List of Tables

1. GENERAL INFORMATION

1.1 PURPOSE OF THIS DOCUMENT

This document records current agreements on implementation details of OSI protocols among the organizations participating in the NBS/OSI Workshop Series for Implementors of OSI Protocols. These decisions are documented to facilitate organizations in their understanding of the status of agreements. This is a standing document that is intended to be updated after each workshop (about every 2-1/2 months).

1.2 PURPOSE OF THE WORKSHOP

In February, 1983 NBS organized the above named workshop to bring together future users and potential suppliers of OSI protocols. The workshop accepts as input the specifications of emerging standards for protocols and produces as output agreements on the implementation and testing particulars of these protocols. This process is expected to expedite the development of OSI protocols and promote interoperability of independently manufactured data communications equipment.

1.3 RELATIONSHIPS OF WORKSHOPS TO EVENTS AND ACTIVITIES

The workshop is held for those organizations expressing an interest in implementing OSI protocols. However, there is no corporate commitment to implementations associated with workshop participation. Other events stem from the workshop to which commitments are attached. Sixteen organizations did make formal commitments to implement and demonstrate some of the protocols at the 1984 National Computer Conference. Commitments were made by General Motors, Boeing Computer Services, and 21 vendors to demonstrate, at AUTOFACT 1985, a set of OSI protocols known as the Manufacturing Automation Protocol or MAP specification. This event was an outgrowth of the workshop in that the implementation decisions reached in the workshops were used for the AUTOFACT demonstration. However, the AUTOFACT demonstration was planned and carried out by GM, BCS, and suppliers they selected. This event had no further affiliation with the workshop.

A different activity, initiated by NBS, is the OSINET, which is to be a long standing, globally distributed network that is put in place for purposes such as test methods development and testing of prototype implementations. Presently, 25 organizations have committed to participate. As with the AUTOFACT demonstration, protocols used on OSINET are those agreed to in the workshop. Also, as with the AUTOFACT demonstration, the OSINET has no other affiliation with the workshop. Unlike the AUTOFACT demonstration, however, OSINET participation is open to any organization committing to the OSINET agreements.

1.4 RELATIONSHIP OF THE WORKSHOP TO THE NBS LABORATORIES

As resources permit, NBS, with voluntary assistance from industry, develops formal protocol specifications, reference implementations, tests and test systems for the protocols agreed to in the workshops. This is work made available to the industry volunteers and to others making valid commitments to organized events and activities such as NCC, AUTOFACT, and OSINET. As soon as this work can be adequately documented it is placed in the public domain through submission to the National Technical Information Service. Any organization may then obtain the work at nominal charge.

The NBS laboratories bear no other relationship to the workshop.

1.5 STRUCTURE AND OPERATION OF THE WORKSHOP

1.5.1 Plenary

The main body of the workshop is a plenary assembly. Any organization may participate. Representation is international. NBS prefers for the business of workshops to be conducted informally, since there are no corresponding formal commitments within the workshop by participants to implement the decisions reached. The guidelines we follow are: 1) one vote per company or independent division, 2) only companies that regularly attend should vote, 3) only companies that plan to sell or buy a protocol should vote on its implementation decisions, 4) only companies knowledgeable of the issues should vote, and 5) no proxy votes are admissible.

1.5.2 Special Interest Groups

Within the workshop there are Special Interest Groups (SIGs). The SIGs receive their instructions for their technical program of work from the plenary. The SIGs meet independently, usually during the workshop. As technical work is completed by a SIG, it is presented to the plenary for disposition. Companies participating in a SIG are expected to participate in the plenary. Voting rules for SIGS are the same as voting rules for the plenary.

Special Interest Groups sometimes correspond with organizations performing related work, such as ANSI committees. Such correspondence should be sent through the plenary to the parent committee, such as ANSC X3T5 or ANSC X3S3. When SIG meetings take place between workshops, the correspondence from these meetings should be addressed directly to the parent committee and copied to the workshop plenary.

Following are procedures for cooperative work among Special Interest Groups.

- Any SIG (SIG 1) or individual having issues to discuss with or requirements of another SIG (SIG 2) should bring the matter to the attention of the chairperson of that SIG (SIG 2).

- o The SIG 2 chairperson should bring the matter before SIG 2 for action.

- o SIG 2 should respond to the concerns or needs of SIG 1 or the individual in a timely manner.

- o If the matter cannot be satisfactorily resolved or if the request is outside the charter assigned to SIG 1, then it should be brought before the plenary.

- o SIGs are expected to complete work in a timely manner and bring the results before the plenary for disposition. However, the plenary may elect to act on any issue within the scope of the workshop at any time.

Following are the charters of the the nine Special Interest Groups.

FTAM SIG

Develop phase 2 product-level specifications.

Future new work items will be defined in a Phase 3 specification. It will contain only extensions of Phase 2 FTAM. It is a goal that Phase 3 will be backward compatible with Phase 2 FTAM. The set of future work items listed below may be changed by the plenary if the work is more appropriate for other SIGs.

High priority work items:

- o Clean up section 10 of this document

- o Specify Reliable File Service

- o Specify Recovery and Restart Data Transfer functional units in the user correctable file service

- o Specify concurrency control parameter.

Low priority work items:

- o Add new document types/constraint sets

- o Define subset of authorization requirements

- o Specify Presentation Context Management functional unit.

X.400 SIG

Develop product-level specifications for Message Handling Systems using the CCITT X.400 Recommendations.

Develop abstract tests for X.400, as requested by the ad hoc rapporteur for

this study question in CCITT. This work is to be submitted by the plenary (after its approval) to The U.S. Department of State as a proposed U.S. contribution to CCITT Study Group VII.

Lower Layer SIG

The Lower Layer SIG will study OSI layers 1-4 and produce recommendations for implementations to support the projects undertaken by the workshop and the work of the other SIGs. Both connectionless and connection-oriented modes of operation will be studied. The SIG will accept direction from the plenary for work undertaken and the priority which it is assigned.

The objectives of the Lower Layer SIG are:

- o Study OSI layers 1-4 as directed by the plenary,
- o Produce and maintain recommendations for implementation of these layers,
- o Where necessary, provide input to the relevant standards bodies concerning layers 1-4, in the proper manner, and
- o Begin work on the implementation specification of the ISO Network Layer Routing Exchange Protocol prior to the ISO draft achieving DIS status.

Performance SIG

The plenary will provide the following inputs to the OSI Performance SIG:

- o the set of applications for which the performance of OSI protocols is of particular concern,
- o the requirements for each application including:
  - performance targets
  - network topology
  - background network loads
  - application traffic characteristics, and
- o this document, "Implementation Agreements Among Implementors of OSI Protocols".

The objectives of the OSI Performance SIG are to:

- o determine whether the OSI protocols are able to meet these performance requirements,
- o report these determinations to the plenary, and

- o where appropriate, provide input to the voluntary standards bodies concerning changes to existing standards and the requirements for new ones, in the appropriate form.

OSI Security Architecture SIG

GOAL: To develop an overall OSI Security Architecture which is consistent with the OSI and which economically satisfies the primary security needs of both the commercial and Government sectors.

APPROACH: To define a security architecture encompassing the security addenda presently being specified at certain OSI layers, the required cryptographic algorithms and related key management functions, and the security management functions which must be performed between the layers and the peer entitities defined in the OSI architecture.

Directory Services SIG

Produce functional implementation agreements based on ISO/CCITT specifications for Directory Services in accordance with the objectives and goals of the plenary.

- o Provide a subset for NBS publication which is functional and forward compatible to further work by this Special Interest Group.

- o Define stable core functionality which can be implemented in the near term.

Virtual Terminal SIG

This Special Interest Group's charter is based upon the implementation of Draft International Standards 9040 and 9041 and their respective addenda, in providing Basic Virtual Terminal Service.

This group will develop agreements for the implementation and testing of the following terminal types.

- o X.29 PAD
- o TELNET
- o Basic Scrolling
- o Basic Paging
- o Basic Forms

Upper Layers SIG

Develop product-level specifications for the implementation of Session service and protocol, Presentation service and protocol, and ACSE service and protocol. These specifications will be developed to support the application layer services FTAM, X.400, VT, and Directory Services. In addition, the SIG is responsible for requirements in common between Multiple Application services, for example, registration of Application Contexts and Abstract Syntaxes.

Office Document Architecture and Office Document Interchange Format SIG

Develop product-level specifications for the architecture and interchange of office documents processed by computers. The standard governing the ODA/ODIF SIG's work is ISO 8613 - Office Document Architecture (ODA) and Interchange Format (ODIF).

1.6 POINTS OF CONTACT

OSI Workshop - General	John Heafner, NBS, 301/975-3618
OSI Workshop - Registration	Mary Lou Fahey, NBS, 301/975-3600
	Joan Wyrwa, NBS, 301/975-3643
FTAM SIG	Rick Peterson, GM, 313/947-0586
X.400 SIG	John Stidd, Xerox, 408/737-4338
Lower Layers SIG	Kevin Miles, DEC, +44-734-868711
Performance SIG	Mary Jane Strohl, CDS,617/460-0808
Security SIG	Denny Branstad, NBS, 301/975-2913
DS SIG	J. J. Cinecoe, WANG, 617/967-5514
VT SIG	TBD
Upper Layers SIG	Mike Ellis, HP, 916/786-8000x4292
ODA/ODIF SIG	TBD
MAP	Gary Workman, GM, 313/947-0599
TOP	Laurie Bride, BCS, 206/763-5719
Government OSI Spec.	John Heafner, NBS, 301/975-3618
OSINET	
Steering Committee	TBD
Technical Committee	Ed Strum, IBM, 415/855-7392
SME (MAP/TOP Sponsorship)	Mark Shaw, 313/271-1500
	Paul Borawski, 313/271-1500

2. THE PROTOCOLS

The selected protocols for which implementation agreements have been made and are being developed are:

- o IEEE 802.2 Logical Link Control
- o IEEE 802.3 CSMA/CD Access Method
- o IEEE 802.4 Token Bus Access Method
- o CCITT Recommendation X.25
- o Private Subnetworks
- o Network Dependent Convergence Sublayer Protocol between X.25 and ISO Connectionless IP
- o X.25 Packet Layer Protocol to support the Connection Oriented Network Service
- o ISO Connectionless Internetwork Protocol
- o ISO Transport Classes 4 and 0 and Connectionless Protocols
- o ISO Session Protocol
- o ISO File Transfer, Access and Management Protocol
- o ISO Presentation Layer Protocol
- o ISO CASE Protocol
- o CCITT 400 Series Recommendations for Message Handling Facility
- o CCITT and ISO Directory Services Protocol

Reference documents and sources for obtaining them are given under References.

3. LOCAL AREA NETWORKS

3.1 IEEE 802.2 LOGICAL LINK CONTROL

The following decisions have been reached with respect to this protocol.

1. Link Service Access Point (LSAP)

The IEEE 802 committee has assigned the code below to address systems using ISO IS 8473 connectionless network protocols. Note that bit zero is transmitted first.

The most significant bit is bit 7, thus this bit pattern represents hexadecimal FE.

0	1	2	3	4	5	6	7
0	1	1	1	1	1	1	1

Fig. 3.1 LSAP bit pattern

2. Type and Class

Only the connectionless type 1, class 1 IEEE 802 link service will be used.

3. Exchange Identification and Test

The Exchange Identification (XID) and Test (TEST) will not be sent. If one is received it will be discarded.

3.2 IEEE 802.3 CSMA/CD ACCESS METHOD

The 48 bit addressing will be used with the 10 megabit/second baseband coaxial cable specification.

3.3 IEEE 802.4 TOKEN BUS ACCESS METHOD

The following options are agreed to with respect to Draft F of token bus. An asterisk means that the option has been approved. The absence of an asterisk means that the option has not been approved.

1. Repeaters
   - Active Regenerative
2. Medium
   - Single Cable Coax *
   - Dual Cable Coax
3. Trunk Cable
   - RG-6 *
   - RG-11 *

	Semi-rigid	*
	Other 75 ohm cables	*
4.	Trunk Connection Unit	
	75 ohm tee connector	
	75 ohm nondirectional passive impedence-matching tap	
	75 ohm directional passive impedence-matching tap	*
5.	Transmit Carrier Frequency	
	RF	*
	Baseband	
6.	Modulation

T	6'	*
U	FM1'	*

4. WIDE AREA NETWORKS

4.1 CCITT RECOMMENDATION X.25

When providing CONS, it is agreed to use X.25 as the standard wide area network protocol. Elements of X.25 are explained in section 6.2.2.

5. PRIVATE SUBNETWORKS

5.1 PRIVATE SUBNETWORKS

The architectures agreed upon allow the use of private subnetworks in addition to private X.25 subnetworks. No particular private subnetwork has been discussed.

6. NETWORK LAYER

6.1 CONNECTIONLESS NETWORK SERVICE (CLNS)

6.1.1 Provisions of CLNS using CLNP (IS 8473)

The following decisions have been reached with respect to this protocol.

- The "Protocol for providing the connection-less service," ISO IS 8473, will be used to provide the CLNS.

- The non-segmenting and the inactive subsets will not be supported.

6.1.2 Agreements on Protocol Functions

- For purposes of demonstration the value to be used to bound the maximum lifetime of the internetwork protocol data unit is three times the network span. The span of the network is considered to be the number of intermediate systems between source and destination plus the destination end system.

- For purposes of testing, intermediate and end systems will log the following conditions:

    - Discarded protocol data units,
    - Error protocol data units (recorded by system generating the error PDU), and
    - Detection of protocol data units containing unsupported type 3 options.

6.1.3 Agreements on Optional Protocol Functions

- The security parameter will not be used.

- Intermediate systems should recognize and support both complete and partial source routing.

  Although end systems may implement source routing (of either type), any requirement for end system source routing is deferred for future study, since support for it may be related to layer management protocols.

- Partial source routing will be supported by intermediate systems. The destination should log the route, if possible.

- The ISO specification will be followed with respect to quality of service.

- o For purposes of testing, checksums will be turned on and used. In operation this is a local decision.

6.1.4 Network Dependent Convergence Sublayer Function (CLNS Over X.25)

A network dependent convergence sublayer protocol operating between CCITT Recommendation X.25 and the ISO Connectionless IP has been agreed to. It shall adhere to the following.

- o Follow ISO 8473 DAD1 (N3601) Working Paper for the SNDCF framework.
- o Only initiate one SVC for all outbound PDUs to any other given intermediate system or PDN end system. Note: this results in at most two SVCs between any pair of systems.
- o Open a connection upon demand.
- o Disconnect SVCs by administrative request and a finite timeout timer.
- o Use the default throughput class.
- o Do not use D-bit or Q-bit.
- o Negotiate window size according to ISO IS 8208. A default of window size two must be supported.
- o Negotiate packet size according to ISO IS 8208. A default of 128 octets/packet must be supported.
- o The SNDCF will "advertise" support for SNSDUs up to 1K via the X.25 M-bit facility.
- o No statistics gathering is required beyond that which the CLNS may gather for the X.25 packet layer or for SNDCF entities.

6.2 CONNECTION MODE NETWORK SERVICE (CONS)

There is interest among a limited set of participants in implementing the connection mode network service. This section records the agreement of the workshop on the provision of a connection mode network service.

6.2.1 Introduction

The X.25 Packet Level Protocol (PLP) is used to provide the OSI Connection-mode Network Service (CONS). This proposal is independent of lower and higher layer protocol considerations, which are also discussed briefly herein.

When providing the CONS, the following shall apply:

- The definition of the CONS is as specified in ISO 8348, "Network Service Definition";

- The mapping of the elements of the CONS to the elements of the X.25/PLP is as specified in ISO 8878, "Use of X.25 to Provide the OSI Connection-mode Network Service"; and

- The general procedures and formats of the X.25/PLP are as specified in ISO 8208, "X.25 Packet Level Protocol for Data Terminal Equipment". Note that this standard provides for the use of the X.25/PLP in environments in addition to an X.25 PSPDN, such as point-to-point topologies as well as LANs. (The details of how to use the X.25/PLP in LANs are given in ISO 8881, "Information Processing Systems - Data Communications - Use Of The X.25 Packet Level Protocol in Local Area Networks.")

6.2.2. Provision of CONS Using X.25/PLP

The provision of the CONS using the X.25/PLP is as described in the second bullet above. This section provides a brief description taken directly from ISO 8878; for more detail, see ISO 8878.

Also note that the X.25/PLP-1984 is capable of supporting the full CONS, including quality-of-service (QOS) aspects. The X.25/PLP-1984 shall be used in LANS and in packet-switched networks allowing the use of the elements of the X.25/PLP-1984 needed to support the CONS. In other packet-switched-network environments, a Subnetwork Dependent Convergence Protocol (SNDCP) shall be used in conjunction with the X.25/PLP-1980 (see section 6.2.5).

6.2.2.1 Overview

6.2.2.1.1 Elements of the X.25/PLP for Support of the CONS

The table below lists the packets and associated fields used when supporting the OSI CONS.

Tbl. 6.1 Packets and fields of X.25/PLP used to support OSI CONS

PACKET TYPES[1]	FIELDS[2]
CALL REQUEST INCOMING CALL CALL ACCEPTED CALL CONNECTED	Facility Field, Call and Called User Data Field
CLEAR REQUEST CLEAR INDICATION	Clearing Cause Code Field, Diagnostic Code Field, Facility Field, Clear User Data Field
DATA	M-Bit, User Data Field
RESET REQUEST RESET INDICATION	Resetting Cause Code Field, Diagnostic Code Field
RESTART INDICATION	Restarting Cause Code Field, Diagnostic Code Field

Notes:

1. The packets shown in the table are used in support of the primitives of the OSI CONS. Other packets not shown in the table (i.e., CLEAR CONFIRMATION, RESET CONFIRMATION, and RESTART CONFIRMATION packets) are essential to the use of the packets shown. Yet other packets (i.e., RESTART REQUEST, DIAGNOSTIC, REGISTRATION REQUEST, and REGISTRATION CONFIRMATION packets) have no relationship to the provision of the OSI CONS.

   In line with these agreements, the INTERRRUPT, INTERRUPT CONFIRMATION, RECEIVE READY, RECEIVE NOT READY, and REJECT packets are not needed to support the OSI CONS because the corresponding aspects of the OSI CONS are not to be used (i.e., the Expedited Data Transfer Service and the Receipt Confirmation Service are not used). However, the RECEIVE READY and RECEIVE NOT READY packets are needed for the proper operation of the X.25/PLP.

2. The information in the fields shown in the table has a direct relationship to the parameters associated with the primitives of the OSI CONS. Other fields not shown in the table (e.g., the Logical Channel Identifier, the Packet Type Identifier, the Address Length Fields and the Facility Length Field) are essential to the use of the appropriate packets.

In addition, it is also necessary for the following optional user facilities and CCITT-Specified DTE Facilities to be used and/or agreed to:

1. optional user facilities

   - o Fast Select (facility used)
   - o Fast Select Acceptance (facility agreed to, if operating in a packet-switched network environment)
   - o Throughput Class Negotiation (facility agreed to and used), and
   - o Transit Delay Selection And Indication (facility used);

Note: When operating in a DTE-to-DTE environment without an intervening packet-switched network, the use of the Fast Select Facility must also be agreed to by the two DTEs. In addition, the Fast Select Acceptance Facility does not apply.

2. CCITT-Specified DTE facilities

   - o Called Address Extension (facility used),
   - o Calling Address Extension (facility used),
   - o End-to-End Transit Delay Negotiation (facility used),
   - o Expedited Data Negotiation (facility used), and
   - o Minimum Throughput Class Negotiation (facility used).

Elements of the X.25/PLP not needed in support of the CONS are:

- o Q-bit
- o Permanent Virtual Circuits (PVCs),
- o Diagnostic packets, and
- o optional user facilities other than those listed above.

Elements of the X.25/PLP not used within the scope of these agreements are:

- o D-bit and
- o INTERRRUPT packets.

6.2.2.1.2 General Operation of X.25/PLP-1984 for Supporting OSI CONS

The X.25/PLP can be used to provide the OSI CONS in an end system connected to a public or private X.25 packet-switched network environment. It can also be used in environments where the end-system is connected to a local area network or where end systems are connected by a dedicated path or by a circuit-switched connection.

The NS provider (more particularly, the Network Layer (NL) entity in an end-system) must provide a translation between

1. the primitives and parameters of the OSI CONS; and
2. the packets and associated fields of the X.25/PLP.

Request and response primitives are translated into packets to be transmitted across the DTE/DCE interface by the NL entity. Received packets, where appropriate, are translated by the NL entity into indication and confirm primitives. These translations are shown in sections 6.2.2.2 through 6.2.2.7.

Note: The Network Service Definition specifies valid sequences of primitives at a NC endpoint and valid parameter responses at the called NC endpoint to Receipt Confirmation negotiation, Expedited Data negotiation, and QOS parameter negotiation. The necessity for the NL entity to police compliance and the NL entity actions to be taken on non-compliance are a local matter and not subject to standardization.

There is also a relationship between some local mechanism used to identify a particular Network Connection (NC) and a Logical Channel (LC) number used to identify a particular virtual circuit. This relationship is a local matter.

6.2.2.2 Network Connection Establishment Phase

Table 6.2 shows the relationships between the primitives/parameters used during the Network Connection Establishment Phase and the packets/fields associated with the Call Setup Procedures.

Tbl. 6.2 CONS: X.25/PLP mapping for the network connection establishment phase

CONS	X.25/PLP-1984
PRIMITIVES:	PACKETS:
N-CONNECT request	CALL REQUEST
N-CONNECT indication	INCOMING CALL
N-CONNECT response	CALL ACCEPTED
N-CONNECT confirm	CALL CONNECTED
PARAMETERS:	FIELDS (INCLUDING FACILITIES):
Called Address	Called Address Extension Facility
Calling Address	Calling Address Extension Facility
Responding Address	Called Address Extension Facility
Receipt Confirmation Selection	See Note 1.
Expedited Data Selection	See Note 1.
QOS Parameter Set	Throughput Class Negotiation Facility[2] Minimum Throughput Class Negotiation Facility Transit Delay Selection And Indication Facility End-to-End Transit Delay Negotiation Facility
NS-User-Data	Call and Called User Data Field Fast Select Facility[3]

Notes to table 6.2:

1. Within the scope of these agreements, the Receipt Confirmation Service and Expedited Data Service will not be used. Therefore, the Network Service provider will indicate the unavailability of these services even if requested by the Network Service user. To do this does not require an explicit protocol mechanism.

2. For proper operation, this optional user facility must also be agreed to for use on the interface.

3. For proper operation, the Fast Select Acceptance Facility must also be agreed to on the interface when accessing a packet-switched network.

6.2.2.3 Network Connection Release Phase

Table 6.3 shows the relationships between the primitives/parameters used during the Network Connection Release Phase and the packets/fields associated with the Call Clearing Procedures.

Tbl. 6.3 CONS: X.25/PLP mapping for network connection release phase

CONS	X.25/PLP-1984
PRIMITIVES:	PACKETS:
N-DISCONNECT request N-DISCONNECT indication	CLEAR REQUEST CLEAR INDICATION, RESTART INDICATION[1], CLEAR REQUEST[2]
PARAMETERS:	FIELDS (INCLUDING FACILITIES):
Originator and Reason	Cause Code and Diagnostic Code Fields[3]
NS-User-Data	Clear User Data
Responding Address	Called Address Extension Facility

Notes to Table 6.3:

1. Receipt of a RESTART INDICATION packet should be treated as receipt of a CLEAR INDICATION packet for every logical channel and then mapped to an N-DISCONNECT indication primitive for every active NC associated with the Packet Level Protocol being restarted. The Restarting Cause Code and Diagnostic Code Fields are then treated in the same manner as the Clearing Cause Code and Diagnostic Code Fields.

2. Used only when the NL entity in the end system originates an N-DISCONNECT indication primitive.

3. The combination of Cause Code and Diagnostic Fields is mapped to/from the combination of Originator and Reason parameters. Where the IS 8208 diagnostic codes are not provided, all Cause/Diagnostic code combinations can be mapped to the Orignator/Reason parameter values of "Undefined".

6.2.2.4 Data Transfer Phase -- Data Transfer Service

Table 6.4 shows the relationships between the primitives/parameters used for the Data Transfer Service and the packets/fields associated with the Data Transfer Procedures.

Tbl. 6.4 CONS: X.25/PLP mapping for the data transfer service

CONS	X.25/PLP-1984
PRIMITIVES: N-DATA request N-DATA indication	PACKETS: DATA DATA
PARAMETERS: NS-User-Data Confirmation Request	FIELDS: User Data, M-bit See Note 1.

Note to table 6.4:

1. Since the Receipt Confirmation Service is not to be provided, a Confirmation Request is not valid.

6.2.2.5 Data Transfer Phase -- Receipt Confirmation Service

This service is not provided by these agreements.

6.2.2.6 Data Transfer Phase -- Expedited Data Transfer Service

This service is not provided by these agreements.

6.2.2.7 Data Transfer Phase -- Reset Service

Table 6.5 shows the relationships between the primitives/parameters used for the Reset Service and the packets/fields associated with the Reset Procedures.

Tbl. 6.5 CONS: X.25/PLP mapping for the reset service

CONS	X.25/PLP-1984
PRIMITIVES:	PACKETS:
N-RESET request	RESET REQUEST
N-RESET indication	RESET INDICATION, RESET REQUEST[1]
N-RESET response	none
N-RESET confirm	none
PARMETERS:	FIELDS:
Originator and Reason	Cause Code and Diagnostic Code Fields[2]

Notes to table 6.5:

1. Used only when the NL entity in the end system originates an N-RESET indication primitive.

2. The combination of Cause Code and Diagnostic Code Fields is mapped to/from the combination of Originator and Reason parameters. Where the IS 8208 diagnostic codes are not provided, all Cause/Diagnostic code combinations can be mapped to the Originator/Reason parameter values of "Undefined".

6.2.3 Requirements for Underlying Layer

As cited in IS 8208, the X.25/PLP requires the following of the underlying Layer 2:

- low duplication rate,
- low missequencing rate,
- low undetected bit-error rate, and
- low loss rate.

