INTRODUCTION

Filled polymers and nanocomposites represent a significant share of the world plastic market, competing strongly with costly high performance plastics. Yet, a major limitation to the potential growth and development of this industry has been a lack of understanding of the interactions between fillers and the polymer matrix and of measurements quantifying such interactions. This limitation has forced the filled polymers industry to adopt empirical approaches for product development, a procedure that necessarily delays product development cycles. Recently, renewed interest in the area of clay nanocomposite materials has spurred a number of industries to initiate research programs for developing applications of these materials. A long term plan for successful application of nanocomposites as materials with unique properties also requires fundamental characterization measurements. Thus, the need to identify critical technology development and state of the art measurement techniques to support the rapid growth of the filled polymers industry is generally recognized as being important.

1.1 Workshop Objective

Problems, Opportunities and Challenges in Filled Polymers

The NIST workshop entitled "Interactions of Polymers with Fillers and Nanocomposites" sought to gather experts on filled polymers and nanocomposites from industry and academia to identify the most critical issues hindering progress on filled polymer technology. Over two days the workshop participants highlighted important scientific and technical problems with the aim of identifying critical measurement techniques and modeling which can improve the performance, manufacture, and applications of filled polymers and nanocomposites. The recommendations of the workshop were used to better define the research efforts of the Polymer Blends and Processing Group in the area of filled polymers and nanocomposites, in addition to laying the foundation for collaborations with industry.

1.2 Executive Summary

Control of *molecular-level interactions* and measurement of *polymer dynamics* at the filler interface were identified by participants at a recent NIST sponsored workshop as the most critical issues in filled polymers and nanocomposites. Although filled polymers already represent a substantial fraction of polymer materials, recent developments in nanocomposites have attracted renewed interest in developing the science and technology base to optimize performance. The workshop focused on identifying the most critical issues hindering improvements in applications of filled polymers and nanocomposites. Of the 75 external participants, 50 were from industry, mostly experts in the area of filled polymer technology. Through productive discussions, the workshop participants highlighted and prioritized a range of future research and measurement needs for filled materials.

The discussions also laid the foundation for future research in this area, and collaborations between NIST, industry, and academia. The Polymer Blends and

Processing Group of the Polymers Division, MSEL initiated research on polymer-filler interactions in 1997 using X-ray, neutron and light scattering in combination with microscopy techniques, and concepts that had been previously applied with great success on polymer blends. The results of the workshop will be used to plan future directions of the NIST work.

1.3 Acknowledgements

The authors would like to thank the speakers for their valuable presentations, and the session coordinators for conducting the meetings of the workshop. In addition, we would like to thank the participants for attending and contributing to the discussion sessions. Furthermore, we would like to express our appreciation to the Conference Facilities Group at NIST for providing the arrangements and organization that made the workshop possible.

1.4 Disclaimer

Commercial equipment, instruments, software, materials or services are identified to adequately report the presentations and discussions that took place. Such identification does not constitute nor imply recommendation, endorsement, or criticism by the National Institute of Standards and Technology (NIST). Nor does NIST take responsibility for the accuracy or source of the various non-NIST numerical values reported in this document, or the use of units other than those of the International System by non NIST authors.

PRESENTATIONS SUMMARY

2.1 Opening Remarks

Dr. Leslie Smith (MSEL Director)
The Materials Science and Engineering Laboratory (MSEL) director, Dr. Leslie Smith emphasized the importance of fillers and nanocomposites to the polymer industry and the need for fundamental measurements in the area. Dr. Smith described the laboratories structure under MSEL and also the different NIST programs, placing emphasis on the Advanced Technology Program and the Measurements and Standards Laboratories. The ways by which NIST identifies needs were summarized: 1) Visits to and by industrial researchers; 2) Through workshops organized by NIST; and 3) Through industrial roadmaps.

