## INTRODUCTION TO NOVEMBER 1990 ISSUE OF THE CEEE TECHNICAL PROGRESS BULLETIN

This is the thirty-first issue of a quarterly publication providing information on the technical work of the National Institute of Standards and Technology (formerly the National Bureau of Standards) Center for Electronics and Electrical Engineering. This issue of the CEEE Technical Progress Bulletin covers the second quarter of calendar year 1990.

Organization of Bulletin: This issue contains abstracts for all Center papers released for publication by NIST in the quarter and citations and abstracts for Center papers published in the quarter. Entries are arranged by technical topic as identified in the table of contents and alphabetically by first author under each subheading within each topic. Unpublished papers appear under the subheading "Released for Publication." Papers published in the quarter appear under the subheading "Recently Published." Following each abstract is the name and telephone number of the individual to contact for more information on the topic (usually the first author). This issue also includes a calendar of Center conferences and workshops planned for calendar years 1990/1991 and a list of sponsors of the work.

Center for Electronics and Electrical Engineering: Center programs provide national reference standards, measurement methods, supporting theory and data, and traceability to national standards.

The metrological products of these programs aid economic growth by promoting equity and efficiency in the marketplace, by removing metrological barriers to improved productivity and innovation, by increasing U.S. competitiveness in international markets through facilitation of compliance with international agreements, and by providing technical bases for the development of voluntary standards for domestic and international trade. These metrological products also aid in the development of rational regulatory policy and promote efficient functioning of technical programs of the Government.

The work of the Center is divided into two major programs: the Semiconductor Technology Program, carried out by the Semiconductor Electronics Division in Gaithersburg, MD, and the Signals and Systems Metrology Program, carried out by the Electricity Division in Gaithersburg and the Electromagnetic Fields and Electromagnetic Technology Divisions in Boulder, CO. Key contacts in the Center are given on the back cover; readers are encouraged to contact any of these individuals for further information. To request a subscription or for more information on the Bulletin, write to CEEE Technical Progress Bulletin, National Institute of Standards and Technology, Metrology Building, Room B-358, Gaithersburg, MD 20899 or call (301) 975-2220.

Center sponsors: The Center Programs are sponsored by the National Institute of Standards and Technology and a number of other organizations, in both the Federal and private sectors; these are identified on page 38.

Note on Publication Lists: Guides to earlier as well as recent work are the publication lists covering the work of each division. These lists are revised and reissued on an approximately annual basis and are available from the originating division. The current set is identified in the Additional Information section, page 31.

## SEMICONDUCTOR TECHNOLOGY PROGRAM

Silicon Materials

Released for Publication

Thurber, W.R., Ehrstein, J.R., and J.R. Lowney, **Comparison of High-Resistivity Measurements of Silicon by AC Impedance, DC Resistance, van der Pauw, and Four-Probe Methods**, to be published as an Extended Abstract of the Fall Meeting of the Electrochemical Society, Seattle, Washington, October 14-19, 1990.

Resistivity measurements by different techniques are compared for high-resistivity silicon. The ac impedance method is emphasized as it is seldom used for silicon but has certain advantages for high-resistivity material. Slices with implanted and annealed surfaces were measured by the impedance method and two-terminal dc resistance. For material with lapped surfaces, results were obtained by ac impedance, van der Pauw, and four-probe methods. The agreement was within 5% for slices and ingot sections greater than 0.1 cm in length and resistivity above 5 k $\Omega$ ·cm.

Littler, C.L., Seiler, D.G., and Loloee, M.R., **Magneto-Optical Investigation of Impurity and Defect Levels in HgCdTe Alloys**, J. Vac. Sci. Technol. A, Vol. 8, No. 2, pp. 1133-1138 (Mar/Apr 1990).

We have observed and described magneto-optical transitions between impurity/defect levels and conduction band Landau levels for a variety of n-type HgCdTe samples with  $0.2 < x < 0.3$ . The activation energies of these levels fall into two categories: (1) 10 to 12 meV above the valence band edge, independent of  $E_g$  and (2) two closely spaced levels at  $-0.5 E_g$ . In addition, the spectra of several

narrow-gap ( $E_g \leq 100$  meV) samples exhibit shallower and deeper acceptor-like levels.

Postek, M.T., Keery, W.J., and Frederick, N.V., **Low-Profile Microchannel-Plate Electron Detector System for SEM**, to be published in the Proceedings of the XIIth International Congress for Electron Microscopy, Seattle, Washington, August 12-18, 1990.

One main impetus of present-day scanning electron microscopy is in the low accelerating voltage mode. This mode of operation is useful for nondestructive inspection especially in the on-line inspection and metrology of semiconductor samples. Today, the majority of the scanning electron microscopes used in nondestructive inspection utilize the standard Everhart/Thornley (E/T) detector or a modification of this detector as the main detection system. The E/T detector, although extremely efficient, suffers from poor signal-to-noise ratio at low accelerating voltages. This type of detector also suffers from alignment difficulties especially where linewidth measurement for semiconductor applications is concerned because of the uneven distribution of the collection field which is possible, especially if the detector is not located in a plane of symmetry of the specimen and electron beam. These limitations and others have recently led investigators to reconsider the design of secondary electron detection systems, especially for low accelerating voltage and metrological applications.

Dimensional Metrology (cont'd.)

**Microchannel-Plate Detector System for Scanning Electron Microscopy Applications**, Rev. Sci. Instrum., Vol. 61, No. 6, pp. 1648-1657 (June 1990).

A new design high-efficiency microchannel-plate detector and amplification system is described for use in the scanning electron microscope. This complete detector system consists of four basic units: (1) the microchannel-plate detector, (2) the video amplifier, (3) the high-voltage power supply, and (4) the control unit. The microchannel-plate detector system is efficient at both high and low accelerating voltages, and is capable of both secondary electron and backscattered electron detection modes. The size of the actual detector is approximately 3.5 mm in thickness and 25.4 mm in diameter. Thus, use of this detector system permits using almost all the sample chamber to accommodate large specimens with only the loss of 3.5 mm of working distance. Another feature is that this system also employs a unique video amplifier where there are no active elements at high voltage. The microchannel-plate detector system enables the investigation of secondary-electron-induced contrast mechanisms and backscattered electron detection at extremely low accelerating voltages, even those below 1.0 keV.

**Potzick, J., Practical Photomask Linewidth Measurements**, Proceedings of SPIE (The International Society for Optical Engineering, P.O. Box 10, Bellingham, WA 98227), Vol. 1261, Integrated Circuit Metrology, Inspection, and Process Control IV, pp. 114-122 (1990).

The measurement cycle for practical accurate photomask linewidth measurements is analyzed as a differential measurement--the linewidth to be measured is compared to a known linewidth on a standard photomask. The linewidth-

measuring instrument is thus a comparator. The conditions necessary for a valid measurement are discussed with regard to both the instrument and the comparison process. The principles discussed here apply to many other types of measurement as well.

Power Devices

Released for Publication

Oettinger, F.F., and Blackburn, D.L., **Semiconductor Measurement Technology: Thermal Resistance Measurements**, to be published as NIST Special Publication 400-86.

This Special Publication reviews the thermal properties of power transistors and integrated circuits and discusses methods for characterizing these properties. The discrete devices discussed include bipolar transistors and metal-oxide-semiconductor field-effect-transistors. Measurement problems common to these devices, such as deciding the reason a particular measurement is required, adequate reference temperature control, selection of a temperature-sensitive electrical parameter, and separation of electrical and thermal effects during measurement, are addressed. Due to the inherent difficulties in measuring and analyzing the thermal properties of active integrated circuits, an approach using specifically designed thermal test chips for evaluation of new die attachment and packaging schemes is finding wide acceptance in the industry. In this Special Publication, indirect (i.e., electrical) measurements, direct (e.g., infrared) measurements, and computer simulation techniques for thermally characterizing integrated circuits are discussed in terms of their usefulness in characterizing VLSI packages.

Hefner, Jr., A.R., **An Investigation of the Drive Circuit Requirements for the Power Insulated Gate Bipolar Transistor (IGBT)**, Conference Record, 21st Annual Power Electronics Specialists Conference (PESC '90), San Antonio, Texas, June 10-15, 1990, pp. 126-137 (June 1990).

The drive circuit requirements of the IGBT are explained with the aid of an analytical model. It is shown that non-quasi-static effects limit the influence of the drive circuit on the time rate-of-change of anode voltage. Model results are compared with measured turn-on and turn-off waveforms for different drive circuits, load circuits, and different IGBT base lifetimes.

Planar silicon photosensor technology, which is suitable for integrating photosensors and circuits, is advancing in four roughly orthogonal directions. These are: 1) the accuracy with which the photosensor output signal can be related to the incident radiation, 2) the level of integration as measured by the number of photosensors in a system, 3) the level of integration as measured by the complexity of the processing of the photosensor output signals before presentation to a human observer or another system, and 4) the complexity of the photosensor structure. A brief overview of each of these areas accompanied by illustrative results is presented.