When operating in a packet-switched (X.25) network environment, the underlying LAPB protocol ensures these requirements. When operating in a LAN environment, LLC 1 can be used. Considerations for LLC 1 are given in DP 8881.

6.2.4 Consideration of OSI Transport Layer Protocol Class

It may be useful to explore the desirability of an alternative to the Transport Class 4 protocol for use over the CONS. See section 7, Transport.

6.2.5 Subnetwork Dependent Convergence Protocol

In cases where an end system is required not to use the elements of the X.25/PLP-1984 needed to support the OSI CONS (e.g., when operating in a packet-switched network environment that will treat as an error the use of any

of the CCITT-specified DTE facilities), then it shall use a Subnetwork Dependent Convergence Protocol (SNDCP) to provide the necessary elements of the OSI CONS to the Network Service user. These elements involve certain aspects of the Network Connection Establishment Phase and the Network Connection Release Phase.

The SNDCP to be used is referred to as the Alternative Procedures for Network Connection Establishment and Release in DP8878. The procedures for the data transfer phase of the SNDCP, as specified in DP8878, are essentially the same as those in sections 6.2.2.4 through 6.2.2.7 of this document.

6.2.5.1 Network Connection Establishment Phase

The procedures for this phase are as specified in DP8878, Annex A, Section 6.1(b) (the Alternative Network Connection Establishment Procedure). These procedures use:

- o A CALL REQUEST packet containing (in addition to the packet header, the Address Fields, and other facilities):

  - the Throughput Class Negotiation Facility if available; otherwise, the throughput of the virtual circuit must be known a priori (by way of the Default Throughput Classes Assignment Facility, for example), and

  - a Call User Data Field containing three octets: a one-octet Protocol ID identifying the X.25/PLP-1980 SNDCP encoded X'84' (as assigned by ISO) and a two-octet Continuation Parameter encoded X'2D00' to indicate the first M-bit sequence (MBS) of DATA packets will contain additional Network Connection (NC) Establishment parameters;

- o A CALL ACCEPTED packet with necessary information for proper X.25 subnetwork interface operation but without any NC Establishment parameters;

- o An MBS of one or more DATA packets with the Q-bit set to 1, sent by the originator of the NC Establishment attempt, containing all necessary NC Establishment parameters encoded according to DP8878, Annex A, Section 8.7(c) (This MBS is known as an N-CR message.); and

- o An MBS of one or more DATA packets with the Q-bit set to 1, sent by the recipient of the NC Establishment attempt (assuming NC acceptance), containing all necessary NC Establishment parameters encoded according to DP8878, Annex A, Section 8.7(d) (This MBS is known as an N-CC message.); see section 6.2.5.2 for NC refusal.

The transit delay of each subnetwork must be estimated.

Similar to the use of the X.25/PLP-1984m the following items are to be noted:

- The Network Service provider will indicate the unavailability, during NC Establishment, of the Receipt Confirmation Service and the Expedited Data Service; therefore, no protocol mechanisms are necessary for the negotiation of these services; and

- NSAP Addresses are carried entirely in the Address Extension Fields of the N-CR and N-CC messages.

A Connect Response Timer may be used as specified in DP8878, Annex A, Section 6.8(a).

Figure 6.1 shows the NC Establishment Phase.

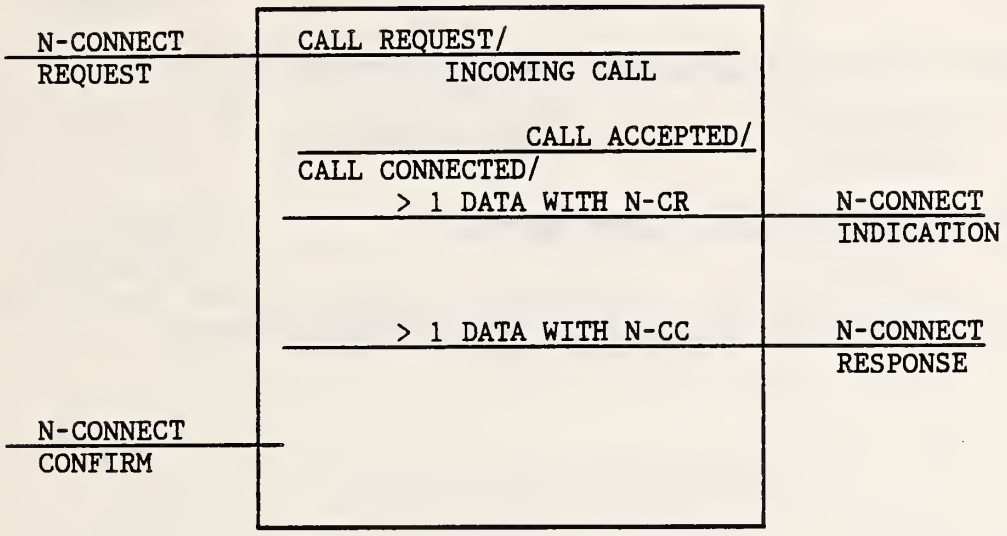

Fig. 6.1 Successful NC establishment

6.2.5.2 Network Connection Release Phase

The procedures for this phase are as specified in DP8878, Annex A, Section 6.2 (b) (the Alternative Network Connection Release Procedure). These procedures are also used to refuse an NC establishment attempt. These procedures use:

- An MBS of one or more DATA packets with the Q-bit set to 1, sent by the originator of the NC release, containing all necessary NC Release parameters encoded according to DP8878, Annex A, Section 8.8(a) (This MBS is known as an N-DR message and serves as an "invitation to clear," that is, initiate X.25 clearing procedures to the recipient.); and

- The X.25 CLEAR REQUEST/INDICATION packet as indicated in DP8878, Annex A, Section 8.8(b).

The above procedures apply to NC release when initiated by the Network Service user. When initiated by the NS provider, the N-DR message will not be sent but the Originator and Reason parameter values shall both be "undefined."

A Disconnect Response Timer may be used per DP8878, Annex A, Section 6.8(b).

Figure 6.2 shows the NC Release Phase.

6.2.5.3 Data Transfer Phase - Data Transfer Service

The Data Transfer Service for the X.25/PLP-1980 SNDCP is the same as for the X.25/PLP-1984 procedures, see section 6.2.2.4 of this document.

6.2.5.4 Data Transfer Phase - Receipt Confirmation Service

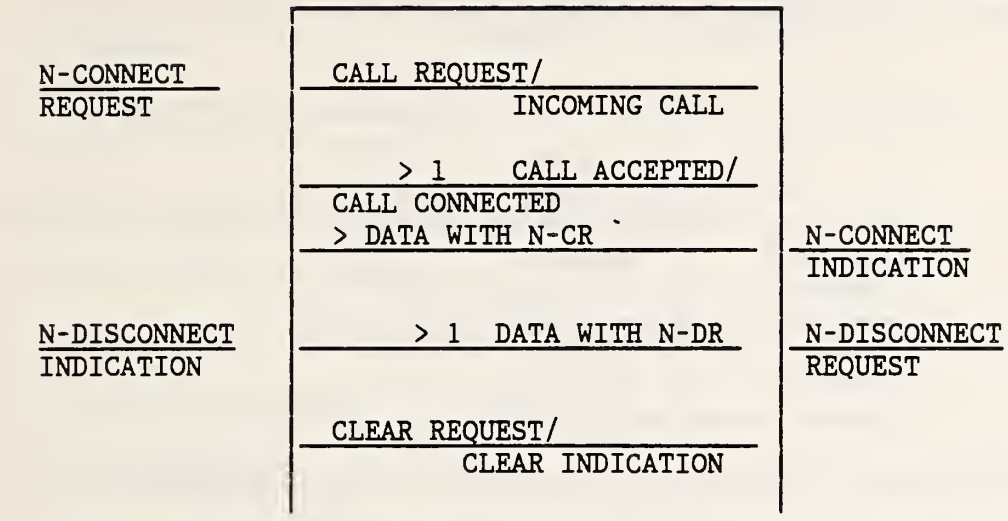
As for the X.25/PLP-1984 procedures, this service is not provided by these agreements.

6.2.5.5 Data Transfer Phase - Expedited Data Transfer Service

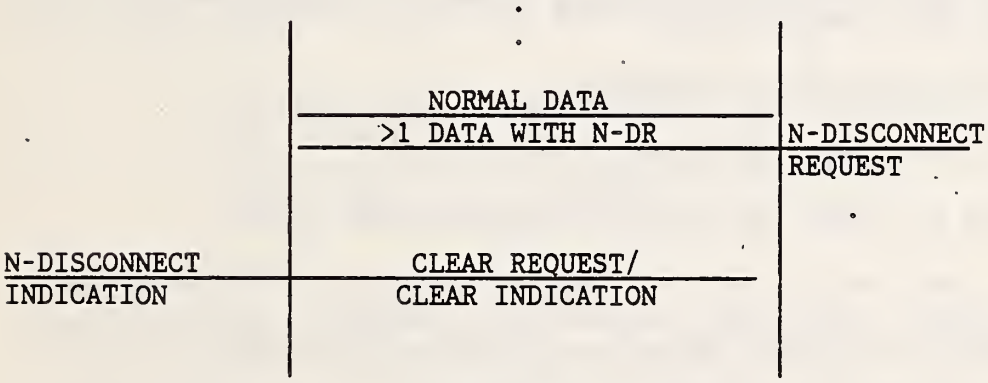
As for the X.25/PLP-1984 procedures, this service is not provided by these agreements.

6.2.5.6 Data Transfer Phase - Reset Service

The Reset Service for the X.25/PLP-1980 SNDCP is the same as for the X.25/PLP-1984 procedures, see section 6.2.2.7 of this document.



(a) NC ESTABLISHMENT REFUSAL

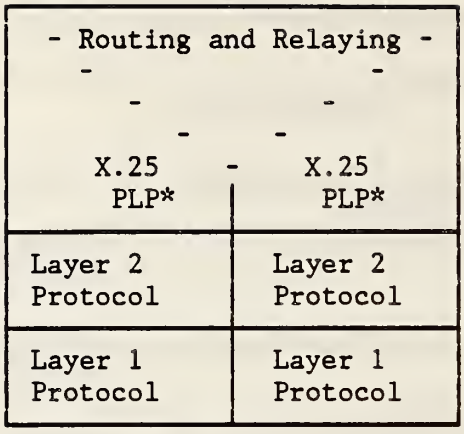


(b) NC RELEASE AFTER DATA TRANSFER

Fig. 6.2 NC release

6.2.6 Interworking

Interworking between subnetworks needs to be specified. The principles of the Internal Organization of the Network Layer, DP 8648, need to be addressed. A generalization of these principles for the OSI CONS case is shown in Figure 6.3.



*This can be either X.25/PLP-1984 or X.25/PLP-1980 with an SNDCP, see section 6.2.5.

Fig. 6.3 Generalized interworking for OSI CONS

The detailed behavior and properties of the Interworking Unit are to be specified in future extensions of this document. DP 8881 and DP 8878 discuss various aspects of interworking.

6.3 ADDRESSING AND ROUTING CRITERIA

The following have been agreed to.

- Do not go beyond ISO routing standardization efforts.
- Keep the end system as simple as possible. Put the needed complexity into the intermediate systems. Minimize memory overhead and enhance performance in the end systems.
- Addressing and routing decisions should include the NBS OSINET that permits inclusion of private subnetworks and end systems on PDNs.
- Permit multiple subnetwork (alternate paths) in a single intermediate system.
- Allow expandability for additional functionality beyond that required for a specific demonstration.
- Support a certain minimal topology. Accommodate multiple LANs, WANs, and private subnetworks.

- o Facilitate efficient implementation of intermediate systems. Minimize memory overhead and enhance performance of intermediate systems.

- o The OSINET will accommodate end systems attached directly to PDNs as one requirement.

6.4 GENERAL ADDRESSING AND ROUTING PRINCIPLES

The following have been agreed to.

1. Support DAD2. This supports criterion no. 1.

2. Routing Management

   Static Routing:

   All end systems and intermediate systems will provide a local mechanism to manipulate (and optionally create) the local routing table. Consistency checking, configuration, and updating of a local table with all other tables will be performed by human operators. The lack of flexibility induced by static procedures can be minimized with the use of the following aids:

   - o alternate static routes
   - o route update utility
   - o FTAM route table distribution
   - o table format via X.409 (ASN-1) encoding.

   Dynamic Routing:

   Endsystem-Intermediate System - A standard that provides the functionality of dynamic routing must be provided. The protocol (see references), Item ISO 18, "Network Layer Management Protocol...", provides for this functionality between end and intermediate systems. This standard is expected to be endorsed (and appropriate implementor agreements drafted) to provide this function at a time when it reaches the draft proposal status.

   Intermediate system-Intermediate System

   To be determined.

3. Routing Principles

The algorithm and data structures used for routing are not specified by this document. Implementors are free to perform these functions in the manner which is most appropriate for their system environment. However, all implementations must have the following characteristics:

o end-systems

End-systems must recognize a destination address on a directly connected subnet and send the NPDU to the destination system. When an NPDU is destined to a system that is not on a directly connected subnet, the NPDU must be sent to an intermediate system for further routing. The end system may, but is not required to, choose the intermediate system used on the basis of the destination subnet.

o intermediate systems

For static routing, intermediate systems must recognize all assigned subnetwork addresses and route NPDU's in the following way: If an NPDU is destined to an end system which is connected to the same subnet as the intermediate system, the NPDU is sent directly to the end system. If an NPDU is destined to an end system which is not connected to the same subnet as the intermediate system, the NPDU is sent to an appropriate intermediate system for further routing. If an NPDU is destined to an end system on an unknown subnet, the NPDU is discarded. If the error flag is set, an error NPDU is sent to the source address specified in the errant NPDU.

4. There is a single NSAP selector for each NSAP within an end system. For each end system NSAP, one and only one NSAP address will be used to identify the NSAP. This conforms to the requirements of DAD2 and supports criterion no. 1 to comply with current ISO standards.

5. Hierarchical NSAP addressing should be used to minimize the size of routing tables. This conforms to criterion no. 9.

6. The NSAP address used at the network service interface is based on one and only one subnetwork point of attachment (SNPA). This makes the hierarchial addressing more specific and implies that subnetwork specific addressing information is embedded in the NSAP address.

7. The encoded network protocol address information (NPAI) conveyed in the IPDU representing an NSAP address contains an encoded subnetwork address corresponding to the selected SNPA. This makes hierarchical addressing more specific as applied to addressing formats. The embedding of the subnetwork address facilitates routing and simplifies routing tables.

8. The workshop participants require control over the DSP encoding of the NSAP address.

9. NBS has obtained an IDI with value 4 from ISO for OSINET so that the AFI encoding "47" may be used.

10. Optionally, the NSAP addressing format should be able to support multiple network layer user entities, e.g., transport entities, within one end system.

11. All of the above principles lead to the address format agreed upon and shown below.

    While one address format is explicitly specified in these agreements (Fig. 6.4), this address format is not meant to preclude the support for other ISO standardized NSAP address formats.

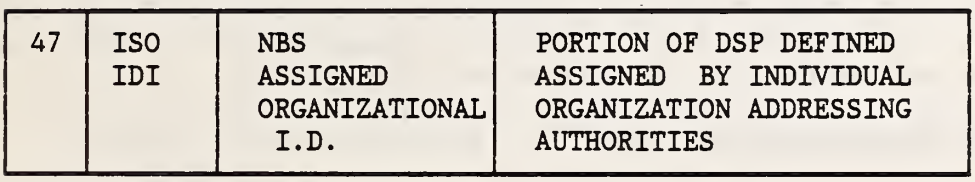


Fig. 6.4 NSAP address format

12. If used in the DSP, an NSAP Selector field is not used for routing purposes nor for locating the end system. It only locates the network layer user entity within the end system attached through the addressed NSAP.

13. In order to fulfill the criteria in section 6.3, item 3, a standard that provides the functionality of dynamic routing must be provided. The protocol referenced under ISO, item #18 "Network Layer Management Protocol ..." provides for this functionality between end and intermediate systems. This standard is expected to be endorsed to provide this function at a time when it reaches draft proposal status.

7. TRANSPORT

These agreements support the integration of LANs, packet networks, and other WANs with the smallest possible set of mandatory protocol sets, in accordance with the other agreements already reached. Nothing here shall preclude vendors from implementing protocol suites in addition to the ones described in this document. Two connection oriented transport classes have been identified for implementation (class 0 and class 4). In addition, there is interest among a limited set of participants in implementing a connectionless transport protocol. Transport class 4 (over CLNP) has been endorsed for general communication between private systems. Transport class 0 (over X.25) is used for communication with public (i.e., PT&T and RPOA) MHS systems operating in accordance with the CCITT X.400 series Recommendations. Communicating entities between private MHS systems over an X.25 network can, by negotiation or bilateral agreement, agree to use transport class 0. The connectionless transport protocol can be used with transaction-type implementations.

7.1 TRANSPORT CLASS 4

7.1.1 Transport Class

The following agreement has been reached with respect to this protocol.

Class 4 will be used with the required implementation of the 31 bit sequence space and 16 bit window size. The full protocol will be used including expedited data and negotiation at connection establishment.

7.1.2 Protocol Interpretation

According to the ISO transport specification, a disconnect request is issued in response to a connect request when the maximum number of transport connections is reached or exceeded.

7.1.3 Rules for Negotiation

- In general, the ISO rules for negotiation will be used, specifics follow.

- All implementations will send the 16/31 window size/sequence space in the CR TPDU. Implementations must all provide the 16/31 ISO option. Implementations must be able to accept the 4/7 in CR TPDU.

- The ISO TPDU size is 128 to 8K octets, always negotiated downward. The ISO rules are to be followed, allowing any valid size in the CR TPDU. TPDU size negotiation is a local implementation issue. Each vendor will decide how it is implemented in their end system.

- The security parameter is optional and user defined in the ISO specification. Implementations should not send the security parameter in the CR TPDU; if received it should be ignored.

- Both transports must agree to not use checksum, according to the ISO specifications. Requesting its use is an implementation choice. All implementations must be able to operate with checksum if requested.

- Use of acknowledgement time parameter is optional in ISO 8073. If an implementation is operating any policy which delays the transmission of AK TPDUs, the maximum amount of time by which a single AK TPDU may be delayed shall be indicated to the peer transport service provider using the acknowledgement time parameter. The value transmitted should be expressed in units of milliseconds and rounded up to the nearest whole millisecond.

- Throughput, priority, and transit delay are optional in the ISO specification. Do not send in the CR TPDU; ignore in the CC TPDU.

- User data in the CR TPDU and the CC TPDU are optional. No implementation should send; all implementations must be prepared to receive.

7.1.4 Retransmission Timer

It is recommended that the value used for the retransmission timer be based upon the round-trip delay experienced on a transport connection. The implementation should maintain, and continually update, an estimate of the round-trip delay for the TC. From this estimate, a value for the retransmission timer is calculated each time it is started. An example technique for maintaining the estimate and calculating the retransmission timer is described below. Further information on similar techniques may be found in the literature [Edge 84, Jain 85, Mill 83].

The value of the retransmission timer may be calculated according to the following formula:

$$t \longleftarrow kE + w$$

In this formula, E is the current estimate of the round-trip delay on the transport connection, w is the value of the acknowledgement time parameter received from the remote transport service provider during connection establishment, and k is some locally administered factor.

A value for k should be chosen to keep the retransmission timer sufficiently small such that lost TPDUs will be detected quickly, but not so small that false alarms are generated causing unnecessary retransmission.

The value of E may be calculated using an exponentially weighted average based upon regular sampling of the interval between transmitting a TPDU and receiving the corresponding acknowledgement. Samples are taken by recording the time of day when a TPDU requiring acknowledgement is transmitted and calculating the difference between this and the time of day when the corresponding acknowledgement is received. New samples are incorporated with the existing average according to the following formula.

$$E \longleftarrow \alpha E + (1 - \alpha)S$$

In this formula, S is the new sample and alpha is a parameter which can be set to some value between 0 and 1. The value chosen for alpha determines the relative weighting placed upon the current estimate and the new sample. A large value of alpha weights the old estimate more heavily causing it to respond only slowly to variations in the round-trip delay.

A small value weights the new sample more heavily causing a quick response to variations. (Note that setting alpha to 1 will effectively disable the algorithm and result in a constant value for E, being that of the initial seed.)

If alpha is set to $1-2^{-n}$ for some value of n, the update can be reduced to a subtract and shift as shown below.

$$E \longleftarrow E + 2^{-n} (S - E)$$

When sampling, if an AK TPDU is received which acknowledges multiple DT TPDUs, only a single sample should be taken being the round-trip delay experienced by the most recently transmitted DT TPDU. This attempts to minimize in the sample any delay caused by the remote transport service provider withholding AK TPDUs.

7.1.5 Keep-Alive Function

The Class 4 protocol detects a failed transport connection by use of an 'inactivity timer'. This timer is reset each time a TPDU is received on a connection. If the timer ever expires, the connection is terminated.

The Class 4 protocol maintains an idle connection by periodically transmitting an AK TPDU upon expiration of the 'window timer'. Thus, in a simple implementation, the interval of one transport entity's window timer must be less than that of its peer's inactivity timer, and vice versa. The following agreements permit communicating transport entities to maintain an idle connection without shared information about timer values.

- In accordance with ISO 8073, clause 12.2.3.9.a, all implementations must respond to the receipt of a duplicate AK TPDU by transmitting an AK TPDU containing the 'flow control confirmation' parameter.

- Implementations must always transmit duplicate AK TPDUs on expiration of the local window timer (see ISO 8073, clause 12.2.3.8.1). Receipt of this TPDU by the remote transport entity will cause it to respond with an AK TPDU containing the 'flow control confirmation' parameter. When this is received by the local transport entity, it will reset its inactivity timer. See figure 7.1.

- It is a local matter for an implementation to set the intervals of its timers to appropriate relative values. Specifically:

    - The window timer must be greater than the round-trip delay. See section 7.1.4.

    - The inactivity timer must be greater than two times the window timer; and should normally be an even greater multiple if the transport connection is to be resilient to the loss of an AK TPDU.

A duplicate AK TPDU (See Figure 7.1.) is one which contains the same values for YR-TU-NR, credit, and subsequence number as the previous AK TPDU transmitted. A duplicate AK TPDU does not acknowledge any new data, nor does it change the credit window.

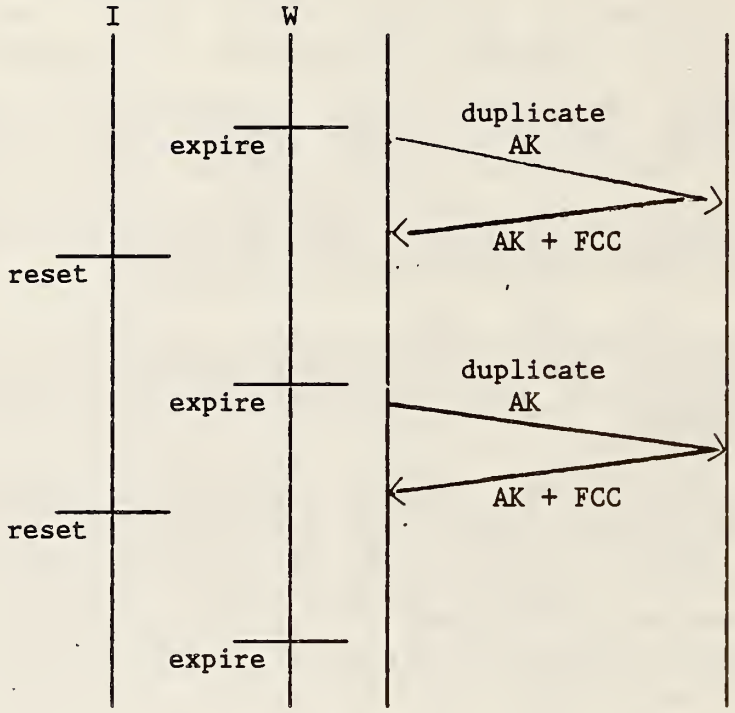

Fig. 7.1 AK exchange on idle connection

7.2 TRANSPORT CLASS 0

7.2.1 Transport Class

Transport class 0 over X.25 is mandatory (see X.400) for use in communicating with public MHS systems operating in accordance with the CCITT X.400 series recommendations. The purpose of the agreements concerning transport class 0 is to allow connection to these public services. Transport class 0 over X.25 can also be used in communicating between PRMDs, but it is agreed that transport class 4 and CLNP over all types of lower layer networks allows a larger range of interoperation and is recommended.

7.2.2 Protocol Interpretation

Transport class 0 is a relatively simple protocol providing little opportunity for conflicting interpretations. A few relevant agreements follow.

- The Disconnect Request (DR) TPDU shall be limited to the first seven octets - "LI" plus "fixed part".

- The Error (ER) TPDU may be used at any time and upon receipt requires that the recipient disconnect the network connection, and by extension the transport connection.

7.2.3 Rules for Negotiation

The ISO rules for negotiations will be used.

7.3 CONNECTIONLESS TRANPORT

Document ISO IS 8072/DAD1 is the Transport Service Definition covering Connectionless-mode Transmission. Document ISO DIS 8602 is the Protocol for providing the Connectionless-mode Transport service.

8. SESSION

Session services are defined to meet the needs of many applications. The Session service is defined in ISO 8326 (CCITT X.215) and the session protocol is defined in ISO 8327 (CCITT X.225). The general agreements about the use of session are documented below in section 8.1, followed by agreements that are related to specific applications.

8.1 GENERAL

The services of the Session kernel functional unit are used as specified in the standard.

Session Connection
Data Transfer
Orderly Release
Provider Abort
User Abort

Basic concatenation is required by the session protocol standard. Extended concatenation is not required and can be refused using the normal negotation mechanisms provided by the session protocol.

Session segmenting is not required and can be refused using the normal negotiation mechanisms of the session protocol.

Reuse of a transport connection is not required and can be refused using the normal negotiation mechanisms of the session protocol.

