Technical Progress Bulletin

Covering Center Programs, July to September 1986 with 1987 CEEE Events Calendar

June 1987

U.S. Department of Commerce National Bureau of Standards National Engineering Laboratory Gaithersburg, Maryland 20899

INTRODUCTION TO JUNE 1987 ISSUE OF THE CEEE TECHNICAL PROGRESS BULLETIN

This is the sixteenth issue of a quarterly publication providing information on the technical work of the National Bureau of Standards Center for Electronics and Electrical Engineering. This issue of the <u>CEEE Technical Progress Bulletin</u> covers the third quarter of calendar year 1986.

Organization of Bulletin: This issue contains abstracts for all Center papers released for publication by NBS in the quarter and citations and abstracts for Center papers published in the quarter. Entries are arranged by technical topic as identified in the table of contents and alphabetically by first author under each subheading within each topic. Unpublished papers appear under the subheading "Released for Publication". Papers published in the quarter appear under the subheading "Recently Published". Following each abstract is the name and telephone number of the individual to contact for more information on the topic (usually the first author). This issue also includes a calendar of Center conferences and workshops planned for calendar year 1987 and a list of sponsors of the work.

Center for Electronics and Electrical Engineering: Center programs provide national reference standards, measurement methods, supporting theory and data, and traceability to national standards.

The metrological products of these programs aid economic growth by promoting equity and efficiency in the marketplace, by removing metrological barriers to improved productivity and innovation, by increasing U. S. competitiveness in international markets through facilitation of compliance with international agreements, and by providing technical bases for the development of voluntary standards for domestic and international trade. These metrological products also aid in the development of rational regulatory policy and promote efficient functioning of technical programs of the Government.

The work of the Center is divided into two major programs: the Semiconductor Technology Program, carried out by the Semiconductor Electronics Division (formerly the Semiconductor Materials and Processes and the Semiconductor Devices and Circuits Divisions) in Gaithersburg, MD, and the Signals and Systems Metrology Program, carried out by the Electrosystems Division in Gaithersburg and the Electromagnetic Fields and Electromagnetic Technology Divisions in Boulder, CO. Key contacts in the Center are given on the back cover; readers are encouraged to contact any of these individuals for further information. To request a subscription or for more information on the <u>Bulletin</u>, write to CEEE Technical Progress Bulletin, National Bureau of Standards, Metrology Building, Room B-358, Gaithersburg, MD 20899 or call (301) 975-2220.

Center sponsors: The Center Programs are sponsored by the National Bureau of Standards and a number of other organizations, in both the Federal and private sectors; these are identified on page 24.

Note on Publication Lists: Guides to earlier as well as recent work are the publication lists covering the work of each division. These lists are revised and reissued on an approximately annual basis and are available from the originating division. The current set is identified in the Additional Information section, page 22.

Silicon Materials

Released for Publication

Hyland, S.L., Ast, P.G., and Baghdadi, A., Oxygen Measurements in Thin Ribbon Silicon, to be published in a Special Issue on Shaped Crystal Growth of the Journal of Crystal Growth.

The oxygen content of thin silicon ribbons grown by the dendritic web technique was measured using a modification of the ASTM method based on Fourier transform infrared spectroscopy. Web silicon was found to have a high oxygen content, ranging from 13 to 19 ppma, calculated using the new ASTM conversion coefficient. The oxygen concentration changed by about 10% along the growth direction of the ribbon. In some samples, a shoulder was detected on the absorption peak associated with interstitial oxygen. A similar shoulder in Czochralski grown material has been variously interpreted in the literature as due to a complex of silicon, oxygen, and vacancies, or to a phase of SiO, developed along dislocations in the material. In the case of web silicon, it is not clear which is the correct interpretation of this peak. [Contact: Aslan Baghdadi, (301) 975-20621

Thurber, W.R., and Lowney, J.R., Methods for Accurate Determination of Emission Rate and Trap Concentration with Application to Platinum-Doped Silicon.

A detailed analysis of junction capacitance was developed which allows one to extract accurate values of emission rate and trap concentration from isothermal transient capacitance measurements. Experiments were performed on silicon diodes doped with platinum. The capacitance-ratio method of determining the emission rate was used to remove the nonexponentiality due to large trap concentration from the capacitance

transients. Arrhenius plots of scaled emission rate gave $E_A = 0.2271 \pm$ 0.0002 eV for the platinum acceptor level in n-type silicon, and $E_{h} =$ 0.3215 ± 0.0012 eV for the platinum donor level in p-type silicon. A new method for determining the trap concentration is derived and verified by use of simulations and data. This method involves the subtraction of capacitance values obtained from two transients with the same fill voltage, but different reverse voltages. It is much simpler than methods which require iterative solutions of Poisson's equation and a priori knowledge of the trap energy. [Contact: W. Robert Thurber, (301) 975-2067]

Analysis Techniques

Wachnik, R.A., The Use of Charge Pumping to Characterize Generation by Interface Traps, IEEE Transactions on Electron Devices, Vol. ED-33, No. 7, pp. 1054-1061 (July 1986).