Device Physics & Modeling

## Released for Publication

Tomizawa, M., Ishibashi, T., Bennett, H.S., and Lowney, J.R., **Verification of Effective Intrinsic Carrier Concentrations for Numerical Simulations of Gallium Arsenide Bipolar Transistors.**

Knowing how the effective intrinsic carrier concentrations vary with doping and carrier densities is essential for predictive numerical simulations of advanced, high-performance GaAs transistors. Theoretical calculations for the effective intrinsic carrier concentrations,  $n_{ie}$ , of GaAs at 300 K have been verified experimentally for the first time by measurements on devices. Two GaAs homojunction bipolar transistors with heavily doped bases and emitters that have widths between 0.05  $\mu\text{m}$  and 0.45  $\mu\text{m}$  were fabricated to compare measured and predicted current-voltage characteristics and dc common emitter gains. The theoretical data for  $n_{ie}$  were implemented into a two-dimensional, drift-diffusion simulator for these transistors. The predicted gain of eight for one of the transistors agreed very well with its measured gain of nine. Without using the new theoretical data for  $n_{ie}$ , the predicted gain would have been four. The predicted gain of 25 for the other transistor also agreed well with its measured gain of 22. Without using the theoretical data, the predicted gain for the second transistor would have been 14. Sensitivity analyses on mobilities, lifetimes, and  $n_{ie}$  show that correct  $n_{ie}$  values are very important for predictive simulations of GaAs bipolar transistors. [Contact: Herbert S. Seabaugh, A.C., Mathias, J.J., and Bell, M.I., **Semiconductor Measurement Technology: EPROP: An Interactive FORTRAN Program for Computing Selected Elec-**

Device Physics & Modeling (cont'd.)

**Electronic Properties of Gallium Arsenide and Silicon**, NIST Special Publication 400-85 (May 1990).

A new computer program, EPROP (an acronym for Electronic PROPERTIES) is presented for use in interpreting measurements and experiments on gallium arsenide and silicon. EPROP computes a solution of the charge balance equation in thermodynamic equilibrium for up to six different impurities. The user supplies the density, energy level, and degeneracy for each impurity, and in response the program returns as many as 28 output parameters, such as the Fermi level, carrier density, and ionized impurity densities. These can be computed as functions of the temperature (or reciprocal temperature) or the density, energy, or degeneracy of any of the six possible impurities. Listings can also be obtained of various temperature-dependent parameters, such as the bandgap, densities of states, and effective masses. The interactive features of the program allow the user to send the output data to any combination of destinations: a terminal, a listing file, and/or up to four graphic output files, all at the user's direction. The user is also given freedom and ability to customize the data output to these destinations through menu-driven controls. The program is written in ANSI standard FORTRAN 77 and has been successfully compiled and run on both mainframe and microcomputers. Documentation is provided to assist the interested user in customizing the program for special applications, extracting portions for use elsewhere, or modifying the code to treat semiconductors other than silicon and gallium arsenide.

Kopanski, J.J., and Avila, R.E., Charge

**Trapping in Cubic Silicon Carbide MIS Capacitors**, to be published in the Proceedings of the ICACSC '90 Meeting, Washington, D.C., April 11-13, 1990.

The charge trapping properties in the insulator and at the insulator-SiC interface of metal-insulator-semiconductor (MIS) capacitors on cubic SiC single crystals have been studied. The interface trap level density,  $D_{it}$ , was determined by the high-frequency capacitance-voltage technique and from the conductance-voltage behavior. The number of active interface traps appears to increase sharply in the range from room temperature to 260 °C. SiC MIS capacitors exhibit a slow-trapping instability when subject to a stress voltage. The bulk oxide trap density,  $N_{ot}$ , and  $D_{it}$  are seen to increase during a voltage stress. The conduction mechanism in thermal oxide layers on SiC is limited by Fowler-Nordheim emission with a barrier height of  $1.8 \pm 0.1$  eV.

Woicik, J.C., Bouldin, C.E., Bell, M.I., Cross, J.O., Tweet, D.J., Swanson, B.D., Zhang, T.M., Sorensen, L.B., King, C.A., Hoyt, J.L., Pianetta, P., and Gibbons, J.F., **Conservation of Bond Lengths in Strained GeSi Layers**.

The combined techniques of X-ray absorption fine structure (EXAFS) and X-ray diffraction have been used to study the strain and bond distortions in epitaxial GeSi on Si(001). In a 31%-Ge, 340-Å pseudomorphic GeSi film, the Ge-Ge and Ge-Si first-neighbor bond lengths have been found to be  $2.44 \pm 0.02$  Å and  $2.38 \pm 0.02$  Å, respectively. The lattice parameter perpendicular to the GeSi/Si(001) interface has been found to be  $a_1 = 5.552 \pm 0.002$  Å, in agreement with the predictions of macroscopic elastic theory. These results show that the bond length strain in the epitaxial layer appears in the second and higher coordination shells, rather than in the nearest-neighbor bond lengths which

Insulators & Interfaces (cont'd.)

remain the same as in unstrained GeSi. A microscopic model is presented which accounts for these findings.

## Recently Published

Marchiando, J.F., **Semiconductor Measurement Technology: A Software Program for Aiding the Analysis of Ellipsometric Measurements, Simple Spectroscopic Models**, NIST Special Publication 400-84 (April 1990).

MAIN2 is a software program for the analysis of spectroscopic ellipsometric measurements. MAIN2 consists mainly of subroutines written in FORTRAN that are used to invert the standard reflection ellipsometry equations for simple systems. Here, a system is said to be simple if the solid material sample is characterized by models which assume at least the following: (1) materials are nonmagnetic; (2) samples exhibit depth-dependent optical properties, such as one with layered or laminar structure atop a substrate that behaves like a semi-infinite half-space; (3) layers are flat and of uniform thickness; and (4) the optical medium within each ambient/layer/substrate is isotropic, homogeneous, local, and linear. The ambient region refers to that region of space which lies external to the layer/substrate structure of the sample. Usually, the ambient region involves a medium of air or vacuum. Each layer is characterized by a thickness and a dielectric function. The dielectric function of a region, i.e., ambient, layer, or substrate, is represented by the Bruggeman effective medium approximation (EMA). Within the EMA, the effective medium of a region is characterized by an aggregate mixture of constituent media, and the dielectric function of each constituent medium is known a priori. The constituent dielectric functions are taken from the litera-

ture. The ellipsometric equations are formulated as a standard damped nonlinear least-squares problem and then solved by an iterative method when possible. The program is sufficiently modular to allow one to modify some of the models used in the calculations.

Waveform Metrology

Released for Publication

Bell, B.A., **Standards in Waveform Metrology Based on Digital Techniques**, to be published in the Journal of Research of the National Institute of Standards and Technology.

Over the last decade, the use of digital synthesis and sampling techniques for generating and measuring electrical waveforms has increased dramatically with the availability of improved digital-to-analog and analog-to-digital converters and related devices. With this evolution has come the need for physical laboratory standards and test methods to support the

performance specifications of digital devices and the instruments in which they are used. This article describes the research and development at NIST of several laboratory standards and test systems that utilize "digital technology" for characterizing data converters and for implementing various waveform synthesis and sampling instruments.

**Gans, W.L., Dynamic Calibration of Waveform Recorders and Oscilloscopes Using Pulse Standards.**

The purpose of this presentation is to convince the reader/listener of two key points. The first is that virtually no one calibrates oscilloscopes or waveform recorders properly and completely at present. The second is that, in most cases, the tools are now available to perform these complete and proper calibrations when the application requires it. After a brief introduction describing the current methods used to calibrate oscilloscopes, the problems associated with oscilloscope vertical channel bandwidth testing are discussed and illustrated. Then, a solution is described that involves using pulse signals and a NIST-developed deconvolution algorithm.

Williams, E.R., **High Accuracy Determination of the Fine Structure Constant via Measurement of the Proton Gyromagnetic Ratio**, Bulletin of the American Physical Society, Vol. 35, No. 4, p. 1069 (April 1990).

The latest experiment at the National Institute of Standards and Technology to measure the gyromagnetic ratio of the proton in  $H_2O$ ,  $\gamma'_p$ , by the low-field method has an uncertainty of 0.11 ppm for  $\gamma'_p$  (low). Using this experimental result, a value for the fine structure constant  $\alpha^{-1} = 137.0359840(51)$  (0.037 ppm) can be calculated. The uncertainty in  $\alpha$  is limited by the uncertainty in the  $\gamma'_p$

Fundamental Elec. Measurements (cont'd.)

experiment. The most difficult part of this experiment was constructing a 2.1-m long solenoid with a precision of a few  $\mu\text{m}$ , then measuring its critical dimensions to 0.05  $\mu\text{m}$ . Instead of measuring the wire locations, we measured the location of the current placed in each winding turn using the magnetic field produced by the current in that turn. We accurately measured the solenoid current in terms of the Josephson volt and Quantum Hall resistance. The resultant magnetic field was uniform to 1 in  $10^7$  over 7-cm diameter sphere. The precision frequency was measured using NMR. When this value of  $\alpha$  is compared with that obtained from the electron magnetic moment anomaly,  $a_e$ , using Dehmelt et al.'s results and Kinoshita's calculation, we have one of the most precise tests of QED theory. The difference between the values of  $\alpha$  obtained from  $a_e$  and  $\gamma'_p$  is  $(0.054 \pm 0.038 \text{ ppm})$ .

Designs using both probe and finline microwave couplers were tested. The probe coupler was about 3 dB more efficient and allowed a smaller chip and a less expensive mount. The reduced operating frequency allows substantial advantages in cost and reliability over more conventional devices that operate at 70 to 100 GHz.