The use of transport expedited is as stated in the session protocol specification. That is, if transport expedited is available it must be used.

The maximum length of the reflect parameter values parameter in the S-P-Exception-Report is 1024 octets.

The user data parameter on S-CONNECT SPDU will allow unlimited length user data as specified in the proposed Session draft addendum. This because the combined P-CONNECT, A-ASSOCIATE, and F-INITIALIZE may exceed the existing 512 byte limit.

A mandatory functional unit is one that must be implemented by the service provider.

An optional functional unit is one which the service provider may implement, but irrespective of whether it is implememted or not, must recognize and respond to correct requests for its use.

8.2 SESSION REQUIREMENTS FOR FTAM

The Phase 2 FTAM requires the following functional units in addition to those specified in section 8.1.

Functional Units	Session Services
Duplex	- - - - - -

Note: Implementation of the Resynchronize functional unit is highly recommended, since the F-CANCEL service may be ineffective when mapped to S-DATA.

8.3 SESSION REQUIREMENTS FOR MESSAGE HANDLING

The MHS application requires the following functional units in addition to those specified in section 8.1.

Functional Units	Session Services
Exceptions	User Exception Reporting Provider Exception Reporting
Activity Management	Activity Start Activity Resume Activity End Activity Interrupt Activity Discard Please Tokens Give Tokens Give Control
Half-duplex	Give Tokens Please Tokens
Minor Synchronize	Minor Synchronization Point Give Tokens Please Tokens

Note: Restricted use is made by the RTS of the session services implied by functional units selected. Specifically,

- o No use is made of S-TOKEN-GIVE, and
- o S-PLEASE-TOKENS only asks for the data token.

The following additional points should be noted.

- o In S-CONNECT, the SynchronizationPointSerial Number should not be present.
- o Format of the SessionConnectionID is described in Version 3 of the X.400-Series Implementor's Guide.

9. SERVICE ACCESS POINTS AND SELECTORS

The following guidelines on the size of n-selectors apply to implementations based on these agreements and therefore to incoming connection requests only. Outgoing connection requests will support the full range of n-selector sizes.

9.1 UPPER LAYER AGREEMENTS

The following upper layer addressing agreements have been reached.

- The combination of NSAP address, TSAP selector, SSAP selector, PSAP selector and PSAP address must be unique to identify an application entity.

- It is implicitly agreed that the procedure followed for the assignment of NSAP addresses insures that they are globally unique.

- The assignment of TSAP, SSAP, and PSAP selectors is a local end system issue and the values are administered locally.

- SSAP selectors are encoded as a string of octets, the meaning of which is known only to the local system. The length of the string cannot exceed 16 octets.

- PSAP selectors are encoded as a string of octets, the meaning of which is known only to the local system. The length of the string cannot exceed 16 octets.

9.2 TRANSPORT CLASS 4 SERVICE ACCESS POINTS OR SELECTORS

The TSAP selector field in the CR and CC TPDUs shall be encoded as a variable length field and will be interpreted as an octet string. The length of the string cannot exceed 32 octets.

9.3 TRANSPORT CLASS 0 SERVICE ACCESS POINTS

For communicating with public MHS systems, Section 5 of X.410 specifies the use and format of TSAP identifiers.

10. ISO FILE TRANSFER & ACCESS MANAGEMENT PROTOCOL

10.0 INTRODUCTION

This section defines Implementors' Agreements based on the ISO File Transfer, Access, and Management (FTAM), as defined in ISO DIS 8571. This Draft International Standard has four parts. Part 1 of the DIS gives general concepts, Part 2 defines the Virtual File Store (VFS), Part 3 defines the File Service, and Part 4 the File Protocol.

FTAM depends on ISO definitions of ASN.1 (ISO DIS 8824 and 8825), the Presentation Service and Protocol (ISO DIS 8822 and 8823), and the Session Service (ISO 8326/CCITT X.215) and Session Protocol (ISO 8327/CCITT X.225), and Transport Class 4. FTAM Phase 2 also requires CASE Services (ISO DIS 8649/2 and Protocol (ISO DIS 8650/2). These services and protocols are defined architecturally in the OSI Reference Model (ISO 7498). This section presumes that the reader is familiar with these standards, and is of a technical level appropriate to implementing or testing them. This section provides detailed guidance for the implementor, and is not an FTAM tutorial.

The general agreements reached with respect to the ISO File Transfer, Access, and Management Protocol (FTAM) are:

> FTAM will be defined in at least two phases. The Phase 1 FTAM implementation specification (section 10.1) is based on the second ISO draft proposal, dated April 30, 1985[1], and the ISO draft proposals 8824 and 8825.
>
> The Phase 2 FTAM specification (section 10.2) is based on the Draft International Standard (DIS) and later will be based on the International Standard (IS). THERE IS NO BACKWARD COMPATIBILITY WITH NBS FTAM PHASE 1.

Backward compatibility is impossible, since Phase 1 uses Session services directly, while Phase 2 uses CASE and Presentation services. Furthermore, there are differences in Filestore, PDU Abstract Syntax, FADU Abstract Syntax, and Transfer Syntax. There also are differences in the Transparency mechanisms and service class negotiations.

Assuming that Phase 2 FTAM implementations will be based on the forthcoming IS, and that this IS or the CASE IS provides the ability to pass "user version" information, a mechanism exists for backward compatibility. It is the goal of these agreements to use the "user version" mechanism to provide at least one level of backward compatibility for all future NBS FTAM Phases, facilitating backward compatibility for future FTAM products.

---

[1] Part 1 is dated April 20, 1985; Part 2 dated April 29, 1985; and Parts 3 and 4 dated April 30, 1985.

10.1 PHASE 1 FTAM IMPLEMENTATION SPECIFICATION

10.1.1 Phase 1 FTAM Services

The subset of file transfer services that has been agreed to is:

F-INITIALIZE
F-SELECT
F-OPEN
F-READ, F-WRITE
F-DATA
F-DATA-END
F-TRANSFER-END
F-CLOSE
F-DESELECT
F-U-ABORT, F-P-ABORT
F-TERMINATE

Implementation of F-CANCEL is optional.

Both F-READ and F-WRITE will be implemented. At most one F-OPEN and one F-READ or F-WRITE is permitted per file selection, but more than one file may be selected sequentially over the lifetime of a connection. A Session connection is established at the beginning of the file activity and is terminated when the file transfer connection is released by an F-TERMINATE.

The limited management subset of services that has been agreed to is:

F-CREATE
F-DELETE
F-READ-ATTRIBUTE

Note that this subset is complete with respect to the ISO limited file management functional unit.

The <user correctable file service> and the <storageAttributeGroup> subset of the virtual filestore attribute group are to be implemented.

10.1.2 Phase 1 Attributes

The following attributes have been agreed upon.

10.1.2.1. File Attributes

Phase 1 FTAM implementations will negotiate the use of Storage file attributes. A value for the following attributes must be maintained.

1. FILENAME

The minimum range of <filename> values specified in DP8571 Part 2 Section 11 is supported (1-8 characters), with no maximum length or format restriction.

Any system that does not support extended <filename> characteristics would reject the F-SELECT or F-CREATE request of such a <filename>. Values of <filename> are to consist of upper-case letters (A-Z) and numbers <0-9>, and must begin with a letter.

2. ACCESS STRUCTURE TYPE

The value of <accessStructureType> type is <unstructured>. The <accessStructureType> attribute values <flat> and <hierarchical> are not used.

3. PRESENTATION CONTEXT NAME J
Two structures for <presentationContextName> have been approved.

VARCRLF: Text format. Each line is variable length and must be terminated by a CRLF pair. Maximal line length is 250 characters plus CRLF. Form feed is excluded. CR and LF cannot occur separately. The ISO 646 character set is to be used.

UNDEF: Octetstring encoding. No embedded structure is recognized.

4. CURRENT FILESIZE

The current filesize value conforms with the second ISO draft proposal.

5. REQUESTED ACCESS

The <Requested access> parameter may have <read>, <replace>, <read attribute>, and <delete file> attribute values.

In addition to the above attributes, implementations are encouraged to maintain the following values.

1. FUTURE FILESIZE

The <futureFilesize> parameter is a provider option, conforming to the second ISO draft proposal.

2. DATE AND TIME OF CREATION

The <dateAndTimeOfCreation> parameter is a provider option. The value conforms with the second ISO draft proposal; its resolution and accuracy are implementation dependent.

10.1.2.2 Activity Attributes

Phase 1 FTAM implementations negotiates the use of Storage activity attributes. Other attributes defined are:

1. CURRENT ACCESS STRUCTURE TYPE

The <current access structure type> has the <unstructured> attribute value.

2. CURRENT PRESENTATION CONTEXT

The <current presentation context> is the same as PRESENTATION CONTEXT, i.e., VARCRLF or UNDEF.

10.1.3 ISO Deviations and Selections

1. F-CANCEL (DP8571/3 8.1 Table 1)

Implementation of the F-CANCEL service for irrecoverable errors in the Read Functional Unit and Write Functional Unit is optional. An implementation that receives an F-CANCEL indication may issue an F-P-ABORT or F-U-ABORT.

2. Grouping Functional Unit (DP8571/3 8.2 1b)

There is no implementaiton of the Grouping Functional Unit. The concatenation constraint on establishing and releasing a <fileOpenRegime> is not supported.

3. F-INITIALIZE (DP8571/3 14.1.2)

Values have been chosen for these F-INITIALIZE parameters:

Parameter	Value
serviceType (DP8571/3 14.1.2.5)	userCorrectable
serviceClass (DP8571/3 14.1.2.6)	file transfer class
functionalUnits (DP8571/3 14.1.2.7)	{read,write, limitedFileManagement}
attributeGroups (DP8571/3 14.1.2.8)	storage
rollbackAvailability (DP8571/3 14.1.2.9)	no rollback
presentationContextName (DP8571/3 13.1.2.11)	defined in section 10.1.2 of this document

The Abstract Syntax for F-INITIALIZE is:

```
F-INITIALIZErequest ::= SEQUENCE{

        protocolId [0] INTEGER {isoFTAM (0)},
        versionNumber [1] IMPLICIT SEQUENCE{
             major INTEGER, minor INTEGER},
             --initially {major 0, minor 0}--
        serviceType [2] INTEGER{
```

```
            reliable (0), userCorrectable (1)}
        serviceClass [3] INTEGER  {transfer (0),
            access (1), management (2)},
        functionalUnits [4] BITSTRING{
            read (0), write (1), fileAccess (2),
            limitedFileManagement (3),
            enhancedFileManagement (4),
            grouping (5), recovery (6),
            restartDataTransfer (7)},
         attributeGroups [5] BITSTRING{
            storage (0), security (1)},
         rollbackAvailability [6] BOOLEAN DEFAULT FALSE,
         presentationContextNames [10] IMPLICIT
            SEQUENCE OF PresentationContextName OPTIONAL,
         identityOfInitiator [7] GraphicString OPTIONAL,
         CurrentAccount OPTIONAL,
         filestorePassword [8] OCTETSTRING OPTIONAL,
         checkpointWindow [9] INTEGER OPTIONAL}

F-INITIALIZEresponse ::= SEQUENCE{
        Diagnostic,
        protocolID [0] INTEGER {isoFTAM (0)},
        versionNumber [1] IMPLICIT SEQUENCE{
           major INTEGER, minor INTEGER},
           --initially {major 0, minor 0}--
        serviceType [2] INTEGER{
           reliable (0), userCorrectable (1)},
        serviceClass [3] INTEGER {transfer (0),
           access (1), management (2)},
        functionalUnits [4] BITSTRING{
           read (0), write (1), fileAccess (2),
           limitedFileManagement (3),
           enhancedFileManagement (4),
           grouping (5), recovery (6),
           restartDataTransfer (7)},
        attributeGroups [5] BITSTRING{
           storage (0), security (1)},
        rollbackAvailability [6] BOOLEAN DEFAULT FALSE,
        presentationContextNames [8] IMPLICIT
           SEQUENCE OF PresentationContextName OPTIONAL,
         checkpointWindow [7] INTEGER OPTIONAL}
```

If the <PresentationContextName> parameter is present, its value will establish the limits of the life of the FTAM association.

4. F-OPEN

The values of the <ProcessingMode> parameters chosen are <read> or <replace> (DP8571/3 17.1.2.2).

With FmOPEN, the <presentationContext> parameter must be present to indicate the context chosen for the transfer, since there is currently no Presentation

Layer implementation (DP8571/3 17.1.2.3).

5. F-DATA

(DP8571/3 24.3.) F-DATA is encoded as:

IDENTIFIER: context specific tag value [55]
Length: (Length of OCTETS)
Contents: (octets)

There is an explicit F-DATA PDU because of the direct FTAM/Session mapping. The ASN.1 definition of F-DATA is:

```
F-DATArequest ::= [55] IMPLICIT OCTETSTRING
```

6. ISO646String ASN.1 TYPE

The ASN.1 type <ISO646String> is used instead of ASN.1 type <GraphicString> in the abstract syntax. Wherever <GraphicString> is specified in the abstract syntax, the abstract syntax is modified by <ISO646String>.

7. Presentation Context

The <PresentationContext> attribute on the SELECT/CREATE request is restricted to only one <presentationContextName>.

<presentationContextName> parameters are encoded as:

```
PresentationContextName  ::= [Application 13]
                                 PrintableString
```

On F-OPEN Requests and Responses, the <presentationContextName> parameter is mandatory, not optional.

8. State Machine

Phase 1 FTAM products will use the state machine in the second ISO draft FTAM proposal, part 4, except where explicitly specified differently in these agreements.

10.1.4 Further Implementation Details

The following recommendations are not specified by the standard but have been agreed upon in order to ensure that different implementations work together smoothly.

1. FTAM Phase 1 Use of Session Service

This FTAM implementation is mapped directly to Session services and does not use CASE. The F-INITIALIZE Request is embedded in the S-CONNECT Request and the F-INITIALIZE Response is embedded in the S-CONNECT Response, instead of being sent as S-DATA request after the Session has been established.

If the F-INITIALIZE Response is a positive confirmation, that Response is mapped onto ACCEPT SPDU. Otherwise, it is mapped onto REFUSE SPDU.

F-U-ABORT and F-P-ABORT are mapped to S-DATA Requests. The receiver of an F-U-ABORT or an F-P-ABORT must issue an S-U-ABORT Request. This avoids S-RELEASE collison should both entries wish to abort simultaneously.

2. Parameter Parsing and Support

Implementations should be able to parse all valid second ISO draft proposal optional parameters if they are present in the PDU. Only those optional parameters specified in the agreements are required to be supported for request and response PDUs.

All second ISO draft proposal optional parameters identified in these agreements as mandatory must be supported. If this parameter is not present, its semantics are a local issue. Furthermore, the request should not be refused.

3. Error Handling and Diagnostics

Error handling and diagnostic action that is permitted by the standard is not restricted. Implementations may return a response with a negative diagnostic or issue an F-U-ABORT request.

In the FTAM second ISO draft proposal, the parameter <diagnostic> is defined as <ImplicitSequenceOfDiagnostics>. The order of the diagnostics in the sequence is arbitrary and has no significance.

4. Rollback

Specifying <No rollback> implies that, in case of failure, the status of the involved files is unpredictable. Implementors of receivers may choose to leave the partially transferred file as is, or they may cancel it.

However, in order to avoid dangling conditions, after a failure (i.e., after an F-U-ABORT or F-P-ABORT) it is recommended that files always be put in a status that does not prevent further access both from remote and local systems.

5. Concurrency

No concurrency rules have been adopted, since the file attributes governing them will not be supported. Therefore, each implementation may choose the degree of concurrency of the local files as a local matter. However, in order to minimize possible errors, the following implementation rules are recommended.

a. A file may be involved in several transfers simultaneously only if accessed in reading mode.

b. If a file is involved in a transfer in writing mode, any other request for access to that file (either for Read or Write) should be rejected.

c. A file cannot be modified by local users while it is involved in a transfer operation, either in F-READ or F-WRITE. (As a practical matter, this may be very difficult to implement, regardless of the protection mechanisms provided by the local operating system.)

6. ASN.1

ISO ASN.1 syntax is used for encoding PDU headers. ASN.1 encoding using the indefinite length style is not supported.

7. Maximum PDU Length

The maximum PDU length is 1024 octets.

8. Response to F-READ-ATTRIBUTE

If an F-READ-ATTRIBUTE request specifies an NBS optional attribute that is not supported by an implementation's virtual filestore, then that attribute will not be returned in the <read attribute> response. It is recommended that an implementation return an appropriate diagnostic in this situation (e.g., 4000, "attribute non-existent").

9. Corrupted S-CONNECT Indication User Data

If a Responder receives an S-CONNECT indication, and the user data carried on that indication are "corrupted" (i.e., decoding the PCI results in an irrecoverable error), then

a. If the user data can be identified as an F-INITIALIZE request, the Responder should respond with an F-INITIALIZE response (-) or F-P-ABORT with diagnostic conveying an irrecoverable error. This is to be carried on an S-CONNECT response (-), i.e., rejecting the connection.

   The Responder should further clarify the error in the <further details> field of the <Diagnostic> PDU.

   Parameters on the F-INITIALIZE response should be reflected where appropriate; where this is not possible, default values should be chosen by the Responder where mandatory parameters are required and cannot be reflected.

b. If the user data cannot be identified as an F-INITIALIZE request, the Responder should respond with an S-U-ABORT and a reason code appropriate to the error.

10.2 PHASE 2 FTAM IMPLEMENTATION SPECIFICATION

10.2.1 Assumptions

1. These agreements are based on the ISO 8571 DIS version of FTAM. When the IS text is approved following the close of DIS ballots, the agreements will be modified as necessary to meet the IS specifications.

2. FTAM protocol machines must be able to parse and process up to 7K octets of File PCI and FTAM user data (including grouped FPDUs) as they would be encoded with the ASN.1 Basic Encoding Rules. It is recommended, however, that Presentation user data not be restricted in size.

3. In order to maximize interoperability, it is important that the implementations of FTAM service providers do not unnecessarily restrict the service user's ability to generate arbitrary file service requests. Otherwise, they may not be able to work with FTAM Responders whose operation is constrained by their mapping of the FTAM virtual filestore to their local filestore. For example, error procedures should only be invoked when an error actually occurs, not at the point of the specification of options which might result in a error.

4. Implementations must be able to parse all valid DIS optional parameters if they are present in the PDU. Only those optional parameters specified as mandatory in these agreements are required to be supported for Request and Response PDUs. If these parameters are not present, a default value is assigned locally. A responder should not refuse a request solely because a parameter that is optional in the FTAM standard, but is mandatory in these agreements, is not present.

5. Consideration of any standarized service interface is not covered by these agreements.

10.2.2 Presentation Agreements

The following Abstract Syntaxes are supported.

ISO 8571-FTAM (including ISO 8571-FADU)
ISO 8650-ACSE1
NBS-AS1
NBS-AS2
NBS-AS3

If the presentation context management functional unit is available, it is possible to use P-ALTER-CONTEXT to negotiate the use of an abstract syntax.

See section 11.2 for definition of the <object Identifier> for <ISO 8571-FTAM> and <ISO 8650-ACSE1>.

10.2.3 FTAM Service Type Agreements

The Reliable File Service level (excluding Recovery and RestartDataTransfer functional units) is to be implemented. Implementing the error recovery protocol machine is not required.

10.2.4 Service Class Agreements

Implementation of the following service classes is defined.

- o File Transfer
- o File Access
- o File Management
- o File Transfer and Management
- o Unconstrained

10.2.5 Functional Unit Agreements

Implementation of the following functional units is defined.

- o Kernel
- o Read
- o Write
- o File Access
- o Limited File Management
- o Enhanced File Management
- o Grouping

10.2.6 File Attribute Agreements

Implementation of the Kernel Group of file attributes is defined. If the optional Storage Group and Security Group are implemented, aspects of their implementation are defined. Implementation of the Private Group is not specified.

Responses to an attribute value request shall always include one of the following:

1. An actual file attribute value.

2. A value indicating that the attribute value is not available at this time. Optionally, a diagnostic may be provided indicating that the attribute is not supported.

The <Contents Type> attribute is limited to the <DocumentTypeName> form.

Mandatory Group

A value for file name and contents type will always be available. Only the Kernel Group of attributes is required.

A minimum range is required for <filename> values (1-8 characters). No maximum length or format restrictions apply. A system that does not support multi-component <filename> values or extended <filename> characteristics may reject a request involving such a <filename>. All systems must be able to interpret a <filename> with single component values. Requests using single component <filename> values are responded to using single component <filename> values. Responses to requests involving <filename> values having two or more components are not defined here but may be interpreted via bilateral or other external agreements. Use of <filename> values with multiple components is discouraged.

Optional Groups

If the optional Storage Group of file attributes is implemented, an actual value must be available for the <PermittedActions> attribute.

If the optional Security Group of file attributes is implemented, an actual value must be available for the <AccessControl> attribute.

Implementation of the <Private> Group is not specified.

10.2.7 Document Type Agreements

These document types are defined.

NBS-1 UNDEF
NBS-2 VARCRLF
NBS-3 8859VARCRLF
NBS-4 TEXT
NBS-5 8859TEXT
NBS-6 SEQUENTIAL
NBS-7 RANDOM
NBS-8 INDEXED
NBS-9 FILE DIRECTORY

Part of our ongoing work is to define, discuss, and propose other file types. Detailed document type definitions are given in Appendix D.

Document type Names:

```
DTN     ::= DTName | DTName params
DTName  ::= OBJECT IDENTIFIER
params  ::= param | :param params
param   ::= PrimType | PrimType, param

PrimType := INT  -  <n*>
          | BIT  -  <n2>
          | IA5  -  <n1>
          | 8859 -  <n1>
          | OCT  -  <n1>
          | UTC
          | GEN
```

| NULL
| BOOL
| FLOAT - <n3, n4>

<n1> - Maximum number of characters/octets in string.

<n2> - Number of bits in string (i.e., nonvarying).

<n3> - The minimum number of bits required to be maintained in the mantissa for relative precision.

<n4> - Number of bits required to represent the largest unbiased integer in 2's complement.

<n*> - Number of octets required to represent, in 2's complement format, the largest integer to be passed.

The primitive data types and minimal size range that an implementation must accept are given in the table 10.1.

Tbl. 10.1 FTAM primitive data types

PRIMITIVE DATA TYPE		REPRESENTATION IN PARAMETER	MINIMUM RANGE (OCTETS)
ASN.1	INTEGER	INT <N*>	(1 - 2)
ASN.1	Bit String	BIT <N2>	(0 - 1)
ASN.1	IA5String	IA5 <N1>	(0 - 134)
NBS-AS1	8859String	8859 <N1>	(0 - 134)
ASN.1	OCTETSTRING	OCT <N1>	(0 - 512)
ASN.1	BOOLEAN	BOOL	
ASN.1	NULL	NULL	
ASN.1	Generalized Time	GEN	
ASN.1	Universal Time	UTC	
NBS-AS1	Floating Point	FLOAT <N3,N4>	

Note: The primitive data types and their maximum ranges for a specific file as described by the parameters above are maintained in the contents type file attribute. The contents type file attribute value is established at the file's creation and cannot be changed via FTAM for the life of the file. This implies that the data element types and ranges and data unit formats are fixed for all accessors of that file as long as the file exists.

An <object identifier> is a string of integers; FTAM <document type> parameterization is achieved by exploiting that structure.

The final registration authority entity is followed by a <data unit> description. The <data unit> description is a series of data element descriptions. Each <data element> description is an integer identical to the ASN.1 type code, followed by any required parameter values, as integers.

The following values correspond to the NBS primitives not found in ASN.1 and the integer value for ":" (separator).

```
FLOAT - 127
 8859 - 126
    :  - 125
```

Following is an example of how an indexed file with three fields (2-byte integer, 4-byte integer and 10-character IA5String), with the key being the second field, would be encoded:

DTN: INT(2), INT(4), IA5(10): INT(4)

This is derived from the grammar for document type names give above. It would be represented in the encoding of the Object Identifier as:

(encoding for base document type name) 125 22 2 4 22 10 125 2 4

This is derived by applying the encoding rules given above.

The following notation allows the transfer of floating point numbers, while retaining their meaning, as defined by existing standards IEC 559 and IEEE 754.

```
FloatingPointNumber  ::= [PRIVATE 0]   CHOICE{
        finite       [0]   IMPLICIT SEQUENCE{
                Sign,
                mantissa BIT STRING,
                exponent    INTEGER},
        infinity          [1] IMPLICIT Sign,
        signallingNaN     [2] IMPLICIT NaN,
        quiteNaN          [3] IMPLICIT NaN,
        zero              [4] IMPLICIT NULL}
Sign                      ::=       INTEGER{
        positive          (0),
        negative          (1)}
NaN                       ::=       INTEGER
```

Notes:
1. The mantissa is a number in the range $(1/2 \leq \text{mantissa} < 1)$.
2. The value is equal to mantissa * 2^{exponent}.
3. The first bit in the mantissa is most significant.
4. See IEEE 754 for definitions of terminology, such as NaN.

10.2.7.1 Character Sets

IA5 and 8859/1 character sets have been specified, and are to be implemented as described below.

1. IA5

The IA5 character set leaves 2 options and 10 characters unspecified. The definitions used are:

2/3	#
2/4	$
4/0	@
5/11	[
5/12	\
5/13	]
5/14	^
6/0	'
7/11	{
7/12	¦
7/13	}
7/14	~

Note: This is exactly the International Reference Version (IRV) specified in the IA5 standard except that the code 2/4 has the graphic rendition "$" instead of the IRV-specified value of the International Currency Symbol.

Control characters should be handled as follows.

a. Semantics of format effectors will be preserved.

b. Transmission control characters, device control characters, information separators, and "other" control characters is simply preserved via their codes.

c. Code extension shall not be used. If it is received, the code extension characters should be preserved, as in the case of the transmission control characters, and any printing characters that form later parts of escape sequences is interpreted as stand alone characters.

d. Combined horizontal and vertical movement of cursor positioning is not be preserved.

