## INTRODUCTION TO JUNE 1985 ISSUE OF THE CEEE TECHNICAL PROGRESS BULLETIN

This is the ninth issue of a quarterly publication providing information on the technical work of the National Bureau of Standards Center for Electronics and Electrical Engineering. This issue of the CEEE Technical Progress Bulletin covers the fourth quarter of calendar year 1984.

Organization of Bulletin: This issue contains abstracts for all Center papers released for publication by NBS in the quarter and citations and abstracts for Center papers published in the quarter. Entries are arranged by technical topic as identified in the table of contents and alphabetically by first author under each subheading within each topic. Unpublished papers appear under the subheading "Released for Publication". Papers published in the quarter appear under the subheading "Recently Published". Following each abstract is the telephone number of the individual to contact for more information on the topic; unless otherwise noted, this person is the first author. This issue also includes a calendar of Center conferences and workshops now planned for calendar year 1985, an announcement of newly released standard reference materials, and a list of sponsors of the work.

Center for Electronics and Electrical Engineering: Center programs provide national reference standards, measurement methods, supporting theory and data, and traceability to national standards.

The metrological products of these programs aid economic growth by promoting equity and efficiency in the marketplace, by removing metrological barriers to improved productivity and innovation, by increasing U. S. competitiveness in international markets through facilitation of compliance with international agreements, and by providing technical bases for the development of voluntary standards for domestic and international trade. These metrological products also aid in the development of rational regulatory policy and promote efficient functioning of technical programs of the Government.

The work of the Center is divided into two major programs: the Semiconductor Technology Program, carried out by the Semiconductor Materials and Processes and Semiconductor Devices and Circuits Divisions in Gaithersburg, MD, and the Signals and Systems Metrology Program, carried out by the Electrosystems Division in Gaithersburg and the Electromagnetic Fields and Electromagnetic Technology Divisions in Boulder, CO. Key contacts in the Center are given on the back cover; readers are encouraged to contact any of these individuals for further information. To request a subscription or for more information on the Bulletin write to CEEE Technical Progress Bulletin, National Bureau of Standards, Metrology Building, Room B-358, Gaithersburg, MD 20899 or call (301) 921-3357.

Center sponsors: The Center Programs are sponsored by the National Bureau of Standards and a number of other organizations, in both the Federal and private sectors; these are identified on page 27.

Note on Publication Lists: Guides to earlier as well as recent work are the publication lists covering the work of each division. These lists are revised and reissued on an approximately annual basis and are available from the originating division [publications from the Semiconductor Technology Program are covered in a single list, available from either Semiconductor Division].

Nyyssonen, D., **Optical Linewidth Measurement on Patterned Metal Layers**, Proc. SPIE - The International Society for Optical Engineering, 480, Integrated Circuit Metrology II, pp. 2-8 [paper given at Conference, Arlington, VA, May 2-3, 1984].

In a previous paper, a waveguide model was developed for the imaging of micrometer-sized lines patterned in thick layers of dielectric materials (silicon dioxide) with application to linewidth measurement on integrated-circuit wafers. This paper describes the extension of this work to metals characterized by their complex index of refraction,  $n + iK$ , as well as the inclusion of a sublayer such as a silicon dioxide insulating layer. This extension allows the modeling of optical imaging and linewidth measurement on metal-on-silicon (MOS) structures. It is shown that the image structure for metals at and near focus is different from that for dielectrics. Thick and thin layer (less than 200 nm) imaging is compared. Experimental image profiles of metal lines at and near focus are also shown. The experimental data were obtained from a bright-field microscope using a laser source (530 nm) and controlled spatial coherence.

Gallium Arsenide Materials

## Released for Publication

Imhoff, E.A., Bell, M.I., and Forman, R.A., **Hot Photoluminescence in Beryllium-Doped Gallium Arsenide.**

Hot photoluminescence in GaAs:Be is reported for the first time. The emission from a sample with  $p = 6.5 \times 10^{16} \text{ cm}^{-3}$  at 10 K consists of a shoulder at  $1.803 \pm 0.002 \text{ eV}$  followed by a series of broad peaks at 1.781, 1.742, 1.704, 1.666, and 1.628 eV (all  $\pm 0.003 \text{ eV}$ ). Analysis of the results supports a decay model involving hot electron-acceptor recombination and implies an L- $\Gamma$  splitting of  $320 \pm 4 \text{ meV}$  in the conduction band at 0 K. Seabaugh, A.C., Bell, M.I., Larrabee, R. D., and Oliver, J.D., **High-Frequency Transient-Resistance Spectroscopy of Deep Levels in Semi-Insulated GaAs, Semi-Insulating III-V Materials: Kahneeta 1984**, D.C. Look and J.S. Blakemore, Eds., pp. 437-445 (Shiva Publishing, Ltd., Cheshire, England, 1984).

A new photoinduced transient-resistance technique is used to characterize deep levels in semi-insulating GaAs. In this technique, termed photoresistance deep-level transient spectroscopy (PR-DLTS), an optical pulse is used to generate excess carriers which are trapped by deep levels in the material. The ac resistance of the specimen is monitored, and the resistance transient which occurs after the illumination ends is signal processed in the same way as the capacitance transient in conventional DLTS. Comparison of this technique with the dc current-transient measurement, photoinduced transient spectroscopy (PITS), shows that it is sensitive to the same trapping/detrapping phenomena. PR-DLTS data for the Cr-related deep level is consistent with published DLTS results. Results are reported for materials grown by the horizontal Bridgman method and by the liquid-encapsulated Czochralski technique, both with and without chromium doping. Nineteen specimens from ten different manufacturers are compared.