Kautz, R.L., and Martinis, J.M., **Noise-Affected I-V Curves in Small Hysteretic Josephson Junctions.**

We investigate the noise-affected I-V curves of small-area Josephson junctions through experiment, simulation, and theory. In particular, we consider I-V curves in which two different states of finite voltage coexist at the same dc bias: a high-voltage state that corresponds to the usual quasiparticle branch and a low-voltage state which is characterized by thermally-activated phase diffusion. The observed hysteresis between the phase-diffusion and quasiparticle branches cannot be explained within the context of the simple RCSJ model but is explained by extended models in which the damping increases with frequency. Frequency-dependent damping is shown to produce a qualitative change in the attractors of the noise-free system which allows the two voltage states to be simultaneously stable. This picture is confirmed by Monte Carlo simulations which accurately

Cryoelectronic Metrology (cont'd.)

reproduce the experimental I-V curves of two different samples over a wide range of temperatures. In addition, we develop analytic expressions for three key parameters of the I-V curve of junctions displaying hysteresis between the phase-diffusion and quasiparticle branches: the initial slope of the phase-diffusion branch and the bias levels at which the junction switches back and forth between the two branches.

Sutton, E.C., Danchi, W.C., Jaminet, P.A., and Ono, R.H., **A Superconducting Tunnel Junction Receiver for 345 GHz**, International Journal of Infrared and Millimeter Waves, Vol. 11, No. 2, pp. 133-150 (1990).

In this paper we discuss the design, fabrication, and testing of a quasiparticle tunnel junction receiver for use at 345 GHz. The design employs small-area Nb/Nb-oxide/PbInAu edge junctions in order to keep the device capacitance small and maintain a modest value for  $\omega R_N C$ . For optimum noise performance and beam properties, the mixer is contained in a waveguide-mounting structure. Our best sensitivity was obtained at 312 GHz where we measured a double sideband (DSB) noise temperature of 275 K. Noise temperatures of 400 K (DSB) or better were obtained out to 350 GHz.

Daywitt, W.D., **First-Order Principal Mode Fields and Distributed Line Parameters for a Slightly Lossy Coaxial Transmission Line**, Digest of the 1990 Conference on Precision Electromagnetic Measurements, Ottawa, Canada, June 11-14, 1990, pp. 404-405 (1990).

A complete set of first-order field equations valid between the outer and center conductors of a slightly lossy coaxial line does not exist even with the considerable history concerning coaxial transmission line calculations. None of the field expressions found in the literature from Russell in 1909 to Stratton in 1941 to Gardiol in 1987 displays a set of fields that will satisfy Maxwell's equations to first order in the skin depth or surface impedance. The purpose of this summary is to present a complete set of principal mode field equations from which the distributed line parameters can be calculated to greater accuracy than previously. However, only the distributed line resistance will be found to be significantly different from the more traditional estimates.

Electro-Optic Metrology (cont'd.)**Method. Part 2: Laguerre-Gauss Basis Functions.**

We use the Laguerre-Gauss functions with Galerkin's method to find approximate but accurate modal solutions to the scalar wave equation. Our solution is well suited to finding the eigenvalues for optical fibers with circularly symmetric index profiles. For noncircular geometry, the use of Hermite-Gauss basis functions is more appropriate, as discussed in Part 1. The method used here is restricted to two-region geometries consisting of a circular core in which the refractive index is arbitrary and a cladding with constant refractive index extending to infinity in the radial direction. We use the step index optical fiber, which has a known exact solution, to test the method.

**Hickernell, R.K., Veasey, D.L., and Aust, J.A., Spatial Resolved Measurement of High Attenuation in Integrated Optic Polarizers,** to be published in the Technical Digest of the 1990 Symposium on Optical Fiber Measurements, Boulder, Colorado, September 11-12, 1990.

We present a method for measuring high attenuation in integrated optic polarizers made by depositing absorbing overlayers on channel waveguides. Based

on the photothermally induced deflection of a probe laser beam, the technique permits in-situ probing along the length of a single guide to measure attenuation on the order of 1000 dB/cm. High spatial resolution of loss variation is achieved. The measurement is not limited by the irreproducibility of input coupling and is minimally affected by depolarization in the coupling optics. We fabricated both TE- and TM-pass polarizers by depositing a layer of hydrogenated amorphous silicon on ion-exchanged glass waveguides and etching to the proper thickness. Loss as high as 760 dB/cm was measured for TM-polarized input at a wavelength of 632.8 nm. We also report the measurement of loss in metal-clad titanium-indiffused lithium niobate waveguide polarizers.

A robust, high-accuracy, broad-banded, alternating current sensor using fiber optics is being developed for space applications at power frequencies as high as 20 kHz. It can also be used in low- and high-voltage 60-Hz terrestrial power systems and in 400-Hz aircraft systems. It is intrinsically EMI immune and has the added benefit of excellent isolation. The sensor uses the Faraday effect in optical fiber and standard polarimetric measurement techniques to sense electrical current. The primary component of the sensor is a specially treated coil of single-mode optical fiber, through which the current-carrying conductor passes. Improved precision is accomplished by temperature compensation via signals from a novel fiber-optic temperature sensor embedded in the sensing head. This paper reports on the technology contained in the sensor and also relates the results

Electro-Optic Metrology (cont'd.)

of precision tests conducted at various temperatures within the wide operating range. It also shows the results of early EMI tests.

Electro-Optic Metrology (cont'd.)

Including the Effect of Whispering Gallery Modes], *Journal of Lightwave Technology*, Vol. 8, No. 5, pp. 768-774 (May 1990).

A new matrix method is used to analyze bent planar optical waveguides. The method is a modification of the numerical analysis matrix method for planar waveguides developed by Ghatak and colleagues at the Indian Institute of Technology, New Delhi (IIT), and may be used with absorbing or leaky structures. The new method is a refinement in that a nonuniform refractive index is approximated by a series of linear profiles rather than by a series of uniform profiles. The method is used to analyze a bent planar waveguide, yielding bend loss directly. The effect of "whispering-gallery" modes has also been studied. The new results suggest that the whispering-gallery explanation advanced previously by the IIT team may not be adequate.

We propose an efficient numerical method to solve for the electromagnetic fields propagating in an optical waveguide that is nonuniform in the direction of propagation (z-direction) as well as in the transverse direction. In this method, the electromagnetic field is first expanded in terms of the Hermite-Gaussian basis functions. The scalar Helmholtz equation is then converted into matrix equations using the orthogonal collocation method. The incident field is sampled at the collocation points as the initial condition. Axial propagation is then determined by solving the matrix equations numerically, using the Runge-Kutta method.

Tu, Y., Goyal, I.C., and Gallawa, R.L., **A Comparison of Two Numerical Techniques for Planar Optical Waveguides of Arbitrary Refractive Index**, National Radio Science Meeting Abstracts, sponsored by USNC/URSI in cooperation with the Institute of Electrical and Electronics Engineers and the University of Colorado, Boulder, Colorado, January 3-5, 1990, p. 260 (1990).

In this paper we determine the eigenfunctions and eigenvalues for optical waveguides having nonuniform refractive index profiles in the transverse direction using two recent techniques. In one technique, we solve the scalar wave equation by expanding the fields in a Fourier series. The expansion is then used to develop matrix equations that result when the waveguide is approximated by a series of rectangular elements of constant refractive index. Far from the core region, artificial boundaries are imposed to require that the fields vanish at those boundaries. The propagation constant and field distribution are then found by solving the eigenvalue and eigenfunction problems.

Baker-Jarvis, J.R., **Transmission/Reflection and Short-Circuit Line Permittivity Measurement Methods**, to be published as an NIST Technical Note.

The transmission/reflection and short-circuit line methods for measuring complex permittivity are examined. Equations for permittivity are developed from first principles. New robust algorithms are presented that eliminate the ill-behaved nature of the commonly-used transmission/reflection method at frequencies corresponding to integer multiples of one-half wavelength in the sample, thereby allowing measurements to be made on samples of any length. An error analysis is presented which yields estimates of the errors incurred due to the uncertainty in scattering parameters, length measurement, and reference plane position. It is found using the equations derived herein that the minimum uncertainty for transmission/reflection measurements occurs at integer multiples of one-half wavelength in the material. In addition, new equations are derived for determining complex permittivity independent of reference plane

Electromagnetic Properties (cont'd.)

position and sample length. New equations for permittivity determination using the short-circuit line are derived which allow positioning the sample arbitrarily in the sample holder.

Geyer, R.G., Janezic, M., Kissick, W.A., and Baker-Jarvis, J.R., **Preliminary Microwave Complex Permittivity Measurements of Heavy-Metal Fluoride Glasses**, to be published in the Proceedings of the Third DoD Symposium of Electromagnetic Windows, Redstone Arsenal, Huntsville, Alabama, November 14-16, 1989.

Heavy-metal fluoride glasses possess a broad transparency range from mid-infrared to near-ultraviolet and are of interest as materials for laser windows, IR domes, lenses, filters, and mid-IR optical fibers. The microwave transmission characteristics of these glasses are also important because of their potential use for dual mode electromagnetic windows. The transmission/reflection method in coaxial line, supplemented by high Q, mode-filtered TE<sub>01P</sub> cylindrical cavity measurements, was used for complex permittivity determinations between 0.5 and 11.0 GHz. On the basis of these early findings, fluorozirconate glasses are about one order of magnitude more lossy at microwave frequencies than silica glass. They show little dispersion except below 2 GHz. A relationship between heavy-metal fluoride glass composition and microwave dielectric characteristics is evident. This suggests that the complex permittivity at microwave frequencies may be compositionally controlled. Fluorozirconate heavy-metal glasses provide optical apertures while absorbing some high-frequency microwave radiation.

