The Thermodynamic Properties of Nitrogen Tetroxide

Robert D. McCarty, Hans-Ulrich Steurer and C. M. Daily

Thermophysics Division
Center for Chemical Engineering
National Bureau of Standards
Boulder, Colorado 80303

A mathematical model of the equation of state of nitrogen tetroxide is presented. Isobaric tables of P-ρ-T and composition for temperatures from the triple point (261.95 K) to 600 K with pressures to 40 MPa are also given. The mathematical model of the equation of state is a 32 term modified Benedict-Webb-Rubin equation. A method of calculating chemical equilibrium for the system is also presented.

Key words: chemical equilibrium; composition; density; equation of state; nitrogen tetroxide; pressure; temperature.

1. Introduction

The thermodynamic properties of nitrogen tetroxide, hereafter referred to as N_2O_4, are of interest in at least two major areas. The fluid is widely used as an oxidizer for small rockets and as an agent in heat transfer problems. A search of the world's literature revealed a substantial experimental data base but few correlations of those data, and the correlations that do exist either cover only portions of the P-ρ-T surface or involve ideal gas assumptions which, for a wide range of pressures and temperatures, result in substantial inaccuracies. The National Bureau of Standards, under contract with NASA Kennedy Space Center, undertook a study to produce a correlation of the thermodynamic properties of N_2O_4 based on the existing experimental data. The following is the final report on that study.

2. Literature Search

A computerized search of the world's literature produced 172 titles concerned with N_2O_4. On the basis of the titles alone, 98 of the 172 appeared to be of possible use in the study. Copies of 62 of the selected references were eventually obtained. Many of these articles are in Russian, in fact 75 of the original 98 selected are of Soviet origin, and copies of some of the articles were difficult or impossible to obtain. A second selection process based on the actual contents of the obtained articles reduced this number even further and references [1-85] include all of the final selection plus those articles which could not be obtained and therefore remain as a possible source of pertinent information. During the course of the second selection process and subsequent correlation, eleven additional articles pertinent to the study were found. The literature search as described above provided an adequate experimental data base for the correlation of N_2O_4 properties.

3. N_2O_4 Dissociation

The fluid commonly referred to as N_2O_4 is not pure N_2O_4, but is in reality a mixture of N_2O_4, NO_2, NO, and O_2. This condition is a result of the following reactions taking place:

$$N_2O_4 \rightleftharpoons 2NO_2 \qquad (1)$$

$$2NO_2 \rightleftharpoons 2NO + O_2 \qquad (2)$$

The extent of these reactions depends on both pressure and temperature and therefore the equilibrium concentration of the various components changes from state point to state point. The time it takes for equilibrium to occur when the state conditions are changed will not be

addressed here, and only equilibrium conditions will be considered. Since the concentration of the various components changes with pressure and temperature, a knowledge of the composition at a given state point is necessary to construct an equation of state. The necessity of composition information complicates any correlation attempt via a mathematical model of the equation of state, and this problem will be discussed in the following sections. P-ρ-T relations of the saturated liquid and vapor are also necessary for the construction of an equation of state. Thus pressure-temperature as well as density-temperature correlations for the saturated liquid and vapor were developed.

4. Vapor Pressure

The chemical reactions described in the previous section have no affect on the dependence of vapor pressure on temperature; therefore, methods previously used [86] on pure fluids were used to produce a mathematical model of N_2O_4 vapor pressure as a function of temperature. Analysis of the vapor pressure data found in the literature led to the selection of the data reported by Giauque and Kemp [87] and Schlinger and Sage [88] to fit the function

$$\ell n\, P = N_1 + N_2\chi + N_3\chi^2 + N_4\chi^3 + N_5\chi^4 + N_6\chi\,(1 - \chi)^{1.5} \qquad (3)$$

where

$$\chi = (1 - T_{tr}/T)/(1 - T_{tr}/T_c) \qquad (4)$$

and

T_{tr} = 261.95 K (triple point temperature)
T_c = 431.372 K (critical point temperature)

The temperature is in kelvin and the vapor pressure is in megapascal. The coefficients to eq (3) are given in Table 1.

