^{28-30}$Si(p, γ)$^{29-31}$P reactions have been studied. New values for the frequently used standard resonances at E_p = 370, 416 and 620 keV in the above reactions, respectively, have been determined. In addition, the strengths of the ^{28}Si(p, γ)^{29}P resonances at E_p = 1381, 1652 and 2088 keV and of the four dominant ^{30}Si(p, γ)^{31}P resonances at E_p = 499, 777, 942 and 983 keV have been determined. The branching ratios and angular distributions of the γ-rays used in the determinations were obtained in the same experimental set-up as the strength measurements. Using these revised resonance strengths, the astrophysical reaction rates of hydrogen burning of ^{29,30}Si in explosive carbon burning have been deduced. The reaction rates found for hydrogen burning of $^{28-30}$Si in the stellar temperature region of $T = (0.3–10) \times 10^9$ K are compared with Hauser-Feshbach calculations.

STELLAR REACTION RATE

E NUCLEAR REACTIONS ^{28}Si(p, γ), E = 0.37, 1.38, 1.65, 2.09 MeV; ^{29}Si(p, γ), MeV, ^{30}Si(p, γ), E = 0.50, 0.62, 0.78, 0.94, 0.98 MeV; measured $\sigma(E_p)$, $I_\gamma(\theta)$. ^{29,30,31}P resonances deduced γ-branchings, resonance strengths. Ge(Li) detector. Natural and enriched targets.

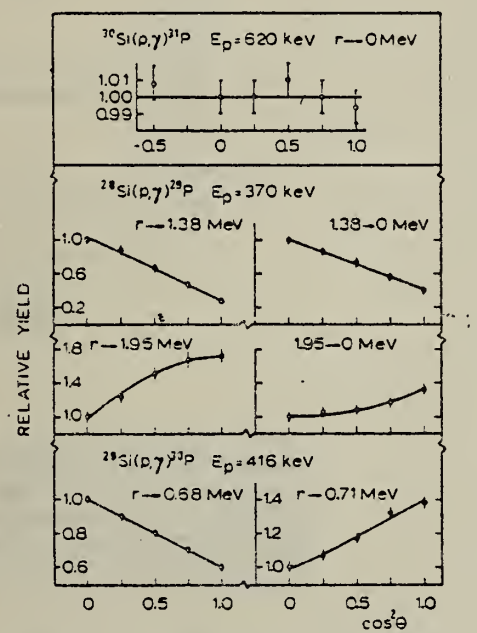

Fig. 1. The results of angular distribution measurements of the standard resonances at E_p = 370, 416 and 620 keV in the $^{28-30}$Si(p, γ)$^{29-31}$P reactions. In the case of the E_p = 620 keV resonance, the experimental points are shown without eccentricity or absorption corrections. In other cases these corrections have been made. The solid lines are the fitted curves of the form $W(\theta) = 1 + a_2 P_2(\cos\theta) + a_4 P_4(\cos\theta)$.

(over)

TABLE I. The A_0, a_k and b_k coefficients obtained from least squares fits to the $^{30}Si(p,\gamma_0)$ data with Eqs. (1) and (2), respectively. The b_k coefficients are given below the a_k coefficients at each energy. Also given in the two right-hand columns are the χ^2 values obtained when the data were fitted directly to the T-matrix element amplitudes and relative phases as described in the text. The errors given for the A_0 values are statistical.

[a] Set I, see text.

[b] Set II, see text.

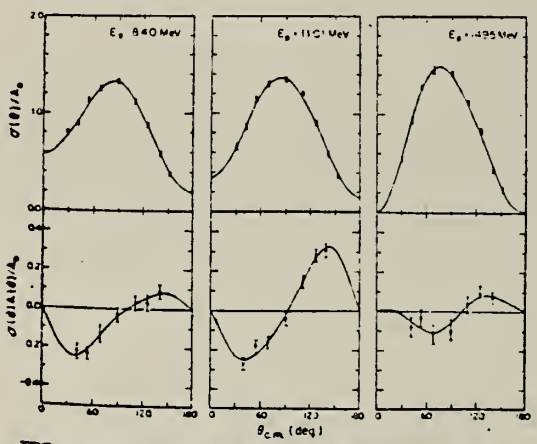

FIG. 4. Typical cross section and analyzing power angular distribution for $^{30}Si(p,\gamma_0)^{31}P$. The errors are statistical. The solid lines are fits through fourth order in Legendre and associated Legendre polynomials.