2. 8859/1

The Latin Alphabet No. 1 is used to specify the printable rendition of C0 and C1. C0 control characters and their associated rules are taken from the IA5 definition. C1 control characters simply have their codes preserved across a transfer.

10.2.7.2 Document Type Negotiation Rules

1. Connection Establishment

In Connection Establishment, <DocumentTypeName> values are negotiated by subset of the proposed base set of <DocumentTypeName> values, without regard to DU syntax parameter(s) that may be supplied on any <DocumentTypeName> that requires a DU syntax specification.

2. File Creation

An F-CREATE Request FPDU must contain a <DocumentTypeName> value from the negotiated set of base <DocumentTypeName> values. If the <DocumentTypeName> used requires DU syntax parameters, then these parameters must be supplied. If the <DocumentTypeName> used requires DU syntax parameters and none are provided on the F-CREATE Request, then the F-CREATE Request FPDU must be rejected.

3. File Opening

It is recommended that the F-OPEN Request use the <DocumentTypeName> form (with appropriate DU syntax parameters) when proposing a <Contents Type>, in preference to the <Constraint Set Name> and <Abstract Syntax Name> form.

Similarly, an F-OPEN response should use the <DocumentTypeName> option (with appropriate DU syntax parameters) in the <Contents Type> field. This allows the receiving entity to use the <DocumentTypeName> attributed to the file instead of receiving a <Constraint Set Name> and <Abstract Syntax Name> pair, which does not reflect the file information contained in the NBS document types.

Note: An F-OPEN response without a <DocumentTypeName> (but carrying the <Constraint Set Name> and <Abstract Syntax Name> form) may cause the initiator to issue an F-CLOSE request.

10.2.7.3 Relationship Between DUs, DEs and Document Types

"Abstract Syntax" is used to refer to the syntactic information which is architecturally passed between the Application and Presentation Layers. The Abstract Syntax defines Data Element (DE) types which are not necessarily ASN.1 primitive types. A Data Element (DE) is the smallest piece of data whose identity is necessarily preserved by the Presentation Service. Data types may be made up of other data types. Data Elements are not defined in terms of other Data Elements.

A <data unit> (DU) is a sequence of one or more data elements. Architecturally, entire, single DEs are passed into and out of the application process. In a real implementation, DUs may be passed.

To maintain DU boundaries during transfer, file structuring information must be passed (ISO 8571-FADU DEFINITIONS, FTAM Part 2 section 5.3.2). A data element is referred to as a File Contents Data Element in ISO 8571-FADU DEFINITIONS.

Document types refer to aspects of local processing and storage. They describe:

- o structural relationship between DUs,
- o structure of DUs, called DU syntax, and
- o data element types found in the file.

Because document types pertain to local processing and storage, the DU syntax makes assertions about the syntax and the size of DUs (records) in storage. Parameters on the document types provide this information about the syntax and size of the DUs.

10.2.8 F-CANCEL ACTION

When an F-CANCEL is sent or received, the following occurs:

- o no more data is sent,
- o <checkPointNumbers> are removed, and
- o state of the file is implementation dependent.

10.2.9 Diagnostic Agreements

1. A <diagnostic> parameter is mandatory only when the Action Result or State Result is not zero. (The nature of these agreements is to provide <diagnostic> information when any result parameter is not <success>.)

2. General catch-all diagnostic action is discouraged.

3. A <furtherDetails> subfield is mandatory. Use of octet string is discouraged.

4. Use of F-P-ABORT for other than protocol errors and catastrophic situations is discouraged.

5. When returning an error status in a file management related diagnostic (i.e., F-READ-ATTRIBUTEresponse or F-CHANGE-ATTRIBUTEresponse), identify the erroneous attribute by using the first two characters of <further-details> to hold a 2-digit number (encoded in IA5String) from the F-READ-ATTRIBUTErequest attributes abstract syntax definition (ISO/DIS 8571/4 section 20-4):

00	Filename
01	Contents-Type
02	Storage Account
03	Date and Time of Creation
04	Date and Time of Last Modification
05	Date and Time of Last Read Access
06	Date and Time of Last Attribute Modification
07	Identity of Creator
08	Identity of Last Modifier
09	Identity of Last Reader
10	Identity of Last Attribute Modifier
11	File Availability
12	Permitted Actions
13	Filesize
14	Future Filesize
15	Access Control
16	Encryption Name
17	Legal Qualifications
18	Private Use

6. The set of File Management <diagnostics>, found in Table 44 of ISO 8571/3 Annex A, must be maintained.

7. The <diagnostic> parameter values defined in FTAM (8571/3 Annex A) are partitioned into sets that apply to:

   a. general FTAM <diagnostics> (all but identification = 1 are recommended against),
   b. Protocol and supporting services,
   c. the <FTAM Regime>,
   d. the <File Selection Regime>,
   e. the <File Open Regime>,
   f. the <Data Transfer Regime>.

Each of those sets is further partitioned into <diagnostics> applicable to each parameter of the corresponding service elements.

In the case where a specific parameter can in no way be accomodated then the request fails and a <diagnostic> indicating one such parameter should be

returned by the responder. In the case where a negotiable parameter cannot be accomodated with exactly the value requested but is negotiated to a different value (as defined in section 10.2.13) then the request formally succeeds but informative <diagnostics> indicating those parameters negotiated should be returned.

10.2.10 Concurrency

The <concurrency control> used by default on the file selection and file open regime for the first file accessor of a file is:

read	shared
insert	exclusive
replace	exclusive
extend	exclusive
erase	exclusive
rattr	shared
cattr	exclusive
del file	exclusive

For subsequent file accessors, the <requestedAccess> and <processingMode> service parameters are checked against this, and access given only if the request is for operations that are shared.

10.2.11 Requested Access

The <RequestedAccess> parameter on <F-SELECT> or <F-CREATE> is used to specify the actions which the initiator may perform during the file selection. The value of the <RequestedAccess> parameter is compared by the responder to the <AccessControl> and <PermittedActions> file attributes and concurrency controls (including those requested by the initiator) currently in place on the file. If the value of the <RequestedAccess> parameter is not consistent with either <AccessControl>, <PermittedActions>, or concurrency controls in place, then the <F-SELECT> or <F-CREATE> must be rejected.

<RequestedAccess> is consistent with <AccessControl> if, for each action requested, that action either requires no password, or the required password has been specified on the <F-SELECT> or <F-CREATE> request.

<RequestedAccess> is consistent with <PermittedActions> i,f for each action requested, that action is allowed by the <PermittedActions> file attribute.

<RequestedAccess> is consistent with <ConcurrencyControl> requested on the <F-SELECT> or <F-CREATE> if, for each action requested, that action has not been specified as <not required> or <not allowed> in the <ConcurrencyControl> parameter.

<RequestedAccess> is consistent with concurrency controls in place on the file if for each action requested no other accessor of the file has set the concurrency control for that action to either <exclusive> or <not allowed>.

10.2.12 Security

10.2.12.1 Optional Password Support

Users may provide values for <InitiatorIdentity> and <FilestorePassword>. Password support in FTAM is not required. If this information is provided, it will be sent to the Responder on the F-INITIALIZE.

The syntax of <InitiatorIdentity> and <FilestorePassword> is system-dependent. <InitiatorIdentity> and <FilestorePassword> will represent 'account' information on the local system, which may be different from the <account> parameter.

10.2.12.2 Access Passwords

Users may provide <accessPasswords>. If the information is provided, the passwords will be sent to the Responder in the <accessPasswords> parameter.

10.2.12.3 Anonymous User Convention

A commonly defined "anonymous user" convention is to be provided for all systems that choose to support this capability. The access available to that user is locally determined. The <InitiatorIdentity> value to be used is ANON, encoded as an <IA5String>. Any password should succeed.

10.2.12.4 Implementation Responsibilities

It is the responsibility of each local system to provide security for its own real filestore. Encryption of passwords will not be done by FTAM.

A user of the file service must be known by the Responder. "Known" is defined by the local Filestore, and is dependent on the level of security provided by the local Filestore.

10.2.13 Negotiation

The guidelines for negotiation that have been agreed upon are outlined in table 10.2.

Tbl. 10.2 FTAM negotiation rules

Service or Parameter	Depends on or may be negotiated down by:
F-INITIALIZE	
Req.Pres.ContextMgmt	Success or failure.
Req.Func. Unit	Negotiated by subset (as per DIS 8571/3 section 10.3). (Affects session functional units.)
Req.Attr. Groups	Negotiated by subset.
Req.Comm.Quality of services	Reference session.
Req.ContentTypeList	Negotiated by subset.
F-SELECT	
Attributes	Only by <filename>. N.B. The <filename> on response and confirm must be that of an existing virtual file.
Requested Access	Negotiated by subset (in case of complete or partial success), must be consistent with Functional Units negotiated, access control attribute, and permitted actions attribute.
F-CREATE	Consistent with Functional Units.
Initial attributes	1. The attributes returned are within the subset negotiated at initialization. 2. The individual attribute values returned must be consistent with negotiation/ranges for that attribute 3. The Responder returns values for all attributes which differ from the actual request.
Requested Access	As in F-SELECT.
F-DELETE	Consistent with Functional Units.
F-READ-ATTR	Consistent with Functional Units, service class, and requested access.
F-CHANGE-ATTR	As for F-READ-ATTRIBUTE.

(Continued on next page.)

Tbl. 10.2 FTAM negotiation rules, continued

Attributes	If any attribute cannot be successfully changed, then an error more severe than warning should be returned and no attribute should be changed.
F-OPEN	
Processing Mode	Not Negotiated. Must be consistent with Functional Unit and Requested Access negotiated, with the permitted actions attribute, and with the contents type name.
Contents Type	As defined in the DIS.
Concurrency Control	More restrictive than the concurrency control of F-SELECT; consistent with the concurrency control of other users.
F-BEGIN-GROUP	Consistent with Functional Units and F-END-GROUP service class.
F-LOCATE	Consistent with Functional Units, F-ERASE, requested access (and therefore with permitted actions) Service Class and Processing Mode.
F-READ F-WRITE	Functional Units, Service Class and number of bulk data transfers, Requested Access and Processing Mode.
F-DATA/F-DATA-END F-CANCEL F-TRANSFER-END	Functional Units and Service Class.

10.2.14 Conformance

This section gives the minimal criteria to be satisfied by implementations of FTAM to be conformant to these agreements.

Conformance to these agreements is stated in terms of the different roles

occupied by FTAM implementations. The interoperability of certain configurations of these roles motivates this approach. Interoperable configurations of these roles is given in section 10.2.14.1

10.2.14.1 Interoperable Configurations

Any implementation conforming to this specification must be able to act in at least one of the following role combinations:

1. initiator and receiver,

2. initiator and sender,

3. responder and sender, or

4. responder and receiver.

Minimal implementations of combination 1 will interoperate with minimal implementations of combination 3. Minimal implementations of combination 2 will interoperate with minimal implementations of combination 4.

Any implementations of roles 1 and 3 will be able to interoperate at the intersection of their capabilities (which will be at least the minimal capabilities described in sections 10.2.14.3 to 10.2.14.8). Any implementations of roles 2 and 4 will be able to interoperate at the intersection of their capabilities (which will be at least the minimal capabilities described in sections 10.2.14.3 to 10.2.14.8).

These role combinations and interoperability are shown in the table below.

Tbl. 10.3 Interoperable configurations

		Initiator		Responder	
		sender	receiver	sender	receiver
Initiator	sender				x
	receiver			x	
Responder	sender		x		
	receiver	x			

10.2.14.2 Relationship to ISO 8571--The FTAM Standard

Any implementation in conformance to ISO 8571 (as defined in ISO 8571/4 section 21 (Conformance)), in addition to the implementation of the minimal protocols and roles enumerated in sections 10.2.14.3 to 10.2.14.8, is considered to be in conforance with these agreements. Any implementation

violating any of the conformance statements in ISO 8571/4 is considered to be in violation of these agreements.

10.2.14.3 Requirements for Document Type Support

The document type NBS-1 shall be supported for purposes of transfer and storage. The details regarding support for NBS-1 in the FTAM dialogue are given in sections 10.2.14.6 and 10.2.14.7.

Support of document types other than NBS-1 (including document types defined elsewhere in these agreements or registered by authorities other than the NBS) are not required by these agreements. However, for the support for any document type these agreements require that the mechanisms for referencing those document types in the protocol be consistent with the protocol in both state and encoding. Support for document types described in these agreements also entails support for :

- o the semantics given in their description,
- o the preferred transfer syntax (via the designated transfer syntax name and the name "{ISO standard 8825}," and
- o the transfer of that document type under access context US (unstructured).

Support for other document types is not required by these agreements.

10.2.14.4 Initiators

Every implementation of an FTAM initiator shall support:

- o the kernel protocol and its mandatory parameters with minimum ranges [Minimum required ranges are specified in section 10.2.14.8.],
- o the grouping protocol and the threshold parameter with a value of 2 for use in the file transfer class,
- o at least one of the read or write protocols [Specific conformance for reading and writing is defined in sections 10.2.14.6 and 10.2.14.7.],

and support the applicable procedures defined in ISO 8571/4 sections 8.1 (FTAM regime establishment), 8.2 (FTAM regime termination), 8.3 (File selection), 8.4 (File deselection), 8.9 (File open), 8.10 (File close), 8.11 (Begin group) and 8.12 (End group), and 10 (File general actions). To support the above protocols and procedures the implementation shall be able to:

- o request the kernel, grouping and at least one of the read or write functional units,

- request the <reliable file service> (but not necessarily any error control procedures) with the "service level" parameter,

- request the file transfer class with the "service class" parameter,

- request optional functional units consistently from those defined for the file transfer service class,

- request the document type NBS-1 using the "document type name" form of the contents type parameter, and

- request a "communication quality of service" consistent with the transport definition in these agreements

as part of the filestore initialization procedures in ISO 8571/4 section 8.1, FTAM regime establishment.

Initiators must be able to operate under all circumstances if the above minimum values are successfully negotiated and returned on an F-INITIALIZEresponse PDU. Initiators must be able to operate with any downward negotiation of requested parameter values as described in section 10.2.13.

Should the supporting services break down, such that FTAM communication is impossible, the FTAM protocol machine shall notify the user with an <F-P-ABORT indication> and <diagnostic> with identifier 1011. Any known "further details" are recommended.

10.2.14.5 Responders

Every implementation of an FTAM responder shall support:

- the kernel protocol and its mandatory parameters with minimum ranges [Minimum required ranges are specified in section 10.2.14.8.],

- the grouping protocol and the threshold parameter with a value of 2 for use in the file transfer class,

- at least one of the read or write protocols [Specific conformance for reading and writing is defined in sections 10.2.14.6 and 10.2.14.7.],

and support the applicable procedures, defined in ISO 8571/4 sections 9.1 (FTAM regime establishment), 9.2 (FTAM regime termination), 9.3 (File selection), 9.4 (File deselection), 9.9 (File open), 9.10 (File close), 9.11 (Begin group) and 9.12 (End group), and 10 (File general actions). To support the above protocols and procedures the implementation shall be able to:

- accept requests for the kernel, grouping and at least one of the read or write functional units,

- o accept requests the <Reliable File Service> (but not necessarily any error control procedures) with the "service level" parameter,

- o accept requests for the file transfer class with the "service class" parameter,

- o accept requests for optional functional units consistently from those defined for the file transfer service class and consistent with its supported roles as specified in section 10.2.13.1,

- o request the document type NBS-1 using the "document type name" form of the contents type parameter, and

- o accept requests for a "communication quality of service" consistent with the transport definition in these agreements

as part of the filestore initialization procedures in ISO 8571/4 section 9.1, FTAM regime establishment.

Responders must be able to operate under all circumstances if the above minimum values are requested on an F-INITIALIZErequest PDU. Responders must not negotiate upward in the sense described in section 10.2.13.

Each responder shall support, for purposes of both communication and processing, the kernel and storage groups of attributes. A value shall always be available for the kernel attributes. (For the storage attributes a value of "no value available" may be the only applicable value.)

Responders must complete each action requested and supported in a manner consistent with its description in ISO 8571/2 sections 6 (Actions on complete files) and 7 (Actions for file access), and must interpret each supported attribute in a manner consistent with its definition in ISO 8571/2 section 8 (File attributes).

Under circumstances where actions cannot be carried out either as requested or consistently with ISO 8571/2 sections 6 (Actions on complete files) and 7 (Actions for file access), the responder must return at least one diagnostic indicating:

- o if the failure was due to either a protocol or filestore failure, and then;

  -- precisely which action failed,
  -- at least one of the parameters that could not be accommodated with the diagnostic type indicating at least the degree of failure, as given by the action and state result parameters; or

- o that the failure was due to unforeseen system shutdown.

Should the supporting services break down, such that FTAM communication is impossible, the FTAM protocol machine shall notify the user with an <F-P-

ABORT indication> and <diagnostic> with identifier 1011. Any known "further details" are recommended.

10.2.14.6 Senders

Every implementation of an FTAM sender shall support the read functional unit as responder or the write functional unit as initiator, and support the applicable procedures defined in ISO 8571/4 sections 11 (State of the bulk data transfer activity), 12 (Bulk data transfer protocol data units), 15 (Bulk data transfer sending entity actions), 17.1 (Discarding), and 17.2 (Cancel).

To support those procedures the implementation shall be able to send files of the NBS document type NBS-1 (UNDEF) and shall be able to send them as user data in PPDUs in blocks of no more than 7168 octets.

10.2.14.6.1 Initiator Senders

Every implementation of an FTAM sender which is also an FTAM initiator shall support:

- the write functional unit and protocol, and
- for the document type NBS-1 the following bulk data transfer specification parameter:

FADU operation	replace
FADU identity	first
Access context	US

and support the applicable procedures, defined in ISO 8571/4 section 13 (Bulk data transfer initiating entity actions).

10.2.14.6.2 Responder Senders

Every implementation of an FTAM sender which is also an FTAM responder shall support:

- the read functional unit and protocol, and
- for the document type NBS-1 the following bulk data transfer specification parameter:

FADU identity	first
Access context	US

and support the applicable procedures, defined in ISO 8571/4 section 14 (Bulk data transfer responding entity actions).

10.2.14.7 Receivers

Every implementaton of an FTAM receiver shall support the read functional unit as initiator or the write functional unit as responder, and support the

applicable procedures, defined in ISO 8571/4 sections 11 (State of the bulk data transfer activity), 12 (Bulk data transfer protocol data units), 16 (Bulk data transfer receiving entity actions), 17.1 (Discarding), and 17.2 (Cancel).

To support those procedures the implementation shall be able to receive files of the NBS document type NBS-1 (UNDEF) and shall be able to receive them as user data in PPDUs in blocks of at least than 7168 octets.

10.2.14.7.1 Initiator Receivers

Every implementation of an FTAM receiver which is also an FTAM initiator shall support:

- o the read functional unit and protocol, and
- o for the document type NBS-1 the following bulk data transfer specification parameter:

FADU identity	first
Access context	US

and support the applicable procedures, defined in ISO 8571/4 section 13 (Bulk data transfer initiating entity actions).

10.2.14.7.2 Responder Receivers

Every implementation of an FTAM receiver which is also an FTAM responder shall support:

- o the write functional unit and protocol, and
- o for the document type NBS-1 the following bulk data transfer specification parameter:

FADU operation	replace
FADU identity	first
Access context	US

and support the applicable procedures, defined in ISO 8571/4 section 14 (Bulk data transfer responding entity actions).

10.2.14.8 Minimum Ranges

Any implementation of any conformant FTAM configuration shall be able to receive and meaningfully process all mandatory parameters for all functional units supported as well as the diagnostic parameter within at least the minimum ranges of values given in table 10.4. (A conforming implementation may support a broader range of values for any parameter.)

Tbl. 10.4 Required minimal parameter support

Parameter	Minimum Range
diagnostic	Values as specified in ISO 8571/3 Annex A (Diagnostic parameter values) tables 42, 43 and 45 which correspond directly to mandatory parameters.
action result	All values.
state result	All values.
F_INITIALIZE	
functional units[1]	"read" (for initiator/receivers and responder/senders) or "write" (for initiator/senders and responder/receivers).
presentation context management[2]	"Not required."
all others	As specified in sections 10.2.14.4 and 10.2.14.5 above.
F_SELECT	
attributes	Only filename is used with a minimum supportable length of 8 characters. Any other attribute supported for other services must have minimum supported lengths as in ISO 8571/2 section 11 (Minimum attribute ranges) table 2.
requested access	"read" for initiator receivers "read" for responder senders "read" for initiator senders "read" for responder receivers
F_OPEN	
processing mode	"read" for initiator receivers "read" for responder senders "replace" for initiator senders "replace" for responder receivers
content type	"NBS-1"

(Continued on next page.)

Tbl. 10.4 Required minimal parameter support, continued

Parameter		Minimum Range
F_READ F_WRITE		
	FADU operation	"read" for initiator receivers "read" for responder senders "read" for initiator senders "replace" for responder receivers
	FADU identity	"first"
	access context	"US"
F_BEGIN_GROUP		
	threshold[3]	For file transfer (a minimal required function)2.

---

1 The parameters, functional units, and presentation context management are not ordered, so "minimum value" cannot be formally defined. The above values are those required for conformance to these agreements but no value conformant to ISO 8571 for use in other applications is regarded to be in violation of these agreements.

2. Other functional units (and service classes) for defined implementations may also be valid provided that they are implemented in accordance with these agreements, specifically section 10.2.14.8.

3 Every implementation must support the threshold value 2 to provide the basic required function of file transfer; any other value in other applications is acceptable.

For any other supported parameters, minimum ranges are taken from the minimum ranges for the attribute corresponding to each as in ISO 8571/2 table 2.

10.2.14.9 Meaning for Support of Options Defined in These Agreements

This section describes requirements and options for service classes defined by these agreements, as well as specific document types, attributes and parameters and their ranges. General recommendations in accordance with DIS 8571/4 section 21.1 are given also; those definitions apply to any defined options.

10.2.14.9.1 Service Classes

The following service classes are defined individually for implementations. Note that no defined implementation is precluded from supporting more than one service class.

- o File access
- o File management
- o Unconstrained

Support of a service class requires adherence to: 1. its definition in DIS 8571/3 section 8 and any related procedures in DIS 8571/4 sections 8-17, 2. requirements given in section 10.2.1-10.2.14 of these agreements, and 3. requirements for parameter and attribute support as defined in section 10.2.14.8.

10.2.14.9.2 General Requirements for Implementations Defined in Section 10.2.14.10

- o Implementations will support the Reliable Service level.

- o Implementations will be able to act both as initiators and responders.

- o Implementations that support either the limited file management or both limited file management and enhanced file management must support both the Storage and Security attribute groups.

- o Implementations must support diagnostics as described in section 10.2.9 of these agreements.

- 0 Implementations that support the file access service class will support the hierarchical file model and support an arc length greater than one.

10.2.14.9.3 Recommended Use of Lower Layer Services

- o Implementations will, additionally, support the mapping of the F-CANCEL PDU on P-RESYNCHRONIZE.

- o Support for the Presentation Context Management functional unit is not required.

- o Implementations will support the Session, Presentation, and ACSE requirements as stated in sections 8, 11, and 12.

10.2.14.9.4 Document Type Requirements for Implementations Defined in Section 10.2.14.10

It is recommended that implementations conformant to these agreements also implement the following document types with the caveats and procedures given. Those document types are defined in Appendix D of these agreements.

- o NBS-2

Caveat: NBS-2 is included only to allow compatibility with file systems storing Phase 1 files.

- o NBS-4
- o NBSm6
- o NBS-7

  Note: Support of this document type entails the naming of FADUs by their position in preorder traversal. NBS-7 applies only to file access.

  Caveat: Other methods of naming FADUs depend on the system, application, and specific file, and as such are not described here.
- o NBS-5

  Note: Support for 8859 strings and their interpretation as defined in section 10.2.7.1 of these agreements.

Support of the following document types is recommended with qualifications.

- o NBS-8

  Note: Only when the file access service class is implemented.
- o NBS-9

  Note: Only when the file management service class is implemented.

Support of NBS-2,3,4,5 require the ability for transfer or access using transfer syntax TS-1.

Support for any document type requires the ability to transfer and store the abstract syntax given in its definition. These agreements do not specify techniques or formats for storage.

Caveat: Specific abstract and transfer syntaxes for the parametrized document types NBS-6,7,8 are not specified in these agreements.

Any document type supported must be identifiable by its document type name as given in Appendix D and, where defined, the parameterization scheme given in section 10.2.7 of these agreements.

10.2.14.9.5 Recommended Parameter for Implementations Defined in Section 10.2.14.10

- o Implementations will not use CCR parameters.
- o Implementations will use the contents type list parameter on the F-INITIALIZE service element.
- o Implementations will use the Account Parameter on the F-INITIALIZE request PDU.
- o Implementations will support the Diagnostic Parameter as stated in section 10.2.9 of these agreements.
- o Implementations will use the Charging Parameter on the F-TERMINATE Service Element.

- o Implementations will use the Identity of Initiator Parameter on the F-INITIALIZE Service Element. Use must be consistent with section 10.2.12 of these agreements.

- o Implementations are not precluded from using other parameters for Security and/or acounting.

10.2.14.9.6 Parameter Ranges for Implementations Defined in Section 10.2.14.10

Parameter ranges for implementations defined in section 10.2.14.10 are as stated for primitive data types in 10.2.7 of these agreements.

10.2.14.9.7 File Attribute Support for Implementations

Implementations defined in section 10.2.14.10 will support file attributes in the following ways.

- o If an attribute is "supported" it implies a value will be returned other than the value "no value available," and the value will follow the rules as stated in these agreemnts and in FTAM 8571 part 2.

- o If an attribute is "optionally supported" a value of "no value available" may be returned.

- o If an attribute is "not supported" a value will not be returned.

