NIST STEP Working Form Programmer's Reference

Stephen Nowland Clark

1 Introduction

The NIST STEP physical file parser [Clark90c], and its associated STEP parser, STEPparse, are Public Domain tools for manipulating product models stored in the STEP physical file format [Altemueller88]. These tools are a part of the NIST PDES Toolkit [Clark90a], and are geared particularly toward building STEP translators. This reference manual discusses the internals of the STEP Working Form, including STEPparse. The reader is assumed to be familiar with the design of the Toolkit ([Clark90a], [Clark90b], [Clark90c]). In some cases, technical knowledge of the Express Working Form [Clark90e] is also required.

The STEP Working Form relies on the NIST Express Working Form [Clark90b] as an in-core data dictionary, which provides a context in which STEP models can be interpreted. The tight dependency of the STEP Working Form abstractions on those of the Express Working Form is due to the schema-independent nature of the former. The STEP Working Form, and, in particular, STEPparse, contain no knowledge of any particular information model. Applications built on these tools can thus manipulate STEP product models in the context of any number of Express information models without requiring recompilation.

1.1 Context

The PDES (Product Data Exchange using STEP) activity is the United States' effort in support of the Standard for the Exchange of Product Model Data (STEP), an emerging international standard for the interchange of product data between various vendors' CAD/CAM systems and other manufacturing-related software [Smith88]. A National PDES Testbed has been established at the National Institute of Standards and Technology to provide testing and validation facilities for the emerging standard. The Testbed is funded by the CALS (Computer-aided Acquisition and Logistic Support) program of the Office of the Secretary of Defense. As part of the testing effort, NIST is charged with providing a software toolkit for manipulating PDES data. This NIST PDES Toolkit is an evolving, research-oriented set of software tools. This document is one of a set of reports which describe various aspects of the Toolkit. An overview of the Toolkit is provided in [Clark90a], along with references to the other documents in the set.

For further information on the STEP Working Form or other components of the Toolkit, or to obtain a copy of the software, use the attached order form.

2 STEPparse Control Flow

A STEPparse translator consists of two separate passes: parsing and output generation. The first pass builds an instantiated `Product` representing the product model specified in the STEP input file. This `Product` can then be traversed by an output module in the second pass, producing whatever report is desired. It is anticipated that users will need output formats other than those provided with the NIST Toolkit. The process of writing a report generator for a new output format is discussed in detail in section 4.

2.1 First Pass: Parsing

The first pass of a STEPparse translator is a very simple parser. The STEPparse grammar itself is independent of any conceptual schema. The lexical analyzer recognizes any entity class name simply as an identifier; the actions associated with rules in the grammar then interpret this name as refering to a particular Express entity, and construct appropriate objects. As each construct is parsed, it is added to the Working Form. Because the STEP physical file format does not allow forward references to as-yet-undefined entity instances, all symbol references can be (and are) resolved during this parsing pass, so that no symbol resolution pass is required.

The STEPparse parser is written using the standard UNIX™ parser generation languages, Yacc and Lex. The grammar is processed by Bison, the Free Software Foundation's[1] implementation of Yacc. The lexical analyzer is produced by Flex[2], a fast, Public Domain implementation of Lex.

2.2 Second Pass: Output Generation

The report or output generation pass manages the production of the various output files. In the dynamically linked version of STEPparse, this pass loads successive output modules dynamically, calling each to traverse the Working Form. The dynamic linking mechanism is discussed briefly in [Clark90d]. It is also possible to build a statically linked translator, with a particular output module loaded in at build time; this is, in fact, the only mechanism available in an environment which is not derived from BSD 4.2 UNIX.

A report generator is an object module, most likely written in C, which has been compiled as a component module for a larger program (i.e., with the `-c` option to a Unix C compiler). In the dynamically linked version, the object module is linked into the running parser, and its entry point (by convention a function called `print_file()`) is

---

1. The Free Software Foundation (FSF) of Cambridge, Massachusetts is responsible for the GNU Project, whose ultimate goal is to provide a free implementation of the UNIX operating system and environment. These tools are not in the Public Domain: FSF retains ownership and copyright priviledges, but grants free distribution rights under certain terms. At this writing, further information is available by electronic mail on the Internet from gnu@prep.ai.mit.edu.
2. Vern Paxson's Fast Lex is usually distributed with GNU software, although, being in the Public Domain, it is not an FSF product and does not come under the FSF licensing restrictions.

called. The code of this module consists of calls to STEP Working Form access functions and to standard output routines. Chapter 4 provides a detailed description of the creation of a new output module.

3 Working Form Implementation

As in the Express Working Form [Clark90d], the Object abstraction is implemented as a `Symbol` header block with a pointer to a private `struct Object`. This C structure contains the real definition of the abstraction, but is never manipulated directly outside of the Object module. Product is implemented as a pointer to a private structure, `struct Product`.

Most stylistic and other conventions from the Express Working Form are equally valid for STEP; they are reiterated here for emphasis.

3.1 Primitive Types

The STEP Working Form makes use of several modules from the Toolkit general libraries, including the Error and Linked_List modules. These are described in [Clark90d].

