TABLE OF CONTENTS

Photonuclear Data-Abstract Sheets
1955-1982

I. Introduction

As used in connection with this collection of data-abstract sheets, the term photonuclear data is taken to mean any data leading to information on the electromagnetic matrix element between the ground state and excited states of a given nuclide. The most common types of reactions included in this compilation are: (e,e'), (γ,γ), (γ,γ'), (γ,n), (γ,p), etc. as well as ground-state particle capture reactions, e.g. (α,γ_0). Two reactions which fit the matrix element criterion are not included in the compilation because of their rather special nature. These are heavy particle Coulomb excitation and the thermal neutron capture reaction (n,γ_0). While the energy region of particular interest extends from 0 to 150 MeV, papers are indexed which report measurements in the region from 150 MeV to 4 GeV. Most of the experiments listed are concerned with the excitation energy range from 8 to 30 MeV, the region of the photonuclear giant resonance.

The hierarchical grouping of the photonuclear data-abstract sheets within the file is by: 1. Target Element, 2. Target Isotope, and 3. by the Bibliographic Reference Code assigned to the paper from which the data on the sheet were abstracted. In this file, colored pages are used to mark the beginning and end of the sheets for each chemical element. A brief historical sketch of the element is given on the divider sheet marking the start of each section; the information for this sketch was derived from references such as the Encyclopaedia Britannica. In those cases where the sheets for a given element make up a major part of a volume, colored pages are also used to delineate sections pertaining to the individual isotopes of the element. Each of the sections of the file, as delineated by two colored divider sheets, represents a 27 year history of the study of electromagnetic interactions in either a specific nuclide or a specifc element.

The data-abstract sheets are filed under the element and/or isotope in which the ground-state electromagnetic transition takes place. For example, the abstract sheet for a total neutron yield measurement for a naturally occurring copper sample would appear in the elemental section of the copper file. On the other hand, a measurement of the ^{62}Cu 9.73 minute positron activity produced in the same sample by photons with energies below the three-neutron separation energy for ^{65}Cu (28.68 MeV) would be filed with the sheets for ^{63}Cu. Similarly a measurement of the ground-state neutron capture cross section in ^{12}C would be filed under ^{13}C while the corresponding ground-state alpha-particle capture cross section would be filed under ^{16}O.

At the end of this volume there is a master list of the abbreviations that have been used in the index section of the abstract sheets. The listings are those used in the final published index, Photonuclear Data Index, 1973-1981, NBSIR 82-2543, issued in August 1982 by the U. S. Department of Commerce, National Bureau of Standards, Washington, DC 20234. In some cases two notations are entered for the same quantity. The second entry is the abbreviation that was used in one or more of the earlier published editions of the index.

NICKEL
Z=28

An alloy of nickel called packfong was used by the Chinese long before the metal was known in Europe. A heavy, reddish brown ore, often found covered with green spots or stains, was used in Germany to color glass green; the miners called the substance Kupfernickel meaning copper demon. The ore resembled copper in color but yielded a brittle unfamiliar product that caused the copper miners considerable trouble.

Axel Fredrik Cronstedt was the first to discover nickel; he worked as a metallurgist in the Swedish Bureau of Mines. In 1751 Cronstedt was investigating a new mineral from the cobolt mines and placed a piece of iron in an acid solution of the ore expecting to see a copper deposit on it. To his great surprise, he was unable to secure a deposit of and kind—— the ore nicolite contained no copper. Futher work yielded the metal. After studying the physical, chemical and magnetic properties of the metal, he announced in the Memoirs of the Stockholm Academy that he had discovered a new metal.

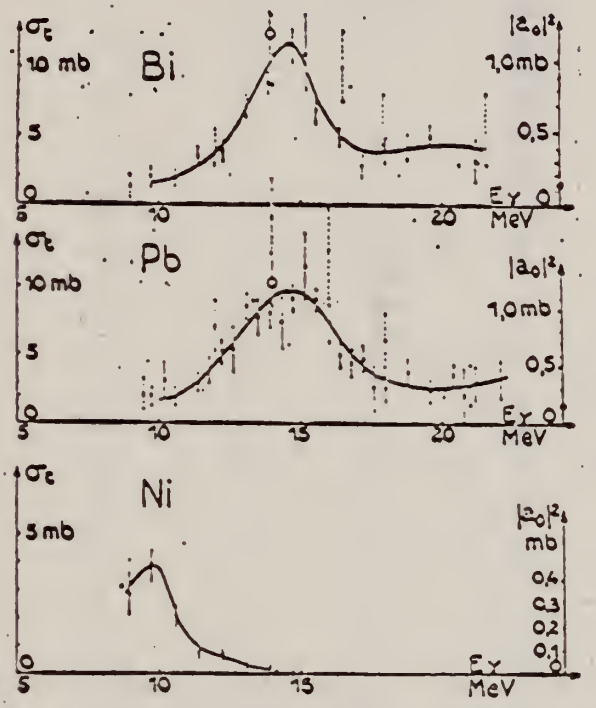

FIG. 8. — Section efficace totale de diffusion élastique et module au carré de l'amplitude de diffusion vers l'avant. Cas de Ni, Pb et Bi.

Cercles vides : module au carré des amplitudes de diffusion absorptive calculées à partir des sections efficaces $\sigma(\gamma, n) + 2\sigma(\gamma, 2n) + \sigma(\gamma, np) + \ldots$ (seule la première réaction intervient vers 14 MeV).

Cercles pleins : limites $(Ze^2/Mc^2)^2$ de la section efficace de diffusion à haute énergie. En réalité, à cause des interactions mésoniques des nucléons et de l'incertitude sur la limite à haute énergie de la diffusion, il vaudrait mieux parler de la section efficace de diffusion vers l'avant au delà de la résonance géante et avant le seuil photomésonique ; on peut montrer que l'expression

$$(Ze^2/Mc^2)^2 (1 + 0{,}8x)^2$$

où x est la fraction de force d'échange entre nucléons, est mieux appropriée.

En pointillés : résultats de Fuller et Hayward.

[a] A large error could be introduced in the cross-section values because of large differences in line intensities quoted by Bartholomew and Higgs and by Groshev *et al.* (Ref. 6).
[b] Because of the low counting rate, thick scatterers were used, which will introduce a systematic error in estimating $(\sigma_{\gamma\gamma})$ for resonances having a high nuclear cross section.
[c] The cross section was evaluated assuming the gamma intensity to be 0.02 photons per 100 captured neutrons (see text).
[d] Reference 6 gives the 7.639 line of iron capture gamma rays as a single line. However, a recent paper by Fieoiger, Kand, and Segel [Phys. Rev. 125, 2031 (1962)] reports two different lines of equal intensities having energies of 7.647 and 7.633 MeV. The present experiment cannot resolve an energy difference of 14 keV, therefore, there is no possibility of deciding which line is responsible for the scattering.

[a] High-energy component of a complex spectrum.
[b] A broad scattered spectrum with no observable peak structure.
[c] There are actually two lines of energies 7.647 and 7.633 MeV having equal intensities in the iron capture gamma spectrum. The cross section has therefore been corrected, although there is no possibility at present of deciding which line is responsible for each resonance.
[d] Is probably an independent level in the complex spectrum of Ni γ rays on Te.
[e] Rough estimate.
[f] May be inelastic component from 7.528 level in Te.
[g] The relative line intensities in this case are due to Groshev and co-workers.
[h] No line is known for the source at this energy.
[i] Difficult to resolve among the many source lines present at this energy.

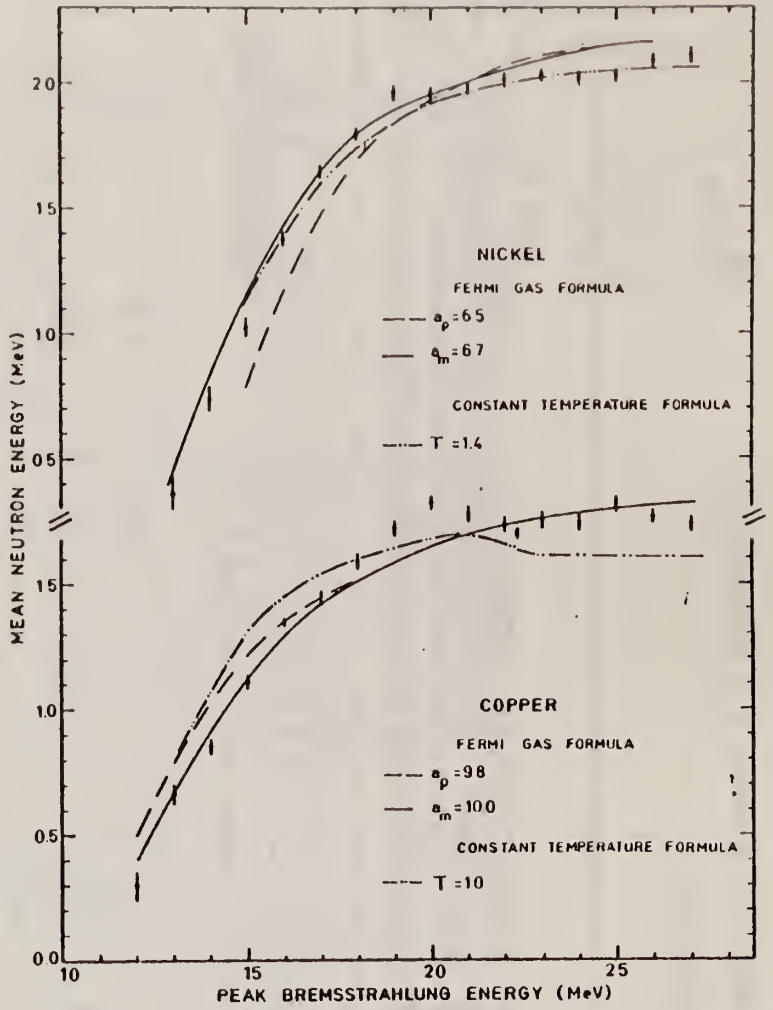

Fig. 6. Same as fig. 5, for nickel and copper.

[a]) Neutron numbers and abundances of respective residual nuclei in (γ, n) experiments.

[b]) These give an assessment of the goodness of fit of a calculated $\hat{E}_n$ versus E_0 curve to the observed data, using the Fermi gas level density formula both without and with pairing corrections.

[c]) Bremsstrahlung photoneutron mean energies $\hat{E}_n$ for peak bremsstrahlung energy $E_0 = 24$ MeV.

[d]) Nuclear temperature from fit with constant-temperature formula.

[e]) Level density parameter a_p derived from the present (γ, n) experiment, using a Fermi gas formula plus pairing correction, and corresponding residual nucleus (the atomic weight shown is the weighted average of atomic weights of the respective isotopes present).

[f]) As column 7, but using data on n-resonance absorption from refs. [1,2]).

[g]) Measurements of $\hat{E}_n(E_0)$ for these nuclei were made only for $E_0 = 21$, 23 and 24 MeV.

See further analysis of this data in reference 79Zil

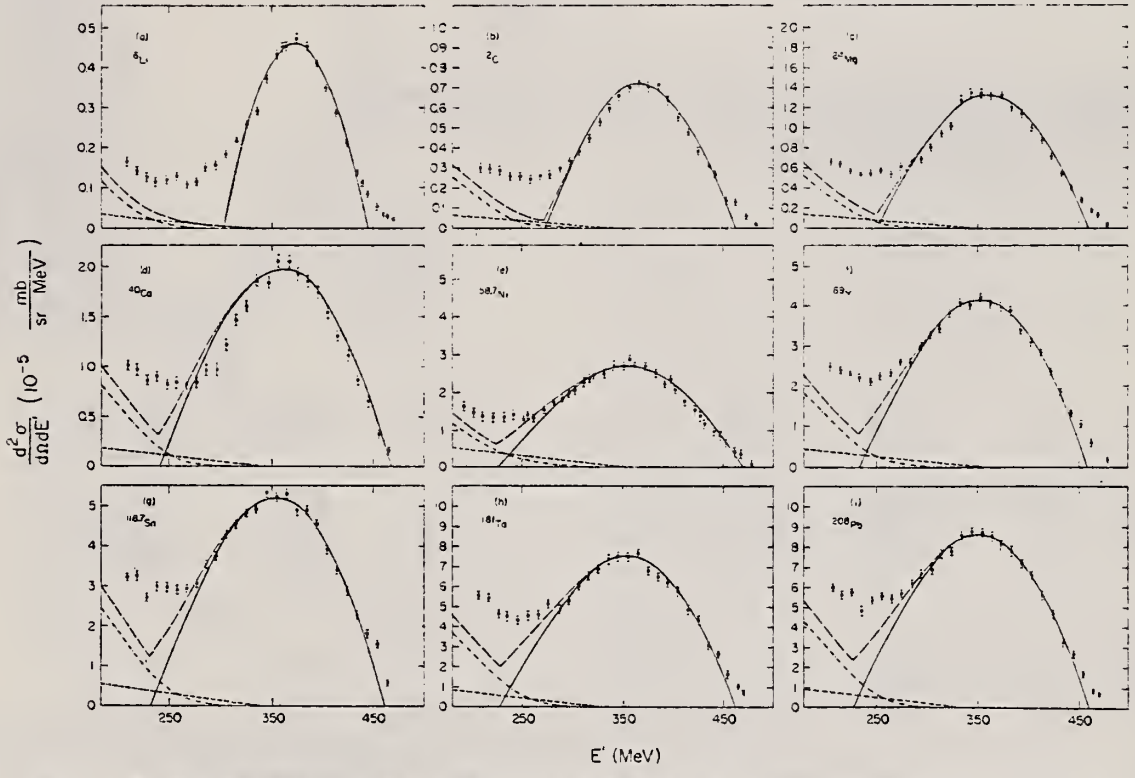

FIG. 1. The measured quasielastic peaks; the errors on the data points do not include an over-all 3% normalization uncertainty. The solid curve is a fit by the Fermi-gas model which yielded k_F (in MeV/c) and $\bar{\epsilon}$ (in MeV) as follows: (a) ^{6}Li (169, 17); (b) ^{12}C (221, 25); (c) ^{24}Mg (235, 32); (d) ^{40}Ca (249, 33); (e) $^{58.7}$Ni (260, 36); (f) ^{89}Y (254, 39); (g) $^{118.7}$Sm (260, 42); (h) ^{181}Ta (265, 42); (i) ^{208}Pb (265, 44). The fitting uncertainty in k_F is ±5 MeV/c and in $\bar{\epsilon}$ it is ±3 MeV. The small-amplitude dashed curve is the s-wave π-production contribution, the dot-dashed curve is the isobar excitation, and the large-amplitude dashed curve is the total result.

Inelastic electron scattering has been used to measure the total hadronic cross sections for absorption of photons with energy 150–500 MeV by nuclei of C, Al, Ni, Mo, and W. The results obtained are compared with calculations carried out in the impulse approximation.

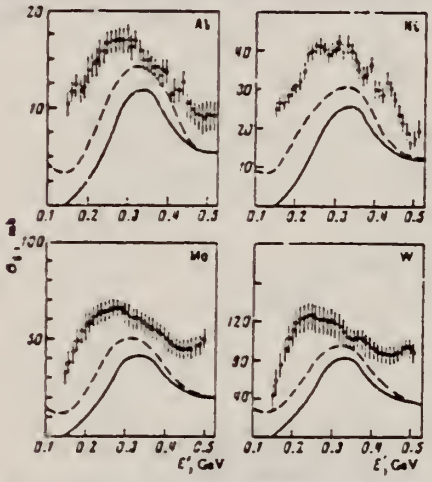

FIG. 5. Total hadronic cross sections for absorption of photons by nuclei.

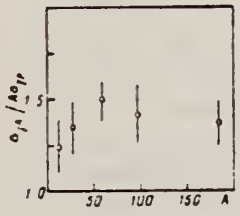

FIG. 6. The ratio $\sigma_{\gamma A}/A\sigma_{\gamma p}$ as a function of A for $k = 0.32$ GeV.

This paper presents energy spectra of α particles emitted following the bombardment of ^{27}Al, ^{nat}Ni, ^{92}Mo, ^{94}Mo, and ^{197}Au with 120-MeV electrons, together with α-particle angular distributions from ^{197}Au and ^{nat}Ni for E_α = 30 and 50 MeV. The data are compared with preequilibrium exciton-model and statistical-model calculations. It is concluded that few-step processes are dominant in the production of α particles with energies above 20 MeV.

PREEQUILIB A EMISS

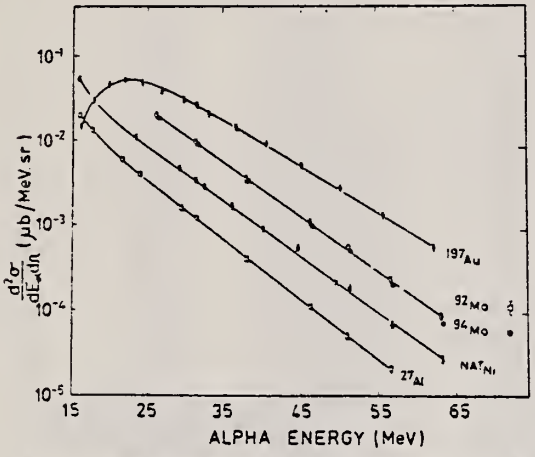

FIG. 1. α-particle energy spectra at θ_α = 30°, for E_e = 120 MeV. Errors shown are the sum of statistical and systematic contributions. The solid lines are a guide to the eye.

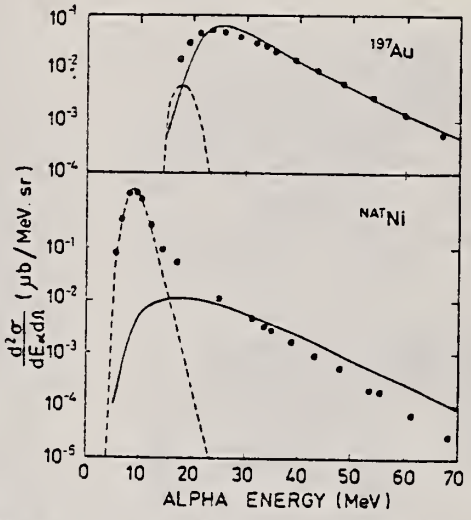

FIG. 2. α-particle energy spectra at θ_α = 30°, for E_e = 120 MeV. The solid circles are experimental points. The solid lines are the results of preequilibrium exciton-model calculations and the dashed lines are the results of statistical calculations neglecting photon absorption above E_γ = 33 MeV.

TABLE I. Temperatures corresponding to the preequilibrium component of the (e,α) reaction, derived from energy spectra at θ_α = 30° for E_e = 120 MeV.

Target	Temperature[a] (MeV)
^{27}Al	5.3
^{nat}Ni	5.5
^{68}Zn	5.4
^{92}Mo	5.6
^{94}Mo	5.4
^{197}Au	6.1

[a] Error is ± 0.2 MeV.

Abstract. New data on electron- and bremsstrahlung-induced 8 MeV α-particle emission from Ni are shown to be consistent with statistical decay of the excited nucleus. This result is in marked disagreement with a recent analysis of a similar experiment but in good agreement with (α, α'x) coincidence experiments.

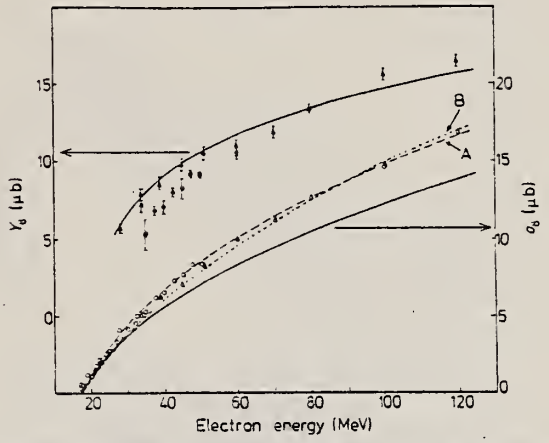

Figure 1. Excitation functions for electron- (open symbols) and bremsstrahlung- (closed symbols) induced yields of 7·5–8·5 MeV α particles from natural nickel. Statistical uncertainties are shown or are smaller than the size of the symbols; the systematic uncertainties are ⩽7%. The triangles show the present data and the circles represent the equivalent data derived from the results of Wolynec *et al* (1979) normalised to the present radiator thickness of 0·169 g cm^{-2}. The full curves result from folding the bremsstrahlung and E1 virtual photon spectra with the (γ, x) cross section of figure 2. The broken curve A is the result of multiplying the E1-only calculation by a factor of 1·2, while the broken curve B is the result of including a 10% EWSR E2 contribution.

[illegible] OF THE VIBRATIONAL SPLITTING OF THE GIANT DIPOLE RESONANCE

D.G. [illegible], E.G. Muirhead and B.M. Spicer, School of Physics, University of Melbourne, Parkville, Victoria 3052, Australia.

The photoneutron yield curves for ^{58}Ni and ^{60}Ni have been measured in 1/4 MeV steps from threshold to 24 MeV, the neutrons being detected in a Halpern-type BF_3 counter system. The cross sections were obtained from the yield curves by the Leiss-Penfold matrix inversion method. A correction, based on the statistical theory of nuclear reactions, has been made for multiple neutron emission. The derived cross sections are shown in figures 1 and 2.

The dotted curves on the figures are the fits to the dipole spectrum, using Lorentz line shapes, and based on the dynamic collective model of the giant resonance (Huber, priv. comm. 1967), in which quadrupole surface vibrations are coupled to the dipole vibration. The poor fit at low energies is attributed to neglect of single particle effects.

Also shown in figure 1 is the result of the collective correlations calculation for ^{60}Ni (Seaborg, Drechsel, Arenhovel and Greiner, Phys. Lett. 23 (1966) 576). Here the surface vibrations are coupled to particle-hole dipole states, not just the dipole state. This calculation for the closed-subshell nucleus ^{60}Ni yields the result shown in the full curve of figure 1. The agreement with experiment is very much improved, indicating the importance of including single particle effects.

The similarity of low energy spectra for ^{58}Ni and ^{60}Ni, coupled with the fact that the same single particle states are filled in the ground state, leads to the expectation that the giant resonance structure will be similar for the two isotopes. This is in fact observed.

We measured the photoproton cross sections for the nuclei Cr^{52}, Ni^{58}, and Ni^{60} from the threshold to 30 MeV. We registered protons with energy larger than 1 MeV. A number of maxima were obtained in the cross sections. The values of the integral cross sections for Cr^{52}, Ni^{58}, and Ni^{60} are equal respectively to 240, 570, and 320 MeV-mb. The anomalously large cross section for the production of photoprotons for Ni^{58}, and also the shift of the centers of gravity of the photoproton cross sections towards higher excitation energies relative to the photoneutron cross sections in the case of Cr^{52} and Ni^{60}, can be attributed to the influence of analog states.

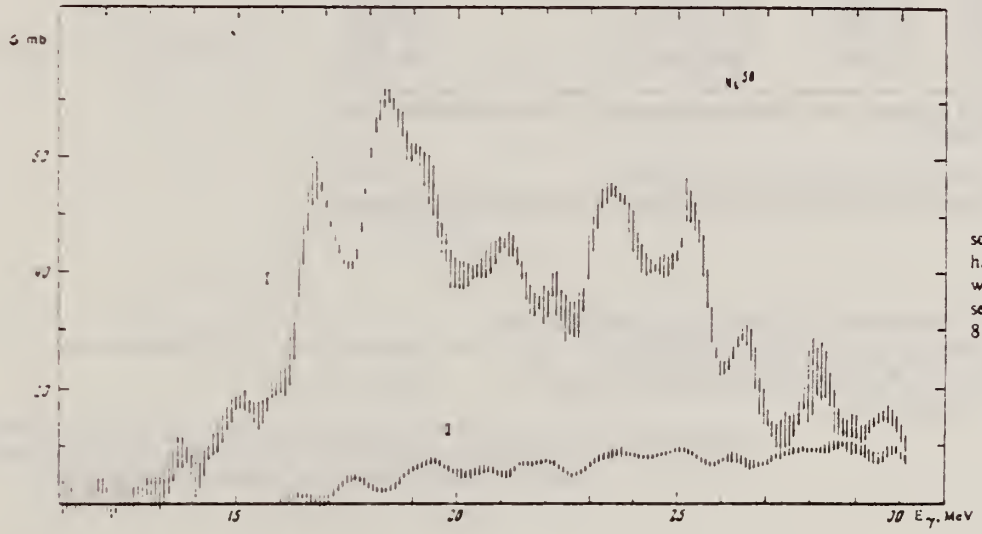

FIG. 2. Photoproton cross sections for Ni^{58}. Cross section I has been obtained for protons with $E_p \geq 1$ MeV and the cross section II for protons with $E_p \geq 8$ MeV.

The photoneutron cross section for ^{58}Ni is interesting both because it is anomalously small and because much structure has been observed in previous experiments.[1-4] We have measured the cross sections, with rather high resolution, for the first time with nearly monoenergetic photons from in-flight annihilation of positrons from the new Livermore electron-positron linac. The experimental method employed was similar to that used in a number of earlier experiments[5] by the Livermore group. The ^{58}Ni content of the target sample was 99.89%. The photon energy resolution varied smoothly from about 50 keV at 10 MeV to approximately 90 keV at 35 MeV.

The experimental results are shown in Fig. 1. The error bars shown are statistical only. In addition there are several sources of systematic uncertainty which could introduce an overall error of up to about 10% in the region of the giant resonance peak, and perhaps 40% at 35 MeV.

The total photoneutron cross section reaches a peak of about 25 mb in the neighborhood of 18 MeV, and exhibits considerable structure which persists well above 20 MeV. Our data are generally in good agreement with the magnitude of the peak cross sections obtained in previous experiments[2-4] but disagree on the details of the observed structure. The (γ,2n) cross section, which has been measured here for the first time, is small (generally $\lesssim$ 1 mb) and appears to vanish by about 33 MeV. The integrated total photoneutron cross section, up to 33.5 MeV, is 286 MeV-mb, while the integrated (γ,2n) cross section is 7.7 MeV-mb.

The distribution of strength in the cross section, up to 25 MeV, is in good qualitative agreement with particle-hole calculations of the E1 transition strengths;[6] however, considerable cross section appears to lie above the region of the calculated dipole strength. Comparison of our data with those of Carver and Turchinetz[1] implies that most of the high-energy cross section results from the (γ,pn) reaction.

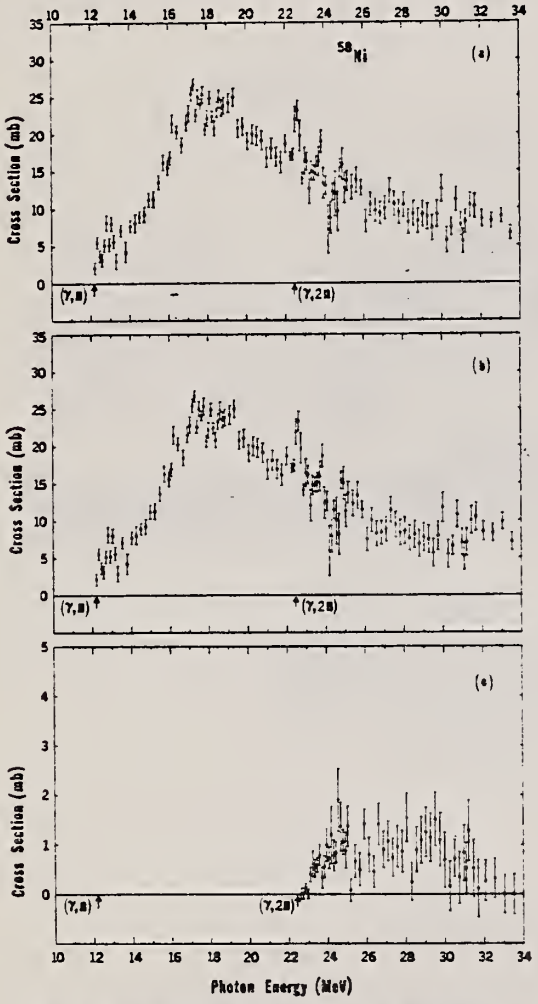

FIG. 2. Measured photoneutron cross sections for ^{58}Ni: (a) $\sigma(\gamma, Sn)$ (see Ref. 17); (b) $\sigma[(\gamma,n)+(\gamma,pn)]$; (c) $\sigma(\gamma, 2n)$.

TABLE II. Integrated photoneutron cross sections and related quantities from the data of the present experiment. The definitions used in this table are

$$\sigma_{int} \equiv \int_{E_{thr}}^{E_{\gamma\,max}} \sigma dE_\gamma, \quad \sigma_{-k} \equiv \int_{E_{thr}}^{E_{\gamma\,max}} E_\gamma^{-k} \sigma dE_\gamma,$$

where E_{thr} is the threshold energy (see Table I) and E_γ is the photon energy; the quantity (γ, Sn) is defined in Ref. 17. Errors on the integrated cross sections are dominated by the systematic errors as discussed in Sec. III of the text.

	^{58}Ni	^{60}Ni
$E_{\gamma\,max}$	33.5 MeV	33.5 MeV
$\sigma_{int}(\gamma, Sn)$	286 MeV mb	704 MeV mb
$\sigma_{int}(\gamma, 2n)$	7.65 MeV mb	72.2 MeV mb
$\sigma_{int}[(\gamma,n)+(\gamma,pn)]$ [a]	278 MeV mb	632 MeV mb
$\sigma_{int}(\gamma, 2n)/\sigma_{int}(\gamma, Sn)$	0.027	0.103
$\sigma_{-1}(\gamma, Sn)$	13.8 mb	35.6 mb
$\sigma_{-2}(\gamma, Sn)$	0.700 mb MeV^{-1}	1.90 mb MeV^{-1}
$\sigma_{int}(\gamma, Sn)/60(NZ/A)$	0.329	0.786

[a] This quantity was obtained by subtracting $\sigma_{int}(\gamma, 2n)$ from $\sigma_{int}(\gamma, Sn)$; direct integration of the single-photoneutron cross sections gave the same values to within 0.5%.

TABLE IV. Comparison of integrated total photoneutron cross sections $\sigma_{int}(\gamma, Sn)$ with those from previous experiments.

(over)

TABLE III. Energies (MeV) at which peaks appear in the (γ,Sn) cross sections of ^{58}Ni and ^{60}Ni. The energies listed are those at which peaks or shoulders exist in the cross section. Actual resonance energies might be slightly different.

Peak No.[a]	^{58}Ni	^{60}Ni
1	12.3	12.6
2	12.8	13.7
3	13.1	14.4
4	13.6	15.1
5	14.2	15.5
6	15.7	16.3
7	16.3	17.0
8	17.3	17.7
9	17.7	18.6
10	18.2	19.6
11	18.6	21.2
12	19.3	22.1
13	22.6	24.5
14	23.8	
15	24.9	
16	25.7	

[a] We have included in the tabulations only the more well-defined peaks (or shoulders). In addition there are possible broad peaks at approximately 20.7, 27.8, and 30.9 MeV in ^{58}Ni, and at 23.5, 26.1, 27.5, and 30.3 MeV in ^{60}Ni, but the data are not sufficiently detailed to make a more definitive judgment about these.

TABLE V. Integrated total photon absorption cross sections and related quantities from the combined data of the present experiment and Ref. 7. The (γ,Xp) cross sections of Ref. 7 have been used rather than those of Ref. 8 because the former extend over a wider energy range; in their mutually inclusive energy range (see Figs. 5 and 6) the integrated cross sections from the two (γ,Xp) measurements agree to within 2% for ^{58}Ni and 10% for ^{60}Ni, the values derived from the data of Ref. 8 being the larger in both cases. The total photon absorption cross section $\sigma(\gamma,\text{total})$ is assumed to be equal to $\sigma(\gamma,Sn)+\sigma(\gamma,Xp)$; that is the photon-scattering cross section is assumed to be negligible and double counting, owing to the presence of $\sigma(\gamma,pn)$ in both $\sigma(\gamma,Sn)$ and $\sigma(\gamma,Xp)$, is ignored. The latter effect is reasonably compensated for, however (see footnote a).

	^{58}Ni	^{60}Ni
$E_{\gamma\ max}$	33.5 MeV[a]	33.5 MeV[a]
$\sigma_{int}(\gamma,\text{total})$	850 MeV mb	1025 MeV mb
$\sigma_{-1}(\gamma,\text{total})$	41.3 mb	48.7 mb
$\sigma_{-2}(\gamma,\text{total})$	2.09 mb MeV^{-1}	2.62 mb MeV^{-1}
$\sigma_{int}(\gamma,\text{total})/(60NZ/A)$	0.98	1.10
$\sigma_{-1}(\gamma,\text{total})/A^{4/3}$	0.18	0.21
$\sigma_{-2}(\gamma,\text{total})/A^{5/3}$	0.002 64	0.002 86

[a] The (γ,Xp) data extend only to 30.1 MeV for ^{58}Ni and 30.5 MeV for ^{60}Ni; above these energies we have used the (γ,Sn) cross section only. Since much of the high-energy cross section probably comes from the (γ,pn) process, the error introduced is probably small and might very well compensate for the double counting of the (γ,pn) cross section below 30 MeV.

7 B.S. Ishkhanov, I.M. Kapitonov, I.M. Piskarev, V.G. Shevchenko, and O.P. Shevchenko, Yad. Fiz. 11, 485 (1970); Sov. J. Nucl. Phys. 11, 272 (1970).

8) K. Shoda, private communication; see also H. Miyase, S. Oikawa, A. Suzuki, J. Uegaki, T. Saito, M. Sugawara, and K. Shoda, in Proceedings of the International Conference on Photonuclear Reactions and Applications, Asilomar, March, 1973, ed. by B.L. Berman (Lawrence Livermore Laboratory, Livermore, 1973), p.553.

17 In our reaction notation we have essentially adopted the convention used by E.G. Fuller, H.M. Gerstenberg, H. Vander Molen, and T.C. Dunn (NBS SP-380, 1973) wherein (γ,Sn) represents the sum of all neutron-producing reactions, (γ,Xp) denotes total proton yield, etc. We use (γ,pn) to represent either the (γ,np) or (γ,pn) reaction since experimentally the two are indistinguishable.

The energy spectra of charged photopions from ^{54}Fe, ^{56}Fe, and ^{58}Ni targets irradiated with bremsstrahlung of maximum energy 500 MeV have been measured at photopion-emission angles of 30, 60, 90, 120, and 150° in the lab system over the kinetic-energy range from 15 to 80 MeV. Isotope effects are found in the π^- yields at 30, 60, and 90°. At all angles and energies, the π^+ yields are the same for all three targets within the experimental error.

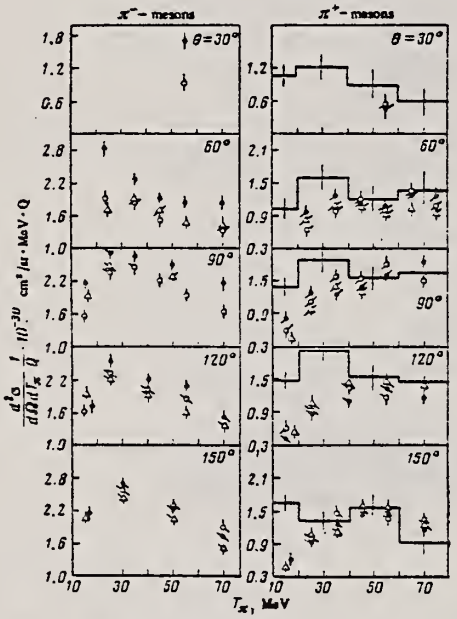

FIG. 1. Energy spectra of charged photopions from ^{54}Fe, ^{56}Fe, and ^{58}Ni targets (open circles, black circles, and triangles, respectively) at $E_0 = 500$ MeV. The error bars represent statistical errors. The histograms on the π^+-meson plots represent the results of cascade-model calculations for ^{56}Fe.

Transverse ($E6$) and longitudinal (C6) cross sections for the excitation of the $J^\pi = 6^+$, $E_x = 5.125$ MeV state in ^{58}Ni were measured by means of inelastic electron scattering. The deduced isoscalar component of the particle-hole wave function is found to be two orders of magnitude greater in amplitude than the isovector. This implies that the particle-hole isospin is relatively pure $\tau = 0$ and is not significantly mixed with $\tau = 1$.

