The NIST PDES Toolkit: Technical Fundamentals

Stephen Nowland Clark

1 Introduction

The NIST PDES Toolkit [Clark90a] provides a set of software tools for manipulating Express [Schenck89] information models and STEP [Altemueller88] product models. It is a research-oriented toolkit, intended for use in a research and testing environment. This document gives a technical introduction to the Toolkit, providing a programmer with basic knowledge of its structure. Also covered are the mechanics of building Toolkit-based applications.

In addition to describing the structure and usage of the Toolkit, we describe three fundamental code libraries which it includes. The most significant of these, libmisc.a, contains various modules of general utility, including such abstractions as linked lists and hash tables. libbison.a is a small library containing support routines and global variables for the Toolkit’s parsers. The third library, libdyna.a, provides a dynamic (run-time) loading facility for .out format object files under BSD 4.2 Unix and derivatives.

1.1 Context

The PDES (Product Data Exchange using STEP) activity is the United States’ effort in support of the Standard for the Exchange of Product Model Data (STEP), an emerging international standard for the interchange of product data between various vendors’ CAD/CAM systems and other manufacturing-related software [Smith88]. A National PDES Testbed has been established at the National Institute of Standards and Technology to provide testing and validation facilities for the emerging standard. The Testbed is funded by the CALS (Computer-aided Acquisition and Logistic support) program of the Office of the Secretary of Defense. As part of the testing effort, NIST is charged with providing a software toolkit for manipulating PDES data. This NIST PDES Toolkit is an evolving, research-oriented set of software tools. This document is one of a set of reports which describe various aspects of the Toolkit. An overview of the Toolkit is provided in [Clark90a], along with references to the other documents in the set.

For further information on the Toolkit, or to obtain a copy of the software, use the attached order form.
1.2 Development Environment and Tools

With the exception of QDES, the prototype STEP model editor, implemented in Smalltalk-80\textsuperscript{TM} [Goldberg85], the NIST PDES Toolkit is implemented in ANSI Standard C [ANSI89]. The parsers are written in Yacc and Lex, the standard UNIX\textsuperscript{TM} tools for generating parsers and lexical analyzers. All software has been developed on Sun Microsystems Sun-3\textsuperscript{TM} and Sun-4\textsuperscript{TM} workstations running the UNIX\textsuperscript{TM} operating system. The development compiler for the Toolkit is GCC, the GNU Project's\textsuperscript{1} C compiler, and the parsers are compiled by Bison, the GNU Project's implementation of Yacc. The lexical analyzers are compiled by Flex\textsuperscript{2}, a Public Domain implementation of Lex. Rules for building the Toolkit are specified using the UNIX Make utility.

2 Structure of the Toolkit

The NIST PDES Toolkit consists of the Express [Clark90b] and STEP [Clark90c] Working Forms, several applications which make use of these Working Forms, and the QDES prototype model editor [Clark90f]. The Working Forms reside in object libraries, which can be linked into applications which use them. The applications distributed with the Toolkit include the various translators described in [Clark90a]. These are: Fed-X-QDES, the Express-to-Smalltalk-80\textsuperscript{TM} translator; Fed-X-SQL [Morris90], the Express-to-SQL translator; STEPparse-SQL, the STEP physical file-to-Smalltalk-80 translator; and STEPwf-SQL [Nickerson90], the STEP-to-SQL database loader.

In addition to the various design and usage documents referenced elsewhere, technical reference manuals on the Express [Clark90d] and STEP [Clark90e] Working Forms are also available, as is an administrative guide for QDES [Clark90g].

The Toolkit distribution may be installed anywhere on a particular filesystem. For simplicity, the root directory of the distribution is referred to as \texttt{~pdes/} throughout the technical documentation. This root directory contains a number of subdirectories of interest, which we now describe. Brief descriptions also appear in \texttt{~pdes/README}.

The directories \texttt{~pdes/bin/}, \texttt{~pdes/include/}, and \texttt{~pdes/lib/} contain, respectively, Toolkit application binaries, C header (.h) files for the Toolkit libraries, and the Toolkit object libraries (.a files) themselves. PostScript\textsuperscript{®} and/or ASCII versions of the Toolkit documentation can be found in \texttt{~pdes/docs/}. Source code for the basic Toolkit libraries described in section 4 appears in \texttt{~pdes/local/}, which contains a subdirectory for each library. Various utility tools which are needed to build or run pieces of the Toolkit are in \texttt{~pdes/etc/}. QDES, the STEP model editor, being written in Smalltalk-80, does not quite fit in a C-oriented directory layout, and so is in