Table 1. Coefficients for eq (3)

$N_1 = -3.98267618$	$N_2 = 5.680987615$	$N_3 = 4.725629483 \times 10^{-1}$
$N_4 = 1.036003737 \times 10^{-1}$	$N_5 = 4.376388591 \times 10^{-2}$	$N_6 = 3.674221706 \times 10^{-1}$

5. Saturation Densities

When formulating a mathematical model of the equation of state of a fluid which is to be a single function for both the liquid and vapor phases, the most difficult task is to get a good representation of the saturation boundary. Toward this end, the saturated liquid and vapor densities were correlated independently as a function of temperature; these functions, together with the vapor pressure equation described above, were used to define the saturation boundary to be used later as input data to the final fit of the global equation of state model. The data selected for the saturated density equations were those of Reamer and Sage [89] for the liquid phase and Mittasch et al. [90] for the vapor phase. The equation for both the liquid and the vapor is

$$\rho_\sigma = \rho_c + e^y\,(\rho_3 - \rho_c) \qquad (5)$$

where

$$y = A_1 \ln \chi + \sum_{L=2}^{4} A_L \left(1 - \chi^{\frac{(L-5)}{3}}\right) + \sum_{L=5}^{9} A_L \left(1 - \chi^{\frac{(L-4)}{3}}\right) \qquad (6)$$

and

$$\chi = (T - T_c)/(T_{tr} - T_c)$$

Temperature is in kelvin, density is in kg/m^3, T_c and T_{tr} are defined above by the vapor pressure equation and the least squares coefficients are given in Table 2.

Table 2. Coefficients for eq (6)

Vapor Phase

A_1 =	$-2.2660241266 \times 10^{1}$	A_5 =	$-1.2654673246 \times 10^{2}$
A_2 =	$4.3895751856 \times 10^{-2}$	A_6 =	$5.7529269561 \times 10^{1}$
A_3 =	-1.3003886603	A_7 =	$-1.3606674467 \times 10^{1}$
A_4 =	$1.9421498376 \times 10^{1}$	$A_8 = A_9$ =	0.0

Liquid Phase

A_1 =	$-5.2151095219 \times 10^{1}$	A_6 =	$2.1307429701 \times 10^{2}$
A_2 =	$8.3309705469 \times 10^{-2}$	A_7 =	$-9.6219871908 \times 10^{1}$
A_3 =	-2.5306505949	A_8 =	$2.4246461727 \times 10^{1}$
A_4 =	$3.9880390339 \times 10^{1}$	A_9 =	-2.4096196971
A_5 =	$-3.4384688608 \times 10^{2}$		

$\rho_c = 550.463\ kg/m^3$ $\quad \rho_{tr_v} = 0.772\ kg/m^3$ $\quad \rho_{tr_\ell} = 1518.18\ kg/m^3$

The triple point densities in Table 2 were obtained by extrapolation of the experimental data and the critical point density is from [88]. Comparisons between calculated and experimental saturation properties are given in Tables A1 through A3.

6. Conversion of P-ρ-T data

Experimental single phase P-ρ-T data from four sources, [34,79,88,89], and the P-ρ-T values for the saturation boundary calculated from eqs (3) and (5) were used to define the equation of state for N_2O_4. A fifth source of P-ρ-T data, [83], was determined to be inconsistent with the other four sources and was not used in the final least squares fit of the mathematical model. Figure 1 is a plot of all P-ρ-T data used in the final least squares fit. All of the densities in the P-ρ-T data mentioned were originally reported by the authors in mass density units (e.g., g/cm^3). Because of the chemical reaction indicated by eqs (1) and (2), use of the P-ρ-T data as input to the least squares estimation of the adjustable parameters of an equation of state which reduces to the ideal gas in the limit of zero density, requires the choice between one of two possible alternatives. The units of density