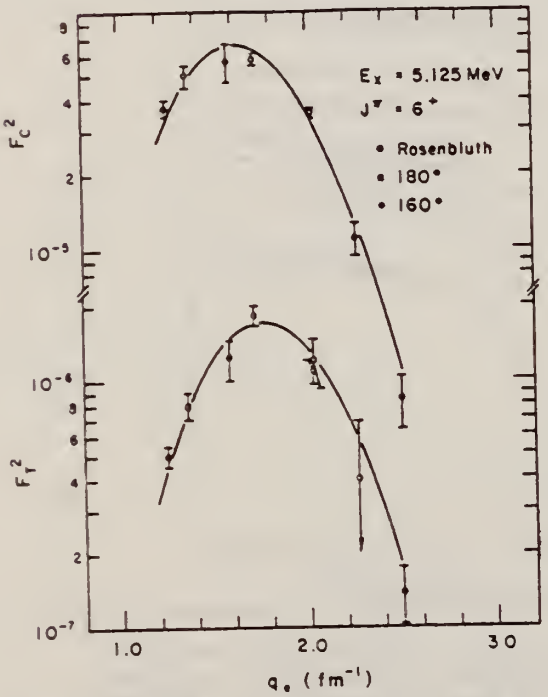

FIG. 2. The extracted transverse and longitudinal form factors compared with calculations described in text.

Analysis is made of reactions interfering with photon activation analysis procedures.

The activation yield curves have been presented for a number of photonuclear reactions in the energy range from 30 to 68 MeV, in order to evaluate quantitatively the interferences due to competing reactions in multielement photon activation analysis. The general features of the yields as functions of both target mass number and excitation energy were elucidated from the data obtained, discussion being given on the results in terms of the reaction mechanism.

Simultaneous neutron activation due to appreciable neutron production from the converter and surrounding materials has also been studied, and, finally, the magnitudes of interferences in real multielement analysis were given in the form of their energy dependences.

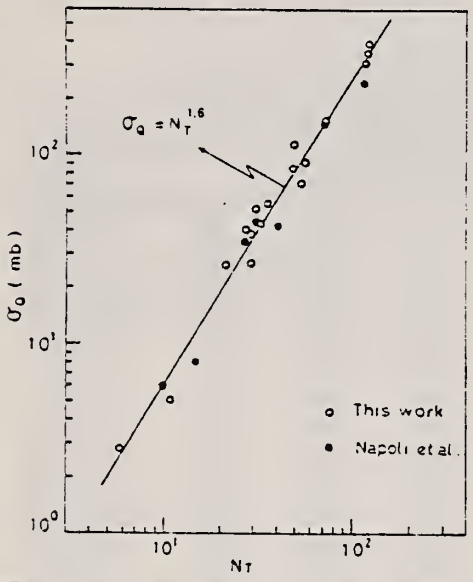

Fig. 2. Yield per equivalent quanta versus target neutron number.

The reaction $^{54}Fe(\alpha,\gamma_0)^{58}Ni$ has been studied for $7.6 \geq E_\alpha \geq 12.8$ MeV. Seventeen angular distributions have been measured in this energy region making it possible to separate the $E2$ strength from the $E1$ strength. The $E1$ cross section reaches a maximum at about the expected energy. A compact $E2$ resonance was observed which agrees quite well with the one measured by inelastic α scattering, with a peak cross section at about 16 MeV and a width of ~3 MeV(half width at half maximum). The observed $E1$ strength equals 0.9% of the isospin allowed $E1$ sum rule. The measured $E2$ strength, however, equals 4.3% of the isoscalar $E2$ sum rule, which is about the same as the fraction of the total $E1$ strength in ^{58}Ni excited by proton capture. Assuming only statistical processes and applying the Hauser-Feshbach formula to calculate the total γ absorption from the measured particle-capture cross sections leads to the conclusion that the (α,γ) reaction exciting the isoscalar giant quadrupole resonance and the (p,γ) reaction exciting the giant dipole resonance must have direct components.

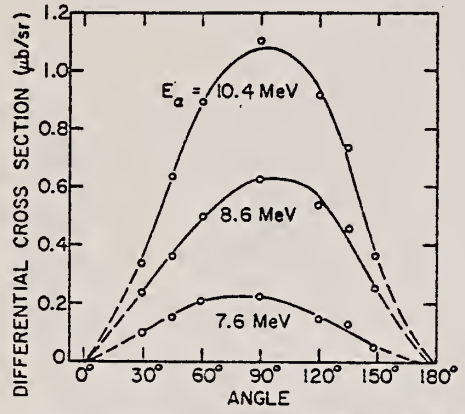

FIG. 2. Angular distributions of the $^{54}Fe(\alpha,\gamma)^{58}Ni$ reaction.

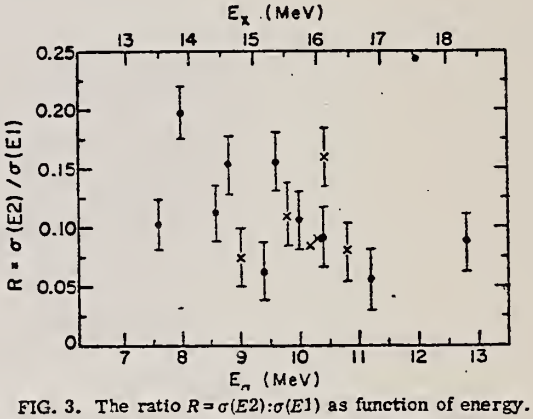

FIG. 3. The ratio $R = \sigma(E2):\sigma(E1)$ as function of energy. The estimated error is indicated. Crosses indicate angular distribution measurements with only three angles.

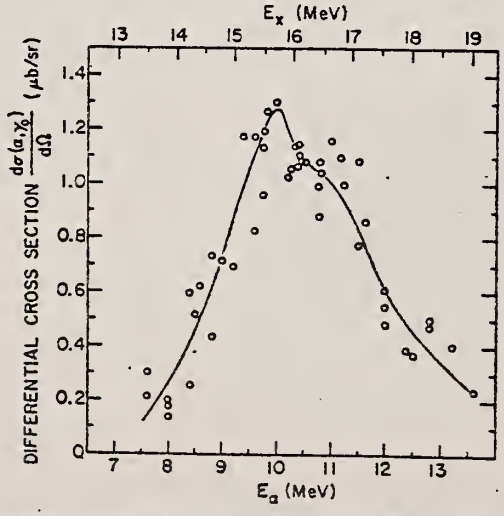

FIG. 4. Differential cross section of the $^{54}Fe(\alpha,\gamma_0)^{58}Ni$ reaction as function of energy. The measurements have been made at 90° for the incoming α beam.

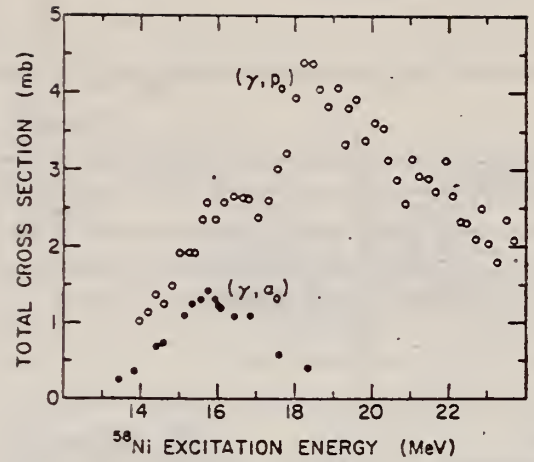

FIG. 7. The cross section of the $^{58}Ni(\gamma,\alpha_0)$ is presented as function of the excitation energy in ^{58}Ni. The small contribution of the GQR is subtracted. For comparison the cross section of the $^{58}Ni(\gamma,p_0)$ (see Ref. 6) is shown.

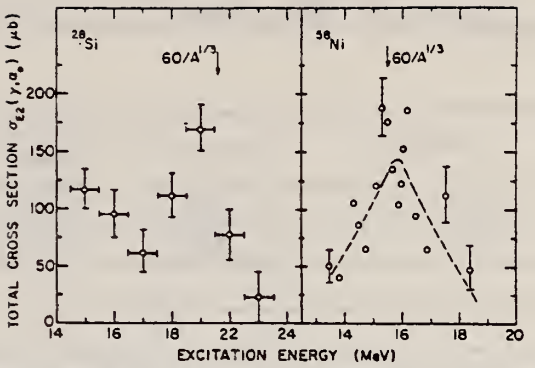

FIG. 8. The cross section of the $^{58}Ni(\gamma,\alpha_0)$ reaction exciting only the GQR is shown as function of the energy. For comparison an older measurement of the reaction $^{28}Si(\gamma,\alpha_0)^{24}Mg$ (Ref. 7) had been partially reanalyzed for a more detailed extraction of the $E2$ strength.

TABEL I. Determination of absolute cross sections of the $^{54,58}Fe(\alpha,\gamma_0)^{58,60}Ni$ reactions by using the known reactions $^{12}C(p,\gamma_0)^{13}N$ and $^{59}Co(p,\gamma_0)^{60}Ni$ for normalization (see text).

Cross sections have been measured for $Ni^{58}(e,e'p)$ and $Ni^{58}(e,e'\alpha)$ reactions. Virtual photon spectra calculated in the distorted wave Born approximation have been used to analyze the experimental results. An electric quadrupole ($E2$) giant resonance has been found which decays principally by the emission of α-particles.

The (e,p) and (e,α) cross sections for targets of ^{58}Ni, ^{60}Ni, and ^{62}Ni have been measured in the electron energy range 16–50 MeV. They have been analyzed using the distorted-wave Born-approximation $E1$ and $E2$ virtual-photon spectra. Protons are emitted primarily following $E1$ absorption but α emission results from a combination of $E1$ and $E2$ absorption. The $E2$ isoscalar giant resonance decays predominantly by α emission for these nuclei..

TABLE I. Resonance parameters for $\sigma_{\gamma,p}$.

Nucleus	E_x (MeV)	Γ (MeV)[a]	$\int_0^{30}\sigma\,dE$ (MeV mb)	SR[b] (%)
^{58}Ni	19.2 ± 0.5	6.5 ± 1.3	738 ± 40	85 ± 5
^{60}Ni	18.5 ± 0.5	9.2 ± 1.8	304 ± 20	34 ± 2
^{62}Ni	21.0 ± 0.5	5.8 ± 1.0	140 ± 10	15 ± 1

[a] Γ is the full width at half maximum.
[b] SR stands for sum rule; the $E1$ SR equals $60\,NZ/A$ MeV mb.

TABLE II. $E1$ components in the (γ,α) reaction.

Nucleus	E_x (MeV)	Γ (MeV)[a]	$\int\sigma dE$ (MeV mb)	SR[b] (%)
^{58}Ni	18.3 ± 0.5	6 ± 1	15.3 ± 1.3	1.8 ± 0.2
^{60}Ni	21.5 ± 1.0	6 ± 1	18.5 ± 1.4	2.1 ± 0.2
^{62}Ni	18.3 ± 1.0	5 ± 1	4.8 ± 0.6	0.5 ± 0.1

[a] Γ is the full width at half maximum.
[b] $E1$ SR equals $60\,NZ/A$ MeV mb.

TABLE III. $E2$ components in the (γ,α) reaction.

Nucleus	E_x (MeV)	Γ (MeV)[a]	$\int\sigma dE$ (MeV mb)	SR[b] (%)
^{58}Ni	16.5 ± 0.5	4.2 ± 1.0	10.4 ± 0.7	56 ± 4
^{60}Ni	16.0 ± 0.5	3.7 ± 0.8	6.9 ± 0.4	52 ± 3
^{62}Ni	16.8 ± 0.5	4.5 ± 1.0	5.1 ± 0.4	28 ± 2

[a] Γ in the full width at half maximum.
[b] $E2$ SR equals $0.22\,Z^2/A^{1/3}$ μb/MeV.

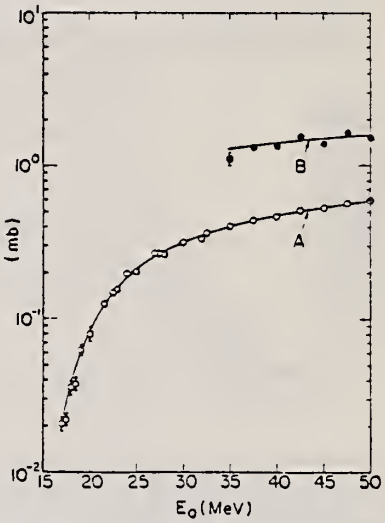

FIG. 2. The cross section for the production of protons, $\sigma_{e,p}(E_0)$, when electrons of total energy E_0 are incident on a ^{62}Ni target (open circles). The closed circles represent the yield of protons obtained when a 0.217-g/cm² Ta foil was placed in the incident electron beam. Curve A is predicted using 1.26 times the (γ,p) cross section of Ref. 6 along with the $E1$ virtual-photon spectra in Eq. (1). Curve B is obtained by taking into account the radiator thickness according to Eq. (2).

(over)

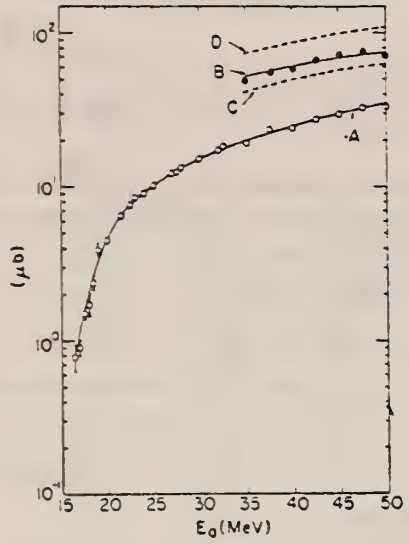

FIG. 3. The measured $\sigma_{e,\alpha}(E_0)$ (open circles) for ^{58}Ni as a function of total incident electron energy, E_0. The closed circles represent the electrodisintegration plus photodisintegration yield obtained when the 0.217-g/cm^2 tantalum foil was interposed in the incident electron beam. Curve *A* is the best fit to the data obtained by using the *E*1 and *E*2 virtual-photon spectra in Eq. (1) along with the two resonance lines whose parameters are given in Tables II and III. Curve *B* is the corresponding result with the radiator in, obtained using Eq. (2). Curve *D* was predicted using the best *E*1 fit to the data, a 22-MeV–wide resonance. Curve *C* was predicted using the best *E*2 fit to the data. This figure is intended to show that both *E*1 and *E*2 components are necessary to explain the (e, α) cross section.

New data are presented on the photodisintegration of the enriched isotopes ^{58}Ni and ^{64}Ni under bombardment by photons with maximum energy 4.5 GeV. The isotope effect in photonuclear reactions with formation of residual nuclei is investigated. The experimental yield values are compared with theoretical calculations by Rudstam's formula. In the results we observe a systematic shift of the experimental disintegration yields in comparison to the calculated values. An exponential dependence is found for the ratios of the yields of the residual nuclei from the ^{58}Ni target to the yields of the same nuclei from ^{64}Ni as a function of the third projection of the isotopic spin of the product nucleus, and an exponential dependence is found for the ratios of the experimental yield values to the theoretical values as a function of the difference of the third projections of the isotopic spins of the target nuclei and the residual nuclei.

The cross section for electron scattering from the isotopes ^{58}Ni and ^{60}Ni has been measured with electrons of 102 MeV at scattering angles of 45, 60, 75, 90, and 105° between 3 and 50 MeV excitation energy. Resonances or resonancelike structures at approximate excitation energies of (7–8) MeV, 13 MeV, (16–17) MeV, (18–19) MeV, 27 MeV, 32 MeV, and 40 MeV were classified on the basis of their momentum transfer dependence and discussed in the framework of the shell model. Difficulties in the extraction of the cross section and model dependencies of the interpretation are discussed.

BEL

[NUCLEAR REACTIONS ^{58}Ni (e,e') and ^{60}Ni (e,e'), E_0=102 MeV. Measured $d^2\sigma/d\Omega dE_x$, bound and continuum states (giant resonances). Deduced multipolarity, reduced matrix element $B(E\lambda)$, sum rule exhaustion of giant resonances, total width of continuum and clustered states.]

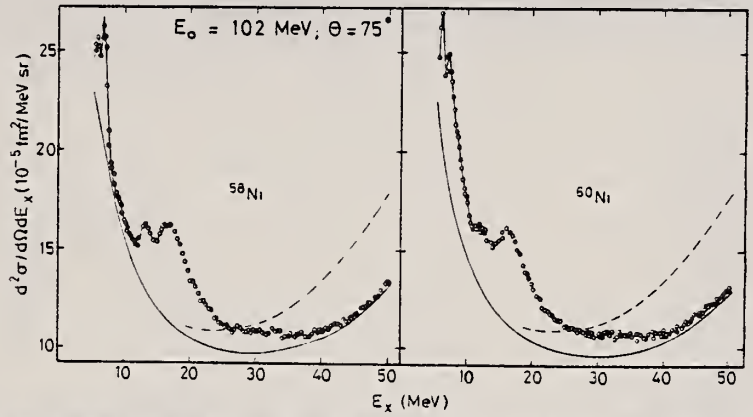

FIG. 4. Comparison of spectra of 102 MeV electrons scattered at 75° from ^{58}Ni and ^{60}Ni. The cross section for ^{60}Ni has been renormalized so that the highest and lowest points in both plots are equal. The spectra were taken with 10 points/MeV but have been reduced for graphical purposes. The broken line is the calculated radiation tail. For demonstration purposes we have subtracted the ghost peak at 8 MeV from the data for ^{58}Ni, but not for ^{60}Ni; the difference is clearly visible. Note the suppressed zero.

TABLE III. Strength of $E1$ components in the present work. The resonance parameters shown were used to approximate the $E1$ strength distribution for the χ^2 fit. As evident from Fig. 8, where mainly $E1$ contributes, the $E1$ strength function is reasonably well described. The $E1$ strength extracted from the resonances, corresponding to integration to infinity, adds up to approximately 110% of the classical $E1$ sum rule. For ease of comparison, we also give the sum rule strength found by integration from 10 to 30 MeV, 94 ± 10 and 87 ± 10% for ^{58}Ni and ^{60}Ni, respectively. The table and Fig. 8 also show that the peak strength is shifted to lower excitation energy by going from ^{58}Ni to ^{60}Ni. Although the gross shift is in agreement with the isospin coupling model[1,37] we do not think it is a sufficient basis for a claim of observed isospin splitting. The average excitation energy, weighted with the $E1$ strength function between 10 and 30 MeV, in contrast, remains virtually unchanged.

(OVER)

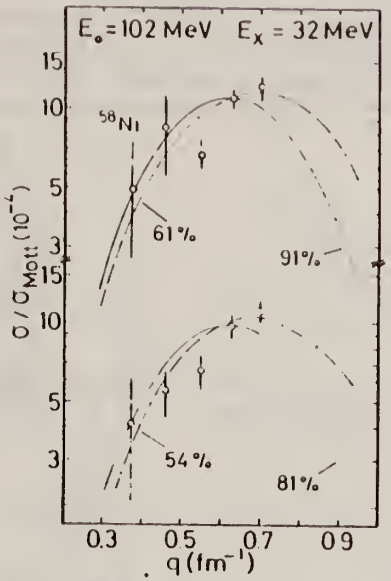

FIG. 14. Comparison between experimental and DWBA cross sections for resonance at 32 MeV. An $E2$ assignment is preferred, but other multipolarities (not taken into account) could contribute. The Goldhaber-Teller model leads to the higher strength; this strength might be regarded as an upper limit. The Myers-Swiatecki model (broken line) assumed $\alpha = 1$ (see text for definition). Extension of the Myers-Swiatecki model by Kodama to higher multipolarities gives values for α ranging from 0.12 to 0.44. Thus the sum rule values given in the figure for the MS model should be regarded as lower limits. The dependence of the experimental points on the momentum transfer suggest the possibility of more than one multipolarity contributing. This possibility was not investigated due to the accuracy limitations at this high excitation energy.

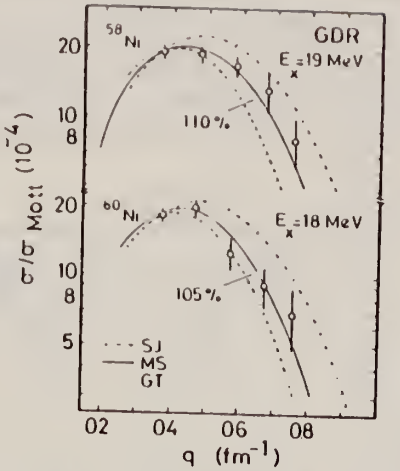

FIG. 9. Comparison between experimental and calculated cross sections for the models of Fig. 8. The curves were normalized to go through the point with the lowest momentum transfer, because this is the one with the least model dependence and the most accurate one. The Myers-Swiatecki model is somewhat favored by this comparison; however, the difficulties with the simultaneous fit of several resonances between 15 and 19 MeV, as discussed in the text, should be noted.

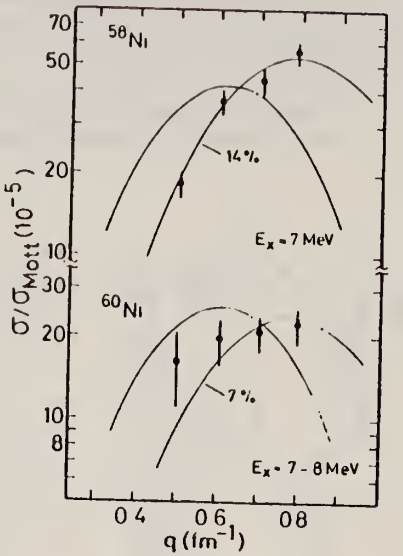

FIG. 11. Comparison of experimental cross sections for a state (group of states?) at 7 MeV in ^{58}Ni and a group of states between 7 and 8 MeV in ^{60}Ni with DWBA calculations. The ^{58}Ni data follow an $E3$ form factor quite well, but the ^{60}Ni data, which carry only half of the ^{58}Ni strength, may include an $E2$ or $E1$ contribution.

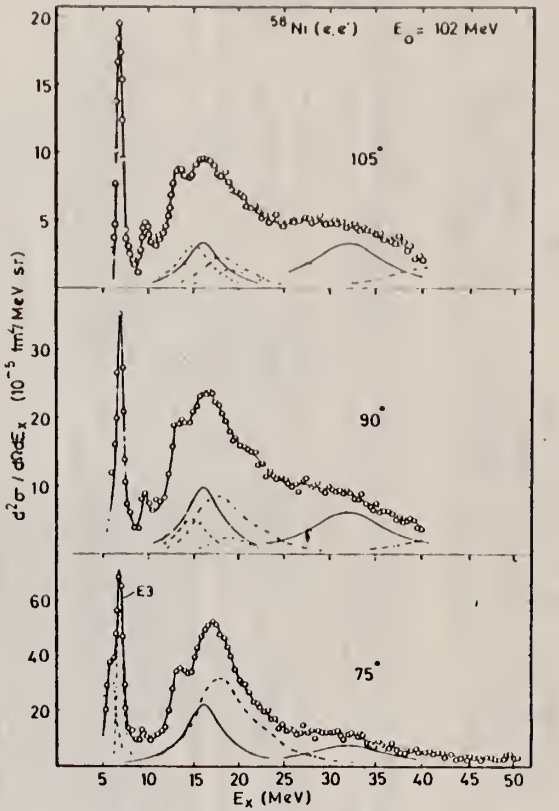

FIG. 5. Comparison of inelastic electron spectra for ^{58}Ni scattered at 75, 90, and 105°. The typical feature of higher multipolarities ($E3$ and $E4$) becoming more pronounced as compared to $E1$ and $E2$ with higher momentum transfer are most clearly visible for the $E3$ states at 7 and 13 MeV. The solid lines represent $E2$, the dotted lines $E3$, the broken lines $E4$, and the broken-dotted ones $E1$. For more details concerning assumptions about multipolarities and their possible interplay the text should be consulted. The tail of the resonance at 40 MeV (broken line) for 90 and 105° has been taken from the ^{60}Ni measurements (Fig. 6) because the ^{58}Ni data extended only to about 40 MeV.

Cross sections have been measured for the reactions ^{58,60}Ni$(e,e'p)$ and ^{58,60}Ni$(e,e'\alpha)$ in the electron-energy range 12–35 MeV. For analysis of the experimental results we used virtual photon spectra calculated in the DWBA. At energies $E\gamma = 16.0 \pm 1.0$ MeV for ^{58}Ni and $E_\gamma = 15.6 \pm 1.0$ MeV for ^{60}Ni we have observed giant electric-quadrupole resonances which decay mainly by α-particle emission. The integrated cross sections for the reactions ^{58}Ni(γ,α) and ^{60}Ni(γ,α) due to $E2$ transitions are respectively 5.4 ± 1.4 and 6.0 ± 3.0 mb-MeV, which amounts to $47 \pm 12\%$ of the total strength of isoscalar $E2$ transitions for ^{58}Ni and $56 \pm 28\%$ for ^{60}Ni. The integrated cross sections for these same reactions due to $E1$ transitions are 15.9 ± 2.3 and 16.9 ± 4.8 mb-MeV, which amount to $1.7 \pm 0.3\%$ of the value given by the sum rule for electric-dipole transitions for ^{58}Ni and $1.8 \pm 0.5\%$ for ^{60}Ni. The measured integrated cross sections for the reactions ^{58,60}Ni(γ,p) are 539 ± 33 and 300 ± 20 mb-MeV.

1. Measurement also made at 100 MeV
2. Assumptions:
   For photons: $\frac{d\sigma}{dr}(\theta)$=constant
   For alphas:
   $\frac{d\sigma}{dr}(\theta)=\sigma(90°)[A(E_0)+B(E_0)\sin^2\theta]$
   $A(E_0)$, $B(E_0)$ determined empirically

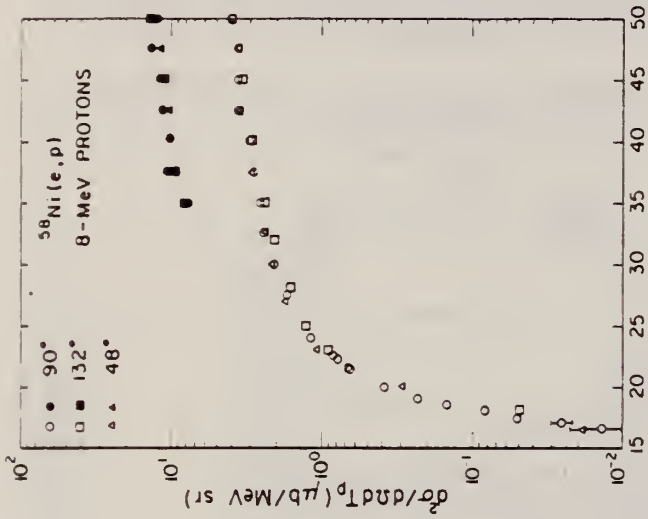

FIG. 4. The differential cross section $d^2\sigma/dT_p d\Omega$ for the production of 8 MeV protons from ^{58}Ni as a function of total incident electron energy E_0. The data were taken at three angles: 132° (squares), 90° (circles), and 48° (triangles). The upper points refer to the yields resulting from electro plus photodisintegration when a 0.217 g/cm^2 Ta foil is interposed in the electron beam.

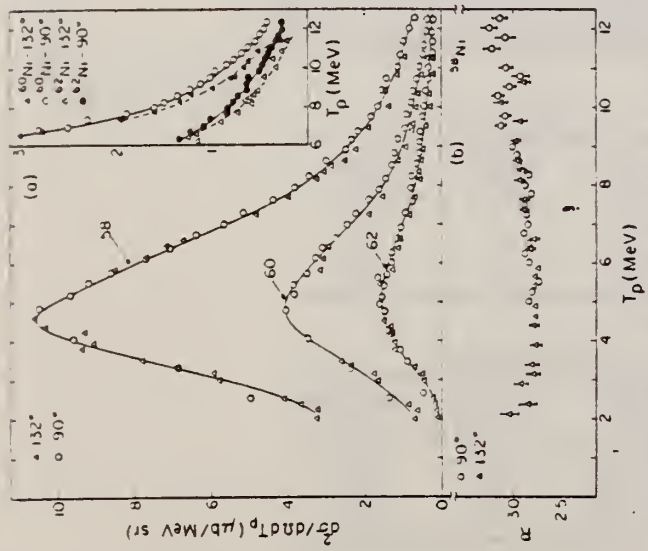

FIG. 3. (a) The proton spectra $d^2\sigma/dT_p d\Omega$ measured at 90° and 132° when 50 MeV electrons are incident on targets of ^{58}Ni, ^{60}Ni, and ^{62}Ni. The insert shows the tails of the energy spectra for ^{60}Ni and ^{62}Ni where the protons are slightly forward peaked. (b) The ratio of the number of protons produced by electro plus photodisintegration in ^{58}Ni to the number produced by electrodisintegration alone. This ratio was determined by placing a 0.217 g/cm^2 Ta radiator in the beam 7.6 cm ahead of the ^{58}Ni target.

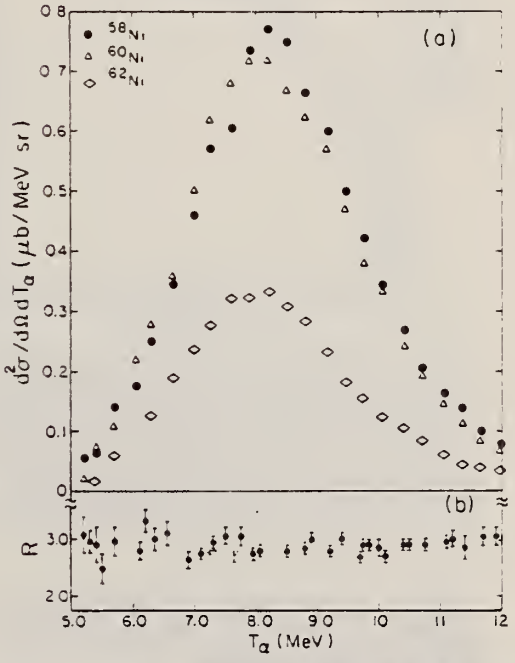

FIG. 2. (a) The α spectra $d^2\sigma/dT_\alpha d\Omega$ measured at 90° when 50 MeV electrons are incident on targets of ^{58}Ni, ^{60}Ni, and ^{62}Ni. (b) The ratio of the number of α particles produced by electro plus photodisintegration in ^{58}Ni to the number produced by electrodisintegration alone. This ratio was obtained by placing a 0.217 g/cm^2 Ta radiator in the beam ahead of the ^{58}Ni target.

(over)

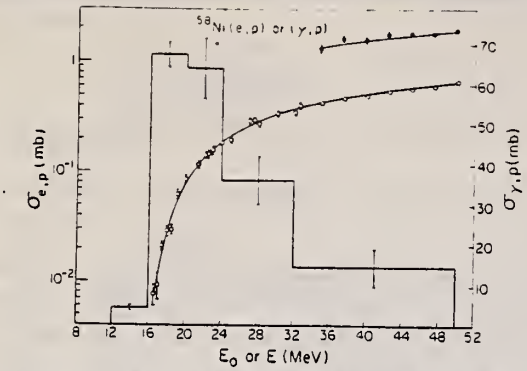

FIG. 5. The cross section (left-hand scale) for the production of protons $\sigma_{e,p}(E_0)$ when electrons of total energy E_0 are incident on a ^{58}Ni target (open circles). The closed circles represent the yield of protons obtained when a 0.217 g/cm^2 Ta foil was interposed in the incident electron beam. The latter have been corrected for the changes in geometry produced by the multiple scattering of the electrons in the radiator. The lines drawn through the points result from folding the histogram, representing the (γ,p) cross section (right-hand scale), with the $E1$ virtual photon spectrum in Eq. (1) and using the Davies-Bethe-Maximon cross section in Eq. (2).

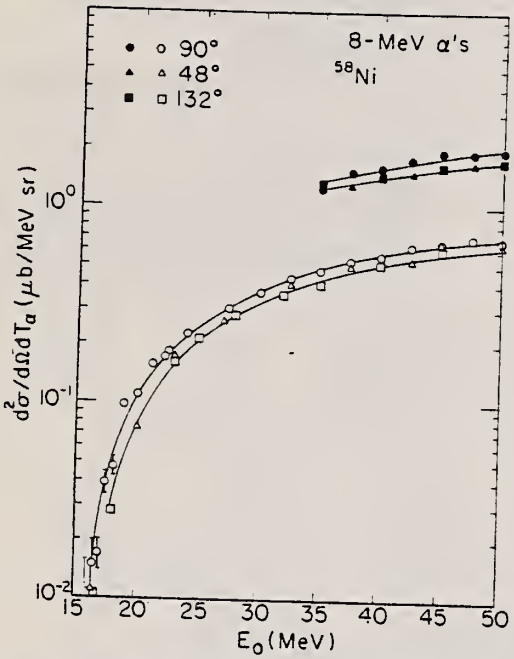

FIG. 9. The differential cross section $d^2\sigma/dT_\alpha d\Omega$ for the production of 8 MeV α particles from ^{58}Ni as a function of total incident electron energy E_0. The data were taken at three angles: 90° (circles), 48° (triangles), and 132° (squares). The upper points refer to the yields resulting from electro plus photodisintegration when a 0.217 g/cm^2 tantalum radiator was interposed in the incident electron beam. The curves drawn through the points are merely to guide the eye.

TABLE IV. Percentage of the $E1$ and $E2$ sums in the α channel. $E1$ sum: $60\,NZ/A$ MeV mb. $E2$ sum: $0.22Z^2A^{-1/3}$ μb/MeV. $E2$ bin: 14–20 MeV. Upper limits of the integrals = 50 MeV.

Nucleus	$E1$		$E2$	
	Schiff	D-B-M	Schiff	D-B-M
^{58}Ni	4.8±0.5	6.0±0.6	24±3	15±3
^{60}Ni	4.4±0.7	5.4±0.7	24±4	15±4
^{62}Ni	2.4±0.3	2.9±0.3	10±2	6±2

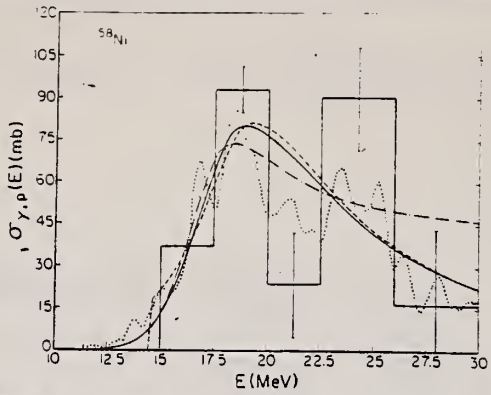

FIG. 6. Various (γ,p) cross section shapes that fit the ^{58}Ni(e,p) data when combined with the $E1$ virtual photon spectrum in Eq. (8). Here only the electrodisintegration data below 30 MeV have been used. The dotted curve represents the data of Ref. 17 multiplied by 1.22. The dashed curve is a Lorentz line having a smaller width below the resonance energy than above and truncated near 15 MeV. The solid curve has a Gaussian shape below and a Lorentz shape above the resonance energy. The dot-dashed curve is a Gaussian below the resonance energy and a Lorentz line plus a constant above. The histogram with 2.5 MeV bins roughly reproduces the structure in the measured (γ,p) cross section.

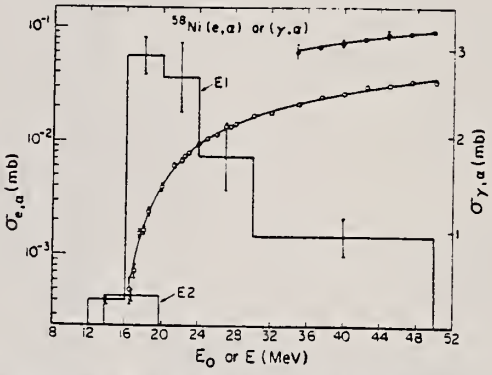

FIG. 11. The ^{58}Ni(e,α) (open circles) cross section (left-hand scale) corrected yield (closed circles) obtained with radiator in. The curves through the points result from combining the histograms, representing the $E1$ and $E2$ (γ,α) cross sections (right-hand scale), in Eqs. (1) and (2) with the $E1$ and $E2$ virtual photon spectra and making use of the Davies-Bethe-Maximon cross section.

10 LEVELS

Abstract: Nuclear resonance fluorescence measurements on ^{58}Ni with bremsstrahlung and Ge(Li) detectors were performed to search for bound state dipole excitations. Ten levels with ground state decay widths larger than 0.3 eV have been observed in the energy region between 6 and 10 MeV for which precise excitation energies, spins and lifetimes are reported. The measured transition probabilities are compared with theoretical estimates of E1 and M1 strength in ^{58}Ni. Since the ^{58}Ni(γ, γ) cross sections were determined relative to strong transitions in ^{208}Pb, the results of a separate ^{208}Pb(γ, γ) measurement are also presented.

E NUCLEAR REACTIONS ^{58}Ni(γ, γ), ^{208}Pb(γ, γ), $E < 10$ MeV; measured E_x, $\sigma(\vartheta)$; deduced lifetimes, spins. Enriched targets.