\textsuperscript{1} The Free Software Foundation (FSF) of Cambridge, Massachusetts is responsible for the GNU Project, whose ultimate goal is to provide a free implementation of the UNIX operating system and environment. These tools are not in the Public Domain; rather, FSF retains ownership and copyright privileges, but grants free distribution rights under certain terms. At this writing, further information is available via electronic mail on the Internet from gnu@prep.ai.mit.edu

\textsuperscript{2} Vern Paxson's Fast Lex is usually distributed with GNU software, although, being in the Public Domain, it is not an FSF product and does not come under the FSF licensing restrictions.
~pdes/applications/qdes/. Finally, the directory ~pdes/src/ contains the
source code for the Working Form libraries, as well as for the PDES applications
distributed with the Toolkit. There is a separate subdirectory for each module and for each
application. This source directory also includes a subdirectory called template/,
which includes a Makefile template to be filled in for new applications which use the
Toolkit.

2.1 Conventions

Each Working Form is composed of a number of data abstractions. Each of these ab-
stractions is implemented as a separate module. Modules share only their interface
specifications with other modules. A module Foo is composed of two C source files,
foo.c and foo.h. The former contains the body of the module, including all non-
inlined functions. The latter contains function prototypes for the module, as well as all
type and macro definitions. In addition, global variables are defined in foo.h. These
declarations are made using two special macros:

```
#define FOO_C
#define INITIALY (value) = value
#define GLOBAL extern
#define INITIALY (value)

#pragma GCC diagnostic ignored "-Wall"
```

This allows the same declarations to be used both in foo.c and in other modules
which use it: when foo.h is included in foo.c, FOO_GLOBAL has storage declared
and is initialized. When foo.h is included elsewhere, an uninitialized extern dec-
laration is produced. Finally, foo.h contains inline function definitions. If the C compi-
ler supports inline functions (as GCC does), these are declared static inline in
every module which includes foo.h, including foo.c itself. Otherwise, they are un-
defined except when included in foo.c, when they are compiled as ordinary func-
tions.

The type defined by module Foo is named Foo. Access functions are named as
FOOfunction(); this function prefix is abbreviated for longer abstraction names, so
that access functions for type Foolhardy_Bartender might be of the form
FOO_BARfunction(). Some functions may be implemented as macros; they are not
distinguished typographically from other functions, and are guaranteed not to have
unpleasant side effects like evaluating arguments more than once. These macros are
thus virtually indistinguishable from functions. Functions which are intended for internal
use only are named FOO_function(), and are usually static as well, unless
this is not possible. Global variables are often named FOO_variable; most enumera-
tion identifiers and constants are named FOO_CONSTANT.

Every abstraction defines a constant FOO_NULL, which represents an empty or missing
value of the same. A permanent copy of an object (as opposed to a temporary copy
which will immediately be read and discarded) can be obtained by calling
FOOcopy (foo). This helps the system keep track of references to an object, ensuring that it is not prematurely garbage-collected. Similarly, when an object or a copy is no longer needed, it should be released by calling FOOfree (foo), allowing it to be garbage-collected if appropriate.

There are, of course, exceptions to all of these rules. The global variable and enumeration identifier rules are the most frequently broken. Library modules which were developed before all of the rules solidified, as well as components which were not developed locally by the Toolkit project, tend to stretch the rules more than the actual Working Form modules, which have tended to be more dynamic later in the project.

2.2 A Note on Memory Management and Garbage Collection

In reading various portions of the Toolkit technical documentation, one may get the impression that some reasonably intelligent memory management is done. This is not true. The Toolkit is primarily a research tool. This is especially true of the Express and STEP Working Forms. Huge chunks of memory are allocated without batting an eye, and often aren't released until an application exits. Hooks for doing memory management do exist (e.g., XXXfree () and reference counts), but currently are largely ignored.

3 Compiling With the Toolkit: The Makefile Template

The file ~pdes/src/template/Makefile (reproduced in Appendix B) in the Toolkit distribution is a skeletal Makefile which can be configured to build a wide variety of applications which use one or both of the Working Forms. This Makefile uses a number of macros and rules which are defined in ~pdes/include/make_rules. It assumes that the source code for the application to be built resides in ~pdes/src/<appl>/.

The following sections discuss the various classes of applications which can be built, and the appropriate configuration for the Makefile. There are several macros defined in the Makefile which are used to configure an application. The most important, in that it determines how the application will use the Working Form(s), is called LIBS. This macro is defined in the section of the Makefile entitled "Library Selection," which contains a number of possible definitions. Each option is preceded by a comment describing the situation in which it is appropriate; exactly one definition should be uncommented. Next, two options are given for the CFLAGS macro: one for STEP applications and one for applications which use only Express. This is not a necessary distinction, since things will always build correctly with the former definition; it is provided for the benefit of those who (like the author) prefer inordinate neatness.
There are two macros which can be used to specify the auxiliary object (.o) files and libraries (.a files) required by the application. Object files should be named in the OFILES macro; several sample definitions are included for the applications provided with the toolkit. The macro MYLIBS can contain any additional libraries which are required by the application.

