INTRODUCTION TO MARCH 1986 ISSUE OF THE CEEE TECHNICAL PROGRESS BULLETIN

This is the twelfth issue of a quarterly publication providing information on the technical work of the National Bureau of Standards Center for Electronics and Electrical Engineering. This issue of the CEEE Technical Progress Bulletin covers the third quarter of calendar year 1985.

Organization of Bulletin: This issue contains abstracts for all Center papers released for publication by NBS in the quarter and citations and abstracts for Center papers published in the quarter. Entries are arranged by technical topic as identified in the table of contents and alphabetically by first author under each subheading within each topic. Unpublished papers appear under the subheading "Released for Publication". Papers published in the quarter appear under the subheading "Recently Published". Following each abstract is the telephone number of the individual to contact for more information on the topic; unless otherwise noted, this person is the first author. This issue also includes a calendar of Center conferences and workshops planned for fiscal year 1986, an announcement of recently issued standard reference materials, and a list of sponsors of the work.

Center for Electronics and Electrical Engineering: Center programs provide national reference standards, measurement methods, supporting theory and data, and traceability to national standards.

The metrological products of these programs aid economic growth by promoting equity and efficiency in the marketplace, by removing metrological barriers to improved productivity and innovation, by increasing U. S. competitiveness in international markets through facilitation of compliance with international agreements, and by providing technical bases for the development of voluntary standards for domestic and international trade. These metrological products also aid in the development of rational regulatory policy and promote efficient functioning of technical programs of the Government.

The work of the Center is divided into two major programs: the Semiconductor Technology Program, carried out by the Semiconductor Electronics Division (formerly the Semiconductor Materials and Processes and the Semiconductor Devices and Circuits Divisions) in Gaithersburg, MD, and the Signals and Systems Metrology Program, carried out by the Electrosystems Division in Gaithersburg and the Electromagnetic Fields and Electromagnetic Technology Divisions in Boulder, CO. Key contacts in the Center are given on the back cover; readers are encouraged to contact any of these individuals for further information. To request a subscription or for more information on the Bulletin, write to CEEE Technical Progress Bulletin, National Bureau of Standards, Metrology Building, Room B-358, Gaithersburg, MD 20899 or call (301) 921-3357.

Center sponsors: The Center Programs are sponsored by the National Bureau of Standards and a number of other organizations, in both the Federal and private sectors; these are identified on page 31.

Note on Publication Lists: Guides to earlier as well as recent work are the publication lists covering the work of each division. These lists are revised and reissued on an approximately annual basis and are available from the originating division.

Baghdadi, A., Gladden, W.K., and Flach, D.R., **Nonlinear Effects of Digitizer Errors in FT-IR Spectroscopy.**

This paper is an investigation of the effects of errors in the analog-to-digital converter (ADC) of a Fourier transform infrared (FT-IR) spectrometer on the photometric accuracy of that spectrometer. The effect of ADC errors on the spectrum after Fourier transformation is calculated analytically for monochromatic, two-line and wide square-band emission spectra. Numerical modeling is used to extend the analysis to absorption spectra, and to include the effects of noise on the amplitude of absorbance bands. These analyses showed that ADC errors can generate artifacts throughout the spectrum, although the largest effects occur at sharp spectral features. Errors as large as 8% in the amplitude of absorbance bands can be produced by ADC errors of one least significant bit (LSB), in a 15-bit ADC. These results were confirmed qualitatively by measuring the net height of the oxygen vibrational band in silicon at 1107 cm^{-1} using four different ADC circuit boards in the same FT-IR spectrometer. At the highest signal levels, the boards disagreed by as much as 4%, even though the static transfer characteristics of the ADC boards (which were measured in a separate experiment) exhibited errors of less than ±2 LSBs.

Kirk, C.P., and Nyyssonen, D., **Modeling the Optical Microscope Images of Thick Layers for the Purpose of Linewidth Measurement,** Proc. SPIE - The International Society for Optical Engineering, Vol. 538, pp. 179-187 [Conference, Santa Clara, California, March 13-14, 1985].

A monochromatic, waveguide model is presented which can predict the optical microscope images of thick layer objects including multi-layer structures, sloping, curved and undercut edges, granular structures such as polysilicon and asymmetric objects. The model is used to investigate the effects of line structure on the optical image and good agreement with experimentally obtained optical image profiles is demonstrated. Implementation of the model is described by way of example and the measurements involved in the different stages of manufacturing an MOS device are discussed.

Nyyssonen, D., **A Practical Method for Edge Detection and Focusing for Linewidth Measurements on Wafers,** Proc. SPIE - The International Society for Optical Engineering, Vol. 538, pp. 172-178 [Conference, Santa Clara, California, March 13-14, 1985].

Lack of precision and accuracy of in-process critical dimension (CD) measurements of linewidth continues to be a serious problem at micrometer and submicrometer dimensions. Even with highly repeatable optical linewidth measurement systems, variable "offsets" or errors have been shown to occur with changes in process variables such as thickness of the patterned layer and sublayers and changes in the indices of refraction of the materials. All of these variations result in changes in the optical phase difference which occurs on reflection at the line edge and, therefore, results in changes in the structure of the optical image. Although an accurate coherent optical edge detection method has been

[1] This work was transferred to the Center for Manufacturing Engineering, Precision Engineering Division, at the beginning of Fiscal Year 1986 (Oct. 1, 1985).

Dimensional Metrology, cont'd.

developed, it requires accurate knowledge of the phase difference, which is not always possible in CD measurements. This paper proposes a new edge detection and focusing method, based on image theory, which can be adapted to most optical microscope-based measurement systems. It does not require knowledge of the phase difference at the line edge. The accuracy of this criterion is compared to the more widely used criteria of the minimum and 50% threshold and it is concluded that, when the phase difference is unknown and varies with normal processing, the new dual threshold method is the superior method.

Linholm, L.W., Cresswell, M.W., Coleman, E.S., and Partlow, W.D., **Design, Fabrication, and Testing of an Interconnect Test Structure for Evaluating VLSI Processes**, to be published in the 1985 Digest of Papers, Government Microcircuit Applications Conference, Orlando, Florida, November 5-7, 1985.

This paper describes a systematic approach to the comparative experimental evaluation of alternative sub-micron lithographic methods using microelectronic test structures. Measurements are presented for both polysilicon and aluminum lines with design geometries of 0.6 to 2.0 µm. These structures provide unambiguous results which can be used as a tool to improve the control and performance of VLSI devices.