3.2 STEP Working Form Manager Module

In addition to the abstractions discussed in [Clark90c], `libstep.a` contains one more (conceptual) module, the package manager. Defined in `step.c` and `step.h`, this module includes calls to intialize the entire STEP (and Express) Working Form package, and to run each of the passes of a STEPparse translator.

3.3 Code Organization and Conventions

Each abstraction is implemented as a separate module. Modules share only their interface specifications with other modules. A module Foo is composed of two C source files, `foo.c` and `foo.h`. The former contains the body of the module, including all non-inlined functions. The latter contains function prototypes for the module, as well as all type and macro definitions. In addition, global variables are defined here, using a mechanism which allows the same declarations to be used both for `extern` declarations in other modules and the actual storage definition in the declaring module. These globals can also be given constant initializers. Finally, `foo.h` contains inline function definitions. In a compiler which supports inline functions, these are declared `static inline` in every module which includes `foo.h`, including `foo.c` itself. In other compilers, they are undefined except when included in `foo.c`, when they are compiled as ordinary functions. `foo.c` resides in `~pdes/src/step/`; `foo.h` in `~pdes/include/`.

The type defined by module Foo is named `Foo`, and its private structure is `struct Foo`. Access functions are named as `FOOfunction()`; this function prefix is abbreviated for longer abstraction names, so that access functions for type `Foolhardy_Bartender` might be of the form `FOO_BARfunction()`. Some

functions may be implemented as macros; these macros are not distinguished typographically from other functions, and are guaranteed not to have unpleasant side effects like evaluating arguments more than once. These macros are thus virtually indistinguishable from functions. Functions which are intended for internal use only are named `FOO_function()`, and are usually `static` as well, unless this is not possible. Global variables are often named `FOO_variable`; most enumeration identifiers and constants are named `FOO_CONSTANT` (although these latter two rules are by no means universal).

Every abstraction defines a constant `FOO_NULL`, which represents an empty or missing value of the type. In addition, there are several operations which are defined for every type; these are primarily general management operations. Each abstraction defines at least one creation function, e.g. `FOOcreate()`. The parameters to this creation function vary, depending on the abstraction. A permanent copy of an object (as opposed to a temporary copy which will immediately be read and discarded) can be obtained by calling `FOOcopy(foo)`. This helps the system keep track of references to an object, ensuring that it is not prematurely garbage-collected. Similarly, when an object or a copy is no longer needed, it should be released by calling `FOOfree(foo)`, allowing it to be garbage-collected if appropriate.

For each abstraction, there is a function `FOOis_foo(obj)` which returns `true` if and only if its argument is a foo. This is useful when dealing with a heterogeneous list, for example.

3.4 Memory Management and Garbage Collection

In reading various portions of the STEP Working Form documentation, one may get the impression that the Working Form does some reasonably intelligent memory management. This is not true. The NIST PDES Toolkit is primarily a research tool. This is especially true of the Express and STEP Working Forms. The Working forms allocate huge chunks of memory without batting an eye, and this memory often is not released until an application exits. Hooks for doing memory management do exist (e.g., `XXXfree()` and reference counts), but currently are largely ignored.

3.5 Object

The Object abstraction is the basic building block of the STEP Working Form. An `Object` is created for each unit of value in a PDES/STEP product model: each entity instance, aggregate, integer, string, etc. On the surface, this would seem to be a reasonably straightforward module to implement: each `Object` has an optional name, a `Type`, and a value. The value may be simple or structured; in either case, it basically comes down to a pointer - either to an array of `Objects`, or to an integer, real, string, etc.

As with most abstractions in the Express Working Form, `Object` is implemented as a `Symbol` header whose `definition` field points at a `struct Object`, which is defined thus:

```
struct Object {
```

```
        Type      type;
        Generic   user_data;
        union {
             Constant  enumeration;
             Integer   integer;
             Logical   logical;
             Real      real;
             String    string;
             Object*   entity;
             Aggregate aggregate;
        }         value;
};
```

The first two fields are pretty straightforward. Note that `user_data` is a generic pointer field. In strict ANSI C, only a pointer can be safely stored into this field and later retrieved; it is safest to only store pointers in this field. In particular, the age-old trick of casting pointers and integers back and forth, never completely portable, is now officially frowned upon.

The `value` union is where things get tricky. This field contains the actual value of the object represented. Unstructured types (numbers, logicals, and strings) are represented directly; e.g., `object.value.integer` contains an integer, and `object.value.string`, a character pointer. The value of an enumeration object is represented as a `Constant`, which will be an element of the appropriate enumeration. The integer representation of this enumeration element can be retrieved by calling `(int)CSTget_value(object.value.enumeration)`.

An entity instance's `value` field, `value.entity`, is a pointer to the base of an array of objects. Each element of this array corresponds to an attribute of the entity; attributes appear in the same order as in a PDES/STEP physical file, with empty attributes explicitly represented by `OBJECT_NULL`. The offset to a particular attribute value is retrieved from the Express data dictionary by calling `ENTITYget_attribute_offset(entity, attribute)`, where `entity` is the entity class of the object in question and `attribute` is the `Variable` representing the attribute to be located.