Integrated Circuit Test Structures

Released for Publication

Cassard, J.M., **KEYS: A Computer Procedure Which Characterizes a Chip, Wafer, or Lot Using SUXES and STAT2.**

The computer procedure KEYS links SUXES, SPICE, and STAT2. Given data points for individual devices, SUXES obtains the model parameters for SPICE which predicts the behavior of an individual device or an entire circuit. After analyzing each test chip on a wafer, STAT2 determines the correlation coefficients and generates wafer maps of selected parameters. These wafer maps are valuable to the designer, modeler, and process engineer.

The entire package accomplishes the following: (1) standardizes the technique of running SUXES and SPICE; (2) simulates and plots the characteristic curves; (3) simulates and plots the results of an optional dynamic circuit (for example, a ring oscillator); (4) does steps (2) and (3) for every test chip on each wafer; (5) summarizes the results from each chip, each wafer, and the lot; (6) rank-orders the parameters for each wafer according to their correlation coefficients with respect to chosen parameters; and (7) generates wafer maps of several quantities. To illustrate the capabilities of KEYS, an example using CMOS technology is given. [(301) 921-3621]

Linholt, L.W., Yen, D., and Cresswell, M.W., **Electrical Linewidth Measurement in the Near- and Sub-Micron Linewidth Region.**

The measurement accuracy of the cross-bridge resistor test structure and test method has been compared to well-characterized optical measurements for samples with near-micron and sub-micron design dimensions patterned in polysilicon films. Results are presented which show that the electrical measurements agree with the corresponding optical measure-

ments to within the respective uncertainties of both measurements. [(301) 921-3541]

Carver, G.P., and Wachnik, R.A., **TERRY-2: A Test Chip for Characterization of the Performance of Buried-Channel Charge-Coupled Device (CCD) Imagers,** NBSIR 84-2894 (December 1984).

Test chip TERRY-2 is intended to be used for characterization of the performance of buried-channel charge coupled device (CCD) imagers fabricated with a double-polysilicon-gate process which includes several implants. Test structures in TERRY-2 address two areas judged to be key ones for CCD performance: device parameters and process parameters, including material properties. TERRY-2 is a modular chip designed for automatic testing; selected devices can be wire bonded for testing various environmental effects; a region containing test structures can be thinned in the same manner as a back-side-illuminated CCD would be; and large devices can be beveled for spreading resistance or physical analysis. This report describes the features of TERRY-2, the test structure designs, and the measurement procedures. The technique of charge pumping for measuring interface state density is discussed in an appendix.

Bennett, H.S., **Modeling GaAs/AlGaAs Devices: A Critical Review.**

Device models for GaAs devices and GaAs/AlGaAs heterostructures are much less advanced than those for silicon devices. This paper critically reviews recent advances in the modeling of GaAs/AlGaAs devices. It is based on the examination of five selected device models which contain features common to the majority of device models for heterostructure bipolar and field effect transistors. Areas requiring improved measurement techniques on processed GaAs and improved physical concepts for GaAs/AlGaAs device models are identified.

Bennett, H.S., and Fuoss, D.E., **Improved Physics for Simulating Submicron Bipolar Devices.**

The conventional device physics in most numerical simulations of bipolar transistors may not predict correctly the measured electrical performance of shallow, heavily doped emitters and bases. This paper presents improved device physics for numerical simulations of solid-state devices with densities up to about  $3 \times 10^{20} \text{ cm}^{-3}$  and with junction depths as small as  $0.1 \mu\text{m}$ . This improved device physics pertains to bandgap narrowing, effective intrinsic carrier concentrations, carrier mobilities, and lifetimes. When this improved device physics is incorporated into device analysis codes such as SEDAN and then used to compute the electrical performance of npn transistors, the predicted values agree very well with the measured values of the current-voltage characteristics and dc common emitter gains for junction depths between 10 and  $0.16 \mu\text{m}$ .

Albers, J., Wilson, C.L., and Blue, J.L., **The Effect of Bevel Angle and Number of Points on Spreading Resistance Data Analysis**, Extended Abstracts of the Electrochemical Society, 84-2, p. 727 (October 1984).

The semiconductor equations are used to obtain the carrier profile along a beveled structure. The spreading resistance is calculated on a scale much finer than the present experimental resolution of the technique. Spreading resistance algorithms are used on data spaced at the present experimental resolution. The difference between atomic and carrier densities along the bevel and the errors inherent in finite-layer algorithms are investigated. This is meant to provide insight into limitations of spreading resistance due to these sources.

Bennett, H.S., **Dependence of Minority Carrier Lifetime on Doping Density in Heavily Doped Silicon**, Solid-State Electronics, 27, pp. 893-904 (October 1984).

The minority carriers determine the essential electrical characteristics of bipolar devices and bipolar-like parasitic paths in field effect devices. The electrical behavior of such devices is frequently described by detailed device models. Among the several input parameters for detailed device models, the dependences of the minority carrier lifetimes as functions of doping density have great uncertainty. Recent results from scattering theory for bandgap narrowing and Fermi energy as functions of doping density are included in the Shockley-Read-Hall expressions for the minority carrier lifetimes. The predicted lifetimes are concave from above with increasing doping for those processing conditions under which the doping and defect densities are not correlated strongly, whereas empirical

Process and Device Modeling, cont'd.

expressions for the Shockley-Read-Hall lifetimes are convex with increasing doping density. Quantitative comparisons between theory and experiment are not possible because measurements of lifetime versus doping density have uncertainties associated with the separation of the Shockley-Read-Hall and Auger recombination mechanisms. A major finding of this research is that improved measurements are needed for minority carrier lifetime in heavily doped silicon as a function of doping density.