Radack, D.J., Yao, C.T., Linholm, L.W., Galloway, K.F., and Lin, H.C., **Comparison of Microelectronic Test Structures for Propagation Delay Measurements**, to be published in the Microelectronics Journal.

This paper presents a comparison of the ring oscillator, the inverter chain, and the delayed Johnson counter for measurement of the propagation delay of an inverter. The paper describes design considerations that will improve the precision and accuracy of the measurement. Additionally, the paper describes modifications to the delayed Johnson counter which allow timing comparisons to be performed on-chip.

Schafft, H.A., **Standards for Electromigration Testing**, to be published in the Proceedings of the 1984 Wafer Reliability Assessment Workshop, Lake Tahoe, California, September 30-October 3, 1984.

This is an edited transcript of a talk given at the 1984 Wafer Reliability Assessment Workshop which includes questions, comments, and responses. The talk described plans for an interlaboratory experiment and other work that is intended to lead to an improved way for characterizing metallizations for electromigration. The talk outlined the steps of the interlaboratory experiment, discussed some of the design features of the test structures to be used, described the electromigration test chip, and mentioned some of the experiments that will be performed.

Yen, D., Glendinning, W. B., and Linholm, L. W., **An Electrical Test Structure for Proximity Effects Measurement and Correction**, J. Electrochem. Soc., Vol. 132, No. 7, pp. 1726-1729 (July 1985).

This paper describes the design of a test structure and electrical test method for estimating the magnitude of proximity effects in electron-beam lithography. The test structure consists of a van der Pauw cross resistor for measuring sheet resistance, a bridge resistor for measuring electrical linewidth, and

IC Test Structures, cont'd.

a second bridge resistor simulating a close line- space environment for measuring electrical linewidth where proximity exposure effects from nearby patterns may be encountered. In this experiment, test structures were delineated in aluminum on silicon wafers using electron-beam exposure and wet chemical etching. Electrical measurements from these test structures are compared to optical measurements to verify the measurement method. In addition, results from the test structures are used to estimate the Gaussian parameters for the Gaussian model commonly used for proximity corrections.

Dutta, P.K., and Wilson, C.L., **Calculation of Surface Potential and Electron Density Near Threshold for a Nonuniformly Doped Channel VDMOS Power Device.**

The surface potential, ψ_s, and electron density, n, along the nonuniformly doped channel of a power DMOS transistor are computed, using both a charge-sheet model and a two-dimensional model. Results are obtained for gate voltages in the range of 2.0 V to 4.0 V. The threshold of the device is about 3.0 V. Nonuniformity in the channel doping of the transistor requires a point-by-point calculation of ψ_s and n, as one progresses from the drain end to the source end. The results indicate that near threshold, a simple charge-sheet model can adequately approximate the rigorous two-dimensional analysis for calculation of ψ_s and n. The charge-sheet model calculation is approximately 800 times faster than the two-dimensional model calculation.

Hefner, A.R., and Blackburn, D.L., **An Analytical Model of the Power Insulated Gate Bipolar Transistor.**

A basic equivalent circuit model for the power Insulated Gate Bipolar Transistor (IGBT) is developed. It is shown that the IGBT behaves as a wide-base bipolar transistor which is supplied base current by a MOSFET. Analytical expressions are developed, using ambipolar transport theory, for the electron and hole current densities and for the excess carrier concentrations in the thick, lightly doped epitaxial layer of the IGBT. Expressions are also developed for the steady-state anode to cathode voltage drop and the transient anode current waveform, which consists of an initial rapid fall followed by a slowly decaying portion. The value of β_{tran} (the ratio of the value of the current immediately after the initial rapid fall to the magnitude of the fall) is shown to depend on the anode loading conditions and to be different from the steady-state common emitter current gain of the wide-base bipolar transistor. Measured and predicted values of β_{tran} for constant anode voltage load conditions as functions of anode current and neutral base width agree to within experimental error, in the current range where ambipolar transport theory is valid. Device parameters extracted from the measured β_{tran}-versus-anode-current characteristics are used to predict the on-state voltage versus current characteristics, which agree to within a few millivolts with the measured results.

Lowney, J.R., **Impurity Bands and Band Tailing in Moderately Doped Silicon.**

The density of states of the valence and conduction bands in silicon has been calculated at room temperature for dopant densities near the transition between the existence of a distinct impurity band and its coalescence with the continuum band to form a band tail. The dopant densities for the three cases considered are: 1) 1.5×10^{18} cm^{-3} acceptors; 2) 6.2×10^{18} cm^{-3} acceptors;

Process & Device Modeling, cont'd.

and 3) 1.2×10^{19} cm^{-3} donors compensated by 6.2×10^{18} acceptors. The calculation is based on multiple-scattering theory with the self-energy calculated self-consistently to all orders of the interaction. The results show a small but significant amount of effective band-gap narrowing.

Roitman, P., Wilson, C.L., Blue, J.L., and Galloway, K.F., **Measurements for Accurate MOS Transistor Simulation,** to be published in the Proceedings of the 3rd International Workshop on the Physics of Semiconductor Devices, Delhi, India, November 27-December 2, 1985.

Measurements and input data required for accurate numerical simulation of MOS transistor characteristics are described. Techniques for determining dopant atom distributions, geometric parameters, and carrier mobility in the channel are discussed. The results are used to simulate the electrical characteristics of self-aligned, silicon-gate, n-channel MOSFETs with phosphorus source-drains having channel lengths of 0.80 µm, 1.83 µm, and 8.17 µm. It is possible to model the drain current for all of the transistors studied without adjustable parameters. If sufficiently accurate parameters are available, the characteristics of submicron transistors can be predicted with ±5% accuracy.

Wilson, C.L., **Using Silicon Device Modeling Techniques for GaAs Devices,** to be published in the Technical Digest, 1985 International Electron Devices Meeting, Washington, DC, December 1-4, 1985.

Numerical models have been developed for Si MOSFETs which achieve high accuracy and retain numerical stability and physical flexibility. The methods used in these models can be applied to GaAs MESFETs to yield a computer model which retains the accuracy and robust numerical properties of two-dimensional Si MOSFET models yet retains most of the physical detail of Monte Carlo simulation. Two significant differences between this model and previous models result. First, by incorporating intraband scattering directly, high field regions of the device are seen to be dominated by alternate regions in which conduction by central valley and satellite valley electrons dominate. Second, the two-dimensional field shape in the part of the transistor between the gate and the drain is critical in calculating the intraband scattering and in determining the average effective mobility.