In addition to the fundamental configuration options discussed above, there are several more macros which can be used to make "cosmetic" changes to an application. At the top of the Makefile is a macro called CC, which selects the C compiler to be used. Common options are /bin/cc (the vendor-supplied compiler under UNIX) and $ (GCC), which should point to the Gnu Project's C Compiler. The contents of MY_CFLAGS are passed to every invocation of $ (CC); this is the place to add debugging and/or optimization flags, for example. The default rule for compiling .c files (from ~pdes/include/make_rules) probably should not be changed, but it appears in the template to provide a hook for unforeseen requirements. Finally, toward the end of the Makefile is a macro called PROG. This macro holds the name of the executable which will be built.

The Makefile provides three targets: $ (PROG) rebuilds the application from scratch, as necessary. The relink target assumes that all .o files and libraries are up-to-date, and simply relinks the application. This is useful, for example, when one of the Toolkit libraries has been rebuilt, but the application source itself has not been changed. The last target, clean, removes $ (PROG) and $ (OFILES). This rule may be modified for a particular application. Any additional rules which are required to build the application can be added at the end of the Makefile.

3.1 STEPParse STEP Translators

The first class of applications which we examine are the STEP translators. These programs parse a STEP Physical File into the STEP Working Form and then invoke one or more report generators which traverse these data structures and produce output files containing some or all of the product model represented in a different format. Although the STEPwf-SQL database loader is usually included in this category, it is not, strictly speaking, a translator: Rather than producing an output file or files containing an SQL representation of the data to be loaded, STEPwf-SQL actually directly loads the database by making calls to SQL-compliant library routines.

The Make macro $(STEP_LIBS) expands to list all of the libraries needed to create a STEP translator. These include: libstep.a and libexpress.a, the STEP and Express Working Form libraries; libmisc.a and libbison.a; and -ll, which provides support for lexical analyzers produced by Lex. The first four are located in ~pdes/lib; libbl.a is normally found in /usr/lib/. The order in which these libraries are listed is significant: libstep and libexpress both include definitions of main(), the standard entry point to a C program. To build a STEP translator, the first definition of main() which the linker finds must be the STEPParse driver, which is in libstep.a.
In addition to these libraries, two more pieces of code are needed to build a complete translator: a report generator and a linkage mechanism for this report generator. The latter is needed because the translator can load its report generator(s) in either of two ways: it can load a specific one at compile time, or it can dynamically load one or more at run time. The dynamic approach has at least two major advantages: It allows multiple output formats to be produced by a single executable; and it allows several reports to be created by a single run of the translator, so that the parsing phase need only be executed once. This approach has the unfortunate disadvantage that it is (currently) only available under BSD 4.2 Unix and its derivates.

In the library selection section of the Makefile, the first two options are alternate definitions of LIBS for building a STEP translator. The first is for a translator with a single, statically bound report generator. This definition selects an auxiliary object file, -pdes/lib/step_static.o, which provides the static linkage. The second alternative, for a translator with dynamically bound report generators, selects -pdes/lib/step_dynamic.o to provide the run-time linking mechanism. In addition, it adds libdyna.a to the link.

If a dynamically loading translator is being built, then no report generator object file should be listed in the OFILES macro, since the report generator will be selected at run time. The first sample definition of OFILES is appropriate here. If a report generator is being loaded at build time, then any object files which are needed to implement it should be listed in this macro. The second option for OFILES lists the QDES/Smalltalk report generator, and is used to build the STEPParse-QDES translator.

### 3.2 Fed-X Express Translators

The process of configuring the Makefile to build an Express translator is similar to that described for STEP translators. The $(EXP_LIBS) macro expands to the list of libraries needed to build a Fed-X translator; these include the same libraries listed in $(STEP_LIBS), with the exception of libstep.a. Again, there are two possible definitions of LIBS. The first selects -pdes/lib/express_static.o for build-time (static) linkage; the second, -pdes/lib/express_dynamic.o and -ldyna for run-time (dynamic) linkage.

As in the case of a STEP translator, a dynamically bound Express translator requires no object files in $(OFILES), while a statically bound translator expects to find the report generator in this macro. The first sample definition of OFILES can again be used in the former case, while the third is used to build the Fed-X-QDES translator.