Tofani, S., Ondrejka, A.R., and Kanda, M., **Time-Domain Method for Absorbing**

**Material Reflectivity Characterization in the 30-1000 MHz Frequency Range.**

A wideband time-domain reflectometer is used to evaluate the reflection characteristics of RF/microwave absorbers. The reflectometer uses an array of two identical broadband antennas, both transmitting and receiving. The method uses the two antennas in a difference mode to remove the undesired signals and to enhance the small reflections being measured. Using this technique, we can separate front surface reflections from those which are generated at greater angles. The spectrum bandwidth of our pulses is 30 MHz to 1000 MHz, and reflection characteristics are measured over this entire range. The method has been used to characterize the reflectivity of three different types of absorber placed in an anechoic chamber. The results are reported together with the measurement accuracy. A discussion regarding main sources of errors is also presented.

Baker-Jarvis, J.R., Geyer, R.G., and Domich, P., **Improvements in Transmission Line Permittivity and Permeability Measurements**, Digest of the 1990 Conference on Precision Electromagnetic Measurements, Ottawa, Canada, June 11-14, 1990, pp. 232-233 (1990).

The transmission/reflection and short-circuit line methods for complex permittivity and permeability determination in transmission line sample holders are examined. New equations for permittivity are presented that eliminate the ill-behaved nature of the commonly used transmission/reflection methods at frequencies corresponding to integer multiples of one-half wavelength in the sample. The equations are also independent of reference plane position. Measurement results and an error analysis are presented. In addition, the scattering equations are solved using an optimization algorithm. The advantages

Electromagnetic Properties (cont'd.)

and disadvantages of an optimization approach are discussed.

Geyer, R.G., Dielectric Characterization and Reference Materials, NIST Technical Note 1338 (April 1990).

Dielectric reference materials are analyzed with respect to fundamental requirements of linearity, homogeneity, and isotropy. Generalized frequency- and temperature-dependent dispersion relations are presented which allow the prediction of broadband dielectric behavior from limited measurement data, determination of valid modal field structure in cavity or waveguide fixtures, and identification of discrepancies and errors in measurement data. An approach for examining the influence of deviations of sample homogeneity on a precisely specified electromagnetic field structure is outlined, and sufficient conditions for isotropic, uniaxial, or biaxial anisotropic dielectric behavior are reviewed in terms of a material's chemical lattice physics. These characteristics direct the choices of suitable reference materials useful for confirming or improving the accuracy of dielectric measurements.

The use of Time Domain Spectroscopy, the measurement of dielectric constant and loss using time-domain response, for monitoring the aging of reactor cable insulation is examined. The method is presented, showing its sensitivity, accuracy, and wide frequency range. The method's ability to acquire a great deal of information in a short time and its superiority to conventional single frequency data are shown. Different cable samples are examined before and after exposure to radiation and changes with exposure are clearly seen to occur. Also, it is shown that a wide range of behavior can be found in different insulation systems. The requirements for performing valid measurements are presented. The need for controlled samples and correlation with other criteria for aging is discussed.

In this paper, I present a history of the scratch-and-dig standard for optical surface quality and show that this standard has since its inception been recognized as a cosmetic standard and not as an objective or performance standard. In addition, I attempt to dispel the myth that the scratch standard was changed during the 1960s and show that scratch number cannot be related to scratch width. Finally, I describe a preliminary aging experiment that suggests that the scratch standards have not aged with time and are, in fact, extremely stable.

Released for Publication

Fenimore, C., and Martzloff, F.D., **Validating Surge Test Standards by Field Experience: High-Energy Tests and Varistor Performance**, to be published in the Proceedings of the IAS/IEEE Annual Meeting, Seattle, Washington, October 9, 1990.

New, high-energy surge tests are emerging in IEEE and IEC standards. Field experience offers a valuable criterion for validating or invalidating proposed standards. A proposal under consideration by the IEC involves so much energy that a varistor of the voltage rating

commonly used in protecting load equipment, if subjected to this test, would almost certainly fail. Yet, reported varistor failure rates do not reflect such a situation. Thus, a re-examination of the premises that led to the proposed test specifications appears necessary. Proposals for high-energy tests as additional waveforms in the new version of IEEE C62.41, on the other hand, lead to current and energy levels that do not place typical varistors in immediate jeopardy. Thus, they appear more consistent with field experience.

One member of a family of materials, the perfluorinated polyethers, is subjected to electrical measurements to determine its suitability as a liquid dielectric. Measures of the breakdown strength and streamer inception voltage are obtained under electrical impulse stress. The breakdown strength is nearly independent of polarity. Under high magnification photography, the cathode-originated streamers are seen to have a subsonic mode of growth. The transition to fast growth occurs on time and spatial scales shorter than those reported in liquid hydrocarbons. The gas phase electrical properties and the high heat of vaporization of this material are considered as mechanisms for this behavior.

Stricklett, K.L., Kelley, E. F., Yamashita, H., Fenimore, C., Pace, M.O., Blalock, T.V., Wintenburg, A.L., and Alexeff, I., **Observations of Partial Discharges in Hexane Under High Magnification**, to be published in the Proceedings of the Tenth International Conference on Conduction and Breakdown in Dielectric Liquids, Grenoble, France, September 10-14, 1990.

Partial discharges are observed in hexane by shadow photography under the applica-

tion of dc voltages. A nonuniform field geometry is employed, and the growth of low-density streamers at a point cathode is recorded. Photographs of the partial discharge streamers are obtained at 200X magnification. The use of an image-preserving optical delay allows a record of the conditions which exist in the liquid prior to the initiation of the low-density streamer to be obtained. A concurrent record of the partial discharge current is obtained. Analysis of these data indicate that electrostatic forces are adequate to describe streamer growth.

Van Brunt, R.J., and Kulkarni, S.V., **Stochastic Properties of Trichel-Pulse Corona: A Non-Markovian Random Point Process**.

The stochastic properties of a negative, point-plane, Trichel-pulse corona discharge have been completely characterized in terms of a set of measured conditional discharge pulse-amplitude and pulse-time-separation distributions. The Trichel-pulse phenomenon is shown to be a clear example of a non-Markovian, marked random point process in which memory effects play an important role. Strong correlations are shown to exist among the amplitudes and time separations of successive discharge pulses which indicate how initiation and growth of any discharge pulse is affected by the presence of residual ion space charge and metastables from previous pulses. The analysis required to assess consistency among the various measured distributions is discussed and used to interpret observed variations in distribution profiles. It is argued that because of the strong correlations between the amplitude of a pulse and the amplitude of and time separation from the previous pulse, memory can propagate indefinitely back in time. The experimental limitations to verifying the extent of memory propagation are analyzed.

Yamashita, H., Kawai, H., Stricklett, K.L., and Kelley, E.F., **The Effect of High Pressure on Prebreakdown Phenomena in N-Hexane**, to be published in the Proceedings of the Tenth International Conference on Conduction and Breakdown in Dielectric Liquids, Grenoble, France, September 10-14, 1990.

The effect of pressure on the initiation of prebreakdown streamers at a point cathode in n-hexane is investigated. Using a high-magnification (100X) high-resolution (1  $\mu\text{m}$ ) optical system and a high-speed camera, the initial growth of low-density streamers at pressures ranging from 0.1 to 1.1 MPa is examined. The initial streamer appears to be a single filament  $4.1 \pm 2.1 \mu\text{m}$  in length. The streamer initiation voltage is shown to increase with pressure and the rate of collapse of the streamer is faster at high pressure.

Ekin, J.W., **Transport Critical Current of**

Superconductors (cont'd.)

**Aligned Polycrystalline  $Y_1Ba_2Cu_3O_{7-\delta}$** , to be published in the Proceedings of the International Conference on Transport Properties of Superconductors, Rio de Janeiro, Brazil, April 29-May 4, 1990.

A study of grain alignment and its effect on the dc transport critical current in fine-grained bulk  $Y_1Ba_2Cu_3O_{7-\delta}$  is reported in magnetic fields from  $10^{14}$  T to 26 T. This paper presents a summary of the main results. The data are interpreted as evidence for two parallel components of intergranular current conduction, one consisting of weak-linked material, the other behaving like intrinsic intragranular material that is not weak-linked. A comparison with unaligned  $YBa_2Cu_3O_7$  indicates that the volume fraction of such nonweak-linked material is significantly enhanced by grain alignment, but still only 0.01 to 0.1% of the grain boundary area.

Moreland, J., Li, Y.K., Goodrich, L.F., Roshko, A., and Ono, R.H., **Novel Procedure for Mapping the  $J_c$ - $H_{c2}$ - $T_c$  Surface and Its Application to High Temperature Superconductors**, to be published in the Proceedings of the Conference on Science and Technology of Thin Film Superconductors, Denver, Colorado, April 30-May 4, 1990.