Wilson, C.L., and Russell, T.J., **Two-Dimensional Modeling of Channel Hot-Electron Effects in Silicon MOSFETs,** to be published in the Technical Digest, 1985 International Electron Devices Meeting, Washington, DC, December 1-4, 1985.

Earlier models have successfully modeled currents associated with device degradation due to channel hot electrons. In this work, a high accuracy two-dimensional model of a silicon MOSFET is combined with a model of the SiO_2-Si interface which includes both (1) the energy dependence of the interface traps within the silicon bandgap and (2) the positional dependence of the oxide charge and the interface traps along the channel of the transistor. This model allows the effects of channel hot electrons on the subthreshold, linear, and saturation regions after injection of the device to be modeled without introducing free parameters.

Harman, G.G., **Acoustic-Emission Tests for Microelectronic Tape Automated Bonding (TAB)**, to be published in the ASNT (American Society for Nondestructive Testing) Nondestructive Testing Handbook, Vol. 5, Acoustic Emission Testing.

An acoustic-emission (AE) test method and equipment for tape automated bonding (TAB) integrity have been developed. The system consists of a precision testing machine that simultaneously applies a clamping force on the semiconductor chip and a lifting force on the electrical interconnecting leads. Acoustic-emission signals are transmitted through a waveguide to the detector. The system also permanently forms (raises) the leads, which is a normal requirement for TAB devices. Large acoustic-emission signals occur when a lead breaks, a bump lifts, or a weld crack propagates. Appropriate AE signal processing is also discussed.

Harman, G.G., **An AE-Monitored Thermal Shock Test for Hybrid Microcircuit Packages**, to be published in the ASNT (American Society for Nondestructive Testing) Nondestructive Testing Handbook, Vol. 5, Acoustic Emission Testing.

An acoustic-emission-monitored test for hybrid microcircuit package integrity was developed. It consists of a hot stage operating at 400°C, a special water-cooled acoustic-emission detector mount, and appropriate signal recording equipment. In use, the detector is coupled to the back of a hybrid package and both are set on the hot stage for approximately 30 s. Any acoustic-emission signals indicate thermal excursion damage to the glass-metal seals. The acoustic-emission signals were correlated with both room temperature and 125°C leak tests of the packages.

Waveform Metrology

Released for Publication

Bell, B.A., Editor, **Proceedings of the Seminar on Digital Methods in Waveform Metrology**, to be published as NBS Special Publication 707.

Modern electronic instrumentation metrology in the low-frequency regime (dc-10 MHz) was discussed in lecture talks and papers presented at NBS, Gaithersburg, MD, on October 18-19, 1983. The seminar program was organized into four main session topics, as outlined in the Seminar Agenda.

This special publication contains complete papers on the subjects presented at the seminar, providing more of the technical details. For the sessions on Precision Waveform Synthesis, Precision Waveform Sampling, and Data Converter Characterization, six formal papers are given describing the hardware and software techniques used for developing NBS laboratory standards and apparatus for testing ac sources and voltmeters, phase angle meters, transient waveform recorders, wideband wattmeters, and digital-to-analog and analog-to-digital converters. For the informal session on Instrumentation Metrology, three subsequent papers have been written for publication which are included for completeness in the Appendices.

Laug, O.B., Stenbakken, G.N., and Leedy, T.F., **Electrical Performance Tests for Audio Distortion Analyzers**, to be published as NBSIR 85-3269.

Electrical performance test procedures for audio distortion analyzers were developed by the National Bureau of Standards for the U.S. Army Communications-Electronics Command. The report provides detailed, step-by-step test procedures that are based on specifications supplied by the Army for purposes of evaluating audio distortion analyzer bid samples. Examples of data sheets and tables are also provided for recording interim and final results.

The report discusses the philosophy of each measurement procedure with a view toward providing an understanding of the basic metrology required to perform the measurements. In addition, the sources of measurement error are discussed. The primary applications and basic principles of modern audio distortion analyzers are also presented.

Nahman, N.S., **Software Correction of Measured Pulse Data,** to be published in the Proceedings at the NATO Advanced Study Institute, Castelvecchio, Lucca, Italy, July 9-23, 1983.

The fundamental concern in the software correction of measured pulse waveform data is the solution of an ill-posed deconvolution problem which arises when one (or both) of the known waveforms is (are) corrupted by errors due to interference, noise, instrumentation drift, etc. The variables concerned are related to each other by the convolution integral. When one of the integrand functions is unknown while the other two functions are known, the convolution equation becomes an integral equation for the unknown waveform. Solution of an ill-posed deconvolution problem is obtained by signal processing or filtering and at most yields an estimate for the unknown waveform. The objective of this discussion is to bring out the

Waveform Metrology, cont'd.

ideas of ill-posedness and to give examples of applications to pulse measurement problems which require deconvolution, i.e., the removal (correction) of pulse source effects and/or measurement system effects as encountered in signal pulse waveform measurements and system impulse response measurements.

Kautz, R.L., **Chaos and Thermal Noise in the RF-Biased Josephson Junction**, J. Applied Physics, Vol. 58, No. 1, pp. 424-440 (1 July 1985).

The effect of thermal noise on chaotic behavior in the rf-biased Josephson junction is studied through digital simulations. In instances for which chaotic behavior occurs in the noise-free system, it is found that the dynamics of the system are almost unchanged by the addition of thermal noise unless the level of thermal noise exceeds that of the chaotic state. In instances for which the only stable states of the noise-free system are periodic solutions, small amounts of thermal noise can induce the junction to hop between two different dynamical states, producing a low-frequency noise level much higher than that of the thermal noise. Such noise-induced hopping can occur either between two periodic solutions or between a periodic solution and a metastable chaotic solution. When a metastable chaotic state is involved, temperatures somewhat higher than those which produce hopping can destabilize the periodic solution to the point where the system spends virtually all of its time in the metastable chaotic state, creating noise-induced chaos. The similarities between chaotic behavior at zero temperature and noise-induced chaos are sufficiently strong that it may be difficult to distinguish the two cases experimentally.

McDonald, D.G., and Frederick, N.V., **Amplification by a Voltage Locked Array of Josephson Junctions**, Applied Physics Letters, Vol. 47, No. 5, pp. 530-532 (1 September 1985).