Kernel Group

1. Filename - supported
2. Contents Type - supported

Storage Group

1. storage account
2. date and time of creation
3. date and time of last modification
4. date and time of last read access
5. date and time of last attribute modification
6. Identity of Creator
7. Identity of Last Modifier
8. Identity of Last Reader
9. Identity of Last Attribute Modifier
10. File Availability - supported
11. Permitted actions - supported
12. Filesize - supported
13. Future Filesize

Security Group

1. access control - supported
2. encryption name
3. legal qualifications

Private Group

1. Private use - not supported

10.2.14.10 Implementation Classes

The following implementation classes (profiles) are defined:

T1: Simple File Transfer
T2: Positional File Transfer
T3: Full File Transfer
A1: Positional File Access
A2: Full File Access
M1: File Store Management

Notes:

1. The File Store Management class is only to be implemented in conjunction with one of the Transfer or Access classes.

2. Class T2 is a subset of T3. A1 and T1 are subsets of A2 and T2, respectively.

Tbl. 10.5 Implementation class support requirements

FU	Service Class T	M	A	T&M	UNCST
					A1,A2
Kernel	T1,T2,T3		A2		T1,T2,T3
Read	T1,T2,T3		A2		A1,A2 T1,T2,T3
Write	T1,T2,T3		A2		A1,A2 T1,T2,T3
Limited File Mgmnt.		M1			M1
Enhanced File Mgmnt.		M1			M1
Graphics	T1,T2,T3				T1,T2,T3
File Access			A2		
Document Types					
NBS-1	T1,T2,T3				T1,T2,T3
NBS-2	T1,T2,T3				T1,T2,T3
NBS-3	T1,T2,T3				T1,T2,T3
NBS-4	T2,T3		A2		A1,A2 T2,T3
NBS-5	T2,T3		A2		A1,A2 T2,T3
NBS-6	T2,T3		A2		A1,A2 T2,T3
NBS-w	T2,T3		A2		A1,A2 T2,T3
NBS-8	T3		A2		A2,T3
NBS-9		M1		M1	

The Transfer, Access, and Management classes as defined above correspond to the SPAG FTAM profiles as described in the "Guide to the Use of Standards," as follows.

Tbl. 10.6 Profile name relations - NBS/OSI to SPAG

Implementation Class	SPAG Profile
T1	A111
T2	A112
T3	A113
A1	A122
A2	A123
M1	A131

For further details on which parameters and file attributes are supported for the SPAG FTAM profiles, see the "Guide to the Use of Standards."

11. ISO PRESENTATION LAYER

The Presentation services are defined to meet the needs of many applications. The Presentation service is defined in ISO DIS 8822 and the Presentation protocol is defined in ISO DIS 8823. General agreements about the implementation of the Presentation layer are documented below in section 11.1, followed by agreements related to specific applications.

Note: When the service definition and protocol specification achieve International Standard status in ISO, these agreements will be aligned with the ISO documents.

11.1 GENERAL

- The services of the Presentation kernel functional unit are used as specified in ISO DIS 8822 and 8823 and must be implemented.
- Presentation connections always use multiple presentation context mode.
- Multiple encoding of user data on connect requests is not required.
- The following abstract syntaxes must be supported.

  ISO 8650-2-ACSE 1 (ACSE PCI)

- Abstract Syntaxes are identified by registered name.
- The following Transfer Syntaxes must be supported for all mandatory and defined abstract syntaxes.

  NBS-TS1 (application of ASN.1 Encoding Rules)

- Transfer Syntaxes are identified by registered name.
- A mandatory functional unit is one which must be implemented by the service provider.
- An optional functional unit is one which may be implemented by the service provider, but irrespective of whether it is implemented or not, it must recognize and respond to correct requests for its use.

11.2 PRESENTATION REQUIREMENTS FOR FTAM

- The following abstract syntaxes must be supported.

  ISO 8571-FTAM (including ISO 8571-FADU)
  NBS-AS1 (primitive data types)

- In addition, the following optional abstract syntaxes may be implemented.

  NBS-AS2 (floating point numbers)
  NBS-AS3 (file directories)

- An implementation must support at least three simultaneous presentation contexts.

- All session requirements for FTAM are reflected in the Presentation layer.

12. ASSOCIATION CONTROL SERVICE ELEMENT

The ACSE service is defined to meet the needs of many applications. The ACSE service is defined in ISO DIS 8649/2 and the ACSE protocol is defined in ISO DIS 8650/2. General agreements about implementation of ACSE are documented below in section 12.1, followed by agreements related to specific applications.

Note: When the service defintion and protocol specification achieve International Standard status in ISO, the agreements will be aligned with the ISO documents.

12.1 GENERAL

- o All services specified in ISO DIS 8649/2 must be implemented.

- o A mandatory parameter is one that must be implemented in the protocol by the service provider. The service user must always make a value for the parameter available.

- o An optional parameter is one that must be implemented in the protocol by the service provider, but the user has the option of making available or not making available a value for the parameter.

12.2 APPLICATION ENTITY TITLES

- o An Application Entity Title will name a specific Application Entity Instance on a specific end system.

- o The naming of Application Entities is external to the specification.

- o Application Entity Titles may be mapped many-to-one to PSAP addresses.

- o An Application Entity TItle is a registered name of type Object Identifier.

12.3 FTAM REQUIREMENTS OF ACSE

- o The <application context> value <ISO FTAM> is used to specify the use of ACSE and the FTAM ASE.

13. X.400 BASED MESSAGE HANDLING SYSTEM

13.1 INTRODUCTION

This is an implementation agreement developed by the Implementor's Workshop sponsored by the U.S. National Bureau of Standards to promote the useful exchange of data between devices manufactured by different vendors. This agreement is based on, and employs protocols developed in accord with, the OSI Reference Model. While this agreement introduces no new protocols, it eliminates ambiguities in interpretations.

This is an implementation agreement for a Message Handling System (MHS) based on the X.400-series of Recommendations (1984) from the CCITT. Figure 13.1.1 displays the layered structure of this agreement.

This agreement can be used over any transport profile. In particular, this profile can be used over the transport protocol class 0 used over CCITT X.25, described in section 7.2 of this document. In addition, this profile can be used over the transport profiles used in support of MAP (Manufacturing Automation Protocol) or TOP (Technical and Office Protocols). Note that the MAP or TOP environment must support the reduced Basic Activity Subset (BAS) as defined in X.410.

The UAs and MTAs require access to directory and routing services. A Directory Service is to be provided for each (vendor-specific) domain. Except insofar as they must be capable of providing addressing and routing described hereunder, these services and associated protocols are not described by this agreement.

The material on PRMD-PRMD message transfer in this implementation specification is intended to be stable enough to provide a reliable guide to implementation of X.400. The material on ADMD-PRMD and ADMD-ADMD is incomplete and serves as an indication of direction.

User Agent Layer	CCITT X.420
Message Transfer Agent Layer	CCITT X.411
Reliable Transfer Service Layer	CCITT X.410
Presentation Layer	CCITT X.410 sec. 4.2
Session Layer	CCITT X.225

Fig. 13.1.1 The layered structure of this implementation agreement

13.2 SCOPE

This agreement applies to Private Management Domains (PRMDs) and Administration Management Domains (ADMDs). Three boundary interfaces are specified:

1. PRMD to PRMD;
2. PRMD to ADMD;
3. ADMD to ADMD.

In case 1, the PRMDs do not make use of MHS services provided by an ADMD. In cases 2 and 3, UAs associated with an ADMD can be the source or destination for messages. Furthermore, in cases 2 and 3, an ADMD can serve as a relay between MDs. Figure 13.2.1 illustrates the interfaces to which the agreement applies.

X.400 protocols other than the Message Transfer Protocol (P1) and the Interpersonal Messaging Protocol (P2) are beyond the scope of this agreement. Issues arising from the use of other protocols or relating to P1 components in support of other protocols are outside the scope of this document. This agreement describes the minimum level of services provided by Management Domains (MDs). Provision for the use of the remaining services defined in the X.400 Series of Recommendations is outside the scope of this document.

This agreement does not cover message exchange between communicating entities within a domain even if these entities communicate via P1 or P2. Bilateral agreements between domains may be implemented in addition to the requirements stated in this document. Conformance to this agreement requires the ability to exchange messages with conforming domains that have made no bilateral agreements.

PRMD = Private Management Domain

ADMD = Administration Management Domain

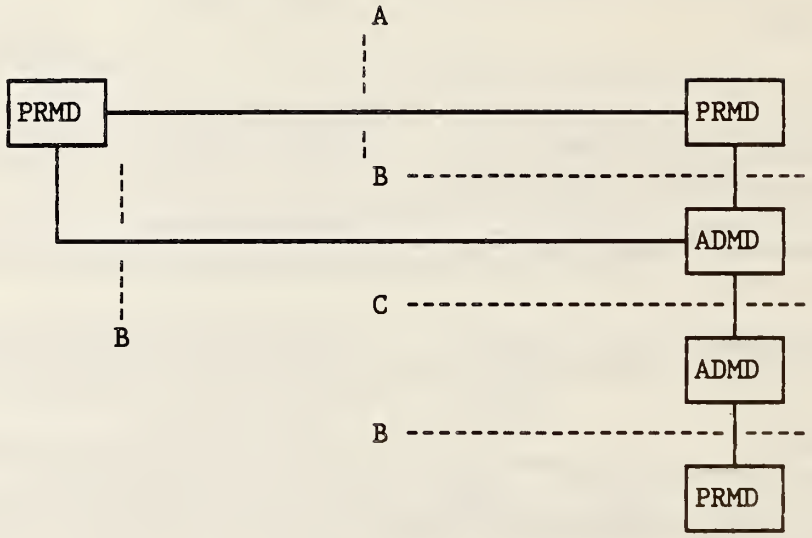

Fig. 13.2.1 This agreement applies to the interface between: (A) PRMD and PRMD; (B) PRMD and ADMD; (C) ADMD and ADMD

13.3 PRMD to PRMD

This section is limited in scope to issues arising from the direct connection (interface A in Figure 13.2.1) of two PRMDs. "Direct" means that no ADMD provides MHS services to facilitate message interchange. "Direct" does not exclude those instances for which ADMDs provide lower layer services (e.g., X.25). Figure 13.3.1 schematically represents the scope of this section.

These issues relate to the use of the UAL (User Agent Layer) and MTL (Message Transfer Layer) services, protocol elements, recommended practices and constraints. In particular, this section addresses the P1 and P2 protocols and their related services in a direct connection environment. This section describes the minimum level of services provided by a PRMD. Provision for the use of the remaining services defined in the X.400 Series of Recommendations is beyond the scope of this section.

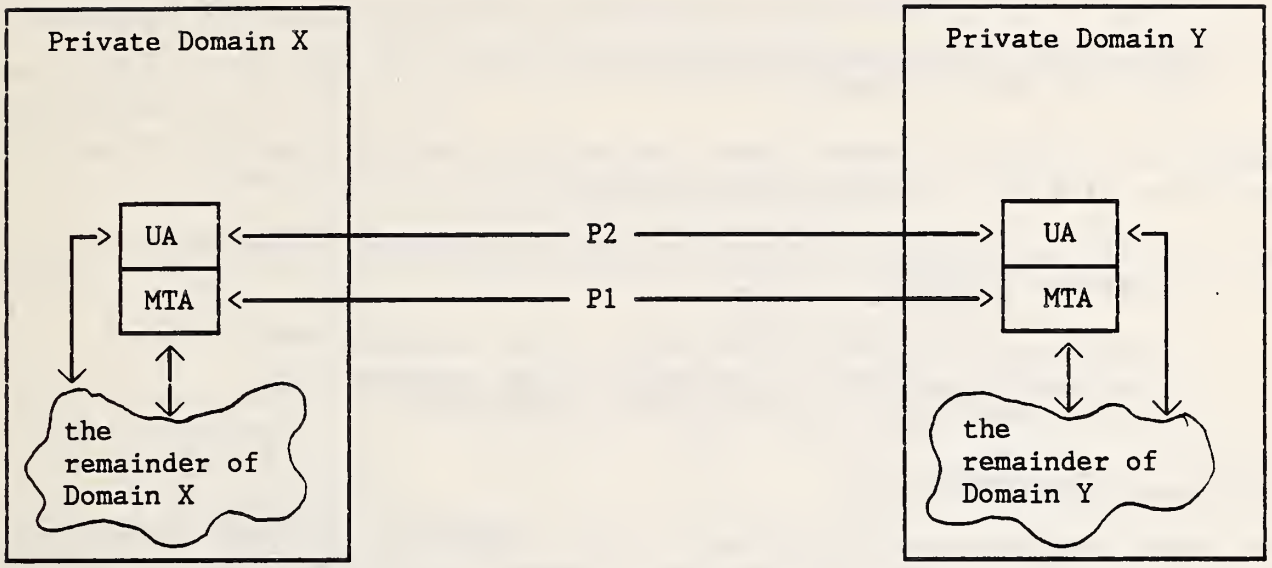

Fig. 13.3.1 Interconnection of private domains

13.3.1 Service Elements and Optional User Facilities

This section identifies those service elements and optional user facilities that must be provided in support of P1 and P2.

13.3.1.1 Classification of Support for Services

The classification of UA and MT-Service elements is used to define characteristics of equipment. Equipment can claim SUPPORT or NON-SUPPORT of a Service; in the case of UA-service elements, a separate classification is given for Origination and Reception.

The service provider is defined as the entity providing the service, in this case, the MTL or the UAL. The service user is either the MHS user or the UAL. The classification of provider and user relates to the sublayer for which the service element is defined.

13.3.1.1.1 Support (S)

This means that:

1. The service provider makes the service element available to the service user.

2. The service user gives adequate support to the MHS to invoke the service element or makes information associated with the service element available.

Support for Origination means that:

1. The service provider makes the service element available to the service user for invocation.

2. The service user gives adequate support to the end user of the MHS to invoke the service element.

Support for Reception means that the service provider makes information associated with the service element available to the service user.

Note: A UA- or MT-service element can carry information from originator to recipient only if:

- o the service element is available to the originator,
- o the service element is available to the recipient, and
- o all intermediate steps carry the information.

13.3.1.1.2 Non Support (N)

This means that the service provider is not required to make the service element available to the service user. However, the service provider should not regard the occurrence of the corresponding protocol elements as an error and should be able to relay such elements. Implementations making a profile available should indicate deviations (additions or deletions) with respect to the requirement in the profile.

13.3.1.1.3 Not Used (N/U)

This means that although the Recommendations allow this service element, this profile does not use it.

13.3.1.1.4 Not Applicable (N/A)

This means that this service element does not apply in this particular case (for originator or recipient).

13.3.1.2 Summary of Supported Services

- o Within a PRMD, a User Agent must support all P2 BASIC IPM Services (X.400) and all P2 ESSENTIAL IPM Optional user facilities (X.401) subject to the qualifiers listed in Appendix A.

- o Within a PRMD, a MTA must support all BASIC MT Services (X.400) and all ESSENTIAL MT optional user facilities (X.401) subject to the qualifiers listed in Appendix A.

- o No support is required of the additional optional user facilities of X.401.

13.3.1.3 MT Service Elements and Optional User Facilities

Tables 13.3.1 through 13.3.3 show the message transfer (MT) service elements and optional user facilities.

Tbl. 13.3.1 Basic MT service elements

Service Elements	Support (S) or Non-support (N)
Access Management	N/U[1]
Content Type Indication	S
Converted Indication	S
Delivery Time Stamp Indication	S
Message Identification	S
Non-delivery Notification	S
Original Encoded Information Types Indication	S
Registered Encoded Information Types	N/U[1]
Submission Time Stamp Indication	S

1 Not applicable to co-resident UA and MTA.

Tbl. 13.3.2 MT optional user facilities provided to the UA-selectable on a per-message basis

MT Optional User Facilities	Categorization	Support (S) or Non-support (N)
Alternate Recipient Allowed	E	S
Conversion Prohibition	E	S
Deferred Delivery	E	N[2]
Deferred Delivery Cancellation	E	N[2]
Delivery Notification	E	S
Disclosure of Other Recipients	E	N[3]
Explicit Conversion	A	N
Grade of Delivery Selection	E	S
Multi-destination Delivery	E	S
Prevention of Non-delivery Notification	A	N
Probe	E	N[4]
Return of Contents	A	N

Tbl. 13.3.3 MT optional user facilities provided to the UA agreed for a contractual period of time

MT Optional User Facilities	Categorization	Support (S) or Non-Support (N)
Alternate Recipient Assignment	A	N
Hold for Delivery	A	N/U
Implicit Conversion	A	N

E: Essential optional user facility.
A: Additional optional user facility.
2 A local facility subject to qualifiers in Appendix A.
3 Support not required for an originating MT user; support must be provided for recipient MT users.
4 Subject to qualifiers in Appendix A.

13.3.1.4 IPM Service Elements and Optional User Facilities

Tables 13.3.4 through 13.3.6 show the IPM service elements and optional user facilities.

Tbl. 13.3.4 Basic IPM service elements

Service Elements	Origination by UAs	Reception by UAs
Access Management	N/U[5]	N/U[5]
Content Type Indication	S	S
Converted Indication	N/A	S
Delivery Time Stamp Indication	N/A	S
Message Identification	S	S
Non-delivery Notification	S	N/A
Original Encoded Information Types Indication	S	S
Registered Encoded Information Types	N/A	N/A[5]
Submission Time Stamp Indication	S	S
IP-message Identification	S	S
Typed Body	S	S

5 Does not apply to co-resident UA and MTA.

Tbl. 13.3.5 IPM optional facilities agreed for a contractual period of time

Service Elements	Categorization	Support (S) or Non-Support (N)
Alternate Recipient Assignment	A	N
Hold for Delivery	A	N
Implicit Conversion	A	N

Tbl. 13.3.6 IPM optional user facilities selectable on a per-message basis

IPM Optional User Facilities	Origination by UAs	Reception by UAs
Alternate Recipient Allowed	A (N)	A (N)
Authorizing Users Indication	A (N)	E (S
Auto-forwarded Indication	A (N)	E (S)
Blind Copy Recipient Indication	A (N)	E (S)
Body Part Encryption Indication	A (N)	E (S)
Conversion Prohibition	E (S)	E (S)
Cross-referencing Indication	A (N)	E (S)
Deferred Delivery	E (N)[6]	N/A
Deferred Delivery Cancellation	A (N/U)[6]	N/A
Delivery Notification	E (S)	N/A
Disclosure of Other Recipients	A (N)	E (S)
Expiry Date Indication	A (N)	E (S)
Explicit Conversion	A (N)	N/A
Forwarded IP-message Indication	A (N)	E (S)
Grade of Delivery Selection	E (S)	E (S)
Importance Indication	A (N)	E (S)
Multi-destination Delivery	E (S)	N/A
Multi-part Body	A (N)	E (S)
Non-receipt Notification	A (N)	A (N)
Obsoleting Indication	A (N)	E (S)
Originator Indication	E (S)	E (S)
Prevention of Non-delivery Notification	A (N)	N/A
Primary and Copy Recipients Indication	E (S)	E (S)
Probe	A (N)	N/A
Receipt Notification	A (N)	A (N)
Reply Request Indication	A (N)	E (S)
Replying IP-message Indication	E (S)	E (S)
Return of Contents	A (N)	N/A
Sensitivity Indication	A (N)	E (S)
Subject Indication	E (S)	E (S)

6 A local facility subject to qualifiers in Appendix A.

13.3.2 X.400 Protocol Definitions

13.3.2.1 Introduction

This section reflects the agreements of the NBS/OSI Workshop regarding P1 and P2 protocol elements.

13.3.2.1.1 Protocol Classification

The protocol classifications are defined:

1. UNSUPPORTED = X

These elements may be generated, but no specific processing should be expected in a relaying or delivering domain. A relaying domain must at least relay the semantics of the element. The absence of these elements should not be assumed, in a relaying or delivering domain, to convey any significance.

2. SUPPORTED = H

These elements may be generated. However, implementations are not required to be able to generate these elements. Appropriate actions shall be taken in a relaying or delivering domain.

3. GENERATABLE = G

Implementations must be able to generate and handle these protocol elements, although they are not necessarily present in all messages generated by implementations of this profile. Appropriate actions shall be taken in a relaying or delivering domain.

4. REQUIRED = R

Implementations of this profile must always generate this protocol element. However, its absence cannot be regarded as a protocol violation as other MHS implementations may not require this protocol element. Appropriate actions shall be taken in a relaying or delivering domain.

5. MANDATORY = M

This must occur in each message as per X.411 or X.420 as appropriate; absence is a protocol violation. Appropriate actions shall be taken in a relaying or delivering domain.

13.3.2.1.2 General Statements on Pragmatic Constraints

- Where a protocol element is defined as a choice of Numeric String and Printable String (i.e., Country Name, Administration Domain Name and Private Domain Identifier), then a numeric value encoded as a printable string is equivalent to the same value encoded as a numeric string.

- The maximum number of recipients in a single MPDU is 32K - 1 (that is, 32767). However, no individual limits on the number of occurrences (recipients) are placed on the following protocol elements: Authorizing Users, Primary Recipients, Copy Recipients, Blind Copy Recipients, Obsoletes and Cross References. Additionally, there is no limit on the number of Reply to Users. This is a local matter for the originating system.

- Use of strings. A Printable String is defined in terms of the number of characters, which is the same number of octets. For T.61 strings the number of octets is twice the number of characters specified.

- The ability to generate maximum size elements is not required, with the exception of the component fields in the Standard Attribute List, in which case it is required.

13.3.2.1.3 MPDU Size

The following agreements govern the size of MPDUs:

- All MTAEs must support at least one MPDU of at least one megabyte.

- The size of the largest MPDU supported by a UAE is a local matter.

13.3.2.2 P1 Protocol Elements

13.3.2.2.1 P1 Envelope Protocol Elements

Table 13.3.7 contains Protocol Elements and their classes.

Tbl. 13.3.7 P1 protocol elements

Element	Class	Restrictions and Comments
MPDU		
UserMPDU	G	
DeliveryReportMPDU	G	
ProbeMPDU	H	
UserMDPU		
UMPDUEnvelope	M	
UMPDUContent	M	
UMPDUEnvelope		
MPDUIdentifier	M	
originator ORname	M	
originalEncodedInformationTypes	G	If this field is absent, then the Encoded Information Type is "unspecified".
ContentType	M	
UAContentID	H	Maximum length = 16 characters.
Priority	G	
PerMessageFlag	G	Maximum length = 2 octets.
deferredDelivery	X	
PerDomainBilateralInfo	X	No limit on number of occurrences.
RecipientInfo	M	Maximum number = 32K - 1 occurrences. More severe limitations are by bilateral agreement.
TraceInformation	M	
UMPDUContent	M	
MPDUIdentifier		
GlobalDomainIdentifier	M	
IA5String	M	Maximum length = 32 characters, graphical subset only. Refer to T.50 for clarification of graphical subset.
PerMessageFlag		
discloseRecipients	H	
conversionProhibited	G	
alternateRecipientAllowed	H	
contentReturnRequest	X	

(Continued on next page.)

Tbl. 13.3.7 P1 protocol elements, Continued

Element	Class	Restrictions and Comments
PerDomainBilateralInfo		
CountryName	M	Maximum length = 3 characters.
AdministrationDomainName	M	Maximum length = 16 characters.
BilateralInfo	M	Maximum depth = 8; maximum length = 1024 octets (including encoding).
RecipientInfo		
recipient	M	
ExtensionIdentifier	M	Maximum value = 32K - 1 (32767).
perRecipientFlag	M	Maximum length = 2 octets.
ExplicitConversion	X	
perRecipientFlag		
ResponsibilityFlag	M	
ReportRequest	M	
UserReportRequest	M	
TraceInformation		Reference should be made to Version 3 of the X.400 Implementor's Guide for information related to Trace sequencing.
GlobalDomainIdentifier	M	
DomainSuppliedInfo	M	
DomainSuppliedInfo		
arrival	M	
deferred	X	
action	M	
converted	H	
previous	X	
ORName		See section 13.3.2.2.2.
EncodedInformationTypes		
bit string	M	Delivery can only occur if match is made with Registered Encoded Information Types. Individual vendors may impose limits. Maximum length = 3 octets.
G3NonBasicParameters	X	
TeletexNonBasicParameters	X	
PresentationCapabilities	X	
DeliveryReportMPDU		
DeliveryReportEnvelope	M	
DeliveryReportContent	M	

Tbl. 13.3.7 P1 protocol elements, Continued

Element	Class	Restrictions and Comments
DeliveryReportEnvelope		
report	M	
originator ORname	M	
TraceInformation	M	
DeliveryReportContent		
original	M	
intermediate	G	
UAContentID	G	
ReportedRecipientInfo	M	Maximum number = 32K - 1 occurrences.
returned	H	Can only be issued if specifically requested in the originating message.
billingInformation	X	Maximum depth = 8; maximum length = 1024 octets (including encoding).
ReportedRecipientInfo		
recipient	M	
ExtensionsIdentifier	M	
PerRecipientFlag	M	
LastTraceInformation	M	
intendedRecipient	H	
SupplementaryInformation	X	Maximum length = 64 characters. Note: This length is subject to change. Value is pending verification by the CCITT SG VIII or IX.
LastTraceInformation		
arrival	M	
converted	H	
Report	M	
Report		
DeliveredInfo	G	Generated if delivery is reported.
NonDeliveredInfo	G	Generated if failure to deliver is reported.

(Continued on next page.)

Tbl. 13.3.7 P1 protocol elements, continued

Element	Class	Restrictions and Comments
DeliveredInfo		
delivery	M	
typeofUA	R	This element must be generated with a PRIVATE value by PRMDs.
NonDeliveredInfo		
ReasonCode	M	
DiagnosticCode	H	Whenever possible, use a meaningful diagnostic code.
ProbeEnvelope		
probe	M	
originator	M	
ContentType	M	
UAContentID	H	Maximum length = 16 characters.
original	G	If this field is absent, then the Encoded Information Type is "unspecified".
TraceInformation	M	
PerMessageFlag	G	
contentLength	H	
PerDomainBilateralInfo	X	
RecipientInfo	M	Maximum number = 32K - 1 occurrences.
GlobalDomainIdentifier		
CountryName	M	Maximum length = 3 characters.
AdministrationDomainName (4)	M	Maximum length = 16 characters or digits.
PrivateDomainIdentifier	R	Maximum length = 16 characters or digits. This element must be generated by PRMDs.
End of Definitions		

13.3.2.2.2 ORName Protocol Elements

Only form 1 variant 1 O/R names are supported.