Dr. Eric Amis (Group Leader, Polymer Blends and Processing Group)
Dr. Eric Amis described the goals of the Polymer Blends and Processing Group and emphasized that the area of filled polymers and nanocomposites was becoming a high priority area for research by this group at NIST. He iterated the purpose of the workshop as gathering the experts in the area of filled polymer technology to highlight the key areas and critical issues hindering progress in the area. The ideas generated through the Workshop would be used guide the blends research efforts at NIST and potentially establish long term collaborations with industry in some critical areas.

Dr. Alamgir Karim (Physicist, Polymers Blends and Processing Group)
Dr. Karim discussed the Blends and Processing Group research program in the area of filled polymers to study fundamental aspects related to measurements of filled polymers and nanocomposites. He described the nature of research being conducted by the group in the area of filled polymers and nanocomposites that take advantage of some unique measurement capabilities at NIST.

2.2 Compounding, Reinforcement and Toughening Session (I)

"Concepts in Rubber Chemistry: The Role of the Filler particle", Gary T. Burns, Dow Corning Corp., Pare Industriel-Zone C, Seneffe B-7180, Belgium

Dr. Burns gave an overview of filled polymer processing technology and discussed properties of fillers that impact material characteristics. One of the problems with elastomers is that they change during compounding so that the initial and final state elastomers are quite different. He emphasized that while much has been done to characterize fillers prior to processing, the state of the filler in the final product is poorly characterized. Also discussed were the two main features controlling properties of the filled materials: Filler structure/geometry and the surface energy.

Regarding filler structure/geometry the primary particle size is the most important contribution to the surface area. The size of typical primary particles is in the range of (3 to 50) nm. In this regard, the measured surface area by gas adsorption may not be the true surface area. The aggregation of the primary particles and packing control porosity,

and hence spatial arrangements of particles within aggregates and of the agglomerates are important. However, while the role of aggregation is important, there is no well defined measure of its reinforcement properties. Additionally, the density makes a difference and is important.

Surface area can be measured by BET (N_2 adsorption) and CTAB adsorption. The relevant formulas for obtaining the surface area of spheres and rods were discussed. Pore volume can be measured by BJH analysis, mercury porosimetry, and dibutyl phthalate absorption. The role of surface roughness is system specific, which implies that there are surface energy effects, so that the measured surface area may not be related to the true surface area.

Concepts of bound and occluded rubber were introduced as measures of polymer-filler interaction. The bound rubber are the rubber molecules which are strongly adhered to the filler surface, while the occluded rubber are the polymer chains trapped in voids of aggregates and are shielded from the applied stress. The bound rubber has a layer of directly attached chains and a second layer of entangled chains. Shape factor could be related to occluded rubber. Bound rubber fraction can be measured by NMR techniques as well as by extraction. All such measurements seem to provide satisfactory results.

On the theoretical side, Dr. Burns discussed the Modified Smallwood-Guth-Gold Equation for predicting the modulus of a filled material as a function of filler volume fraction only.

In his concluding remarks, he stated the following needs for advancing the understanding of filled polymers: 1) Development of a generalized equation with well-defined variables such as filler shape, filler porosity, filler-filler and filler-polymer interactions; 2) Accepted techniques to measure these variables; 3) Characterization of the state of the filler not only before but after mixing as well.

Discussion- The point was raised that occluded and bound rubber are related to hysteresis behavior and that rheological effects often differ from observed mechanical behavior.

Fig. 7

"Dynamic Studies of Compounds-Latest Results", Henry Yang, M. Gerspacher and
C.P.O' Farrell, Sid Richardson Carbon Co., Fort Worth, TX

Dr. Yang discussed the role of filler distribution on high and low frequency
rheological behavior. He stated that carbon black has no porosity or surface groups and
that the crystal edges in the particles are the active sites. Nevertheless, there are a

9

number of different interactions, which need to be identified and quantified, and the relevance of each interaction needs to be determined.

The high frequency behavior is dominated by the polymer while the low frequency behavior is dominated by the filler properties. Increasing filler dispersion lowers reinforcement while it increases the attenuation coefficient. Low strain, low frequency behavior can be related to the filler-filler interactions and low strain, high frequency behavior can be related to the filler-polymer interactions.