We have studied a new type of Josephson junction amplifier which is based on a two-junction array; the junctions are mutually phase locked at the Josephson self-oscillation frequency. With this frequency at 82 GHz, the voltages of the junctions remain equal (locked) for a bias current range as large as 60% of the critical current. Over a much smaller bias range, with an applied signal frequency of 1 kHz, a small-signal power gain of 19 dB was measured, accompanied by a negative resistance input impedance. This performance is consistent with a quasi-static theory of the amplifier.

McGrath, W.R., Raisanen, A.V., Richards, P.L., Harris, R.E., and Lloyd, F.L., **Accurate Noise Measurements of Superconducting Quasiparticle Array Mixers**, IEEE Transactions on Magnetics, Vol. MAG-21, No. 2, pp. 212-215 (March 1985). [Proceedings of Applied Superconductivity Conference, San Diego, California, September 9-13, 1984]

We have constructed a 30-40 GHz test apparatus which allows us to measure the noise temperatures of superconductor-insulator-superconductor (SIS) mixers with an accuracy of better than ±1 K. This is a factor of six improvement over earlier measurements. The most accurate measurement made thus far of a mixer

Cryoelectronic Metrology, cont'd.

which uses a single Pb-alloy junction yielded $T_M = 9.2 \pm 0.9$ K; and mixer gain: $C_M = 0.240 \pm 0.005$. In addition, SIS mixers employing arrays of N = 1, 5, 10, 25, and 50 tunnel junctions in series have been tested. The input power required to saturate the array mixers was found to increase as N^2 and the gain and noise temperatures of the array mixers were independent of N.

Muhlfelder, B., Beall, J.A., Cromar, M.W., Ono, R.H., and Johnson, W.W., **Well Coupled, Low Noise, dc SQUIDS,** IEEE Transactions on Magnetics, Vol. MAG-21, No. 2, pp. 427-429 (March 1985). [Proceedings of Applied Superconductivity Conference, San Diego, California, September 9-13, 1984]

We have designed, fabricated, and tested a Double Transformer (DT) coupled dc SQUID (Superconducting Quantum Interference Device) with low noise, an input inductance of 1 μH, and a smooth input-output characteristic. A transmission line model is presented to explain a resonance in the input-output characteristic of early versions of this device. Guided by the results of numerical simulations, a new version of this device has been built and tested. Experimental results are presented that show that the resonance can be moved to a higher voltage by reducing the area of the SQUID loop. The voltage-external flux characteristic of some of these new devices agrees to within 10% with computer simulations. The minimum detectable energy per unit bandwidth (MDE) referred to the SQUID loop is 10 h, where h is Planck's constant. Computer simulations indicate an MDE of 6 h.

Ono, R.H., Beall, J.A., and Harris, R.E., **Fabrication of a Miniaturized DCL OR Gate,** IEEE Transactions on Magnetics, Vol. MAG-21, No. 2, pp. 846-849 (March 1985). [Proceedings of Applied Superconductivity Conference, San Diego, California, September 9-13, 1984]

Using niobium edge junctions and electron-beam lithography (EBL), we have made direct-coupled-logic (DCL) OR gates with 1-μm minimum linewidths. The gate cell, containing an isolator and a buffer section, fits into an area of approximately 25 by 30 μm^2.

Our computer simulations show that these gates can have switching times of less than 10 ps. We have simulated the DCL circuit with several values of the most space-consuming element, an inductor. This paper describes the results of these simulations and presents a detailed description of the 7-level fabrication process. The mix of optical and electron-beam lithography used relies heavily on an inexpensive, yet powerful, circuit layout program.

Lewis, R.L., **Spherical-Wave Source-Scattering-Matrix Analysis of Coupled Antennas; A General System Two-Port Solution.**

Expressions are given for the coupling between two antennas in terms of each antenna's spherical-wave source-scattering matrix. A comparison with the "classical" scattering matrix representation is given in sufficient detail to permit conversion back and forth between the source-scattering matrix and the classical scattering matrix. The paper concludes with expressions for the transmission formulas, showing two different expressions corresponding to reversing the direction of propagation. However, if both antennas are reciprocal with equal characteristic waveguide impedances, then the two-port scattering matrix is a symmetric matrix.

Lewis, R.L., and Wittmann, R.C., **Improved Spherical and Hemispherical Scanning Algorithms.**

A probe-corrected spherical-scanning algorithm has been developed which is applicable when the antenna under test radiates negligibly into its rear hemisphere. Compared to an efficient version of the best previously published full-sphere scanning algorithm, it is found that our hemispherical scanning algorithm is over three and a half times more efficient. Improvements have also been made to full-sphere scanning, with the result that our new spherical scanning algorithm is twice as efficient as the best previous full-sphere algorithm. We also show that our new formulations constitute an exact inversion of the band-limited spherical-coordinate representation of the received signal (i.e., no aliasing errors are introduced).

Newell, A.C., and Repjar, A.G., **Development of Near-Field Test Procedures for Communication Satellite Antennas, Phase I, Part 1**, to be published as NBSIR 85-3031.

The purpose of this program is to define and further develop the capabilities of near-field antenna test techniques, specifically for the requirements associated with the development and verification testing of reconfigurable, multibeam, frequency reuse, commercial satellite antennas. Phase I, Part 1 gives a general survey, definition, and description of near-field and compact range measurement methods as they apply to satellite antenna systems testing. Each of these methods is evaluated to determine how well it meets the measurement requirements. Included for each technique is a summary of the measurement method, discussions on probe correction and data processing, measurement hardware considerations, a results-available section, and measurement accuracy and range certification considerations. The basis for the choice of the best measurement technique is established with the planar near-field measurement method receiving the best score for the directive antennas considered. As a result, further study will focus on this technique and will be reported on subsequently. A detailed presentation of planar near-field measurements theory is presented in Appendix A.

Hill, D.A., **Out-of-Band Response of Reflector Antennas**, NBSIR 85-3021 (April 1985).

The response of reflector antennas to out-of-band frequencies has been analyzed using physical optics. A simple approximate expression has been obtained for the effective aperture, and this expression yields both the receiving pattern and the frequency dependence on the on-axis gain. The theory has been compared with published out-of-band measurements, and the pattern agreement is good, but the measured gain falls below the theory. This discrepancy is caused by mismatch loss in the coax-to-waveguide adapter.

Muth, L.A., **A Theory of Mutual Impedances and Multiple Reflections in an N-Element Array Environment,** NBS Technical Note 1078 (February 1985).