Table 13.3.8 contains ORName protocol elements.

Tbl. 13.3.8 ORName protocol elements

Element	Class	Restrictions and Comments
ORName		
StandardAttributeList	M	
DomainDefinedAttributeList	X	
StandardAttributeList (1)		
CountryName	R	As defined in X.411, Maximum length = 3 characters.
AdministrationDomainName (4)	R	Maximum length = 16 characters or digits.
X121Address	X	Maximum length = 15 digits.
TerminalID	X	Maximum length = 24 characters.
PrivateDomainName (2)	G	Maximum length = 16 characters.
OrganizationName (2)	G	Maximum length = 64 characters.
UniqueUAIdentifier	X	Maximum length = 32 digits.
PersonalName	G	Maximum length of values of sub-elements = 64 characters. Note: The possibility that this value may be reduced to 40 characters is for further study by the CCITT.
OrganizationalUnit (3)	G	Maximum length = 32 characters per occurrence. A maximum of four occurrences are allowed.
DomainDefinedAttributeList (5)		Maximum = 4 occurrences.
type	M	Maximum length = 8 characters.
value	M	Maximum length = 128 characters.
PersonalName		
surName	M	Maximum length = 40 characters.
givenName	G	Maximum length = 16 characters.
initials	G	Maximum length = 5 characters; excluding surname initial and punctuation and spaces.
generationQualifier	G	Maximum length = 3 characters.

(Continued on next page.)

Tbl. 13.3.8 ORName Protocol Elements, Continued

Notes:

1. The following apply for comparison of the Standard Attributes of an O/R Name:

   a. Lower case is interpreted as upper case (for IA5).

   b. Multiple spaces may be interpreted as a single space. Originating domains shall only transmit single significant spaces. If multiple spaces are transmitted, non-delivery may occur.

2. At least one of these must be supplied.

3. These should be sent in ascending sequence, from the least significant <Organizational Unit> (lowest in organization hierarchy) to the most significant. Only those specified should be sent. (That is, an unspecified <Organizational Unit> should not be sent along as a field of [null] content, nor zero length, etc.)

4. This attribute shall contain one space in all ORNames of messages originated in a PRMD that is not connected to an ADMD, and in ORNames of recipients reachable only through a PRMD; otherwise, this attribute shall contain an appropriate ADMD name.

5. Many existing mail systems require attributes not present in these agreements. Domain Defined Attributes are a method of providing these. Failure to support the specification of DDAs may prevent successful interworking with such existing mail systems until such time as all mail systems are capable of supporting delivery via the standard attribute list only. Specific recommendations on the use of DDAs are in the Recommended Practices section.

13.3.2.3 P2 Protocol Profile (Based on [X.420])

Tables 13.3.9 and 13.3.10 classify the support for the P2 protocol elements required by this profile. The tables give restrictions and comments in addition to [X.420].

Restriction on length is one of the types of restrictions. The reaction of implementations to a violation of this restriction is not defined by this profile.

13.3.2.3.1 P2 Protocol - Heading

Table 13.3.9 below specifies the support for protocol elements in P2 Headings.

Tbl. 13.3.9 P2 heading protocol elements

Element	Class	Restrictions and Comments
UAPDU		
IM-UAPDU	G	
SR-UAPDU	X	
IM-UAPDU		
Heading	M	
Body	M	
Heading		
IPMessageId	M	
originator ORname	R	
authorizingUsers	H	
primaryRecipients	G	At least one of primaryRecipients,
copyRecipients	G	copyRecipients, or blindCopyRecipients must be
blindCopyRecipients	H	present.
inReplyTo	G	
obsoletes	H	
crossReferences	H	
subject	G	Maximum length = 256 octets; the ability to generate the maximum size subject is not required.
expiryDate	H	
replyBy	H	
replyToUsers	H	
importance	H	Appropriate action is for further study.
sensitivity	H	Appropriate action is for further study.
autoforwarded	H	

(Continued on next page.)

Tbl. 13.3.9 P2 heading protocol elements, continued

Element	Class	Restrictions and Comments
IPmessageId		
ORName	H	
PrintableString	M	Maximum length = 64 characters.
ORDescriptor		
ORName	H	Specify the ORName whenever it is possible. See Appendix B.
freeformName	H	Maximum length = 64 characters, graphical subset only (128 octets.)
telephoneNumber	X	Maximum length = 32 characters. This allows for punctuation. It does not take into account possible future use by ISDN.
Recipient	M	
ORDescriptor	M	
reportRequest	X	
replyRequest	H	
Body		No limit on number of BodyParts.
BodyPart	G	No limit on length of any BodyPart or the depth of ForwardedIPMessage BodyParts nested. Classification is subject to pending CCITT resolution

Element	Class	Restrictions and Comments
ReceiptInformation		
receipt	M	
typeOfReceipt	H	
SupplementaryInformation	X	Maximum length = 64 characters. Note: This value is pending verification by the CCITT SG VIII or IX.
End of Definitions		

13.3.2.3.2 P2 Protocol - BodyParts

All BodyParts with identifiers in the range 0 up to and including 16K -1 are legal and should be relayed. BodyPart identifiers corresponding to X.121 Country Codes should be interpreted as described in section 13.4.3.2.1.

13.3.2.3.2.1 Privately Defined BodyParts

This section describes an interim means for identifying privately defined BodyParts. This section shall be replaced in a future edition taking into account CCITT recommendations with equivalent functionality.

```
BodyPart  ::=  CHOICE
   [0]IMPLICIT IA5Text,
   [1]IMPLICIT TLX,
         .
         .
         .
   [234]IMPLICIT UKBodyParts,
         .
         .
         .
   [310]IMPLICIT USABodyParts,
         .
         .
         .                    ]
```

Where UKBodyParts and USABodyParts are defined as:

```
  SEQUENCE  BodyPartNumber, ANY

  BodyPartNumber ::= INTEGER
```

In the EncodedInformationTypes of the P1 Envelope, the undefined bit must be set when a message contains a privately defined BodyPart. Each UA that expects such BodyParts should include undefined in the set of deliverable

EncodedInformationTypes it registers with the MTA.

All BodyPartNumbers assigned must be interpreted relative to the BodyPart in which they are used, which is that tagged with the value [310] for those defined within the United States. The NBS assigns unique message BodyPartNumbers for privately defined formats within the United States.

Implementations are required to generate and image IA5Text.

Implementations should specify the other BodyPart types supported.

If an implementation supports a particular BodyPart type for reception, it should also be able to support that BodyPart type for reception if this is part of a ForwardedIPMessage.

For the BodyPart types currently considered, support for the protocol elements is as indicated in table 13.3.10.

13.3.2.3.2.2 P2 BodyPart Protocol Elements

Tbl. 13.3.10 P2 BodyParts

Note: This element is not an addition to the definition of the BodyPart. It is described here to show that the SEQUENCE may contain zero elements. A Problem Report has been submitted to the CCITT to clarify whether this is permissible. The NBS/OSI Workshop will adopt the CCITT decision.

13.3.3 Reliable Transfer Server (RTS)

13.3.3.1 Implementation Strategy

Based on X.410 clause 3 and X.411 clause 3.5.

13.3.3.2 RTS option selection

- The maximum number of simultaneous associations is not limited in this profile; if the capacity of a system is exceeded, it should not initiate or accept additional associations.
- Associations are established by the MTA which has messages to transfer.
- Associations are released when they are not needed. Associations may also be ended prematurely due to internal problems of the RTS.
- For both monologue and two way alternate associations, the initiator keeps the initial turn.

When establishing an RTS association, the following rules apply to the use of parameters in addition to those in X.410 clause 3.2.1:

Dialogue mode:	Monologue must be supported for this profile; two-way alternate is used only if both partners agree.
Initial turn:	Kept by the initiator of the association.

The 'priority-mechanism' and the 'transfer-time limit' are regarded as local

matters.

13.3.3.3 RTS Protocol Options and Clarifications

Realization of the RTS protocol is subject to the following rules in addition to those specified in X.410 clause 4:

1. One RTS association corresponds to one or more consecutive session connections (not concurrent ones). The first is opened with ConnectionData of type OPEN, and subsequent ones are opened with type RECOVER.

2. Recovery of a Session connection is only by RTS initiator.

3. Checkpoint size:

   - o Checkpointing and No Checkpointing should be supported. Whenever possible, checkpointing should be used.

   - o The minimum checkpointSize is 1 (that is, 1024 octets).

4. Window size:

   - o Minimal value of 1 (if checkpointing is supported).

   - o WindowSize = 1 means: After an S-SYNCH-MINOR request is sent, wait until the confirmation is received before issuing an S-DATA, S-SYNCH-MINOR, or S-ACTIVITY-END request.

5. APDUs should not be blocked into one activity.

6. Only one SSDU shall be transferred:

   - o Between two adjacent minor synch points.

   - o Between minor synch points and adjacent S-ACTIVITY-START and S-ACTIVITY-END requests.

   - o Between S-ACTIVITY-START and S-ACTIVITY-END without checkpoints.

7. A monologue association is defined as follows:

   - The RTS user responsible for establishing the association is called the initiator.
   - The initiator keeps the initial turn.
   - APDUs are transferred in the direction of the initiator to the recipient only.
   - There shall be no token passing.
   - Only the initiator can effect an orderly release of the association.

8. A two-way alternate session is as described in X.410.

9. In the UserData parameter of the S-U-ABORT, the ReflectedParameter will not be used in the AbortInformation element.

10. When the S-ACTIVITY-RESUME is used to resume an activity in the same session connection as the one in which it started, this must happen immediately after the activity has been interrupted (i.e., no intervening activity can occur). Otherwise, [X.410 clause 4.3 paragraph 1] may be violated.

11. When S-ACTIVITY-RESUME is used to resume an activity started in another session connection, the following conditions must be met:

    - The current session connection is of type "recover".
    - The value of OldSessionConnectionIdentifier in S-ACTIVITY-RESUME must match the value of the SessionConnectionIdentifier parameter used in the S-CONNECT of the prior session connection. This value is also identical to the SessionConnectionIdentifier in the ConnectionData (in PConnect, in SS-UserData) for the current session connection.
    - This must occur as the first activity of the next session connection for the same RTS-association. It must be the first, otherwise [X.410 clause 4.5.1 point 1] is violated.

      Note: It is in the same RTS-ASSOCIATION because the use of S-ACTIVITY-RESUME only makes sense within the scope of one RTS association.

12. If the transfer of an APDU is interrupted before the confirmation of the first checkpoint, the value of the SynchronizationPointSerialNumber in S-ACTIVITY-RESUME should be zero, and the S-ACTIVITY-RESUME must be immediately followed by an S-ACTIVITY-DISCARD.

13. In S-TOKEN-PLEASE, the UserData parameter shall contain an integer conforming to X.409 which conveys the priority.

14. The receiving RTS can use the value of the Reason parameter in the S-U-EXCEPTION-REPORT to suggest to the sending RTS that it should either interrupt or discard the current activity.

    As stated in Version 3 of the X.400 Series Implementor's Guide, "On receipt of an 'unrecoverable procedure error' the current activity is not recoverable and the sending RTS issues an S-ACTIVITY-DISCARD. On receipt of any other reason code (including a nonspecific error), the sending RTS issues an S-ACTIVITY-INTERRUPT followed by an S-ACTIVITY-RESUME."

15. In the case of S-P-ABORT, the current activity (if any) is regarded as interrupted, rather than discarded.

16. The following table illustrates the legal negotiation possibilities allowed by X.410 clause 4.2.1 regarding checkpoint size and window size.

Tbl. 13.3.11 Checkpoint window size of IP

		acceptor answer		
		CS = 0 (or unspecified) WS unspecified	CS = m WS = j (or unspecified)	CS = n WS = j (or unspecified)
initiator proposal	CS = 0 (or unspecified) WS = i (or unspecified)	legal	legal	legal
	CS = k WS = i (or unspecified)	legal	legal	not allowed

Legend:

- o CS means CheckpointSize
- o WS means WindowSize
- o i, j, k, m, and n are integer values with the following relations:

  $0 < m < k < n$ (values assigned to CS)
  $0 < j < i$ (values assigned to WS)

- o For unspecified parameters, the default applies. In this case, the numeric relations apply, that is, the default values substitute for the unspecified integer.

13.3.3.4 RTS Protocol Limitations

The RTS Protocol Limitations for this profile are listed in table 13.3.12.

Tbl. 13.3.12 RTS protocol elements

Element	Class	Restriction
PConnect	M	
DataTransferSyntax	M	Value = 0.

End of Definitions		

13.3.4 Use of Session Services

The session requirements and use of session are covered in section 8 of this document.

13.3.5 Data Transfer Syntax

This section defines Presentation Transfer Syntax and notation rules applicable to these agreements. Implementations must conform EXACTLY as specified in X.409 with no further restrictions. Appendix C defines rendition of IA5 Text and T61 characters.

13.4 PRMD to ADMD and ADMD to ADMD

13.4.1 Introduction

This section defines the implementation agreements that apply to the interface between two management domains when at least one is an ADMD. A message arriving at an ADMD has either no recipient within that domain or one or more recipients within that domain. In the former case, the ADMD serves as a relay between two or more domains and the actions required of that ADMD are independent of the nature (PRMD or ADMD) of the domains. In the latter case, the ADMD is responsible for delivering messages to the proper recipient(s) within its jurisdiction, and may also be responsible for relaying the message.

Given the two roles for an ADMD, this section describes two distinct sets of functional requirements for an ADMD. The first is the relaying requirement that is needed to provide PRMD and other ADMD interworking. The second is analogous to the PRMD's support to its customers through the integrated UAs. These are distinct functional differences. The services provided to the UAs of an ADMD are independent of the requirement that an ADMD provide a function

for interworking with any type of Management Domain (MD). Figure 13.4.1 illustrates the two roles played by an ADMD.

This section is presented in the form of deviations from the agreements applicable to PRMD-to-PRMD (section 13.3.0). Unless explicitly noted in the remainder of this section, all of the specifications for PRMD to PRMD apply to PRMD to ADMD and ADMD to ADMD.

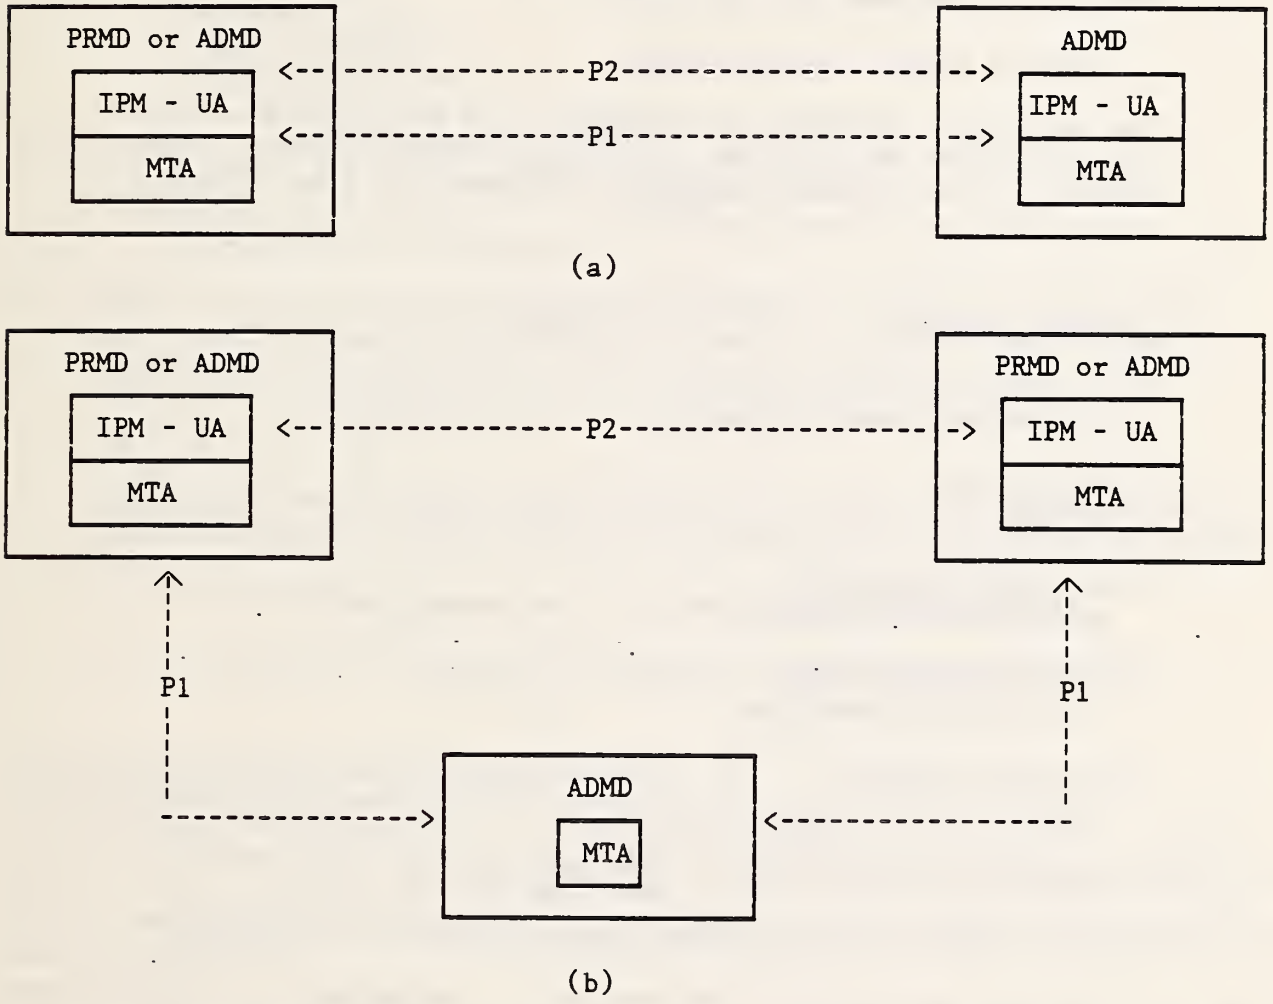

Fig. 13.4.1 An ADMD may (b) or may not (a) serve as a relay.

13.4.2 Additional ADMD Functionality

The following defines the additional ADMD specific functionality required over and above that specified in the PRMD section.

1. ADMDs will relay all content types (not just P2) unchanged in the absence of a request for conversion.

2. P1 Protocol Classification Changes

   The following describes the changes to the PRMD P1 Protocol classifications required for a delivering Administration Domain (with respect to the original message; this means the domain which originates the delivery reports).

Protocol Elements	Class	
DeliveryReportContent		
intermediate TraceInformation	G	See note 1.
DeliveredInfo		
typeOfUA	H	
ReportedRecipientInfo		
SupplementaryInformation	H	See note 2.
GlobalDomainIdentifier		
PrivateDomainIdentifier	H	
DomainSuppliedInfo		
Previous GlobalDomainIdentifier	H	Required for loop detection.

For relaying administration domains, the clasifications are all "X".

For originating administration domains, these are all "NOT APPLICABLE".

Note 1: If the intermediate trace information is requested by a domain other than the originating domain, return of the desired information cannot be assured, as the return path of the delivery report may be different from the original message and may exclude that domain.

Note 2: Domains providing access to TELEX/TELETEX recipients, whether directly or indirectly as a result of bilateral agreements between domains, must ensure that this information, when present, is accessible by the recipient of the delivery report.

3. O/R Names

   O/R Names shall consist of:

CountryName
AdministrationDomainName

as well as one of the following:

PrivateDomainName
PersonalName
OrganizationName
OrganizationalUnit
UniqueUAIdentifier
X121Address

and permits the optional inclusion of a

DomainDefinedAttributeList

Note that the destination PrivateDomainName or OrganizationName must be present if destined for a PRMD. The ADMD relaying the message to that destination PRMD requires this element.

P1 Originator Name

Management Domains (MDs) must specify in the ADMD name field of the O/R Name StandardAttributeList in P1, the name of the administration domain:

- to which the message is being sent (in recipient names)
- from which the message originated (in the originator name).

13.4.3 Interworking with Integrated UAs

If the message originates at a UA owned by an ADMD, or is delivered to such a UA, the O/R Name follows the same Form 1 Variant 1 constraints as the base specifications; except that the ADMD name is the name of the ADMD that owns the UA and instead of supplying a PRMD Name, one (or more) of the following must be provided:

OrganizationName
OrganizationalUnit
PersonalName

and may optionally include a

DomainDefinedAttributeList

13.4.4 Differences with other Profiles

13.4.4.1 NTT Profile

There are no outstanding issues regarding interworking between NTT-conformant systems and NBS-conformant systems with the exception of the number of

recipients. The ExtensionIdentifier field may contain a maximum value of 32K-1; however, according to the current NTT profile, if a message with more than 256 recipients is received, the NTT-conformant domain will generate a nondelivery notification. This also applies to the ReportedRecipientInfo in a delivery report.

13.4.4.2 CEPT Profile

For further study.

13.4.5 Connection of PRMDs to Multiple ADMDs

Given that Management Domain names (both PRMD and ADMD) shall be unique within the U.S., then when an ADMD is presented a message for transfer from a PRMD, it will accept O/R Names (both originator and recipient) which have an AdministrationDomainName field value different than the administration's name. "Accept" implies the attempt to route/deliver the message shall be made, as appropriate, based upon the knowledge that MD names are unique.

Whether this functionality is required by an administration for conformance to this agreement is for further study.

If a PRMD is connected to two or more ADMDs which are not effectively connected (either directly or via a third ADMD), full X.400 functionality shall not be available. Problems occur especially in the areas of:

- o Naming
- o Routing
- o Replying.

13.4.6 Connection of an ADMD to a Routing PRMD

It is possible for a collection of interconnected private domains to establish one domain as the "gateway" to an ADMD, and hence to the world.

If an ADMD is connected to such a gateway PRMD, the individual private domains shall be registered with the administration. Administrations need not support such connections.

Note also that upon receipt by the ADMD of a message originating somewhere within the PRMD collection, that the TraceInformation may contain more than one element.

13.4.7 Management Domain Names

All Management Domain Names (both Private and Administration) shall be unique within the U.S.

A central naming authority shall be established to register domain names.

13.4.8 Envelope Validation Errors

For validation errors, a non-delivery notice shall be generated (if possible) with reason code of 'unableToTransfer' and diagnostic code of 'invalidParameters' (unless specified otherwise).

ADMDs will validate P1 Envelopes in the following areas:

- The X.409 syntax of all elements should be checked.

- The pragmatic constraint limits (lengths of fields and number of occurrences of fields) should be checked.

- Semantic validation of the following elements should be done:

  originator O/R Name
  recipient O/R Name in the RecipientInfo
  priority

  Only recipient Names with the responsibility flag set should be validated. The validation of O/R names is defined in 13.5.3.3; the validation of priority is defined in 13.5.3.6.1.

- MPDU Identifier Validation

  Validation of the GlobalDomainIdentifier component of the MPDU Identifier is performaed upon reception of a message (i.e., as a result of a TRANSFER.Indication).

  The country name should be known to the validating domain, and depending on the country name, validation of the ADMD name may also be possible.

  Additional validation of the GlobalDomainIdentifier is performed against the corresponding first entry in the TraceInformation. If inconsistencies are found during the comparison, a non-delivery notice with the above defined reason and diagnostic codes is generated.

  A request will be generated to the CCITT for a more meaningful diagnostic code (such as 'InconsistentMPDUIdentifier').

13.4.9 Quality of Service

13.4.9.1 Domain Availability

13.4.9.1.1 ADMD Availability

The goal is to provide 24 hour per day availability. Note that there will be periods of time when an ADMD may be unavailable due to maintenance windows in its supporting network or in an MTA within the domain.

13.4.9.1.2 PRMD Availability

Although the goal of PRMD availability is also 24 hours per day, business

reasons are likely to dictate some different level of availability. ADMDs shall require a profile from the PRMD that indicates its schedule of regular availability to the ADMD.

13.4.9.2 Delivery Times

In the absence of standardized quality of service parameters, the following are agreed to. When standardized parameters from CCITT Study Group I become available, they shall be adopted.

The following delivery time targets are established:

Delivery Class	95% Delivered Before
Urgent	3/4 hour
Normal	4 hours
Non-Urgent	24 hours

The interval(s) between retries and the number of retry attempts that an ADMD uses in attempting delivery to a PRMD or integrated UA, will be locally determined domain parameters. However, the total elapsed times after which delivery attempts will be stopped are as follows. This implies that, after these times, a Non-Delivery Notice will be generated.

Delivery Class	NonDelivery Forced After
Urgent	4 hours
Normal	24 hours
Non-Urgent	36 hours

Both tables apply to the period between acceptance by the originating MTA in the originating administration domain to the time of delivery in the destination adminstration domain. Transit time within PRMDs in NOT included in the above times.

13.4.10 Billing Information

All aspects relating to billing, charging, tariffs, and settlement, and in particular to the use of the billingInformation field in the delivery report, is subject to bilateral agreement, and shall not be addressed in these implementation agreements.

No ADMD shall require a PRMD to supply or process billing information.

13.4.11 Transparency

No P1 extensions are to be allowed. Should an ADMD receive a message containing P1 extensions, it shall generate a non-delivery notice (if possible) with reason code of unableToTransfer and diagnostic code of invalidParameters.

The CCITT has been requested to establish a more meaningful diagnostic code

(such as protocolError) for this occurrence.

P2 extensions shall be relayed transparently by ADMDs.

13.4.12 For Further Study

Issues requiring further study are:

- o RTS Password Management
- o Intra-Domain Routing
- o Multi-Vendor Domains

13.5 ERROR REPORTING

This section describes appropriate actions to be taken upon receipt of protocol elements which are not supported in this profile, malformed MPDUs, unrecognized O/R Name forms, content errors, errors in reports, and unexpected values for protocol elements.