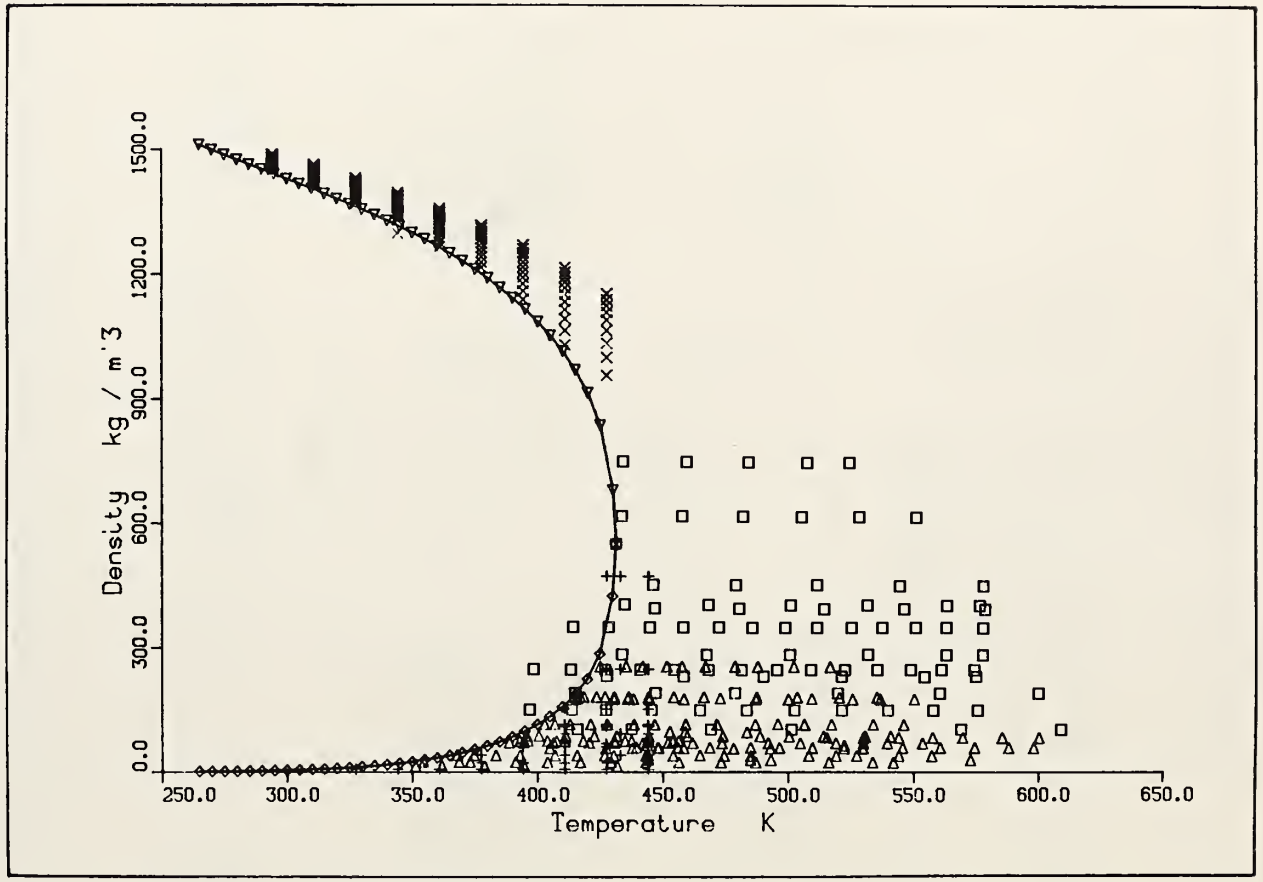

Figure 1. P-T Plot of Input Data, x from [90], □ from [80], + from [89], △ from [35], ▽ from eq (5), ◇ from eq (5).

may be left in absolute units, in which case the value of the gas constant, R, is a function of the molecular mass, or the units of density may be changed to molar units (e.g., mol/L). Both of the options require a knowledge of the molecular mass, which in turn is a function of the changing composition. Very little information about the composition of the system at moderate and high densities was found in the search of the world's literature. The composition of the system may be calculated via thermodynamics if the equation of state for each of the pure components is known. In this particular case the equations of state for pure N_2O_4 and pure NO_2 are not available since neither fluid exists in a pure state over the global P-T range. Because of this, ideal gas assumptions are usually made which allow the composition calculation to be performed. This procedure works reasonably well at low and even moderate densities but is grossly in error in the liquid region. For a reaction of the type

$$aA + bB = cC + dD \tag{7}$$

the ΔG_R^o, which is the ideal gas Gibbs free energy of reaction at 0.101325 MPa (1 atm) and the temperature of the system, may be calculated by

$$\Delta G_R^o = cG_C^o + dG_D^o - aG_A^o - bG_B^o \tag{8}$$

where the G_C^o etc., are the ideal gas Gibbs free energies for the pure components at the same state conditions. In this case, the ideal gas Gibbs free energies are available in the literature; see, for example, [87,91,92]. Defining the extent of the reactions indicated by eqs (1) and (2) as α and β, respectively, and starting with one mole of N_2O_4, the molar amounts of the components are given by