The most convoluted object value representation is that for aggregates. An aggregate value is represented as a pointer to a `struct Aggregate`, defined as

```
struct Aggregate {
     int             low;
     int             high;
     Expression      max;
     Object*         contents;
};
```

The last field, `contents`, holds the actual contents of the aggregate, as an array of `Objects`. The `low` field provides a lower bound on allowable indices into this array, and doubles as a logical offset to the first element of the array. This value is 1 for any

non-array aggregate. Thus, when `low` is 1, `some_aggregate[1]` is found at `contents[0]`. Similarly, in an array whose `low` is 10, the `some_array[12]` is found at `contents[12-10 = 2]`. `low` remains constant in any particular aggregate object. The `high` field gives an upper bound on the indices of currently filled slots in an aggregate object. Every index into the aggregate beyond `high` which is in bounds is guaranteed to return `OBJECT_NULL`. The end result is that a loop of the form `for (i = low; i <= high; ++i) <use contents[i-low]>` will always hit all of the elements of an aggregate. This function of offsetting by the lower bound is bundled into the various aggregate indexing functions of the working form (`OBJaggr_at()`, `OBJlist_insert()`, etc.), so that the indices which a user sees will be the ones which would be expected based on the Express model. In the current implementation, `high` in an aggregate whose type (from Express) gives a finite upper bound always remains constant at this bound. In the case of an aggregate with no specified upper bound, however, `high` may vary with the number of elements actually in the aggregate. The expression (from Express) giving the absolute upper bound on an aggregate is cached in `aggregate->max`. `high` is never allowed to be greater than the value of this expression.

The two calls `OBJaggr_at()` and `OBJaggr_at_put()` can be used with any kind of aggregate, although they are intended to be used primarily for building general aggregates which will later be `OBJtype_cast()` into specific types of aggregates. This is how STEPparse builds aggregates, since it is considerably easier than figuring out at parse time what type of aggregate should be built. The various class-specific manipulations (list concatenation, set intersection, etc.) are provided by calls requiring aggregates of a particular class: `OBJlist_concat()`, `OBJset_intersect()`, etc. It should be noted that the calls for combning aggregates are destructive: each modifies its first argument to hold its computed result. In general, the two arguments may safely be set equal. Exceptions are noted in the individual function specifications.

Finally, a word about type conversion (also known as casting, as in C). Type conversions of existing `Objects` are handled by `OBJtype_cast(Object, Type, Error*)`. Only certain conversions are allowed; other attempted casts leave the `Object` unchanged and return an error code. Clearly, any `Object` can trivially be cast into its own type. The different numeric types can be cast about at will. A general aggregate can be cast into any specific aggregate class; otherwise, an aggregate can only be cast into another aggregate type of the same class: an array cannot be cast into a set, etc. Each element of the aggregate being cast must, of course, be recursively cast into the appropriate base type; each of these conversions is subject to the same rules as any other cast. Finally, an entity `Object` can be converted into an instance of a supertype of its class, or into an instance of a `SELECT` type containing some type to which it can be cast. These casts of entity instances in fact do not modify the `Object` being cast.

3.6 Product

A product in STEP contains a large number of interrelated entity instances, and is represented by the `Product` abstraction. Each `Product` is named, and includes a pointer to the Express model which provides the scope in which its component `Objects` are

defined. These component objects can be retrieved from the `Product` in several ways: a specific (external) entity instance can be retrieved by name; a `Linked_List` of all of the (external) entity instances in the `Product` can be requested; or a particular entity class in the `Product`'s conceptual schema can be queried for all of its instances (note that this last method retrieves both internal and external entity instances). Internal (embedded) entity instances and non-entity `Objects` must appear as attribute values or aggregate elements somewhere in the `Product`, and are only accessible via `ENTITYget_instances()` and component retrieval from the containing `Objects`.

The above three access methods are supported by storing three references to each `Object` in a `Product`. When an `Object` is added to a `Product`, it is added to the end of the list of external objects. This list preserves the order in which the `Objects` were added to the `Product`, and so is appropriate for applications, such as writing a STEP physical file, which require that there be no forward references to as-yet-undefined `Objects`. Each external `Object` is also added to a dictionary which the `Product` maintains, to allow retrieval by name. And when an entity object is first created, it is added to the instance list of its class.

4 Writing An Output Module

We now turn to the topic of actually writing a report generator. The end result of this process will be an object module (UNIX `.o` file) which can be loaded into STEPparse. This module contains a single entry point which traverses a given `Product` and writes its output to a particular file. The conceptual entry point is conventionally called `print_file()`, while the physical entry point, which simply dispatches to `print_file()`, is called `entry_point()`.