We have used an ac lock-in method for measuring the dynamic resistance versus current ( $dV/dI$ - $I$ ) curves to determine  $J_c(T,H)$ . The sample current consisted of a small constant oscillating current added to a variable dc current. The dc current was either slowly ramped for  $dV/dI$ - $I$  measurements or controlled keeping the  $dV/dI$  level constant while ramping temperature or field. In this way, it was possible to measure  $J_c(T)$  at constant  $H$ . The temperature is controlled between 4 and 300 K using a bathysphere cryostat. The bathysphere cryostat was inserted into a high field magnet for measurements at fields up to 7 T. We have measured several high-

temperature superconductors including YBCO thin films. In addition, we have measured the  $dV/dI$ - $I$  curve of a simulator with a V-I curve having the form  $V = 10 \mu V \times (I/1.4 A)^{13}$ . Upon numerical integration, our data for the superconductors and the simulator are consistent with that obtained using a dc method using an analog nanovoltmeter to measure the V-I curves directly.

Peterson, R.L., and Ekin, J.W., **Critical-Current Diffraction Patterns in Superconductor Weak-Links.**

We discuss the characteristics of the critical current as a function of magnetic field in grain boundary Josephson barriers. Diffraction patterns occur not just for SIS junctions but for all types of Josephson links, including SNS junctions which may be present at grain boundaries in high- $T_c$  superconductors. We also discuss the generality of the Airy diffraction pattern, which is expected to characterize most grain-boundary barriers more accurately than the Fraunhofer pattern. The transport critical current density in many bulk, granular high- $T_c$  superconductors has a power law dependence on very low magnetic fields, characteristic of averaged diffraction patterns, and cannot be fitted by an exponential magnetic field dependence which may result from the material properties of the barriers.

Takagi, T., Chiang, Y.-M., and Roshko, A., **Origin of Grain Boundary Weak Links in  $BaPb_{0.75}Bi_{0.25}O_3$  Superconductors.**

Although  $BaPb_{0.75}Bi_{0.25}O_3$  (BPB) has a comparatively large superconducting coherence length of  $\sim 7$  nm and no reported anisotropy in its superconducting parameters, polycrystalline BPB exhibits the same rapid decrease in transport critical-current density ( $J_{ct}$ ) with low applied

Superconductors (cont'd.)

field (<5 mT) that is characteristic of grain boundary weak-links in cuprate superconductors (e.g.,  $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$ ,  $\text{YBa}_2\text{Cu}_3\text{O}_{7-x}$ ). We have studied the effects of processing thermal history on the formation and morphology of grain boundary phases, and on the chemistry of BPB boundaries with and without second phase, in order to understand the origin of these weak links. Scanning Transmission Electron Microscopy (STEM) and Auger Electron Spectroscopy (AES) results show the presence of a Pb-Bi-Ba-O phase that is wetting and liquid above  $\sim 570^\circ\text{C}$ , but which retracts to three-grain junctions upon slow cooling or annealing at lower temperatures. The composition of the grain boundaries as well as  $J_{ct}$  vs. temperature measurements suggest that the boundaries act as SIS tunnel junctions. [Contact: Alexana Roshko, (303) 497-5420]

## ELECTROMAGNETIC INTERFERENCE

Radiated Electromagnetic Interference

Released for Publication

Adams, J. W., Status Report on Shielding Effectiveness Measurements: Release of ASTM D4935-89, to be published in the Proceedings of the Fourth International Society for the Advancement of Material and Process Engineering (SAMPE) Conference, Albuquerque, New Mexico, June 13, 1990.

The American Society of Testing and Materials (ASTM) released Standard D4935-89, Standard Test Method for Measuring the Electromagnetic Shielding Effectiveness of Planar Materials, in November 1989. Some background efforts of ASTM Committee D.09.12.14 to accomplish this are reviewed, with emphasis on results of the measurement round robins that led to the acceptance of the standard in April of 1989. Very good agreement was obtained during these round robins conducted by five different workers at five different organizations. The samples

Radiated EMI (cont'd.)

used were plastic based, but treated three different ways. Surface roughness of the sample is an important factor in determining measurement uncertainty. The design of the sample holder and the measurement procedure given in this ASTM standard were developed at the National Institute of Standards and Technology (NIST). The comprehensive effort at NIST also established why this measurement method was chosen over numerous others. How and when calculations can be used to obtain near-field data from the measured far-field data are covered.

Masterson, K.D., and Kanda, M., **Broadband, Photonic Electric Field Sensors for EMP and HPM Applications**, to be published in the Proceedings of the Fifth National Conference on High Power Microwave Technology (DOD), West Point, New York, June 11-15, 1990.

Photonic sensors offer the potential to measure high-power electromagnetic fields more accurately than has been available in the past. This is primarily due to their immunity from interference generated by such fields, the high information capacity of optical fibers, and the minimal perturbation of the field by an

all-dielectric sensor. An overview of system design based on transfer functions for the individual components is presented with particular emphasis placed on the electro-optic modulator. Using this approach, we summarize the characteristics of two measurement systems that have been fabricated at the National Institute of Standards and Technology, and we design a measurement system based on a Mach-Zender interferometric modulator that would be applicable to HPM measurements. When operating with a 1-GHz detection bandwidth, we estimate that the probe could measure field levels from 200 V/m to over 1 MV/m and operate over a frequency range from 0.5 to over 10 GHz. This would cover much of the region of interest for HPM.

Crawford, M.L., Ladbury, J.M., Riddle, B.F., and Larsen, E.B., **EMR Test Facilities: Evaluation of a Small Reverberating Chamber Located at RADC, Griffiss AFB, Rome, New York, NISTIR 90-3939** (June 1990).

This report describes measurement procedures and results from evaluating a small reverberating chamber located at Rome Air Development Center (RADC), Rome, New York. The chamber was developed for measuring and analyzing the electromagnetic susceptibility/vulnerability of weapon systems and the radio frequency (rf) shielding effectiveness of enclosures and materials. A brief description of the facility is given, including instrumentation for its evaluation and calibration by the National Institute of Standards and Technology (NIST). Work was done earlier at NIST to evaluate the RADC large reverberating chamber. A follow-on project to construct and evaluate a small chamber is discussed in this report. Measurements include: 1) voltage standing wave ratio of the transmitting and receiving antennas; 2) coupling efficiency of the chamber; 3) effectiveness of the chamber tuner; 4) E-field uniformity in the test zone; 5) calibration of test E-fields based on receiving antenna power measurements and calibrated dipole probe voltage measurements; 6) responses of standard equip-

ment under test to test fields in the RADC reverberating chamber and the NIST anechoic chamber; and 7) performance of the reverberating chamber excited by rf pulses at ten frequencies from 0.9 to 18 GHz, four pulse widths from 0.1 to 3  $\mu$ s, and for two values of chamber Q. Conclusions are that the chamber can be used at frequencies down to 500 MHz for cw testing, and for pulsed rf immunity testing with pulse widths as short as 0.3  $\mu$ s. Estimates of measurement uncertainties are given.

Hill, D.A., **Magnetic Dipole Excitation of an Insulated Conductor of Finite Length**, IEEE Transactions on Geoscience and Remote Sensing, Vol. 28, No. 3, pp. 289-294 (May 1990).

Excitation of currents on an insulated conductor of finite length with arbitrary terminations is studied for a magnetic dipole source. For matched terminations, the results agree closely with previous results for an infinitely long conductor, but other terminations produce end reflections that cause standing waves. Specific calculations are presented for a vertical magnetic dipole source because this source produces the appropriate horizontal electric field and could be used in a borehole-to-borehole configuration. Numerical results for the induced current and secondary magnetic field indicate that long conductors produce a strong anomaly over a broad frequency range for any type of termination.

Wittmann, R.C., **Spherical Near-Field Scanning: Determining the Incident Field Near a Rotatable Probe**, 1990 Antennas and Propagation Symposium Digest, Dallas, Texas, May 7-11, 1990, Vol. 1, pp. 224-227 (1990).

Many radar cross-section, electromagnetic interference/electromagnetic compatibility, and antenna measurements require a known incident field within a test volume. To evaluate systems designed to produce a specific incident field (compact ranges, for example), we must measure the actual illumination for comparison with design specifications. Beyond its diagnostic value, these

incident field data can also be used for error estimation and for calculating first-order corrections.

In this paper, we develop a spherical near-field scanning algorithm for determining incident fields inside a probe's "minimum sphere." This differs from the well-known spherical near-field scanning formulation which determines fields outside the source's minimum sphere. The scanner size depends on the extent of the region of interest and not on the extent of the (possibly much larger) source. The data may be collected using a standard roll-over-azimuth positioner.

Conducted Electromagnetic Interference

Released for Publication

Fenimore, C., and Martzloff, F.D., **Validating Surge Test Standards by Field Experience: High-Energy Tests and Varistor Performance**, to be published in the Proceedings of the IAS/IEEE Annual Meeting, Seattle, Washington, October 9, 1990.

New, high-energy surge tests are emerging in IEEE and IEC standards. Field experience offers a valuable criterion for validating or invalidating proposed standards. A proposal under consideration by the IEC involves so much energy that a varistor of the voltage rating commonly used in protecting load equipment, if subjected to this test, would almost certainly fail. Yet, reported varistor failure rates do not reflect such a situation. Thus, a re-examination of the premises that led to the proposed test specifications appears necessary. Proposals for high-energy tests as additional waveforms in the new version of IEEE C62.41, on the other hand, lead to current and energy levels that do not place typical varistors in immediate jeopardy. Thus, they appear more consistent with field experience.