A small rectangular pulse technique for measuring the charge pumping current has been proposed as a method to character-

Analysis Techniques (cont'd.)

ize interface traps near mid-gap. It is shown theoretically and experimentally that the small rectangular pulse technique can be used to predict the surface generation current measured on a metal oxide-semiconductor field-effect transistor or a gated diode. This new technique has the advantage that the measured current is at least 10 to 100 times larger than the surface generation current. [Contact: Gary P. Carver, (301) 975-

Postek, M.T., Electron Detection Modes and Their Relation to Linewidth Measurement in the Scanning Electron Microscope, Proceedings of the 44th Annual Meeting of the Electron Microscopy Society of America, Albuquerque, New Mexico, August 10-15, 1986, pp. 646-649.

The basic premise underlying the use of the scanning electron microscope for linewidth measurement for semiconductor research and production applications is that the video image acquired, displayed, and ultimately measured reflects accurately the structure of interest. This paper demonstrates that depending the mode of electron detection upon (secondary, backscattered, or converted backscattered secondary electrons) and accelerating voltage used to image and measure the structure of interest, a variety of results can be obtained. The reasons for these differences are discussed relative to the coupling of this type of work with electron beam/sample interaction modeling to enable the acquisition of more precise linewidth measurements.

Cresswell, M.W., Pessall, N., Linholm, L.W., and Radack, D.J., The Use of Artificial Intelligence and Microelectronic Test Structures for Evaluation and Yield Enhancement of Microelectronic Interconnect Systems, Proceedings of the Third International IEEE Conference on VLSI Multilevel Interconnection, Santa Clara, California, June 9-11, 1986, pp. 331-340.

A major factor limiting the production and performance of high-density VLSI integrated circuits is the fabrication of reliable interconnect systems. Properly designed microelectronic test structures and appropriate test methods can be used to characterize the processes used to fabricate these systems. However, the computer-controlled testing of comprehensive process evaluation and diagnosis structures often results in large guantities of data which cannot be readily or effectively interpreted by As a result, important feathe user. tures of the data are often overlooked or not considered in the evaluation of the fabrication processes. This paper describes an expert system for assisting CEEE Technical Progress Bulletin - June 1987

Albers, J., Semiconductor Measurement Technology: Results of the Monte Carlo Calculation of One- and Two-Dimensional Distributions of Particles and Damage: Ion Implanted Dopants in Silicon, to be published as NBS Special Publication 400-79.

The TRansport of Ions in Matter (TRIM) Monte Carlo code was used to calculate the two-dimensional distributions of particles, primary damage, and electronic and nuclear energy loss for implantation of a line beam source into silicon Approximate two-dimensional targets. distributions of the Frenkel pairs (vacancy-interstitial) created by the primary displacement damage of the target atoms were calculated by means of the Kinchin-Pease equation. These particle, damage, and energy loss distributions allowed for the calculation of the one-dimensional distributions of these quantities for implantation into unmasked targets. A superposition technique was used to construct the twodimensional particle and approximate Frenkel pair distributions for implantation past a mask edge. The energetic ions used in the calculations were in two groups: those used as intentional dopants in silicon device fabrication and those which either limited lifetime or acted as gettering sites. The onedimensional particle distributions as well as the lateral particle profile at maximum lateral penetration under the mask edge were parameterized by means of standard polynomial fitting techniques. Geist, J., Recent Improvements in

Radiometric Accuracy Based on New Detector Technology.

Until recently, the best accuracy achievable in the measurement of radiometric properties was limited by the accuracy of the ultimate radiometric standard to which the measurement could be traced. Since about 1980, however, there have been such dramatic improvements in the accuracy of detector-based standards that this is no longer the case. These new radiometric standards are briefly reviewed in this paper, with emphasis on the intercomparisons that demonstrate their accuracy.

Marchiando, J.F., and Albers, J., Effects of Ion-Implantation Damage on Two-Dimensional Boron Diffusion in Silicon.

Well-defined control of boron implanted in silicon during a high-temperature short-time anneal is important in calculation of shallow p-n junction profiles in metal oxide-semiconductor fieldeffect transistors (MOSFETs). During an anneal, boron may exhibit enhanced diffusion lasting about a second. Here, displacement damage is removed largely by release and condensation of single vacancies, which enhance the boron diffusion via the charged vacancy mechanism. Model 2-D distributions of boron and displacement damage implanted near a mask edge are used to calculate the redistribution of boron resulting from a seven-second anneal. Boron redistributes further into the bulk, while leaving the channel length unaffected. The redistribution agrees favorably with that reported in the literature. [Contact: Jay F. Marchiando, (301) 975-20881

Bennett, H.S., Band Structure and Density of States Changes in Heavily Doped Silicon, Journal of Applied Physics, Vol. 59, No. 8, pp. 2837-2844 (April 15, 1986).

Device Physics and Modeling (cont'd.)

The Klauder self-energy method is applied to calculating the effects of one-body interactions among the dopant ions and the carriers in heavily doped silicon at 300 K. Many-body interactions of exchange energy for majority carriers and of correlation energy for minority carriers are estimated by interpretation of optical absorption measurements and by calculations based on degenerate theory. When densities exceed 5 \times 10¹⁹ cm⁻³, one-body and manybody terms become of the same order of magnitude and should be included in calculations of band-structure changes and of properties such as carrier transport which depend on the density of states.

Bennett, H.S., Device Physics for Transistors, Bipolar Modeling GaAs of the Semiconductor Proceedings Research Corporation Conference on Technology, Tempe, Bipolar Arizona, April 24-25, 1986, S. A. Abbas, Ed., Paper II.17.