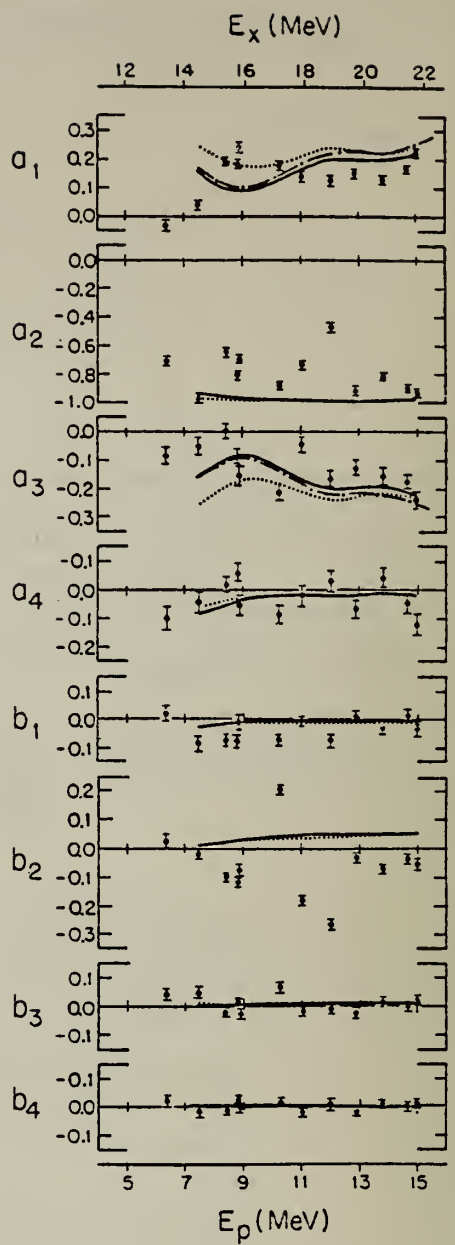

FIG. 9. The a_k and b_k coefficients for the $^{30}Si(p,\gamma_0)^{31}P$ reaction. As discussed in the text, the curves are the results of DSD model calculations with the following conditions: dotted curves—complex dipole form factor, solid curves—real dipole form factor, and dot-dashed curvee—real dipole form factor with semidirect isoscalar quadrupole form factor set to zero.

DEFINITIONS OF ABBREVIATIONS AND SYMBOLS

Note: In this list definitions are given for various photoneutron reactions in which the following symbols are used: N, NL, nN, SN and XN. Corresponding definitions apply for reactions involving other nuclear particles where the symbols N (neutron) is replaced by, e.g. P, D, T, HE, A etc. Where unknown reactions result in the production of a specific radionuclide, the chemical symbol and mass number is listed as the reaction product, e.g. a G,NA22 reaction in ^{59}Co.

A	alpha particle
ANAL	analysis
ABI	absolute integrated cross-section data
ABX	absolute cross-section data
ABY	absolute yield data. Often means cross-section per equivalent quantum is listed.
ACT	measurement of induced radioactivity of the target
ASM	asymmetric, asymmetry
AVG	average
BBL	bubble chamber
BEL B(EL)	reduced electric radiative transition probability
BF3	BF_3 neutron counter with moderator e.g., Halpern detector, long counter
BML	reduced magnetic radiative transition probability, B(ML)
BREAKS	levels located by "breaks" in the yield curve
BRKUP	breakup
BRMS	bremsstrahlung
BTW	between
C	continuous. Used to describe a photon source or a detector response function. Contrast with D = discrete.
CCH	cloud chamber
CF	compared with
CHRGD	charged
CMPT	Compton
COIN COINC	coincidence, coincide
COH	coherent
CK	Cerenkov
D	deuteron or discrete. When discrete, it is used to describe a photon source or a detector response function. Contrast with C = continuous.
DLTE	energy loss
DLTQ	momentum transfer
DST	distribution
DT BAL	detailed balance
E	electron
E/	inelastically scattered electron
E+	positron
EDST	energy distribution or spectrum
E/N	used only to indicate a coincidence experiment as in (E,E/N).