In most cases, there will be a one-to-one correspondence between Objects in the instantiated Working Form and records to be written on the output. When this is the case, the meat of the report generator can be made fairly simple. Since a list of all of the Objects in the Working Form is available, it is easy to iterate over this list and output each Object in sequence:

```
STEPprint(Product product, FILE* file)
{
        Linked_List list;
        list = PRODget_contents(product);
        LISTdo(list, obj, Object)
                OBJprint(obj, file);
        LISTod;
}
```

The only remaining problem is to write a function `OBJprint()` which emits the output record for a single Object. Given the variety of types of Objects, this function will probably be controlled by a large `switch` statement, selecting on the Object's type class (numbers, strings, and aggregates all have to be printed differently). Code to deal with multi-dimensional arrays an internal/external entity references can get tricky, and

should be written carefully. An example of a fairly simple report generator is that used by STEPparse-QDES. The source code for this module is in `~pdes/src/STEPparse_qdes/step_output_smalltalk.c`.

4.1 Layout of the C Source

The layout of the C source file for a report generator which will be dynamically loaded is of critical importance, due to the primitive level at which the load is carried out. The very first piece of C source in the file must be the `entry_point()` function, or the loader may find the wrong entry point to the file, resulting in mayhem. Only comments may precede this function; even an `#include` directive may throw off the loader. An output module is normally layed out as shown:

```
void
entry_point(void* product, void* file)
{
     extern void print_file();
     print_file(product, file);
}

#include "step.h"

... actual output routines . ..

void
print_file(void* product, void* file)
{
     print_file_header((Product)product,
          (FILE*)file);
     STEPprint(product, file);
     print_file_trailer((Product)product,
          (FILE*)file);
}
```

The `print_file()` function will probably always be quite similar to the one shown, although in many cases, the file header and/or trailer may well be empty, eliminating the need for these calls. In this case, `STEPprint()` and `print_file()` will probably become interchangeable.

Having said all of the above about templates, code layout, and so forth, we add the following note: In the final analysis, the output module really is a free-form piece of C code. There is one and only one rule which must be followed: The entry point (according to the `a.out` format) to the `.o` file which is produced when the report generator is compiled must be appropriate to be called with a `Product` and a `FILE*`. The simplest (and safest) way of doing this is to adhere strictly to the layout given, and write an `entry_point()` routine which jumps to the real (conceptual) entry point. But any other convention which guarantees this property may be used.

4.2 Output Module Linkage Mechanisms

One of the powers of STEPparse is the flexibility which it gives a user with regard to generating output. An important component of this flexibility on BSD Unix systems is the dynamic loading of output modules. Both static and dynamic binding of output modules are supported by STEPparse. This is implemented by physically breaking the object code from the Working Form manager (`step.c`) into three separate `.o` files: the initialization code and the first pass of STEPparse are compiled into `step.o`, which is stored in `libstep.a`. The static linking version of the second pass (without any output module) is compiled into `step_static.o`; and the dynamic loading version into `step_dynamic.o`. Sources for all of these components reside in `step.c`; the various sections are extracted via conditional compilation: When this file is compiled with the preprocessor symbols `reports` and `static_reports` defined, `step_static.o` is produced. With `reports` and `dynamic_reports` defined, `step_dynamic.o` is produced; and with none of these defined, `step.o` is produced.

Since `step_static.o` and `step_dynamic.o` both define the function `STEPreport()`, only one can be linked into any given executable. This selection is what determines whether a STEPparse translator links in output modules statically or dynamically. Note that a suitable output module (`.o` file) must appear *after* `step_static.o` in the linker's argument list when a statically linked translator is being built.

5 Working Form Routines

The remainder of this manual consists of specifications and brief descriptions of the access routines and associated error codes for the STEP Working Form. The error codes are manipulated by the Error module [Clark90d]. Each subsection below corresponds to a module in the Working Form library. The Working Form Manager module is listed first, followed by the remaining data abstractions in alphabetical order.

5.1 Working Form Manager

Procedure: STEPinitialize
Parameters: Error* errc - buffer for error code
Returns: void
Description: Initialize the STEP Working From package. In a typical STEP translator, this is called by the default `main()` provided in the Working Form library. Other applications should call this function at initialization time.
Errors: none

Procedure: STEPparse
Parameters: String filename - the name of the file to be parsed
Express data_model - conceptual schema (as produced by `EXPRESSpass_2()`)
Returns: Product - the product model parsed
Description: Parse a STEP physical file into the Working Form

Procedure: STEPreport
Parameters: Product product - the product to output
Returns: void
Description: Invoke one or more report generators for a STEP Working Form model.
Description: Invoke one (or more) report generator(s). When this function is compiled with `-Ddynamic_reports`, it will repeatedly prompt for report generators and output files, dynamically loading and executing them. When it is compiled with `-Dstatic_reports`, a report generator must also be included at link time, with the entry point `print_file(Express, FILE*)`.