### 3.3 Other Applications

We now turn to the more free-form applications which might make use of the Express and/or STEP working forms. A notable difference between these applications and the translators is that the programmer must define the flow of control, by providing main(). As mentioned above, both the STEP library and the Express library include definitions of main() which are used to drive the respective translators; source code for these can be found in -pdes/src/step/step.c and -pdes/src/express/fedex.c, respectively. These might serve as useful start-
ing points for other applications. In general, the first two passes of the Express parser (EXPRESSpass_1() and EXPRESSpass_2()) will have to be run in any application, unless a conceptual schema is to be built by hand. EXPRESSpass_3() invokes a report generator via the selected linkage mechanism. The call which invokes the STEP parser is STEPParse(); this is the simplest way of building an instantiated STEP model. An example of instantiating the model by hand is in ~pdes/src/step/test/wf_test.c. A STEP report generator is invoked by calling STEPreport(); unfortunately, Express and STEP report generators and associated linkages currently cannot coexist in a single executable. This restriction is not due to anything fundamental, and so may disappear should there be sufficient demand.

Assume for the moment the no STEP or Express report generators are needed. In this case, it is quite simple to configure the Makefile to use one or both of the Working Form(s): First, set LIBS to either $(STEP_LIBS) or $(EXP_LIBS), depending on which Working Form is needed (remember that the former includes the latter, so that it is never necessary to use both macros at once). These are the last two sample definitions in the library selection section. Next, in OFILES and MY_LIBS list the object files and libraries which the application uses. Bear in mind that the application’s main() must appear in $(OFILES) in order to override the default one which will otherwise be found in one of the Working Form libraries.

We now return to the problem of an application which will use a STEP or Express report generator without being just a translator. A main() must be provided for this application and included in the OFILES macro, just as in the previous case. What gets messy is the library selection. To use a Fed-X report generator in an application which uses only the Express working form, or to use a STEPParse report generator in a STEP application, just select the appropriate LIBS macro for a translator with the same report generator linkage, one of the first four sample definitions. To build an application which produces Fed-X reports while using the STEP working form, choose either the static or the dynamic binding option from the section "STEP applications with Express report generators" in the Makefile template. This will select the full set of STEP libraries, and pull in the specified Fed-X output linkage.

4 Basic Libraries

This section discusses the three basic libraries in the Toolkit. Portions of the libraries are discussed in varying levels of detail, according to the level of code reuse from other sources (who may or may not provide additional documentation).

4.1 The Library of Miscellany: libmisc.a

This library contains various modules which are used throughout the Toolkit. The abstractions in most common use are String, Linked_List, Dictionary, and Error. Other modules in this library are Stack, Dynamic, and Hash. The object library is ~pdes/lib/libmisc.a, and the sources can be found in ~pdes/local/libmisc/ (.h files in ~pdes/include/).
The file -pdes/include/basic.h includes various simple definitions: a
typedef Boolean, as an enumeration of {false, true}; a Generic pointer
type; MAX and MIN macros, etc. It is included by every source file in the Toolkit.

4.1.1 Dictionary

A Dictionary consists of a naming function and a homogeneous collection. The collection
is ordered alphabetically according to the items' names, as reported by the naming function. The current implementation of this module makes no claim to efficiency: it is simply a wrapper around the Linked List module. Entries are added by insertion sort, and retrieval is by linear search.

Type: Naming_Function
Description: This is the type of the function which a Dictionary expects to use to retrieve the name of one of its entries. It is a function of a single Generic parameter and returns a String.

Procedure: DICTadd_entry
Parameters: Dictionary dictionary - dictionary to modify
           Generic entry - entry to be added
           Error* errc - buffer for error code
Returns: Generic - the added entry, or NULL on failure
Requires: Entry is of an appropriate type for the dictionary's naming function.
Description: Adds an entry to a dictionary, provided that the dictionary does not yet contain a definition for the entry's name (as given by the dictionary's naming function).
Errors: ERROR_duplicate_entry - An entry with the given name already appears in the dictionary

Procedure: DICTcopy
Parameters: Dictionary dictionary - the dictionary to copy
Returns: Dictionary - a shallow copy of the dictionary

Procedure: DICTcreate
Parameters: Naming_Function func - the naming function to be used by the new dictionary
Returns: Dictionary - the newly created dictionary
Description: Creates an empty dictionary. Entries will be sorted according to the strings they produce when passed to the naming function given in this call. Thus, item1 will precede item2 exactly when strcmp(func(item1), func(item2)) < 0.

