ABSTRACT

Data are summarized from 107 laboratory tests on reinforced concrete columns with rectangular cross sections. In these tests the axial load on the column was held nearly constant while cyclic lateral loads were applied to cause column deformations in the inelastic range. The data in this report were obtained from test programs in the United States, Canada, New Zealand, and Japan. Synopses of each test program are presented and the geometric and material properties of each column test specimen are summarized. Plots of lateral load vs. lateral deflection are also shown for each specimen. The lateral load-lateral deflection histories for all specimens are presented in digital format on a computer disk. Much of this data has only been available in analog format, and is presented for the first time in digital format in this report.

KEYWORDS: building technology; cyclic lateral loads; digital data base; earthquake engineering; experiments; inelastic behavior; rectangular reinforcement; reinforced concrete columns

ACKNOWLEDGMENTS

We would like to thank the many researchers who provided reports and data to be included in this summary. In a number of cases we requested authors to retrieve data from experiments completed several years before, and they graciously searched their archives for the information we requested. This project was funded by the Federal Highway Administration, the National Center for Earthquake Engineering Research, and the California Department of Transportation. The authors gratefully acknowledge this support.

Chapter 1: Introduction

The purpose of this document is to summarize and make available for general use a substantial body of experimental data from cyclic lateral load tests on rectangular reinforced concrete columns. These data were collected, digitized and summarized as part of a larger study of the seismic performance of bridge piers¹, conducted in the Building and Fire Research Laboratory of the National Institute of Standards and Technology. It is hoped that this data will be useful to other researchers, especially for the calibration of damage models.

Lateral force-lateral deflection data were obtained from 107 column tests conducted by researchers in the United States, Canada, New Zealand and Japan. While the data set is not exhaustive, it represents a significant portion of the available test data.

In some cases the authors were able to obtain digital lateral force-lateral deflection data directly from the researchers who performed the column tests. In the majority of cases, however, precision photo-enlargements of lateral force-lateral deflection plots were prepared from report figures. These enlargements were then digitized manually using a digitizing tablet. Thus, the accuracy of the data was limited by the accuracy of the published figures.

Not every test from every test series was reported in this summary. For some specimens analog plots were either not available or were not clear enough to be used for digitization. Only data from specimens with a constant axial compressive load (not a fluctuating, tensile, or zero axial load) were digitized. Furthermore, only data from specimens in which the lateral load was applied along one of the principal axes of the cross section (not along the diagonal of the cross section or along a bi-direction loading path) were digitized.

The data are reported in Chapters 2 through 4 of this report. In Chapter 2 a summary of each test program is given. This includes bibliographic citations, a brief description of the test program, loading conditions, scale, material properties, geometry, and so on. The names of digital files containing lateral force-lateral deflection data are also given. In Chapter 3 plots of lateral force vs. lateral deflection are presented for all 107 specimens. Finally, in Chapter 4, the digital test data are presented by means of computer disks.

Chapter 2: Description of Cyclic Lateral Load Tests on Rectangular Reinforced Concrete Columns

Three types of specimens were tested in the experimental programs described in this report: simple cantilever specimens (Figure 1); double-ended specimens (Figure 2); and double curvature specimens (Figure 3). To present the data from these three types of specimens in a uniform format, all data is reported in terms of an equivalent simple cantilever column. Thus, for cantilever specimens (Figure 1) the forces and deflections reported are simply the same as those reported by the original researchers. For double ended specimens (Figure 2) the lateral forces reported are one-half the forces applied to the central stub of the specimen, and the lateral deflections reported are the lateral deflections of the central stub relative to the two fixed end points. For double curvature specimens (Figure 3) the lateral forces reported are those applied to each end beam of the specimen, and the lateral deflections reported are one-half the relative lateral displacements of the two end beams. The reported length "L" of each specimen is shown in Figures 1 to 3.

All data shown in the tables of this chapter were those reported by the researchers performing the original study, unless noted by an asterisk. Data noted by an asterisk were derived from data supplied in the original report. Caution should be exercised in interpreting the values of "transverse reinforcement ratio." Some researchers computed the transverse reinforcement ratio as a volumetric ratio, while others computed it in the same manner as the shear reinforcement ratio is computed for a flexural member. Therefore, to insure a uniform interpretation of the term "transverse reinforcement ratio", when using the data given in this report the ratio should be recalculated for the specific purpose at hand, based on the geometric data presented in the sketch of each cross section.