Martzloff, F.D., **Coupling, Propagation, and Side Effects of Surges in an Industrial Building Wiring System**, IEEE Transactions on Industry Applications, Vol. 26, No. 2, pp. 193-203 (March/April 1990).

Measurements were made in an industrial building to determine the propagation characteristics of surges in the ac power wiring of the facility. The surges, of the unidirectional type or the ring-wave type described in ANSI/IEEE Standard C62.41-1980, were injected at one point of the system and the resulting surges arriving at other points were measured. The results show how unidirectional surges couple through transformers and produce a ring wave component in the response of the system. An unexpected side effect of these surges, applied to the power lines only, was the apparent damage suffered by the data line input components of some computer-driven printers.

The quality of the power supplied to sensitive electronic equipment is an important issue. Monitoring disturbances of the power supply has been the objective of various site surveys, but results often appear to be instrument-dependent or site-dependent, making comparisons difficult. After a review of the origins and types of disturbances, the types of monitoring instruments are described. A summary of nine published surveys reported in the last 20 years is presented, and a close examination of underlying assumptions allows meaningful comparisons which can reconcile some of the differences. Finally, the paper makes an appeal for improved definitions and applications in the use of monitoring instruments.

**NEW CALIBRATION SERVICES OFFERED**

The explosive growth of optical fiber use in the communications industry has resulted in a demand for calibration services. NIST's Boulder, Colorado, laboratory now offers measurements of optical laser power and energy at wavelengths and power levels of interest to fiber optic producers and users. Measurements are based on a standard reference instrument called the C-series calorimeter. An electrically calibrated pyroelectric radiometer (ECPR) is calibrated against the calorimeter and is then used to calibrate optical power meters at wavelengths of 850, 1300, and 1550 nm. To improve calibration capabil-

Additional Information (cont'd.)

ities, NIST is preparing test measurement systems for detector linearity, detector uniformity, and detector spectral responsivity. These systems should be available in 6 months. For a paper outlining NIST's optical power measurement capabilities, contact Fred McGehan, Div. 360, NIST, 325 Broadway, Boulder, Colorado 80303. **NEW NIST RESEARCH MATERIAL**

NIST has announced the availability of Research Material 8458, a well-characterized artificial flaw used as an artifact standard in eddy current non-destructive evaluation (NDE). The new Research Material (RM) is the outcome of work carried out by the Division to address the need for calibration standards for eddy-current NDE, for example as used to detect fatigue cracks in aircraft structures. The RM flaw is produced in an annealed aluminum alloy block by first indenting the block and then compressively deforming the resulting notch until it is tightly closed. The next operation is to restore a flat finish to the block face, after which the block is heat treated to the original temper. The controlled flaw has been named the "CDF notch," after its inventors (listed on patent application) Thomas E. Capobianco (Electromagnetic Technology Division), William P. Dube (Division 583), and Ken Fizer (Naval Aviation Depot, NAS Norfolk, Virginia).

In the past, the challenge has been to manufacture artificial flaws that closely simulate the mechanical properties of fatigue cracks. Currently used artifacts include electrical-discharge-machined and saw-cut notches, both of which are relatively poor representations of fatigue cracks as their widths are too great. The Division-developed method provides notches that can be made controllably in a variety of geometries,

have known dimensions, with widths that are narrow enough to provide an acceptable representation of fatigue cracks.

An NIST Research Material is not certified by NIST, but meets the International Standards Organization definition of "a material or substance one or more properties of which are sufficiently well established to be used in the calibration of an apparatus, the assessment of a measurement method, or for assigning values to materials." The documentation issued with RM 8458 is a "Report of Investigation." **EMERGING TECHNOLOGIES IN ELECTRONICS...AND THEIR MEASUREMENT NEEDS, SECOND EDITION**

This report assesses the principal measurement needs that must be met to improve U.S. competitiveness in emerging technologies within several fields of electronics: semiconductors, superconductors, magnetics, optical fiber communications, optical fiber sensors, lasers, microwaves, video, and electromagnetic compatibility. The report seeks feedback from industry and Government agencies on the assessment. The feedback will guide the development of NIST programs that provide U.S. industry with new documented measurement methods, new national reference standards to assure the accuracy of those measurement methods, and new reference data for electronic materials. Copies may be obtained by ordering Report No. PB90-188087/AS (\$23.00 hard copy, \$11.00 microfiche) from the National Technical Information Service, 5285 Port Royal Road, Springfield, Virginia 22161, (703) 487-4650.

**JAN. 1, 1990 CHANGES IN THE U.S. ELECTRICAL UNITS**

Effective January 1, 1990, the U.S. as-maintained (i.e., "practical") units of voltage and resistance were increased by

Additional Information (cont'd.)

9.264 ppm and 1.69 ppm, respectively. The increases in the U.S. legal units of current and of electrical power will be about 7.57 ppm and 16.84 ppm, respectively. These changes result from efforts by the major national standardizing laboratories, including the National Institute of Standards and Technology (NIST), formerly the National Bureau of Standards (NBS), to re-evaluate their as-maintained units in terms of the International System of Units (SI). The consequence of this activity has been the introduction of standards representing the SI units of voltage and resistance by the International Committee of Weights and Measures, an international body created by the Treaty of the Meter.<sup>1</sup> The use of these standards world-wide beginning January 1, 1990, will result in international consistency of electrical measurement as well as coherence among the practical units of length, mass, electricity, time, etc., inherent in the definitions of the SI.

Implementation of Changes at NIST

These changes have been instituted in the U.S. by NIST using the new, internationally-adopted constants  $K_{J-90} = 483\ 597.9\ \text{GHz/V}$  exactly and  $R_{K-90} = 25\ 812.807\ \Omega$  exactly with the Josephson and quantum Hall effects to establish representations of the SI volt and ohm, respectively. The representation of the SI volt is attained by using  $K_{J-90}$  in the formula

$$U_J(n) = \frac{f}{K_J} \quad n = 1, 2, 3, \dots$$

to give the voltages  $U_J(n)$  of the steps produced by the ac Josephson effect at a frequency  $f$ . The past value,  $K_{J-72}$ , was  $483\ 593.42\ \text{GHz/V(NBS-72)}$ , thus leading to the 9.264 ppm change. Likewise,  $R_{K-90}$  is used in the following formula for the resistance of the  $i^{\text{th}}$  plateau of a quantum Hall effect device,

$$R_H(i) = \frac{R_K}{i} \quad (R_K = R_H(1))$$

to realize a representation of the SI ohm. The most recent past national unit of resistance,  $\Omega(\text{NBS-48})_t$ , was based on a group of five Thomas one-ohm standards and had an uncompensated drift rate of approximately -0.053 ppm per year. Since the quantum Hall effect is used as the national standard, the U.S. representation of the ohm has no drift. (The past unit of voltage,  $V(\text{NBS-72})$ , was based on the Josephson effect since 1972, and accordingly had a zero drift rate.)

Reassignments to Non-adjustable Standards

Since the U.S. practical volt and ohm units increased on January 1, 1990, the changes must be implemented in non-adjustable standards calibrated in terms of  $V(\text{NBS-72})$  and/or  $\Omega(\text{NBS-48})$  only by reducing the values assigned to them proportionally. The examples given below show how to do this for a standard cell and a standard resistor.

Sample Adjustments of Values of Standards

Standard cell:

"Old" emf 1.0180564 V(NBS-72)

Multiply "Old" emf by 0.999990736 to get emf in terms of the present volt representation  $1.01804697 \approx 1.0180470\ \text{V}$

Standard resistor:

"Old" resistance value 9999.976  $\Omega(\text{NBS-48})_{01/01/90}$

<sup>1</sup>Note that the SI Units have not been redefined; rather, they have been realized more accurately and a quantum physics representation of the ohm has been introduced, thus leading to the changes in magnitude of the practical or as-maintained units.

Additional Information (cont'd.)

Multiply "Old" resistance by 0.99999831 to get the resistance in terms of the present ohm representation

$$9999.9591 \approx 9999.959 \Omega$$

In the above, "Old" refers to the value of the standard which would have been in use on January 1, 1990, had the changes not been made; i.e., if a correction curve based on its past assigned values has been employed to obtain the currently-used value for a standard, the above represents a downward shift of the curve starting January 1, 1990. For resistance, the slope of the curve also changed (slightly) since  $\Omega(\text{NBS-48})$  has a drift rate and  $\Omega(\text{NIST-90})$  does not.

Do not send your standards to NIST for recalibration on January 1, 1990, unless they are normally due then. The changes are accurately known and corrections to existing standards may be applied.

Adjustment of Instrumentation

An assigned or calibrated value of a standard is merely a label giving the magnitude of the parameter embodied in the standard. The actual emf or resistance of a standard did not change on January 1, 1990; only what it is called should have changed. In the same sense, meter readings are labels giving the magnitudes of the parameters being measured. Readings taken after January 1, 1990 using unadjusted meters will be too large in magnitude. Adjustments to meters must have the effect of reducing the amplitudes of readings for fixed emf's or resistances.

Adjustable voltage and current sources or adjustable resistors for which nominal output is desired, on the other hand, must have their outputs increased proportionally by the above amounts. DVM calibrators are probably the largest class of this type of instrument.