Iterator: DICTdo ... DICTod
Usage: Dictionary dict;
DICTdo(dict, <variable>, <type>)
   process_value(<variable>);
DICTod;
Description: The macro pair DICTdo() ... DICTod; are used to iterate over a dictionary. type is a C language type; variable is declared to be of this type within the block bracketed by these two macros, and is successively assigned each entry in the dictionary, in sorted order.
<table>
<thead>
<tr>
<th>Procedure</th>
<th>Parameters</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DICTempty</td>
<td>Dictionary dictionary - the dictionary to test</td>
<td>Boolean - is the dictionary empty?</td>
<td>This procedure checks if the dictionary is empty. If so, it returns true; otherwise, it returns false.</td>
</tr>
<tr>
<td>DICTfree</td>
<td>Dictionary dictionary - the dictionary to free</td>
<td>void</td>
<td>This procedure releases a dictionary. It is no longer used by the caller; if there are no other references to it, all storage associated with it may be released.</td>
</tr>
<tr>
<td>DICTlookup</td>
<td>Dictionary dictionary - the dictionary to look in</td>
<td>Generic - the name to look for</td>
<td>It looks up a name in a dictionary. If no matching entry can be found, NULL is returned.</td>
</tr>
<tr>
<td>DICTpeek_first</td>
<td>Dictionary dictionary - the dictionary to peek at</td>
<td>Generic - the first entry in the dictionary</td>
<td>This procedure non-destructively retrieves the first entry from a dictionary.</td>
</tr>
<tr>
<td>DICTremove_entry</td>
<td>Dictionary dictionary - the dictionary to remove from</td>
<td>Generic - the entry removed</td>
<td>This procedure removes the named entry from a dictionary, and returns this entry to the caller. If no entry with the given name can be found, NULL is returned.</td>
</tr>
</tbody>
</table>

### 4.1.2 Dynamic

This module puts a clean wrapper on the routines in `libdyna.a` (see section 4.3). Only two calls are provided.

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Parameters</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DYNAsinit</td>
<td>-- none --</td>
<td>void</td>
<td>This procedure initializes the dynamic loading module. It must be called with <code>argv</code> in scope, as it is actually a macro which examines <code>argv[0]</code>. Alternatively, call <code>DYNAsinit(String me)</code>, whose single parameter should be <code>argv[0]</code>. This method is not recommended, but will work in situations where, for some reason, the value of <code>argv[0]</code> is available while <code>argv</code> itself is not.</td>
</tr>
<tr>
<td>DYNALoad</td>
<td>String filename - the name of the object file to load</td>
<td>void Funcptr - the loaded file's entry point</td>
<td>This procedure loads the named object file into the currently running image, and performs symbol relocation as necessary. The entry point to the file is returned as a pointer to a function of no arguments which returns <code>void</code>. If an error occurs during the loading process, it is reported to <code>stderr</code> and NULL is returned as the entry point.</td>
</tr>
</tbody>
</table>
4.1.3 Error

Error reporting throughout the Toolkit is managed by the Error abstraction. This module was not present in the initial Toolkit design; rather, it has grown in response to needs which have appeared over the course of the Toolkit’s development. Some of the specifications and behavior thus seem contrived. The Error module allows subordinate routines to report error conditions to their callers, and allows the callers to strongly influence the form of the message reported to the user. In order to do this, the caller is trusted to test for and report error conditions. A caller who breaches this trust is asking for trouble, since it is the act of actually reporting the error which gives control of the program to the Error module, allowing it to take appropriate steps (such as halting the program on a fatal error).

Modules which wish to report error conditions create instances of type Error at initialization time. Routines which may report errors then expect a pointer to an error buffer as a parameter, declared by convention as the last parameter, Error* errc. On exit, this buffer will contain either ERROR_none, indicating successful completion, or some error code. The caller may then report the error, filling in the necessary blanks in the format specification (see below), attempt to recover, or simply ignore it (realizing that ignoring any but the most innocuous errors will most likely lead to trouble later on).

An Error has two main components. The severity of an error indicates how serious the error is. A warning may be reported to the user, but is not really considered an error. Continuing past a warning, or even 100 warnings, should cause no serious problems. An error, on the other hand, must be noted by the program: The program need not halt immediately, but at some point in the future, it will become impossible to proceed. An error of "exit" severity causes the program to exit immediately, as gracefully as possible. An error of "dump" severity causes the program to dump core and exit immediately. All of these actions are taken only when the error is reported (with ERRORreport()), rather than when the error is discovered.

The other component of an error is its text. This is a printf-style format string, whose arguments will be filled in when the error is reported. For example, the text for ERROR_memory_exhausted is "Out of memory allocating %d for %s." When this error is reported, the amount of memory requested and its intended purpose should be provided by the programmer:

```
ERRORreport(ERROR_memory_exhausted,
            block_size, "file buffer block");
```

For specifications of the Errors defined in libmisc.a, see section 4.1.8.

For greater flexibility in error reporting, Errors can be enabled and disabled individually. Disabled errors which are given to ERRORreport() will be ignored, just as ERROR_none is.