Note: H is given in plots and data files, not 2H

Gill, Wayne Douglas; Park, R.; and Priestley, M.J.N., "Ductility of Rectangular Reinforced Concrete Columns With Axial Load," Report 79-1, Department of Civil Engineering, University of Canterbury, Christchurch, New Zealand, February 1979, 136 pages.

Also reported in Park, R., Priestley, M.J.N., and Gill, W.D., "Ductility of Square-Confined Concrete Columns," *Journal of the Structural Division*, ASCE, Vol. 108, No. ST4,

April 1982, pp. 929-950.

Master of Engineering Report by Gill. Four full-size column sections were subjected to a static cyclic lateral load sequence over a range of axial compressive loads. Two different tie arrangements, both conforming to DZ3101 requirements, were used. These tests were conducted using a double-ended specimen, a self-reacting load frame with a hydraulic ram to apply cyclic lateral load, and a universal testing machine to apply constant axial load.

Ang tested four columns designed according to the Second Draft (1980) of the Concrete Design Code DZ3101 for different load levels. Only two involved square (rectangular) columns. These tests were conducted using a double-ended specimen, a self-reacting load frame with a hydraulic ram to apply cyclic lateral load, and a universal testing machine to apply constant axial load.

Four columns of square cross-section were tested; the quantity of transverse confining steel used ranged from 17 to 46 percent of the NZS 3101:1982 recommended quantity for ductile detailing. These tests were conducted using a double-ended specimen, a self-reacting load frame with a hydraulic ram to apply cyclic lateral load, and a universal testing machine to apply constant axial load.

Tanaka, H.; and Park, R., "Effect of Lateral Confining Reinforcement on the Ductile Behaviour of Reinforced Concrete Columns," Report 90-2, Department of Civil Engineering, University of Canterbury, June 1990, 458 pages.

PhD thesis by Tanaka. Eight columns with square cross sections were tested. (One specimen with a rectangular cross section was also tested, as described in the next section). Specimens one through four were conducted using a double-ended specimen, a self-reacting load frame with a hydraulic ram to apply cyclic lateral load, and a universal testing machine to apply constant axial load. Specimens five through eight incorporated a true cantilever column setup.

B. Tests Conducted in Japan

1982 Arakawa, Arai, Egashira, and Fujita

Arakawa, Takashi; Arai, Yasuyuki; Egashira, Keiichi; and Fujita, Yutaka, "Effects of the Rate of Cyclic Loading on the Load-Carrying Capacity and Inelastic Behavior of Reinforced Concrete Columns," *Transactions of the Japan Concrete Institute*, Vol. 4, 1982, pp 485-492.

Ten double-curvature specimens were tested under constant axial load and cyclic lateral load. The main variable was the rate of lateral loading. A digitizable analog plot was available from the authors for only one of the tests, specimen 102. This specimen was tested at a cyclic lateral load rate of 0.5 Hz.

Zhou, Xiaoshen; Satoh, Toshio; Jiang, Weishan; Ono, Arata; and Shimizo, Yasushi, "Behavior of Reinforced Concrete Short Column Under High Axial Load," *Transactions of the Japan Concrete Institute*, Vol. 9, 1987, pp. 541-548.

Thirty-five double curvature column specimens, at approximately 2/5 scale, were tested under constant axial load and cyclic lateral load. The main objective of the test series was to investigate the seismic performance of columns under high compressive stress. Digitizable analog plots from only nine specimens were available in the paper.

All Specimens
(Hoop detail unclear. Corner hooks assumed)

Kanda, Makoto; Shirai, Nobuaki; Adachi, Hiromi; and Sato, Toshio, "Analytical Study on Elasto-Plastic Hysteretic Behaviors of Reinforced Concrete Members," *Transactions of the Japan Concrete Institute*, Vol. 10, 1988, pp. 257-264. (Specimens 85STC-3 and 85PDC-3 only)

Six double curvature specimens were tested. In three of the tests ("STC" series) pseudo-static cyclic loads were applied in the form of a sawtooth wave with gradually increasing amplitude. In the remaining three tests ("PDC" series) a pseudo-dynamic testing procedure was followed, to simulate earthquake loading of the columns. The three specimens in each series had different details for anchorage of the longitudinal bars. The influence of the anchorage detail is not discussed in the paper by Kanda et al. because the paper mainly focuses on finite element modeling methods. Digital files of load-deflection data for all six tests were obtained directly from the researchers who performed the tests.