Guidelines

The National Conference of Standards Laboratories (NCSL) and NIST have formed NCSL *ad hoc* Committee 91.4, Changes in the Volt and Ohm to assist industry and government laboratories in coming into compliance with the changes. A major responsibility of the committee is the generation and publication of a set of guidelines which describes unambiguous methods for adjusting standards and instruments, or their values, and delineates other types of problems which may arise, e.g., voltage values called out explicitly in maintenance procedures, values imbedded in software, and the like. These guidelines have been published as NIST Technical Note 1263, "Guidelines for Implementing the New Representations of the Volt and Ohm Effective January 1, 1990." This document is available at no charge through the NIST Electricity Division. To receive a copy, contact Sharon Fromm at 301-975-4222.

For further information, contact Norman B. Belecki (301-975-4223), Ronald F. Dziuba (301-975-4239), Bruce F. Field (301-975-4230), or Barry N. Taylor (301-975-4220).

**U.S. REPRESENTATIONS OF ELECTRICAL POWER AND ENERGY**

Watt, Var, Volt-Ampere  
Joule, Watthour, Varhour  
Volt-Ampere-hour, and Q-hour

Background

By international agreement, starting on January 1, 1990, the U.S. put into place new representations of the volt and ohm based, respectively, on the Josephson and Quantum Hall effects and which are highly consistent with the International Systems of Units (SI). Implementation of the new volt and ohm representations in the U.S. required that on January 1, 1990, the value of the present national volt representation maintained by the National Institute of Standards and Technology

Additional Information (cont'd.)

(NIST, formerly the National Bureau of Standards) be increased by 9.264 parts per million (ppm) and that the value of the national ohm representation be increased by 1.69 ppm (1 ppm = 0.0001%). The resulting increase in the national representation of the ampere is 7.57 ppm. The resulting increase in the national representations of the electrical quantities of power, namely the watt, var, and volt-ampere, and the quantities of energy, namely the joule, watthour, varhour, volt-ampere-hour, and Q-hour is 16.84 ppm.

The adjustment for electrical power and energy is generally very small compared to revenue metering measurement uncertainties (typically greater than  $\pm 0.1\%$ ) and therefore are not likely to have a significant effect. Adjustments do not need to be applied in the above instances. However, for the highest accuracy calibrations of power and energy standards having uncertainties less than  $\pm 0.020\%$ , adjustments should be made. Accordingly, all Reports of Calibration and Reports of Test issued by NIST after January 1, 1990, reflect the appropriate changes.

For instruments calibrated prior to January 1, 1990, adjustments to the calibration values due to the change in the volt and ohm can be made without instrument recalibration. The adjustments are exact and, if properly applied, will not introduce any errors. Examples given below will illustrate proper procedures for applying the new adjustments.

Adjustments for Wattmeters, Varmeters, and Volt-Ampere Meters

Calibrations of wattmeters, varmeters, and volt-ampere meters at NIST provide customers with corrections and uncertainties given in units of watts, vars, or volt-amperes, as appropriate. Applying the appropriate adjustment due to the new representations of the volt and ohm

for power measuring instruments (i.e., wattmeters for "real power" and varmeters for quadrature or imaginary power) requires minor calculations. First, it is necessary to assess the magnitude of the calibration uncertainty in percent and then decide if applying adjustments for the change in the volt and ohm are required. To determine the percentage uncertainty, simply divide the uncertainty in watts, vars, or volt-amperes by the product of the applied voltage and current times the power factor (the real power) and multiply that quantity by 100, as

$$U\% = [(U_w, U_v, \text{ or } U_{va}) / (V_a \times I_a \times PF)] \times 100,$$

where

U% is the uncertainty in percent,  
 $U_w$  is the calibration uncertainty in watts,  
 $U_v$  is the calibration uncertainty in vars,  
 $U_{va}$  is the calibration uncertainty in volt-amperes,  
 $V_a$  is the applied voltage in volts,  
 $I_a$  is the applied current in amperes, and  
 PF is the power factor (including its sign).

For example, if the uncertainty is stated on a Report of Calibration as  $\pm 0.060$  watts for the calibration of a wattmeter at an applied voltage of 120 V and an applied current of 5 A at unity power factor, then

$$\begin{aligned} \text{Percent Uncertainty} = U\% &= [(\pm 0.060 \text{ W}) / \\ & (120 \text{ V} \times 5 \text{ A} \times 1)] \times 100 \\ &= \pm 0.010\%. \end{aligned}$$

If the percentage uncertainty, as calculated above, is less than  $\pm 0.020\%$ , (as it is in the above example), then it is recommended that an adjustment of 0.0017% (0.001684% rounded to four significant decimal places) due to the new representations of the volt and ohm be applied.

The second step is the calculation of how

Additional Information (cont'd.)

large the adjustment will be (in units of watts, vars, or volt-amperes, as appropriate), due to the reassignment of the volt and ohm. For the same example given above, if the calibration correction was given in a Report of Calibration as +0.052 watts, then the adjustment due to the change in the volt and ohm may be calculated by multiplying the product of the applied voltage and current times the power factor by 0.000017 (0.0017% expressed in proportional parts), as

$$\begin{aligned} \text{Adjustment} &= (V_a \times I_a \times \text{PF}) \times 0.000017 \\ \text{Adjustment} &= (120 \text{ V} \times 5 \text{ A} \times 1) \times \\ &\quad 0.000017 = 0.010 \text{ watts.} \end{aligned}$$

The resulting product should be rounded to the same number of significant decimal places as the old calibration correction was given. This result is then subtracted from the old calibration correction, as in the following example:

Old Calibration Correction	
(prior to 1/1/90)	= (+0.052 watts)
less 0.000017 x Applied	
Volt-amperes x PF	= <u>-(+0.010 watts)</u>
New Calibration Correction	
(after 1/1/90)	= (+0.042 watts)

If the old calibration correction (prior to 1/1/90) at test conditions of 120 V, 5 A, and at a power factor of 0.5 lag, happened to be a negative quantity, for example, -0.031 watts, then the old calibrations correction would be decreased (made more negative) by 0.0017% of the applied volt-ampere product times the power factor, as in the following example:

Old Calibration Correction	
(prior to 1/1/90)	= (-0.031 watts)
less 0.000017 x Applied	
Volt-amperes x PF	= <u>-(+0.005 watts)</u>
New Calibration Correction	
(after 1/1/90)	= (-0.036 watts)

The process of making the corresponding

change for the varmeter corrections is identical to that shown above. For volt-ampere meters, the adjustment is made independent of the power factor (i.e., a value of PF = 1 may be used). However, most varmeter and volt-ampere meter calibrations have stated uncertainties greater than  $\pm 0.020\%$ , and hence, would not require an adjustment.

Adjustments for Joule, Watt-, Var-, Volt-Ampere- and Q-Hour Meters

Applying adjustments to electric energy measuring instruments (i.e., joule, watthour, varhour, volt-ampere-hour, and Q-hour meters) for changes in the representation of the volt and ohm, is more straightforward because the common calibration constant for energy metering is expressed as a "percentage registration." The amount the registration is to be adjusted can be subtracted directly as a percentage, regardless of power factor.

For example, if a watthour meter has a registration of 100.015% before January 1, 1990, then after that date, the new assigned registration would be decreased by 0.0017% (rounded from 0.001684%) as

Old percentage registration	
(prior to 1/1/90)	= 100.015%
less amount due to change	
in volt and ohm	= <u>-0.0017%</u>
New percentage registration	
(after 1/1/90)	= 100.0133%
Rounded to three significant	
decimal places	= 100.013%

The process of making the corresponding changes for the joule, varhour, volt-ampere-hour and Q-hour meters are identical to that shown above. If the associated uncertainty of the calibration is greater than  $\pm 0.020\%$ , no adjustments are necessary, as stated in the instances for wattmeters, varmeters, and volt-ampere meters. The uncertainties for varhour, volt-ampere-hour, and Q-hour meters are seldom less than  $\pm 0.020\%$ , and hence adjustments generally do not need to be made.

**NEW BROCHURE FOR SEMICONDUCTOR SRMs**

Standard Reference Materials for Semiconductor Manufacturing Technology lists a series of SRMs for use in characterizing semiconductor materials and processes. The SRMs include a series of silicon resistivity materials for calibrating four-probe and eddy-current test equipment [Technical Contact: James R. Ehrstein, (301) 975-2060]; sizing materials for calibrating optical microscopes [Technical Contact: Robert D. Larrabee, (301) 975-2298]; SRMs for optical measurements [Technical Contact: Jon Geist, (301) 975-2066]; and sizing materials for calibrating scanning electron microscopes, SRMs for mechanical testing, X-ray and photographic films, X-ray diffraction, and the chemical analysis of materials [General Contact: Office of Standard Reference Materials, Cindy Leonard, (301) 975-2023].