The accuracy and reliability of predictions from numerical simulations of advanced bipolar transistors depend on model input parameters. These parameters include the variations with doping and carrier concentrations in both n-type and p-type material of 1) the valence and conduction band edges, 2) the effective intrinsic carrier concentrations, 3) the minority carrier mobilities, and 4) the minority carrier lifetimes. This paper contains a summary of recent advances in device physics for modeling silicon bipolar transistors with submicrometer dimensions and high concentrations of dopant ions and carriers. It also contains preliminary results in device physics for modeling those regions of GaAs bipolar transistors which have high concentrations of either dopant ions or carriers. The latter results are based on lessons learned trom modeling advanced silicon

bipolar devices. [Contact: Herbert S. Bennett, (301) 975-2079]

Bennett, H.S., Gaitan, M., Roitman, P., Russell, T.J., and Suehle, J.S., Modeling MOS Capacitors to Extract Si-Si0 Interface Trap Densities in the Presence of Arbitrary Silicon Doping Profiles, IEEE Transactions on Electron Devices, Vol. ED-33, No. 6, pp. 759-765 (June 1986).

The MOS capacitor model in SEDAN has been modified to include the effects of an energy-dependent Si-SiO₂ interface trap density and arbitrary silicon substrate doping profiles. These modifications have been used to calculate the quasi-static C-V characteristics of MOS capacitors and to compare them with those measured by the Kuhn technique for as-received and for gamma-irradiated p-well and n-type silicon MOS capaci-The average substrate doping is tors. obtained from high-frequency C-V curves. For the n-type substrate, the dopant redistribution was estimated with SUPREM TI. Experimental and theoretical C-V curves were made to agree by varying the voltage offset due to fixed oxide charge and both the magnitude and the energy distribution of interface trapped The distributions of interface charge. traps which gave the best fits between experiment and theory have peaks near mid gap for the p-well and n-type silicon MOS capacitors. Berning, D.W., and Blackburn, D.L., Power MOSFET Failure During Turn-Off: The Effect of Forward Biasing the Drain-Source Diode, Conference Proceedings of the 1986 IEEE Industrial Applications Society Annual Meeting, Denver, Colorado, September 25-October 3, 1986, pp. 335-339.

The effects on the turn-off failure of power metal oxide-semiconductor fieldeffect transistors (MOSFETs) which result from forward biasing the intrinsic drain-source diode immediately prior to

Device Physics and Modeling (cont'd.)

turn-off are discussed. A nondestructive test circuit is used to measure the turn-off characteristics of individual devices under a variety of conditions. It is shown that the drain voltage at which the device fails decreases as either the diode forward current or the reverse recovery current is increased. If the diode is forward biased, the voltage at failure can be less than one-half of the voltage at which the device fails if the diode has not been forward biased (and often less than one-half the manufacturer-rated voltage capability for the device). Also, if turn-off of the MOSFET is attempted with the diode conducting, the device loses its tast turn-off capability due to charge storage effects. A parallel resonant power converter circuit is employed to demonstrate how the intrinsic drain-source diode may and may not be used safely in practical applications.

Radiation Effects

Released for Publication

Hefner, A.R., Blackburn, D.L., and Galloway, K.F., The Effect of Neutrons on the Characteristics of the Insulated Gate Bipolar Transistor (IGBT), to be published in the IEEE Transactions on Nuclear Science.

The effects of neutrons on the operating characteristics of Insulated Gate Bipolar Transistors (IGBT) are described. Experimental results are presented for devices that have been irradiated up to a fluence of 10^{13} neutrons/cm², and an analytical model is presented which explains the observed effects. It is found that with increasing neutron fluence, the on-state voltage increases, the switching time decreases, and the saturation current decreases. For the range of fluences studied, the observed effects result from a reduction in

minority carrier lifetime in the IGBT and not from changes in the effective dopant density. The effects of neutrons on the IGBT are compared with their known effects on power MOSFETs, and it is shown that the IGBT characteristics begin to degrade at a fluence that is an order of magnitude less than the fluence at which the power MOSFET begins to degrade. At high fluences, the IGBT takes on the characteristics of a power MOSFET.

Candela, G.A., Chandler-Horowitz, D., Novotny, D.B., Vorburger, T., and Giauque, G.H., Film Thickness and Refractive Index Standard Reference Material Calibrated by Ellipsometry and Profilometry, Proc. SPIE - The International Society for Optical Engineering, Vol. 661, pp. 402-407, SPIE, P.O. Box 20, Bellingham, WA 98227 (1986) [conference Quebec, Canada, June 2-6, 1986].

A Standard Reference Material (SRM) has been designed and fabricated, and will be calibrated for thickness and refractive index using a highly accurate ellipsometer. The SRM consists of a three-inch diameter silicon wafer with a silicon dioxide film of uniform thickness. The design and preparation of the SRM is discussed and the ellipsometric measurement results and their comparisons with stylus profilometry are presented, along with an analysis of the precision of the measurements. The ellipsometric accuracy depends upon the wafer oxide film, the model that represents the film-interface-substrate system, and the methods used to make the measurements. Use of both correct sample preparation and correct model is important in order to obtain high accuracy for comparisons of optical thickness as determined by the ellipsometer and mechanical thickness as determined by the stylus profilometer. This SRM will be available initially in three nominal oxide film thicknesses of 50, 100, and 200 nm. The SRM can be used to calibrate many different optical and mechanical thickness monitoring instruments as well as the ellipsometer for which it was specifically designed. [Contact: George A. Mazer, J.A., and Ehrstein, J.R., Effect of Sintering on the Sheet Resistance Directly Under an Aluminum/Silicon Ohmic Contact, Extended Abstracts of the Electrochemical Society 169th Meeting, Boston, Massachusetts, May 4-9, 1986, pp. 396-397.