1989 Arakawa, Arai, Mizoguchi and Yoshida

Arakawa, Takashi; Arai, Yasuyuki; Mizoguchi, Mitsuo; and Yoshida, Minoru, "Shear Resisting Behavior of Short Reinforced Concrete Columns Under Biaxial Bending-Shear," *Transactions of the Japan Concrete Institute*, Vol. 11, 1989, pp. 317-324.

Fourteen double-curvature specimens were tested. The main variables studied were the direction of loading (0, 22.5, or 45 degrees, with respect to the principal axes of the cross section), and the level of axial compression or tension. Two plots were digitized from tests in which the lateral loads were applied at 0 degrees to the principal axes, and axial compression load was applied.

Muguruma, Hiroshi; Watanabe, Fumio; and Komuro, Tsutomu, "Applicability of High Strength Concrete to Reinforced Concrete Ductile Column," *Transactions of the Japan Concrete Institute*, Vol. 11, 1989, pp. 309-316.

Eight columns were tested. The tests focused on high-strength concrete in combination with high-strength lateral reinforcement. The main variable studied were the compressive strength of the concrete, the axial load level, and the yield strength of the confining reinforcement. Double-ended specimens were tested. A self-reacting load frame with hydraulic ram to apply cyclic lateral load and a universal testing machine to apply constant axial load were used. Digital load-deflection data were obtained directly from the researchers who performed the study.

Four double curvature specimens were tested. The main variable studied in this series was the axial load level. One specimen was tested with fluctuating axial load; one was tested with axial tension; and two were tested with constant axial compression. Only results from the two tests with constant axial compression are reported here.

C. Tests Conducted in North America

1973 Wight and Sozen

(hoops are welded)

Wight, J.K.; and Sozen, M.A., "Shear Strength Decay in Reinforced Concrete Columns Subjected to Large Deflection Reversals," *Structural Research Series No. 403*, Civil Engineering Studies, University of Illinois, Urbana-Champaign, Ill., Aug. 1973, 290 pages.

The main variables studied in this series were the axial load level, the transverse reinforcement content, and the displacement ductility demand. Twelve double-ended specimens were tested, but axial load was applied to only seven of the specimens. The central stub of each column was clamped so that it was immobile. Axial loads were applied by a self-reacting system of high strength steel rods and hydraulic ram. Lateral loads were applied by actuators at each end of the specimen; bending was about the strong axis of the cross section. Data was given for each end of the specimen, so in this report 14 load-displacement plots are presented: two plots for each axially loaded specimen.

1975 Atalay and Penzien

Atalay, M.B.; and Penzien, J., "The Seismic Behaviour of Critical Regions of Reinforced Concrete Components as Influenced by Moment, Shear and Axial Force," Report No. EERC 75-19, University of California, Berkeley, Dec. 1975, 226 pages.

The main variables studied in this series were the level of axial stress; the quantity of lateral reinforcement; and the displacement history applied to the specimen. Twelve double-ended specimens were tested, however, only ten of the analog load-deflection plots could be digitized. The two ends of each specimen had pinned boundary condition, and cyclic lateral displacements were applied to the central stub. Axial loads were applied by a hydraulic actuator reacting against a buttress. (Note that a second loading sequence was applied to specimens 1 to 8, but data from the second loading sequence is not reported here).

Umehara, H.; and Jirsa, J.O., "Shear Strength and Deterioration of Short Reinforced Concrete Columns Under Cyclic Deformations," PMFSEL Report No. 82-3, Department of Civil Engineering, University of Texas at Austin, Austin, Texas, July 1982, 256 pages.

Ten short rectangular columns were tested and the results compared to the results of previous tests on square columns. The main variables investigated were the applied lateral load history and the level of axial load. Of the ten columns tested in this series, only three were subjected to both an applied constant axial load and a uniaxial lateral loading path. The ends of the specimens were restrained against rotation.