**1990/1991 CEEE CALENDAR**

October 24-26 (Boulder, CO)

**Symposium on Optical Materials for High Power Lasers** (Boulder Damage Symposium). The Symposium is the principal forum for the exchange of information on the physics and technology of materials for high-power lasers. Co-sponsors in addition to NIST are ASTM -- Standards for Materials, Products, Systems & Services; the Center for Research in Electro-Optics and Lasers at the University of Central Florida; the Defense Advanced Research Projects Agency; Lawrence Livermore National Laboratory, Los Alamos National Laboratory; SPIE -- the International Society for Optical Engineering; and the Weapons Laboratory of the U.S. Air Force. Topics on the agenda include new materials, bulk damage phenomena, surface and thin-film damage, preparation of optical material, measurement of optical material properties, design consideration for high-power systems, and fundamental mechanisms of laser-induced damage.

[Contact: Aaron A. Sanders, (303) 497-5341]

November 13, 1990 (Gaithersburg, MD)

**Ion Implant Users Group Meeting.** NIST, in cooperation with DoD, will host the second meeting of the Ion Implant Users Group on Tuesday, November 13, 1990, at NIST in Gaithersburg. Topics to be discussed at the meeting include charging, safety, and uniformity, as well as the Group's resources. The inaugural meeting of the Ion Implant Users Group was held on August 27, 1990 at NIST. The Group is open to anyone; operators, technicians, process engineers, and researchers are encouraged to become members. The scope of the topics is open to those related to ion implantation in general, with particular emphasis on topics not addressed elsewhere. The Group plans to meet on a quarterly basis; the third meeting of this informal group has been set for Thursday, February 28, 1991 at NIST.

1990/1991 CEEE Calendar (cont'd.)

January 20-31, 1991 (New Orleans, LA)

**SEMATECH/ASTM/SEMI/NIST Workshop on Silicon Materials for Mega-IC Applications.** To foster the understanding of circuit requirements and silicon properties that affect circuit performance, SEMATECH, ASTM, SEMI, and NIST are sponsoring this Workshop on mega-IC applications. Working sessions will consider requirement and specification issues on the following topics: silicon substrate and epi wafers, epitaxial processes, silicon on insulator technologies, contamination issues, and diagnostics and metrology. As this Workshop is being held in conjunction with meetings of SEMI Standards Committees and ASTM Committee F-1 on Electronics, a parallel aim of the Workshop is to provide guidance to and increased participation in the silicon-related standards work of ASTM and SEMI. [Contact: Robert I. Scace, (301) 975-2220]

March 18-21, 1991 (Research Triangle Park, NC)

**First International Workshop on the Measurement and Characterization of Ultra-Shallow Doping Profiles in Semiconductors.** Sponsored by Microelectronics Center of North Carolina (MCNC) in cooperation with the Semiconductor Research Corporation, the National Institute of Standards and Technology, and Northern Telecom Electronics, this workshop will provide a forum for a thorough discussion and evaluation of the different one- and two-dimensional techniques available for the measurement of ultra-shallow doping profiles in semiconductors. To be presented are invited papers by preeminent authors assessing the state of the art of different measurement techniques along with a prognosis for future extension of each technique. Topics to be covered by contributed papers include sputter depth

profiling techniques, spreading resistance measurements, other electrical characterization techniques, and microscopy for junction profiling and interface characterization. Strategies for forming very shallow junctions will be featured in a plenary session.

[Contact: James R. Ehrstein, (301) 975-2060]

September 8-11, 1991 (Research Triangle Park, NC)

**Third Workshop on Radiation-Induced and/or Process-Related Electrically Active Defects in Semiconductor-Insulator Systems.** This workshop is sponsored by the Microelectronics Center of North Carolina (MCNC), North Carolina State University, and the University of North Carolina at Charlotte, in cooperation with the Semiconductor Research Corporation, the IEEE Electron Devices Society, and the National Institute of Standards and Technology. Some areas of interest are: relationships between processing and electrically active defect densities, measurement methods, theoretical modeling of electrically active defects, process control of the sensitivity of insulators to ionizing radiation, removal of radiation damage, controlled radiation standard sources, and memory effects. [Contact: Jeremiah R. Lowney, (301) 975-2048]

2. PERFORMING ORGANIZATION REPORT NUMBER
3. PUBLICATION DATE November 1990

# BIBLIOGRAPHIC DATA SHEET

**TITLE AND SUBTITLE**  
Center for Electronics and Electrical Engineering Technical Progress Bulletin Covering  
Center Programs, April to June 1990, with 1990/1991 CEEE Events Calendar

**AUTHOR(S)**  
A. Gonzalez, compiler

**PERFORMING ORGANIZATION (IF JOINT OR OTHER THAN NIST, SEE INSTRUCTIONS)**  
U.S. DEPARTMENT OF COMMERCE  
NATIONAL INSTITUTE OF STANDARDS AND TECHNOLOGY  
Gaithersburg, MD 20899

7. CONTRACT/GRANT NUMBER
8. TYPE OF REPORT AND PERIOD COVERED April-June 1990

**SPONSORING ORGANIZATION NAME AND COMPLETE ADDRESS (STREET, CITY, STATE, ZIP)**

**SUPPLEMENTARY NOTES**  
All technical information included in this document has been approved for publication  
previously.

**ABSTRACT (A 200-WORD OR LESS FACTUAL SUMMARY OF MOST SIGNIFICANT INFORMATION. IF DOCUMENT INCLUDES A SIGNIFICANT BIBLIOGRAPHY OR  
LITERATURE SURVEY, MENTION IT HERE.)**

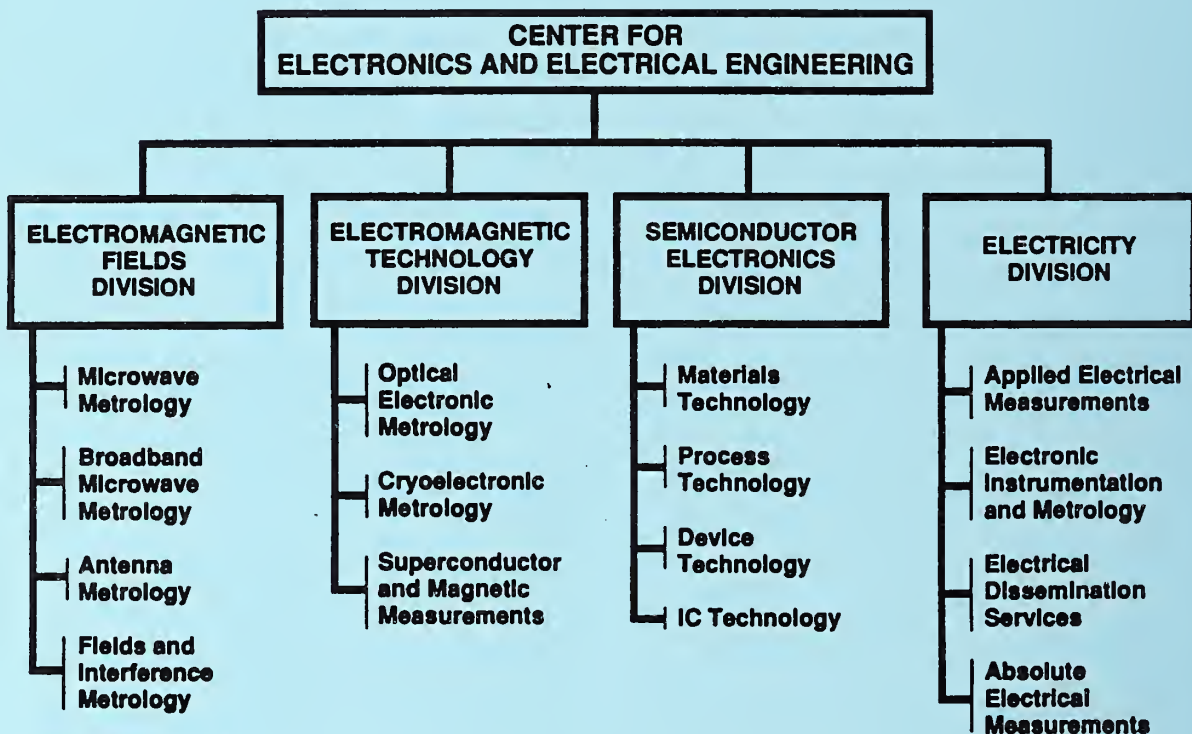

This is the thirty-first issue of a quarterly publication providing information on the  
technical work of the National Institute of Standards and Technology (formerly the  
National Bureau of Standards) Center for Electronics and Electrical Engineering. This  
issue of the CEEE Technical Progress Bulletin covers the second quarter of calendar year  
1990. Abstracts are provided by technical area for both published papers and papers  
approved by NIST for publication.

**KEY WORDS (6 TO 12 ENTRIES; ALPHABETICAL ORDER; CAPITALIZE ONLY PROPER NAMES; AND SEPARATE KEY WORDS BY SEMICOLONS)**  
antennas; electrical engineering; electrical power; electromagnetic interference;  
electronics; instrumentation; laser; magnetics; microwave; optical fibers; semiconductors;  
superconductors

<b>AVAILABILITY</b> UNLIMITED FOR OFFICIAL DISTRIBUTION. DO NOT RELEASE TO NATIONAL TECHNICAL INFORMATION SERVICE (NTIS). ORDER FROM SUPERINTENDENT OF DOCUMENTS, U.S. GOVERNMENT PRINTING OFFICE, WASHINGTON, DC 20402. ORDER FROM NATIONAL TECHNICAL INFORMATION SERVICE (NTIS), SPRINGFIELD, VA 22161.	14. NUMBER OF PRINTED PAGES 44
	15. PRICE A03