Berkowitz, H.L., and Albers, J., **Simplified Method for Calculating Four-Probe Resistances on Nonuniform Structures**, Extended Abstracts of the Electrochemical Society, 84-2, p. 751 (October 1984).

A simple method for calculating the four-probe resistance as an integral involving only the kernel of the correction factor integral (and independent of the probe radius and the probe-current density) is presented. Analytic expressions are derived for uniform layers and are investigated as a function of the probe spacing. For nonuniform resistivity structures, a simple numerical procedure is presented for the evaluation of the four-probe resistance and is compared with more extensive techniques. Galloway, K.F., **Measurements for VLSI Models**, Proceedings of the Second International Workshop on the Physics of Semiconductor Devices, S.C. Jain and S. Radhakrishna, Eds. (Tata McGraw-Hill, New Delhi, 1984), pp. 98-105.

The complexity of VLSI makes an experimental approach to design and fabrication unrealistic. Accurate, computer-based models for simulating processes, devices, and circuits are required to competitively develop VLSI technologies.

The effectiveness of these models is often limited by the accuracy of the physical parameters used as input for the simulations. This paper summarizes results from two recent projects on measurement technology for obtaining parameters for VLSI models to illustrate the research in this area at the National Bureau of Standards.

Wilson, C.L., and Blue, J.L., **Two-Dimensional Modeling of N-Channel MOSFETs Including Radiation-Induced Interface and Oxide Charge**, IEEE Transactions on Nuclear Science, NS-31, No. 6, pp. 1448-1452 (December 1984).

A model of the radiation-induced charges produced in n-channel MOSFETs is presented. The model is applicable for the unirradiated device and accurately predicts device characteristics for doses of up to 500 krad(Si). The model is verified by comparing the results obtained with the model to n-channel MOSFETs for doses of 0, 10, 50, 100, and 500 krad(Si). Detailed comparison of the model with a 7.8- $\mu\text{m}$  channel length transistor, to eliminate short-channel effects, shows excellent agreement between the model and measured current-voltage characteristics in the sub-threshold region, the triode region, and the saturation region. Analysis of the model parameters shows that the oxide charge and interface trap density are linear with dose in these devices. The mobility decrease used in the model can best be accounted for by the combined effects of scattering from oxide and interface charge in the channel.

Wilson, C.L., Roitman, P., Marchiando, J.F., and Blue, J.L., **Modeling of the Process Sensitivity of Submicron Silicon MOSFETs**, Extended Abstracts of the Electrochemical Society, 84-2, p. 709 (October 1984).

When short-channel MOSFET transistor models are compared to experimental

Process and Device Modeling, cont'd.

data, the uncertainty in the process models used as inputs often requires that some of the process model parameters be adjusted to fit the data. In this work the process sensitivity of the source-drain junction is modeled. We find that sensitivity of the saturated drain current to the source-drain junction depth increases sharply at some critical value of the junction depth. This value of junction depth is reached when the junction depth is equal to the zero biased depletion region width. As the contribution of the source drain junction to the sum of the depletion width and the junction depth becomes significant, the total change in channel field caused by the source-drain junction is a maximum.

Cryoelectronic Metrology

## Released for Publication

Kautz, R.L., **Chaos and Thermal Noise in the rf-Biased Josephson Junction.**

The effect of thermal noise on chaotic behavior in the rf-biased Josephson junction is studied through digital

simulations.

Metastable chaotic states are identified in the limit of zero temperature. Such states take the form of long-lived transients which suddenly give way to stable periodic solutions. It is shown that for an ensemble of systems in the metastable chaotic state, the number of systems continuing to behave chaotically decays exponentially in time. This result suggests that a deterministic system can display behavior analogous to radioactive decay.

At non-zero temperatures, small amounts of thermal noise can induce hopping between two states which correspond to a stable periodic solution and a metastable chaotic solution at zero temperature. The noise associated with thermally induced hopping can exceed that of chaos and could be confused with chaos in experimental investigations. At somewhat higher temperatures, the periodic solution is destabilized to the point where the system spends virtually all its time in the metastable chaotic state, creating thermally induced chaotic behavior. The similarities between chaotic behavior at zero temperature and thermally induced chaos are sufficiently strong that it may be difficult to distinguish the two cases experimentally.

Wittmann, R.C., and Yaghjian, A.D., **The Receiving Antenna as a Linear Differential Operator: Application to Spherical Near-Field Scanning.**

The general receiving antenna is represented as a linear differential operator converting the incident field and its derivatives at a single point in space ( $0'$ ) to the output voltage of the receiving antenna. The coefficients of the derivatives of the operator are determined explicitly in terms of the multipole coefficients of the antenna's receiving spectrum (far field) phase-referenced to the point  $0'$ . When the linear operator representation is applied to the special probes used in spherical near-field measurements, a probe-corrected spherical transmission formula is revealed that retains the form and applicability of the nonprobe-corrected equations. The new spherical transmission formula is shown to be consistent with previous transmission formulas involving rotational and translational addition theorems.

Antenna Metrology, cont'd.

**Correction Parameters for Circularly Polarized Probes**, Proc. Annual Conference of the Antenna Measurement Techniques Association, Atlanta, GA, pp. 3A3-1 - 3A3-29 (October 2-4, 1984).