TABLE 2

Results from the ^{58}Ni(γ, γ) experiment

E_x (keV)	$\frac{I(90°)}{I(125°)}$	J	Γ_0 [a]) (eV)	τ [b]) (fs)

NI57 PROD. RATES

σ_q σ_c ratios, F values and ^{57}Ni production rates are measured with 40 and 80 MeV electron beams as a function of the Z value and thickness of bremsstrahlung converters.

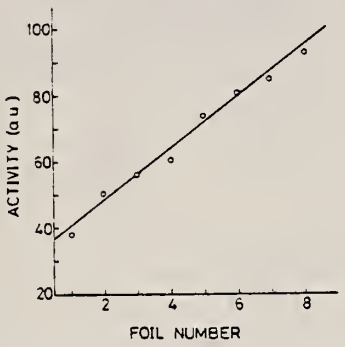

FIG. 1. ^{57}Ni activities (arbitrary units) of a stack of 8 Ni foils irradiated with 80 MeV electrons.

	σ_γ(mb)	σ_q(mb)	σ_q, σ_c
40 MeV	0.21	8.0	38
80 MeV	0.28–0.38	13.4–14.0	48–37

TABLE 1. F values for the ^{58}Ni(γ,n)^{57}Ni reaction[a]

Radiator thickness (mm)	Radiator 40 MeV			80 MeV		
	Ni	Ta	Pt	Ni	Ta	Pt
0.1			3.1			3.6
0.2		4.2	3.4		3.2	3.5
0.6	4.0			4.8		
1.0		3.4				
Mean	3.6 ± 0.2			3.8 ± 0.4		

[a] F is a measure for the ratio of activities produced by bremsstrahlung and by electrons. Its definition is given in the text.

TABLE 2. Activities (μCi) of Ni foils (0.1 mm) after 1 h irradiation using 50 μA electrons

(a) *EVA, thin converters, no deflecting magnet (f = 1)*[a]								
	40 MeV				80 MeV			
Converter (mm)	None[b]	Ni	Ta	Pt	None[b]	Ni	Ta	Pt
0.0	20				45			
0.1				20				50
0.2			40	30			80	100
0.7		50				110		
1.0			130					
(b) *EVA, standard converters*								
	Thin 15	Middle 10	Thick 1		Thin 55	Middle 45	Thick 7	
(c) *MEA (LECH-hall), thin W-converters with deflecting magnet*								
Converter (mm)		f[a]				f[a]		
0.05		4[d]	0.44		12		0.81	
0.125		6	0.24		16		0.57	
0.25		7[d]	0.14		19[d]		0.37	
0.50		9[d]	0.09		26[d]		0.25	

[a] f is the "Ausbeute Faktor".[4]
[b] No converter was used, the given activities are mainly produced by the ^{58}Ni(e,e'n)^{57}Ni reaction.
[c] Except for the thin and middle converters used at 80 MeV, the converters are thick enough to stop all the electrons.
[d] Calculated, see text.

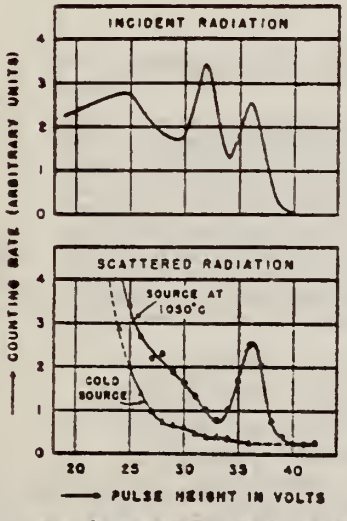

FIG. 2. Resonance fluorescence in Ni^{60}. The pulse-height distribution of the incident radiation (top) clearly shows two peaks corresponding to the 1.17-Mev and the 1.33-Mev gamma rays emitted in the decay of Co^{60}. The scattered radiation with the gaseous source consists mainly of 1.33-Mev resonance radiation, indicating that this gamma ray is the one leading to the ground state of Ni^{60}.

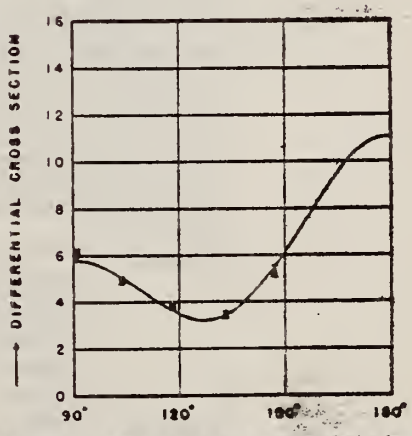

FIG. 3. Angular distribution of the resonance radiation from the 1.33-Mev level in Ni^{60}. The solid line represents the theoretical angular distribution for an excited state with spin 2 and a ground state with spin 0, corrected for the finite angular resolution. The differential cross section is given in arbitrary units.

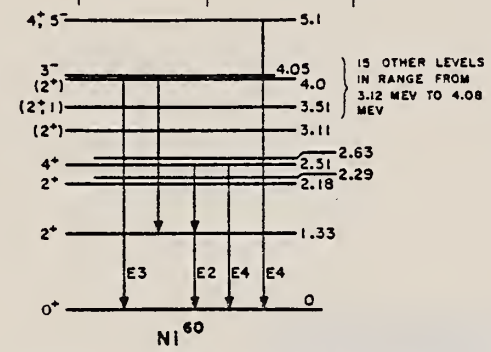

FIG. 15. Energy-level diagram for Ni^{60}. (See caption for Fig. 13.) A number of levels have been omitted from the diagram (see reference 16).

FIG. 13. In this and the following four figures are shown portions of the energy-level structures of the nuclei investigated in the present experiment. The information is, for the most part, taken from reference 15. The γ-ray transitions shown are those whose decay rates were determined directly in the present experiment or inferred from a knowledge of the γ-ray branching ratios in de-excitation of the nucleus. The spin and parity of each level are shown at the left, where known, and the energy of the excited states in Mev on the right. The best assignments of the transition multipolarities are indicated. This figure shows the energy-level structure of Ni^{58}.

Ref 15: Data on the decay schemes are taken principally from Nuclear Data Sheets, National Academy of Sciences, National Research Council (U.S. Government Printing Office, Washington, D.C., 1959)

Ref 16: Mazari et al - Phys. Rev. 107, 365 (1957).

TABLE IV. Vibrational parameters for the levels in the even-even nuclei in the present experiment: $B(E\lambda)$ is the reduced transition probability; B_λ and C_λ are the mass transport and the effective surface-tension parameters of the harmonic-oscillator approximation to the nuclear surface energy; $B_{\lambda,\mathrm{sp}}$ is the value appropriate to a hydrodynamic model; $\beta_\lambda{}^4$ is the distortion parameter of a nuclear shape of multipole order λ; and R is the nuclear radius ($R = R_0 A^{1/3}$ for $R_0 = 1.20$ f).

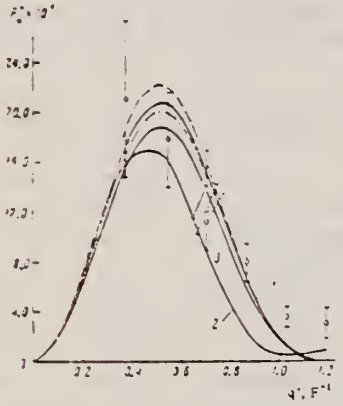

FIG. 2. Giant-resonance form factor as a function of momentum transfer. Points: O—data for Ni^{60}, X—for Ni^{64}, □—for Ni^{58}. The dashed curve, curve 1, and the dot-dash curve were calculated from formula (2) for the nuclei $Ni^{58,60,64}$ respectively, with k = 19 MeV. Curve 3 was calculated from the same formula for Ni^{60} with k = 21 MeV. Curve 2 is a calculation according to the Goldhaber-Teller collective model.

Table I. Absolute differential cross sections for inelastic scattering of electrons with excitation of the giant resonance in nickel isotopes

Nucleus	θ, deg	E_0, MeV	q, F^{-1}	q', F^{-1}	dσ/dΩ, cm^2/sr	F^2

MEASUREMENTS ON THE VIBRATIONAL SPLITTING OF THE GIANT DIPOLE RESONANCE

D.G. Owen, E.G. Muirhead and B.M. Spicer, School of Physics, University of Melbourne, Parkville, Victoria 3052, Australia.

The photoneutron yield curves for ^{58}Ni and ^{60}Ni have been measured in 1/4 MeV steps from threshold to 24 MeV, the enutrons being detected in a Halpern-type BF_3 counter system. The cross sections were obtained from the yield curves by the Leiss-Penfold matrix inversion method. A correction, based on the statistical theory of nuclear reactions, has been made for multiple neutron emission. The derived cross sections are shown in figures 1 and 2.

The dotted curves on the figures are the fits to the dipole spectrum, using Lorentz line shapes, and based on the dynamic collective model of the giant resonance (Huber, priv. comm. 1967), in which quadrupole surface vibrations are coupled to the dipole vibration. The poor fit at low energies is attributed to neglect of single particle effects.

Also shown in figure 1 is the result of the collective correlations calculation for ^{60}Ni (Seaborn, Drechsel, Arenhovel and Greiner, Phys. Lett. 23 (1966) 376). Here the surface vibrations are coupled to particle-hole dipole states, not just the dipole state. This calculation for the closed-subshell nucleus ^{60}Ni yields the result shown in the full curve of figure 1. The agreement with experiment is very much improved, indicating the importance of including single particle effects.

The similarity of low energy spectra for ^{58}Ni and ^{60}Ni, coupled with the fact that the same single particle states are filled in the ground state, leads to the expectation that the giant resonance structure will be similar for the two isotopes. This is in fact observed.

We measured the photoproton cross sections for the nuclei Cr^{52}, Ni^{58}, and Ni^{60} from the threshold to 30 MeV. We registered protons with energy larger than 1 MeV. A number of maxima were obtained in the cross sections. The values of the integral cross sections for Cr^{52}, Ni^{58}, and Ni^{60} are equal respectively to 240, 570, and 320 MeV-mb. The anomalously large cross section for the production of photoprotons for Ni^{58}, and also the shift of the centers of gravity of the photoproton cross sections towards higher excitation energies relative to the photoneutron cross sections in the case of Cr^{52} and Ni^{60}, can be attributed to the influence of analog states.

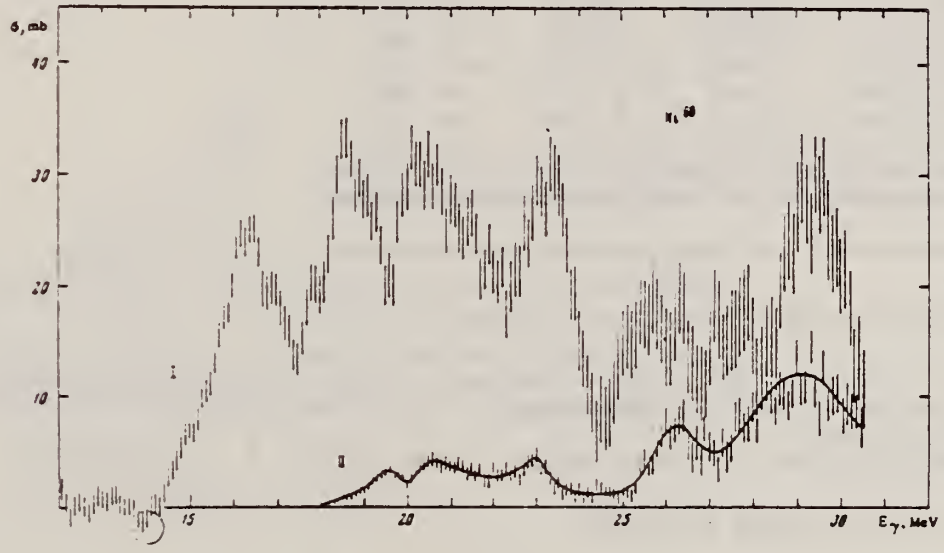

FIG. 3. Photoproton cross sections for Ni^{60}. The cross sections I and II were obtained for protons with $E_p \geq 1$ MeV and $E_p \geq 8$ MeV, respectively.

No data given for ^{51}V, ^{59}Co, ^{58}Ni.

59772 DETERMINATION OF PHOTONUCLEAR REACTION CROSS SECTIONS. Tikhonov, A. N.; Shevchenko, V. G.; Galkin, V. Ya.; (and others). Vestn. Mosk. Univ., Ser. III. Fiz. Astron.; 11: No. 2, 208-14(Mar-Apr 1970). (In Russian).

An operative system for the automatic handling of data is described for the determination of photonuclear reaction cross sections with a 35-MeV betatron. The system provides for fully automatic processing of experimental data as accumulated in the analyzer all the way to obtaining the cross section of a photonuclear reaction. Bremsstrahlung which is generated at the target of the betatron passes through a collimator and then impinges on the desired material. The neutrons thus produced are recorded by a BF_3 detector using a paraffin moderator. The pulses are sent to the memory of a pulse-height analyzer. This system is illustrated with data from (γ,n) reactions with the nuclei ^{51}V, ^{59}Co, ^{58}Ni, and ^{60}Ni. (K.S.W.)

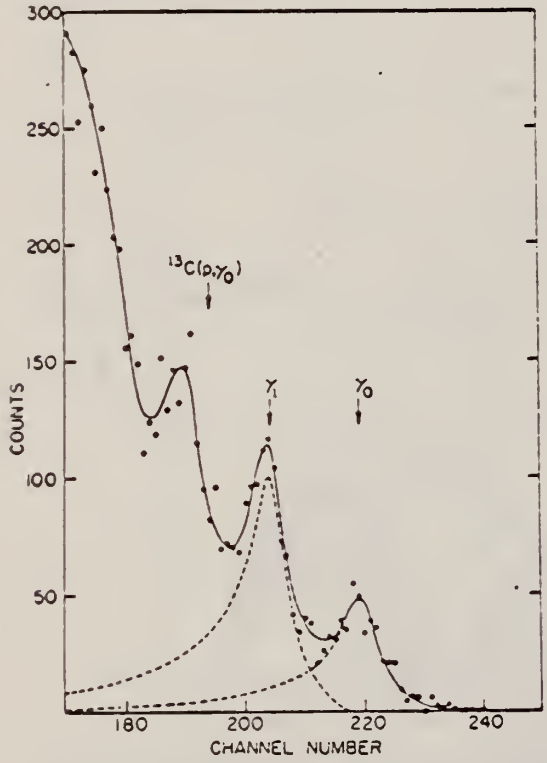

FIG. 1. Spectrum of high-energy γ rays from radiative capture of protons by ^{59}Co. Only the region of the pulse-height spectrum which corresponds to $E_\gamma > 13$ MeV is shown. The 7.6-MeV bombarding energy results in 17.00- and 15.67-MeV γ rays from the ground-state (γ_0) and first-excited-state (γ_1) transitions, respectively. The next lower peak is due to transitions to a group of higher excited states in ^{60}Ni. Also indicated is the position at which γ rays from the reaction $^{13}C(p,\gamma_0)^{14}N$ would appear. The dashed lines indicate the contributions from the γ_0 and γ_1 transitions obtained by fitting the data as described in the text.

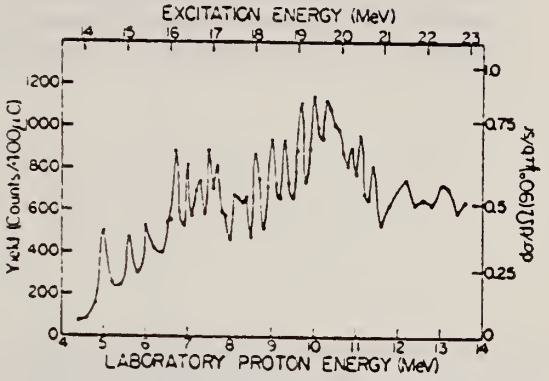

FIG. 2. Excitation function for the reaction $^{59}C(p,\gamma_0)$-^{60}Ni. The solid line is intended merely to guide the eye. The uncertainty associated with each data point is ±10% of the yield.

[over]

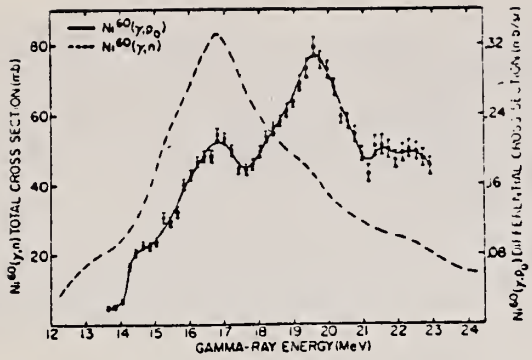

FIG. 3. Excitation functions for the reactions ^{59}Ni-$(\gamma,p_0)^{59}$C at 90°, obtained by detailed balance from the data of Fig. 1 averaged over a 600-keV interval, and ^{60}Ni$(\gamma,n)^{59}$Ni obtained from Ref. 23. Note the different cross-section scales for the two reactions. Above the ^{60}Ni$(\gamma,2n)$ threshold, the photoneutron data have been corrected for multiple neutron emission to yield the ^{60}Ni(γ,n) cross section. The indicated error bars were obtained from the averaging procedure. The solid line through the ^{60}Ni(γ,p_0) data points is drawn to guide the eye.

[23]K. Min and T.A. White, Phys. Rev. Letters 21, 1200 (1968).

The radiative-capture reaction ^{59}Co$(p,\gamma)^{60}$Ni has been studied for proton energies from 4.40 to 13.60 MeV. Cross-section and angular-distribution data were measured with a large anticoincidence-shielded NaI(Tl) detector. The yield curve for ground-state capture shows two broad peaks, at ^{60}Ni excitations of 16.6 and 19.6 MeV; these are interpreted as the $T_<$ and $T_>$ components of the giant dipole resonance. The results of a detailed calculation ignoring isospin effects do not adequately explain all of the observations; a simple 1p-1h calculation using eigenfunctions of T describes the results quite well. The first-excited-state-capture yield curve is similar to the ground-state curve, shifted in energy by ~300 keV. The data suggest that most of the observed strength in the giant dipole resonance based on the first excited state of ^{60}Ni is concentrated in 2^- states.

As in the case of ^{58}Ni[1] we report, in this paper, the first high-resolution measurement of the ^{60}Ni photoneutron cross sections with nearly monoenergetic photons from in-flight annihilation of positrons. The experimental details, including resolution and systematic uncertainties, are the same as those in the ^{58}Ni work.[1] The target sample enrichment was 99.79% ^{60}Ni.

Our experimental results are shown in Fig. 1. The total photoneutron cross section reaches a peak value of about 75 mb just above 16 MeV. There is some structure evident, superimposed on the general shape of the giant resonance, which is somewhat less prominent than that observed in ^{58}Ni; it does not agree in detail with the structure observed in previous experiments[2-4] on ^{60}Ni performed with bremsstrahlung photons. The magnitude of the peak cross section observed in this and previous experiments[2-4] are in reasonably good agreement, however. The integrated total photoneutron cross section is 705 MeV-mb, about 2.5 times as large as that for ^{58}Ni

Unlike the ^{58}Ni case, the ^{60}Ni (γ,2n) cross section forms a significant fraction of the total in the region above 20 MeV, although it appears to drop to nearly zero at 33 MeV. The statistics are sufficiently good that definite structure can be discerned in the cross section. The integrated (γ,2n) cross section is 73 MeV-mb, almost an order of magnitude larger than in the ^{58}Ni case.

As in the case of ^{58}Ni, the measured cross section is in qualitative agreement, up to about 25 MeV, with the distribution of dipole strength calculated by Tanaka.[5] The collective correlations calculation of Seaborn, et al[6] appears to provide some additional dispersion of the dipole strength to higher energies, yet there still appears to be too much experimental cross section above 25 MeV to be explained by the shell-model calculations done thus far.

† Work performed under the auspices of the U. S. Atomic Energy Commission.

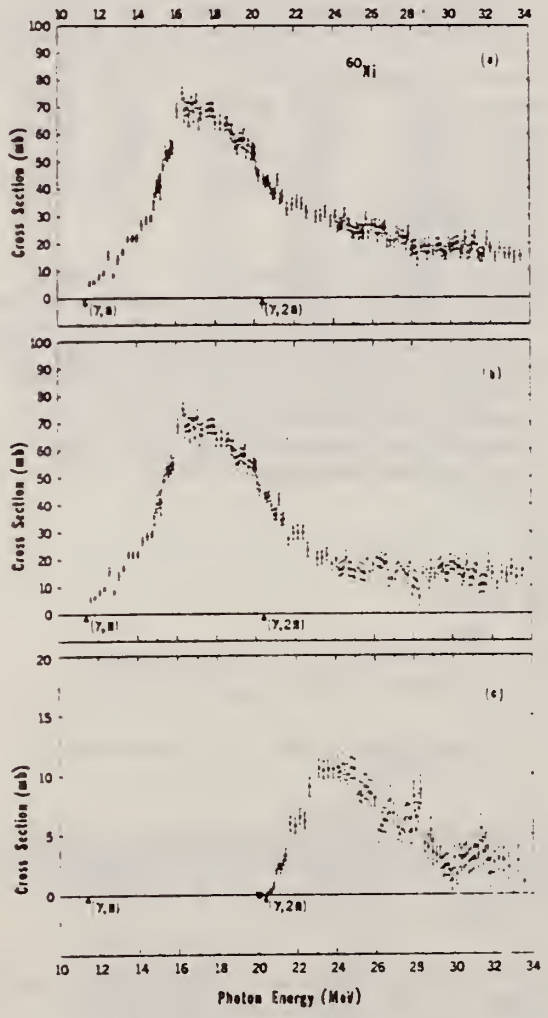

FIG. 3. Measured photoneutron cross sections for ^{60}Ni: (a) $\sigma(\gamma, Sn)$ (see Ref. 17); (b) $\sigma[(\gamma,n)+(\gamma,p\,n)]$; (c) $\sigma(\gamma, 2n)$.

TABLE II. Integrated photoneutron cross sections and related quantities from the data of the present experiment. The definitions used in this table are

$$\sigma_{\rm int} \equiv \int_{E_{\rm thr}}^{E_{\gamma\,\max}} \sigma dE_\gamma, \quad \sigma_{-k} \equiv \int_{E_{\rm thr}}^{E_{\gamma\,\max}} E_\gamma^{-k} \sigma dE_\gamma,$$

where $E_{\rm thr}$ is the threshold energy (see Table I) and E_γ is the photon energy; the quantity (γ, Sn) is defined in Ref. 17. Errors on the integrated cross sections are dominated by the systematic errors as discussed in Sec. III of the text.

	^{58}Ni		^{60}Ni	
$E_{\gamma\,\max}$	33.5	MeV	33.5	MeV
$\sigma_{\rm int}(\gamma, Sn)$	286	MeV mb	704	MeV mb
$\sigma_{\rm int}(\gamma, 2n)$	7.65	MeV mb	72.2	MeV mb
$\sigma_{\rm int}[(\gamma,n)+(\gamma,pn)]$ [a]	278	MeV mb	632	MeV mb
$\sigma_{\rm int}(\gamma, 2n)/\sigma_{\rm int}(\gamma, Sn)$	0.027		0.103	
$\sigma_{-1}(\gamma, Sn)$	13.8	mb	35.6	mb
$\sigma_{-2}(\gamma, Sn)$	0.700	mb MeV^{-1}	1.90	mb MeV^{-1}
$\sigma_{\rm int}(\gamma, Sn)/60(NZ/A)$	0.329		0.786	

[a] This quantity was obtained by subtracting $\sigma_{\rm int}(\gamma, 2n)$ from $\sigma_{\rm int}(\gamma, Sn)$; direct integration of the single-photoneutron cross sections gave the same values to within 0.5%.

TABLE IV. Comparison of integrated total photoneutron cross sections $\sigma_{\rm int}(\gamma, Sn)$ with those from previous experiments.

(over)

TABLE III. Energies (MeV) at which peaks appear in the (γ,Sn) cross sections of ^{58}Ni and ^{60}Ni. The energies listed are those at which peaks or shoulders exist in the cross section. Actual resonance energies might be slightly different.

Peak No. [a]	^{58}Ni	^{60}Ni
1	12.3	12.6
2	12.8	13.7
3	13.1	14.4
4	13.6	15.1
5	14.2	15.5
6	15.7	16.3
7	16.3	17.0
8	17.3	17.7
9	17.7	18.6
10	18.2	19.6
11	18.6	21.2
12	19.3	22.1
13	22.6	24.5
14	23.8	
15	24.9	
16	25.7	

[a] We have included in the tabulations only the more well-defined peaks (or shoulders). In addition there are possible broad peaks at approximately 20.7, 27.8, and 30.9 MeV in ^{58}Ni, and at 23.5, 26.1, 27.5, and 30.3 MeV in ^{60}Ni, but the data are not sufficiently detailed to make a more definitive judgment about these.

TABLE V. Integrated total photon absorption cross sections and related quantities from the combined data of the present experiment and Ref. 7. The (γ,Xp) cross sections of Ref. 7 have been used rather than those of Ref. 8 because the former extend over a wider energy range; in their mutually inclusive energy range (see Figs. 5 and 6) the integrated cross sections from the two (γ,Xp) measurements agree to within 2% for ^{58}Ni and 10% for ^{60}Ni, the values derived from the data of Ref. 8 being the larger in both cases. The total photon absorption cross section $\sigma(\gamma,\text{total})$ is assumed to be equal to $\sigma(\gamma,Sn)+\sigma(\gamma,Xp)$; that is the photon scattering cross section is assumed to be negligible and double counting, owing to the presence of $\sigma(\gamma,pn)$ in both $\sigma(\gamma,Sn)$ and $\sigma(\gamma,Xp)$, is ignored. The latter effect is reasonably compensated for, however (see footnote a).

	^{58}Ni	^{60}Ni
$E_{\gamma\,\max}$	33.5 MeV [a]	33.5 MeV [a]
$\sigma_{\text{int}}(\gamma,\text{total})$	850 MeV mb	1025 MeV mb
$\sigma_{-1}(\gamma,\text{total})$	41.3 mb	48.7 mb
$\sigma_{-2}(\gamma,\text{total})$	2.09 mb MeV^{-1}	2.62 mb MeV^{-1}
$\sigma_{\text{int}}(\gamma,\text{total})/(60NZ/A)$	0.98	1.10
$\sigma_{-1}(\gamma,\text{total})/A^{4/3}$	0.18	0.21
$\sigma_{-2}(\gamma,\text{total})/A^{5/3}$	0.002 64	0.002 86

[a] The (γ,Xp) data extend only to 30.1 MeV for ^{58}Ni and 30.5 MeV for ^{60}Ni; above these energies we have used the (γ,Sn) cross section only. Since much of the high-energy cross section probably comes from the (γ,pn) process, the error introduced is probably small and might very well compensate for the double counting of the (γ,pn) cross section below 30 MeV.

[7] B.S. Ishkanov, I.M. Kapitonov, I.M. Piskarev, V.G. Shevchenko, and O.P. Shevchenko; Yad. Fiz. 11, 485 (1970); Sov. J. Nucl. Phys. 11, 272 (1970).

[8] K. Shoda, private communication; see also H. Miyase, S. Oikawa, A. Suzuki, J. Uegaki, T. Saito, M. Sugawara, and K. Shoda, in Proceedings of the International Conference on Photonuclear Reactions and Applications, Asilomar, March, 1973, ed. by B.L. Berman (Lawrence Livermore Laboratory, Livermore, 1973) p.553.

[17] In our reaction notation we have essentially adopted the convention used by E.G. Fuller, H.M. Gerstenberg, H. Vander Molen, and T.C. Dunn NBS SP-380, 1973; wherein (γ,Sn) represents the sum of all neutron-producing reactions, (γ, Xp) denotes total proton yield, etc. We use (γ,pn) to represent either the (γ,np) or (γ,pn) reaction, since experimentally the two are indistinguishable.

Monoenergetic photons and a high-resolution NaI spectrometer have been used to measure the absolute 120° scattering cross sections to the ground state and to the first excited state in ^{60}Ni for excitations between 15 and 22 MeV. The inelastic scattering to the first excited state was found to be about 15% of the elastic throughout this energy range. Our results do not appear to be in quantitative agreement with the predictions of the dynamic collective model.

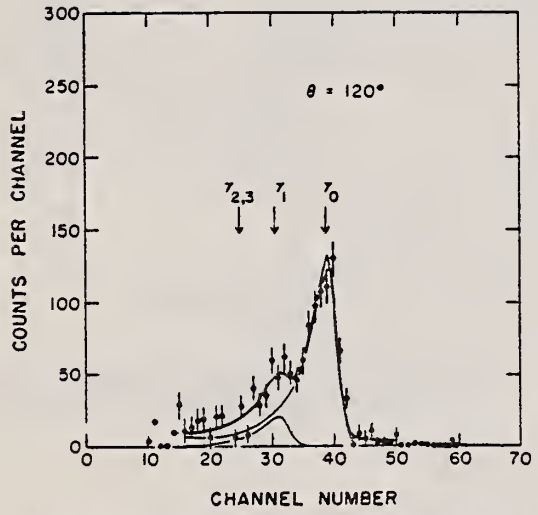

FIG. 2. Scattering spectrum for monoenergetic 19.81-MeV photons incident on ^{60}Ni. The fitting procedure by which elastic and inelastic scattering was separated is shown. The shapes of the detector response to monoenergetic photons used in the fit were measured directly by placing the detector in the tagged photon beam.

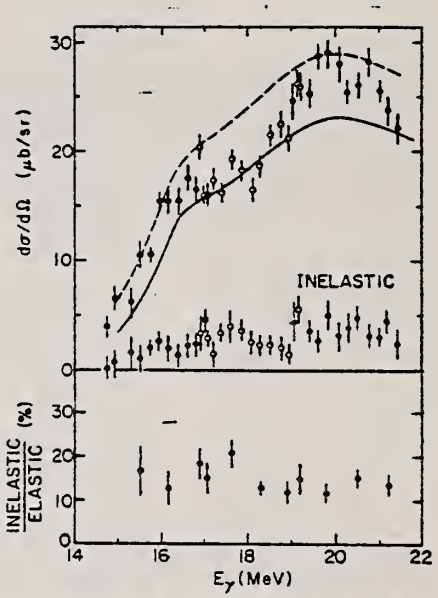

FIG. 3. The cross sections at an angle of 120° for elastic and inelastic scattering to the first excited state in ^{60}Ni are shown at the top. The solid curve shows the elastic cross section predicted by dispersion relations using $\sigma(\gamma,n)$ data for the total absorption cross section. The dashed curve indicates an estimate of the contribution that would come from including $\sigma(\gamma,p)$ as well. The ratio of inelastic to elastic scattering is shown below. The open and solid data points represent the three different energy ranges scanned by the monochromator.

Alpha-particle energy and angular distributions have been measured for the reaction $^{60}Ni(e,\alpha)e'X$ using electrons of energies 33, 60, and 120 MeV. Statistical-model calculations give good quantitative agreement in the region of the peak of the α energy spectra. Higher-energy α particles exhibit a forward-peaked angular distribution and a cross section several orders of magnitude above the statistical-model predictions, indicating the presence of a direct-reaction component.

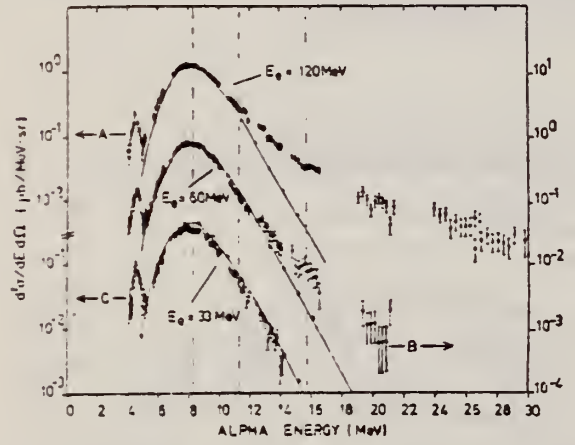

FIG. 1. Alpha-particle energy spectra at $\theta_\alpha = 90°$, for $E_e = 120$ MeV (curve *A*, upper left-hand scale), $E_e = 60$ MeV (curve *B*, right-hand scale), and $E_e = 33$ MeV (curve *C*, lower left-hand scale). Errors shown are absolute. The solid lines are the results of a statistical calculation assuming photon absorption below $E_\gamma = 33$ MeV. The dashed lines mark the mean energies at which angular distributions were taken.

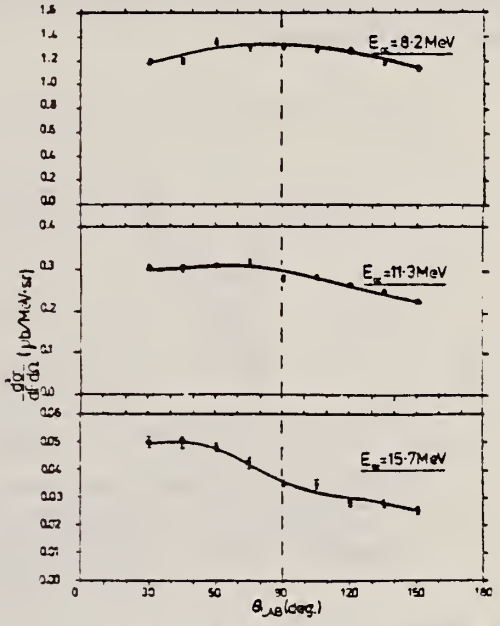

FIG. 2. Alpha-particle angular distributions at $E_e = 120$ MeV averaged over the α energy ranges 7.7–8.7 MeV, 10.6–11.9 MeV, and 14.8–16.4 MeV. Errors shown are relative. The solid lines are merely to guide the eye.

Analysis is made of reactions interfering with photon activation analysis procedures.

The activation yield curves have been presented for a number of photonuclear reactions in the energy range from 30 to 68 MeV, in order to evaluate quantitatively the interferences due to competing reactions in multielement photon activation analysis. The general features of the yields as functions of both target mass number and excitation energy were elucidated from the data obtained, discussion being given on the results in terms of the reaction mechanism.

Simultaneous neutron activation due to appreciable neutron production from the converter and surrounding materials has also been studied, and, finally, the magnitudes of interferences in real multielement analysis were given in the form of their energy dependences.

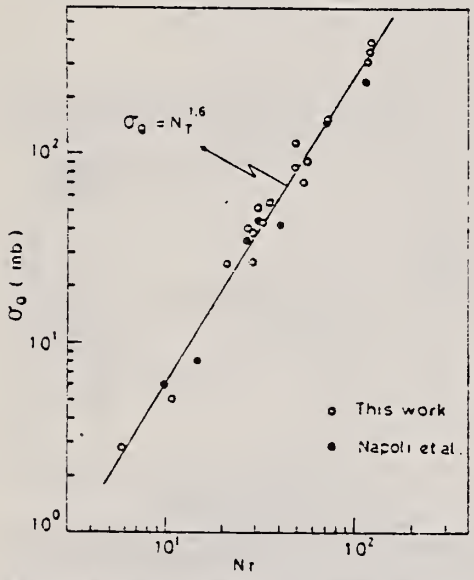

Fig. 2. Yield per equivalent quanta versus target neutron number.

The angular distributions of cross section and of analyzing power for the $^{59}Co(\vec{p},\gamma_0)$ ^{60}Ni reaction have been measured throughout the giant dipole resonance region of ^{60}Ni. In addition, the 90° yield curve has been measured for E_p from 5.8 to 16.5 MeV. The data are analyzed to deduce the amplitudes and phases of the T matrix elements involved. Comparison of the results is made to both the dynamic collective model calculation of Ligensa and Greiner and to a direct-semidirect model calculation. The direct-semidirect calculation indicates that the reaction proceeds predominantly via the radiative capture of $d_{5/2}$ protons. Isospin splitting is also discussed.

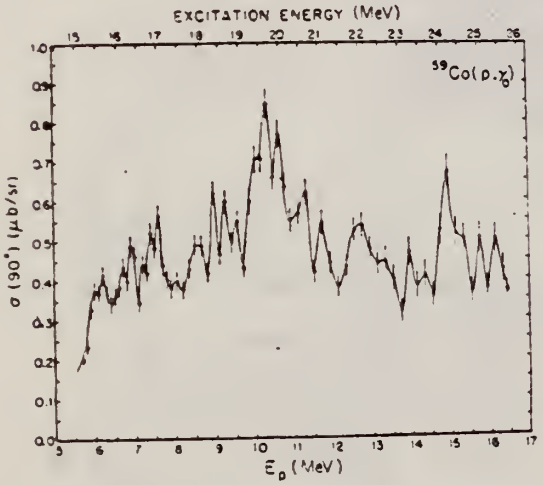

FIG. 2. The 90° yield curve for the $^{59}Co(p,\gamma_0)$ ^{60}Ni reaction. The error bars represent the statistical error associated with the data points and the solid curve is a smooth line drawn through the data points.