A general theoretical approach is formulated to describe the complex electromagnetic environment of an N-element array. The theory reveals the element-to-element interactions and multiple reflections within the array. From the formulation, it is found that the interaction between an excited element and an open-circuited element can be viewed as the sum of terms describing all possible signal paths within the array environment which start from the radiating element and terminate on the element under observation. Within all paths except the most direct one, multiple reflections between subgroups of elements take place. The resulting solution is highly structured and recursive and is discussed in detail in the text. Illustrative examples are provided to facilitate understanding of these ideas.

Wyss, J.C., and Sheeran, S.T., **A Practical Optical Modulator and Link for Antennas,** J. Lightwave Technology, Vol. LT-3, No. 2, pp. 316-321 (April 1985).

This paper describes a practical application of a technique for coupling an antenna to a receiver using a passive fiber-optic link. This technique should avoid pickup and electromagnetic perturbations normally associated with the use of electrically conductive cables. Laser light (632.8 nm) is modulated at the antenna by an electrooptic lithium-tantalate crystal and is then transmitted with a fiber-optic cable to the receiver electronics. Using an avalanche photodiode, the amplitude-modulated optical signal is converted to an electrical signal. The crystal is mounted directly on an antenna without amplifiers or other electrically powered components. Using a broad-band antenna with fields generated in an anechoic chamber and a standard TEM cell, the frequency response as measured dropped 3 dB per 1.0 GHz from 100 MHz to at least 2.0 GHz, with a signal-to-noise ratio of 5 dB with a 1.0-V/m field and a 1.0-kHz bandwidth. A dynamic range of at least 60 dB is shown.

[An identical invited paper will be published in the Proceedings of the Test and Measurement World Expo, San Jose, California, May 13-15, 1985.]

This paper describes a Bessel null technique to measure the frequency response of a frequency-modulated rf carrier and a program to automate frequency response measurements of signal generators with output frequencies from 0.450 to 2000 MHz. The measurements obtained using this technique are more accurate than those obtained by a highly trained technician using a manual system.

Automated measurement of this process is desirable since the manual method is subject to the following problems: (1) excessive time, (2) error in finding the null, and (3) lack of assurance that the null is the first Bessel null. Automated measurements can be performed using a system controller, a spectrum analyzer, a function generator, and a voltmeter (all of which are compatible and controllable remotely).

The nonlinear relationship between modulating signal amplitude and the center frequency amplitude of the carrier is a major obstacle to automated measurement. This problem was solved by obtaining an approximate formula for this nonlinear curve.

Assurance that the null found is the first Bessel null is provided by the analysis of the frequency response of the signal generator under test as displayed on the spectrum analyzer.

Bennett, H.E., Milam, D., Guenther, A.H., and Newman, B.E., **Laser Induced Damage in Optical Materials: 1983**, to be published as NBS Special Publication 688.

The Fifteenth Annual Symposium on Optical Materials for High Power Lasers (Boulder Damage Symposium) was held at the National Bureau of Standards in Boulder, Colorado, November 14-16, 1983. The Symposium was held under the auspices of ASTM Committee F-1, Subcommittee on Laser Standards, with the joint sponsorship of NBS, The Defense Advanced Research Project Agency, the Department of Energy, the Office of Naval Research, and the Air Force Office of Scientific Research. Approximately 200 scientists attended the Symposium, including representatives of the United Kingdom, France, Israel, and West Germany. The Symposium was divided into sessions concerning Materials and Measurements, Mirrors and Surfaces, Thin Films, and Fundamental Mechanisms. As in previous years, the emphasis of the papers presented at the Symposium was directed toward new frontiers and new developments. Particular emphasis was given to materials for high power apparatus. The wavelength range of prime interest was from ~0.6 μm to the uv region. Highlights included surface characterization, thin film-substrate boundaries, and advances in fundamental laser-matter threshold interactions and mechanisms. The scaling of damage thresholds with pulse duration, focal area, and wavelength was discussed in detail. Harold E. Bennett of the Naval Weapons Center, Arthur H. Guenther of the Air Force Weapons Laboratory, David Milam of the Lawrence Livermore National Laboratory, and Brian E. Newman of the Los Alamos National Laboratory were co-chairmen of the Symposium.

Young, M., and Johnson, E.G., Jr., **Redefining the Scratch Standards**, NBS Technical Note 1080 (February 1985). [Some of this material was presented in a paper, Tunable Scratch Standards, given at the conference of the International Society for Optical Engineering, Measurement and Effects of Surface Defects and Quality of Polish, Los Angeles, CA, January 21-22, 1985, and published in Proc. SPIE, Vol. 525, pp. 70-77, SPIE, P.O. Box 20, Bellingham, WA 98227 (1985).]

The scratch standard (MIL-0-13830A) is a cosmetic standard that is effected by a visual comparison with a set of submasters that are in turn evaluated by comparison with a set of master standards. Both manufacture and certification of the submasters are somewhat unreliable. In this paper, we show that the submasters can be classified according to the relative power scattered at a relatively small angle. We have designed etched gratings with which to replace the submasters; these gratings have the appearance of scratches but diffract light into a broad peak between 5 and 10 degrees off the axis of the incident beam. We have classified some prototypes both by comparison with the master standards and by a photoelectric measurement; agreement between the two methods is good. We suggest that such gratings be used as the submasters and possibly that they be classified by a photoelectric, rather than visual, measurement.

Young, M., **Scratch Standards Should not be Used to Predict Damage Threshold** in Laser Induced Damage in Optical Materials: 1982, Proceedings of a Symposium, H.E. Bennett, A.H. Guenther, D. Milam, and B.E. Newman, Eds., NBS Special Publication 669 (January 1984).

The scratch and dig standards are the most widely used surface quality standards in the industry. In the Proceedings of the 1980 Symposium, H. Bennett showed theoretically that damage ought to be initiated near a defect and related damage threshold to defect size. Evidently, because of one or both of these considerations, some purchasers may use the scratch standards to specify the surface quality of components intended for high power laser systems. Although damage is often associated with the presence of a defect, this is an inappropriate use of these purely cosmetic standards; the classification of a particular scratch correlates only very loosely with its width or depth. Even if a component is made of glass, little or nothing pertinent to damage threshold

Other Fast Signal Topics, cont'd.

may be determined by classifying a scratch according to the cosmetic standard.