In order to accurately determine the far-field of an antenna from near-field measurements the receiving pattern of the probe must be known so that probe correction can be performed. When the antenna to be tested is circularly polarized, the measurements are more accurate and efficient if circularly polarized probes are used. Further efficiency is obtained if one probe is dual polarized to allow for simultaneous measurements of both components. A procedure used by the National Bureau of Standards for determining the plane-wave receiving parameters of a dual-mode, circularly polarized probe is described herein. First, the on-axis gain of the probe is determined using the three antenna extrapolation technique. Second, the on-axis axial ratios and port-to-port comparison ratios are determined for both the probe and source antenna using a rotating linear horn. Far-field pattern measurements of both amplitude and phase are then made for both the main and cross components. In the computer processing of the data, the on-axis results are used to correct for the non-ideal source antenna polarization, scale the receiving coefficients, and correct for some measurement errors. The plane wave receiving parameters are determined at equally spaced intervals in k-space by interpolation of the corrected pattern data.

Wittmann, R.C., **Probe Correction in Spherical Near-Field Scanning, Viewed as an Ideal Probe Measuring an Effective Field**, 1984 International Symposium Digest, Antennas and Propagation, Vol. II, pp. 674-677 [paper given at IEEE Antennas and Propagation Society Meeting, Boston, MA, June 25-29, 1984].

In order to reduce measurement and computation complexity, most probe-corrected, spherical near-field scanning facilities use a special "symmetric" probe, the output of which exhibits a  $\sin \chi - \cos \chi$  dependence as the probe is rotated about its axis by an angle  $\chi$ . We show here that such a probe is mathematically equivalent to ideal dipole probes measuring an effective field. Computational efficiency and structural simplicity result, since much of the effort concerns the calculation of the effective field, and this may be accomplished with a no-probe correction algorithm.

Noise Metrology, cont'd.

Wait, D.F., **The Impact of Automation on NBS Noise Temperature Measurements**, to be published in the forthcoming special issue of the Proceedings of the IEEE on Radio Measurement Methods and Standards (invited paper).

The accuracy of calibrating a thermal noise source using the National Bureau of Standards' automated radiometer and cryogenic, primary noise standards is typically  $\pm 2\%$ , compared with  $\pm 3\%$  for corresponding services that used manual radiometers and hot primary standards. Using the automated radiometer, a noise source can typically be calibrated at three frequencies in the time a manual radiometer requires to calibrate one. The automated radiometer contains a 6-port reflectometer and noise sources with reflection coefficients as great as 0.3 can be tolerated without significantly affecting the calibration accuracy. This makes it practical to use a single broad-band, coaxial noise standard from 0.03 GHz to 14 GHz. The 6-port reflectometer also makes it possible to calibrate sources with connectors different from the primary standard's without almost no additional accuracy degradation.

Engelsrath, A., Larson, D.R., Phelan, R.J., and Franzen, D.L., **Attenuation of Multimode Fused Silicon Optical Fibers Cooled to Liquid Helium Temperature**, Proc. SPIE - The International Society for Optical Engineering, 500, Fiber Optics: Short-Haul and Long-Haul Measurements and Applications II, pp.

124-130 [paper given at conference, San Diego, California, August 19-24, 1984].

The feasibility of bringing an optical signal through an optical fiber to a detection and processing system at liquid helium temperature was examined. The attenuation of three commercially available multimode optical fibers, from two different manufacturers with different buffer coatings, was measured under different cooling conditions. It was found that the attenuation depends on the cooling condition and has hysteresis effects. Independent of the  $\lambda$  tested (0.4-1.65  $\mu\text{m}$ ) the attenuation stayed below 0.1 dB/m under controlled slow cooling and under 0.5 dB/m with very fast cooling. Therefore, optical fibers can be used to bring optical signals into a liquid-helium-cooled dewar for detection and processing.

SPIE - The International Society for Optical Engineering, 500, Fiber Optics: Short-Haul and Long-Haul Measurements and Applications II, pp. 88-93 [paper given at conference, San Diego, California, August 19-24, 1984].

The phase space diagram for parabolic and step index fibers leads to a graphic representation of the bound, leaky, and refracted rays of ray theory. This concept is used to predict the attenuation of typical components of local area networks. The technique uses power transfer matrices to track the evolution of power distribution in ray packets. In particular, we predict and then measure the power transfer of two ray packets for a step index fiber. The comparison is encouraging.

Major, J.R., Livingston, E.M., and Adair, R.T., **Automatic Frequency Response of Frequency Modulated Generators Using the Bessel Null Method**, to be published in the Proceedings of the 24th ARFTG Conference, Baltimore, MD, December 4-6, 1984.

This paper describes a Bessel null technique to measure the frequency response of a frequency-modulated rf carrier and a program to automate frequency response measurements of signal generators with output frequencies from 0.450 to 2000 MHz. The measurements obtained using this technique are more accurate than those obtained by a highly trained technician using a manual system.

Automated measurement of this process is desirable since the manual method is subject to the following problems: (1) excessive time, (2) error in finding the null, and (3) lack of assurance that the null is the first Bessel null. This can be performed using a system controller, a spectrum analyzer, a function generator, and a voltmeter (all of which are compatible and controllable remotely (or by buss)).

A major obstacle to automated measurement is the nonlinear relationship of modulating signal amplitude relative to the center frequency amplitude of the carrier. This problem was solved by obtaining an approximate formula for this nonlinear curve.

Assurance that the null found is the first Bessel null is provided in the analysis of a filtered response of the frequency versus amplitude of the test signal generator output which is displayed on the spectrum analyzer.

Young, M., and Johnson, E.G., **Redefining the Scratch Standards**, to be published as NBS Technical Note 1080 [a related paper, Tunable Scratch Standards, authors Young, M, Johnson, E.G.,

E.G., and Goldgraben, R., was given at the SPIE 1985 Los Angeles Technical Symposium on Optical & Electro-Optical Engineering, Conference on Measurement and Effects of Surface Defects and Quality of Polish, and is to be published in the proceedings of that Conference].