$$n_{N_2O_4} = 1 - \alpha \ , \tag{9}$$

$$n_{NO_2} = 2\alpha - 2\alpha\beta \ , \tag{10}$$

$$n_{NO} = 2\alpha\beta \ , \tag{11}$$

and

$$n_{O_2} = \alpha\beta \ . \tag{12}$$

The equilibrium constant is

$$K = e^{-\frac{\Delta G_R^o}{RT}} \tag{13}$$

For the type of reaction described by eq (8), the equilibrium constant may also be written as

$$K = \frac{f_C^c \, f_D^d}{f_A^a \, f_B^b} \tag{14}$$

where the K is the same as in eq (13) and the f is the fugacity of the ith pure component. The relation between fugacity and partial pressure is given by

$$f = \gamma p \tag{15}$$

where γ is the fugacity coefficient. Assuming γ to be nearly 1 (ideal gas) then an approximation for K is given by

$$K = \frac{p_C^c \, p_D^d}{p_A^a \, p_B^b} \quad . \tag{16}$$

The partial pressure, by definition, is p = x P, which may be expressed as

$$p_{N_2O_4} = P(1 - \alpha)/(1 + \alpha + \alpha\beta) \quad , \tag{17}$$

$$p_{NO_2} = P(2\alpha - 2\alpha\beta)/(1 + \alpha + \alpha\beta) \quad , \tag{18}$$

$$p_{NO} = P(2\alpha\beta)/(1 + \alpha + \alpha\beta) \quad , \tag{19}$$

$$p_{O_2} = P(\alpha\beta)/(1 + \alpha + \alpha\beta) \tag{20}$$

where P is the total pressure of the system. The equilibrium constants for the two reactions are then

$$K_{eq\ (1)} = \frac{4\,\alpha^2(1 - \beta)^2 P}{(1 + \alpha + \alpha\beta)(1 - \alpha)} \tag{21}$$

and

$$K_{eq\ (2)} = \frac{\beta^{3/2}\,\alpha^{1/2}\,P^{1/2}}{(1 + \alpha + \alpha\beta)^{1/2}(1 - \beta)} \tag{22}$$

Now returning to eq (14) and removing the ideal gas assumption made by eq (16) and substituting p for f results in

$$K = \frac{p_C^c \, p_D^d \, \gamma_C^c \, \gamma_D^d}{p_A^a \, p_B^b \, \gamma_A^a \, \gamma_B^b} \tag{23}$$

Equating eq (23) to eq (13) and solving for the right side of eq (16) results in

$$\frac{p_C^c \, p_D^d}{p_A^a \, p_B^b} = e^{\frac{-\Delta G_R^o}{RT}} \frac{\gamma_A^a \, \gamma_B^b}{\gamma_C^c \, \gamma_D^d} \quad . \tag{24}$$

ΔG_R^o is available in the literature, and may be calculated provided equations of state for the pure components are available. Equilibrium constants calculated via eq (24) are

then equated to eqs (21) and (22) to solve for α and β, which in turn gives the average molecular mass of the system at a given P and T by

$$M = M_{N_2O_4}/(1 + \alpha + \alpha\beta) \quad . \tag{25}$$

7. Equation of State for the Pure Components

The procedure for determining the average molecular mass as outlined above requires the fugacity of the pure components of the mixture, and since neither N_2O_4 nor NO_2 exists as a pure fluid, a generalized equation of state proposed by Peng and Robinson [93] was used for N_2O_4 and NO_2. The Peng-Robinson equation of state is a two parameter equation of state of the form