Van der Pauw-type measurements with a specially designed test structure and spreading resistance measurements indicate that the sheet resistance directly under a sintered 1% Si-Al/Si ohmic contact is lower than the sheet resistance of the diffused layer away from the contact. These results agree with transmission-line calculations made with measurements from six-terminal Kelvin test structures, and allow an improved calculation of the circuit-loading (or front-contact) resistance. [Contact: James R. Ehrstein, (301) 975-2060]

Mountain, D.J., Russell, T.J., and Galloway, K.F., Effect of Post-Oxidation Anneal on Electrical Characterization of Thin Oxides, Extended Abstracts of the Electrochemical Society 169th Meeting, Boston, Massachusetts, May 4-9, 1986, pp. 382-383.

The effect of pre- and post-oxidation treatments on thin oxide electrical characteristics was examined. Pre-oxidation clean and post-oxidation anneal (POA) times and ambients were varied. Three POA times and two gases (argon and nitrogen) were compared. Flatband voltages, oxide breakdown fields, and interface trap densities were measured for thin (20-nm) oxides. Interface trap densities were measured using the charge-pumping technique. Data indicate an optimum process can be designed. A sacrificial oxidation cleaning sequence and a long (120-min) POA in nitrogen gave the oxide with the best electrical characteristics.

Bouldin, C.E., Forman, R.A., Bell, M.I., Donovan, E.P., and Hubler, G.K., EXAFS Measurements of Ion and Implanted Amorphous Surface Layers.

Extended x-ray-absorption fine-structure (EXAFS) measurements of ion-damaged amorphous Ge (a-Ge) show that low-temperature annealing causes a structural relaxation in the as-implanted a-Ge. It is found that there is a sharpening of the first shell in the radial distribution but no change occurs in the firstshell distance or coordination number. No higher shells in the radial distribution are observed either before or after annealing, indicating that these shells remain highly disordered. The observed structural relaxation is an amorphousamorphous transition; no nucleation of microcrystals takes place. EXAFS measurements are made using conversion electron detection, which is essentially total electron yield detection in ambient conditions, allowing the EXAFS measurements to be near-surface sensitive with a sampling depth of 600 to 800 Å. Novotny, D.B., Measurement of the Separation Distance in Contact and Proximity Lithography, to be published in the Journal of the Electrochemical Society.

A method is presented for measuring the separation distance between the substrate surface and the mask surface in contact and proximity optical lithography. This method utilizes the analysis of the Fresnel diffraction pattern produced by a slit aperture in the mask and physically replicated in the photoresist. From the analysis, the image distance producing the observed Fresnel diffraction pattern is obtained and is used to calculate the separation distance. The conditions for the application of this method are presented and an easy method for computer-generation of Fresnel diffraction patterns the is described. A simplified method for estimating the separation distance from the number of diffraction pattern peaks and valleys is also given. Results are presented showing that a finite separation distance may exist in hard "contact" lithography and that this measurement method is applicable from distances from near zero to 20 or more micrometers.

Extended x-ray-absorption fine-structure

Other Semiconductor Topics

measurements were made on icosahedral MnAl and MnSiAl, and on the periodic standards a-phase of MnSiAl and orthorhombic phase of MnAl₆. Experimental evidence is presented that a cage of Mn atoms at the vertices of an icosahedron is the structural unit in the icosahedral MnSiAl and MnAl phases. The connections among these icosahedral units and between them and the Al atoms are different in the icosahedral phases and in the α -phase. As in the α -phase, the Mn icosahedra do not share vertices in the icosahedral phases; i.e., they are separated from one another. It is suggested that the i-phase grows by randomly nucleating together Mn icosahedra along their 20 threefold directions, as allowed by local steric constraints. [Contact: Charles E. Kautz, R.L., Global Stability of Phase Lock Near Chaotic Crisis in the RF-Biased Josephson Junction.

The global stability of phase lock in the radio-frequency-biased Josephson junction is studied through digital simulations. Global stability is determined by calculating the lifetime of the phase-locked state in the presence of thermal noise. This lifetime, the mean time required for thermal noise to induce a 2π phase slip, increases exponentially with inverse temperature in the limit of low temperatures, and the lowtemperature asymptote can be parameterized in terms of an activation energy ε and an attempt time τ_0 . The activation energy is a useful measure of global stability for both periodic and chaotic phase-locked states. The behavior of ε and τ_o is studied over a range of critical current densities which take the system from a region of harmonic motion through a perioddoubling cascade and into a region of phase-locked chaotic behavior which is ended by a chaotic crisis. At the crisis point, the activation energy goes to zero and the attempt time goes to

infinity. The results are used to determine the optimum critical current density for series-array voltage standards. [Contact: Richard L. Kautz, (303) 497-3391 or -3988]

Raisanen, A.V., Crete, D.G., Richards, P.L., and Lloyd, F.L., Low Noise SIS Mixer with Gain for 80-115 GHz.