The scratch standard (MIL-0-13830A) is a cosmetic standard that is effected by a visual comparison with a set of submasters that are in turn evaluated by comparison with a set of master standards. Both manufacture and certification of the submasters are somewhat unreliable. In this paper, we show that the submasters can be classified according to the relative power scattered at a relatively small angle. We have designed etched gratings with which to replace the submasters; these gratings have the appearance of scratches but diffract a broad peak between 5 and 10 degrees off the axis of the incident beam. We have classified some prototypes both by comparison with the master standards and by a photoelectric measurement; agreement between the two methods is good. We suggest that such gratings be used as the submasters and possibly that they be classified by a photoelectric rather than visual measurement.

We have developed apparatus for measuring the scattered light from the artifact as a function of angle, using a silicon photodiode as the detector; this apparatus and its design considerations are briefly described. We applied a number of tests to evaluate the performance of this optical system, including determination of uniformity of illumination, impulse response, and detector linearity.

We also provide a discussion of basic diffraction theory, which leads to the instrumental conclusion that the width of the illuminating beam should be no greater than several hundred times the width of the scratch.

Hill, D.A., **Radio Propagation in a Coal Seam and the Inverse Problem**, NBS Journal of Research, 89, No. 5, pp. 385-394 (September-October 1984) [related paper to be published at the Conference Proceedings of the International Symposium on Antennas and EM Theory, Beijing, China, August 24-26, 1985].

The longwall method of coal mining in underground coal seams is very efficient in uniform seams, but coal seam anomalies can make the method unprofitable and unsafe. This paper describes the theoretical basis for detection of coal seam anomalies using medium frequency (MF) radio transmission over paths on the order of 200 meters in length. The key to the method is the sensitivity of the attenuation rate of the coal seam mode of propagation to changes in the coal seam parameters, such as height or electrical conductivity. From a large number of transmission paths, the principles of tomography can be used to reconstruct an image of the seam.

**B.A., An Automatic AC/DC Thermal Voltage Converter and AC Voltage Calibration System**, NBSIR 84-2973 (November 1984).

An automatic ac/dc difference calibration system is described which uses direct measurement of thermoelement emfs. In addition to ac/dc difference testing, the system can be used to measure some important characteristics of thermoelements, as well as to calibrate ac voltage calibrators and precision voltmeters. The system operates over a frequency range from 20 Hz to 100 kHz, covering the voltage range from 0.5 V to 1 kV. For all voltages the total measurement uncertainties expected (including the uncertainty of the specific reference thermal converters used) were 50 parts per million (ppm) at frequencies from 20 Hz to 20 kHz, inclusive, and 100 ppm at higher frequencies up to 100 kHz. The results of initial inter-comparisons between the new system and the manual NBS calibration system, using single-range, coaxial-type, thermal voltage converters as transfer standards, are reported. The results show that the agreement between the two systems is better than the uncertainties originally expected, since the intercomparison of ac/dc differences differed by no more than 15 ppm.

Young, M., **Can You Describe Optical Surface Quality with One or Two Numbers?**, Proc. SPIE - The International Society for Optical Engineering, 406, Optical Specifications: Components and Systems, pp. 12-22 [paper given at conference, April 5-7, 1983, Arlington, VA].

This talk discusses two optical surface quality standards, total integrated scatter (TIS) and the scratch and dig standard (MIL-0-13830A). I begin by using Fourier optics to show that the well known expression,  $I_t/I(0) = 4k^2\sigma^2$ , which relates scattered power to rms roughness  $\sigma$ , is truly valid only for certain classes of surfaces. Vector scattering theory applied to a more general case shows that in fact optics can measure only a bandwidth limited roughness that can be related to scattered power only if the surface statistics are known. For this reason, the standard should perhaps be regarded as a scattered light standard and not as a surface roughness standard. I conclude by describing our use of a novel optical system to develop an objective measurement technique to aid in the manufacture of the artifacts used to implement the scratch standard.

Superconductors

Released for Publication

Fickett, F.R., **Investigation of a Practical Superconductor with a Copper Matrix.**

In this report we summarize the work performed on four International Copper Research Association projects covering a span of about six years. The main goal of the work was to investigate the in-situ superconductors, those produced by the relatively rapid cooling of a melt containing essentially non-miscible components. The component with the higher melting point precipitates out as small particles during the cooling. Subsequent drawing of the resulting boule results in fine filaments of this material (the superconductor) in the lower-melting matrix (usually oxygen-

free copper or a copper-tin alloy).

Goldfarb, R.B., and Clark, A.F., **Hysteretic Losses in NbTi Superconductors.**

When subjected to transient magnetic fields, superconductors exhibit losses. At low frequencies, most of the dissipation is hysteretic. Hysteresis loops were measured in an axial field for eight multifilamentary NbTi superconducting wires with different filament sizes and different ratios of copper-to-superconductor. The full-penetration field  $H_p$ , a function of critical current density  $J_c$  and filament radius, was estimated from the hysteresis loops. There was good agreement between measured hysteresis and that predicted from the peak applied field and  $H_p$ . The estimate of  $H_p$  provides a method to assess  $J_c$ .

Hong, M., Maher, D.M., Ellington, M.B., Hellman, F., Geballe, T.H., Ekin, J.W., and Holthuis, J.T., **Further Investigations of the Solid-Liquid Reaction and High-Field Critical Current Density in Liquid-Infiltrated Nb-Sn Conductors**, to be published in the Proceedings of the 1984 Applied Superconductivity Conference, San Diego, CA, September 9-13, 1984.