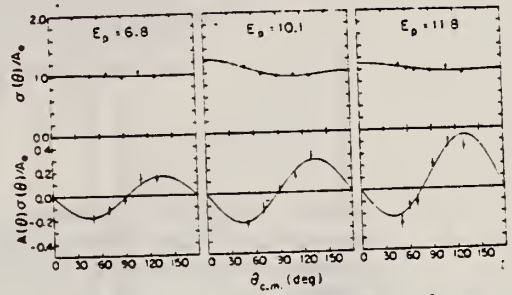

FIG. 3. Typical data at three energies for the quantities $\sigma(\theta)/A_0$ and $\sigma(\theta)A(\theta)/A_0$. The errors bars represent the statistical errors associated with the data points. The solid curves are the result of fitting the data as described in the text.

over

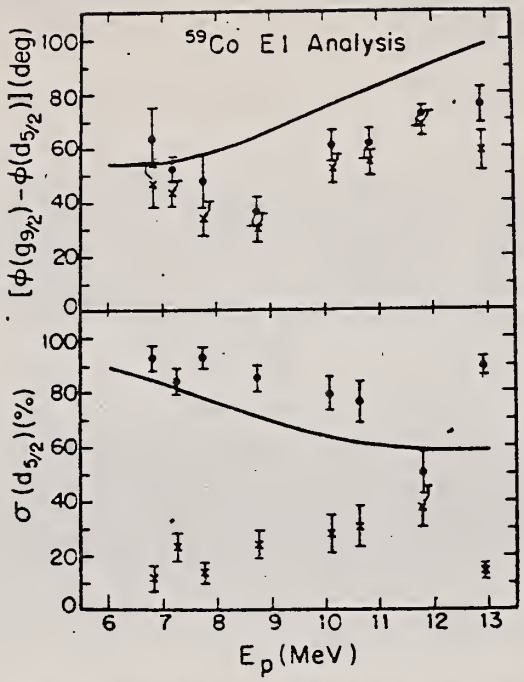

FIG. 5. Comparison of the transition matrix elements extracted from the present data with those from a direct-semidirect reaction model calculation as described in the text. The solid curve shows the results of the calculation. The results are presented as a percentage of the cross section, $\sigma(d_{5/2}) + \sigma(g_{9/2})$, where $\sigma(d_{5/2}) = d_{5/2}^2$, etc. The error bars represent the statistical errors associated with the data.

TABLE I. The a_k and b_k coefficients obtained from least squares fits to the data as described in the text. Also presented are the a_k coefficients from Ref. 1.

Analysis of data in reference 6.

POLARIZED PROTONS

Measurements of cross sections and analyzing powers are examined for polarized proton capture on ^{14}C, ^{30}Si, ^{54}Fe, ^{56}Fe, ^{58}Fe, ^{59}Co, and ^{88}Sr at energies which cover the giant dipole resonance region. These data are used to extract the relative amplitudes and phases of the contributing $E1$ T-matrix elements. A typical result exhibits two solutions. Calculations using the direct (or a direct-semidirect) capture model appear to provide a means for choosing the physical solution.

[NUCLEAR REACTIONS: $^{14}C(\vec{p},\gamma_g)$, $^{30}Si(\vec{p},\gamma_g)$, $^{54}Fe(\vec{p},\gamma_g)$, $^{56}Fe(\vec{p},\gamma_g)$, $^{58}Fe(\vec{p},\gamma_g)$, $^{59}Co(\vec{p},\gamma_g)$, $^{88}Sr(\vec{p},\gamma_g)$; measured $\sigma(\theta)$ and $A(\theta)$ over energy region of the giant dipole resonance. Deduced T-matrix amplitudes and phases. Compare results to direct-semidirect model calculations.]

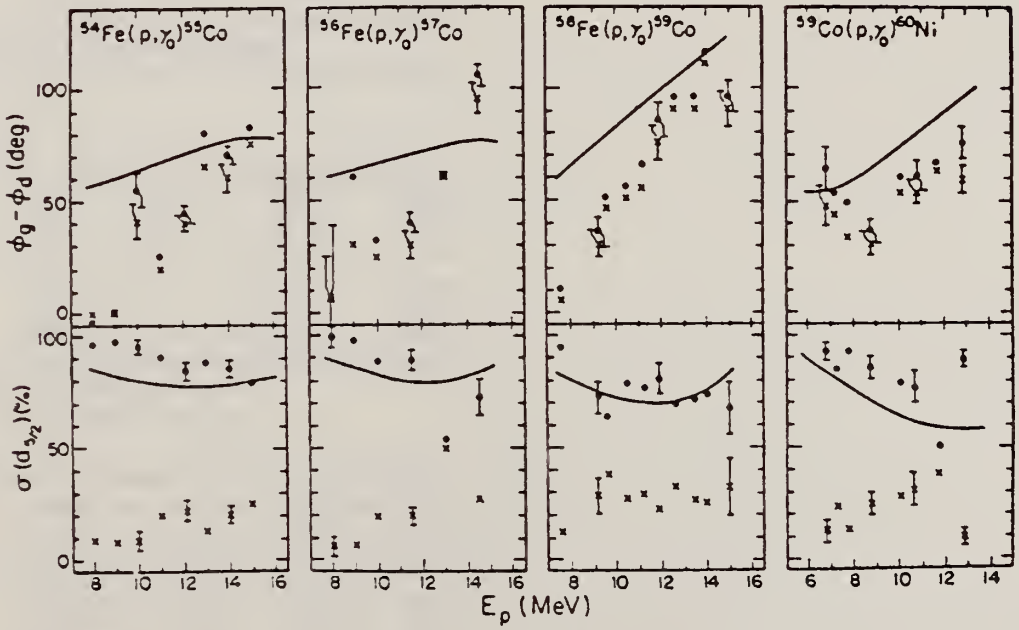

FIG. 2. Same as Fig. 1 for the target nuclei of ^{54}Fe, ^{56}Fe, ^{58}Fe, and ^{59}Co. The remaining cross section is due to the $g_{7/2}$ matrix element.

FIG. 1. The two solutions (dots and x's) resulting from a pure $E1$ analysis of the data are shown along with the results of the calculation for target nuclei of ^{14}C, ^{88}Sr, and ^{30}Si. The remaining cross section in the case of ^{14}C and ^{88}Sr is due to the $s_{1/2}$ matrix element. In the case of ^{30}Si it arises from the $p_{1/2}$ matrix element. The error bars represent typical statistical errors associated with the data points. The amplitudes are presented in terms of the percentage of the total cross section for which they are responsible. The curves represent DSD calculations as described in the text. The dashed curves in the case of ^{88}Sr were obtained using the optical model parameters of Ref. 16 while the solid lines were obtained from the parameters of Ref. 18.

The (e,p) and (e,α) cross sections for targets of ^{58}Ni, ^{60}Ni, and ^{62}Ni have been measured in the electron energy range 16–50 MeV. They have been analyzed using the distorted-wave Born-approximation $E1$ and $E2$ virtual-photon spectra. Protons are emitted primarily following $E1$ absorption but α emission results from a combination of $E1$ and $E2$ absorption. The $E2$ isoscalar giant resonance decays predominantly by α emission for these nuclei.

The cross section for electron scattering from the isotopes ^{58}Ni and ^{60}Ni has been measured with electrons of 102 MeV at scattering angles of 45, 60, 75, 90, and 105° between 3 and 50 MeV excitation energy. Resonances or resonancelike structures at approximate excitation energies of (7–8) MeV, 13 MeV, (16–17) MeV, (18–19) MeV, 27 MeV, 32 MeV, and 40 MeV were classified on the basis of their momentum transfer dependence and discussed in the framework of the shell model. Difficulties in the extraction of the cross section and model dependencies of the interpretation are discussed.

BEL

[NUCLEAR REACTIONS ^{58}Ni (e,e') and ^{60}Ni (e,e'), E_0=102 MeV. Measured $d^2\sigma/d\Omega dE_x$, bound and continuum states (giant resonances). Deduced multipolarity, reduced matrix element $B(E\lambda)$, sum rule exhaustion of giant resonances, total width of continuum and clustered states.]

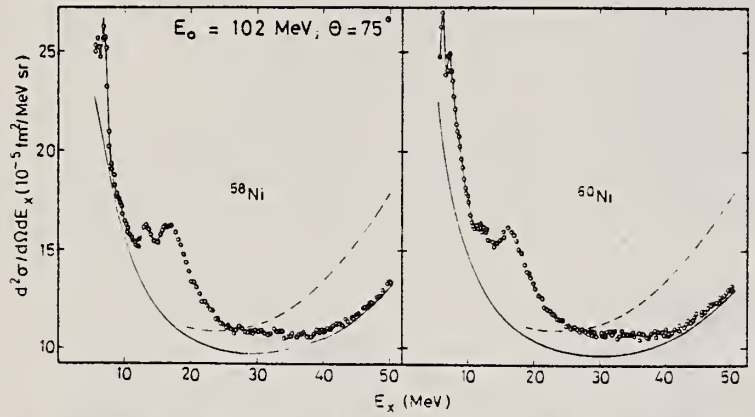

FIG. 4. Comparison of spectra of 102 MeV electrons scattered at 75° from ^{58}Ni and ^{60}Ni. The cross section for ^{60}Ni has been renormalized so that the highest and lowest points in both plots are equal. The spectra were taken with 10 points/MeV but have been reduced for graphical purposes. The broken line is the calculated radiation tail. For demonstration purposes we have subtracted the ghost peak at 3 MeV from the data for ^{58}Ni, but not for ^{60}Ni; the difference is clearly visible. Note the suppressed zero.

TABLE III. Strength of $E1$ components in the present work. The resonance parameters shown were used to approximate the $E1$ strength distribution for the χ^2 fit. As evident from Fig. 8, where mainly $E1$ contributes, the $E1$ strength function is reasonably well described. The $E1$ strength extracted from the resonances, corresponding to integration to infinity, adds up to approximately 110% of the classical $E1$ sum rule. For ease of comparison, we also give the sum rule strength found by integration from 10 to 30 MeV, 94 ± 10 and 87 ± 10% for ^{58}Ni and ^{60}Ni, respectively. The table and Fig. 8 also show that the peak strength is shifted to lower excitation energy by going from ^{58}Ni to ^{60}Ni. Although the gross shift is in agreement with the isospin coupling model[1,37] we do not think it is a sufficient basis for a claim of observed isospin splitting. The average excitation energy, weighted with the $E1$ strength function between 10 and 30 MeV, in contrast, remains virtually unchanged.

(OVER)

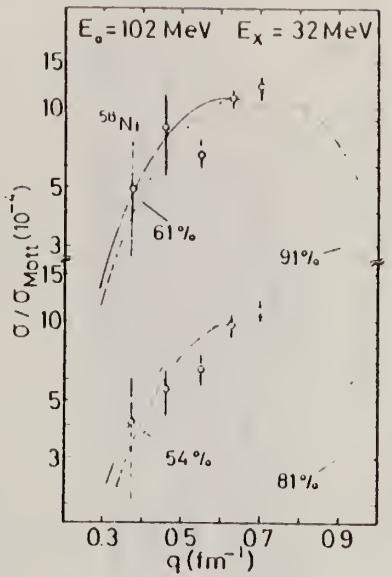

FIG. 14. Comparison between experimental and DWBA cross sections for resonance at 32 MeV. An $E2$ assignment is preferred, but other multipolarities (not taken into account) could contribute. The Goldhaber-Teller model leads to the higher strength; this strength might be regarded as an upper limit. The Myers-Swiatecki model (broken line) assumed $\alpha = 1$ (see text for definition). Extension of the Myers-Swiatecki model by Kodama to higher multipolarities gives values for α ranging from 0.12 to 0.44. Thus the sum rule values given in the figure for the MS model should be regarded as lower limits. The dependence of the experimental points on the momentum transfer suggest the possibility of more than one multipolarity contributing. This possibility was not investigated due to the accuracy limitations at this high excitation energy.

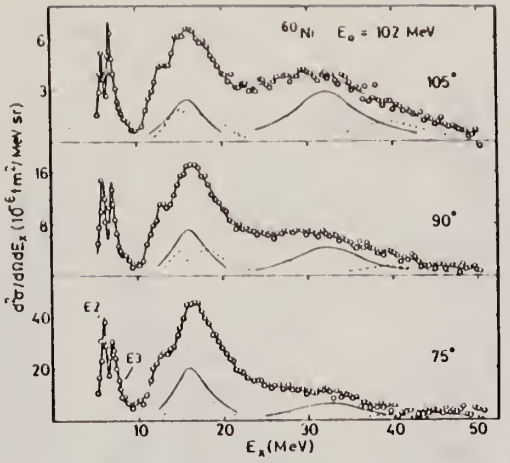

FIG. 6. Similar to Fig. 5, but for ^{60}Ni. The $E1$ has been omitted and the $E4$'s at 15 and 19 MeV have been added into one line for clarity (but see remark in Sec. IV F).

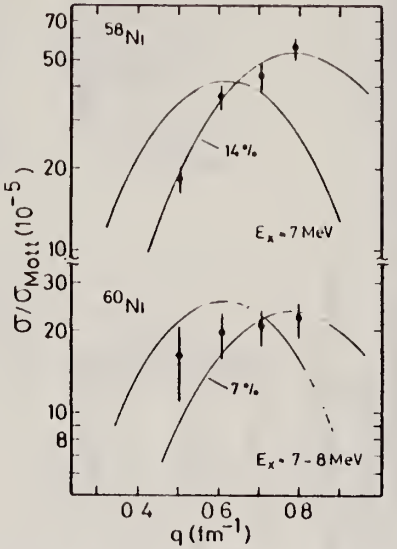

FIG. 11. Comparison of experimental cross sections for a state (group of states?) at 7 MeV in ^{58}Ni and a group of states between 7 and 8 MeV in ^{60}Ni with DWBA calculations. The ^{58}Ni data follow an $E3$ form factor quite well, but the ^{60}Ni data, which carry only half of the ^{58}Ni strength, may include an $E2$ or $E1$ contribution.

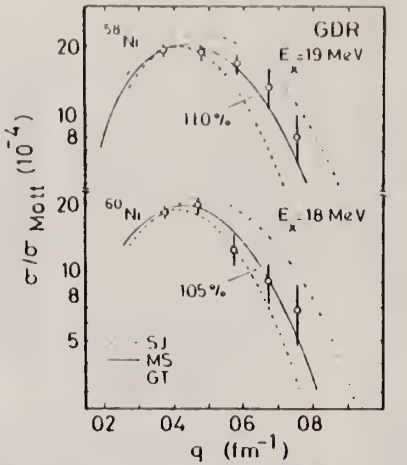

FIG. 9. Comparison between experimental and calculated cross sections for the models of Fig. 8. The curves were normalized to go through the point with the lowest momentum transfer, because this is the one with the least model dependence and the most accurate one. The Myers-Swiatecki model is somewhat favored by this comparison; however, the difficulties with the simultaneous fit of several resonances between 15 and 19 MeV, as discussed in the text, should be noted.

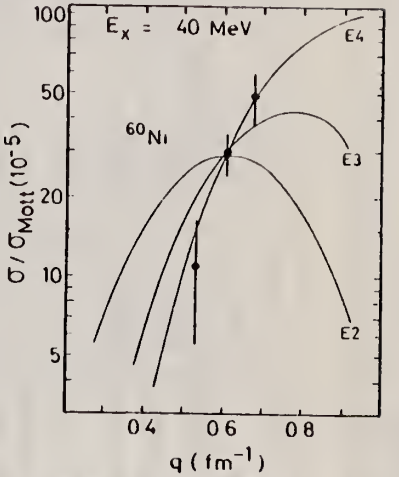

FIG. 16. Comparison of cross section at 40 MeV with DWBA calculations. The experimental points follow an $E4$ curve. These are two problems connected with this resonance. First, it may be doubted that it is real, that is, it may be produced by our special choice of background, because if we add one more parameter to the background function it virtually disappears. Second, it exhausts a rather large fraction of the $4\hbar\omega$ isoscalar strength, namely (150 ± 75)%, compared to the 50% predicted (Ref. 25, Table I).

VIRT PHOTON ANALYSIS

Cross sections have been measured for the reactions ^{58,60}Ni$(e,e'p)$ and ^{58,60}Ni$(e,e'\alpha)$ in the electron-energy range 12–35 MeV. For analysis of the experimental results we used virtual photon spectra calculated in the DWBA. At energies $E\gamma = 16.0 \pm 1.0$ MeV for ^{58}Ni and $E_\gamma = 15.6 \pm 1.0$ MeV for ^{60}Ni we have observed giant electric-quadrupole resonances which decay mainly by α-particle emission. The integrated cross sections for the reactions ^{58}Ni(γ,α) and ^{60}Ni(γ,α) due to $E2$ transitions are respectively 5.4 ± 1.4 and 6.0 ± 3.0 mb·MeV, which amounts to $47 \pm 12\%$ of the total strength of isoscalar $E2$ transitions for ^{58}Ni and $56 \pm 28\%$ for ^{60}Ni. The integrated cross sections for these same reactions due to $E1$ transitions are 15.9 ± 2.3 and 16.9 ± 4.8 mb·MeV, which amount to $1.7 \pm 0.3\%$ of the value given by the sum rule for electric-dipole transitions for ^{58}Ni and $1.8 \pm 0.5\%$ for ^{60}Ni. The measured integrated cross sections for the reactions ^{58,60}Ni(γ,p) are 539 ± 33 and 300 ± 20 mb·MeV.

^{62}Ni	0.24 ± 0.01	0.22	0.19

TABLE VI. $\sigma_{e,\alpha}$ at 100 MeV.

Nucleus	$\sigma_{e,\alpha}$(meas) (mb)	$\sigma_{e,\alpha}$(calc) (mb)	$\sigma_{e,\alpha}$(corr) (mb)
^{58}Ni	0.069 ± 0.002	0.084	0.063
^{60}Ni	0.063 ± 0.002	0.081	0.060
^{62}Ni	0.033 ± 0.001	0.036	0.027

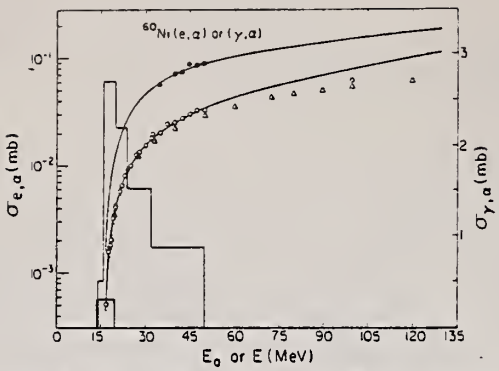

FIG. 12. The measured $\sigma_{e,\alpha}(E_0)$ for ^{60}Ni as a function of total incident electron energy E_0 (open circles). The full circles represent the electro plus photodisintegration yield obtained when the 0.217 g/cm^2 foil was interposed in the incident electron beam and the triangles show the data of Ref. 25. The smooth curves through the points result from combining the histograms, representing the $E1$ and $E2$ (γ,α) cross sections (right-hand scale), in Eqs. (1) and (2) with the $E1$ and $E2$ virtual photon spectra and making use of the Davies-Bethe-Maximon bremsstrahlung cross section. These integrals have been extended to 130 MeV assuming that the (γ,α) cross section is zero above 50 MeV. That the measured cross sections lie below this curve probably stems from the failure of the long wavelength approximation.

Quasimonochromatic photons have been used to measure elastic and inelastic photon scattering cross sections in the giant dipole resonance region of ^{52}Cr, Fe, ^{60}Ni, ^{92}Mo, and ^{96}Mo in an experiment in which the elastic and inelastic scattering are resolved. The elastic scattering cross sections show clear evidence for isospin splitting of the giant dipole resonance. The inelastic scattering to low-lying vibrational levels, which is a measure of the coupling between the giant dipole resonance and collective surface vibrations, is in qualitative agreement with the predictions of the dynamic collective model. However, when examined in detail, this model does not provide an adequate description of the scattering data.

[NUCLEAR REACTIONS ^{52}Cr, Fe, ^{60}Ni, ^{92,96}Mo (γ,γ'), $14 \le E_\gamma \le 22$ MeV; measured E_γ, $E_{\gamma'}$, $d\sigma/d\Omega$ for γ_0,γ_1. Compared to DCM predictions. Tagged photons.]

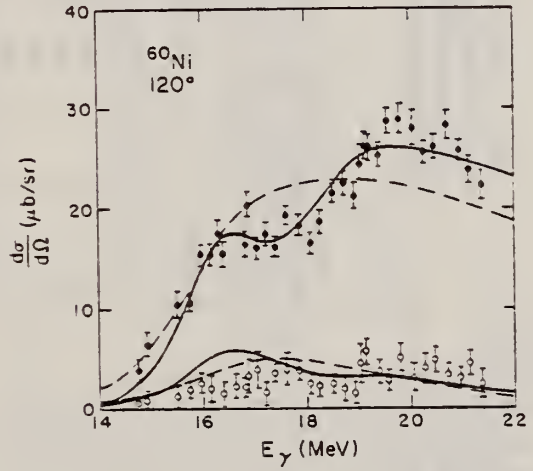

FIG. 6. Elastic (closed circles) and inelastic (open circles) scattering cross sections at $\theta = 120°$ for ^{60}Ni. The error bars represent statistical uncertainties only. The solid (dashed) lines are DCM calculations for the elastic and inelastic cross sections including (not including) the effect of isospin splitting.

The most stringent test to date of the concept of isospin splitting of the giant dipole resonance in a medium-weight nucleus has been performed by a study of the (γ,n_0), (γ,p_0), and (γ,γ) reaction channels for ^{60}Ni. The ground-state photoneutron cross section for ^{60}Ni was measured and compared with the already known (γ,p_0) reaction cross section in order to demonstrate isospin splitting. The relative strength and separation of the isospin-dependent components of the resonance were estimated from an analysis of photon scattering data.

PACS numbers: 25.20.+y, 24.30.Cz, 27.50.+e

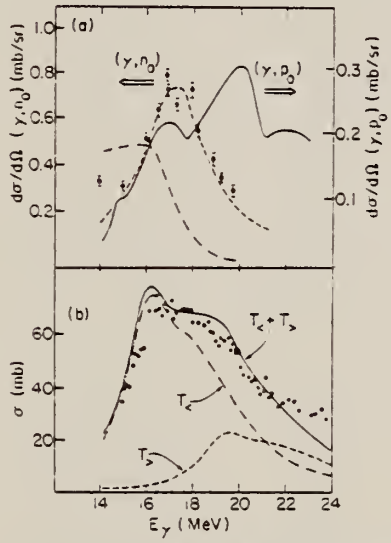

FIG. 1. (a) Ground-state photoneutron (points) and photoproton (solid line) cross sections for ^{60}Ni. The data points are the results of the present measurement. The solid line is from Ref. 5. The dashed curve is a Lorentzian of width 3.4 MeV and peak cross section adjusted to fit the (γ,n_0) data. The dash-dotted curve is a Hauser-Feshbach statistical calculation of the (γ,n_0) cross section. (b) Total photoneutron cross sections for ^{60}Ni from Ref. 7 (circles) and the calculated photoabsorption cross section σ_γ for ^{60}Ni (solid line). The dashed and dash-dotted lines are the calculated $T_>$ and $T_<$ components, respectively, of σ_γ. The calculation was performed in the framework of the dynamic collective model with parameters adjusted to fit the elastic photon scattering data.

TABLE VI. Energies and parameters for resonances in the reaction ^{61}Ni(γ, n). The ±20% error in the quantity $\Gamma_{\gamma 0}\Gamma_n/\Gamma$ for all resonances is due mainly to the uncertainty in the absolute normalization of the data. The energies given in column 2 are calculated from those of column 1 by applying a correction for recoil effects. For unassigned levels, column 4 gives $g\Gamma_{\gamma 0}\Gamma_n/\Gamma$.

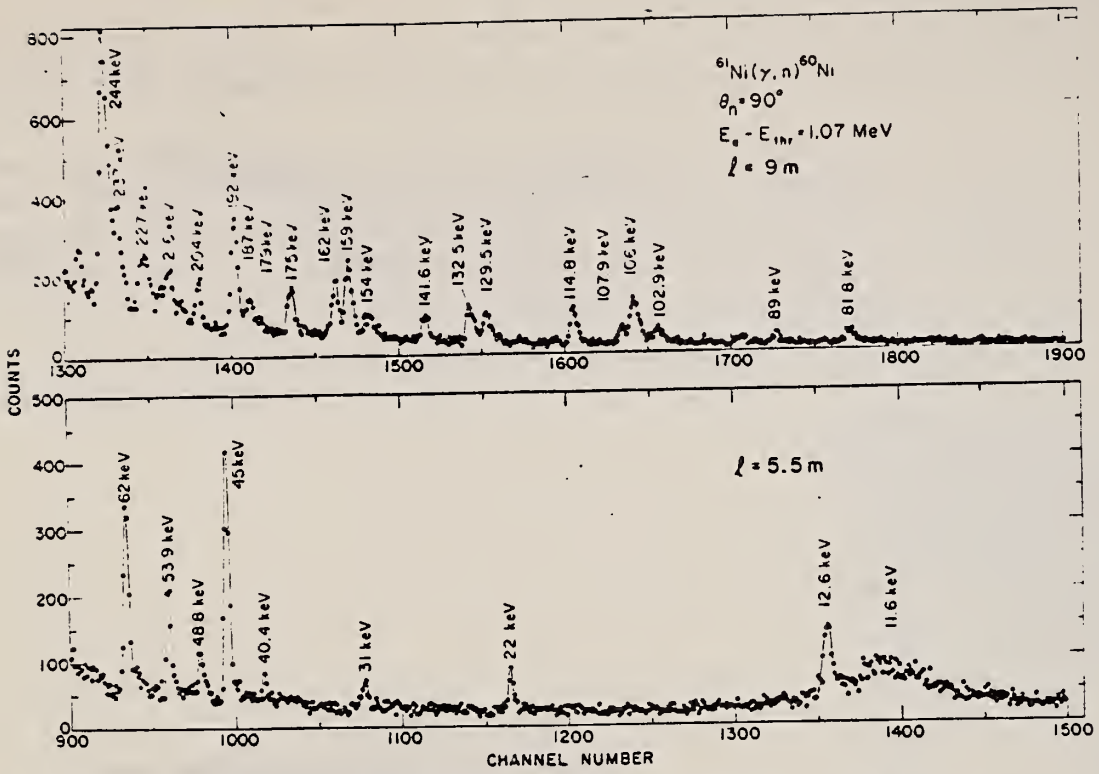

FIG. 7. Photoneutron time-of-flight spectrum for $^{61}Ni(\gamma,n)$. The upper section was taken with a flight path of 9 m the lower section with a flight path of 5.5 m.

TABLE VII. Integrated yields and reduced widths for electric and magnetic dipole radiation. Integrated yields are given for all resonances observed, but reduced widths for magnetic dipole transitions are calculated only from yields for p-wave levels above 100-keV neutron energy (see discussion in Sec. IV). The number of resonance widths used to obtain each $\bar{k}$ is given by n. The errors given were calculated by assuming that the individual $\Gamma_{\gamma 0}$'s follow a Porter-Thomas distribution.

Abstract. Lifetimes of 49 excited states below 1.65 MeV have been measured in ^{24}Mg, ^{27}Al, ^{48}Ti, ^{58}Ni, ^{59}Co, ^{61,62}Ni, ^{63,65}Cu, ^{64,66,68}Zn, ^{75}As, ^{103}Rh, ^{113,115}In, ^{116,118,120}Sn and ^{121,123}Sb by means of nuclear resonance fluorescence experiments. The levels are excited by bremsstrahlung x-ray photons. The self-absorption technique applied to suitable cases provides nuclear absorption cross sections, widths and lifetimes from which the x-ray spectral distributions are also obtained. Scattering experiments are performed for all other cases in order to obtain widths and lifetimes from these x-ray photon curves. The Compton effect in the sample is taken into account. Self-absorption provides $g\Gamma_0$ from which Γ is deduced using adopted J^π and Γ_0/Γ values; scattering provides $u = g(\Gamma_0^2/\Gamma)W(\theta)$ from which Γ is also deduced with J, Γ_0/Γ and mixing ratios taken from the literature. Thanks to simultaneous determination of the x-ray spectra all the lifetimes as given by our programs with their statistical errors form an unusually coherent set of values.

NUCLEAR REACTIONS (γ, γ), bremsstrahlung excitation; natural isotopes: ^{24}Mg, ^{27}Al, ^{48}Ti, ^{58}Ni, ^{59}Co, ^{61,62}Ni, ^{63,65}Cu, ^{64,66,68}Zn, ^{75}As, ^{103}Rh, ^{113,115}In, ^{116,118,120}Sn and ^{121,123}Sb; $E \simeq 0.5$–1.65 MeV; measured $g\Gamma_0$ or $g(\Gamma_0^2/\Gamma)W(\theta)$; deduced $T_{1/2}$.

Remarque. Pour calculer δ^2 quand nous ne disposons que de $B(E2)$, pour un mélange (E2) + (M1), nous déduisons $g\Gamma_0(E2) \propto B(E2)E_\gamma^5$; en admettant $W(\theta)=1$ et connaissant Γ_0/Γ, notre détermination de u donne une première approximation de $g\Gamma_0$ d'où une valeur de $\delta^2=(g\Gamma_0(E2))/(g\Gamma_0-g\Gamma_0(E2))$ qui permet d'améliorer $W(\theta)$ et $g\Gamma_0$ de proche en proche.

[a] Swann (1971); [b] Robinson *et al* (1967); [c] $W(\theta)=0.99$ calculé d'après la formule de Celliers *et al* (1977); [d] Abbondanno *et al* (1978); [e] Sayer *et al* (1972); [f] Tuttle *et al* (1976); [g] d'après $B(E2)$ de Barnes *et al* (1966); [h] calculé d'apres Booth *et al* (1973); [i] Williams *et al* (1975); [j] Dietrich *et al* (1970).

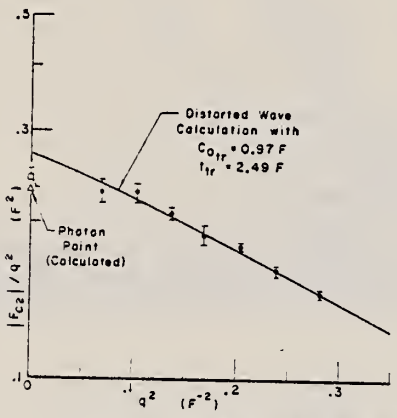

FIG. 1. Form factor for the first excited (2^+) state of Ni^{62}, as a function of momentum transfer squared. The solid points represent measured form factors divided by the square of the momentum transfer plotted logarithmically as a function of the square of the momentum transfer. The line is a plot of theoretical results using the computer program of Ref. 9 to calculate form factors corresponding to transition charge densities described by the parameters $c_{0\,tr}$ and t_{tr} [Eq. (3)]. The open triangle at $q = 0$ represents the photon point, calculated from Eqs. (2) and (4), using the parameters quoted in the figure. The square represents the results of the Coulomb-excitation experiment of Ref. 12.

The (e,p) and (e,α) cross sections for targets of ^{58}Ni, ^{60}Ni, and ^{62}Ni have been measured in the electron energy range 16–50 MeV. They have been analyzed using the distorted-wave Born-approximation $E1$ and $E2$ virtual-photon spectra. Protons are emitted primarily following $E1$ absorption but α emission results from a combination of $E1$ and $E2$ absorption. The $E2$ isoscalar giant resonance decays predominantly by α emission for these nuclei.

The (e,p) and (e,α) cross sections for targets of ^{58}Ni, ^{60}Ni, and ^{62}Ni have been measured in the electron energy range 16–100 MeV. They have been analyzed using the distorted-wave Born approximation $E1$ and $E2$ virtual photon spectra. Protons are emitted primarily following $E1$ absorption but α-emission results from a combination of $E1$ and $E2$ absorption.

[NUCLEAR REACTIONS ^{58,60,62}Ni(e,p) and ^{58,60,62}Ni(e,α); measured $\sigma(E_0,E_x,48°)$, $\sigma(E_0,E_x,90°)$, $\sigma(E_0,E_x,132°)$; obtained $\sigma(e,p)$, $\sigma(e,\alpha)$; deduced $\sigma^{E1}_{\gamma,p}(E)$, $\sigma^{E1}_{\gamma,\alpha}(E)$, $\sigma^{E2}_{\gamma,\alpha}(E)$.]

(E,XP) VIRTUAL PHOTON G,XP

(E,XA) VIRTUAL PHOTON G,XA

1. Measurement also made at 100 MeV
2. Assumptions:
   For photons: $\frac{d\sigma}{dr}(\theta)$=constant

   For alphas:

$$\frac{d\sigma}{dr}(\theta)=\sigma(90°)[A(E_0)+B(E_0)\sin^2\theta]$$

$A(E_0)$, $B(E_0)$ determined empirically

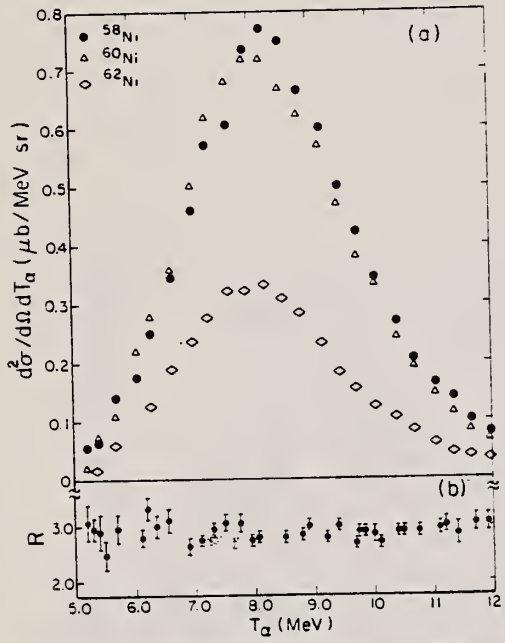

FIG. 2. (a) The α spectra $d^2\sigma/dT_\alpha d\Omega$ measured at 90° when 50 MeV electrons are incident on targets of ^{58}Ni, ^{60}Ni, and ^{62}Ni. (b) The ratio of the number of α particles produced by electro plus photodisintegration in ^{58}Ni to the number produced by electrodisintegration alone. This ratio was obtained by placing a 0.217 g/cm^2 Ta radiator in the beam ahead of the ^{58}Ni target.

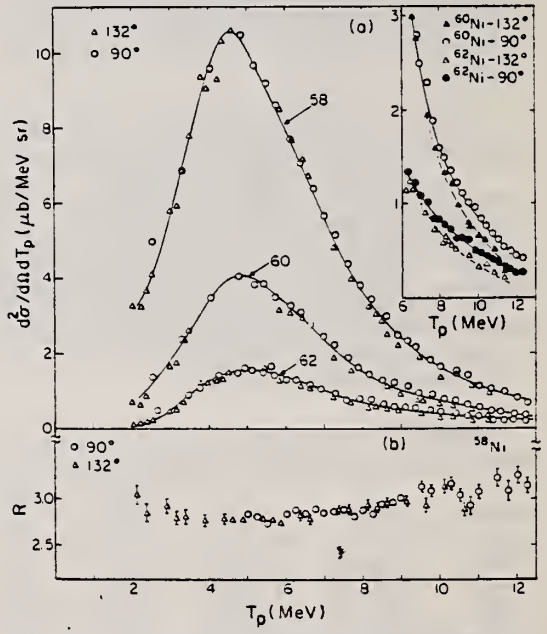

FIG. 3. (a) The proton spectra $d^2\sigma/dT_p d\Omega$ measured at 90° and 132° when 50 MeV electrons are incident on targets of ^{58}Ni, ^{60}Ni, and ^{62}Ni. The insert shows the tails of the energy spectra for ^{60}Ni and ^{62}Ni where the protons are slightly forward peaked. (b) The ratio of the number of protons produced by electro plus photodisintegration in ^{58}Ni to the number produced by electrodisintegration alone. This ratio was determined by placing a 0.217 g/cm^2 Ta radiator in the beam 7.6 cm ahead of the ^{58}Ni target.

Abstract. Lifetimes of 49 excited states below 1.65 MeV have been measured in ^{24}Mg, ^{27}Al, ^{48}Ti, ^{58}Ni, ^{59}Co, ^{61,62}Ni, ^{63,65}Cu, ^{64,66,68}Zn, ^{75}As, ^{103}Rh, ^{113,115}In, ^{116,118,120}Sn and ^{121,123}Sb by means of nuclear resonance fluorescence experiments. The levels are excited by bremsstrahlung x-ray photons. The self-absorption technique applied to suitable cases provides nuclear absorption cross sections, widths and lifetimes from which the x-ray spectral distributions are also obtained. Scattering experiments are performed for all other cases in order to obtain widths and lifetimes from these x-ray photon curves. The Compton effect in the sample is taken into account. Self-absorption provides $g\Gamma_0$ from which Γ is deduced using adopted J^π and Γ_0/Γ values; scattering provides $u = g(\Gamma_0^2/\Gamma)W(\theta)$ from which Γ is also deduced with J, Γ_0/Γ and mixing ratios taken from the literature. Thanks to simultaneous determination of the x-ray spectra all the lifetimes as given by our programs with their statistical errors form an unusually coherent set of values.