Several superconductor-insulatorsuperconductor (SIS) quasiparticle mixers have been designed and tested for the frequency range from 80 to 115 GHz. The sliding backshort is the only adjustable radio-frequency (rf) tuning element, simplifying optimization of mixer performance compared to designs previously described in the literature of radio astronomy receivers. The rf filter reactance is used as a fixed rf-matching element. A mixer which uses a single 2 \times 2 μ m² Pb-alloy junction in a 1/4-height waveguide mount has a coupled conversion gain of $G_M(DSB) =$ 2.6 ± 0.5 dB with an associated noise temperature of $T_M(DSB) = 16.4 \pm 1.8 \text{ K}$ at the best double-sideband (DSB) operation point. The receiver noise temperature $T_R(DSB)$ is 27.5 ± 0.8 K. This mixer provides single-sideband (SSB) receiver noise temperatures below 50 K over the frequency range from 91 to 96 GHz, the minimum being $T_R(SSB) = 44$ ± 4 K. These SSB values are calculated from the DSB measurements. [Contact: Frances L. Lloyd, (303) 497-3254 or -3988]

Hamilton, C.A., Kautz, R.L., and Lloyd, F.L., The NBS Josephson Array voltage Standard, CPEM 86 Digest, 1986 Conference on Precision Electromagnetic Measurements, Gaithersburg, Maryland, June 23-27, 1986, pp. 108-109.

It has been realized for many years that the accuracy of Josephson voltage standards can be substantially improved by using many junctions in series to generate a large voltage. A simple series extension of the single junction standard requires individual control of the bias current, for example, for each junction of 100 mV using 20 junctions. In 1977 Levinsen et al. suggested a method to avoid the multiple bias problem by using constant-voltage steps which cross the zero-current axis of the plot of junction current as a function of voltage (I-V curve). This allows a large array of junctions to share a common current bias at or near zero. With an array of 1000 or more junctions, a quantized voltage of 1 V is possible. After nearly ten years of effort, the problems of fabrication, stability, and radio-frequency energy distribution are largely solved and Josephson standards at the 1-V level are a reality. This paper reviews the design and operation of series array voltage standards and describes the efforts at NBS to engineer a versatile, reliable, and easily used voltage standard system.

Baird, R.C., Daywitt, W.C., Newell, A.C., Perera, S., Repjar, A.G., Wait, D.F., and Estin, A.J., Calibration Requirements for EHF Satellite Communication Systems, to be published as NBSIR 86-3058.

The calibration and measurement support requirements of millimeter-wave satellite systems such as MILSTAR have been investigated. Needs for measurements on satellite systems are reviewed. An overview of the various means available for calibrating antenna gain, one of the key parameters that need to be measured accurately, is presented. Essentially three new measurement problems arise because of operating in the upper superhigh frequency (3 to 30 GHz) and extremely high frequency (EHF, 30 GHz to quasi-optical) ranges. First, without

Page 10

Antenna Metrology (cont'd.)

adequate methods to measure the atmospheric loss, the accuracy of effective isotropic radiated power (EIRP) measurements in the 20 to 45 GHz range can be no better than 0.5 dB to 3 dB (depending on frequency and antenna elevation angle), which is inadequate for MILSTAR requirements. Second, standards and measurement support services are not presently available from the National Bureau of Standards and are needed to support millimeter-wave antenna gain and thermal noise measurements. Third, if the sun and/or moon are to be used as a basis for measuring the earth terminal figure of merit G/T, earth terminal antenna gain, or satellite EIRP in the millimeter region, we need appropriate characterization of these sources in that region. Engen, G.F., In Search of a More Realistic Accuracy Statement for Microwave Metrology.

The concept of "measurement accuracy" is fundamental to all of metrology. Given two different techniques for measuring the same parameter, an evaluation of their respective accuracies typically plays a major role in an assessment of their relative merit.

Historically, the accuracy achieved by the microwave metrologist has been limited by detector performance, hardware imperfections, and connector problems. Today, the effect of hardware imperfections has been largely eliminated by more complete modeling. Moreover, the performance of the detection systems has been improved to the point where, in many cases, the nonideal behavior of connectors is the major error source. Although important refinements in connectors have also been realized, it is quite possible that these have not kept pace with the other developments.

In any case, it is useful to pose the following question: Assume a measurement system which, apart from being fitted with connectors typical of those in general use, is otherwise perfect. How much measurement accuracy can one realistically claim for it? [Contact: Cletus A. Hoer, (303) 497-3705]

Juroshek, J.R., A Study Into Measurements of Connector Repeatability Using Highly Reflecting Loads.

This paper investigates the repeatability of measurements of reflection coefficient, Γ , of highly reflecting devices with changes in the radio-frequency (rf) connector joint. In this analysis, the changes in the connector joint are due to the disconnecting and reconnecting of the connector pair. It is shown that many of the measurement discrepancies observed in actual practice can be explained with a simple connector model. The paper shows that the sensitivity of measuring rf connector changes can be enhanced by using highly reflecting loads. The changes in Γ due to changes in resistance or reactance can be four times greater for highly reflecting devices $(|\Gamma| \approx 1)$, as compared to nonreflecting devices $(|\Gamma| \approx 0)$. Experiments on two devices with 14-mm connectors are described, to compare with theory. The basic principles described in this paper should be beneficial to designers of connectors who need to detect small changes in connector parameters, and to designers of calibration standards who need to be concerned with small connector imperfections that contribute a major part of the measurement uncertainty. Fenimore, C., The Artificial Boundary Integral Method (ABIM): Flow Into an Aperture.