1985 Bett, Klingner and Jirsa

Bett, Bart J.; Klingner, Richard E.; and Jirsa, James O., "Behavior of Strengthened and Repaired Reinforced Concrete Columns Under Cyclic Deformations," PMFSEL Report No. 85-3, Department of Civil Engineering, University of Texas at Austin, Austin, Texas, December 1985, 75 pages.

Three columns at two-thirds scale were tested. Two columns were strengthened by adding reinforced concrete jackets before testing. Results from these strengthened specimens are not reported here; only data from the one unstrengthened specimen were digitized for this report. The specimens were subjected to a constant axial load, and the ends of the specimens were restrained against rotation.

1988 Azizinamini, Johal, Hanson, Musser, and Corley

Specimens NC-2 and NC-4

Azizinamini, Atorod; Johal, Lakhpal S.; Hanson, Norman W.; Musser, Donald W.; and Corley, William G., "Effects of Transverse Reinforcement on Seismic Performance of Columns - A Partial Parametric Investigation," Project No. CR-9617, Construction Technology Laboratories, Skokie, Illinois, Sept. 1988.

Twelve full-scale tests were conducted. Eleven of the specimens had a square cross section, and one had a circular cross section. The main variables studied were the level of axial load, type of transverse reinforcement, and the amount and spacing of transverse reinforcement. Digitizable load deflection plots were available for only two of the tests on columns with square cross sections. The tests were conducted using a double-ended specimen, a self-reacting load frame with a hydraulic ram to apply cyclic lateral load, and a universal testing machine to apply constant axial load.

Saatcioglu, Murat; and Ozcebe, Guney, "Response of Reinforced Concrete Columns to Simulated Seismic Loading," American Concrete Institute, ACI Structural Journal, January-

February, 1989, pp. 3-12.

The authors conducted a series of tests on 14 cantilever column specimens. The columns cross section was square, and three different lateral reinforcement configurations were tested. The main variables investigated were axial load, confining reinforcement, and deformation path. Of the fourteen specimens, seven had lateral displacements applied along a principal axis of the cross section ("U" series); four had lateral displacements applied along a diagonal of the cross section ("D" series); and two had bidirectional lateral displacement patterns ("B" series). Only certain specimens from the "U" series are presented here. Of the "U" series specimens, U1 had no axial load applied, and U5 had variable axial load, so results for U1 and U5 are not presented. Lateral load vs. lateral displacement data files were obtained directly from the researchers who performed the tests. The data file for specimen U2 was not readable, so data for U2 is not presented.

Unit	Lateral Reinforcement				
No.	Bar dia.	Spacing (ctrs.) mm			
	mm	(ctrs.) mm			
U3	10	75			
U4	10	50

Chapter 3: Plots of Digitized Lateral Load-Lateral Deflection Data

This chapter contains plots of digital load-deflection test data for the 93 specimens described in this report. Each plot is identified by the test name shown in the upper left corner of the figure. Note that for double-ended specimens (Figure 2, page 3), the force shown in the plot is one-half the force applied at the center stub of the specimen; and for double curvature specimens (Figure 3, page 3) the displacement shown in the plot is one-half the relative displacement between the two end beams of the specimen.

Chapter 4: Digital Data Files

Enclosed is one high density (1.44 megabytes) DOS compatible disk. The disk contains 107 digital data files listing lateral deflection-lateral force data, as described in this report.

The files are stored on the disk in a compressed format. To decompress the files, first copy the only file on the disk, RECTCOL.EXE onto the computer hard disk. There should be at least 3 megabytes of disk space available to perform the expansion. Then type the command

RECTCOL.EXE

and all of the files will be automatically decompressed. The original compressed files, RECTCOL.EXE, may then be erased from the hard disk.

The names of the 107 digital data files correspond to those given in Chapter 2 of the report. All the data files (once they have been de-compressed) are in a format which is readable by common spreadsheet programs. The first line of each file is a short descriptive title. The second line is the total number of deflection-force data pairs, "n", to follow in the data file (i.e., the number of data points in the file). The remaining "n" lines are the deflection-force data pairs, in units of mm and kN.

Charger 4: Digital Data Filos-