Superior superconducting properties, such as high  $J_c$ 's and  $T_c$ 's, have been obtained from reacted liquid-infiltrated Nb-Sn composite wires. These excellent properties are attributed to the chemistry and structure of the material which is prepared by a unique solid (Nb)-liquid (Sn) reaction. From heat capacity measurements, sharp bulk superconducting transitions of the A15 phase occur at 17.2-18 K and the weight fraction of A15 in the composite wire is ~23%. Analytical electron microscopy techniques have shown that: the microstructure of these conductors consists of alternating large-grain and small-grain filaments; these two types of

Superconductors, cont'd.

filaments correspond to BCC Nb(Sn) and cubic A15 Nb<sub>7.5±x</sub>Sn<sub>2.5∓x</sub> phases, respectively; the A15 filaments (< 0.5 μm) are chemically homogeneous in terms of measured X-ray intensity ratios to within ±7% which implies that  $x \sim 1.5$ ; and the A15 grains are essentially free of extended lattice disorder down to a resolution of ~0.34 nm.

Recent work in which Nb is alloyed with Ta has shown that these superconducting properties can be improved upon; e.g., high overall  $J_c$ 's of  $\sim 1.8 \times 10^4$  cm<sup>2</sup> at 20 T and 4.2 K have been measured. Also, the liquid-infiltrated Nb(Ta)-Sn composites have a damage strain tolerance nearly double that of commercial bronze-processed Nb-Sn conductors.

**of Liquid-Infiltration Nb-Ta/Sn Multifilamentary Superconductor**, Applied Physics Letters, 45, No. 3, pp. 297-299 (1 August 1984).

Data are presented on the strain dependence of the critical current and critical field of Nb-Ta/Sn superconductors fabricated by the liquid Sn infiltration process. The results show that liquid infiltrated Nb-Ta/Sn superconductors have several significant advantages over bronze-process Nb/Sn superconductors: an overall  $J_c$  that is 3-10 times higher for magnetic fields in the range 13-20 T, an irreversible (damage) strain limit twice as large, and a  $J_c$  elastic-strain sensitivity less than half as large at fields above ~16 T. These improved properties are attributed to several unique characteristics of the liquid infiltration process: a tough Nb-Ta matrix, fine equiaxial A15 grains, and a uniform stoichiometric Sn concentration.

[(303) 497-3785]

Cryogenic Engineering Conference, Helsinki, Finland, July 31-August 3, 1984, pp. 365-368.

Several different configurations of magnetic monopole detectors have been built and operated at the National Bureau of Standards. These have been designed based on the following objectives: (1) Study of the noise characteristics; (2) Simplicity and ease of changing configurations; (3) Operation in relatively large magnetic fields; and (4) Optimum detector area. Satisfying these objectives has resulted in several compromises, but also a flexible and useful apparatus for studying the behavior of the SQUID - detector loop combination with particular emphasis on noise sources that can simulate a monopole signal. Several sources of noise and techniques for their elimination will be discussed. Data from the spectral analysis of the noise signals is presented.

A system is being developed to monitor and collect electromagnetic (EM) field strength at 10 selected locations simultaneously. The system has two modes of operation: (1) for sampling EM fields that are stationary for times of the order of 200 ms, and (2) for sampling changing EM fields with a system resolution of 10  $\mu$  sec. Sensing elements consist of three orthogonal dipoles, each dipole feeding a separate data input channel for a total of 30 channels. Rf energy is converted to DC by a small diode detector at each dipole. Several sets of 30 sensing elements each are planned to cover specific measurement regions of amplitude and frequency. One of the initial sets will use 0.6 cm resistive dipoles; measurements of rf fields with this set will normally be taken in the range 100 MHz to 18 GHz, with an amplitude capability of up to several hundred volts per meter. Other sets will range in length up to 5 cm and may eventually include small loops. System computer data processing proceeds in real time and includes computation of total scalar amplitude at each of 10 probe locations, and statistical processing of resultant data.

Cruz, J.E., and Larsen, E.B., **Screen-room Measurements of Antenna Factors**, to be published in the Proceedings of the IMTC/85 Instrumentation/Measurement Technology Conference, Tampa, FL, March 21-22, 1985.

The measurement of electromagnetic fields in a shielded enclosure (screen-room) has serious problems because of uncertain antenna factors and multipath reflections from conductive surfaces. Most electromagnetic interference antennas at NBS are calibrated in a known field at an open field site using the standard antenna method. Because these antenna factors are not necessarily applicable for making measurements in an enclosed screenroom, the measurement errors are difficult to determine. This paper presents the results of antenna factors determined in a screenroom using the two-antenna method. These antenna factors are compared with antenna factors determined at an open field site and in an anechoic chamber. Experimental data are presented to show the variability of antenna factor as a function of frequency and location in the screenroom thereby providing an example of errorbounds.

FitzGerrell, R.G., **Site Attenuation**, to be published in the Proceedings of the North American Radio Science Meeting and the International IEEE/AP-S

Symposium, Vancouver, B.C., June 17-21, 1985.

Site attenuation is defined as the minimum relative insertion loss between two polarization-matched antennas located on a test site when one antenna is moved vertically over a specified height range. The following parameters must also be specified: separation distance between the two antennas, measured horizontally; antenna type and polarization; and impedance of the receiving and transmitting systems attached to the antenna terminals.