Using a boundary integral, one may approximate certain irrotational, effectively incompressible, steady flows into an aperture. Here, a three-dimensional flow is estimated with a small computation. The flow boundary is a plane wall with an opening. The artificial boundary is the hole on which the outflow is an unknown function of position; the outflow may be approximated from measurements by a deconvolution. Three spaces of computational elements are considered and evaluated. The domain of the flow is the upper half-space in the upstream region for which the Green's function is known. The flow is approximated by reconvolution. This investigation was stimulated by the need to characterize the airflow into an ion counter. [Contact: Ronald B. McKnight, (301) 975-2428]

Van Brunt, R.J., Common Parameterizations of Electron Transport, Collision Cross Section, and Dielectric Strength Data for Binary Gas Mixtures.

Previously used parameterizations of dielectric strengths (electrical breakdown data) for gas mixtures in terms of electron collision and transport parameters are reviewed. A new method of fitting experimental data on dielectric strengths for binary electronegative gas mixtures is proposed based upon the principal assumption that the electron kinetic energy distributions in the gas are maxwellian. The method provides physical insight into such behavior as pressure-dependent or pressure-independent synergisms, and is useful in checking the consistency between dielectric strength data and available information on electron transport and ionization, attachment, and momentum-transfer collision cross sections. The method is applied here to the mixtures SF_6/N_2 , CCl_2F_2/N_2 , and SF_6/CCl_2F_2 . [Contact: Richard J. Van Brunt, (301) 975-2425]

Ekin, J.W., Effect of Irregularity in Filament Cross Sectional Area ("Sausaging") on Electric-Field Vs. Current Characteristics of NbTi Superconductors.

Measurements of a correlation between filament irregularity ("sausaging"), and the shape of a superconductor's electric-field-versus-current (E-I) characteristic are reported. The shape of the E-I characteristic is quantified in terms of the resistive transition parameter n, defined by EaIn. LOW values of n indicate significant filament irregularity. It is proposed that the parameter n could be used as a valuable index of filament quality in evaludifferent superconductors ating for practical applications. A model is also suggested to explain this effect in terms of a locally depressed filament critical-current density, which forces current to transfer across the normalmatrix material into neighboring filaments.

Also reported is the relationship between n and the statistical distribution of filament diameters measured for the NbTi superconductors studied. This relationship may be useful as a quick method of estimating the extent of sausaging in practical multifilamentary NbTi superconductors from measurements of n. [Contact: John W. Randa, J., and Kanda, M., A Lattice Approach to Volumes Irradiated by Unknown Sources, to be published as NBS Technical Note 1303.

We suggest an approach to the characterization of electromagnetic environments irradiated by unknown sources. The approach is based on the numerical solution of Maxwell's equations subject to the constraints imposed by the measured values of the field at a small number of measurement points and by boundary conditions. A thorough examination is presented of two methods for the numerical solution. The examples attempted demonstrate the approach, but reveal that neither technique is fully successful. Possible future directions are suggested.

[A paper based on the contents of this Technical Note is scheduled for presentation at the Seventh Symposium and Technical Exhibition on EMC (Zurich, Switzerland, March 1987) under the title "A Lattice Approach to Environments Irradiated by Unknown Sources" and will appear in the proceedings of that Symposium. A second paper based on this material has been submitted to the IEEE Transactions on Electromagnetic Compatibility with the title "A New Approach to Volumes Irradiated by Unknown Sources.] [Contact: James P. Randa, (303) 497-3150]

Wilson, P.F., and Ma, M.T., Techniques for Measuring the Shielding Effectiveness of Materials, to be published in the Proceedings of the 7th International EMC Symposium and Exhibition, Zurich, Switzerland, March 1987. [A more complete version appeared as NBS Technical Note 1095 (May 1986).]

Four methods for measuring the shielding effectiveness of materials under various conditions are considered. Coaxial transmission line holders and a timedomain system are used to simulate plane-wave shielding performance. The dual transverse electromagnetic (TEM) cell and an apertured TEM cell in a reverberating chamber are used to investigate near-field shielding capability. Both theoretical and experimental results are discussed. [Contact: Perry F. Wilson, (303) 497-38421

Crawford, M.L., and Koepke, G.H., Design, Evaluation, and Use of a Reverberation Chamber for Performing Electromagnetic Susceptibility/Vulnerability Measurements, NBS Technical Note 1092 (April 1986).

This report presents the results of work at the National Bureau of Standards to evaluate, document, develop (when necessary) and describe the methodology for performing radiated susceptibility/vulnerability measurements using a reverberation chamber. The report describes the reverberation chamber theory of

Radiated EMI (cont'd.)

operation, construction, evaluation, functional operation, and use for performing immunity measurements. It includes an estimate of measurement uncertainties derived empirically from test results and from comparisons with anechoic chamber measurements. Finally, it discusses the limitations and advantages of the measurement technique to assist potential users in determining the applicability of this technique to their electromagnetic compatibility measurement needs.

Crawford, M.L., and Koepke, G.H., Electromagnetic Radiation Test Facilities - Evaluation of Reverberation Chambers Located at NSWC, Dahlgren, VA, NBSIR 86-3051 (June 1986).