5.2 Object

Procedure: OBJaggr_at
Parameters: Object object - object to examine
int index - index of requested element
Error* errc - buffer for error code
Returns: Object - value at requested position
Description: Retrieves the value at some position in an aggregate. Note that the calls which are specific to a particular aggregate class are much to be preferred.
Errors: `ERROR_index_out_of_range` - the index is outside of the bounds of the aggregate

Procedure: OBJaggr_at_put
Parameters: Object object - object to modify
int index - index at which to put element
Object value - value to insert
Error* errc - buffer for error code
Returns: void
Description: Store a value into an aggregate object. Note that the calls which are specific to a particular aggregate class are much to be preferred.
Errors: `ERROR_index_out_of_range` - the index is outside of the bounds of the aggregate

Procedure: OBJaggr_lower_bound
Parameters: Object object - object to examine
Error* errc - buffer for error code
Returns: int - the lower bound of the object
Description: Retrieves the lower bound of an aggregate object. For an array, this is the index of the first element of the array. For other aggregates, it is 1.
Errors: none

Procedure: OBJaggr_upper_bound
Parameters: Object object - object to examine
Error* errc - buffer for error code
Returns: int - the upper bound of the object
Description: Retrieves the upper bound of an aggregate object. For an aggregate with a constrained size, this is the value of the upper limit or index. For an aggregate with an infinite upper bound, the value returned is guaranteed to be larger than the highest index of a filled slot in the aggregate.
Errors: none

Procedure: OBJarray_at
Parameters: Object array - array to examine
int index - index of requested element
Error* errc - buffer for error code
Returns: Object - value at requested position
Description: Retrieves the value at some position in an array.
Errors: `ERROR_index_out_of_range` - the index is outside of the bounds of the aggregate

Procedure: OBJarray_at_put
Parameters: Object array - array to modify
int index - index at which to put element
Object value - value to insert
Error* errc - buffer for error code
Returns: void
Description: Store a value into an array object.
Errors: `ERROR_index_out_of_range` - the index is outside of the bounds of the aggregate

Procedure: OBJbag_add
Parameters: Object bag - bag to modify
Object item - item to add
Error* errc - buffer for error code
Returns: void
Description: Inserts an object into a bag.
Errors: `ERROR_bag_full` - there is no more room in the bag

Procedure: OBJbag_includes
Parameters: Object bag - bag to test
Object item - item to test for
Error* errc - buffer for error code
Returns: Boolean - does this bag contain this item?
Errors: none

Procedure: OBJbag_intersect
Parameters: Object bag - bag to intersect into
Object unitee - bag to intersect with
Error* errc - buffer for error code
Returns: void
Description: Intersects two bags. This operation is destructive: the first bag holds the resulting intersection on return.
Errors: none

Procedure: OBJbag_remove
Parameters: Object bag - bag to remove from
Object item - item to remove
Error* errc - buffer for error code
Returns: void
Description: Remove a single occurence of some item from a bag, if it appears.
Errors: none

Procedure: OBJbag_remove_all
Parameters: Object bag - bag to remove from
Object remove - bag of items to remove
Error* errc - buffer for error code
Returns: void
Description: Removes all items in a bag from some other bag. This is bag subtraction. This operation is destructive: the first bag holds the result on return.
Errors: none

Procedure: OBJbag_subset
Parameters: Object bag - bag to test as superset
Object subset - bag to test as subset
Error* errc - buffer for error code
Returns: Boolean - does the first bag contain the second as a subset?
Description: This implementation is not completely correct. In particular, the following returns `true`: `OBJbag_subset({a, b, c}, {a, a})`.
Errors: none

Procedure: OBJbag_unite
Parameters: Object bag - bag to unite onto
Object unitee - bag to unite with
Error* errc - buffer for error code
Returns: void
Description: Adds the contents of a bag to another bag. This operation is destructive: the first bag holds the resulting union on return. It is not safe to unite a bag with itself.
Errors: none

Procedure: OBJcopy
Parameters: Object object - object to copy
Returns: Object - a shallow copy of the object

Procedure: OBJcreate
Parameters: Type type - type to instantiate
Error* errc - buffer for error code
Returns: Object - a new, empty object of the given type
Errors: `ERROR_cannot_instantiate` - the type given cannot be instantiated (e.g., `Generic`)

Procedure: OBJcreate_entity
Parameters: Entity entity - entity class to instantiate
Linked_List attributes - list of attribute values
int line - source line number of the instance to be created
Error* errc - buffer for error code
Returns: Object - a new entity instance, as described
Description: A new object of the specified entity type is created. There should be a one-to-one correspondence between the values on the attribute value list and the list of attributes for the entity being instantiated.
Errors: `ERROR_insufficient_attributes` - not enough attribute values in the list provided
`ERROR_too_many_attributes` - too many attribute values in the list provided

Procedure: OBJcreate_ud_entity
Description: Create a user-defined entity. This procedure is not yet implemented.

Procedure: OBJfast_get_attribute
Parameters: Object object - object to examine
Variable attribute - attribute to retrieve
Error* errc - buffer for error code
Returns: Object - value of attribute
Description: Retrieves the value of an attribute from an entity instance. This call is faster than `OBJget_attribute()` when the caller already has the actual attribute record for the desired attribute, rather than simply having its name (as expected by `OBJget_attribute()`).
Errors: none

Procedure: OBJfast_put_attribute
Parameters: Object object - object to modify
Variable attribute - attribute to store into
Object value - value to store into attribute
Error* errc - buffer for error code
Returns: void
Requires: TYPEget_class(OBJget_type(object)) == TYPE_ENTITY
Description: Store a value into an attribute of an entity instance. This call is faster than `OBJput_attribute()` when the caller already has the actual attribute record for the desired attribute, rather than simply having its name (as expected by `OBJput_attribute()`).
Errors: Same as for `OBJput_attribute()`.