FitzPatrick, G.J., Forster, E.O., Kelley, E.F., and Hebner, R.E., **Streamer Initiation in Liquid Hydrocarbons,** to be published in the Conference Record, 1985 Conference on Electrical Insulation and Dielectric Phenomena, Buffalo, New York, October 21-24, 1985.

Using 93X magnification and a framing rate of 2×10^7 frames/s, the initiation of prebreakdown streamers in toluene, isooctane, and a white oil have been photographed. The initial growth from a negative point electrode was a thin pencil-like structure, having a growth rate of 2 to 3×10^4 cm/s, which subsequently branched into a tree-like structure. Positive streamers were found to develop into a more filamentary structure than negative streamers. Under nominally identical conditions, a positive streamer may grow, then disappear; may grow to bridge the gap; or may grow to a certain length, then persist.

Van Brunt, R.J., **Water Vapor-Enhanced Electron Avalanche Growth in SF_6 for Nonuniform Fields.**

When trace water vapor content is increased from 10 to 100 parts per million by volume in SF_6 at pressures from 200 to 300 kPa, a dramatic enhancement occurs in the mean size of electron avalanches formed near a positive point electrode. Although this effect can be attributed to a change in gas composition, it is not due to a change in the ionization rate for the gas. It is proposed that the avalanche enhancement is due primarily to an increase in the probability for initiating electron

Power Systems Metrology, cont'd.

release from minor negative ions associated with water vapor that collisionally detach more readily at a given field strength than the predominant negative ions associated with SF_6. The profiles of the electron avalanche size distributions exhibit a monotonic decrease of probability with increasing number of electrons for avalanches with fewer than 10^7 electrons, but pronounced peaks appear in the distributions as the mean electron number exceeds 10^7. These peaks are not consistent with the behavior expected from a stochastic model of electron avalanche growth in nonuniform electric fields which neglects the influence of space charge.

Ramboz, J.D., and Petersons, O., **Emerging New Requirements for Electric Power and Energy Measurements**, Proceedings of the 1985 Workshop and Symposium of the National Conference of Standards Laboratories, Boulder, Colorado, July 15-18, 1985, pp. 3-12.

Advances in electronic instrumentation technology have brought greater stability and precision to transducers that are utilized for measuring electric power and energy. An advantage of instruments based on electronic transducers is that they can be readily adapted to the measurement of other quantities such as current, voltage, reactive and apparent power, power factor, demand, time-of-day readings, etc. The increases in the cost of energy during the past decade have stimulated the acceptance of new instrument technology by the users associated with the electric power industry. The electronic instruments have especially found acceptance in metering installations for large loads and at interchange points between utilities. Modern instruments, because of their accuracy capabilities, are also advantageous in those applications where the efficiency of large equipment such as generators and transformers has to be measured. A large number of instruments used as physical standards by the industry and submitted recently to the National Bureau of Standards (NBS) for calibration have been of the electronic type. The calibration accuracies requested from NBS for power and energy measurements have increased at least fivefold (uncertainty reduction from ±0.05% to ±0.01%) within the past several years. Calibrations for different quantities and values are being requested. These changing calibration requirements and the response of NBS to meet the requests of its calibration clientele are discussed.

Siddagangappa, M.C., and Van Brunt, R.J., **Decomposition Products from Corona in SF_6/N_2 and SF_6/O_2 Mixtures**, Proceedings of the Eighth International Conference on Gas Discharges and Their Applications, Oxford, England, September 16-20, 1985, pp. 247-250.

Absolute concentrations of SOF_4, SOF_2, SO_2F_2, SO_2, NO, N_2O, and H_2O produced from continuous, dc, point-plane negative corona at a current of 40 A were measured in SF_6/N_2 and SF_6/O_2 mixtures containing trace amounts of H_2O and 1 to 95% N_2 or 1 to 10% O_2 for a total gas pressure of 200 kPa (~2 atm). The absolute and SF_6-normalized charge rates-of-production for these by-products have been determined as a function of N_2 or O_2 content. The results are interpreted in terms of a model for electric-discharge-induced decomposition of SF_6 discussed previously by Van Brunt. The presence of N_2 accelerates the rate of SF_6 decomposition by inhibiting the recombination of SF_6 dissociation products. At levels up to 10%, O_2 actually lowers the rates of oxyfluoride and SO_2 production due to its effect in reducing the mean energy of electrons in the discharge and thus the dissociation rate of SF_6.

Goldfarb, R.B., and Clark, A.F., **AC Losses in Nb-Ti Measured by Magnetization and Complex Susceptibility.**

DC magnetization and complex AC susceptibility were measured at 4 K as functions of longitudinal DC field for a multifilamentary Nb-Ti superconductor with no transport current. Minor hysteresis loops were obtained in the dc measurements. The full-penetration field H_p, a function of applied field H, was deduced directly for each minor loop. The values for H_p were fit to the Kim-type equation, $H_p(H) = H_p(0)/(1+H/H_k)$, where $H_p(0)$ and H_k are constants. The minor-hysteresis-loop areas gave losses that were in excellent agreement with Carr's theoretical critical-state equation, $W = (4\mu_0 H_0 H_p/3)(1-H_p/2H_0)$, where H_0 is the maximum applied field for each loop. An expression was obtained for the ideal reversible differential susceptibility, $\chi_{rev} = \phi_0/8\pi\mu_0(H-H_{c1})\lambda^2$, where ϕ_0 is the flux quantum, H_{c1} is the lower critical field, and λ is the penetration depth. H_{c1} and λ for the sample were deduced from the shape of the major hysteresis loop. Clem's theoretical expressions for the real (χ') and imaginary (χ'') components of AC susceptibility are functions of AC field amplitude h, H_p, and χ_{rev}. The predicted susceptibilities based on these expressions were in good agreement with measured curves of χ' and χ'' as functions of h and H. The measured χ' and χ'' were independent of frequency up to 1 kHz, as expected when bulk hysteresis is the primary loss mechanism.

Goodrich, L.F., Dube, W.P., Pittman, E.S., and Clark, A.F., **The Effect of Aspect Ratio on Critical Current in Multifilamentary Superconductors.**

Experimental data and discussion are presented on the critical current of straight superconductors as a function of the orientation of a perpendicular applied magnetic field. Commercial, multifilamentary NbTi and Nb_3Sn samples were measured in a radial access magnet that allowed an arbitrary angle setting. The change in critical current was measured at different magnetic fields to scale the effect for use in a standard test method. For a NbTi sample, the critical current with the magnetic field parallel to the wider face of the conductor is higher than that with the perpendicular orientation. The effect can be as high as 40% for a NbTi sample with an aspect ratio of 6. The effect in Nb_3Sn is opposite that in NbTi. A discussion of the most likely cause of the effect, which accounts for the difference between NbTi and Nb_3Sn, is given.