An alternate routine for reporting errors is ERRORreport_with_line(), which inserts a line number indication at the beginning of a message. Particularly when line numbers are included, it may be useful to sort error messages before printing them. This can be done by asking that error messages be buffered. When this message buffer
is flushed, its contents are sorted according to the third column, which is where \texttt{ERRORreport\_with\_line()} puts the line number. This feature is used in the second pass of Fed-X, for example, where the Express Working Form data structures are walked in the most convenient order, which bears little resemblance to the order in which the original constructs appeared in the source file. Any error messages encountered are buffered, and all are sorted and flushed after the entire pass is complete, resulting in sensibly ordered output.

<table>
<thead>
<tr>
<th>Type:</th>
<th>Severity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description:</td>
<td>This type is an enumeration of \texttt{SEVERITY_WARNING}, \texttt{SEVERITY_ERROR}, \texttt{SEVERITY_EXIT}, \texttt{SEVERITY_DUMP}, and \texttt{SEVERITY_MAX} (which is guaranteed to be the highest possible severity of any error).</td>
</tr>
</tbody>
</table>

| Procedure:   | \texttt{ERRORbuffer\_messages} |
| Parameters:  | Boolean flag - to buffer or not to buffer |
| Returns:     | void |
| Description: | Selects buffering of error messages. Buffering is useful when error messages are produced by \texttt{ERRORreport\_with\_line()}, as it allows the messages to be sorted according to line number before being displayed. |

| Procedure:   | \texttt{ERRORclear\_occurred\_flag} |
| Parameters:  | -- none -- |
| Returns:     | void |
| Description: | Clear the flag which is used to remember whether any errors have occurred. |

| Procedure:   | \texttt{ERRORcreate} |
| Parameters:  | String message - message to print for error |
|              | Severity severity - severity of error |
|              | Error* \texttt{err} - buffer for error message |
| Returns:     | void |
| Description: | Create a new error. The meanings of the various severity levels are as follows: \texttt{SEVERITY\_WARNING} indicates that a warning message should be generated. This will not interfere with later operation of the program. \texttt{SEVERITY\_ERROR} produces an error message, and the fact that an error has occurred will be remembered (e.g., so that no reports will be generated). \texttt{SEVERITY\_EXIT} indicates that the error is fatal, and should cause the program to exit immediately. \texttt{SEVERITY\_DUMP} causes the program to exit immediately and produce a core dump. \texttt{SEVERITY\_MAX} is guaranteed to be the highest severity level available. The message string may contain \texttt{printf}-style formatting codes, which will be filled when the message is printed. |

| Procedure:   | \texttt{ERRORdisable} |
| Parameters:  | Error error - the error to disable |
| Returns:     | void |
| Description: | Disable an error, so that the \texttt{ERRORreport} calls will ignore it. |

| Procedure:   | \texttt{ERRORenable} |
| Parameters:  | Error error - the error to enable |
| Returns:     | void |
| Description: | Enable an error, ensuring that the \texttt{ERRORreport} calls will report it. |
**4.1.4 Hash**

The Hash module emulates UNIX's `hsearch(3)` package with dynamic hashing. The module header reads, in part:

```
Dynamic hashing, after CACM April 1988 pp 446-457,
by Per-Ake Larson.
Coded into C, with minor code improvements, and with
hsearch(3) interface,
by ejp@ausmelb.oz, Jul 26, 1988: 13:16;
```

The code was downloaded from the Internet, and is used in the Toolkit with only cosmetic changes. Note that this is an incomplete implementation of a hash table abstraction: only insertion and named retrieval are supported.
Type: Action
Description: This type is an enumeration of HASH_FIND, HASH_INSERT.

Type: Element
Description: The entries in a hash table are stored as Elements. An Element has a char* (string) key, a char* data field, and a next pointer.

Procedure: HASHcreate
Parameters: unsigned count - estimated maximum number of table elements
Returns: Hash_Table - the new hash table
Description: Creates a new, empty hash table.

Procedure: HASHdestroy
Parameters: Hash_Table table - the table to be destroyed
Returns: void
Description: Destroys a hash table, releasing all associated storage.

Procedure: HASHsearch
Parameters: Hash_Table table - the table to search
Element item - the item to search for/insert
Action action - the action to take on the search item
Returns: Element - the result of the action
Description: If the table already contains an entry whose key matches that of the item given, this entry is returned unchanged. Otherwise, if action is HASH_INSERT, the item given is inserted into the hash table and returned, and if action is HASH_FIND, NULL is returned, indicating that no matching entry could be located.

4.1.5 Linked List

The Linked List abstraction represent heterogeneous linked lists. Each element of a list is treated as an object of type Generic; any object which can be cast to this type can be stored in a list. Note that the programmer must provide himself with a mechanism for determining the type of an object retrieved from a list: this module maintains no such type information.

Type: Link
Description: Each element of a linked list is stored as a Link, which has next and prev pointers and a Generic data field.