NUCLEAR REACTIONS (γ, γ'), bremsstrahlung excitation; natural isotopes; ^{24}Mg, ^{27}Al, ^{48}Ti, ^{58}Ni, ^{59}Co, ^{61,62}Ni, ^{63,65}Cu, ^{64,66,68}Zn, ^{75}As, ^{103}Rh, ^{113,115}In, ^{116,118,120}Sn and ^{121,123}Sb; $E \simeq 0.5$–1.65 MeV; measured $g\Gamma_0$ or $g(\Gamma_0^2/\Gamma)W(\theta)$; deduced $T_{1/2}$.

Remarque. Pour calculer δ^2 quand nous ne disposons que de $B(E2)$, pour un mélange (E2) + (M1), nous déduisons $g\Gamma_0(E2) \propto B(E2)E_\gamma^5$; en admettant $W(\theta)=1$ et connaissant Γ_0/Γ, notre détermination de u donne une première approximation de $g\Gamma_0$ d'où une valeur de $\delta^2=(g\Gamma_0(E2))/(g\Gamma_0-g\Gamma_0(E2))$ qui permet d'améliorer $W(\theta)$ et $g\Gamma_0$ de proche en proche.

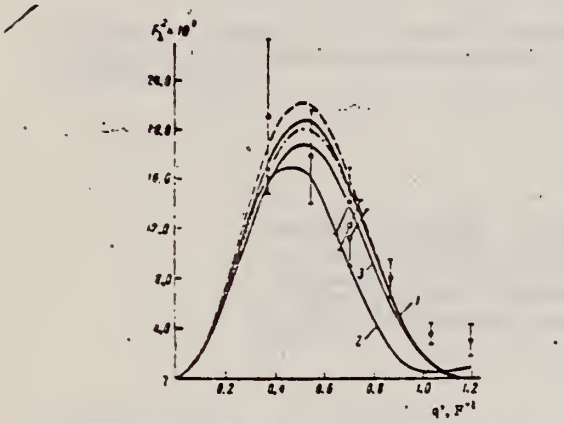

FIG. 2. Giant-resonance form factor as a function of momentum transfer. Points: O—data for Ni^{60}, X—for Ni^{64}, □—for Ni^{58}. The dashed curve, curve 1, and the dot-dash curve were calculated from formula (2) for the nuclei $Ni^{58,60,64}$ respectively, with k = 19 MeV. Curve 3 was calculated from the same formula for Ni^{60} with k = 21 MeV. Curve 2 is a calculation according to the Goldhaber-Teller collective model.

Table I. Absolute differential cross sections for inelastic scattering of electrons with excitation of the giant resonance in nickel isotopes

Nucleus	θ, deg	E_0, MeV	q, F^{-1}	q', F^{-1}	dσ/dΩ, cm^2/sr	f_0^2 (×10⁻³)
Ni^{58}	20	198.7	0.345	0.536	(2.02±0.70)·10⁻³⁰	2.11±0.63
	30	193.1	0.507	0.658	(3.79±0.81)·10⁻³⁰	1.78±0.38
	40	187.6	0.662	0.793	(4.50±1.05)·10⁻³⁰	1.12±0.23
	50	182.0	0.816	0.940	(2.54±0.50)·10⁻³⁰	0.80±0.15
	60	176.4	0.970	1.092	(1.49±1.03)·10⁻³¹	0.36±0.08

The yields of (γ, p) reactions on ^{62}Ni, ^{64}Ni, and ^{53}Cr are studied in ranges of $E_{\gamma max}$ near the respective thresholds. Considerable differences are found between the curve shapes, yields, and observed thresholds for the Ni isotopes and ^{53}Cr.

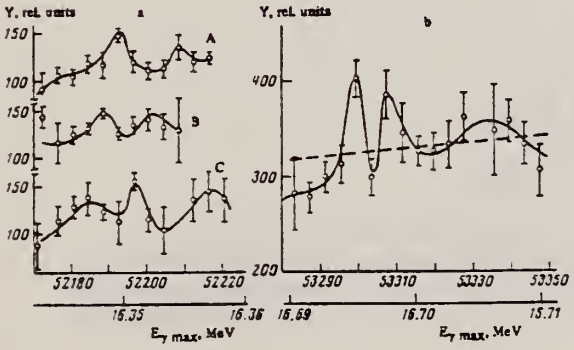

FIG. 5. Yield of ^{64}Ni(γ, p)^{63}Co in the region of E_γ max = 16.35 MeV (a); yield of ^{64}Ni(γ, p)^{63}Co in the region of E_γ max = 16.70 MeV (b).

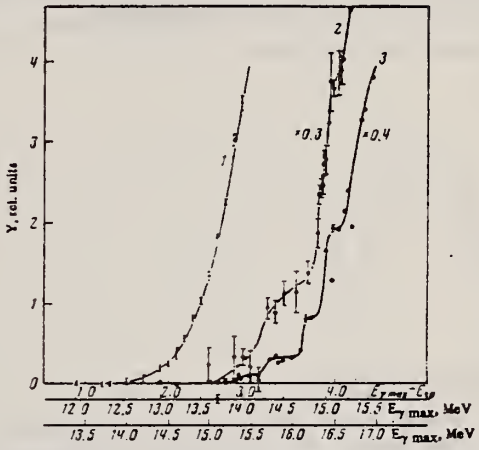

FIG. 3. Yields of the reactions ^{53}Cr(γ, p)^{52}V (curve 1), ^{64}Ni(γ, p)^{63}Co (curve 2), and ^{62}Ni(γ, p)^{61}Co (curve 3) as functions of E_γ max. Lowest scale for ^{64}Ni(γ, p); middle scale for ^{62}Ni(γ, p) and ^{53}Cr(γ, p).

New data are presented on the photodisintegration of the enriched isotopes ^{58}Ni and ^{64}Ni under bombardment by photons with maximum energy 4.5 GeV. The isotope effect in photonuclear reactions with formation of residual nuclei is investigated. The experimental yield values are compared with theoretical calculations by Rudstam's formula. In the results we observe a systematic shift of the experimental disintegration yields in comparison to the calculated values. An exponential dependence is found for the ratios of the yields of the residual nuclei from the ^{58}Ni target to the yields of the same nuclei from ^{64}Ni as a function of the third projection of the isotopic spin of the product nucleus, and an exponential dependence is found for the ratios of the experimental yield values to the theoretical values as a function of the difference of the third projections of the isotopic spins of the target nuclei and the residual nuclei.

# COPPER
Z=29

Copper was probably discovered about 8000 B.C. by Neolithic man during the late stone age. Crude hammers, knives, and other utensils were created from this malleable metal. The early age of copper had its greatest development in Egypt where records show that mining, extracting, and refining of copper ws done on the Sinai peninsula. Copper was produced extensively about 3000 B.C. on the island of Cyprus and supplied most of the Roman needs for the metal. The ore was known as *aes cyprium* (ore of cyprus), this was shortened to *cyprium* and later corrupted to *cuprum*. From this comes the English name copper.

YIELD DATA TABLE:

It should be noted that the yield of photoprotons of the energy considered rises smoothly with Z for the elements plotted in Fig. 3, and that starting already with Al, no direct proportionality to Z is observed on account of the effect of the Coulomb barrier. For illustration, we give the yields of photoprotons Y(γ, p) per proton in the nucleus for several elements in relative units (the error in these measurements was estimated to be ±10%):

	Li^6	Li^7	Be	C	Al	Cu
$Y(\gamma,p)$ =	1.49	1.57	1.5	1.31	1.00	0.56

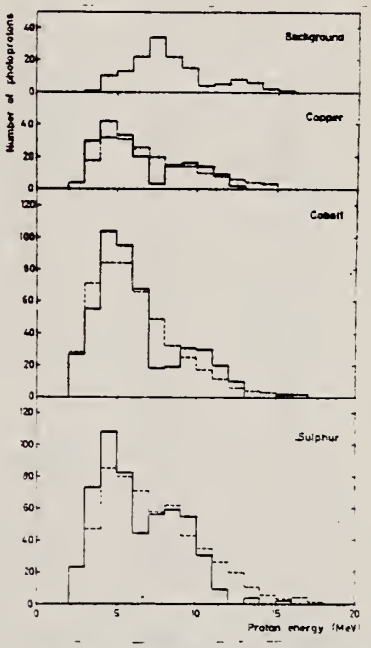

Figure 8: Energy distribution of the photoproton tracks giving intersection points in the area $-8.4 > x_t > -11.6$ and $-3.0 < x_t < 3.0$.

The lowest section shows the photoprotons from the sulphur exposure. The dashed line is the expected distribution from ref. 19 [Cujec-Dobovisek, Congr. Intern. de Phys. Nucleaire (1958) 634]. The second section shows the photoprotons from the colbalt exposure. The dashed line is the expected distribution from ref. 20 [Toms and Stephens, Phys. Rev. 95, 1209 (1954)]. The third section shows the photoprotons from the copper exposure. The dashed line is the expected distribution from ref. 21 [Lin'kova et al, Soviet JETP 38, 780 (1960)]. The background is subtracted in these 3 sections, but shown in the uppermost section. It originates from the entrance window.

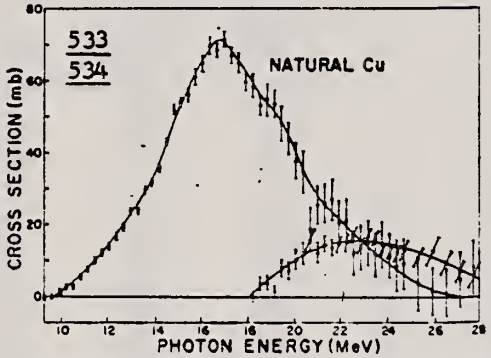

FIG. 2. Measured cross sections for (γ,n) and $(\gamma,2n)$ reactions on natural Cu. The top curve was obtained from single neutron counting data and consists of $\sigma(\gamma,n)+\sigma(\gamma,np)$. The lower curve consists of $\sigma(\gamma,2n)$ and was obtained from double-neutron counting data.

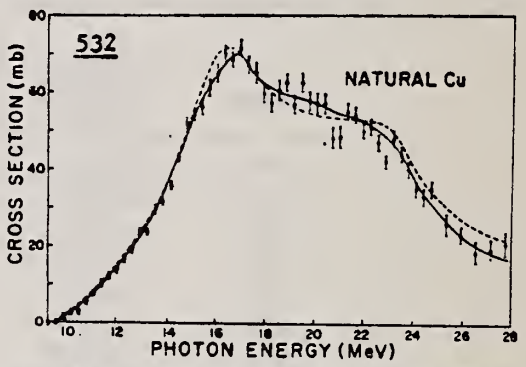

FIG. 1. Solid curve gives the average of data points of the total cross section $[\sigma(\gamma,n)+2\sigma(\gamma,2n)+\sigma(\gamma,np)]$ for natural Cu. The dashed line represents the total cross section given by the sum of the total cross sections measured for Cu^{63} and Cu^{65} and adjusted for isotopic abundances.

TABLE I. Integrated cross sections up to 28 MeV for copper isotopes.

Element	Reaction	Integrated cross section (MeV-mb)	Fraction of total integrated cross section	Total (MeV-mb)
Natural Cu	$(\gamma,n)+(\gamma,np)$	525±52	0.67	
	$(\gamma,2n)$	110±11	0.14	
	(γ,p)[a]	152±50	0.19	787±113

[a] High-energy component of a complex spectrum.
[b] A broad scattered spectrum with no observable peak structure.
[c] There are actually two lines of energies 7.647 and 7.633 MeV having equal intensities in the iron capture gamma spectrum. The cross section has therefore been corrected, although there is no possibility at present of deciding which line is responsible for each resonance.
[d] Is probably an independent level in the complex spectrum of Ni γ rays on Te.
[e] Rough estimate.
[f] May be inelastic component from 7.528 level in Te.
[g] The relative line intensities in this case are due to Groshev and co-workers.
[h] No line is known for the source at this energy.
[i] Difficult to resolve among the many source lines present at this energy.

22571 RESONANCE SCATTERING OF GAMMA RAYS BY COPPER. Tumbev, G. Khr. Compt. Rend. Acad. Bulg. Sci., 20: 541-3(1967). (In Russian).

Gamma rays from the capture of thermal neutrons can be used to investigate resonance scattering in the region of 6 to 9 MeV. The advantage of using monochromatic gamma rays for investigating resonance scattering is obvious in this case where excitation of only one level is to be expected. Resonance scattering by copper was observed with the use of TiO_2 having a weight of 1350 g as a source of gamma rays. Source and scatterer were natural isotopic mixtures. Resonance gamma rays having an energy E_{gamma} = 6.41 MeV showed an increased count rate due to nuclear resonance scattering of gamma rays from Ti on Cu. Control experiments were carried out with the source and without it. The cross-section for the gamma ray resonance scattering $\sigma_{\gamma\gamma}$ was determined from the count rates under the 6.41 MeV photopeaks at different reactor power levels for a 4 in. × 6 in. NaI(Tl) crystal. The value of $\sigma_{\gamma\gamma}$ was found to be 16.6 ± 3.4 mb. Since a natural mixture of copper isotope was used as the scattering agent, it was not possible to determine whether ^{62}Cu or ^{65}Cu scattered the 6.41-MeV gamma rays by resonance. (TTT)

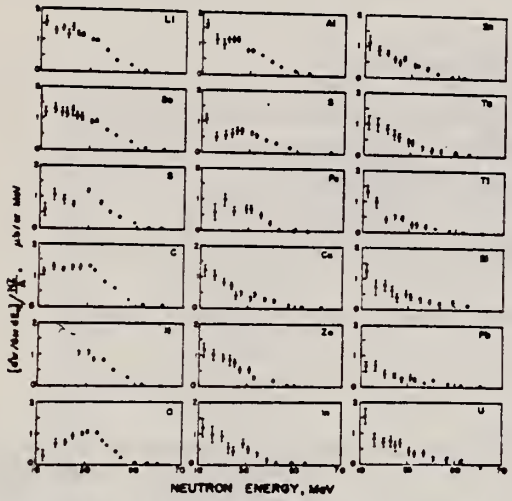

FIG. 6. Observed neutron spectra due to 55–85-MeV difference photon spectra. The effective cross sections have been divided by NZ/A.

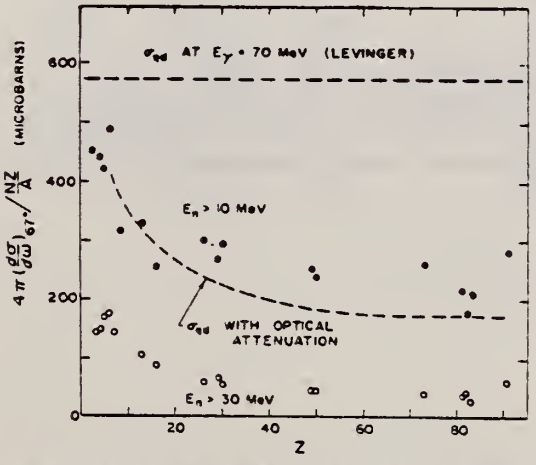

FIG. 7. Effective cross sections for production of fast neutrons with energies greater than 10 MeV (solid circles) and 30 MeV (open circles) by the 55–85-MeV photon difference spectrum. The dashed curves are modified quasideuteron model predictions as discussed in the text.

TABLE I. Comparison of present cross-section values in mb for production of high-energy photoneutrons by 55–85-MeV photons with measured cross sections $\sigma(\gamma,Tn)$, also in mb, for total photoneutron production. The present cross-section values are uncertain by 8 to 10% because of counting statistics and normalization errors; in addition all values depend on an absolute normalization in terms of the deuteron photodisintegration cross section, which is known to about 10% at these energies.

28260 PHOTONEUTRON REACTIONS ON COPPER. Ishkhanov, B. S.; Kapitonov, I. M.; Lazutin, E. V.; Piskarev, I. M.; Shevchenko, V. G. Vestn. Mosk. Univ., Ser. III. Fiz. Astron.; 11: 606-13(Nov-Dec 1970). (In Russian).

The structure of photoneutron differential cross section in copper was studied. The energy dependence of cross sections of photoneutron reactions on copper at excitation from the threshold to 30 MeV was determined. Theoretical and experimental data were compared. (R.V.J.)

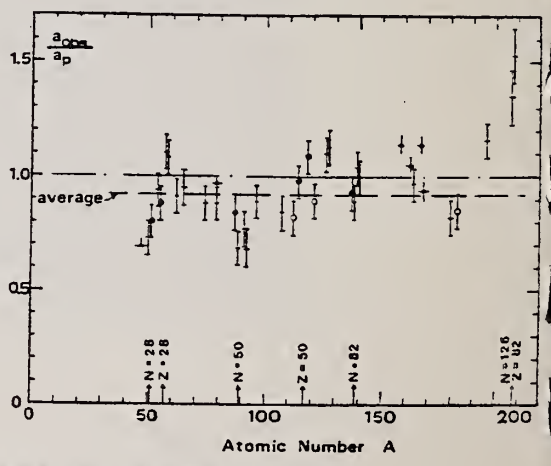

Fig. 15. Ratio a_{obs}/a_p versus atomic number A. Here a_{obs} is the level density parameter taken from the neutron resonance work of refs. [1,2]), and a_p is the level density parameter derived from the present (γ, n) work. Filled circles represent points where nuclei in the neutron resonance and in the (γ, n) experiment were the same. Open circles represent points where the respective nuclei were approximately matched. Triangles represent points which are based on measurement of neutron mean energies at two bremsstrahlung energies only.

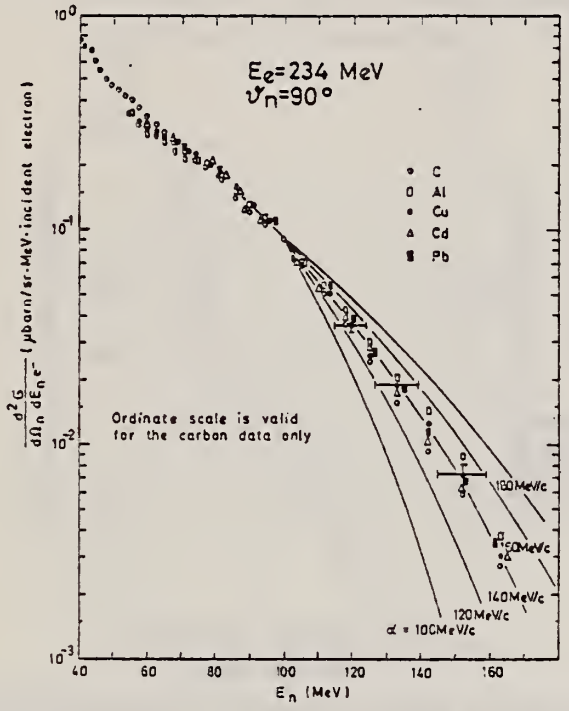

Fig. 8. Comparison of the shape of the high-energy part of the photoneutron spectra from C, Al, Cu, Cd and Pb. These measurements were performed with the same γ-shower spectrum, produced in a 0.3 cm thick lead sheet (see Fig. 2b). All spectra were fitted to the value for carbon at E_n=100 MeV. The values predicted by a quasi-deuteron model (solid lines), which are also fitted at E_n=100 MeV, were calculated with the parameters (defined in the text): E_b=−10 MeV, E_{well}=30 MeV and $C'L$=19.0 for different impulse parameters α=100, 120, 140, 160 and 180 MeV/c

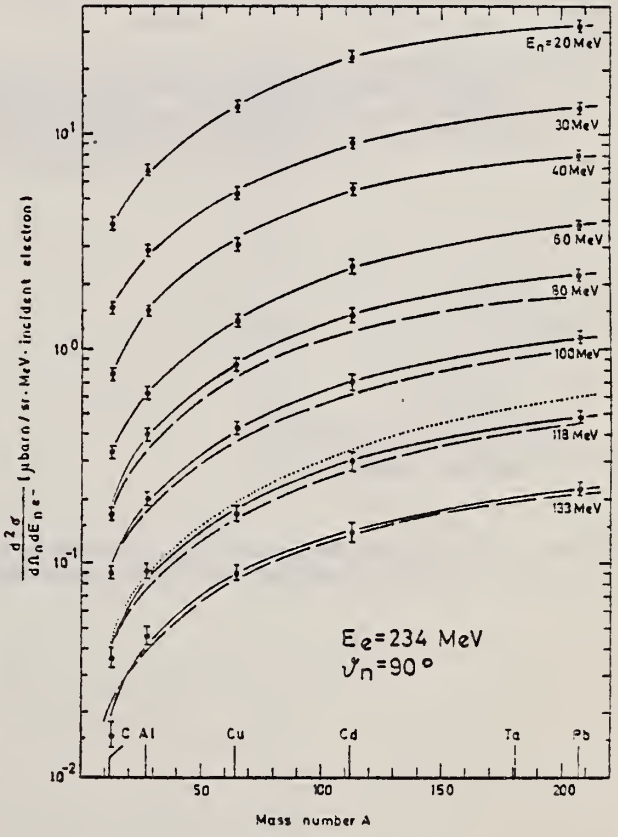

Fig. 9. Dependence of the production cross section on the mass number A with the neutron energy as parameter, measured at E_e=234 MeV. The γ-quanta were produced in a 0.3 cm thick lead sheet (see Fig. 2b) in front of the target of mass number A. The solid lines are fit curves through the measured values. The dashed lines are values calculated using a quasi-deuteron model with the parameters (defined in the text): E_b=−10 MeV, E_{well}=30 MeV, α=140 MeV/c and $C'L$=19.0. The dotted curve represents the dependence NZ/A, fitted at A=12. The error bars correspond to the statistical error

(over)

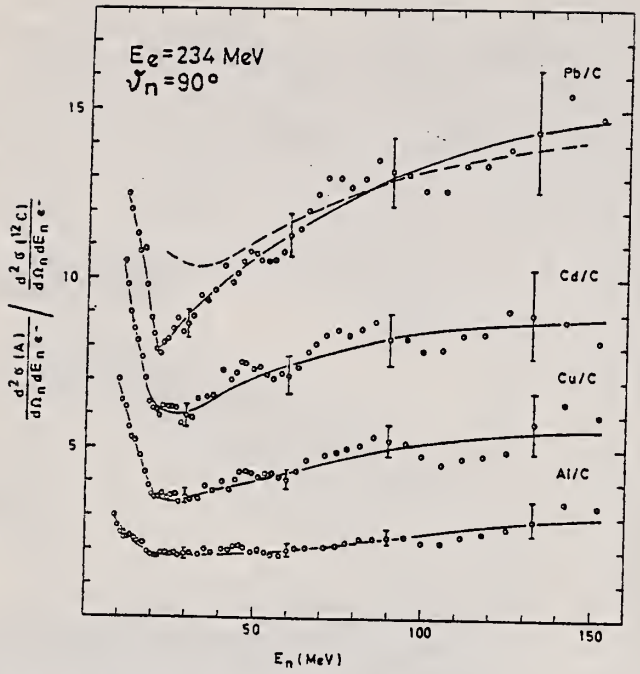

Fig. 10. Neutron yield from targets of mass number A relative to carbon, measured at $E_e = 234$ MeV. The target arrangement is that of Fig. 2b. The solid lines are fit curves through the experimental values. The dashed curve shows the energy dependence of the ratio of the nuclear absorption factors $f_a(\mathrm{Pb})/f_a(\mathrm{C})$, taken from Fig. 6. The error bars correspond to the statistical error

The induced-activity method has been used to study the ratio of the cross sections for photo- and electrodisintegration of nuclei for the reactions $^{27}Al \rightarrow ^{24}Na$ and $^{63,65}Cu \rightarrow ^{58}Co$ in the energy interval 300–1200 MeV. The results of the measurements are compared with calculations with various assumptions regarding the spectra of virtual and real photons.

Abstract: Yields and isomeric yield ratios of nuclei produced in the irradiation of ^{45}Sc and ^{nat}Cu with bremsstrahlung of E_γ^{max} = 2 GeV have been measured by the activation method. The experimental yields are compared to predictions with a Rudstam formula modified to photonuclear reactions.

*GEV,J=1-10,K=1-19

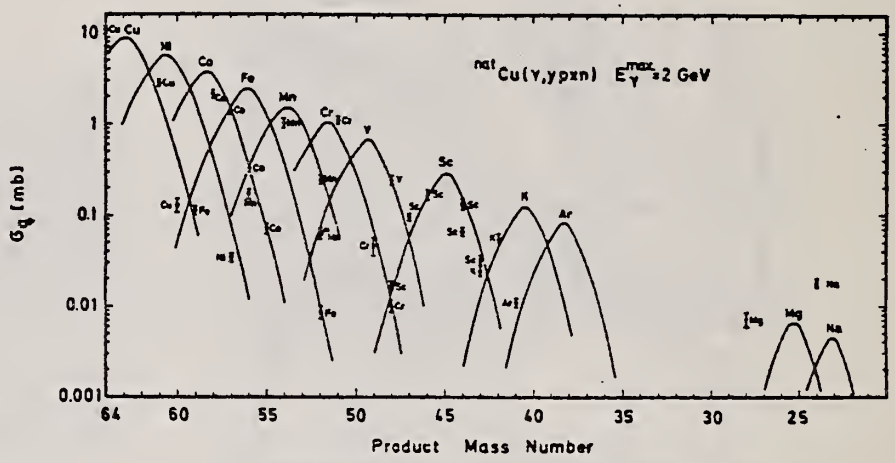

Fig. 2. Yields of nuclei produced in the irradiation of ^{nat}Cu with bremsstrahlung of E_γ^{max} = 2 GeV. The curves are calculated with eq. (1).

We discuss data concerning the ratios of the yields of different isomeric states in the elements ^{44}Sc and ^{52}Mn. Experimental results are presented for measurement of the yields of ^{44g,m}Sc and ^{52g,m}Mn in disintegration of targets of ^{51}V, ^{55}Mn, and Cu by photons with energies from 2 to 5 GeV; theoretical values of yields for these elements were obtained by means of the five-parameter Rudstam formula. The pattern of formation of high-spin states in photodisintegration reactions is discussed in terms of the cascade-evaporative model.

Abstract: The photoproduction of charged pions in the sub GeV region has been studied for two nuclear targets, copper and lead, by using a magnetic spectrometer. The photon energies are determined in steps of 50 MeV by a subtraction method for the bremsstrahlung spectrum. The observed pion momentum spectra reveal characteristic features of quasi-free production (QFP) even for such heavy nuclei as copper and lead. The data are compared with results obtained by a PWIA calculation, which give a good fit to the data. The QFP cross sections per relevant nucleon at 44.2° and the average photon energy (k) = 668 MeV are found to be approximately proportional to $A^{-1/3}$.

*AVG PHOTON ENERGY

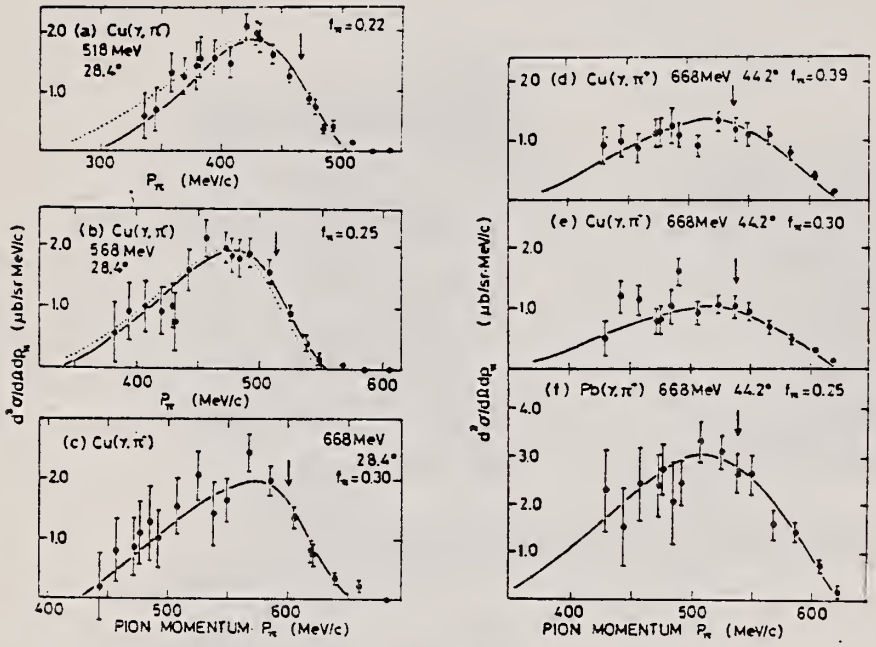

Fig. 1. Typical examples of the measured pion spectra. Errors are statistical only. The solid curves are $f_\pi \times$ (PWIA calculation) with parameter values $p_F = 270$ MeV/c, $\varepsilon = 25$ MeV and f_π being shown in the figure. The dotted curves in (a) and (b) correspond to the cases in which $p_F = 300$ MeV/c while ε is unchanged, and $\varepsilon = 35$ MeV while p_F is unchanged, respectively. Arrows denote the values of the pion momentum, p_{free}, which is calculated from the assumption that the target nucleon is free and at rest.

over

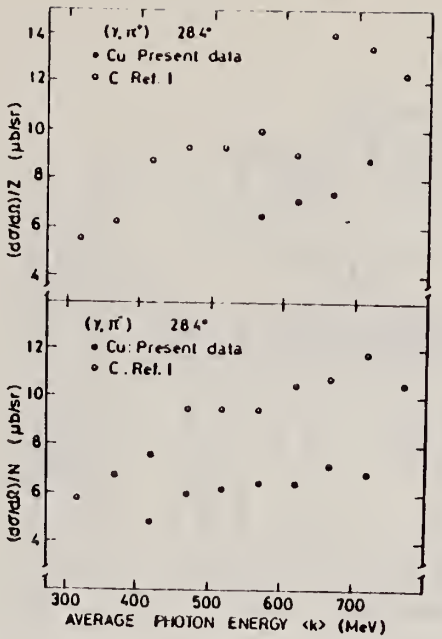

Fig. 3. The QFP cross section at $\theta_\pi = 28.4°$ for copper as a function of $\langle k \rangle$. Note that the plotted values are those divided by the proton (neutron) number Z (N) for π^+ (π^-), together with the same quantities for carbon taken from I for comparison. Errors of the order of 10% due to fitting uncertainty are not shown.

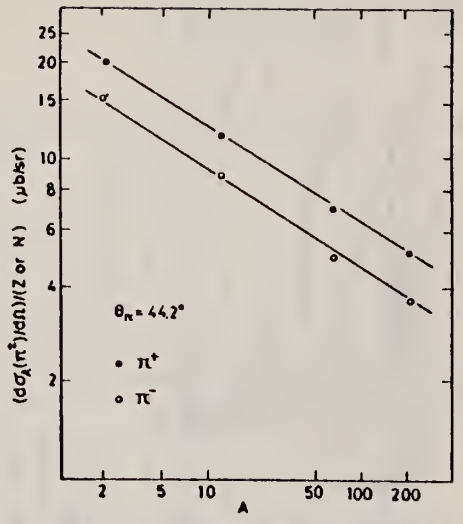

Fig. 4. The QFP cross section at $\theta_\pi = 44.2°$ and $\langle k \rangle = 668$ MeV as a function of the mass number A. The π^- (π^-) cross section is divided by Z (N). Errors of the order of 10% due to fitting uncertainty are not shown. Data points at $A = 2$ are taken from ref. [3]). The solid lines are:

$$\frac{d\sigma_A(\pi^+)}{d\Omega}\frac{1}{Z} = 24.3A^{-0.3}, \quad \text{and} \quad \frac{d\sigma_A(\pi^-)}{d\Omega}\frac{1}{N} = 18.4A^{-0.3},$$

in units of μb/sr.

QFP = QUASI-FREE PRODUCTION

TABLE 2

The energy and angular distributions of p, d, t, ^{3}He and ^{4}He from the three targets Cu, Ag and Au were measured at five different angles for bremsstrahlung with peak energy 500 MeV. The measurements were made using a telescope consisting of four surface-barrier detectors. The experimental data are compared with cascade-evaporation calculations. For the ^{4}He-distributions the calculations were extended to include the contribution from knock-out of surface alphas by the cascade nucleons. The comparison shows that the main contribution comes from evaporation but that there is a direct component of the order of 10%.

DATA ALSO IN 81AR3

Double differential cross sections for the photo-emission of protons and charged pion production were investigated for a number of target nuclei (He, Be, C, O, Al, Ti, Cu, Sn, Pb) in the photon energy range k = (215–386) MeV. On the basis of these experimental results the total hadronic cross section was determined.

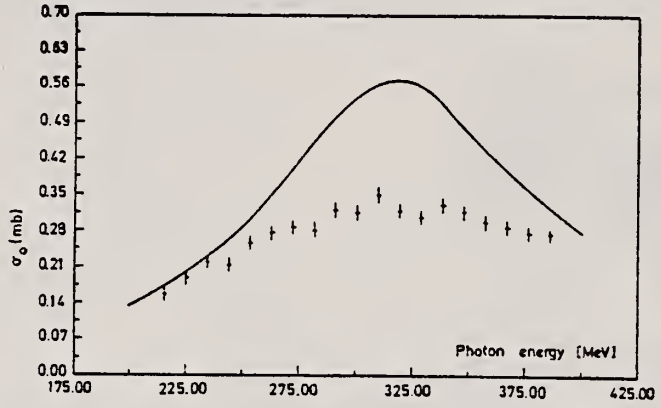

Fig. 7. Parameter σ_0 as a function of photon energy (data points) compared to the mean cross section for a free nucleon (solid line).

The total hadronic cross sections for all measured elements can be parametrized in the form

$$\sigma(k,A) = \sigma_0(k) \cdot A^x ,$$

A being the atomic number, with a constant exponent x = 1.1. The photon energy dependence of σ_0 is shown in fig. 7. Compared to the mean cross section for a free nucleon (the solid line in fig. 7) the excitation of the Δ-resonance is suppressed. Such a suppression is expected in the Δ-hole model [11].

Abstract: Double differential cross sections for the photoemission of protons and charged pion photoproduction were investigated for a number of target nuclei (He, Be, C, O, Al, Ti, Cu, Sn, Pb) using the tagged bremsstrahlung beam at the Bonn 500 MeV-Synchrotron in the photon range k = (215-386)MeV. On the basis of these experimental results the total hadronic cross section was determined.

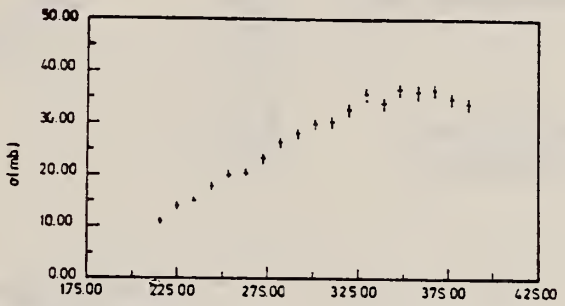

Fig. 2. Cross section for the process: γ + Pb → p + X. The proton threshold is 58 MeV.

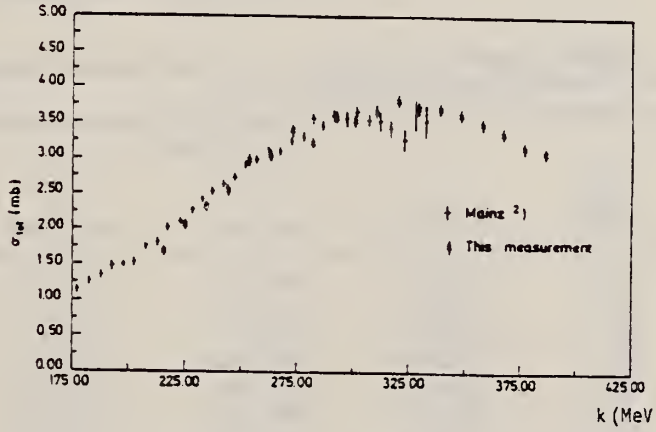

Fig. 3. Total hadronic cross section for Be. The data are compared to the cross section taken from ref.[2]).

The photon energy dependence of the total cross sections for heavier nuclei are similar to the Be results. The complete data set can be parametrized in the form

$$\sigma(k,A) = \sigma_0(k) \cdot A^x.$$

The exponent is constant x = 1.1. The photon energy dependence of σ_0 is shown in fig. 4. Compared to the mean cross section for a free nucleon, the excitation of the Δ-resonance is suppressed.