This report describes measurement procedures and results obtained from evaluating the reverberation chamber facilities located at the Naval Surface Weapons Center, Dahlgren, Virginia. Two chambers were tested referred to as 1) the half chamber, and 2) the full chamber. The facilities were developed by the NSWC for use in measuring and analyzing the electromagnetic susceptibility/vulnerability of weapon systems and the shielding effectiveness of enclosures and shielding materials. A brief description of each facility is given, including the instrumentation used for performing the evaluation and calibration of the facilities by the National Bureau of Standards. Measurements described include: 1) evaluation of the voltage standing wave ratios of the chamber's transmitting and receiving antennas; 2) measurement of the chamber's insertion loss or coupling efficiency versus frequency; 3) measurement of the effectiveness of the chamber tuners; 4) determination of the electric-field uniformity in the chamber's test zones versus frequency; 5) determination of the absolute amplitude calibration of the test electric fields in the chambers, based upon received power measurements of the reference antenna and calibrated dipole probe antenna measurements; and 6) comparison of the response of reference equipment under test to test fields established inside the NSWC reverberation chambers and the NBS reverberation chamber. These results can then be compared to anechoic chamber results. Conclusions given indicate that the NSWC chambers can be used at frequencies down to approximately 150 MHz. Estimates are given of the measurement uncertainties derived empirically from the test results. [Contact: Myron L. Crawford, (303) 497-5497]

Crawford, M.L., and Koepke, G.H., Performing EM Susceptibility/Vulnerability Measurements Using a Reverberation Chamber, EMC EXPO 86, International Conference on Electromagnetic Compatibility, Washington, D.C., June 16-19, 1986, pp. T28.7-T28.13.

This paper discusses the design, evaluation, and use of a reverberation chamber for performing electromagnetic susceptibility (EMS) measurements of electronic equipment. Included are brief descriptions of the test procedures, application advantages and limitations, some EMS test results, intrepretation of test results relative to free-space test methods, and an estimate of measurement uncertainties.

Friday, D.S., Methodology for Statistical Control of the Anechoic Chamber Field Generation System, NBSIR 85-3033 (January 1986).

The microwave anechoic chamber in question is an NBS laboratory facility in which standard plane-wave electromagnetic fields are generated. This chamber enables specialized measurements and electromagnetic interference/electromagnetic compatibility tests to be conducted on antennas and other devices. This paper is concerned with methodology Radiated EMI (cont'd.)

for assuring that the standard field patterns generated in the NBS and similar chambers are repeatable. Procedures are proposed for developing a data base from measurements obtained by placing the system, which generates the fields, in certain relevant reference configurations. Methodology is presented for developing statistical control charts to monitor both the location and the scale parameters of these data over time. [Contact: Dennis S. Friday, (303) 497-5395]

Hill, D.A., Out-of-Band Response of a Coax-to-Waveguide Adapter, IEEE Transactions on Electromagnetic Compatibility, Vol. EMC-28, No. 3, pp. 156-158 (August 1986).

The input impedance and transmission coefficients of a coax-to-waveguide adapter are analyzed for out-of-band frequencies. Numerical results are shown for an S-band adapter for frequencies from 2 to 10 GHz. The above-band response is frequency sensitive because of the presence of higher-order propagating modes in the waveguide. [Contact: David A. Hill, (303) 497-3472]

Hill, D.A., and Francis, M.H., Out-of-Band Response of Antenna Arrays, NBSIR 86-3047 (June 1986).

The response of antenna arrays to outof-band frequencies has been analyzed using the effective aperture approach. An average value of effective aperture can be obtained by averaging out the incidence angle and the polarization of the incident field. Far-field patterns have also been calculated by treating the array element excitations as random variables. The randomness in the element excitations causes a decrease in directivity and an increase in sidelobe level. Out-of-band measurements of reflection coefficient and near-field response have been made on two large slotted-waveguide arrays for frequencies

from 2 to 18 GHz. Both arrays are narrow band, attributable to the large impedance mismatch at out-of-band frequencies. [Contact: David A. Hill, (303) 497-3472]

Wilson, P.F., and Ma, M.T., Simple, Approximate Expressions for Higher-Order Modes and Resonances in TEM Cells, IEEE Transactions on Electromagnetic Compatibility, Vol. EMC-28, No. 3, pp. 125-130 (August 1986).

Simple, approximate expressions for determining the cutoff frequencies of the first few higher-order modes and the associated resonances in transverse electromagnetic (TEM) cells are presented. Both symmetric and asymmetric cells are discussed with examples. [Contact: Perry F. Wilson, (303) 497-3842]

Wilson, P.F., and Ma, M.T., A Study of Techniques for Measuring the Electromagnetic Shielding Effectiveness of Materials, NBS Technical Note 1095 (May 1986).

Shielding effectiveness relates to a material's ability to reduce the transmission of propagating fields in order electromagnetically to isolate one region from another. Because a complex material's shielding capability is difficult to predict, it often must be A number of measurement measured. approaches are studied including the use of a shielded room, coaxial transmission line holders, time-domain signals, the dual transverse electromagnetic (TEM) cell, and an apertured TEM cell in a reverberation chamber. In each case, we consider the system's frequency range, test sample requirements, test field types, dynamic range, time required, analytical background, and present data taken on a common set of materials. Martzloff, F.D., and Key, T.S., A Consensus on Powering and Grounding Sensitive Electronic Equipment, to be published in the Proceedings of the IEEE/IAS Conference, Denver, Colorado, September 29-October 3, 1986.

As sensitive electronic processing systems proliferate, concern with the quality of power supplied to these systems increases. Efforts to alleviate perceived power supply problems have sometimes been misguided and have led to violations of the National Electrical Code. A new IEEE Working Group has been formed to prepare a guide document, which the paper describes while inviting participation from the engineering community.