Site attenuation is a measure of performance of an open test site used to determine the levels of emissions, usually undesired, from sources of electromagnetic fields or to calibrate monopole and dipole antennas used for field strength measurements. An ideal site consists of an obstruction-free plane ground and the hemisphere above it - both infinite in extent. Ground constants may range from typical earth values to values for good conductors. Site attenuation measurements are used to compare performance of real sites to some standard or reference site. Calculations presented here provide a reference for measurements to be made of a 30 m by 60 m wire mesh ground screen.

Hill, D.A., and Koepke, G.H., **An Array of Dipoles for Plane Wave Synthesis**, to be published in the Proceedings of the 1985 International Symposium on Antennas and Propagation, Kyoto, Japan, August 20-25, 1985.

Phased arrays can be used to produce a nearly uniform plane wave in the near field. This paper describes a small array of dipoles which we have studied theoretically and experimentally. The element excitations are determined from a near-field synthesis technique that optimizes the field uniformity throughout the test volume.

Larsen, E.B., and Cruz, J.E., **E and H Fields in Transmission Lines and Coils for Susceptibility Testing, Probe Calibration, and RF Exposure Chambers**, to be published in the Proceedings of the IMTC/85 Instrumentation/Measurement Technology Conference, Tampa, FL, March 21-22, 1985.

This paper deals with the instrumentation and design equations for several systems used to generate calculable electric (E) and magnetic (H) fields for electromagnetic compatibility (EMC) testing. These "standard" electromagnetic (EM) fields with known magnitude are used to: (a) test the susceptibility of electronic equipment to radiated fields, (b) calibrate E and H field probes for measuring and mapping fields, and (c) expose biological specimens in a known EM environment. The design and use of so-called transverse electromagnetic (TEM) cells terminated in their characteristic impedance are not described here because these devices are discussed adequately elsewhere.

Ma, M.T., and Koepke, G.H., **Measurements of Unintentional Emissions**.

A new method for determining the radiation characteristics of leakage from electronic equipment or other unintentional radiators for interference stud-

ies is presented. The theoretical background and specific measurement procedures for the method using a transverse electromagnetic cell are outlined. The theory and measurements have been verified by the results of a simulated theoretical example and an experiment using a spherical dipole radiator. Mathematical analysis of the uncertainties in the final, extracted results when the experimental data are degraded by the background noise and measurement imperfections is also available.

Muth, L.A., **A Theory of Mutual Impedances and Multiple Reflections in an N-Element Array Environment**, to be published as NBS Technical Note 1078.

A general theoretical approach is formulated to describe the complex electromagnetic environment of an N-element array. The theory reveals the element-to-element interactions and multiple reflections within the array. From the formulation, it is found that the interaction between an excited element and an open-circuited element can be viewed as the sum of terms describing all possible signal paths within the array environment which start from the radiating element and terminate on the element under observation. Within all paths except the most direct one, multiple reflections between subgroups of elements take place. The resulting solution is highly structured and recursive and is discussed in detail in the text. Illustrative examples are provided to facilitate understanding of these ideas.

Randa, J., and Kanda, M., **A Finite-Element Action Approach to the Characterization of Complex Electromagnetic Environments**, to be published in the Proceedings of the 1985 International Symposium on Antennas and EM Theory, Beijing, China, August 25-27, 1985.

We outline an approach to the characterization of complicated electromagnetic

Electromagnetic Interference, cont'd.

environments based on a finite-element approximation to the action functional of the electromagnetic field. A stationary point of the action is found by a numerical search, subject to constraints imposed by boundary conditions and by measurements of the field at some number of points. The technique is illustrated by a simple example.

Randa, J., and Kanda, M., **Directional Scanning of Complex Electromagnetic Environments**, to be published in the Proceedings of the 1985 International Symposium on Antennas and Propagation, Kyoto, Japan, August 20-22, 1985.

As rf and microwave sources (both intentional and inadvertent) multiply, the electromagnetic (EM) environment in which electronic devices (and people) must function becomes increasingly complicated, while at the same time its characterization becomes more important. In order to completely characterize an EM environment without knowledge of the radiating sources, the sampling theorem requires that systematic measurements of the amplitude and phase of the field be made throughout the volume at spacings of no more than one-half wavelength (of the highest frequency present). This is often impossible and seldom convenient. There is a need for practical techniques which would determine useful properties of an EM environment from relatively few measurements. One recent suggestion for such a technique is to use directional measurements at a single point in conjunction with a plane-wave expansion of the field. This paper reports the formulation of the technique and the results of a simulation using it.

[(303) 497-3150]

Randa, J., and Kanda, M., **A Directional Scanning Technique for Characterization of Complex Electromagnetic Environments**, to be published in the Proceedings of the North American Radio Science Meeting and International

IEEE/AP-S Symposium, Vancouver, B.C., June 17-21, 1985.

The problem of characterizing complicated electromagnetic environments without actually measuring the field(s) throughout the entire volume of interest is of great practical importance in the areas of EMI/EMC electromagnetic hazard assessment, etc. The question is how to obtain useful information about the volume of interest from a reasonably small number of measurements.

A recent suggestion which appears to hold considerable promise is to use a directional probe to measure at one point the field incident from different directions and then to reconstruct or bound the field throughout the volume by using these measurements in conjunction with a plane-wave expansion of the field. We have now completed the formulation and performed simulations for the (vector) electric field, and we report the results in this paper. Simulation results are encouraging.

Wilson, P.F., Adams, J.W., and Ma, M.T., **Measurements of the Electromagnetic Shielding Capability of Materials**, to be published in the forthcoming special issue of the Proceedings of the IEEE on Radio Measurement Methods and Standards (invited paper).