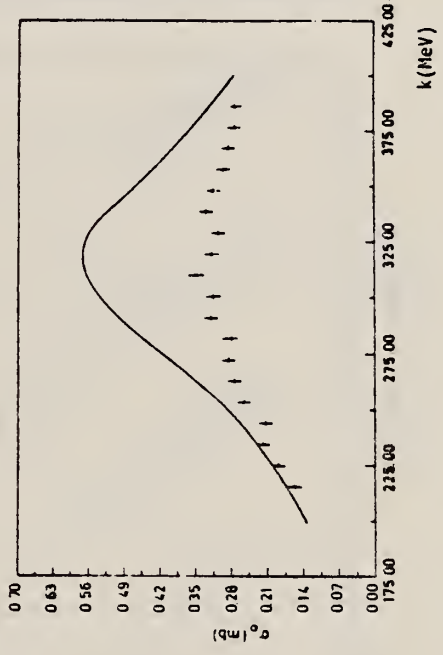

Fig. 4. Parameter σ_0 compared to the cross section for a free nucleon (full line).

Inclusive photoproton cross sections for the reaction Cu(γ,p)X have been measured for a photon energy of 300 MeV at proton angles 45°, 90°, and 135°, and for 150 MeV at 45°. The data are compared with an intranuclear-cascade calculation and with Ni($\pi^{\pm}$,p) data. The angular distribution is analyzed to obtain an estimate of the number of nucleons involved in the interaction.

[NUCLEAR REACTIONS Cu(γ,p)X, E=150 MeV, θ=45°, E=300 MeV, θ=45°, 90°, 135°; measured $\sigma(E_p,\theta)$; intranuclear cascade analysis.]

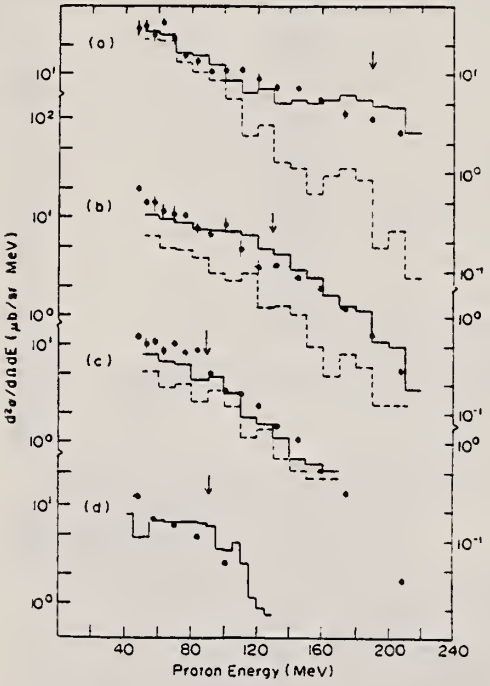

FIG. 2. Cu(γ,p)X cross sections: (a) 300 MeV, 45°; (b) 300 MeV, 90°; (c) 300 MeV, 135°; (d) 150 MeV, 45°. Only statistical errors are shown. Also plotted are the results of a cascade calculation where the solid lines represent the total yield, and the dashed lines the yield due to quasifree pion production only. The arrows indicate the proton energies expected for free deuteron photodisintegration kinematics.

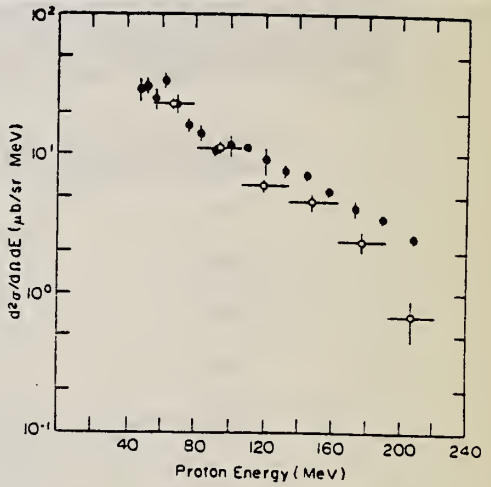

FIG. 3. Comparison of the present data at 300 MeV, 45° (closed circles) with Bonn Cu(γ,p)X data (Ref. 26) for E_γ=291 MeV, 44° (open circles).

A study is reported of the γ-decay of analog resonances in the $^{58}Ni(p\gamma)^{59}Cu$ reaction. The following analogs of the excited states of ^{59}Ni were observed: 0.466, 0.878, and 1303 keV. The quantities μ_γ and the values of B(M1) have been determined for transitions from the analogs to the ^{59}Cu levels. Analog β and γ-transitions are compared, and analog-antianalog transitions are analyzed.

We measured the γ spectra of the resonance decay in the reaction $^{60}Ni(p, \gamma)^{61}Cu$ at proton energies E_p = 1588, 1599, 1605, and 1620 keV. These resonances are identified as the components of the fine structure of the analog state $p_{3/2}$. The intensities of the population of the state of ^{61}Cu with excitation energy up to 3 MeV are obtained. The decay scheme of these states is constructed. Comparison with beta decay points to the need for taking into account the l part in the operator of the $M1$ γ transition when assessing the role of the polarization effects in the γ decay of isobar analog resonances. The analog-antianalog transition is slowed down by an approximate factor 10 compared with the single-particle estimate.

Ref. J.G. Campbell
Australian J. Phys. 8, 445 (1955)

Elem. Sym.	A	Z
Cu	63	29

Method: $Li^7(p,\gamma)$ reaction; 700 keV electrostatic generator; radioactivity

Ref. No.: 55 Ca 1 | EGF

Reaction	E or ΔE	E_o	Γ	$\int \sigma dE$	Jπ	Notes
$Cu^{63}(\gamma,n)$	~ 350 - 700 keV	17.5 - ~ 17.85				

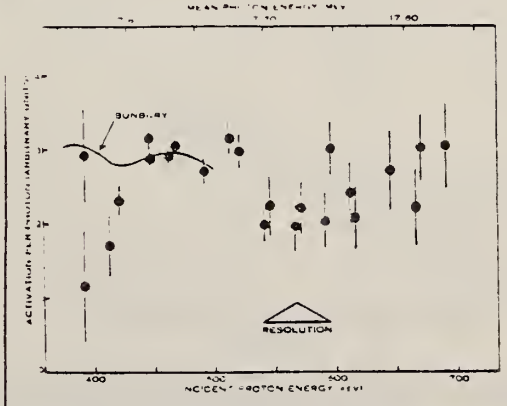

Fig. 2. A set of results for [illegible]. Also shown are results of Burcham (1954)

Ref. M.B. Scott, A.O. Hanson, D.W. Kerst
Phys. Rev. 100, 209 (1955)

Elem. Sym.	A	Z
Cu	63	29

Method Monoergic electrons from 22 MeV Betatron.

Ref. No.	
55 Sc 1	EGF

Reaction	E or ΔE	E_o	Γ	$\int \sigma dE$	Jπ	Notes
(γ,n)	12-20	16.8	4.5	0.41 MeV-mb		σ_{max} = 80 mb. Errors estimated to be 25%.

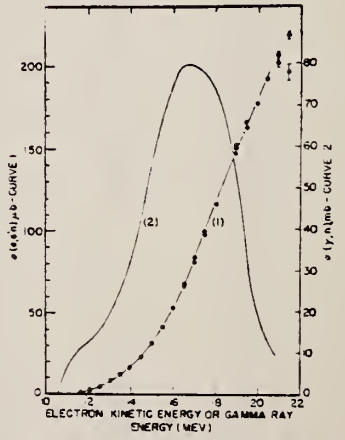

FIG. 5. The electrodisintegration activity as a function of the kinetic energy of the electron, normalized so as to represent the electrodisintegration cross section, is shown as curve 1. The statistical errors are less than the size of the points except where they are shown. The photodisintegration activity is proportional to the product of curve 1 by F as given in Fig. 4. The (γ,n) cross section as obtained from this product by the photon difference method is shown as curve 2.

Ref. R.L. Hines
Phys. Rev. 105, 1534 (1957)

Elem. Sym.	A	Z
Cu	63	29

Method: Michigan University synchrotron; Victoreen counter; betatron 10.1 min.

Ref. No.: 57 Hi 1 | EGF

Reaction	E or ΔE	E_o	Γ	$\int \sigma dE$	Jπ	Notes
(e,e'n)	29.5 46.5 63.5 81.5	16 .				97% electric dipole and 3% electric quadrupole required to fit experimental points. No corrections made for nuclear signs; these would tend to increase fraction of E_2. $Cu^{63}(\gamma,n)\ Cu^{62}$ cross section from Katz and Cameron [Can. J. Phys. 29, 518 (1951)].

Elem. Sym.	A	Z
Cu	63	29

Method: $Li^7(p,\gamma)$ rays; GH counter; BF_3; 4π neutron

Ref. No.: 59 Na 1 | EH

Reaction	E or ΔE	E_o	Γ	$\int \sigma dE$	Jπ	Notes
$Cu^{63}(\gamma,n)$	Bremss. 17.6					σ = 42.5 ±15% mb The ratio 1:2 was used as the intensity ratio of 14.8 to 17.6 MeV photons and the results of betatron experiments to make the correction. The incident flux was determined by calculating how many electrons should be ejected per photon from a metal foil placed in front of a geiger counter.

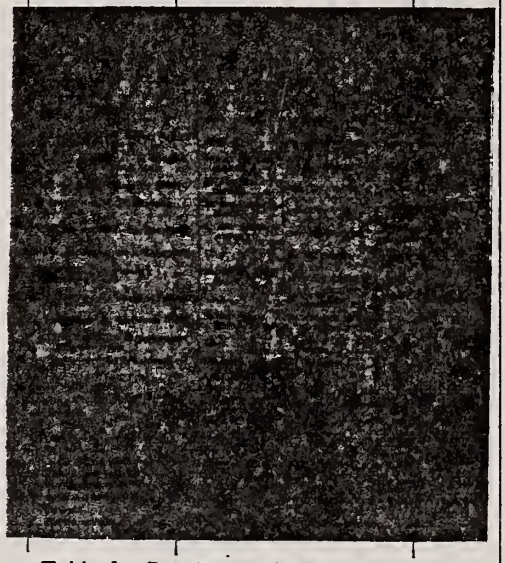

Table I. Results obtained.

Reaction	λ (min⁻¹)	σ(Li-pγ) (mb)	σ(17.6 Mev)** (mb)
$Cu^{63}(\gamma, n)Cu^{62}$	0.0695*±2%	37.7±15%	42.5
$Zn^{64}(\gamma, n)Zn^{63}$	0.018	20.7±18%	23.3
$Ag^{109}(\gamma, n)Ag^{108}$	0.295	54.6±16%	61.5

* The decay constant of Cu^{62} was determined in our measurement.

** For the reduction to 17.6 Mev monochromatic γ-ray, we used the ratio 1:2 as the intensity ratio of 14.8 Mev to 17.6 Mev γ-ray, and the results of bremsstrahlung experiments as the excitation curve for each elements.

REL TO PROTONS

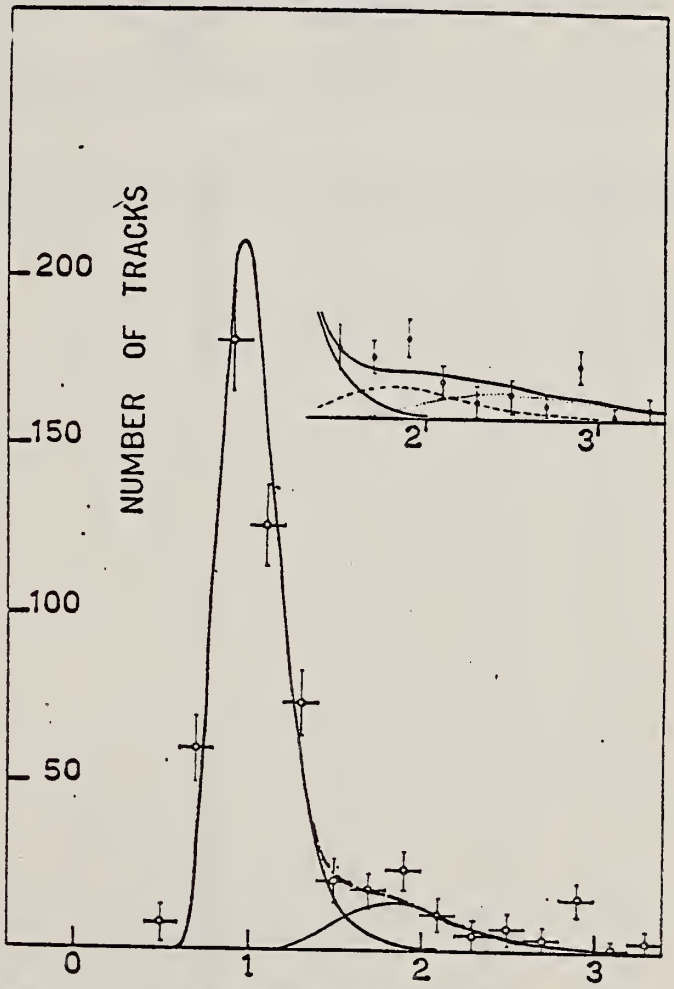

Fig. 6 — Total mass histogram for the plates exposed in positions nºs 1, 2, 8 and 9. The full lines give the calculated shapes of the proton and deuteron peaks, normalized respectively to 460 and 65 tracks; the dot-dashed line is the sum of the two peaks. In the inset the same experimental data is shown, but the deuteron curve is normalized to 42 tracks, while the dotted line corresponds to 44 alpha particles; the dot-dashed line is the sum of the three peaks.

Reaction	E or ΔE	E_o	Γ	$\int \sigma dE$	Jπ	Notes
$Cu^{63}(\gamma,\gamma)$	0.92-1.0	0.961 ±0.003				Lifetime of 0.961 MeV level = $6X10^{-13}$ sec ± factor of 2. Detector at 90°.

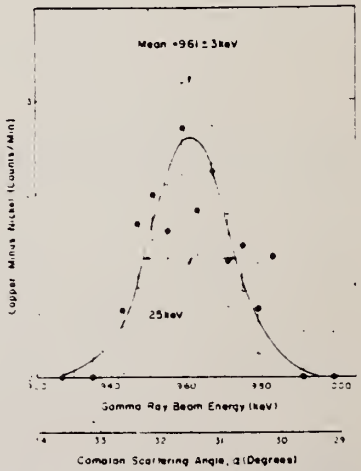

Fig. 2 The difference in counting rate of the NaI(Tl) counter for elastic scattering from the copper and nickel targets is plotted against the Compton scattering angle. The second abscissa scale gives the energy of the γ-rays striking the target corresponding to each angle. Each point represents four hours of counting with the copper target and four hours of counting with the nickel target.

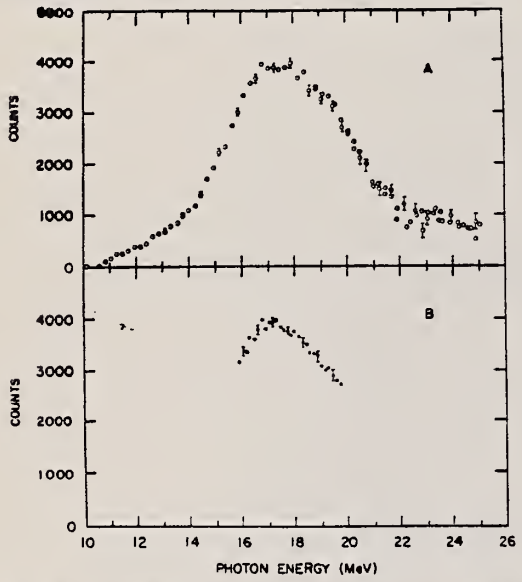

FIG. 8. (A) The $^{63}Cu(\gamma,n)$ yield versus annihilation γ-ray energy for 2% γ-ray resolution. This yield is the difference between the positron and electron data shown in Fig. 7. (B) The $^{63}Cu(\gamma,n)$ yield versus annihilation γ-ray energy for 1.5% γ-ray resolution. These data were approximately normalized to the data in Fig. 8(A).

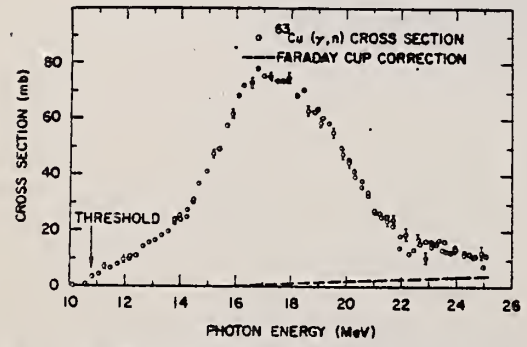

FIG. 9. The $^{63}Cu(\gamma,n)$ cross section versus photon energy for 2% γ-ray resolution. The data shown were corrected for the emission of secondary electrons from the Faraday cup, and the magnitude of this correction is also shown. See text for discussion of errors.

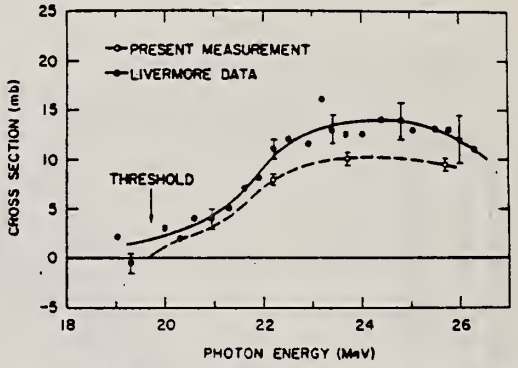

FIG. 12. The $^{63}Cu(\gamma,2n)$ cross section from the present measurement and from the measurement by Fultz *et al.* at Livermore (Ref. 5). The latter data were shifted upward in energy by 2.7% as explained in the caption of Fig. 11. The error bars include only the statistical uncertainties in the yield measurements. See text for a discussion of the errors. The dashed curve through the present data was used in the integration and is drawn on the basis of the data points, the threshold energy, and the shape of the Livermore data.

TABLE I. $^{63}Cu(\gamma,2n)$ cross sections. See text for a discussion of errors.

γ-ray energy (MeV)	Cross section (mb)
22.2	8.0±0.5
23.7	10.0±0.5
25.7	9.3±0.5

TABLE II. Integrated photoreaction cross sections of ^{63}Cu up to 25 MeV.

Experiment	Reaction	Integrated cross section (MeV mb)	Total (MeV mb)
Present	(γ,n)	490±40	
	$(\gamma,2n)$	36±12[a]	
	(γ,pn)	60±15[b]	586±67
Fultz *et al.*	$(\gamma,n)+(\gamma,pn)$	515±52[c]	
	$(\gamma,2n)$	48± 5[d]	563±57

[a] Based on the dashed curve in Fig. 12.
[b] Derived from (γ,n) data of present work and $[(\gamma,n)+(\gamma,pn)]$ data of Fultz *et al.* (Ref. 5).
[c] Energy scale of these data (Ref. 5) shifted by the factor 1.027. Without the shift the result is 511±51.
[d] Energy scale of these data (Ref. 5) shifted by the factor 1.027. Without the shift the result is 56±6.

Summary

The cross-sections of the (γ, p) (γ, d) reactions were investigated. Li^7, Be^9, C^{12}, Si^{28}, Cu^{63}, Mo^{96} and Ta^{181} targets were irradiated with the bremsstrahlung of 700 and 1200 MeV maximum energy from the Kharkov PhTI Ac. Sci. UkrSSR linear accelerator. The photoprotons and deuterons were detected by the scintillation telescope at 30°, 60°, and 120° with the beam. Possible mechanisms of the proton and deuteron photoproduction are discussed. The qualitative agreement of *A* dependence of the cross-sections is observed with a suggestion on the meson mechanism for these reactions.

Abstract: The ^{62}Ni(p, p), (p, p'γ) and (p, γ) reactions were studied in the vicinity of the $\frac{3}{2}^-$ fragmented analogue of the first excited state of ^{63}Ni. The overall proton energy resolution was about 300 eV. The γ-rays were detected with both NaI(Tl) and Ge(Li) detectors. Elastic and inelastic proton widths and partial and total γ-ray widths were measured for each of the fourteen fine structure states of the analogue. Statistically significant correlations were observed between the elastic proton widths, the inelastic proton widths and the total γ-ray widths.

E NUCLEAR REACTION ^{62}Ni(p, p), (p, p'γ), (p, γ); E = 2.3-2.7 MeV, measured $\sigma(E)$, ^{63}Cu isobaric analogue resonance, J, π, Γ, Γ_p, $\Gamma_{p'}$, Γ_{γ_f} for fine structure resonances.

[a]) Resonant energy for resonances which are very close to another resonance observed in the capture excitation function.

[b]) The j-value assignment is tentative for resonances with elastic widths $\leqq 10$ eV.

[c]) The estimated uncertainty in the γ-ray widths is 30 % for widths greater than 50 meV, 50 % for widths between 10 and 50 meV, and 100 % for widths less than 10 meV. The limit of observability for the γ-ray widths is about 5 meV.

[d]) These strengths are calculated assuming that the transition is either pure M1 or E2. If the spin and parity of the final state is unknown, then no entry is shown.

24 LEV 1.32-4.51 MEV

The properties of levels in ^{63}Cu and ^{65}Cu have been investigated using the resonance fluorescence technique with bremsstrahlung serving as the source of exciting radiation. The energies and scattering cross sections for 24 levels in ^{63}Cu and 30 levels in ^{65}Cu up to about 4.5 MeV were measured. A few levels known to exist in the region of 2 MeV for both nuclei were not observed. For a number of the lower lying levels, spin and parity assignments have been made through angular distribution measurements and limits on J^π set by others. Mixing ratios for a few of these are also given. Where J^π and the ground state branching ratios are known the partial widths for decays to the ground state are presented. Comparisons are made with the predictions of the latest theoretical calculations.

COMMENTS: $f \sim \exp(-Bp^2)$

$B = \dfrac{E}{p^4(d^2\sigma/d\Omega dpQ)}$

*E,GEV, 999=4.5 GEV

The A^n-dependence and momentum spectra of photoprotons in the nuclei ^{12}C, ^{27}Al, ^{63}Cu, ^{118}Sn, and ^{208}Pb have been studied experimentally for maximum bremsstrahlung energies of 2.0, 3.0, and 4.5 GeV. The A-dependence shows that the proton photoproduction mechanism for $E_\gamma > 400$ MeV is identical for the entire kinetic-energy region 65–280 MeV and the angle region 45–150° for the secondary protons studied. The dependence of the exponent n on the transverse momentum $p_\perp$ is in good agreement with the same dependence for protons produced in nuclei by primary protons. In the momentum spectra of the invariant cross section $f = (E/p^2)(d^2\sigma/d\Omega\, dpQ) \sim \exp(-Bp^2)$ it is observed that the parameter B does not depend on the incident-photon energy and on the target nucleus, but depends on the proton-detection angle.

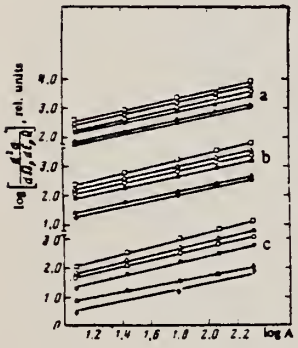

FIG. 1. Differential cross section for proton photoproduction as a function of atomic number A of the nucleus at $E_0 = 2$ GeV. The lines a correspond to $\vartheta_p = 60°$, b to 90; and c to 150°. Points: □—$E_p = 64$, △—80, ○—101, ■—137, ▲—209, and ●—280 MeV.

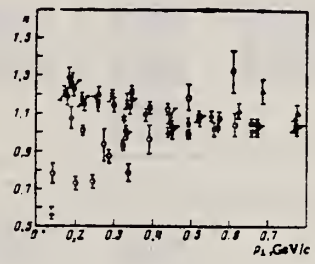

FIG. 3. The same as Fig. 2. Experimental points: ▲—$E_0 = 0.13$, ○—0.25, △—0.4, □—1.2, ▫—2.0, ×—3.0, and ●—4.5 GeV.

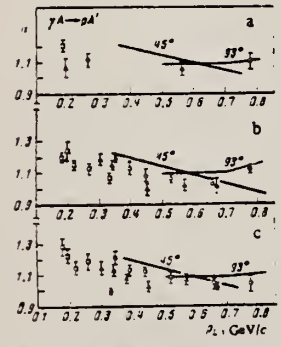

FIG. 2. Dependence of the exponent n in the A^n dependence of the cross section for the reaction $\gamma A \to pA'$ as a function of proton transverse momentum: a—$E_0 = 2.0$ GeV, b—$E_0 = 3.0$ GeV, c—$E_0 = 4.5$ GeV. The points for a and b: △—$\vartheta_p = 60°$, ○—90°, □—150°; for c: △—$\vartheta_p = 46°$, ○—86°, □—136°. The curves show the dependence of n on $p_\perp$ for the reaction $A(p, p')A'$ taken from Ref. 9.

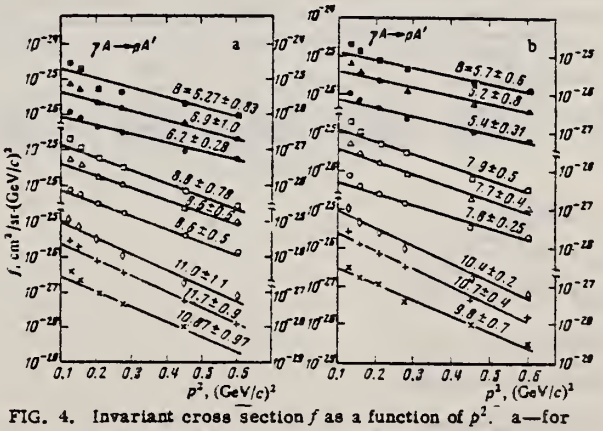

FIG. 4. Invariant cross section f as a function of p^2. a—for $E_0 = 2.0$ GeV, b—for $E_0 = 3.0$ GeV. Experimental points: ●, ▲, ■—for $\vartheta_p = 60°$ for the respective nuclei ^{12}C, ^{63}Cu, and ^{208}Pb; ○, △, □—the same for $\vartheta_p = 90°$; ×, +, ◇—the same for $\vartheta_p = 150°$.

Measurements are reported of the angular distributions of γ-rays due to transitions from the analog resonances corresponding to the ground and the first and second excited states of ^{63}Ni to the levels of ^{63}Cu. The spins of the following resonances have been determined: 8743 keV (3/2) and 8640 keV (5/2).

The total cross section of hadron photoproduction on C, Cu and Pb nuclei is measured for six energy values in the range 12–30 GeV. The obtained cross-section values for C and Cu nuclei have a weak energy dependence at high energies (above 20 GeV). The cross section for the Pb nucleus is somewhat higher in comparison with that expected, and energy dependence is not observed. The A-dependence of the effective number of hadrons agrees with VDM predictions.

*Energy in GeV

Analysis is made of reactions interfering with photon activation analysis procedures.

The activation yield curves have been presented for a number of photonuclear reactions in the energy range from 30 to 68 MeV, in order to evaluate quantitatively the interferences due to competing reactions in multielement photon activation analysis. The general features of the yields as functions of both target mass number and excitation energy were elucidated from the data obtained, discussion being given on the results in terms of the reaction mechanism.

Simultaneous neutron activation due to appreciable neutron production from the converter and surrounding materials has also been studied, and, finally, the magnitudes of interferences in real multielement analysis were given in the form of their energy dependences.

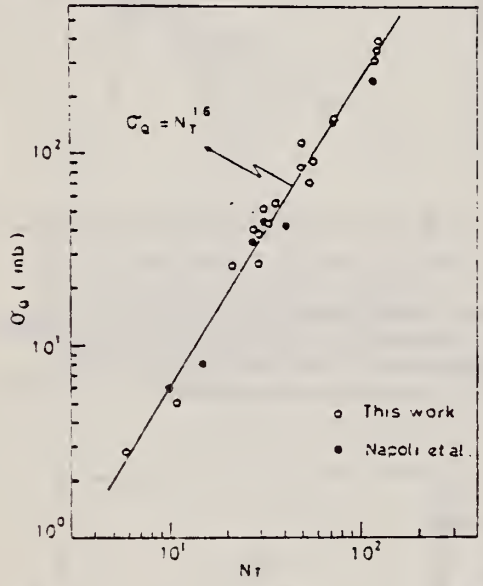

Fig. 2. Yield per equivalent quanta versus target neutron number.

α particles from the electrodisintegration of seven nuclei with Z between 29 and 79 have been observed. Energy spectra at 50° in the laboratory for six nuclei and angular distributions for five nuclei are reported. The cross sections exhibit a broad peak whose magnitude decreases with increasing Z; the energy of the peak increases as Z increases. Angular distributions at the highest energies measured become increasingly forward peaked suggesting a direct-reaction process.

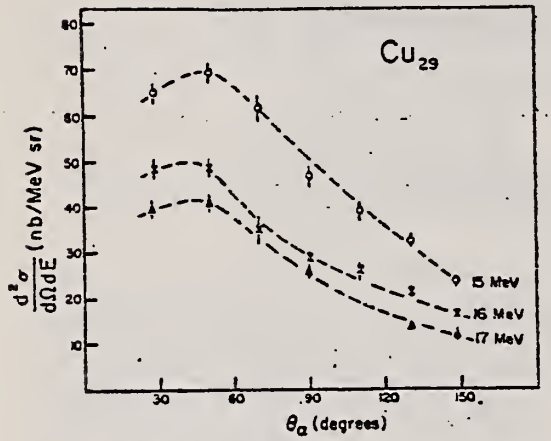

FIG. 1. High energy angular distributions for copper (Z=29). The expected forward peaking due to the importance of the direct process is seen.

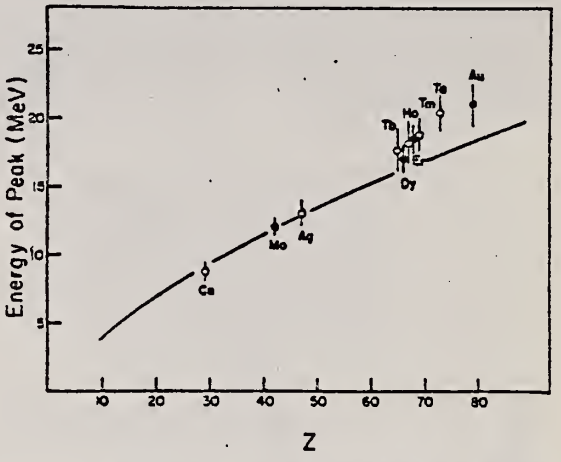

FIG. 3. Energy of the cross section peak as a function of Z. The solid line is the energy of the classical Coulomb barrier. The closed circles are the current work; the open circles are from Ref. 1.

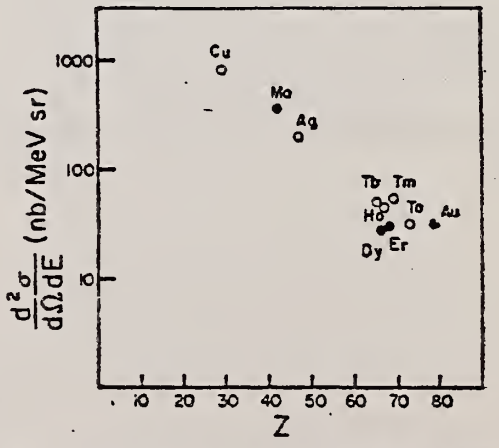

FIG. 4. Magnitude of cross section peak as a function of Z. The closed circles are the current work; the open circles are from Ref. 1.

A beam of quasimonochromatic photons at energy 12–25 MeV has been utilized to measure the cross section for the $^{63}Cu(\gamma,n)$ reaction by detecting the induced beta activity with a two-crystal scintillation gamma spectrometer. The results are in good agreement with Ref. 12 and differ appreciably from other data obtained in bremsstrahlung beams.

The reactions $^{12}C \rightarrow {}^{11}C$ and $^{63}Cu \rightarrow {}^{62}Cu$ have been studied by the induced-activity method at electron and photon energies from 0.32 to 1.2 GeV. Activation of the targets was carried out directly by an electron beam. The use of targets in the form of stacks permitted cross sections to be obtained for photodisintegration and electrodisintegration of the nuclei. Comparison of the experiment with theoretical calculations in the plane-wave approximation indicates a dominant role of $E1$ transitions of photons in these reactions.

Abstract: The angular dependences of proton photoproduction from the nuclei ^{12}C, ^{63}Cu and ^{208}Pb irradiated by bremsstrahlung γ-quanta with maximum energy 4.5 GeV, both in the cumulative region (i.e. in the kinematical region in which the production of protons in the collision of γ-quanta of the given energy with the quasi-free nuclear nucleon is forbidden) and in the non-cumulative region, are investigated. The experimental data obtained are compared with the results of theoretical calculations of cumulative proton photoproduction according to the following models: the "quasi-two-body" scaling model, the low-nucleon correlation model, the fluctuon model and the cluster model.

Abstract. Lifetimes of 49 excited states below 1.65 MeV have been measured in ^{24}Mg, ^{27}Al, ^{48}Ti, ^{58}Ni, ^{59}Co, ^{61,62}Ni, ^{63,65}Cu, ^{64,66,68}Zn, ^{75}As, ^{103}Rh, ^{113,115}In, ^{116,118,120}Sn and ^{121,123}Sb by means of nuclear resonance fluorescence experiments. The levels are excited by bremsstrahlung x-ray photons. The self-absorption technique applied to suitable cases provides nuclear absorption cross sections, widths and lifetimes from which the x-ray spectral distributions are also obtained. Scattering experiments are performed for all other cases in order to obtain widths and lifetimes from these x-ray photon curves. The Compton effect in the sample is taken into account. Self-absorption provides $g\Gamma_0$ from which Γ is deduced using adopted J^π and Γ_0/Γ values; scattering provides $u = g(\Gamma_0^2/\Gamma)W(\theta)$ from which Γ is also deduced with J, Γ_0/Γ and mixing ratios taken from the literature. Thanks to simultaneous determination of the x-ray spectra all the lifetimes as given by our programs with their statistical errors form an unusually coherent set of values.

NUCLEAR REACTIONS (γ, γ'), bremsstrahlung excitation: natural isotopes: ^{24}Mg, ^{27}Al, ^{48}Ti, ^{58}Ni, ^{59}Co, ^{61,62}Ni, ^{63,65}Cu, ^{64,66,68}Zn, ^{75}As, ^{103}Rh, ^{113,115}In, ^{116,118,120}Sn and ^{121,123}Sb; $E \simeq 0.5$–1.65 MeV; measured $g\Gamma_0$ or $g(\Gamma_0^2/\Gamma)W(\theta)$; deduced $T_{1/2}$.

Remarque. Pour calculer δ^2 quand nous ne disposons que de $B(E2)$, pour un mélange (E2) + (M1), nous déduisons $g\Gamma_0(E2) \propto B(E2)E_\gamma^5$; en admettant $W(\theta) = 1$ et connaissant Γ_0/Γ, notre détermination de u donne une première approximation de $g\Gamma_0$ d'où une valeur de $\delta^2 = (g\Gamma_0(E2))/(g\Gamma_0 - g\Gamma_0(E2))$ qui permet d'améliorer $W(\theta)$ et $g\Gamma_0$ de proche en proche.

The (e,α) cross section for ^{65}Cu has been measured in the electron energy range 14–34 MeV. The results have been analyzed using the distorted-wave Born approximation $E1$ and $E2$ virtual photon spectra and the $E1$ and $E2$ components of the corresponding (γ,α) cross section were obtained. To assess the accuracy of the virtual photon analysis, the $(e,2n)$ cross section for ^{63}Cu was also measured and the obtained $(\gamma,2n)$ cross section is compared with direct measurement of this cross section performed with annihilation gamma rays.

[NUCLEAR REACTIONS ^{65}Cu(e,α) and ^{63}Cu$(e,2n)$. Measured $\sigma_{e,\alpha}(E_0)$ and $\sigma_{e,2n}(E_0)$. Deduced $\sigma^{E1}_{\gamma,\alpha}(E)$, $\sigma^{E2}_{\gamma,\alpha}(E)$, and $\sigma^{E1}_{\gamma,2n}(E)$.]

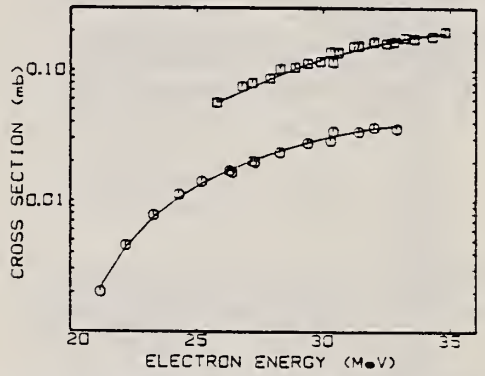

FIG. 3. $\sigma_{e,2n}(E_0)$ for ^{63}Cu (circles) and the yield of electrodisintegration plus photodisintegration (squares). The smooth curves are the best fit to the data and were obtained by combining the histogram shown in Fig. 5 with the $E1$ virtual photon spectrum and the Davies-Bethe-Maximom (DBM) bremsstrahlung cross section in Eqs. (1) and (2).