$$P = \frac{RT}{v - b} - \frac{a(T)}{v(v + b) + b(v - b)} \tag{26}$$

which can be written as a cubic as

$$Z^3 = (1 - B)Z^2 + (A - 3B^2 - 2B)Z - (AB - B^2 - B^3) = 0 \tag{27}$$

where

$$A = \frac{a(T)P}{R^2 T^2} \quad , \tag{28}$$

$$B = \frac{bP}{RT} \quad , \tag{29}$$

and

$$Z = \frac{P}{\rho RT} \quad . \tag{30}$$

At the critical point,

$$a(T) = 0.45724 \frac{R^2 T_c^2}{P_c} \quad , \tag{31}$$

$$b = 0.07780 \frac{RT_c}{P_c} \quad , \tag{32}$$

and

$$Z_c = 0.307 \quad . \tag{33}$$

At temperatures other than the critical temperature,

$$a(T) = a(T_c)\, f(T_r, W) \tag{34}$$

where

$$f(T_r, W)^{1/2} = 1 + k(1 - T_r^{1/2}) \quad , \tag{35}$$

and

$$k = 0.37464 + 154226W - 0.26993W^2 \tag{36}$$

with $T_r = T/T_c$ and W is the acentric factor (i.e., $-\log_{10} \left(\frac{P_{sat}}{P_c}\right)_{T_r = 0.7}$). Given the critical pressure and temperature and the acentric factor, the fugacity coefficient of the ith component in a mixture can be calculated from

$$\ln f_i = b_i \left(\frac{Z_x - 1}{b_x}\right) - \ln (Z_x - b_x) - a_x \ln \left(\frac{Z_x + 2.414214\ b_x}{Z_x - 0.414214\ b_x}\right)\left(\frac{1}{2\sqrt{2}\ b_x}\right)\left(\frac{2\sum_j x_j a_{ij}}{a_x} - \frac{b_i}{b_x}\right) \tag{37}$$

where

$$a_x = \sum \sum x_i x_j a_{ij} , \tag{38}$$

$$b_x = \sum x_i b_i , \tag{39}$$

and

$$a_{ij} = (1 - \delta_{ij}) a_i^{1/2} a_j^{1/2} . \tag{40}$$

The x_i is the mole fraction of component i and δ_{ij} is an empirical binary interaction parameter, usually determined from experimental data. Since composition of the mixture is, in this case, the unknown, the solution becomes an iterative one. An initial value is assigned to the composition, usually obtained from the ideal gas solution; the extent of reaction is calculated which results in a new composition and the procedure is repeated until the composition stops changing. The critical pressure, the critical temperature and the acentric factor are all that is needed to carry out the composition calculation. These parameters were estimated by selecting 20 P-ρ-T data points for the liquid phase from [89], and 20 P-ρ-T data points for the vapor phase from [35,79,90]. The high density liquid data points were assigned a composition of pure N_2O_4, since Gray and Rathbone report only 0.12 percent disassociation of the liquid at the normal boiling point. The low density data points were assigned a composition of the equilibrium ideal gas. The acentric factor of N_2O_4 (0.0141345) was assigned to NO_2, ΔG_R^o was taken from the literature and the δ was set equal to zero. A nonlinear least squares minimization was then performed which minimized the sum of the squares of the deviations between the calculated and the assigned compositions of the 40 selected data points. The pseudo critical parameters of the hypothetical pure N_2O_4 and parameters of the hypothetical pure N_2O_4 and NO_2 were taken as the adjustable parameters. The least squares fit gave the following pseudo critical parameters:

N_2O_4:	T_c	= 547.4567 K
	P_c	= 22.0951 MPa
NO_2:	T_c	= 239.3036 K
	P_c	= 10.325 MPa

The critical parameters and acentric factors for the other components were taken to be:

NO: T_c = 180.15 K
P_c = 6.4848 MPa
W = 0.0312 acentric factor

O_2: T_c = 154.75 K
P_c = 5.0764 MPa
W = 0.0998 acentric factor.

All of the P-ρ-T data selected to define the equation of state were converted to molar densities via the method outlined above.

8. Mathematical Model of the Equation of State

A 32 term modified Benedict-Webb-Rubin equation of state was used to represent the equation of state of dissociated N_2O_4.

$$\begin{aligned} P = {} & \rho RT + \rho^2(N_1T + N_2T^{1/2} + N_3 + N_4/T + N_5/T^2) + \rho^3(N_6T + N_7 + N_8/T + N_9/T^2) \\ & + \rho^4(N_{10}T + N_{11} + N_{12}/T) + \rho^5(N_{13}) + \rho^6(N_{14}/T + N_{15}/T^2) \\ & + \rho^7(N_{16}/T) + \rho^8(N_{17}/T + N_{18}/T^2) + \rho^9(N_{19}/T^2) \\ & + e^{-\gamma\rho^2}[\rho^3(N_{20}/T^2 + N_{21}/T^3) + \rho^5(N_{22}/T^2 + N_{23}/T^4) \\ & + \rho^7(N_{24}/T^2 + N_{25}/T^3) + \rho^9(N_{26}/T^2 + N_{27}/T^4) \\ & + \rho^{11}(N_{28}/T^2 + N_{29}/T^3) + \rho^{13}(N_{30}/T^2 + N_{31}/T^3 + N_{32}/T^4)] \end{aligned} \tag{41}$$