Procedure: LISTadd_all
Parameters: Linked_List list - list to add to
Linked_List items - items to add
Returns: void
Description: Add the contents of items to the end of list.

Procedure: LISTadd_first
Parameters: Linked_List list - list to add to
Generic item - item to add
Returns: Generic - the item added
Description: Add an item to the front of a list.
Procedure: LISTadd_last
Parameters: Linked_List list - list to add to
Generic item - item to add
Returns: Generic - the item added
Description: Add an item to the end of a list.

Procedure: LISTcopy
Parameters: Linked_List list - the list to copy
Returns: Linked_List - the copy create
Description: Make a shallow copy of a list.

Procedure: LISTcreate
Parameters: -- none --
Returns: Linked_List - the list created
Description: Create an empty list.

Iterator: LISTdo ... LISTod
Usage: 
Linked_List list;
LISTdo(list, <variable_name>, <type>)
  process_value(<variable_name>);
LISTod;
Description: The macro pair LISTdo() ... LISTod; are used to iterate over a list. type is a C language type; variable is declared to be of this type within the block bracketed by these two macros. variable is successively assigned each value on the list, in turn.

Procedure: LISTfree
Parameters: Linked_List list - list to free
Returns: void
Description: Release a linked list. Indicates that the list is no longer used by the caller; if there are no other references to it, all storage associated with it may be released. Note that the actual items on the list are not free’d, as their destructors are unknown.

Procedure: LISTpeek_first
Parameters: Linked_List list - list to examine
Returns: Generic - the first item on the list
Requires: !LISTempty(list)

Procedure: LISTremove_first
Parameters: Linked_List list - list to remove from
Returns: Generic - the item removed
Description: Remove the first item from a list and return it.

4.1.6 Stack

This module implements the classic LIFO Stack. It is implemented as a set of macros wrapped around the Linked List abstraction. Stacks may be heterogeneous.

Procedure: STACKcreate
Parameters: -- none --
Returns: Stack - a new, empty stack
Procedure: STACKempty
Parameters: Stack stack - the stack to be tested
Returns: Boolean - is the stack empty?

Procedure: STACKfree
Parameters: Stack stack - the stack to free
Returns: void
Description: Release a stack. Indicates that the stack is no longer used by the caller; if there are no other references to it, all storage associated with it may be released. Note that the actual items on the stack are not free'd, as their destructors are unknown.

Procedure: STACKpeek
Parameters: Stack stack - the stack to peek at
Returns: Generic - the top item on the stack
Requires: !STACKempty(stack)
Description: Peeks at the top of a stack, returning it without removing it from the stack.

Procedure: STACKpop
Parameters: Stack stack - the stack to pop
Returns: Generic - the top item on the stack
Requires: !STACKempty(stack)
Description: Removes the top item from a stack and returns it to the caller.

Procedure: STACKpush
Parameters: Stack stack - the stack to push onto
Generic item - the item to push
Returns: void
Description: Pushes an item onto the top of a stack.

4.1.7 String

This module defines macros and functions for manipulating C strings. Some routines provide special functionality, while others simply rename standard calls from the C library to fit the naming scheme of the Toolkit. The String type is a synonym for char*.

Procedure: STRINGcompare
Parameters: String s1 - first comparison string
String s2 - second comparison string
Returns: int - measure of equality of strings
Description: This is an alias for the standard C call strcmp(). The result is 0 when the two arguments are equal, negative when s1 precedes s2 in lexicographical order, and positive when s1 follows s2.

Procedure: STRINGcopy
Parameters: String string - the string to copy
Returns: String - a deep copy of the argument
Description: Allocates a String large enough to hold the (NUL-terminated) argument, copies the argument into this String, and returns it to the caller.
**Procedure:** STRINGcopy_into  
**Parameters:** String dest - the destination string  
String src - the string to be copied  
**Returns:** dest  
**Requires:** STRINGlength(dest) >= STRINGlength(src)  
**Description:** This is an alias for the C library call strcpy(). The source string is copied into the destination string, which must be of equal or greater length.

**Procedure:** STRINGcreate  
**Parameters:** int length - length of string to create  
**Returns:** String - a new, empty string of at least the given length

**Procedure:** STRINGdowncase_char  
**Parameters:** char c - the character to convert  
**Returns:** char - the argument character, as lower case if it is a letter

**Procedure:** STRINGequal  
**Parameters:** String s1 - first string for comparison  
String s2 - second string for comparison  
**Returns:** Boolean - are the two strings equal?  
**Description:** Compares two strings for value equality. This call is equivalent to strcmp(s1, s2) == 0.

**Procedure:** STRINGfree  
**Parameters:** String string - the string to be released  
**Returns:** void  
**Description:** Allows all storage associated with a string to be reclaimed. References to the string may no longer be valid.