	N stands for any outgoing particle measured in coincidence with an inelastically scattered electron. Distinguish from eg., (E,N) which is used to represent an electron induced reaction when only the outgoing particle N is detected.
EMU	emulsions (photographic plates)
EXCIT	excited
F	fission
FMF	form factor
FM-1	inverse femtometers
FRAG	fragment
G	photon
G/	inelastically scattered photon
G-WIDTH	gamma-ray transition width
HAD	hadrons, hadron production
HE He3	^{3}He particle
INT	interaction, integral, intensity
INC	includes
ION	ionization chamber
ISOB	isobaric
ISM	isomer
J	multiplicity of particle defined by following symbol e.g. (G,PJN) with remark J = 2,3,5,7
JPI J-PI	spin and parity of a nuclear state
K	second multiplicity index, e.g. (G,JPKN) with both J & K positive integers greater than 1
KE	kinetic energy
L	may be an integer or zero that always follows a reaction product symbol. This is used to indicate transitions to specific states in the residual nuclide. When the letter is used as in (G,NL) the cross section given is that for the sum of transitions to two or more specific final states.
LFT	excited state lifetime
LIM	limit
LV,LVS	level, levels
LQD	liquid
MAG	magnetic spectrometer
MEAS	measurement(s)
MGC	magnetic Compton spectrometer
MGP	magnetic pair spectrometer
MOD	moderated neutron detector not employing a BF_3 counter, e.g. rhodium foil, Szilard-Chalmers reaction, ^{3}He, ^{6}Li reactions, GD loaded liquid scintillator, etc.
MSP	mass spectrometer
MULT	multiple, multipole, multiplicity
MU-T	used only in combination with G to indicate a total photon absorption cross section measurement, i.e. (G,MU-T)
N	neutron (see also XN and SN). The notation (G,N) is used to indicate a reaction in which only a single neutron is emitted, i.e. the reaction that can, in many cases, be measured by observing the radioactive decay of the residual nuclide.

nN	where n is any integer. (G,nN) indicates the sum over all reaction cross sections in which n neutrons are emitted.
NAI	NaI(Tl) spectrometer
NEUT	neutron(s)
NOX	no cross-section data
P	proton (see also XP)
PART	particle(s)
PHOT	photon(s)
PI	pion, usually written as PI+, PI-, PI0 to indicate charge
POL	polarized or polarization
Q-SQUAR	momentum transfer squared (q^2)
RCL	recoil
REL	relative
RLI	relative integrated cross-section data
RLX	relative cross-section data
RSP	reaction spectrometer
RLY	relative yield data
SCTD	scattered
SCD	semiconductor (solid state) detector
SCI	scintillator detector other than NaI, e.g., CsI, KI, organic (liquid or solid), stilbene, He
SEP	separation
SEP ISOTP	separated isotope used
SIG	SIGMA (cross section)
SN	sum of neutron producing reactions, $\sigma(\gamma,SN)=\sigma(\gamma,N) + \sigma(\gamma,NP) + \sigma(\gamma,2N) + \sigma(\gamma,3N)$ + etc.
SPC	photon or particle energy spectrum
SPK	spark chamber
SPL	spallation
STAT	statistical
SYM	symetric, symmetry
T	triton
TEL	counter telescope
THR	threshold for reaction or threshold detector, e.g., $^{29}Si(n,p)^{29}Al$.
TOF	time-of-flight detector
TRK	tracks of particles or fragments observed in solid materials (glass, mylar, etc.)
TRNS	transition
UKN UNK	unknown
VIB	vibrational
VIR PHOT	virtual photon(s)
XN	all neutrons, total neutron yield, $\sigma(\gamma,XN) = \sigma(\gamma,N) + 2\sigma(\gamma,2N) + 3\sigma(\gamma,3N) + \sigma(\gamma,NP)$ + etc.
XP	all protons, total proton yield $\sigma(\gamma,XP) = \sigma(\gamma,P) + \sigma(\gamma,NP) + 2\sigma(\gamma,2P)$ + etc.
XX XXX	reaction products defined in REMARKS
YLD	yield

PI	a 4π geometry was used or a method like radioactivity or a total absorption measurement		products was determined. The polarized particle is indicated in REMARKS.
99	energy defined in REMARKS	* or @	symbols used to indicate that the units associated with the numerals on one or both sides of the symbol in a specific column are not MeV. The units are defined in REMARKS.
S	indicates the measurement involved beams or targets that were either polarized or aligned, or that the polarization of the reaction

10. SUPPLEMENTARY NOTES

☐ Document describes a computer program; SF-185, FIPS Software Summary, is attached.

11. ABSTRACT (A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here)

These abstract sheets cover most classes of experimental photonuclear data leading to information of the electromagnetic matrix element between the ground and excited states of a given nucleus. This fifteen volume work contains nearly 7200 abstract sheets and covers 89 chemical elements from hydrogen through americium. It represents a twenty-seven year history of the study of electromagnetic interactions. The sheets are ordered by target element, target isotope, and by an assigned bibliographic reference code. Information is given on the type of measurement, excitation energies studied, source type and energies, detector type, and angular ranges covered in the measurement. For a given reference, the relevant figures and tables are mounted on a separate sheet for each nuclide studied.

12. KEY WORDS (Six to twelve entries; alphabetical order; capitalize only proper names; and separate key words by semicolons)

data-abstract sheets, elements, experimental, isotopes, nuclear physics, photonuclear reactions