Procedure: OBJfree
Parameters: Object object - object to free
Error* errc - buffer for error code
Returns: void
Description: Release an Object. Indicates that the object is no longer used by the caller; if there are no other references to the object, all storage associated with it may be released.
Errors: none

Procedure: OBJget_attribute
Parameters: Object object - object to examine
String attributeName - name of attribute to retrieve
Error* errc - buffer for error code
Returns: Object - value of the named attribute
Description: Retrieves the value of a named attribute from an entity instance. This call is the slower method for retrieving an attribute value. If the actual attribute recored is already available, use `OBJfast_get_attribute()` instead.
Errors: none

Procedure: OBJget_line_number
Parameters: Object object - object to examine
Returns: int - line number of object
Errors: none

Procedure: OBJget_name
Parameters: Object object - object to examine
Returns: String - the object's name
Description: Retrieves the name of an object. Unnamed objects, which would normaliy be embedded entities and non-entities, yield `STRING_NULL`.
Errors: none

Procedure: OBJget_type
Parameters: Object object - object to examine
Returns: Type - the type of the object
Errors: none

Procedure: OBJget_user_data
Parameters: Object object - object to examine
Error* errc - buffer for error code
Returns: Generic - value of user data field for this object
Errors: none

Procedure: OBJget_value
Parameters: Object object - object to examine
Error* errc - buffer for error code
Returns: Generic - the object's value
Description: Retrieves the value of a single-valued object. The value returned will be a `char*` for a string object, a `Constant` for an enumeration object, and a pointer to an `int`, `double`, or `Boolean` for an integer, real, or logical object, respectively. See `OBJarray_at()`, `OBJbag_includes()`, `OBJlist_at()`, and `OBJset_at()` to read from an aggregate. See `OBJget_attribute()` to read from an entity instance.
Errors: none

Procedure: OBJinitialize
Parameters: Error* errc - buffer for error code
Returns: void
Description: Initialize the Object module. This is called by STEPinitialize().
Errors: none

Procedure: OBJis_external
Parameters: Object object - object to examine
Returns: Boolean - is this an external object (non-embedded entity)?
Errors: none

Procedure: OBJis_internal
Parameters: Object object - object to examine
Returns: Boolean - is this an internal object (embedded entity)?
Errors: none

Procedure: OBJlist_add_first
Parameters: Object list - list to modify
Object item - item to insert
Error* errc - buffer for error code
Returns: void
Description: Adds an item to the beginning of a list. This function is not yet implemented.
Errors: none

Procedure: OBJlist_add_last
Parameters: Object list - list to modify
Object item - item to insert
Error* errc - buffer for error code
Returns: void
Description: Adds an item to the end of a list. This function is not yet implemented.
Errors: none

Procedure: OBJlist_concat
Parameters: Object list - list to concatenate onto
Object tail - list to concatenate
Error* errc - buffer for error code
Returns: void
Description: Concatenate a list onto the end of another. This operation is destructive: the first list is modified so that it includes a copy of the second. Changes to the second will not appear in the first. This function is not yet implemented.
Errors: none

Procedure: OBJput_attributc
Parameters: Object object - objcct to modify
String attributeName - namc of attribute to store into
Objcct value - value to store into attribute
Error* errc - buffer for crror code
Returns: void
Requires: TYPEget_class(OBJget_type(objcct)) == TYPE_ENTITY
Description: Stores a value into a named attribute of an entity instance. This call is the slower method for storing into an attribute. If the actual attribute record is available, for example from travcrsing the `Entity`'s attribute list, use `OBJfast_put_attribute()` instead.
Errors: `ERROR_aggregate_expected` - value given for an aggregate was not an aggregate
`ERROR_array_expected` - value given for an array was not an array
`ERROR_bag_expected` - value givcn for a bag was not a bag
`ERROR_entity_expected` - value given for an entity was not an entity
`ERROR_external_expected` - an `external` attribute was given an internal (embeddcd) entity as a value
`ERROR_inappropriate_entity` - the entity given as a value was not of an expected class
`ERROR_integer_expected` - value given for an integer was not an integer
`ERROR_internal_expected` - an `internal` attribute was given an external entity reference as a value
`ERROR_list_expected` - value given for a list was not a list
`ERROR_logical_expected` - value given for a logical was not a logical
`ERROR_number_expected` - value given for a number was not a number
`ERROR_set_expected` - value given for a set was not a set
`ERROR_string_expected` - value given for a string was not a string
`ERROR_incompatible_types` - the value given is not of the expected type, in some way not covcred by any of the above messages

Procedure: OBJput_linc_number
Parameters: Object object - objcct to modify
int numbcr - line number for object
Returns: void
Description: Sct an object's line numbcr.
Errors: none