**Procedure:** STRINGlength  
**Parameters:** String string - the string to measure  
**Returns:** int - the actual length of the string, excluding the NUL terminator  
**Description:** This call is equivalent to strlen(string).

**Procedure:** STRINGlowercase  
**Parameters:** String string - the string to convert  
**Returns:** String - lowercased version of the argument  
**Description:** A new string is created and returned which contains the same value as the argument, but with all letters replaced with their lowercase counterparts.

**Procedure:** STRINGsubstring  
**Parameters:** String str - string to extract a substring from  
int from - beginning index for substring  
int to - ending index for substring  
**Returns:** String - the specified substring  
**Description:** A new string is created and returned whose value is a particular substring of some string. The index of the first character of a string is 0.

**Procedure:** STRINGupcase_char  
**Parameters:** char c - the character to convert  
**Returns:** char - the argument character, as upper case if it is a letter
Procedure: STRINGuppercase
Parameters: String string - the string to convert
Returns: String - uppercased version of the argument
Description: A new string is created and returned which contains the same value as the argument, but with all letters replaced with their uppercase counterparts.

4.1.8 Error Codes

This section specifies all of the Errors which are defined in libmisc.a. Note that each is a global variable; storage is allocated by the module named for each.

Error: ERROR_duplicate_entry
Defined In: Dictionary
Severity: SEVERITY_ERROR
Meaning: A name was duplicated in a dictionary
Format: %s - the duplicated name

Error: ERROR_empty_list
Defined In: Linked_List
Severity: SEVERITY_ERROR
Meaning: Illegal operation on an empty list
Format: %s - the context (function) in which the error occurred

Error: ERROR_free_null_pointer
Defined In: Error
Severity: SEVERITY_DUMP
Meaning: A NULL pointer was freed
Format: %s - the name of the offending function

Error: ERROR_memory_exhausted
Defined In: Error
Severity: SEVERITY_EXIT
Meaning: A malloc (2) request could not be satisfied
Format: %d - number of bytes requested
%s - intended use for memory

Error: ERROR_none
Defined In: Error
Severity: N/A
Meaning: No error occurred. In another life, this might have been called ERROR_NULL. But then, who knows?!
Format: -- none --

Error: ERROR_not_implemented
Defined In: Error
Severity: SEVERITY_EXIT
Meaning: An unimplemented function was called.
Format: %s - the name of the function
4.2 The Bison Support Library: libbison.a

The Bison support library is based on the standard UNIX Yacc support library libyacc.a, with modifications to support better error handling/reporting, implementation differences between Yacc and Bison (and also between Lex and Flex), and more careful use of global variables, this latter to allow more than one Bison parser to be linked into a single executable. The library is in ~pdes/lib/libbison.a, and sources can be found in ~pdes/local/libbison/.

The definitions of yyerror() in yyerror.c and yywhere() in yywhere.c are from [Schreiner85].

Several variable declarations in these two files had to be modified for Bison/Flex parsers. A documented difference between Lex and Flex is that the token buffer, yytext, is declared as a char* in Flex and as a char[] in Lex. Also, Flex does not provide Lex's yyleng variable. Other variables which need to be declared extern in Bison parsers so as not to collide when multiple parsers are linked together have storage allocated in yyvars.c. This file also defines a function yynewparse(), which can be used to restart a Bison parser.

A word on the ~pdes/etc/uniquify_* scripts. These csh scripts modify the code produced by Yacc/Bison/Lex/Flex so that multiple scanners and parsers can coexist in a single executable. For the most part, it is sufficient to change some global variable declarations to be static. Each script strips any of several suffixes off of the filename it is given to determine the actual name of the parser/scanner and then prepends this name to type and function declarations which are externally visible. Thus, a parser called expyacc.y ends up with the entry point exp_yyparse(), expects tokens of type exp_YSTYPE, and calls exp_yylex() to get these tokens. Similarly, a scanner called stepscan.l would provide step_yylex() as an entry point, and would produce tokens of type step_YSTYPE.
4.3 **BSD Unix Dynamic Loading: libdyna.a**

This package was retrieved from the Internet. Authorship information seems to have been lost. The routines provided are at the level of reading *a.out* headers and walking through symbol tables. We will not attempt to document this library; there are `.doc` files in the source directory, `~pdes/local/libdyna/`, which include examples of the package's use.

"The NIST PDES Toolkit: Technical Fundamentals"

Stephen Nowland Clark

The Product Data Exchange Specification (PDES) is an emerging standard for the exchange of product information among various manufacturing applications. A software toolkit for manipulating PDES data has been developed at the National PDES Testbed at NIST. A technical overview of this PDES Toolkit is provided. Fundamental software libraries are described, and techniques for creating applications based on the Toolkit are discussed.