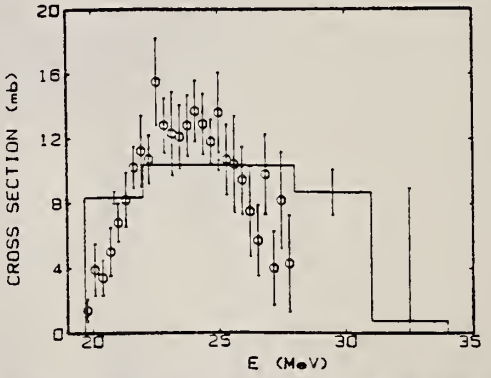

FIG. 5. ^{63}Cu$(\gamma,2n)$ cross section. The histogram is the result derived from this work and the points show the measurement of Fultz *et al.*[1]

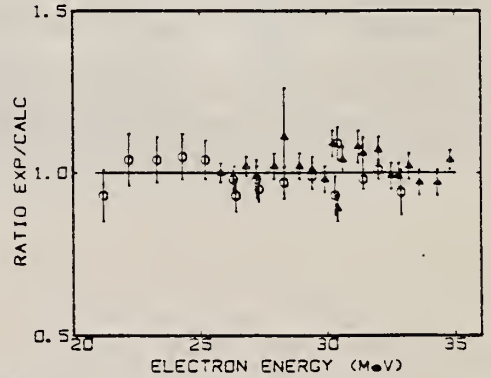

FIG. 6. Ratio of measured to calculated $(e,2n)$ cross section (circles) and measured to calculated yield of electrodisintegration plus photodisintegration (triangles).

Sample enriched to 99.7% Cu^{65}.

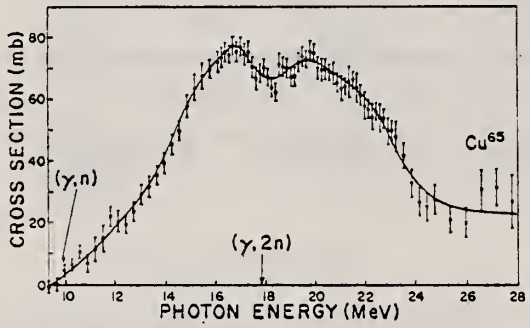

FIG. 6. Total cross section $[\sigma(\gamma,n)+2\sigma(\gamma,2n)+\sigma(\gamma,np)]$ for Cu^{65} obtained from single-neutron counting data.

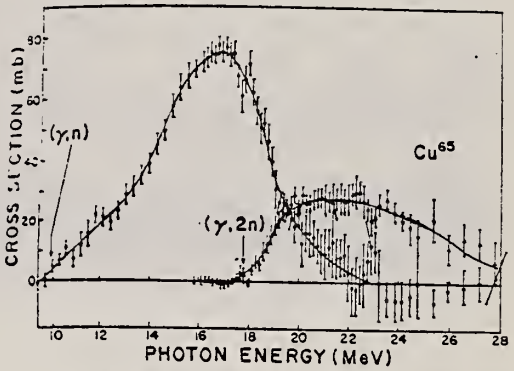

FIG. 7. Partial cross sections for Cu^{65}. The top curve consists of $\sigma(\gamma,n)+\sigma(\gamma,np)$. The lower curve consists of $\sigma(\gamma,2n)$ and was obtained from double-neutron counting data.

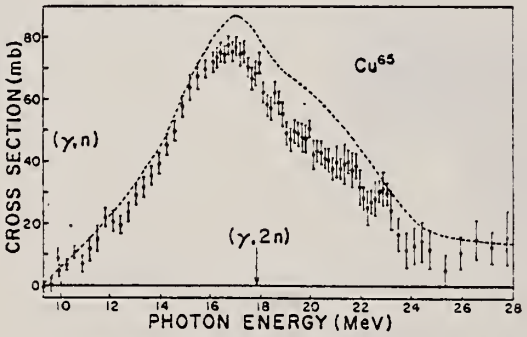

FIG. 8. The data points represent the sum $\sigma(\gamma,n)+\sigma(\gamma,np)+\sigma(\gamma,2n)$. The dashed line represents the nuclear formation cross section $\sigma(\gamma,n)+\sigma(\gamma,2n)+\sigma(\gamma,np)+\sigma(\gamma,p)$ for which the $\sigma(\gamma,p)$ data was obtained from Ref. 20.

8 = 8.484 MEV

The results of the angular distribution measurement of the elastically scattered radiation in the $^{65}Cu(\gamma,\gamma)$ reaction (E_γ = 8484 keV) are shown in Fig. 2. A parametric plot of A_{22} and A_{44} vs. $\delta' = \delta/(1+|\delta|)$ is also reported. Two values for δ are consistent with these measurements. They are $\delta = -0.14 \pm 0.02$ and $\delta = 0.61 \pm 0.01$. The experimental asymmetry ratio is $K = 1.10 \pm 0.02$, which is only consistent with the value $K = 1.07$ calculated for $\delta = 0.61$ and for the resonant level spin value $j^\pi = 5/2^-$. Thus, the decay from this level to the $3/2^-$ ground state is an M1-E2 mixture, with mixing ratio $\delta^2 = 0.37 \pm 0.01$.

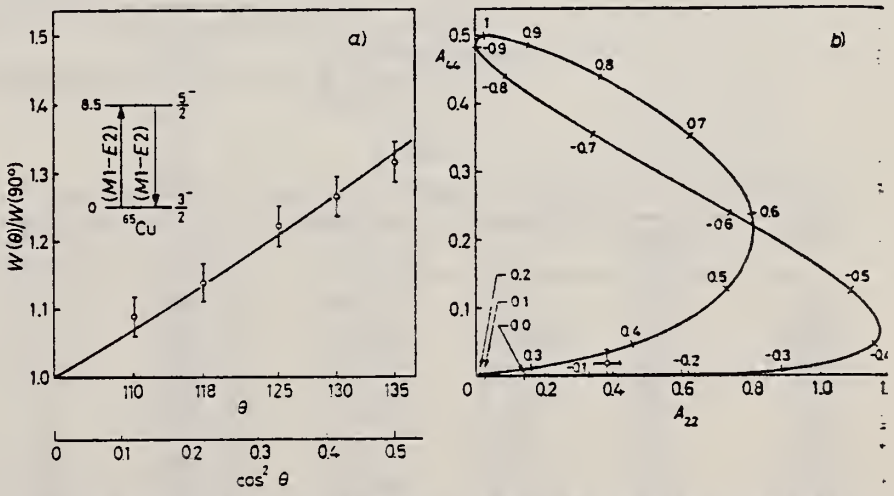

Fig. 2. – *a*) Angular distribution of resonantly scattered photons in ^{65}Cu. The solid line is the least-square fit through the data points. $\delta^2 = 0.37 > 0.01$, $W(\theta) = 1 + a\cos^2\theta + b\cos^4\theta$, $a = 0.56 \pm 0.04$, $b < 0.21$. *b*) Parametric plot of A_{22} and A_{44} *vs.* $\delta' = \delta/(1+|\delta|)$. The experimental values $A_{22} = 0.38 \pm \pm 0.04$ and $A_{44} < 0.04$ are also shown.

The properties of levels in ^{63}Cu and ^{65}Cu have been investigated using the resonance fluorescence technique with bremsstrahlung serving as the source of exciting radiation. The energies and scattering cross sections for 24 levels in ^{63}Cu and 30 levels in ^{65}Cu up to about 4.5 MeV were measured. A few levels known to exist in the region of 2 MeV for both nuclei were not observed. For a number of the lower lying levels, spin and parity assignments have been made through angular distribution measurements and limits on J^π set by others. Mixing ratios for a few of these are also given. Where J^π and the ground state branching ratios are known the partial widths for decays to the ground state are presented. Comparisons are made with the predictions of the latest theoretical calculations.

8 STATES .77-4.26 MeV

We report the results of an experimental study of low-lying states in ^{65}Cu by the method of inelastic scattering of electrons with energy $E_0 = 120$ MeV in the region of momentum transfer to the nucleus $q' = 0.78$–$1.15F^{-1}$. Values are obtained for the reduced transition probability $B(E\lambda)\uparrow$ from the ground state of the nucleus to excited states with $\omega = 0.77$, 1.11, 1.48, 2.62, 3.16, 3.52 3.85, and 4.26 MeV.

TABLE I. Value of reduced probability $B(E\lambda)\uparrow$ for transition of the nucleus from the ground state to an excited state.

Analysis is made of reactions interfering with photon activation analysis procedures.

The activation yield curves have been presented for a number of photonuclear reactions in the energy range from 30 to 68 MeV, in order to evaluate quantitatively the interferences due to competing reactions in multielement photon activation analysis. The general features of the yields as functions of both target mass number and excitation energy were elucidated from the data obtained, discussion being given on the results in terms of the reaction mechanism.

Simultaneous neutron activation due to appreciable neutron production from the converter and surrounding materials has also been studied, and, finally, the magnitudes of interferences in real multielement analysis were given in the form of their energy dependences.

We report the results of a study of the reaction $\gamma A \to pX$ at an angle $\theta_{\gamma p} = 100°$ lab in a beam of quasimonochromatic polarized photons. The measurements were made for three values of photon energy ($E_\gamma = 0.69$, 1.40, and 1.95 GeV) in the nuclei ^{12}C, ^{64}Cu, and ^{207}Pb. The range of kinetic energies of the protons was ≃100–230 MeV. It is shown that the slope parameter B for the invariant cross section $f = C\exp(-Bp^2)$ is a weak function of A and does not depend on E_γ, but the parameter $C_\gamma = C/A\bar{\sigma}$, increases with increase of E_γ, the slope of the lines $C_\gamma(E_\gamma)$ being greater for larger A.

COH-BRMS .69*1.95 GEV

At the present time it is rather well established that the experimental values of the invariant cross section $f = (E/p^2)(d^2\sigma/d\Omega dp)$ of the reaction

$$aA \to bX \qquad (1)$$

in the cumulative region[1,2] are described by an exponential dependence of the form $f = C\exp(-Bp^2)$. Most of the experiments in which reaction (1) induced by various particles (π, p, γ, ...), has been studied were designed to study the energy, angular, and A dependence of the parameters B and C.[3-9] As a result of the investigations it is has been established that the parameter B does not depend on the mass number A of the target nucleus, on the type of incident particle, or on its energy, beginning with $E_a \simeq 1$ GeV, while the parameter $C_a = C/\sigma_{tot}$ (σ_{tot} is the total cross section for the aA interaction) does not depend on the type of particle a. In addition to the established properties of the quantities B and C it would be interesting to check the dependence of the parameters B and C on the direction of polarization of the initial particle. For this purpose it is necessary to measure the asymmetry Σ of the cross section for reaction (1) as a function of the direction of the initial-particle polarization vector.

In the present work we report the results of a study of the photoproduction of cumulative protons at an angle $\vartheta_{\gamma p} = 100^\circ$ in the laboratory system in the nuclei ^{12}C, ^{64}Cu, and ^{207}Pb for three photon energy values ($E_\gamma = 0.69$, 1.40, and 1.95 GeV). The possibility of measurement at a definite photon energy was based on the use of the method of subtraction of the coherent peak[10,11] in the spectrum of quasimonochromatic polarized photons emitted by electrons in passing through a diamond crystal.[12] The existence of a significant degree of polarization of the photons in the coherent peak has enabled us to measure the value of the cross-section asymmetry Σ of the reaction $\gamma A \to pX$. The asymmetry was calculated from the relation

$$\Sigma = \frac{1}{\bar{P}_\gamma}\frac{y' - y^-}{y' + y^- - 2y^*},$$

where y', y^- are the reaction yields in the case of perpendicular and parallel orientation of the photon polarization vector with respect to the reaction plane in the coherent bremsstrahlung spectrum; y^* is the reaction yield for an ordinary bremsstrahlung spectrum; $\bar{P}_\gamma$ is the average value of photon polarization in the subtracted coherent peak.

Measurements of Σ were made in the nuclei ^{12}C, ^{64}Cu, and ^{207}Pb for protons with kinetic energy respectively $T_p = 173$, 164, and 163 MeV. The energy bin was $\Delta T = 60$ MeV.

The experimental apparatus and measurement technique have been described in detail elsewhere.[13]

Numerical values of Σ with their standard deviations $\sigma(\Sigma)$ are given in the table.

The values of $\sigma(\Sigma)$ contain both the statistical error and the error in determination of the quantity $\bar{P}_\gamma$.[13]

From the figure, where we have shown Σ as a function of E_γ for the three nuclei it can be seen that the absolute values of the asymmetry in the region investigated are insignificant and depend weakly on E_γ. We note that Σ for carbon is close to zero for all E_γ, and the maximum value 0.29 ± 0.16 is achieved in the case of lead for $E_\gamma = 1.95$ GeV. The data show that within experimental error the asymmetry is almost indepen-

Abstract. Lifetimes of 49 excited states below 1.65 MeV have been measured in ^{24}Mg, ^{27}Al, ^{48}Ti, ^{58}Ni, ^{59}Co, ^{61,62}Ni, ^{63,65}Cu, ^{64,66,68}Zn, ^{75}As, ^{103}Rh, ^{113,115}In, ^{116,118,120}Sn and ^{121,123}Sb by means of nuclear resonance fluorescence experiments. The levels are excited by bremsstrahlung x-ray photons. The self-absorption technique applied to suitable cases provides nuclear absorption cross sections, widths and lifetimes from which the x-ray spectral distributions are also obtained. Scattering experiments are performed for all other cases in order to obtain widths and lifetimes from these x-ray photon curves. The Compton effect in the sample is taken into account. Self-absorption provides $g\Gamma_0$ from which Γ is deduced using adopted J^π and Γ_0/Γ values; scattering provides $u = g(\Gamma_0^2/\Gamma)W(\theta)$ from which Γ is also deduced with J, Γ_0/Γ and mixing ratios taken from the literature. Thanks to simultaneous determination of the x-ray spectra all the lifetimes as given by our programs with their statistical errors form an unusually coherent set of values.

NUCLEAR REACTIONS (γ, γ), bremsstrahlung excitation; natural isotopes: ^{24}Mg, ^{27}Al, ^{48}Ti, ^{58}Ni, ^{59}Co, ^{61,62}Ni, ^{63,65}Cu, ^{64,66,68}Zn, ^{75}As, ^{103}Rh, ^{113,115}In, ^{116,118,120}Sn and ^{121,123}Sb; $E \simeq 0.5$–1.65 MeV; measured $g\Gamma_0$ or $g(\Gamma_0^2/\Gamma)W(\theta)$; deduced $T_{1/2}$.

Remarque. Pour calculer δ^2 quand nous ne disposons que de $B(E2)$, pour un mélange (E2) + (M1), nous déduisons $g\Gamma_0(E2) \propto B(E2)E_\gamma^5$; en admettant $W(\theta)=1$ et connaissant Γ_γ/Γ, notre détermination de u donne une première approximation de $g\Gamma_0$ d'où une valeur de $\delta^2=(g\Gamma_0(E2))/(g\Gamma_0-g\Gamma_0(E2))$ qui permet d'améliorer $W(\theta)$ et $g\Gamma_0$ de proche en proche.

The (e,α) cross section for ^{65}Cu has been measured in the electron energy range 14—34 MeV. The results have been analyzed using the distorted-wave Born approximation $E1$ and $E2$ virtual photon spectra and the $E1$ and $E2$ components of the corresponding (γ,α) cross section were obtained. To assess the accuracy of the virtual photon analysis, the $(e,2n)$ cross section for ^{63}Cu was also measured and the obtained $(\gamma,2n)$ cross section is compared with direct measurement of this cross section performed with annihilation gamma rays.

[NUCLEAR REACTIONS ^{65}Cu(e,α) and ^{63}Cu$(e,2n)$. Measured $\sigma_{e,\alpha}(E_0)$ and $\sigma_{e,2n}(E_0)$. Deduced $\sigma^{E1}_{\gamma,\alpha}(E)$, $\sigma^{E2}_{\gamma,\alpha}(E)$, and $\sigma^{E1}_{\gamma,2n}(E)$.]

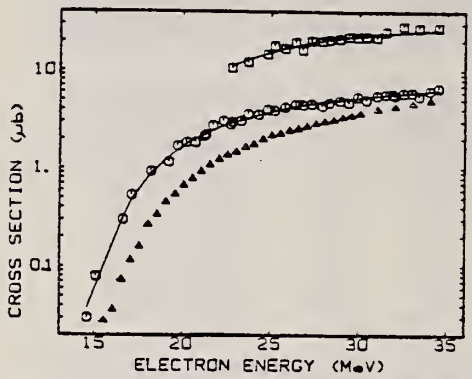

FIG. 4. $\sigma_{e,\alpha}(E_0)$ for ^{65}Cu (circles) and the yield of electrodisintegration plus photodisintegration (squares). The smooth curves are the best fit to the data and were obtained by combining the $E1$ and $E2$ histograms of Fig. 7 with the virtual photon spectra and the DBM bremsstrahlung cross section in Eqs. (1) and (2). The triangles show the (e,α) cross section from Ref. 6.

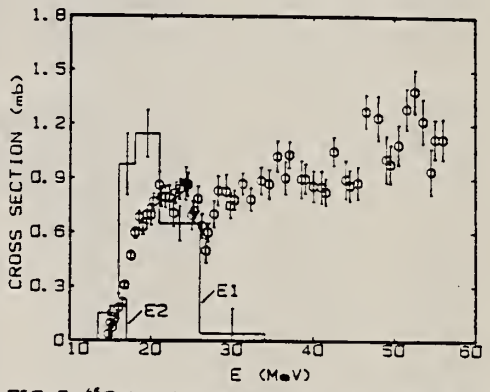

FIG. 7. ^{65}Cu(γ,α) cross sections. The $E1$ and $E2$ histograms are the results from this work. The points show the (γ,α) cross section from Ref. 6.

# ZINC
Z=30

Zinc, in combination with copper, was known in Roman times as the alloy brass; the individual metal was not isolated until much later. The first smelting and extraction of the impure metal was carried out in China and India about 1000 A.D. Paracelsis (1490-1541) refers to zinc as a bastard form of copper. This is the earliest authenticated use of the word "zinc" to describe the metal.

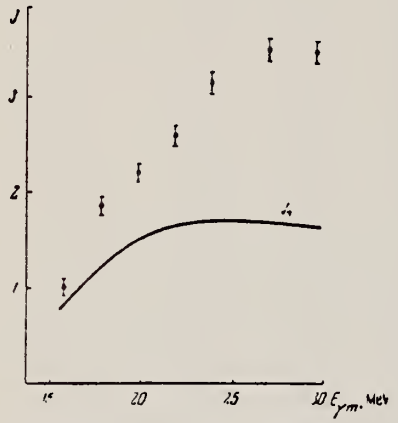

FIG. 5. Dependence on E_{γ_m} of the yield of photoprotons with energies $\epsilon_p \geq 3$ mev from zinc. I_T is the curve calculated according to evaporation theory and normalized according to the data on angular distribution on the assumption that at $E_{\gamma m} = 20.8$ mev the isotropic part of the yield (75%) is determined by evaporation. I is the yield in relative units reduced to the same ionization in a thick-walled ionization chamber.

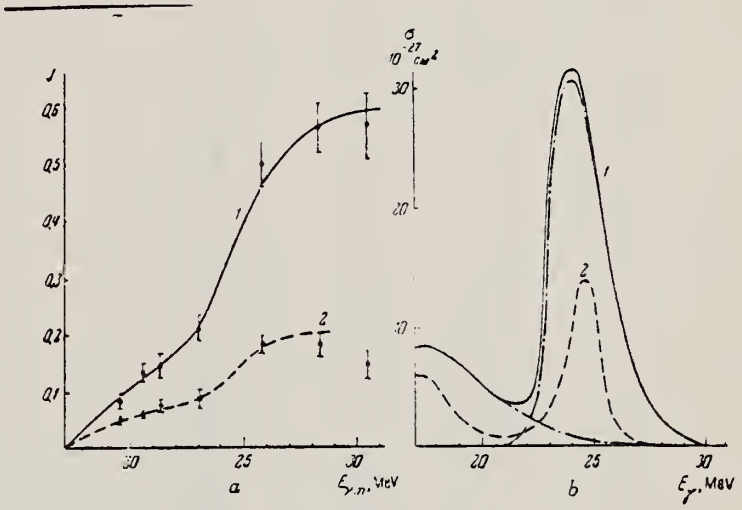

FIG. 6. a – dependence on $E_{\gamma m}$ of the yield of fast photoprotons from zinc; b – cross-section for the emission of fast protons from zinc. $1 - \epsilon_p \geq 9$, $2 - 8 \leq \epsilon_p \leq 10$ mev.

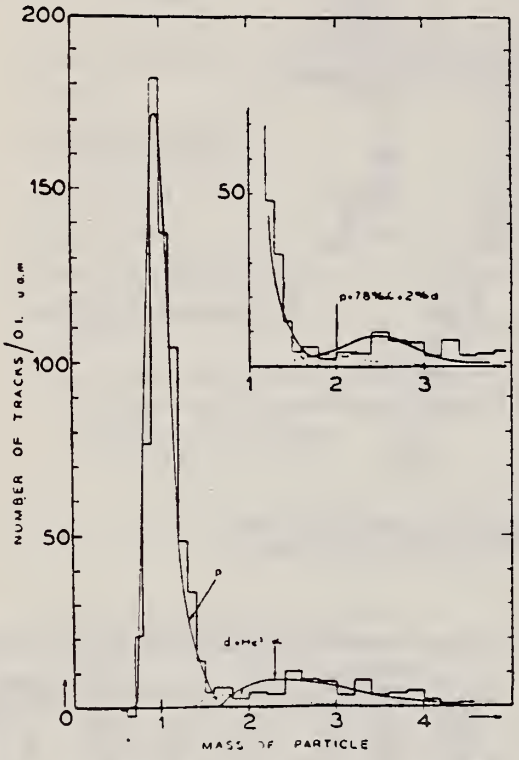

Fig. 2' "Mass" histogram for the 1917 tracks measured in four plates irradiated at -165°, -45°, +45° and +105° to the incident beam, respectively (positions nº 1, 5, 8 e 10). Only tracks with ranges less than 140μ were included. The dashed curves calculated shapes of the proton, deuteron and alpha particles peaks for a standard error of 2.3% in O, normalised respectively to 616 protons, 28 deuterons and 110 alpha particles. In the lower part, the full curve gives the sum of the alpha and proton curves (i.e. with 0% of deuterons). In the upper part the full curve represents the sum of the three particles curves (i.e: with 2% of deuterons and 7.8% of alpha particles).

[a] High-energy component of a complex spectrum.
[b] A broad scattered spectrum with no observable peak structure.
[c] There are actually two lines of energies 7.647 and 7.633 MeV having equal intensities in the iron capture gamma spectrum. The cross section has therefore been corrected, although there is no possibility at present of deciding which line is responsible for each resonance.
[d] Is probably an independent level in the complex spectrum of Ni γ rays on Te.
[e] Rough estimate.
[f] May be inelastic component from 7.528 level in Te.
[g] The relative line intensities in this case are due to Groshev and co-workers.
[h] No line is known for the source at this energy.
[i] Difficult to resolve among the many source lines present at this energy.

T.D. Newton, Can. J. Phys. 34, 804 (1956).

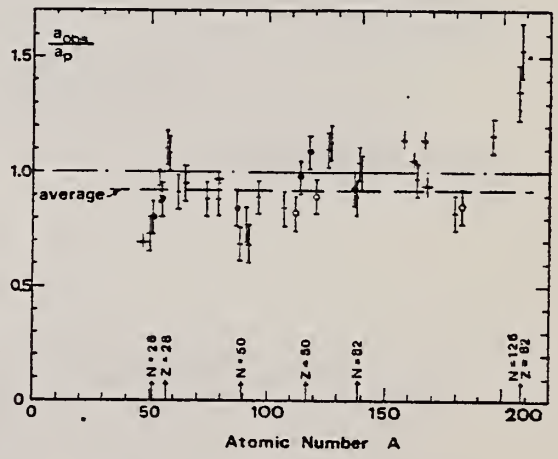

Fig. 15. Ratio a_{obs}/a_p versus atomic number A. Here a_{obs} is the level density parameter taken from the neutron resonance work of refs. [1,2]), and a_p is the level density parameter derived from the present (γ, n) work. Filled circles represent points where nuclei in the neutron resonance and in the (γ, n) experiment were the same. Open circles represent points where the respective nuclei were approximately matched. Triangles represent points which are based on measurement of neutron mean energies at two bremsstrahlung energies only.

[a] Neutron numbers and abundances of respective residual nuclei in (γ, n) experiments.

[b] These give an assessment of the goodness of fit of a calculated $\hat{E}_n$ versus E_0 curve to the observed data, using the Fermi gas level density formula both without and with pairing corrections.

[c] Bremsstrahlung photoneutron mean energies $\hat{E}_n$ for peak bremsstrahlung energy $E_0 = 24$ MeV.

[d] Nuclear temperature from fit with constant-temperature formula.

[e] Level density parameter a_p derived from the present (γ, n) experiment, using a Fermi gas formula plus pairing correction, and corresponding residual nucleus (the atomic weight shown is the weighted average of atomic weights of the respective isotopes present).

[f] As column 7, but using data on n-resonance absorption from refs. [1, 2]).

[g] Measurements of $\hat{E}_n(E_0)$ for these nuclei were made only for $E_0 = 21$, 23 and 24 MeV.

Experimental Measurements of Vibrational Splitting of the Giant Dipole Resonance*

P. H. Cannington, D. G. Owen, R.J.J. Stewart, E. G. Muirhead and B. M. Spicer

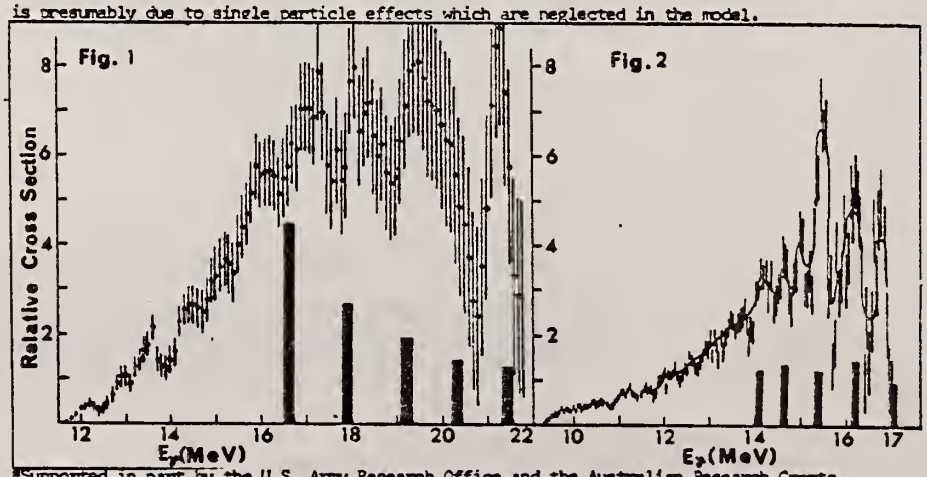
University of Melbourne, Australia

The yield curve for the reaction $Zn^{64}(\gamma,n)$ has been measured in 0.1 MeV steps from threshold to 23 MeV, and that for $Pr^{141}(\gamma,n)$ has been measured in 0.05 MeV steps from threshold to 17.5 MeV. In both cases, the positron activity of the residual nucleus was detected by counting annihilation radiation. The cross sections were obtained from the yield curve by the Leiss-Penfold method.

The cross section for the $Zn^{64}(\gamma,n)$ reaction is shown in Fig. 1. Also shown are the predictions of Greiner[1], whose model considers the Goldhaber-Teller type dipole vibration, the low energy surface vibrations of spherical nuclei, and the coupling of these two vibrations. The predictions show only the energy, and integrated absorption cross section for the several transitions.

The $Pr^{141}(\gamma,n)$ cross section is shown in Fig. 2, and the calculations of Huber[2] are shown in blocked form; their detail is the same as above. In this case, the surface vibration phonon energy was not so easily fixed as in the case of even-A Zn^{64}. There were, in the case of Pr^{141}, two possible choices indicated by the low energy spectra of neighbouring nuclei. The more suitable one is indicated in Fig. 2.

In both cases, the amount of structure found experimentally exceeds that predicted by the dipole-surface vibration-interference model. However, by worsening the experimental resolution, the agreement can be readily improved. The surplus structure in both cross sections is presumably due to single particle effects which are neglected in the model.



*Supported in part by the U.S. Army Research Office and the Australian Research Grants Committee.

The measurement of (γ, n) cross sections in spherical medium weight nuclei is of great interest for determining the coupling of low energy surface vibrations and high energy dipole oscillations. The coupling has been theoretically investigated by Huber et al.[1] and found to result in a considerable splitting of the photonuclear resonance. Experimentally bremsstrahlung measurements have indicated a pronounced structure in (γ, n) cross sections [2,3] which is not present in measurements with γ-rays from positron annihilation in flight[4,5]. In this experiment a photoactivation method and monochromatic γ-rays from the $^{3}H(p,\gamma)^{4}He$ reaction were employed to measure the (γ, n) cross section for ^{50}Cr and ^{64}Zn. The γ-rays were monitored by a NaI(Tℓ) crystal enclosed in a lead and paraffin shield to reduce background radiation. The positron activity was determined by a coincidence detector consisting of two NaI(Tℓ) crystals set on the annihilation radiation photopeaks. The γ-ray energy was varied in steps of 150 keV from 20.43 to ≈ 22.2 MeV and the energy resolution was less than 110 keV over the entire energy range. The experimental cross sections of the two reactions were found to vary smoothly as a function of energy. The results for the $^{64}Zn(\gamma, n)$ process do not agree with those of Owen et al.[2], who observed two resonances ≈ 0.5 to 1 MeV wide in the same energy range. The shape of the ^{50}Cr (γ, n) cross section is in fair agreement with the calculation of Huber et al.[1] for widths of the dipole states of the order of 3 MeV.

SEP ISOTOPES

Total photoneutron cross sections have been obtained for ^{64}Zn and ^{68}Zn. The measurements were carried out from threshold to 27 MeV in 50-keV steps. A distinct structure is observed in the cross sections. The half-width of the curves is about 10 MeV. The integrated cross sections for ^{64}Zn and ^{68}Zn without taking into account multiple processes are 800 ± 80 and 1630 ± 160 MeV mb. The experimental data are compared with the predictions of the dynamic collective model and with the concept of isospin splitting of the giant resonance.

Abstract: The inelastic electron scattering cross sections for the quadrupole transitions to the 2_1^+ and 2_2^+ states in the even Zn isotopes ^{64}Zn, ^{66}Zn and ^{68}Zn and for the hexadecapole transition to the 4_1^+ state in ^{64}Zn have been measured in a momentum transfer range up to $q = 2.2$ fm^{-1}. In the framework of the vibrational model these states are considered as one- and two-quadrupole-phonon states. The measurements are characterized by high statistical accuracy and by an overall resolution of $\delta E/E_0 = 10^{-3}$ which permitted separation of almost all members of the two-phonon triplet. The measured cross sections are analyzed with phenomenological models as well as with a Fourier-Bessel expansion of the transition charge density. The latter analysis yields realistic error bands for the transition charge densities and model-independent values for the reduced transition probabilities and transition radii.

E NUCLEAR REACTIONS ^{64,66,68}Zn(e, e'), E = 100–275 MeV; measured $d\sigma/d\Omega(E, \theta)$. ^{64,66,68}Zn levels deduced transition charge density, $B_\tau(E\lambda)$ and transition charge radii R_{tr}. Enriched targets.

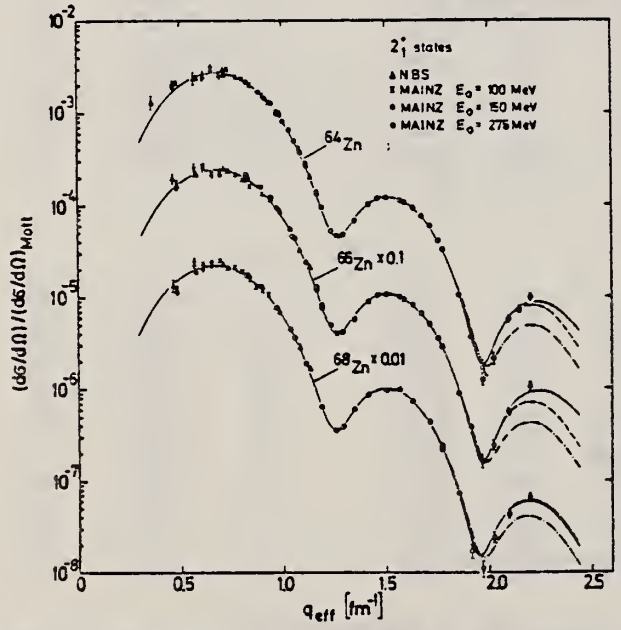

Fig. 3. Cross sections divided by the Mott cross section for the allowed transitions to the 2_1^+ state in ^{64}Zn, ^{66}Zn and ^{68}Zn versus the effective momentum transfer. The measured cross sections are transformed to a common incident energy E_0 = 275 MeV. The curves represent best fit DWBA calculations with the Fourier-Bessel expansion of the transtion charge density (solid line), the modified Tassie model (dashed line) and the Gaussian model (dashed-dotted line).

The cross section of the reaction $^{64}Zn(\gamma, n)^{63}Zn$ was investigated for the high-energy component of the neutron spectrum ($\epsilon_n \geq 3.7$ MeV). An analysis of the results indicates that the interpretation of the structure observed in the cross section of the $^{64}Zn(\gamma, n)^{63}Zn$ as a manifestation of isospin splitting is in error.

The yield curve of the reaction $^{64}Zn(\gamma, n)^{63}Zn$ was measured for neutrons with $\epsilon_n > 3.7$ MeV; the energy spectra of the photoneutrons were also measured at various values of the bremsstrahlung maximum energy $E_{\gamma m}$. It is concluded from analysis of the obtained data and from comparison with the results of analogous studies made for iron isotopes that the probability of decay of doorway states into more complex configurations increases with increasing distance from the region of nuclei with filled shells.

Abstract. Lifetimes of 49 excited states below 1.65 MeV have been measured in ^{24}Mg, ^{27}Al, ^{48}Ti, ^{58}Ni, ^{59}Co, ^{61,62}Ni, ^{63,65}Cu, ^{64,66,68}Zn, ^{75}As, ^{103}Rh, ^{113,115}In, ^{116,118,120}Sn and ^{121,123}Sb by means of nuclear resonance fluorescence experiments. The levels are excited by bremsstrahlung x-ray photons. The self-absorption technique applied to suitable cases provides nuclear absorption cross sections, widths and lifetimes from which the x-ray spectral distributions are also obtained. Scattering experiments are performed for all other cases in order to obtain widths and lifetimes from these x-ray photon curves. The Compton effect in the sample is taken into account. Self-absorption provides $g\Gamma_0$ from which Γ is deduced using adopted J^π and Γ_0/Γ values; scattering provides $u = g(\Gamma_0^2/\Gamma)W(\theta)$ from which Γ is also deduced with J, Γ_0/Γ and mixing ratios taken from the literature. Thanks to simultaneous determination of the x-ray spectra all the lifetimes as given by our programs with their statistical errors form an unusually coherent set of values.

NUCLEAR REACTIONS (γ, γ'), bremsstrahlung excitation; natural isotopes: ^{24}Mg, ^{27}Al, ^{48}Ti, ^{58}Ni, ^{59}Co, ^{61,62}Ni, ^{63,65}Cu, ^{64,66,68}Zn, ^{75}As, ^{103}Rh, ^{113,115}In, ^{116,118,120}Sn and ^{121,123}Sb; $E \simeq 0.5$–1.65 MeV; measured $g\Gamma_0$ or $g(\Gamma_0^2/\Gamma)W(\theta)$; deduced $T_{1/2}$.

Remarque. Pour calculer δ^2 quand nous ne disposons que de B(E2), pour un mélange (E2) + (M1), nous déduisons $g\Gamma_0$(E2) $\propto B(E2)E_\gamma^5$; en admettant $W(\theta)=1$ et connaissant Γ_0/Γ, notre détermination de u donne une première approximation de $g\Gamma_0$ d'où une valeur de $\delta^2=(g\Gamma_0(E2))/(g\Gamma_0-g\Gamma_0(E2))$ qui permet d'améliorer $W(\theta)$ et $g\Gamma_0$ de proche en proche.