Procedure: OBJput_name
Parameters: Object object - object to modify
String name - namc for object
Returns: void
Description: Sets the name (identifier) of an object; normally, only entity instances which are not embedded arc named.
Errors: none

Procedure: OBJput_user_data
Parameters: Object object - object to modify
Generic valuc - user data value for object
Error* errc - buffer for error code
Returns: Generic - old value of user data field for this object
Description: Stores a value into an object's user data field
Errors: none

Procedure: OBJput_value
Parameters: Object object - object to modify
Generic value - value for object
Error* errc - buffer for error code
Returns: void
Description: Sets the value of a single-valued object. The value given should be a `char*` for a string object. For an integer, real, or logical object, it should be an `int*`, `double*`, and `Boolean*`, respectively. For an enumeration object, the value given should be of type `Constant`. See `OBJaggr_at_put()`, `OBJarray_at_put()`, `OBJbag_add()`, `OBJlist_add_first()`, `OBJlist_add_last()`, and `OBJset_add()` to store into an aggregate. See `OBJput_attribute()` to store into an entity instance.
Errors: none

Procedure: OBJset_add
Parameters: Object set - set to modify
Object item - item to add
Error* errc - buffer for error code
Returns: void
Description: Inserts an object into a set, if it is not already present.
Errors: `ERROR_set_full` - there is no more room in the set

Procedure: OBJset_includes
Parameters: Object set - set to test
Object item - item to test for
Error* errc - buffer for error code
Returns: Boolean - does this set contain this item?
Errors: none

Procedure: OBJset_intersect
Parameters: Object set - set to intersect into
Object with - set to intersect with
Error* errc - buffer for error code
Returns: void
Description: Intersects two sets. This operation is destructive: the first set holds the resulting intersection on return.
Errors: none

Procedure: OBJset_remove
Parameters: Object set - set to remove from
Object item - item to remove
Error* errc - buffer for error code
Returns: void
Description: Remove an item from a set, if it appears.
Errors: none

Procedure: OBJset_remove_all
Parameters: Object set - set to remove from
Object remove - set of items to remove
Error* errc - buffer for error code
Returns: void
Description: Removes all items in a set from some other set. This is set subtraction. This operation is destructive: the first set holds the result on return.
Errors: none

Procedure: OBJset_subset
Parameters: Object set - set to test as superset
Object subset - set to test as subset
Error* errc - buffer for error code
Returns: Boolean - does the first set contain the second as a subset?
Errors: none

Procedure: OBJset_unite
Parameters: Object set - set to unite onto
Object unitee - set to unite with
Error* errc - buffer for error code
Returns: void
Description: Forms the union of two sets. This operation is destructive: the first set holds the resulting union on return.
Errors: none

Procedure: OBJtype_cast
Parameters: Object object - object to be cast
Type type - type to cast to
Error* errc - buffer for error code
Returns: Object - the object, cast to the requested type
Description: Converts an object to a new type, if possible. If the cast is successful (`*errc == ERROR_none`), the original object should no longer be used. It is guaranteed to be valid only when an error is reported. This call does not report errors to `stderr`; it is the callers responsibility to check `*errc` and to call `ERRORreport(*errc, (String)context)` if it is not `ERROR_none`.
Errors: `ERROR_aggregate_expected` - value given for an aggregate was not an aggregate
`ERROR_array_expected` - value given for an array was not an array
`ERROR_bag_expected` - value given for a bag was not a bag
`ERROR_entity_expected` - value given for an entity was not an entity
`ERROR_inappropriate_entity` - the entity given as a value was not of an expected class
`ERROR_integer_expected` - value given for an integer was not an integer
`ERROR_list_expected` - value given for a list was not a list
`ERROR_logical_expected` - value given for a logical was not a logical
`ERROR_number_expected` - value given for a number was not a number
`ERROR_set_expected` - value given for a set was not a set
`ERROR_string_expected` - value given for a string was not a string
`ERROR_incompatible_types` - the value given is not of the expected type, in some way not covered by any of the above messages

5.3 Product

Procedure: PRODadd_object
Parameters: Product product - product to modify
Object object - entity instance to add
Returns: void
Requires: TYPEget_class(OBJget_type(object)) == TYPE_ENTITY
Description: Adds an entity instance to a product model. The instance is assumed already to have been added to the instance list of its class, since `OBJcreate_entity()` does this.
Errors: none

Procedure: PRODcreate
Parameters: String name - name for new product
Express model - conceptual schema in which to create product
Returns: Product - a new, empty product
Description: Creates an empty product within a particular conceptual schema.
Errors: none

Procedure: PRODget_conceptual_schema
Parameters: Product product - product to examine
Returns: Express - conceptual schema in which the product exists
Errors: none

Procedure: PRODget_contents
Parameters: Product product - product to examine
Returns: Linked_List - entity instances which make up the product
Description: Retrieves a list of the objects in a product model, in the order in which they were created.
Errors: none

Procedure: PRODget_name
Parameters: Product product - product to examine
Returns: String - the name of the product
Errors: none

Procedure: PRODget_named_object
Parameters: Product product - product to examine
String name - name of object to retrieve
Returns: Object - the named object
LDescription: Retrieves a named object from a STEP product model, if it is defined.
Errors: none

Procedure: PRODintiialize
Parameters: -- none --
Returns: void
Description: Initializes the Product module. This is called by STEPinitialize().
Errors: none

6 STEP Working Form Error Codes

The Error module, which is used to manipulate these error codes, is described in [Clark90d]. All STEP Working Form error codes are defined in the Object module.