Taking R = 0.00831434 $MPa \cdot dm^3 \cdot mol^{-1} \cdot K^{-1}$ and γ = -0.00698534, a weighted least squares fit of 447 P-ρ-T data points was performed. The resulting coefficients to eq (41) are reported in Table 3. A comparison of the calculated and input densities and pressures is given in Appendix A in Table A1. Equation (41) was constrained to the critical point values given in Table 4.

9. Derived Thermodynamic Properties

In theory, if a valid equation of state exists for a fluid and the necessary ideal gas specific heat capacities exist, the derived thermodynamic properties such as the real gas enthalpies, entropies, etc. may be calculated. In the case of a chemically reacting fluid, a knowledge of the effects of the chemical reaction on these properties is also necessary. In the case of reacting N_2O_4, with the addition of eq (41), all of the necessary pieces to the calculation are available. The thermodynamic equations for these calculations are well known and may be found in many text books as well as in the world's literature; see, for example, Stai et al. [94]. There are many papers in the literature which report experimental specific heat capacities, enthalpies, and the velocity of sound for N_2O_4; see, for example, [31,65,95]. Equation (41) was used to calculate specific heat capacities which were compared to the experimental values found in the literature. The agreement was not good. Differences on the average of 30 to 50 percent were encountered. On the basis of these comparisons, derived properties were omitted from the property tables in Appendix B.

10. Discussion

In the initial stages of this investigation, least squares fits of eq (41) using the P-ρ-T data from the literature without regard to composition were unsuccessful. Even though eq (41) has 32 adjustable parameters, and therefore a good deal of flexibility, the fits to the unconverted data were not satisfactory. The gas phase data, without the liquid phase data, could be fit very well and vice versa, but when both liquid and gas data were included in the fit, deviations in density of several percent were observed. After the experimental densities were converted to molar densities via the method outline earlier in this paper, the least squares fits to all of the data improved, and judging from the comparisons in Appendix A, densities calculated with eq (41) are probably accurate to within 0.5 percent except in the usual problem areas of the saturation boundary and the critical region. However, as mentioned in the previous section, eq (41) does not calculate derived thermodynamic properties which agree with measured data reported in the literature.

11. Conclusions

Since the equation of state for N_2O_4 presented here does not perform well for derived thermodynamic properties such as specific heat capacities, etc., the correlation of N_2O_4 properties is only partially complete. This undoubtedly could be corrected by improving the composition calculation. The composition calculation could be improved by including specific heat capacity data with the P-ρ-T data as input to the fitting procedure of the Peng-Robinson equation of state for the hypothetical pure N_2O_4 and NO_2 fluids. However, this is a new and untried technique, and although it worked for the P-ρ-T data, including specific heat capacity as input, places an added demand on a very simple equation of state, and a more complicated equation of state may be necessary.

Appendix B.

Note: Compositions in the following table have been calculated on the basis of 1 mol/L of pure N_2O_4. Some of the calculated composition for NO and O_2 at the low temperatures were very small negative numbers. Since negative compositions are not realistic, all of the negative compositions were changed to zero.

Table B1. Isobaric tables of N2O4 properties calculated with equations from this work.

0 .101325 MPa Isobsr

10. SUPPLEMENTARY NOTES

☐ Document describes a computer program; SF-185, FIPS Software Summary, is attached.

11. ABSTRACT (A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here)

A mathematical model of the equation of state of nitrogen tetroxide is presented. Isobaric tables of P-ρ-T and composition for temperatures from the triple point (261.95 K) to 600 K with pressures to 40 MPa are also given. The mathematical model of the equation of state is a 32 term modified Benedict-Webb-Rubin equation. A method of calculating chemical equilibrium for the system is also presented.

12. KEY WORDS (Six to twelve entries; alphabetical order; capitalize only proper names; and separate key words by semicolons)

chemical equilibrium; composition; density; equation of state; nitrogen tetroxide; pressure; temperature.