Discussion- Questions were raised concerning the lack of surface groups and porosity in carbon blacks.

*"**Flow-induced Microstructural Changes in Filled Polymeric Liquids**"*, Saad A. Khan, Srinivasa R. Raghavan, Department of Chemical Engineering, North Carolina State University, Raleigh, NC 27695-7905
One of the aspects of interest in filled systems is to elucidate microstructural changes caused by flow fields, and to evaluate whether these changes persist over long periods of time. This point becomes particularly relevant in non-traditional composite systems where the particle/filler interactions can lead to a wide range of rheological behavior, such as in fumed silica systems in low molecular weight polymers. In fumed silica systems, the surface characteristics can be tailored to give rise to two different classes of filled materials: (a) colloidal gels (networks); and (b) colloidal (stabilized) suspensions. In the case for gels, a three-dimensional network of colloidal (fumed silica) particles extends throughout the volume of the system. Under the action of oscillatory pre-shear at large deformations, the microstructure is disrupted into distinct entities. The critical variable is not the shearing time but the strain amplitude. The equilibrium microstructure can be changed with pre-shear and shows anomalous behavior in terms of the existence of a minimum in the recovered dynamic elastic modulus ($G\square$) when examined as a function of pre-shear strain amplitude. To better understand the changes occurring during shear, the concept of fractal dimension was introduced. Changes in the power law behavior of $G\square$ and the critical strain amplitude versus filler volume fraction was observed following preshear. This could be related to changes in fractal dimension from 1.75 before shear to 2.02 following moderate preshear. While the fractal dimension before shear was experimentally obtained, that following shear was obtained using the model of Potanin et al. and requires further experimental verification.

In the case of stabilized suspensions, a dramatic increase in steady-shear viscosity was observed at high shear-rates (shear-thickening). Likewise, a dramatic enhancement in the dynamic properties (complex modulus G^* or complex viscosity η^*) was also observed under large oscillatory deformations and high frequencies – a phenomenon

referred to as strain-thickening. A unique correlation between steady shear-thickening and dynamic strain-thickening was established utilizing a "modified Cox-Merz rule." While these shear and strain thickening behavior are consistent with the formation of hydrodynamic clusters, direct evidence of microstructural rearrangements during shear would be highly desirable.

Discussion- The role of particle and orientation and utility of techniques such as rheo-optics was raised. Since the structures are not anisotropic, it was doubtful there would be much orientation, hence the rheo-optical techniques would not be very useful.

COLLOIDAL GELS

● Show anomalous recovery behavior on being subjected to oscillatory shear at moderate strains.

● Attributed to changes in fractal dimension due to shear

COLLOIDAL SUSPENSIONS

● Show shear-thickening under steady shear and strain-thickening under oscillatory shear. The two phenomena can be correlated by an extended Cox-Merz rule.

● Both phenomena are attributed to hydrodynamic forces which induce cluster formation

Above hypotheses need to be experimentally verified.
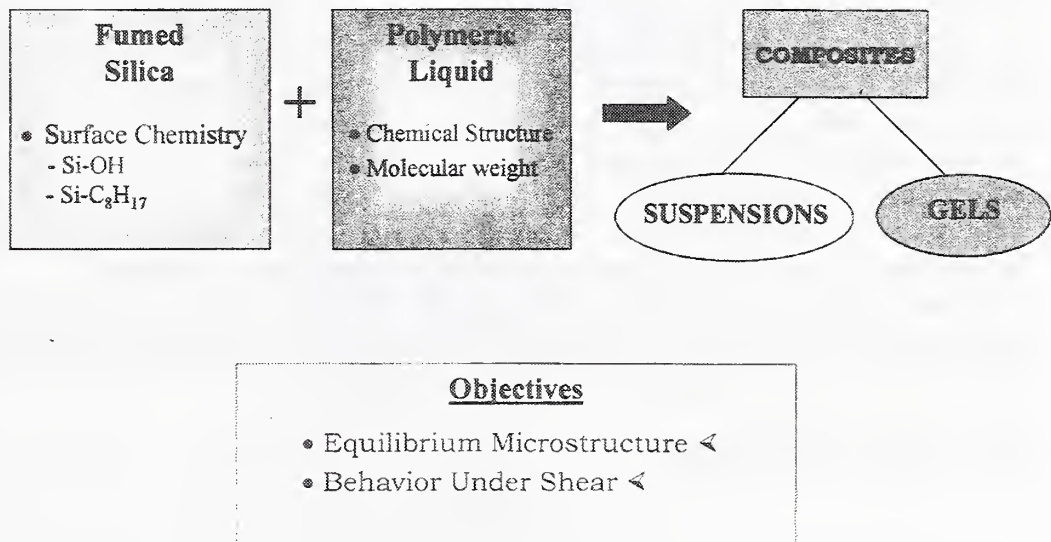