Error: ERROR_aggregate_expected
Severity: SEVERITY_ERROR
Meaning: A non-aggregate value was provided for an aggregate attribute
Format: %s - attribute name

Error: ERROR_array_expected
Severity: SEVERITY_ERROR
Meaning: An aggregate of a specific non-array class was provided for an array attribute
Format: %s - attribute name

Error: ERROR_bag_expected
Severity: SEVERITY_ERROR
Meaning: An aggregate of a specific non-bag class was provided for a bag attribute
Format: %s - attribute name

Error: ERROR_bag_full
Severity: SEVERITY_WARNING
Meaning: An item was inserted into an already full bag
Format: -- none --

Error: ERROR_cannot_instantiate
Severity: SEVERITY_ERROR
Meaning: An attempt was made to instantiate an uninstantiable type
Format: %s - type name

Error: ERROR_entity_expected
Severity: SEVERITY_ERROR
Meaning: A non-entity Object was provided for an attribute having an entity type
Format: %s - attribute name

Error: ERROR_external_expected
Severity: SEVERITY_WARNING
Meaning: An embedded (internal) entity was provided for an attribute with "external" reference class
Format: %s - attribute name

Error: ERROR_inappropriate_entity
Severity: SEVERITY_ERROR
Meaning: An entity of the wrong type was provided for an attribute having an entity type
Format: %s - attribute name

Error: ERROR_incompatible_types
Severity: SEVERITY_ERROR
Meaning: Some other type problem was encountered in specifying an attribute of some object.
Format: %s - attribute name

Error: ERROR_index_out_of_range
Severity: SEVERITY_WARNING
Meaning: An attempt was made to index an aggregate object outside of the legal bounds
Format: %d - index value

Error: ERROR_insufficient_attributes
Severity: SEVERITY_WARNING
Meaning: Too few attribute values were provided for a particular entity instantiation
Format: %s - entity instance identifier

Error: ERROR_integer_expected
Severity: SEVERITY_ERROR
Meaning: A non-integer value was provided for an integer attribute
Format: %s - attribute name

Error: ERROR_internal_expected
Severity: SEVERITY_WARNING
Meaning: An non-embedded (external) entity was provided for an attribute with "internal" reference class
Format: %s - attribute name

Error: ERROR_list_expected
Severity: SEVERITY_ERROR
Meaning: An aggregate of a specific non-list class was provided for a list attribute
Format: %s - attribute name

Error: ERROR_logical_expected
Severity: SEVERITY_ERROR
Meaning: A non-logical value was provided for a logical attribute
Format: %s - attribute name

Error: ERROR_number_expected
Severity: SEVERITY_ERROR
Meaning: A non-numeric value was provided for a numeric attribute
Format: %s - attribute name

Error: ERROR_set_duplicate_entry
Severity: SEVERITY_ERROR
Meaning: A duplicate entry was added to a set
Format: -- none --

Error: ERROR_set_expected
Severity: SEVERITY_ERROR
Meaning: An aggregate of a specific non-set class was provided for a set attribute
Format: %s - attribute name

Error: ERROR_set_full
Severity: SEVERITY_WARNING
Meaning: An item was inserted into an already full set
Format: -- none --

Error: ERROR_string_expected
Severity: SEVERITY_ERROR
Meaning: A non-string Object was provided for a string attribute
Format: %s - attribute name

Error: ERROR_too_many_attributes
Severity: SEVERITY_WARNING
Meaning: Too many attribute values were provided for a particular entity instantiation
Format: %s - entity instance identifier

Error: ERROR_undefined_reference
Severity: SEVERITY_ERROR
Meaning: A reference was made to an unknown entity instance identifier
Format: %s - entity instance identifier

Error: ERROR_unknown_entity
Severity: SEVERITY_ERROR
Meaning: A reference was made to an unknown entity class (type)
Format: %s - entity class name

11. ABSTRACT (A 200-WORD OR LESS FACTUAL SUMMARY OF MOST SIGNIFICANT INFORMATION. IF DOCUMENT INCLUDES A SIGNIFICANT BIBLIOGRAPHY OR LITERATURE SURVEY, MENTION IT HERE.)

The Product Data Exchange Specification (PDES) is an emerging standard for the exchange of product information among various manufacturing applications. The neutral exchange medium for PDES product models is the STEP physical file format. The National PDES Testbed at NIST has developed software to manipulate and translate STEP models. This software consists of an in-memory working form and an associated physical file parser, STEPparse. The internal operation of the STEPparse parser is described. The implementation of the data abstractions which make up the STEP Working Form is discussed, and specifications are given for the Working Form access functions. The creation of STEP translators using STEPparse is discussed.