13.5.1 MPDU Encoding

The MPDU should have a context-specific tag of 0, 1, or 2. If it does not have one of these tags, it is not possible to figure out who originated the message. Therefore, the way this error is reported is a local matter.

13.5.2 Contents

Once delivery to the UA has occurred, it is not possible to report errors in P2 information to the originator. In addition, it seems unreasonable to insist that the MTA that delivers a message ensures that the P2 content of the message is okay. As a result, the handling of content errors is a local matter.

13.5.3 Envelope

13.5.3.1 Pragmatic Constraint Violations

In all cases of pragmatic constraint violation, a nondelivery report should be generated with a ReasonCode of unableToTransfer, and a DiagnosticCode of invalidParameters. Note: it would be desirable for the CCITT to add a DiagnosticCode of pragmaticConstraintViolation to allow a more meaningful description of this problem. A request for this new DiagnosticCode has been submitted.

13.5.3.2 Protocol Violations

If not all required protocol elements are present, a nondelivery report with a ReasonCode of unableToTransfer and a DiagnosticCode of invalidParameters should be generated. Note: it would be desirable for the CCITT to add a DiagnosticCode of protocolViolation to allow a more meaningful description of this problem. A request for this new DiagonsticCode has been submitted.

If a protocol element is expected to be of one type, but is encoded as another, then a nondelivery report with a ReasonCode of unableToTransfer and a DiagnosticCode of invalidParameters should be generated. Note: it would be desirable for the CCITT to add a DiagnosticCode of protocolViolation to allow a more meaningful description of this problem. A request for this new DiagnosticCode has been submitted.

13.5.3.3 O/R Names

The domain that has responsibility for delivering a message should also have the responsibility to send the nondelivery notification if the message cannot be delivered. Therefore, each domain should only validate the O/R Names of recipients with responsibility flags set to TRUE. In addition, a nondelivery notification can only be sent if the originator's O/R Name is valid.

If any element in the O/R Name is unrecognized or if the CountryName, AdministrationDomainName, and one of PrivateDomainName and OrganizationName (and, for ADMDs, PersonalName and OrganizationalUnit) are not all present, then a nondelivery report should be generated with a ReasonCode of unableToTransfer, and a DiagnosticCode of unrecognizedORName. If the message can be delivered even though the ORName is invalid, delivery is a local matter. Note, however, that if the message is delivered, the invalid ORName might be propagated through the X.400 system (e.g., by forwarding).

If the O/R Name has all of the appropriate protocol elements and the message still cannot be delivered to the recipient, the following DiagnosticCodes may appear in the nondelivery report: unrecognizedORName, ambiguousORName, and uaUnavailable.

13.5.3.4 TraceInformation

Since non-relaying domains need not do loop suppression, domains with responsibility for delivering the message need not be concerned about the semantics of the TraceInformation, that is, arrival time and converted EncodedInformationTypes can be provided to the UA without inspection by the MTAs of the domain as long as the TraceInformation is properly encoded according to X.409.

Loop detection in a relaying domain occurs as a message leaves a domain. If the subsequent domain already appears in the Trace Information and does not appear in a "previous" field of a trace information element with a "rerouted" indication, a loop has occurred. A non-delivery notice should be generated with reason code of 'unableToTransfer' and diagnostic code of 'loopDetected'.

CCITT Study Group VII will address this in its October 1986 meeting.

Note that a domain may insert several instances of Trace information into a message. The first must be a "relayed" indication. Additional entries shall only be of type "rerouted" and must contain the "previous" GlobalDomainIdentifier. The "previous" field indicates that domain to which delivery was previously attempted (and not, as might be inferred from the name, the domain which relayed the message prior to this relaying domain). If

this is not the case, a non-delivery notice shall be returned with a reason code of 'unableToTransfer' and a diagnostic code of 'invalidParameters'.

A request shall be made to CCITT for a more meaningful diagnostic code (such as 'invalidTraceInformation').

13.5.3.5 Unsupported X.400 Protocol Elements

The protocol elements defined in X.400 but unsupported by this profile are: the deferredDelivery and PerDomainBilateralInfo parameters of the UMPDUEnvelope, the ExplicitConversion parameter of RecipientInfo, and the alternateRecipientAllowed and contentReturnRequest bits of the PerMessageFlag. Appropriate actions are described below for domains that do not support the protocol elements.

13.5.3.5.1 deferredDelivery

The domain shall do one of the following:

- o deliver at once,
- o hold for deferred delivery,
- o return a nondelivery notification with a ReasonCode of unableToTransfer.

Note: It would be desirable for the CCITT to add a diagnostic code of noBilateralAgreement to allow a more meaningful description of this problem. A request for this new diagnostic code has been submitted.

13.5.3.5.2 PerDomainBilateralInfo

If a domain receives this service element, the service element can be ignored, and the message should be delivered if possible.

13.5.3.5.3 ExplicitConversion

If ExplicitConversion is requested the message should be delivered if possible. That is, if the UA is registered to accept the EncodedInformationTypes of the message, then the message should be delivered even though the domain could not perform the requested conversion. If delivery is not possible, then a nondelivery report should be generated with a ReasonCode of conversionNotPerformed with no DiagnosticCode.

13.5.3.5.4 alternateRecipientAllowed

If a domain receives this service element the service element can be ignored, and this message should be delivered if possible.

13.5.3.5.5 contentReturnRequest

If a domain receives this service element, the service element can be ignored, and the message should be delivered if possible.

13.5.3.6 Unexpected Values for INTEGER Protocol Elements

There are three INTEGERs in the P1 Envelope. Appropriate actions are described below for domains receiving unexpected values for Priority, ExplicitConversion, and ContentType.

13.5.3.6.1 Priority

Additional values for Priority have been suggested by at least one group of implementors as upward compatible changes to the X.400 Recommendations. Therefore, if a domain receives an unexpected value for Priority, and this value is greater than one byte in length, a nondelivery report should be generated with a ReasonCode of unableToTransfer and DiagnosticCode of invalidParameters. If the value is less than or equal to one byte, the domain can either generate a nondelivery report as previously specified or default the Priority to normal and deliver the message.

13.5.3.6.2 ExplicitConversion

The message should be delivered if possible. That is, if the UA is registered to accept the EncodedInformationTypes of the message, then the message should be delivered even though the domain could not perform the requested conversion. If delivery is not possible, then a nondelivery report should be generated with a ReasonCode of conversionNotPerformed with no DiagnosticCode.

13.5.3.6.3 ContentType

If the ContentType is not supported, then a nondelivery report should be generated with a ReasonCode of unableToTransfer, and a DiagnosticCode of invalidParameters. Note: it would be desirable for the CGITT to add a DiagnosticCode of contentTypeNotSupported to allow a more meaningful description of this problem. A request for this new DiagnosticCode has been submitted.

13.5.3.7 Additional Service Elements

In the absence of bilateral agreements to the contrary, receipt of privately tagged elements and protocol elements in addition to those defined in X.400 will result in a nondelivery report with a ReasonCode of unableToTransfer and a DiagnosticCode of invalidParameters.

13.5.4 Reports

There is no mechanism for returning a delivery or status report due to errors in the report itself. Therefore the handling of errors in reports is a local matter.

13.6 MHS USE OF DIRECTORY SERVICES

Recommendation X.400 recognizes the need of MHS users for a number of directory service elements. Directory service elements are intended to assist users and their UAs in obtaining information to be used in submitting messages

for delivery by the MTS. The MTS may also use directory service elements to obtain information to be used in routing messages. Some functional requirements of directories have been identified and are listed below.

- o Verify the existence of an O/R name.
- o Return the O/R address that corresponds to the O/R name presented.
- o Determine whether the O/R name presented denotes a user or a distribution list.
- o Return a list of the members of a distribution list.
- o When given a partial name, return a list of O/R name possibilities.
- o Allow users to scan directory entries.
- o Allow users to scan directory entries selectively.
- o Return the capabilities of the entity referred to by the O/R name.
- o Provide maintenance functions to keep the directory up-to-date.

In addition to functionality, a number of operational aspects must be considered. These include user-friendliness, flexibility, availability, expandability, and reliability.

Currently, these aspects of directory service elements and procedures are under study by both the CCITT and the ISO. Both organizations are committed to the development of a single Directory Service specification for use by MHS and all other OSI based applications.

Given the incomplete nature of the ongoing activities within the CCITT and the ISO, no implementation details will be provided now for MHS use of Directory Services. Implementation agreements for MHS Use of Directory Services will be issued when current activities within the CCITT and the ISO are stable.

It is recognized that these agreements enable a wide variety of naming and addressing attributes (see section 13.3.5.3.3 ORName Protocol Elements) wherein each PRMD may adopt particular routing schemes within its domain. These agreements make no attempt to recommend a standard practice for electronic mail addressing.

Inter-PRMD addressing may be secured according to practices outside the scope of these agreements, such as:

- o manual directories
- o on-line directories
- o ORName address specifications
- o ORName address translation.

Further, each PRMD may adopt naming and addressing schemes wherein the user view may take a form entirely different from the attributes reflected in section 13.3.4.2.2 herein. And, each PRMD may have one user view for the originator form and another for the recipient form, and perhaps other forms of user addressing. In some cases (e.g., receipt notification) these user forms must be preserved within the constraints of these implementation agreements. However, mapping between one PRMD user form to another PRMD user form, via the X.400 ORName attributes of these agreements, is outside the scope of these agreements.

13.7 CONFORMANCE

In order to ensure that products conform to these implementation agreements, it is necessary to define the types and degrees of conformance testing products that must pass before they may be classified as conformant. This section defines the conformance requirements and provides guidelines for the interpretation of the results from this type of testing.

In order to achieve a minimum level of confidence in the conformance of a product, the most basic requirements a product must meet to be classified as conformant to these agreements are provided. This minimal set was defined to ensure that the resulting MHS network will provide a reasonable interpersonal messaging facility to its users while still giving a reasonable assurance that conforming products can soon be made available. In addition, the full conformance requirements for products implementing all aspects of X.400 Messaging governed by these agreements are provided.

This section is incomplete and will be enhanced in future versions of this agreement. Later versions will reflect the problems of conformance testing and will outline specific practices and recommendations to aid the development of conformance tests and procedures.

13.7.1 Definition of Conformance

For this section, the term conformance is defined by the following:

- The tests indicated for this section are intended to establish a high degree of confidence in a statement that the implementation under test (IUT) conforms (or does not conform) to the agreements of this section.

- Conformance to a service element means that the information associated with the service element is made accessible to the user (person or process) whenever this agreement says that this information should be available.

  Accessible means that information must be provided describing how a user (person or process):

  - causes appropriate information to be displayed, or

  - causes appropriate information to be obtained.

- Conformance to P1, P2, and RTS as part of an X.400 OSI application requires that only the external behavior of that OSI system adheres to the relevant protocol standards.

  In order to achieve conformance to this section, it is not required that the inter-layer interfaces be available for testing purposes.

- Conformance to the protocols requires:
  - that MPDUs correspond to instances of syntactically correct data units,
  - MPDUs in which the data present in the fields and the presence (or absence) of those fields is valid in type and semantics as defined in X.400, as qualified by this profile,

    correct sequences of protocol data units in responses (resulting from protocol procedures).
- Statements regarding the conformance of any one implementation to this profile are not complete unless a Protocol Implementation Conformance Statement (PICS) is supplied.
- The term "Implementation Under Test" (IUT) is interchangeable with the term "system" in the definition of conformance, and may refer to:
  - a domain, which may be one or more MTA's with co-located or remote UA's,
  - a single instance of an MTA and co-located UA with X.400 (P1, P2, RTS and session) software,
  - a relaying product with P1, RTS and session software,
  - a gateway product.
- Tests for conformance apply independently to:
  - origination,
  - reception,
  - relaying.

13.7.2 Conformance Requirements

Conformance to this specification requires that all the services listed as supported in sections 13.3 and 13.4 of these agreements are supported in the manner defined, in either the CCITT X.400 Recommendations or these agreements.

It is the intention to adopt, where and when appropriate the testing methodology and/or the abstract test scenarios currently being defined by the CCITT X.400 Conformance Group. However it is recognized that formal CCITT Recommendations relating to X.400 Conformance Testing will not be available until 1988.

13.7.2.1 Initial Conformance

This section is intended to provide guidelines to vendors who envisage having X.400 products available prior to any formal mechanism, or 'Conformance Test Center' being made accessible that would allow for conformance to this product specification to be tested.

It is feasible that vendors and carriers will want to enter bilateral test agreements that will allow for initial trials to be carried out for the purposes of testing initial interworking capabilities. It is equally feasible that for purposes of testing interoperability, only a subset of this specification will initially be tested. Therefore it is recommended that the following subset of total information be made accessible to allow for meaningful testing.

Note: By claiming conformance to this subset of information the vendor or carrier cannot claim conformance to this entire specification.

There are two aspects to the requirements, interworking and service, as described in the following sections.

13.7.2.1.1 Interworking

The interworking requirements for conformance implies that tests be done to check for the syntax and semantics of protocol data elements for a system as defined by their classifications (i.e., X, H, G, R, and M). For an origination system, this implies that the protocol elements generated must be correct. For a relay system, the correct protocol elements should be relayed as appropriate. And for a recipient system, a message with correct protocol elements must not be rejected where appropriate.

13.7.2.1.2 Service

For information available to the recipients via the IPMessage Heading and Body, the following should be made accessible:

- o IPMessage ID - only the PrintableString portion of the IPMessageId needs to be accessible.
- o subject
- o primaryRecipients
- o copyRecipients
- o blindCopyRecipients
- o authorizingUsers
- o originator
- o inReplyTo

- replyToUsers
- importance
- sensitivity
- IA5Text BodyPart

14. DIRECTORY SERVICES PROTOCOLS

APPENDIX A: INTERPRETATION OF SERVICE ELEMENTS

The work on service element definitions is limited to those that are defined as 'supported' in section 13.3 of this specification. Furthermore it is not the intent of this section to define how information should be made available or presented to a MHS user, nor is it intended to define how individual vendors should design their products. In addition, statements on conformance to a specific service element and the allocation of error codes that are generated as a result of violations of the service should be defined in the sections on conformance and errors as part of the main product specification. The main objective is to provide clarification, where required, on the functions of a service element, and in particular what the original intent of the Recommendations were.

SERVICE ELEMENTS

The following Service Elements defined in X.400 have been examined and require further text to be added to their definitions to represent the proposed implementation of these service elements by the X.400 SIG.

The service element clarifications are to be taken in the context of this profile.

Service elements not referenced in this section are as defined in X.400.

PROBE

A PRMD need not generate probes.

If a probe is addressed to and received by a PRMD, the PRMD must respond with a Delivery Report as appropriate at the time the probe was processed.

DEFERRED DELIVERY

In the absence of bilateral agreements to the contrary, Deferred Delivery and Deferred Delivery Cancellation are local matters (i.e., confined to the originating domain) and need not be provided.

The extension of Deferred Delivery beyond the boundaries of the initiating domain is via bilateral agreement as specified in Section 3.4.2.1 of X.411.

Content Type Indication

It is required that both an originating and recipient domain be able to support P2 content type. The ability for domains to be able to exchange content types other than P2 will depend on the existence of bilateral or multi-lateral agreements.

Original Encoded Information Types Indication

It is required that both an originating and recipient domain be able to support IA5 text. Support for other encoded information types, for the purposes of message transfer between domains, will depend on the existence of bilateral or multi-lateral agreements.

The use of the 'unspecified' form of encoded information type should only be used when the UMPDU content represents an SR-UAPDU or contains an auto-forwarded IM-UAPDU.

The original encoded information type of a message is not meaningful unless a message is converted en route to the recipient. These agreements support only IA5 text, which should not undergo conversion. The original encoded information types should be made accessible to the recipient for upward compatibility with the use of non-IA5 text message body parts.

Registered Encoded Information Types

A UMPDU with an 'unspecified' value for Original Encoded Information Type shall be delivered to the UA.

Delivery Notification

The UAContentID may be used by the recipient of the delivery notification for correlation purposes.

Disclosure of Other Recipients

This service is not made available by originating MTAE's to UAE's, but must be supported by relaying and recipient MTAE's.

By supporting the disclosure of other recipients the message recipient can be informed of the O/R names of the other recipient(s) of the message, as defined in the P1 envelope, in addition to the O/R Descriptors within the P2 header.

These agreements do not support initiation of disclosure of other recipients, but the information associated with it should be made accessible to the recipient for upward compatibility with support for the initiation of this service element.

Typed Body

As defined in X.400 with the addition of the Private Body Types that are to be supported. At present there is no mechanism provided within X.420 that would allow you to respond to reception of an unsupported body type.

Action taken in this situation is a local matter.

Blind Copy Recipient Indication

It should be considered that the recipient's UA acts on behalf of the recipient, and therefore may choose to disclose all BCC recipients to each other. Therefore it is the responsibility of the originating domain to submit two or more messages, depending on whether or not each BCC should be disclosed to each other BCC.

Auto Forwarded Indication

A UA may choose not to forward a message that was previously auto-forwarded. In addition there is no requirement for an IPM UA that does not support non-receipt or receipt notification to respond with a non-receipt notification when a message is auto-forwarded.

Primary and Copy Recipients Indication

It is required that at least one primary recipient be specified; however, for a forwarded message this need not be present. The recipient UA should be prepared to accept no primary and copy recipients to enable future interworking with Teletex, Fax, etc.

Sensitivity Indication

A message originator should make no assumptions as to the semantic interpretation by the recipients UA regarding classifications of sensitivity. For example, a personal message may be printed on a shared printer.

Reply Request Indication

In requesting this service an originator may additionally supply a date by which the reply should be sent and a list of the intended recipients of the reply. If no such list is provided then the initiator of the reply sends the reply to the originator of the message and any recipients the reply initiator wishes to include. The replytoUsers and the replyBy date may be specified without any explicit reply being requested. This may be interpreted by the recipient as an implicit reply request. Note that for an auto-forwarded message an explicit or implicit reply request may not be meaningful.

Body Part Encryption

The original encoded information type indication includes the encoded information type(s) of message body parts prior to encryption by the originating domain. The ability for the recipient domain to decode an encrypted body part is a local matter. Successful use of this facility can only be guaranteed if there exists bilateral agreements to support the exchange of encrypted body parts.

Forwarded IP message Indication

The following use of the original encoded information type in the context of forwarded messages is clarified:

- If forwarding a private message body part the originator of the forwarded message shall set the original encoded information types in the P1 envelope to undefined for that body part.

- The encoded information types of the message being forwarded should be reflected in the new original encoded information types being generated.

- See Appendix B on recommended practices for the use of the delivery information as part of Forwarded IP-message.

Multipart Body

It is the intent of multipart bodies to allow for the useful and meaningful structuring of a message that is constructed using differing body part types. For example, it is not recommended that a message made up of only IA5 text should be represented as a number of IA5 body parts, each one representing a paragraph of text.

APPENDIX B: RECOMMENDED PRACTICES

B.1 RECOMMENDED PRACTICES IN P2

1. ORDescriptor

   Vendors following the NBS/OSI Workshop guidelines shall, whenever possible, generate the ORName portion of an ORDescriptor in ALL IPM heading fields.

2. ForwardedIPMessage BodyParts

   ForwardedIPMessage BodyParts should be nested no deeper than eight. There is no restriction on the number of ForwardedIPMessage BodyParts at any given depth.

3. DeliveryInformation

   It is strongly recommended that DeliveryInformation be supplied in both forwarded and autoforwarded message body parts. DeliveryInformation is useful when a message has multiple forwarded message body parts because without it, the EncodedInformationType(s) of the component forwarded messages cannot be deduced easily. DeliveryInformation is useful for autoforwarded messages because the EncodedInformationType of an autoforwarded message is "unspecified" and the EncodedInformationType(s) of the message cannot be determined easily without it. Absence of the EncodedInformationType(s) makes it difficult for a UA to easily determine whether the message can be rendered.

B.2 RECOMMENDED PRACTICES IN RTS

1. In the case where S-U-ABORT indicates a temporaryProblem, reestablishment of the session should not be attempted for a "sensible" time period (typically not less than five minutes).

   In instances where this delay is not required or necessary, report a localSystemProblem.

2. S-U-EXCEPTION-REPORT reason codes can be interpreted as follows:

   - o receiving ability jeopardized (value 1)
     Possible meaning: The receiving RTS knows of an impending system shutdown.

   - o local ss-User error (value 5)
     Possible meaning: <for further study>.

   - o irrecoverable procedure error (value 6)
     Possible meaning: the current activity is NOT recoverable.

   - o non specific error (value 0)
     Possible meaning: <for further study>.

   - o sequence error (value 3): The S-ACTIVITY-RESUME request specified a minor synchronization point serial number which does not match the checkpoint data.

B.3 RECOMMENDED PRACTICES WITH X.409

The following practices are recommended for use with X.409.

1. The maximum length of a primitive data element is 256.

2. Bit Strings should be built using primitive form. The constructor form should not be used except in the case of very long Bit Strings (e.g., 63Fax or Voice).

3. All defined bits of a Bit String should be present.

   - o Note that, in accordance with X.409, defined bits need not be present; missing bits are assumed to be zero.

   - o To ensure upward compatibility, Bit Strings of excess length must also be allowed; the excess bits are ignored.

4. The maximum definite length should be (2**32)-1. <For further study>.

5. It is intended that implementations support upwardly compatible changes to X.409, as defined in Version 3 of the X.400-Series Implementor's Guide, but no guarantees will be made about initial implementations.

6. The concrete encoding of ANY must be a valid X.409 type, and can only be omitted if it is an OPTIONAL element in a SET or SEQUENCE.

B.4 RECOMMENDED PRACTICES FOR ORName

Table 13.3.8 stipulates that the StandardAttributeList must contain either PrivateDomainName or OrganizationName. It is recommended that, for both originator and recipients in a private domain, the PrivateDomainName field be used.

It is recommended that there should be a DomainDefinedAttribute to be used in addresing UAs in existing mail systems, in order to curtail the proliferation of different types of DomainDefinedAttributes used for the same purpose. The syntax of this DomainDefinedAttribute conforms to the CCITT Pragmatic Constraints, and thus has a maximum value length of 128 octets and a type length of 8 octets, each of type Printable String. Only one occurrence is allowed.

This DomainDefinedAttribute has the type name "ID" (in uppercase). It contains the unique identifier of the UA used in addressing within the domain. This DomainDefinedAttribute is to be exclusively used for routing within the destination domain (i.e., once routed to that domain via the mandatory components of the StandardAttributeList); any other components of the StandardAttributeList may be provided. If they conflict delivery is not made.

The contents of this parameter need not be validated in the originating domain or any relaying domain, but simply transferred intact to the next MTA or domain.

APPENDIX C: RENDITION OF IA5Text AND T61String CHARACTERS

C.1 GENERATING AND IMAGING IA5Text

The characters that may be used in an IA5String are the graphic characters (including Space), control characters and Delete of the IA5 character repertoire ISO 646.

The graphic characters that may be used with a guaranteed rendition are those related with positions 2/0 to 2/2, 2/5 to 3/15, 4/1 to 5/10, 5/15 and 6/1 to 7/10 in the basic 7-bit code table.

The other graphic characters may be used but have no guaranteed rendition.

The control characters that may be used but have no guaranteed effect are a subset consisting of the format effectors 0/10 (LF), 0/12 (FF) and 0/13 (CR) provided they are used in one of the following combinations:

CR LF	to start a new line
CR FF	to start a new page (and line)
LF .. LF	to show empty lines (always after one of the preceding combinations).

The other control characters or the above control characters in different combinations may be used but have no guaranteed effect.

The character Delete may occur but has no guaranteed effect. The IA5String in a P2 IA5Text BodyPart represents a series of lines which may be divided into pages. Each line should contain from 0 to 80 graphic characters for guaranteed rendition. Longer lines may be arbitrarily broken for rendition. Note that X.408 states that for conversion from IA5Text to Teletex, the maximum line length is 77 characters.

C.2 GENERATING AND IMAGING T61String

For further study.

APPENDIX D: FTAM DOCUMENT TYPES

Part 1: Document Types
Part 2: Constraint Sets
Part 3: Abstract Syntaxes
Part 4: Transfer Syntaxes

Part 1: Document Types

Entry number: NBS-1

Document Type Name:

{ISO registration-authority NBS FTAM( ) document(6) UNDEF(0)}

Document Descriptor Value: unstructured binary file

Document Semantics:

The document consists of a single data unit. The data unit consists of an unbounded sequence of data elements. Each data element is is an octet string.
Note: The boundaries between transferred data elements are not maintained by the filestore.

Scope and Field of Application:

This document type defines the contents of a file for storage and for transfer using FTAM.

Constraint Set Name:

{ISO standard 8571 constraint set name(5) unstructured(1)}

Abstract Syntax:

The abstract syntax of each Data Element is an instance of the ASN.1 data type OctetString.

Abstract Syntax Name:

{ISO registration-authority NBS FTAM( ) abstract syntax(2) NBS-AS1(0)}

Transfer Syntax:

An implementation supporting this abstract syntax shall support a transfer syntax for each data element obtained by applying the ASN.1 Basic Encoding Rules (ISO x825) to the data element and concatenating the resulting octets.

Note: This transfer syntax is not self-delimiting.

Implementations may optionally support other named transfer syntaxes for this abstract syntax.

Transfer Syntax Name:

{ISO registration-authority NBS FTAM( ) transfer syntax(3) NBS-TS1(0)}

Concatenation:

Concatenation of this type with itself is possible, and produces a document of the same type consisting of one data unit which is the concatenation of the octet string(s) from one file with the octet string(s) of the other file.

Note: The boundary of the original octet string(s) is no longer visible.

Simplifications:

A document of this type cannot be accessed as any other document type.