The (e,p) and (e,α) cross sections for ^{56}Fe, ^{59}Co, and ^{64}Zn have been measured in the electron energy range 16—100 MeV. They have been analyzed using the distorted-wave Born approximation $E1$ and $E2$ virtual photon spectra. The $E1$ and $E2$ components in the proton and α channels have been obtained.

[b]Reference 14.

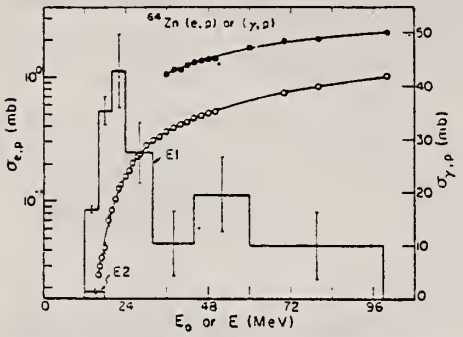

FIG. 5. The $\sigma_{e,p}(E_0)$ for ^{64}Zn. See caption of Fig. 3.

FIG. 3. The measured $\sigma_{e,p}(E_0)$ for ^{56}Fe as a function of total incident electron energy E_0 (open circles). The full circles represent the yield $Y_{e,p}(E_0)$ obtained when a 0.217 g/cm^2 tantalum foil was placed in the electron beam ahead of the target. The smooth curves are the best fits to the data and were obtained by combining the histograms representing the $E1$ and $E2$ (γ,p) cross sections (right-hand scale) in Eqs. (1) and (2) with the $E1$ and $E2$ DWBA virtual photon spectra and by making use of the DBM bremsstrahlung cross section. The size effect correction described in the text has been applied to the virtual photon spectra.

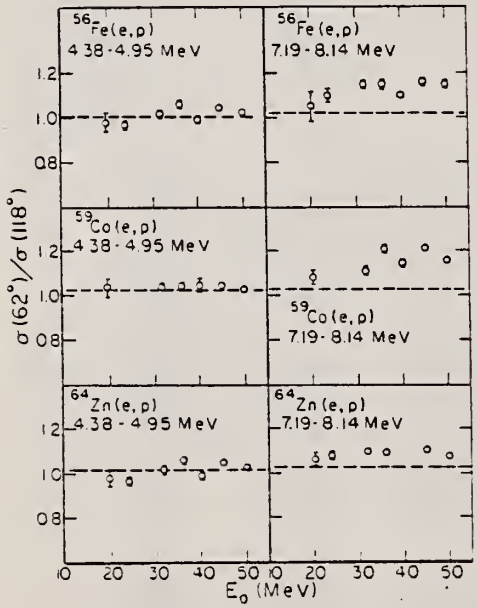

FIG. 9. The ratios of the number of protons observed in the indicated energy bite ΔT_p at 62° to the same number observed at 118°, $\sigma(62°)/\sigma(118°)$, as a function of incident electron energy.

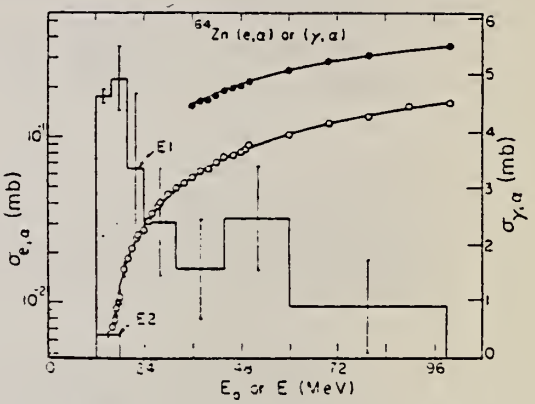

FIG. 8. The $\sigma_{e,\alpha}(E_0)$ for ^{64}Zn. See caption of Fig. 3.

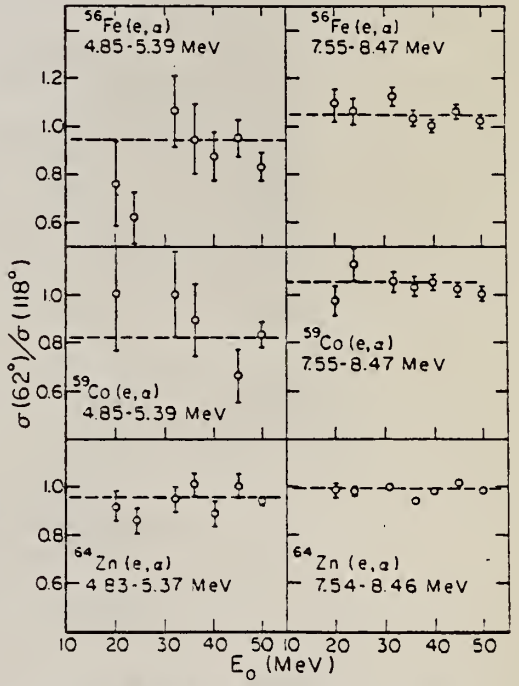

FIG. 10. The ratios of the number of α particles observed in the indicated energy bite ΔT_α at 62° to the same number observed at 118°, $\sigma(62°)/\sigma(118°)$, as a function of incident electron energy.

Abstract: The inelastic electron scattering cross sections for the quadrupole transitions to the 2_1^+ and 2_2^+ states in the even Zn isotopes ^{64}Zn, ^{66}Zn and ^{68}Zn and for the hexadecapole transition to the 4_1^+ state in ^{64}Zn have been measured in a momentum transfer range up to $q = 2.2$ fm^{-1}. In the framework of the vibrational model these states are considered as one- and two-quadrupole-phonon states. The measurements are characterized by high statistical accuracy and by an overall resolution of $\delta E/E_0 = 10^{-3}$ which permitted separation of almost all members of the two-phonon triplet. The measured cross sections are analyzed with phenomenological models as well as with a Fourier-Bessel expansion of the transition charge density. The latter analysis yields realistic error bands for the transition charge densities and model-independent values for the reduced transition probabilities and transition radii.

LEVELS 1.039, 1.873

E NUCLEAR REACTIONS ^{64,66,68}Zn(e, e'), E = 100–275 MeV; measured $d\sigma/d\Omega(E, \theta)$. ^{64,66,68}Zn levels deduced transition charge density, $B_\tau(E\lambda)$ and transition charge radii R_{tr}. Enriched targets.

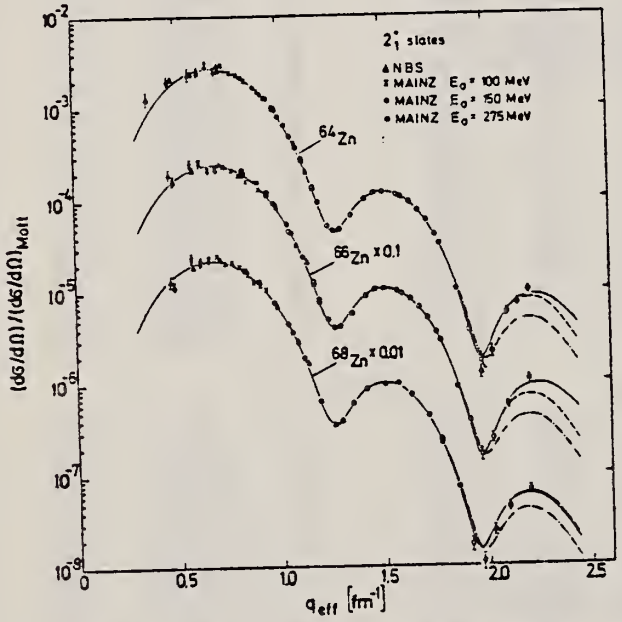

Fig. 3. Cross sections divided by the Mott cross section for the allowed transitions to the 2_1^+ state in ^{64}Zn, ^{66}Zn and ^{68}Zn versus the effective momentum transfer. The measured cross sections are transformed to a common incident energy E_0 = 275 MeV. The curves represent best fit DWBA calculations with the Fourier-Bessel expansion of the transtion charge density (solid line), the modified Tassie model (dashed line) and the Gaussian model (dashed-dotted line).

Abstract. Lifetimes of 49 excited states below 1.65 MeV have been measured in ^{24}Mg, ^{27}Al, ^{48}Ti, ^{58}Ni, ^{59}Co, ^{61,62}Ni, ^{63,65}Cu, ^{64,66,68}Zn, ^{75}As, ^{103}Rh, ^{113,115}In, ^{116,118,120}Sn and ^{121,123}Sb by means of nuclear resonance fluorescence experiments. The levels are excited by bremsstrahlung x-ray photons. The self-absorption technique applied to suitable cases provides nuclear absorption cross sections, widths and lifetimes from which the x-ray spectral distributions are also obtained. Scattering experiments are performed for all other cases in order to obtain widths and lifetimes from these x-ray photon curves. The Compton effect in the sample is taken into account. Self-absorption provides $g\Gamma_0$ from which Γ is deduced using adopted J^π and Γ_0/Γ values; scattering provides $u = g(\Gamma_0^2/\Gamma)W(\theta)$ from which Γ is also deduced with J, Γ_0/Γ and mixing ratios taken from the literature. Thanks to simultaneous determination of the x-ray spectra all the lifetimes as given by our programs with their statistical errors form an unusually coherent set of values.

NUCLEAR REACTIONS (γ, γ), bremsstrahlung excitation; natural isotopes; ^{24}Mg, ^{27}Al, ^{48}Ti, ^{58}Ni, ^{59}Co, ^{61,62}Ni, ^{63,65}Cu, ^{64,66,68}Zn, ^{75}As, ^{103}Rh, ^{113,115}In, ^{116,118,120}Sn and ^{121,123}Sb; $E \simeq 0.5$–1.65 MeV; measured $g\Gamma_0$ or $g(\Gamma_0^2/\Gamma)W(\theta)$; deduced $T_{1/2}$.

Remarque. Pour calculer δ^2 quand nous ne disposons que de $B(E2)$, pour un mélange (E2) − (M1), nous déduisons $g\Gamma_0(E2) \propto B(E2)E_\gamma^5$; en admettant $W(\theta) = 1$ et connaissant Γ_0/Γ, notre détermination de u donne une première approximation de $g\Gamma_0$ d'où une valeur de $\delta^2 = (g\Gamma_0(E2))/(g\Gamma_0 - g\Gamma_0(E2))$ qui permet d'améliorer $W(\theta)$ et $g\Gamma_0$ de proche en proche.

SEP ISOTOPES

Total photoneutron cross sections have been obtained for ^{64}Zn and ^{68}Zn. The measurements were carried out from threshold to 27 MeV in 50-keV steps. A distinct structure is observed in the cross sections. The half-width of the curves is about 10 MeV. The integrated cross sections for ^{64}Zn and ^{68}Zn without taking into account multiple processes are 800±80 and 1630±160 MeV mb. The experimental data are compared with the predictions of the dynamic collective model and with the concept of isospin splitting of the giant resonance.

The yields of (γ, p) reactions on ^{30}Si, ^{68}Zn and ^{130}Te have been measured as a function of the bremsstrahlung end-point energy, $E_{\gamma,\max}$, in the energy range 75–800 MeV, using the activation method. Cross sections have been deduced and are compared to results obtained using a semi-empirical model.

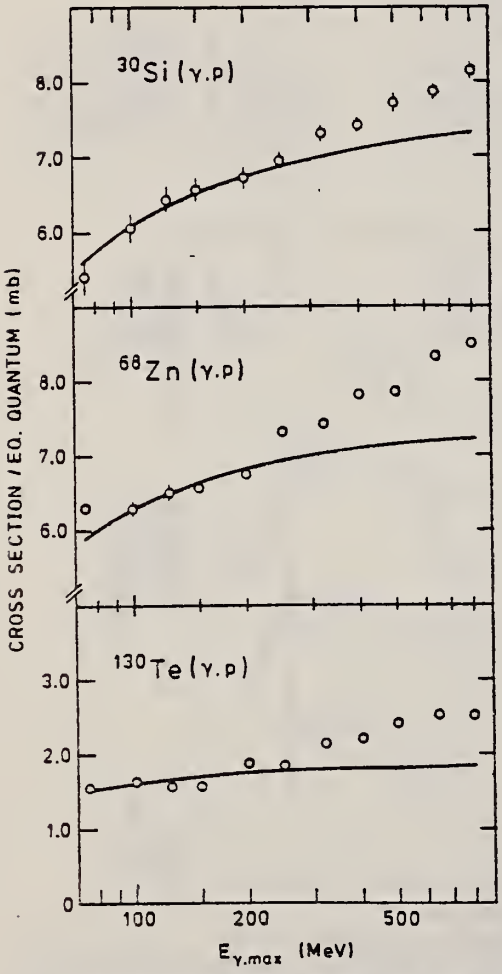

Fig. 1. Measured yields for the (γ, p) reactions in ^{30}Si, ^{68}Zn and ^{130}Te. The solid lines are the fitted yields due to the giant resonance and quasideuteron cross sections

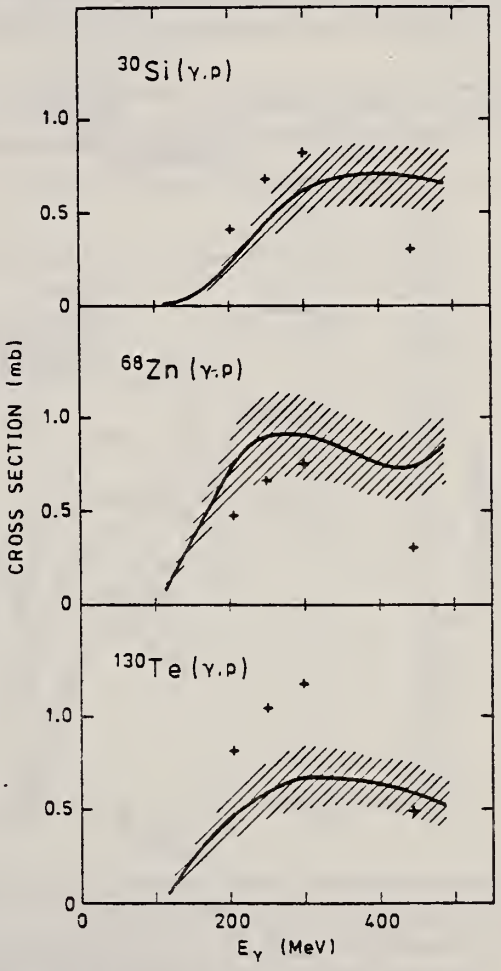

Fig. 2. The solid curves show the smoothed cross sections arising from photoproduction of mesons and the hatched areas indicate the estimated errors. +sings are values calculated using the semi-empirical formalism

Abstract: The inelastic electron scattering cross sections for the quadrupole transitions to the 2_1^+ and 2_2^+ states in the even Zn isotopes ^{64}Zn, ^{66}Zn and ^{68}Zn and for the hexadecapole transition to the 4_1^+ state in ^{64}Zn have been measured in a momentum transfer range up to $q = 2.2$ fm^{-1}. In the framework of the vibrational model these states are considered as one- and two-quadrupole-phonon states. The measurements are characterized by high statistical accuracy and by an overall resolution of $\delta E/E_0 = 10^{-3}$ which permitted separation of almost all members of the two-phonon triplet. The measured cross sections are analyzed with phenomenological models as well as with a Fourier-Bessel expansion of the transition charge density. The latter analysis yields realistic error bands for the transition charge densities and model-independent values for the reduced transition probabilities and transition radii.

LEVELS 1.077, 1.883

E NUCLEAR REACTIONS ^{64,66,68}Zn(e, e'), E = 100–275 MeV; measured $d\sigma/d\Omega(E, \theta)$. ^{64,66,68}Zn levels deduced transition charge density, $B_\lambda(E\lambda)$ and transition charge radii R_{tr}. Enriched targets.

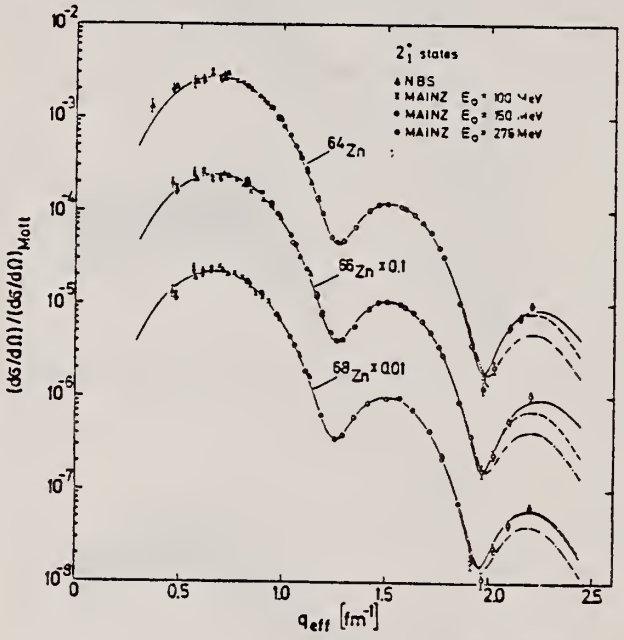

Fig. 3. Cross sections divided by the Mott cross section for the allowed transitions to the 2_1^+ state in ^{64}Zn, ^{66}Zn and ^{68}Zn versus the effective momentum transfer. The measured cross sections are transformed to a common incident energy E_0 = 275 MeV. The curves represent best fit DWBA calculations with the Fourier-Bessel expansion of the transtion charge density (solid line), the modified Tassie model (dashed line) and the Gaussian model (dashed-dotted line).

Abstract. Lifetimes of 49 excited states below 1.65 MeV have been measured in ^{24}Mg, ^{27}Al, ^{48}Ti, ^{58}Ni, ^{59}Co, ^{61,62}Ni, ^{63,65}Cu, ^{64,66,68}Zn, ^{75}As, ^{103}Rh, ^{113,115}In, ^{116,118,120}Sn and ^{121,123}Sb by means of nuclear resonance fluorescence experiments. The levels are excited by bremsstrahlung x-ray photons. The self-absorption technique applied to suitable cases provides nuclear absorption cross sections, widths and lifetimes from which the x-ray spectral distributions are also obtained. Scattering experiments are performed for all other cases in order to obtain widths and lifetimes from these x-ray photon curves. The Compton effect in the sample is taken into account. Self-absorption provides $g\Gamma_0$ from which Γ is deduced using adopted J^π and Γ_0/Γ values: scattering provides $u = g(\Gamma_0^2/\Gamma)W(\theta)$ from which Γ is also deduced with J, Γ_0/Γ and mixing ratios taken from the literature. Thanks to simultaneous determination of the x-ray spectra all the lifetimes as given by our programs with their statistical errors form an unusually coherent set of values.

NUCLEAR REACTIONS (γ, γ'), bremsstrahlung excitation; natural isotopes; ^{24}Mg, ^{27}Al, ^{48}Ti, ^{58}Ni, ^{59}Co, ^{61,62}Ni, ^{63,65}Cu, ^{64,66,68}Zn, ^{75}As, ^{103}Rh, ^{113,115}In, ^{116,118,120}Sn and ^{121,123}Sb; $E \simeq 0.5$–1.65 MeV; measured $g\Gamma_0$ or $g(\Gamma_0^2/\Gamma)W(\theta)$; deduced $T_{1/2}$.

Remarque. Pour calculer δ^2 quand nous ne disposons que de $B(E2)$, pour un mélange (E2) + (M1), nous déduisons $g\Gamma_0(E2) \propto B(E2)E_\gamma^5$; en admettant $W(\theta) = 1$ et connaissant Γ_0/Γ, notre détermination de u donne une première approximation de $g\Gamma_0$ d'où une valeur de $\delta^2 = (g\Gamma_0(E2))/(g\Gamma_0 - g\Gamma_0(E2))$ qui permet d'améliorer $W(\theta)$ et $g\Gamma_0$ de proche en proche.

GALLIUM

A=31

Gallium is a bluish-white metallic solid that becomes a liquid at near room temperature. It was discovered in 1875 by the French chemist, Lecoq de Boisbaudran, by spectroscopic examination of concentrates from a Pyrenean zinc blend. The position of the emission lines corresponded to those predicted for "eka-aluminum" a missing element between aluminum and indium in Mendeléyev's periodic scheme of the elements. He named it gallium from the Latin *gallia* in honor of his fatherland.

σ_m is the peak value of the cross section, E_m is the peak energy and $\int_0^\infty \sigma(E)dE$ is the integrated cross section. The upper limit of the integration is indicated in parentheses.

[a]) Value obtained subtracting the $(\gamma, 2n)$ reaction contribution from the $\sigma(\gamma, Tn)$.
[b]) Value obtained by subtracting the $Ni^{60}(\gamma, n)Ni^{57}$ reaction contribution from the $\sigma(\gamma, Tn)$ for natural nickel corrected for the $(\gamma, 2n)$ reaction contribution.

$\frac{T(M1)_{s.p.}}{T_{exp}}\frac{g_0}{g_1}$		4.5	4	18

$\sigma_{scatt}^{GeCl_4}$ and $\sigma_{scatt}^{GeBr_4}$ are the cross sections for resonance scattering obtained with gaseous sources of $GeCl_4$ and $GeBr_4$, respectively, σ_{scatt}^{solid} the cross section with a solid source of $GeCl_4$ and A_2 the anisotropy in the angular distribution of the resonantly scattered radiation. The level width Γ and the lifetime τ are deduced from the observed self-absorption ε, g_1 and g_0 are the statistical factors of excited and ground state, respectively. $N(E_r)_{exp}$ the relative number of γ-quanta in the emission line which falls into an energy interval of 1 eV around the absorption line E_r and $N(E_r)_{Ge}$ the expected values for a gaseous source of Ge atoms. In lines 10 and 11, the experimental results for the line width Γ_{exp} and the transition probability T_{exp} are compared with predictions of a pure vibrational model $\Gamma(E2)_{vibr}$ and the single-particle model omitting spin factors $T(M1)_{s.p.}$.

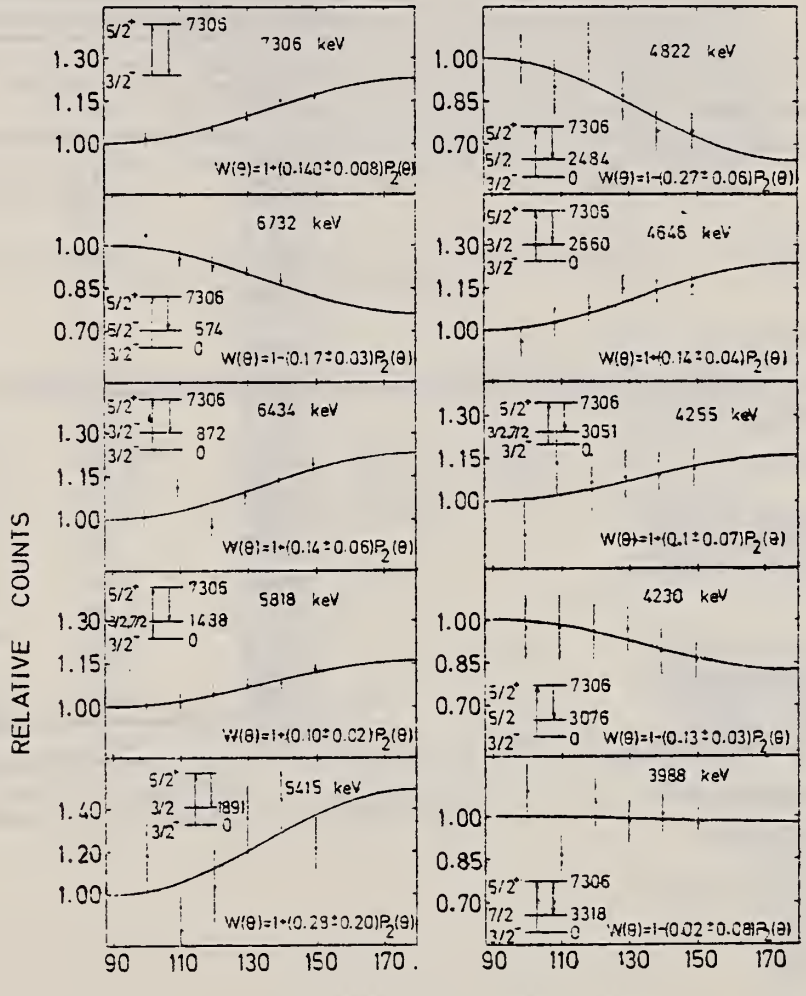

FIG. 4. Angular distributions of the elastic and inelastic transitions deexciting the 7306-keV level in ^{69}Ga as measured using a 20-cm^3 Ge(Li) detector. The solid lines have the form $W(\theta) = 1 + AP_2(\cos\theta)$ and are least-square fits to the experimental distribution. In each case the corresponding γ-γ cascade is indicated.

(over)

Elastic and inelastic scattering of monochromatic photons were used for studying nuclear energy levels in ^{69}Ga; the photons were produced by thermal neutron capture in copper and vanadium. The decay of one resonance at 7306 keV excited by the copper γ source and another resonance at 6874 keV excited by the vanadium γ source were studied in detail and 30 low-lying levels were observed from the ground state up to 3.4 MeV, 17 of which are believed to be new levels in ^{69}Ga. The angular distribution of some elastic and inelastic lines were measured and the following spin determinations were made (keV, J^π): 320, $\frac{1}{2}^-$, $(\frac{3}{2}^-)$; 574, $\frac{5}{2}^-$; 872, $\frac{3}{2}^-$; 1488, $\frac{3}{2}^-$, $\frac{7}{2}^-$; 1525 $(\frac{1}{2}, \frac{3}{2})$; 1891, $\frac{3}{2}^-$;(1978), $(\frac{1}{2}, \frac{3}{2})$; 2457, $\frac{3}{2}$; 2484, $\frac{5}{2}$; (2565), $(\frac{1}{2}, \frac{3}{2})$; 2660, $\frac{5}{2}$; 3051, $(\frac{3}{2}, \frac{7}{2})$; 3076, $\frac{5}{2}$; 3318, $(\frac{7}{2})$; 6874, $\frac{1}{2}^{(+)}$ and 7306, $\frac{5}{2}^+$, where parentheses denote uncertain J^π assignments. The parity of the 7306-keV level was directly determined using a Compton polarimeter. The total radiative width of the 7306-keV level was measured and found to be $\Gamma = 0.105 \pm 0.020$ eV. For the 6874-keV level, a positive correlation coefficient was obtained, $\rho = 0.69$, between the (γ,γ') and (d,n) transition strengths leading to the same final states in ^{69}Ga. The levels of ^{69}Ga are compared with recent theoretical calculations.

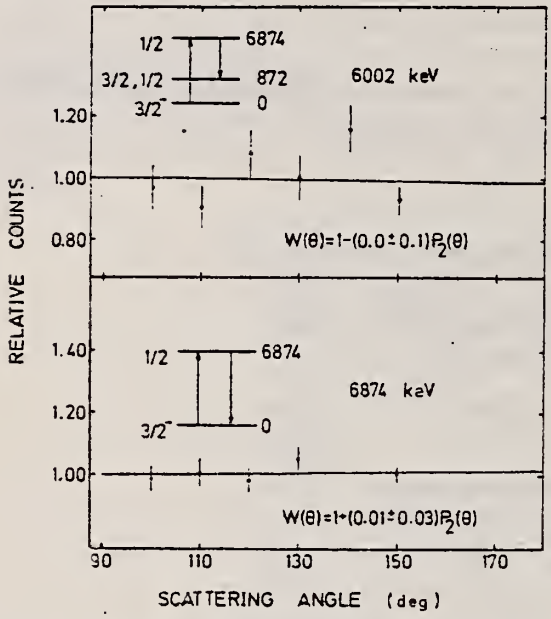

FIG. 5. Angular distribution of the elastic and one inelastic transition deexciting the 6874-keV level in ^{69}Ga as measured using a 30-cm^3 Ge(Li) detector. See caption to Fig. 4.

TABLE II. γ energies of the scattered radiation from a Ga target using V γ rays. Intensities are normalized relative to the 6874-keV resonance line. Asterisks denote transitions believed to correspond to a possible resonance at 7310-keV resonance in ^{71}Ga. Daggers indicate unidentified transitions.

Isobaric analog resonances in ^{69}Ga corresponding to the ground ($1/2^-$) and first excited ($9/2^+$) parent states of ^{69}Zn have been studied by the ^{68}Zn(p,γ) reaction. The γ decay of the ground state of ^{69}Zn is compared with the β decay of the parent isobaric analog state. The latter is a pure Gamow-Teller transition to the ground ($3/2^-$) and third ($3/2^-$) excited states, while both Gamow-Teller and Fermi matrix elements can contribute in the decay to the second excited ($1/2^-$) state of ^{69}Ga. The $M1$ decay widths obtained from the γ decay of the $J^\pi = 1/2^-$ isobaric analog state are in good agreement with the widths extracted from the logft values in the first two of the three β-decay branches. However, the $M1$ decay width to the third excited state disagrees with the value deduced from the logft value of the β decay of the ^{69}Zn g.s. to this state. In addition, the $M1$ transition strength of the $9/2^+$ ($T_>$) state to the $9/2^+$ ($T_<$) state in ^{69}Ga has been measured and is compared with the recently published systematic trends for the analog to antianalog transition in other f-p shell nuclei.

[NUCLEAR REACTIONS ^{68}Zn(p,γ), E=3.2–3.8 MeV. ^{69}Ga deduced resonances, measured E_γ and Γ_γ, $M1$ strength.]

TABLE I. γ-decay properties of the IAR of the ($\frac{1}{2}^-$) ground state of ^{69}Zn at E_p=3.250 MeV.

Transition	Assumed multipole order	Γ_γ (eV)	$B(M1)$ (μ_N^2)	$B(E2)$ (e^2fm^4)	$B(M1,\sigma)$ [a] (μ_N^2)
IAR → g.s $\frac{1}{2}^- \rightarrow \frac{1}{2}^-$	$M1$	0.88 ±0.20	0.080	...	0.085

DEFINITIONS OF ABBREVIATIONS AND SYMBOLS

Note: In this list definitions are given for various photoneutron reactions in which the following symbols are used: N, NL, nN, SN and XN. Corresponding definitions apply for reactions involving other nuclear particles where the symbols N (neutron) is replaced by, e.g. P, D, T, HE, A etc. Where unknown reactions result in the production of a specific radionuclide, the chemical symbol and mass number is listed as the reaction product, e.g. a G,NA22 reaction in ^{59}Co.

A	alpha particle
ANAL	analysis
ABI	absolute integrated cross-section data
ABX	absolute cross-section data
ABY	absolute yield data. Often means cross-section per equivalent quantum is listed.
ACT	measurement of induced radioactivity of the target
ASM	asymmetric, asymmetry
AVG	average
BBL	bubble chamber
BEL B(EL)	reduced electric radiative transition probability
BF3	BF_3 neutron counter with moderator e.g., Halpern detector, long counter
BML	reduced magnetic radiative transition probability, B(ML)
BREAKS	levels located by "breaks" in the yield curve
BRKUP	breakup
BRMS	bremsstrahlung
BTW	between
C	continuous. Used to describe a photon source or a detector response function. Contrast with D = discrete.
CCH	cloud chamber
CF	compared with
CHRGD	charged
CMPT	Compton
COIN COINC	coincidence, coincide
COH	coherent
CK	Cerenkov
D	deuteron or discrete. When discrete, it is used to describe a photon source or a detector response function. Contrast with C = continuous.
DLTE	energy loss
DLTQ	momentum transfer
DST	distribution
DT BAL	detailed balance
E	electron
E/	inelastically scattered electron
E+	positron
EDST	energy distribution or spectrum
E/N	used only to indicate a coincidence experiment as in (E,E/N).

	N stands for any outgoing particle measured in coincidence with an inelastically scattered electron. Distinguish from eg., (E,N) which is used to represent an electron induced reaction when only the outgoing particle N is detected.
EMU	emulsions (photographic plates)
EXCIT	excited
F	fission
FMF	form factor
FM-1	inverse femtometers
FRAG	fragment
G	photon
G/	inelastically scattered photon
G-WIDTH	gamma-ray transition width
HAD	hadrons, hadron production
HE He3	^{3}He particle
INT	interaction, integral, intensity
INC	includes
ION	ionization chamber
ISOB	isobaric
ISM	isomer
J	multiplicity of particle defined by following symbol e.g. (G,PJN) with remark J = 2,3,5,7
JPI J-PI	spin and parity of a nuclear state
K	second multiplicity index, e.g. (G,JPKN) with both J & K positive integers greater than 1
KE	kinetic energy
L	may be an integer or zero that always follows a reaction product symbol. This is used to indicate transitions to specific states in the residual nuclide. When the letter is used as in (G,NL) the cross section given is that for the sum of transitions to two or more specific final states.
LFT	excited state lifetime
LIM	limit
LV,LVS	level, levels
LQD	liquid
MAG	magnetic spectrometer
MEAS	measurement(s)
MGC	magnetic Compton spectrometer
MGP	magnetic pair spectrometer
MOD	moderated neutron detector not employing a BF_3 counter, e.g. rhodium foil, Szilard-Chalmers reaction, ^{3}He, ^{6}Li reactions, GD loaded liquid scintillator, etc.
MSP	mass spectrometer
MULT	multiple, multipole, multiplicity
MU-T	used only in combination with G to indicate a total photon absorption cross section measurement, i.e. (G,MU-T)
N	neutron (see also XN and SN). The notation (G,N) is used to indicate a reaction in which only a single neutron is emitted, i.e. the reaction that can, in many cases, be measured by observing the radioactive decay of the residual nuclide.

nN	where n is any integer. (G,nN) indicates the sum over all reaction cross sections in which n neutrons are emitted.
NAI	NaI(Tl) spectrometer
NEUT	neutron(s)
NOX	no cross-section data
P	proton (see also XP)
PART	particle(s)
PHOT	photon(s)
PI	pion, usually written as PI+, PI-, PIO to indicate charge
POL	polarized or polarization
Q-SQUAR	momentum transfer squared (q^2)
RCL	recoil
REL	relative
RLI	relative integrated cross-section data
RLX	relative cross-section data
RSP	reaction spectrometer
RLY	relative yield data
SCTD	scattered
SCD	semiconductor (solid state) detector
SCI	scintillator detector other than NaI, e.g., CsI, KI, organic (liquid or solid), stilbene, He
SEP	separation
SEP ISOTP	separated isotope used
SIG	SIGMA (cross section)
SN	sum of neutron producing reactions, $\sigma(\gamma,SN)=\sigma(\gamma,N) + \sigma(\gamma,NP) + \sigma(\gamma,2N) + \sigma(\gamma,3N)$ + etc.
SPC	photon or particle energy spectrum
SPK	spark chamber
SPL	spallation
STAT	statistical
SYM	symetric, symmetry
T	triton
TEL	counter telescope
THR	threshold for reaction or threshold detector, e.g., $^{29}Si(n,p)^{29}Al$.
TOF	time-of-flight detector
TRK	tracks of particles or fragments observed in solid materials (glass, mylar, etc.)
TRNS	transition
UKN UNK	unknown
VIB	vibrational
VIR PHOT	virtual photon(s)
XN	all neutrons, total neutron yield, $\sigma(\gamma,XN) = \sigma(\gamma,N) + 2\sigma(\gamma,2N) + 3\sigma(\gamma,3N) + \sigma(\gamma,NP)$ + etc.
XP	all protons, total proton yield $\sigma(\gamma,XP) = \sigma(\gamma,P) + \sigma(\gamma,NP) + 2\sigma(\gamma,2P)$ + etc.
XX XXX	reaction products defined in REMARKS
YLD	yield

4PI	a 4π geometry was used or a method like radioactivity or a total absorption measurement
999	energy defined in REMARKS
$	indicates the measurement involved beams or targets that were either polarized or aligned, or that the polarization of the reaction products was determined. The polarized particle is indicated in REMARKS.
* or @	symbols used to indicate that the units associated with the numerals on one or both sides of the symbol in a specific column are not MeV. The units are defined in REMARKS.

11. ABSTRACT (A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here)

These abstract sheets cover most classes of experimental photonuclear data leading to information of the electromagnetic matrix element between the ground and excited states of a given nucleus. This fifteen volume work contains nearly 7200 abstract sheets and covers 89 chemical elements from hydrogen through americium. It represents a twenty-seven year history of the study of electromagnetic interactions. The sheets are ordered by target element, target isotope, and by an assigned bibliographic reference code. Information is given on the type of measurement, excitation energies studied, source type and energies, detector type, and angular ranges covered in the measurement. For a given reference, the relevant figures and tables are mounted on a separate sheet for each nuclide studied.

12. KEY WORDS (Six to twelve entries; alphabetical order; capitalize only proper names; and separate key words by semicolons)

data-abstract sheets, elements, experimental, isotopes, nuclear physics, photonuclear reactions