July 28-30 (Vail, CO)

Short Course on Optical Fiber Measure-This course is sponsored by ments. the National Bureau of Standards and the University of Colorado with the cooperation of members of industry who serve as faculty together with staff from the Electromagnetic Technology and Electromagnetic Fields Divisions. The course is intended for scientists and engineers involved in optical fiber characterization and emphasizes concepts, techniques, and apparatus used in measuring engineering parameters of telecommunications-grade fibers.

The following major topic areas are addressed: optics for communications, emphasizing geometric optics concepts; fiber properties and parameters; indexprofile measurements; fiber bandwidth measurements in the frequency and time domains; fiber attenuation measurements; connector and splice losses; optical time-domain reflectometry concepts and applications; single-mode fibers; statistics and error analyses, measurement uncertainties; and fibers for sensors. Office of Conference [Contact: Services, University of Colorado (303) 492-8630; Robert L. Gallawa (303) 497-3761; or Matt Young (303) 497-3223]

September 14-16 (Research Triangle Park, NC)

VLSI and GaAs Packaging Workshop. This Workshop is co-sponsored by the Components, Hybrids, and Manufacturing Technology Society of IEEE and NBS; attendees are expected to be knowledgeable in the field and to participate in discussions. Topic areas include: VLSI and wafer scale package design (characterization and implementation, cost and performance driven solutions); package thermal design (characteristics, results, and issues); package interconnection options (wire bonding, TAB, flip chip, or optical); GaAs IC packaging (high speed packaging considerations); package electrical issues (reduction of parasitics and improvements in electrical performances); integrating package design (from die to system, including assembly and test issues); VLSI package materials advancements; die-attach solutions for large chips; new failure mechanisms in VLSI packaging. [Contact: George G. Harman, (301) 975-2097]

September 22-25 (Boulder, CO)

Noise Measurement Seminar. This fourday course is presented and hosted by the Electromagnetic Fields Division in cooperation with representatives from industry and the NBS Time and Frequency Division. It is intended for practicing noise metrologists and technical managers responsible for systems in which accurate measurements of thermal and phase noise are important. Attendees will learn the most important precautions to take in making accurate noise measurements and will receive a set of notes that are suitable for use in solving precision noise measurement prob-Course topics include reference lems. thermal noise sources; thermal noise measuring systems and techniques; phase noise; and the problems of measuring thermal noise in passive components, amplifiers, and communication systems.

The course design combines formal lectures on theory presented by NBS staff and industry experts with demonstrations in NBS laboratories and demonstrations of commercial equipment. A special feature of the Seminar is the opportunity each day for attendees to share their experiences in solving specific problems or their insights on practical noise measurement issues through short presentations to the assembled group. Time is scheduled for group discussions of these presentations and other topics raised by the Seminar.

September 23-25 (Gaithersburg, MD)

Workshop on the Role of Optics in Power System Electrical Measurements. This Workshop is sponsored by NBS, the Bonneville Power Administration (BPA), the Electric Power Research Institute (EPRI), and the Empire State Electric Energy Research Corporation (ESEERC) and is intended for research and development engineers in utilities and in companies that supply equipment to the utility industry. The objective of this workshop is to identify anticipated opportunities for improved measurement techniques that should arise as power systems individually and collectively evolve to meet the needs of the 1990s. Presentations will stress the design and testing of optical systems for 60-Hz voltage or current measurement; the interfacing of electronic or optical components with existing metering and control systems; opportunities for new measurement hardware resulting from increased automated control of power systems and of the testing of power system components; and optical techniques for the measurement of electric and magnetic fields in power systems or system components. The results of an NBS study evaluating optical techniques for power-system electrical measurements and carried out in agreement with BPA, EPRI, and ESEERC will be presented as an invited keynote. [Contact: Robert E. Hebner, (301) 975-2403]

October 26-28 (Boulder, CO)

Symposium on Optical Materials for High Power Lasers (Nineteenth Boulder Damage Symposium). This Symposium is cosponsored by the National Bureau of Standards, the American Society for Testing and Materials, the Air Force Office of Scientific Research, the Office of Naval Research, and the Defense Advanced Research Projects Agency and constitutes a principal forum for the exchange of information on the physics and technology of materials for highpower lasers.

Topics to be discussed include new materials, bulk damage phenomena, surface and thin-film damage, design considerations for high-power systems, and fundamental mechanisms of laser-induced damage. Proceedings of the Symposium will be published (Note: The collection of Symposium proceedings contains information on optics for all aspects of high-power/high-energy lasers, including environmental degradation, durability, fabrication, material growth and deposition processes, and testing). [Contact: Susie A. Rivera (303) 497-5342]

December 10-11 (Gaithersburg, MD)

Power Semiconductor Devices Workshop. This Workshop, sponsored jointly by IEEE and NBS, is intended to bring together for interactive participation those actively working in the field of power semiconductor devices. It will be held in conjunction with the 1987 IEEE International Electron Devices Meeting in Washington, DC. Four specific topic areas have been selected, based on the response to a questionnaire sent to over 200 power device researchers worldwide. They are: power and high voltage integrated circuits, discrete devices, device modeling, and packaging. Attendees are expected to be prepared to contribute to the development of responses to specific questions that arise in the context of the particular topic areas; a final schedule identifying the topic areas should be available at the end of October.