Entry Number: NBS-2

Document Type Name:

{ISO registration-authority NBS FTAM( ) document(6) VARCRLF(1)}

Document Descriptor Value: unstructured text file

Document Semantics:

The document consists of a single data unit. The data unit consists of an unbounded sequence of data elements. Each data element is an IA5String. The last two characters of each data element are carriage return followed by line feed. Neither the character carriage return nor the character line feed may appear elsewhere in the data element.

Note: The boundaries between transferred data elements are not maintained by the filestore.

Scope and Field of Application:

The document type defines the contents of a file for transfer using FTAM.

Note that this document type should only be used for transferring entire text files in the case where NBS-4 is not supported. It has an implicit structure which allows, for example, text files stored in UNIX format (lines terminated by LF) to be converted to a format in which lines are terminated by CR followed by LF and vice versa.

Constraint Set Name:

{ISO standard 8571 constraint set name(5) unstructured(1)}

Abstract Syntax:

The abstract syntax of each Data Element is an instance of the ASN.1 data type IA5String.

Abstract Syntax Name:

{ISO registration-authority NBS FTAM( ) abstract syntax(2) NBS-AS1(0)}

Transfer Syntax:

An implementation supporting this abstract syntax shall support a transfer syntax for each data element obtained by applying the ASN.1 Basic Encoding Rules (ISO 8825) to the data element and concatenating the resulting octets.

Note: This transfer syntax is not self-delimiting.

Implementations may optionally support other named transfer syntaxes for this abstract syntax.

Transfer Syntax Name:

{ISO registration-authority NBS FTAM( ) transfer syntax(3) NBS-TS1(0)}

Concatenation:

Concatenation of this type with itself is possible, and produces a document of the same type consisting of one data unit which is the concatenation of the octet string(s) from one file with the octet string(s) of the other file.

Note: The boundary of the original octet string(s) is no longer visible.

Simplification:

A document of this type can be accessed as a document of type NBS-1 by specifying a document type of NBS-1 in the Contents Type parameter of the F-OPEN request, and limiting access context to US on F-READ.

Entry Number: NBS-3

Document Type Name:

{ISO registration-authority NBS FTAM( ) document(6) 8859VARCRLF(2)}

Document Descriptor Value: unstructured text file

Document Semantics:

The document consists of a single data unit. The data unit consists of an unbounded sequence of data elements. Each data element is an 8859String. The last two characters of each data element are carriage return followed by line feed. Neither the character carriage return nor the character line feed may appear elsewhere in the data element.

Note: The boundaries between transferred data elements are not maintained by the filestore.

Scope and Field of Application:

The document type defines the contents of a file for transfer using FTAM.

Note that this document type should only be used for transferring entire text files in the case where NBS-5 is not supported. It has an implicit structure which allows, for example, text files stored in UNIX format (lines terminated by LF) to be converted to a format in which lines are terminated by CR followed by LF and vice versa.

Constraint Set Name:

{ISO standard 8571 constraint set name(5) unstructured(1)}

Abstract Syntax:

The abstract syntax of each data element is an instance of the data type 8859String.

Abstract Syntax Name:

{ISO registration-authority NBS FTAM( ) abstract syntax(2) NBS-AS1(0)}

Transfer Syntax:

An implementation supporting this abstract syntax shall support a transfer syntax for each data element obtained by applying the ASN.1 Basic Encoding Rules (ISO 8825) to the data elements and concatenating the resulting octets.

Note: This transfer syntax is not self-delimiting.

Implementations may optionally support other named transfer syntaxes for this abstract syntax.

Transfer Syntax Name:

{ISO registration-authority NBS FTAM( ) transfer syntax(3) NBS-TS1 (0)}

Concatenation:

Concatenation of a document of this type with another document of this type is possible and produces a document of the same type consisting of one data unit which is the concatenation of the octetstring(s) of one file with the octetstring(s) of the other file.

Note: The boundary of the original OctetString is no longer visible.

Simplification:

A document of type NBS-3 can be accessed as a document of type NBS-1 by specifying a document type of NBS-1 in the Contents Type parameter of the F-OPENrequest, and limiting access context to US on F-READ.

Entry number: NBS-4

Document type name:

{ISO registration-authority NBS FTAM( ) document(6) Text(3) parameter}

Note: "parameter" is a parameter which will be appended to the registered identifier in an OBJECT IDENTIFIER.

Document Descriptor Value: Sequential Text File

Document Semantics:

The document consists of an unbounded series of data units. Each data unit contains one data element which is a character string. Each character is taken from the IA5 character set.

Scope and Field of Application:

The document type defines the contents of a file for storage and for transfer using FTAM.

Note: Storage refers to apparent storage within the virtual filestore.

Constraint Set Name:

{ISO standard 8571 constraint set name(5) sequential flat(2)}

Additional Constraints:

FADU Identity will be limited to begin, end, first and next.

Abstract Syntax:

The abstract syntax of each data element is an instance of the data type IA5String.

The abstract syntax of each data unit is specified by the parameter.

Abstract Syntax Name:

{ISO registration-authority NBS FTAM( ) abstract syntax(2) NBS-AS1(0)}

Transfer Syntax:

An implementation supporting this abstract syntax shall support a transfer syntax for each data element obtained by applying the ASN.1 Basic Encoding Rules (ISO 8825) to the data elements and concatenating the resulting octects.

Note: This transfer syntax is not self-delimiting.

Implementations may optionally support other named transfer syntaxes for this abstract syntax.

Transfer Syntax Name:

{ISO registration-authority NBS FTAM( ) transfer syntax(3) NBS-TS1(0)}

Concatenation:

Concatenation of a document of this type with another document of this type is possible and produces a document of the same type consisting of a series of IA5Strings which is the result of placing the series of IA5Strings from one file of this type after the last IA5String in the original file.

Note: The boundary of the original sequence is no longer visible.

Simplification:

A document of type NBS-4 can be accessed as a document of type NBS-1 by specifying a document type of NBS-1 in the Contents Type parameter on the F-OPENrequest, and limiting access context to UA on F-READ.

Entry number: NBS-5

Document Type Name:

{ISO registration-authority NBS FTAM( ) document(6) 8859Text(4) parameter}

Note: "parameter" is a parameter which will be appended to the registered identifier in an Object Identifier.

Document Descriptor Value: Sequential Text File

Document Semantics:

The document consists of an unbounded series of data units. Each data unit contains one data element which is a character string. Each character is taken from the ISO 8859/1 character set.

Scope and Field of Application:

The document type defines the contents of a file for storage and transfer using FTAM.

Note: Storage refers to apparent storage within the virtual filestore.

Constraint Set Name:

{ISO standard 8571 constraint set name(5) sequential flat(2)}

Additional Constraints:

FADU Identity will be limited to begin, end, first and next.

Abstract Syntax:

The abstract syntax of each data element is an instance of the data type 8859String.

The abstract syntax of each data unit is specified by the parameter.

Abstract Syntax Name:

{ISO registration-authority NBS FTAM( ) abstract syntax(2) NBS-AS1(0)}

Transfer Syntax:

An implementation supporting this abstract syntax shall support a transfer syntax for each data element obtained by applying the ASN.1 Basic Encoding Rules (ISO 8825) to the data elements and concatenating the resulting octets.

Note: This transfer syntax is not self-delimiting.

Implementations may optionally support other named transfer syntaxes for this abstract syntax.

Transfer Syntax Name:

{ISO registration-authority NBS FTAM( ) transfer syntax(3) NBS-TS1 (0)}

Concatenation:

Concatenation of a document of this type with another document of this type is possible and produces a document of the same type consisting of a series of 8859Strings which is the result of placing the series of 8859Strings from one file immediately following the last 8859String in the original file.

Note: The boundary of the original series is no longer visible.

Simplification:

A document of type NBS-5 can be accessed as a document of type NBS-1 by specifying a document type of NBS-1 in the Contents Type parameter on F-OPENrequest, and limiting access context to UA on F-READ.

Entry Number: NBS-6

Document Type Name:

{ISO registration-authority NBS FTAM( ) document(6) SEQUENTIAL(5) parameter}

Note: "parameter" is a parameter which will be appended to the registered identifier in an Object Identifier.

Document Descriptor Value: Sequential File

Document Semantics:

The document consists of an unbounded series of data units. Each data unit contains an unbounded series of data elements. Each data element is a data type from the set of primitive data types defined in the main body of this document. Each data unit contains the same data element types in the same order as all other data units.

Scope and Field of Application:

The document type defines the contents of a file for storage and transfer using FTAM.

Note: Storage refers to apparent storage within the virtual filestore.

Constraint Set Name:

{ISO standard 8571 constraint set name(5) sequential flat(2)}

Additional Constraints:

FADU Identity will be limited to begin, end, first, and next.

Abstract Syntax:

The abstract syntax of each data element is an instance of one of the primitive data types defined in the main body of this document.

The Abstract syntax of each data unit is specified by the parameter.

Abstract Syntax Name:

{ISO registration-authority NBS FTAM( ) abstract syntax(2) NBS-AS1(0)}
optionally, {ISO registration-authority NBS FTAM( ) abstract syntax(2) NBS-AS2(1)}

Transfer Syntax:

An implementation supporting this abstract syntax shall support a transfer

syntax for each data element obtained by applying the ASN.1 Basic Encoding Rules (ISO 8825) to the data elements and concatenating the resulting octets.

Note: This transfer syntax is not self-delimiting.

Implementations may optionally support other named transfer syntaxes for this abstract syntax.

Transfer Syntax Name:

{ISO registration-authority NBS FTAM( ) transfer syntax(3) NBS-TS1(0)}

Concatenation:

Concatenation of a document of this type with another document of this type is possible and produces a document of the same type consisting of a series of data units which is the result of placing the series of data units from one file immediately following the last data unit of the original file.

Note: The boundary of the original file is no longer visible.

Simplification:

A document of type NBS-6 can be accessed as a document of type NBS-1 by specifying a document type of NBS-1 in the Contents Type parameter in the F-OPENrequest, and limiting access context to UA on F-READ.

Entry number: NBS-7

Document Type Name:

{ISO registration-authority NBS FTAM( ) document(6) RANDOM(6) parameter}

Note: "parameter" is a parameter which will be appended to the registered identifier in an Object Identifier.

Document Descriptor Value: Random Access File

Document Semantics:

The document consists of an unbounded series of data units. Each data unit contains an unbounded series of data elements. Each data element is a data type from the set of primitive data types defined in the main body of this document. Each data unit contains the same data types in the same order as all other data units in the file.

Scope and Field of Application:

The document type defines the contents of a file for storage and transfer using FTAM.

Note: Storage refers to apparent storage within the virtual filestore.

Constraint Set Name:

{ISO registration-authority NBS FTAM( ) constraint set name(5)
NBS Ordered Flat(2)}

Abstract Syntax:

The abstract syntax of each data element is an instance of one of the primitive data types defined in the main body of this document.

The abstract syntax of each data unit is specified by the parameter.

Abstract Syntax Name:

{ISO registration-authority NBS FTAM( ) abstract syntax(2) NBS-AS1(0)} optionally, {ISO registration-authority NBS FTAM( ) abstract syntax(2) NBS-AS2(1)}

Transfer Syntax:

An implementation supporting this abstract syntax shall support a transfer syntax for each data element obtained by applying the ASN.1 Basic Encoding Rules (ISO 8825) to the data element and concatenating the resulting octets.

Note: This transfer syntax is not self-delimiting.

Implementations may optionally support other named transfer syntaxes for this abstract syntax.

Transfer Syntax Name:

{ISO registration-authority NBS FTAM( ) transfer syntax(3) NBS-TS1(0)}

Concatenation:

Concatenation of a document of this type with another document of this type is possible and produces a document of the same type consisting of a series of data units which is the result of placing the series of data units from one file immediately following the last data unit of the original file.

Note: The boundary of the original file is no longer visible.

Simplification:

A document of type NBS-7 can be accessed as a document of type NBS-1 by specifying a document type of NBS-1 in the Contents Type parameter of the F-OPENrequest, and limiting access context to UA on F-READ.

A document of type NBS-7 can be accessed as a document of type NBS-6 by specifying a document type of NBS-6 in the Contents Type parameter of the F-OPENrequest.

Entry Number: NBS-8

Document Type Name:

{ISO registration-authority NBS FTAM( ) document(6) INDEXED(7) p1 p2}

Note: "p1" and "p2" are parameters which will be appended to the registered identifer in an Object Identifier.

Document Descriptor Value: Indexed Sequential File

Document Semantics:

The document consists of an unbounded series of data units. Each data unit is an unbounded series of data elements. Each data element is a data type from the set of primitive data types defined in the main body of this document. Each data unit contains the same data types in the same order as all other data units in the file.

Each data unit in the file has a key associated with it. The key of each data unit is of the same data type as the key of all other data units in the file and is a single data element from the set of primitive data types defined in the main body of this document.

The primitive data types and minimum size range of each unit which an implementation must accept as a key value are given in the following table.

Key Type	Minimum Range (octets)
ASN.1 Integer	(1-2)
ANS.1 IA5String	(0-16)
NBS-AS1 8859String	(0-16)
ASN.1 OctetString	(0-16)
ASN.1 GeneralizedTime	
ASN.1 UniversalTime	
NBS-AS2 FloatingPoint	

Scope and Field of Application:

The document type defines the contents of a file for storage and for transfer using FTAM.

Constraint Set Name:

{ISO registration-authority NBS FTAM( ) constraint set name(2)
Indexed Flat(1)}

Abstract Syntax:

The abstract syntax of each data element is an instance of one of the primitive data types defined in the main body of this document.

The Abstract syntax of each data unit is specified by the parameter p1.

The Abstract syntax of the data unit key (FADU Identifier) is specified by the parameter p2.

Abstract Syntax Name:

{ISO registration-authority NBS FTAM( ) abstract syntax(2) NBS-AS1(0)}
optionally, {ISO registration-authority NBS FTAM( ) abstract syntax(2)
NBS-AS2(1)}

Transfer Syntax:

An implementation supporting this abstract syntax shall suport a transfer syntax for each data element obtained by applying the ASN.1 Basic Encoding Rules (ISO 8825) to the data elements and concatenating the resulting octets.

Note: This transfer syntax is not self-delimiting.

Implementations may optionally support other named transfer syntaxes for this abstract syntax.

Transfer Syntax Name:

{ISO registration-authority NBS FTAM( ) transfer syntax(3) NBS-TS1(0)}

Concatenation:

A document of this type may not be concatenated with a document of this type or any other type.

Simplification:

A document of type NBS-8 can be accessed as a document of type NBS-1 by specifying document type NBS-1 in the Contents Type parameter on the F-OPENrequest, and limiting access context to UA on F-READ.

A document of type NBS-8 can be accessed as a document of type NBS-6 by specifying document type NBS-6 in the Contents Type parameter on the F-OPENrequest.

A document of type NBS-8 can be accessed as a document of type NBS-7 by specifying document type NBS-7 in the Contents Type parameter on the F-OPENrequest.

Entry Number: NBS-9

Document Type Name:

{ISO registration-authority NBS FTAM( ) document(6) FILE_DIRECTORY(8)}

Document Descriptor Value: FileDirectory File

Document Semantics:

The document consists of an unbounded sequence of data units. Each data unit consists of one and only one data element of type FileDirectoryEntry (a complex data type defined in the main body of this document).

Scope and Field of Application:

This document defines the contents of a file for transfer (not for storage) using FTAM.

Constraint Set Name:

{ISO registration-authority NBS FTAM( ) constraint set name(5) Sequential Flat(1)}

Additional Constraints:

FileDirectory Files may be Selected, Opened, Read, Closed, Created, and Deleted. They may not be Written or Modified (except as a side-effect of actions performed on individual files contained within a FileDirectory). DataUnits within a FileDirectory may only be accessed sequentially.

Abstract Syntax:

An indefinite series of data units. Each data unit contains one data element of type FileDirectoryEntry. Each data element consists of a required FileName and a number of optional Attributes.

Abstract Syntax Name:

{ISO registration-authority NBS FTAM( ) abstract syntax(3) filedirectory entry(0)}

Transfer Syntax:

An implementation supporting this data type shall support a transfer syntax for each data value obtained by applying ASN.1 Basic Encoding Rules to the data type FileDirectoryEntry in the data value and concatenating the resulting octets.

Note: This transfer syntax is not self-delimiting.

Implementations may also support other named transfer syntaxes for this abstract syntax.

Transfer Syntax Name:

{ISO registration-authority NBS FTAM( ) transfer syntax(3) NBS-TS1(0)}

Concatenation:

A document of this type cannot be concatenated with a document of this type or any other type.

Simplification:

A document of this type cannot be simplified.

Part 2: Constraint Sets

Constaint Set Title: NBS-Ordered Flat

Constraint Set Name:

{ISO registration-authority NBS FTAM( ) constraint set name(5)
NBS Ordered Flat(2)}

Field of Application: Files which are structured into a sequence of individual FADUs and to which access may be made on a FADU basis by position in the sequence.

Node Names: none

Actions: Locate, Read, Replace, Insert, Erase

Special Action Parameters: none

Special Action Semantics:
Erase: Used on the root node to empty the file. When used on a leaf node, it leaves a FADU with no associated data unit.
Insert: Allowed only at end of file. The new node is inserted following all existing nodes in the file or on a leaf node with no existing data unit. The inserted data unit is asociated with the currently existing leaf node.

Available Access Contexts: HA, FA, UA, US

Erase and Locate Context: HA

Constraints on Structure: The root node shall not have an associated data unit. All children of the root node shall be leaf nodes and may have an associated data unit. All arcs from the root node shall be of length one.

Creation State: Root node without an associated data unit.

FADU Identity: begin, end, first, last,
current, next, previous,
traversal number (greater than or equal to one)

Location After Open: root node

Beginning of File: root node

End of File: No node is selected. Previous gives the last node in the traversal sequence, current and next result in an error.

Constraint Set Title: Indexed Flat

Constraint Set Name:

{ISO registration-authority NBS FTAM( ) constraint set name(5)
NBS Indexed Flat(1)}

Field of Application: This constraint set is for representing single key ISAM files where the keys are the FADU identifiers for the leaf nodes. The keys are restricted to being single primitive data types, and restricted to all keys being of the same primitive data type.

Node Names: Any single primitive data type.

Actions: Locate, Read, Replace, Insert, Erase

Special Action Parameters: none

Special Action Semantics:

Locate: The specified FADU is made the current FADU. If the FADU Id form is used, the least recently inserted FADU with the specified FADU at level 1 is located.

Read: Allowed at root and leaves. If there is another FADU after (in pre-order traversal order) the one read with the same FADU Id, a diagnostic on TRANSFER_END will indicate this fact.

Insert: Insert the specified FADU (level 1 only) in the lexical order of the key primitive data type. Ifthere is already another FADU with the specified FADU Id, insert the new one after (in pre-order traversal) the existing FADUs and indicate that this was done via a diagnostic on TRANSFER_END.

Replace: Allowed only at leaves and only in access context US (DU only w/o delimiters). Only allowed with write operation of "current" (i.e., preceded by locate) or "Previous" (i.e., preceded by read).

Erase: If the addressed FADU is the root, the file is reduced to the initial state.

Available Access Contexts: HA, FA, UA, US

Erase and Locate Context: HA

Constraints on Structure: The root node shall not have an associated data unit or/and FADU Id. All children of the root node shall be leaf nodes and shall have an associated data unit and FADU Id. All arcs from the root node shall be of length one. Some primitive types may not be supported as keys.

Creation State: Root node without an associated data unit or FADU Id.

FADU Identity: begin, end,
current, next, previous,
FADU Id

Location After Open: root node

Beginning of File: root node

End of File: No node is selected. Previous gives the last node in the traversal sequence, current and next result in an error.

Part 3: Abstract Syntaxes

Abstract Syntax: NBS-AS1

Abstract Syntax Name:

{ISO registration-authority NBS FTAM( ) Abstract Syntax(2) Basic(0)}

Abstract Syntax Definition:

```
DE ::=Choice{INTEGER,
             BOOLEAN,
             IA5String,
             8859String,
             OCTETSTRING,
             UniversalTime,
             GeneralizedTime,
             Null}
8859String ::=[PRIVATE 1] Implicit 8859CharacterString

Transfer syntax name:     -- 8859CharacterString is a string of characters from
                             the ISO 8859 character set
{ISO registration-authority NBS FTAM( ) Transfer Syntax(4) NBS-TS1 (0)}
```

Abstract Syntax: NBS-AS2

Abstract Syntax Name:

{ISO registration-authority NBS FTAM( ) abstract syntax(2) FloatingPoint(1)}

Abstract Syntax Definition:

```
      FloatingPointNumber ::= [PRIVATE 0] CHOICE
              {
                 finite [0] IMPLICIT SEQUENCE
                 {
                           Sign,
                           mantissa BITSTRING,
                           exponent INTEGER
                        },
                  infinity [1] IMPLICIT Sign,
                  signalling NaN [2] Implicit NaN,
                  quietNaN [3] IMPLICIT NaN,
                  zero [4] IMPLICIT NULL
              }
       Sign ::= INTEGER ({positive(0), negative(1)}

       NaN ::= INTEGER
```

Transfer Syntax Name:

{ISO registration-authority NBS FTAM( ) transfer syntax(3) NBS-TS1(0)}

Abstract Syntax: NBS-AS3

Abstract Syntax Name:

{ISO registration-authority NBS FTAM( ) abstract syntax(2) FileDirectoryElement(2)}

Abstract Syntax Definition:

```
    FileDirectoryEntry ::=[PRIVATE 2] IMPLICIT SEQUENCE{
                                    fileName GraphicString,
                                      ContentsType}
  ContentsType ::=CHOICE
                document-type-Name[0] IMPLICIT OBJECT IDENTIFIER,
                constraint-set-and-abstract-syntax [1] IMPLICIT SEQUENCE{
                        constraint-set-Name[0] IMPLICIT OBJECT IDENTIFIER,
                        Abstract-syntax-Name[1] IMPLICIT OBJECT IDENTIFIER}
```

Transfer Syntax Name:

{ISO registration-authority NBS FTAM( ) transfer syntax(3) NBS-TS1(0)}

Part 4: Transfer Syntaxes

Transfer Syntax: NBS-TS1

Transfer Syntax Name:

{ISO registration-authority NBS FTAM( ) transfer syntax(3) NBS-TS1(0)}

Encoding Rules:

ASN.1 Basic Encoding Rules shall apply.

The first bit of a "mantissa" must be "1".

Transfer Syntax Definition:

The transfer syntax shall be that which results from applying the encoding rules described above to the individual data elements.

APPENDIX E: KNOWN ERRORS IN ISO AND CCITT DOCUMENTS

This appendix lists errors that are known in ISO and CCITT documents. Known errors are removed from this appendix when corrected text is available from ISO and CCITT. This appendix is for information only.

FTAM DIS Errors

Following is a list of known errors in the FTAM DIS which are expected to be corrected in the forthcoming IS. These errors are listed here for information only and will be removed when the IS text is available.

1. The Access Context parameter on the F-READrequest and F-WRITErequest is specified as OPTIONAL instead of mandatory in the FTAM protocol abstract syntax.

The expected correction is to make this parameter mandatory.

2. The Contents Type List is defined as a SEQUENCE of Document Type Name and Constraint-Set, Abstract-Syntax in the FTAM protocol abstract syntax.

The expected solution is to use the following definition:

```
Contents-Type-List ::= IMPLICIT SEUENCE OF CHOICE{
   document-types [0] IMPLICIT Document-Type-Name,
   constraint-set-and-abstract-syntax[1] IMPLICIT SEQUENCE
      constraint-sets [0] IMPLICIT Constraint-Set-Name
      abstract-syntax [1] IMPLICIT Abstract-Syntax-Name}
```

3. The processing-mode parameter on the F-OPEN request is not defined correctly in the FTAM protocol abstract syntax.

The expected correction is:

```
processing-mode [0] IMPLICIT BITSTRING {
                    read (0),
                    insert (1),
                    replace (2),
                    erase (3),
                    extend (4) }
```

4. In part 2 clause 5.3.2 the application tags conflict with tags in part 4 in the protocol abstract syntax.

The expected correction is to use the following definitions in part 2 clause 5.3.2:

```
Node-Descriptor-Data-Element ::= [Application 21] IMPLICIT...
Enter-Subtree-Data-Element   ::= [Application 22] Implicit Null...
Exit-Subtree-Data-Element    ::= [Application 23] IMPLICIT Null...
```

5. An object identifier for the CASE protocol abstract syntax is not defined.

The expected correction is:

{iso standard 8650 abstract syntax (1) acse (1)}

ADDENDUM 1

Note on FTAM and X.400 Character Sets

On July 21, 1986, a group of twelve individuals from the FTAM and X.400 SIGs met to resolve differences in recommended use of character sets. The following was agreed (in favor, 9; opposed, 2; abstaining, 1) by these individuals:

"Both SIGs should implement IA5 for the current phase of development, and independently support expanded character sets. It is recommended that the FTAM and X.400 SIGs support both 8859/1 and 6937/2 in the next phase of their agreements."

Neither SIG brought forward to the plenary on Thursday, July 24, 1986, a recommendation on this issue. However, it was raised for plenary discussion. The plenary felt (in favor, 22; opposed, 3; abstaining, 1) that this information should be carried in some form in this document in addition to inclusion in the minutes. Hence, it is included as an addendum so as to keep the information associated with this document while showing that it has not been accepted for inclusion in the main body of this document.

Index

You will receive the documents from the next workshop by either attending the workshop or completing and returning the form below.

☐ Document describes a computer program; SF-185, FIPS Software Summary, is attached.

11. ABSTRACT (A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here)

This document records current agreements on implementation details of Open Systems Interconnection protocols among the organizations participating in the NBS/OSI Workshop Series for Implementors of OSI Protocols. These decisions are documented to facilitate organizations in their understanding of the status of agreements. This is a standing document that is updated after each workshop (about every two and one-half months). A reference list of standards and a list of contributing organizations are included in the Appendix.

12. KEY WORDS (Six to twelve entries; alphabetical order; capitalize only proper names; and separate key words by semicolons)

local area networks; NBS/OSI Workshop; network protocols; Open systems interconnection; OSINET; testing protocols