Shielding effectiveness is usually measured in terms of insertion loss, that is, the reduction in the fields coupled between a transmitter and receiver achieved by introducing the shield material or case, etc. Although the insertion loss concept is simply stated, problems arise when one attempts to interpret specific insertion loss measurements. Insertion loss values obtained in practice depend not only on the shield material introduced but also on antenna types used and their orientations, incident field distribution, and contact resistance. Variations in these factors can yield almost any level of insertion loss for the same shield sample. These concepts will be discussed

Electromagnetic Interference, cont'd.

briefly to emphasize both the difficulty in making even relative insertion loss comparisons and the importance of controlling and understanding the measurement configurations.

Juroshek, J.R., and Hoer, C.A., **A High-Power Automatic Network Analyzer for Measuring the RF Power Absorbed by Biological Samples in a TEM Cell**, IEEE Transactions on Microwave Theory and Techniques, MTT-32, No. 8, pp. 818-824 (August 1984).

A device for measuring the radiofrequency (RF) power absorbed by biological samples while they are being irradiated in a transverse electromagnetic (TEM) cell is described. The report discusses the design, calibration, and performance of this automated measurement system. The power absorption analyzer is based on a six-port type of automatic network analyzer, and operates at an incident power to the TEM cell of 1 to 1000 W, over a frequency range of 100 to 1000 MHz. Experiments show that an absorbed power of 0.02 to 0.05 percent of the incident power can be measured. Measurements of the power absorbed by a 1-percent saline solution were made using the power absorption analyzer and by an independent calorimetric measurement. The two measurement techniques show excellent agreement.

Shafer, J.F., **Field Strength Levels in Vehicle Resulting From Communications Transmitters**, National Institute of Justice Report No. 200-83 (June 1984).

This report provides the results of an exploratory study to measure the electric field strength levels inside an automobile from communications equipment (transmitters and associated antennas) typical of that likely to be operated in and around the automobile as a law-enforcement vehicle. Field strengths were measured with a calibrated probe at 10 locations within the test vehicle, with and without the driver's door open, and with and without front-seat occupants, at frequencies representing the frequency bands of 25 to 50, 150 to 174, 400 to 512, and 806 to 866 MHz. Levels of output power are given for the data presented. Field strength levels are also given for the situation when a metallic prisoner shield or a personal transceiver is used in a vehicle, together with a mobile transceiver, in some cases. Also included are field strength measurements of speed measuring radar devices used in vehicles.

Wilson, P.F., Chang, D.C., and Ma, M.T., **Input Impedance of a Probe Antenna in a TEM Cell**, IEEE Transactions of Electromagnetic Compatibility, EMC-26, No. 4, pp. 154-161 (November 1984).

The input impedance of a probe antenna exciting a transverse electromagnetic (TEM) cell is analyzed via a variational formulation. The resulting impedance is shown to consist of two distinct terms; an ordinary rectangular waveguide contribution and a gap perturbation. Numerically generated curves for both are given and suggest that a simple algebraic approximation for the input impedance should normally suffice. The resistive portion is found to be proportional to the square of the probe length, while the reactive portion is largely capacitive. These results should enhance the use of probes in-

Electromagnetic Interference, cont'd.

serted in TEM cells either to excite or to measure fields.

**1985 CEEE CALENDAR**

June 10-14 (Boulder, CO)

**Antenna Parameter Measurement by Near-Field Techniques.** This course is designed for engineers and scientists concerned with the accurate measurement of microwave antenna parameters. Major emphasis will be placed on the theory of near-field antenna-antenna interactions; application to near-field scanning on planar, cylindrical, and spherical surfaces; and the computation of desired antenna characteristics from near-field data. Results comparing planar, cylindrical, and spherical methods will be presented, and the limitations and advantages of each method discussed. In addition, less detailed treatment will be offered of the extrapolation method for determining absolute gain and polarization. [Contact: Richard L. Lewis (303) 497-5196]

December 5 (Gaithersburg, MD)

**1985 Power Semiconductor Devices Workshop.** This Workshop is jointly sponsored by the IEEE Electron Devices Society and NBS and is held in conjunction with the IEEE Electron Devices Meeting in Washington, D.C., which it follows. Topic areas include: packaging, power integrated circuits, three-terminal devices, and modeling. The format of the Workshop calls for each topic area to be addressed by working groups of 15 to 30. Reports from the working groups will be developed and presented orally to all attendees in a concluding session. [Contact: Sandra B. Kelley (301) 921-3541]

#### NEW STANDARD REFERENCE MATERIALS

The first practical superconducting standard reference material (SRM) has been released by the Electromagnetic Technology Division to the NBS Office of Standard Reference Materials for sale to the public. The certified parameter of SRM 1457, Superconducting Critical Current -- NbTi Wire, is critical current at magnetic fields of 2, 4, 6, and 8 tesla at a temperature of 4.2 K and an electric field criterion of 0.2  $\mu\text{V}/\text{cm}$ . Information is given to permit the user to determine critical current for temperatures in the range 3.90 to 4.24 K

## NEW STANDARD REFERENCE MATERIAL, cont'd.

and electric field criteria from 0.05 to 0.2  $\mu\text{V}/\text{cm}$ .

SRM 1457 consists of a 2.2-m length of a multifilimentary, niobium-titanium, copper-stabilized wire, wound in a single layer on a spool having a core diameter of 8.7 cm. The wire is evaluated for 34 parameters relating to current, voltage, magnetic field, temperature, strain, and physical specimen characteristics.

In conjunction with ASTM Standard Test Method B714-82, D-C Critical Current of Composite Superconductors, the new SRM is intended to provide means for calibrating apparatus used to measure key parameters of superconductor products and thus should be useful to buyers and sellers of superconductors, users of superconducting equipment, and researchers in superconducting technology.