Superconductors, cont'd.

the Energy Gap of NbTi Filaments in High-Field Magnet Wires, to be published in the Proceedings of the International Cryogenic Materials Conference in Advances in Cryogenic Engineering - Materials, Vol. 32, Boston, Massachusetts, August 12-16, 1985.

Squeezable electron tunneling (SET) junctions consisting of superconducting NbTi filaments (extracted from magnet wires) and sputtered Nb thin-film counter electrodes were used to determine the energy gap at the surface of the filaments. The current versus voltage curves of junctions immersed in liquid helium at 4 K were measured for a series of filaments taken from the same wire. Each filament had been etched to remove a surface layer of varying thickness so that the energy gap could be determined as a function of depth into the surface of an average filament. It was found that some manufacturing processes yield filaments having surface layers with reduced energy gaps of 0.4 meV compared to measured interior bulk values ranging from 1.2 to 1.3 meV.

Ekin, J.W., Yamashita, T., and Hamasaki, K., **Effect of Uniaxial Strain on the Critical Current and Critical Field of Chevrel Phase $PbMo_6S_8$ Superconductors,** IEEE Transactions on Magnetics, Vol. MAG-21, No. 2, pp. 474-477 (March 1985). [Proceedings of Applied Superconductivity Conference, San Diego, California, September 9-13, 1984]

The first measurements of the effect of uniaxial strain on the critical current of a Chevrel-phase superconductor, $PbMo_6S_8$, have been obtained at 4.2 K in magnetic fields from 2 T to 24 T. The data show there is a very significant reversible effect of elastic strain on the critical current of $PbMo_6S_8$, comparable in magnitude to that observed in Nb_3Sn. This is because both the peak pinning force and upper critical field are very sensitive to elastic strain. A correlation is noted between the elastic strain effect, radiation sensitivity, and crystal phase.

Hong, M., Maher, D.M., Ellington, M.B., Hellman, F., Geballe, T.H., Ekin, J.W., and Holthuis, J.T., **Further Investigations of the Solid-Liquid Reaction and High-Field Critical Current Density in Liquid-Infiltrated Nb-Sn Superconductors,** IEEE Transactions on Magnetics, Vol. MAG-21, No. 2, pp. 771-774 (March 1985). [Proceedings of Applied Superconductivity Conference, San Diego, California, September 9-13, 1984]

Superior superconducting properties, such as high critical current density (J_c) and transition temperature (T_c), have been obtained from reacted liquid-infiltrated Nb-Sn composite wires. These excellent properties are attributed to the chemistry and structure of the material which is prepared by a unique solid (Nb)-liquid (Sn) reaction. From heat capacity measurements, sharp bulk superconducting transitions of the A15 phase occur at 17.2-18 K and the weight fraction of A15 in the composite wire is ~23%. Analytical electron microscopy techniques have shown that: the microstructure of these conductors consists of alternating large- grain and small-grain filaments; these two types of filaments correspond to BCC Nb(Sn) and cubic A15 $Nb_{75\pm x}Sn_{25\mp x}$ phases, respectively; the A15 filaments (<0.5 μm) are chemically homogeneous in terms of measured x-ray intensity ratios to within ±7% which implies that x ~ 1.5; and the A15 grains are essentially free of extended lattice disorder down to a resolution of ~0.34 nm.

Recent work in which Nb is alloyed with Ta has shown that these superconducting properties can be improved upon; e.g., high overall J_c's of ~1.8×10^4 A/cm^2 at 20 T and 4.2 K have been measured.

Superconductors, cont'd.

Also, the liquid-infiltrated Nb(Ta)-Sn composites have a damage strain tolerance nearly double that of commercial bronze-processed Nb-Sn conductors.

Cruz, J.E., Driver, L.D., and Kanda, M., **Design of the National Bureau of Standards Isotropic Magnetic Field Meter (MFM-10) 300 kHz to 100 MHz**, to be published as NBS Technical Note 1085.

A broadband magnetic field meter has been developed at the National Bureau of Standards (NBS) for the frequency range of 300 kHz to 100 MHz. The isotropic antenna unit consists of three mutually orthogonal loops, each 10 cm in diameter. The magnetic field probe described in this paper has a measurement range of 0.1 to 30 A/m. The readout of the meter is in terms of the Hermitian or "total" magnitude of the magnetic field strength which is equal to the root-sum-square value of the three perpendicular magnetic field components at the measurement point. This magnetic field meter has nearly perfect isotropy over its dynamic range.

The electronic circuitry of the meter obtains the total magnitude of all field polarizations and all signals in the entire frequency band. The sensor is isotropic and is well suited for measuring the near field of an emitter, including regions of multiple reflections and standing waves. The meter can be used to monitor either the weak plane wave fields in the far zone of a transmitter or the complicated fields very close to a radiofrequency leakage source. The features described in this paper are: electronic design, physical construction, alignment and adjustment of the meter, and design considerations.

We present an approach to measurements of complex electromagnetic environments based on the numerical minimization of the electromagnetic action functional on a lattice in Euclidean space time. The technique allows one to determine the minimum power density consistent with a few measurements of the electric or magnetic field within a given volume. Knowledge of the external sources irradiating the volume is not required. [Contact: (303) 497-3150]

Wilson, P.F., and Ma, M.T., **Factors Influencing Material Shielding Effectiveness Measurements,** to be published in the Proceedings of the IEEE 1985 International Symposium on Electromagnetic Compatibility, Wakefield, Massachusetts, August 20-22, 1985.

A material's shielding effectiveness is often measured in terms of insertion loss, that is, the field reduction between a transmitter and receiver achieved by introducing the shield material. The insertion loss concept is simply stated; however, ambiguities arise when one attempts to interpret specific insertion loss measurements. Insertion loss data depend not only on the shield material tested, but also on the measurement procedure. The antenna types used and their positioning, the incident waveform and its wave impedance, and the contact resistance between the test material and its mount (if any) can all affect insertion loss measurements, sometimes dramatically. These concepts are discussed based on the simple model of coupling through an electrically small aperture, loaded and unloaded, with the shield material. Emphasis is on the importance of understanding and recognizing these factors when making or interpreting the results of shielding effectiveness measurements. [Contact: (303) 497-3842]

Cruz, J.E., and Larsen, E.B., **Screenroom Measurements of Antenna Factors,** Proceedings of the IEEE Instrumentation and Measurement Technology Conference, Tampa, Florida, March 20-22, 1985, p. 208.

The measurement of electromagnetic fields in a shielded enclosure (screenroom) has serious problems because of uncertain antenna factors and multipath reflections from conductive surfaces. Most electromagnetic interference antennas at NBS are calibrated in a known field at an open-field site using the standard antenna method. Because these antenna factors are not necessarily applicable for making measurements in a screenroom, the measurement errors are difficult to determine. This paper presents the results for antenna factors determined in a screenroom using the two-antenna method. These antenna factors are compared with antenna factors determined at an open-field site and in an anechoic chamber. Experiment data are presented to show the variability of antenna factor as a function of frequency and location in the screenroom, thereby providing an indication of error bounds.

Ma, M.T., Kanda, M., Crawford, M.L., and Larsen, E.B., **A Review of Electromagnetic Compatibility/Interference Measurement Methodologies,** Proceedings of the IEEE, Vol. 73, No. 3, pp. 388-411 (March 1985).

This paper presents a review summary of radiated emission and susceptibility measurement methodologies currently used for assessing the electromagnetic compatibility/interference (EMC/EMI) characteristics of electronic devices and systems. In particular, measurement methods using open sites, transverse electromagnetic (TEM) cells, reverberating chambers, and anechoic chambers are discussed, in the light of their technical justifications and bases, their strengths and limitations, and interpretation of the measurement results.

Wilson, P.F., and Ma, M.T., **Shielding-Effectiveness Measurements with a Dual TEM Cell,** IEEE Transactions on Electromagnetic Compatibility, Vol. EMC-27, No. 3, pp. 137-142 (August 1985).

Small-aperture theory is used to investigate the dual transverse electromagnetic (TEM) cell. Analyzing coupling through an empty aperture versus a loaded aperture leads to a simple model of dual-TEM-cell material shielding-effectiveness (SE) measurements. Experimental data are compared to theory with good agreement in the case of an empty aperture. Some of the difficulties in analyzing a loaded aperture are discussed.

1986 CEEE Calendar

22-23 April (Gaithersburg, MD)

Workshop on Test Procedures for Precision Instrumentation and ATE Systems. This Workshop is intended to provide a forum for the exchange of information among researchers, users, manufacturers, testing companies, and calibration laboratories on the procedures used in testing the performance of precision instrumentation and automatic test equipment systems. Technical topics planned include first-article and acceptance testing, bid-sample testing, maintenance and calibration testing, developing and writing specifications and procedures, "minimum-use" specifications, test accuracy ratios, economic tradeoffs of testing, case histories of

1986 CEEE Calendar, cont'd.

specific test programs, optimum calibration strategies, and recommended practices. The Workshop proceedings will be published by the Institute of Electrical and Electronics Engineers.

23-27 June (Gaithersburg, MD)

1986 CPEM (Conference on Precision Electromagnetic Measurements). CPEM 86 is being sponsored by the U.S. National Bureau of Standards, the IEEE Instrumentation and Measurement Society, and the Union Radio Scientifique Internationale. The Conference will present papers covering the theory, design, performance, simulation, and application of electromagnetic standards, measurements, techniques, instruments, and systems. Sessions are tentatively planned to cover the following technical areas: electromagnetic-related fundamental constants and standards; direct current, low frequency, and radiofrequency; time, time interval, and frequency; antennas and fields; microwaves and millimeter waves; infrared, visible, and ultraviolet radiation; lasers; electro-optics and fiber optics; cryoelectronics; automated measurements; and technical calibration services. The Conference language will be English. [Contact: Sara Torrence, (301) 921-2721. (For technical information, contact John R. Sorrells, (301) 921-2727 or Norman B. Belecki, (301) 921-2715.)]

9-10 September (Boulder, CO)

Symposium on Optical Fiber Measurements. This fourth biennial Symposium is devoted to measurements on optical fiber, related components, and systems. It is sponsored by NBS in cooperation with the IEEE Optical Communications Committee and the Optical Society of America and is intended to provide a forum for reporting the results of recent measurements research and for evaluating these results in terms of future directions. About one-quarter of the sessions will be workshops led by invited panelists. Summaries of presented papers will be published in a technical digest to be distributed at the Symposium.

RECENTLY ISSUED STANDARD REFERENCE MATERIALS

The first practical superconducting standard reference material (SRM) has been released by the Electromagnetic Technology Division to the NBS Office of Standard Reference Materials for sale to the public. The certified parameter of SRM 1457, Superconducting Critical Current -- NbTi Wire, is critical current at magnetic fields of 2,4,6, and 8 tesla at a temperature of 4.2 K and an electric field criterion of 0.2 μV/cm. Information is given to permit the user to determine critical current for temperatures in the range 3.90 to 4.24 K and electric field criteria from 0.05 to 0.2 μV/cm.

SRM 1457 consists of a 2.2-m length of a multifilimentary, niobium-titanium, copper-stabilized wire, wound in a single layer on a spool having a core diameter of 8.7 cm. The wire is evaluated for 34 parameters relating to current, voltage, magnetic field, temperature, strain, and physical specimen characteristics.

In conjunction with ASTM Standard Test Method B714-82, D-C Critical Current of Composite Superconductors, the new SRM is intended to provide means for calibrating apparatus used to measure key parameters of superconductor products and thus should be useful to buyers and sellers of superconductors, users of superconducting equipment, and researchers in superconducting technology.

10. SUPPLEMENTARY NOTES

All technical information included in this document has been previously approved for publication.

[ ] Document describes a computer program; SF-185, FIPS Software Summary, is attached.

11. ABSTRACT (A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here)

This is the twelfth issue of a quarterly publication providing information on the technical work of the National Bureau of Standards Center for Electronics and Electrical Engineering. This issue of the CEEE Technical Progress Bulletin covers the third quarter of calendar year 1985. Abstracts are provided by technical area for both published papers and papers approved by NBS for publication.

12. KEY WORDS (Six to twelve entries; alphabetical order; capitalize only proper names; and separate key words by semicolons)

antennas; electrical engineering; electrical power; electromagnetic interference; electronics; instrumentation; laser; magnetics; microwave; optical fibers; semiconductors; superconductors

13. AVAILABILITY