Fig. 5

"Recent Industrial Developments: From Anti-Static Polymers to Artificial Marble", Moshe Narkis, Dept. of Chemical Engineering, Technion, Israel Institute of Technology, Haifa, Israel

Dr. Narkis commented that while compression molding studies are available in the literature they are of little interest to industry. This is because injection molding is typically used in industry and so these types of studies are preferred by industry. He stated the need for new anti-static injection moldable composites since most current materials become insulating when they are injection molded. He illustrated these ideas with carbon black, glass fibers, and polypropylene (PP) with 3 other component fillers. Finally, he urged the need to better understand multicomponent (greater than 3) immiscible systems and stated the need for better conductivity definitions.

Discussion- Question was raised concerning the possibility of measuring the conductivity during and after processing. Another question was raised concerning the effect of carbon black structure on its capacity to migrate.

2.3 Compounding, Reinforcement and Toughening Session (II)

"A comparative study of microstructure and fracture behavior of a conventional filled polymer and a nanocomposite", Albert F. Yee, J.P.Harcup, J. Du, and J. Lee, Dept. Materials Science & Engineering, The University of Michigan, Ann Arbor

This talk focussed on fracture and toughening mechanisms in macro and nanocomposite materials. One of the goals of this research work on fracture and toughening was to explore the size scale of interfacial properties. Dr. Yee mentioned that there was a lack of theoretical models for satisfactorily explaining toughening of filled materials. This is a different approach than what most traditional filled systems entail. Instead of a rigid particle in a rubbery matrix to get enhanced modulus (amongst other properties), one has a rigid matrix filled with rubbery particles to get improved fracture resistance. He elaborated on crack shielding and crack pinning in this context. The idea of bound rubber becomes important as well for toughening. It was also noted that better dispersion does not necessarily lead to better properties and he stated the need to examine the dynamics of processes to get an understanding of the mechanics involved. In this regard, measure of the morphology alone is insufficient to understand fracture and toughening in filled materials.

Discussion- Questions on the effect of orientation (A: Hasn't been looked at) and the effect of aggregation on the interface (A: Not sure).

Fig. 2

Modeling for Steady-State Toughening

- This model is for toughening by shear yielding of the matrix.
- The constituitive behavior (power-law hardening) is for toughened material, NOT for pure matrix.
- A large n (strain-hardening exponent) corresponds to a low hardening material.
- Plane-strain crack-tip field for a power-law hardening material can be described by HRR fomulation.
- Steady-state toughening can be evaluated by an energy-balance approach.

Steady-State Toughening Efficiency

- A significant toughening effect can be obtained only when the ratio of cohesive strength to yield stress (σ_c/σ_0) exceeds a certain value. This can be achieved by decreasing the plastic-flow stress (σ_0) and/or increasing the cohesive strength (σ_c).
- Steady-state toughening efficiency ($\Delta J_{ss}/J_0$) increases with increasing the ratio of cohesive strength (σ_c) to yield stress (σ_0) and/or strain-hardening exponent (n).

Fig. 3

21

"Metallocene Impact Modifiers: Influence of TPO Paintability and Cohesive Strength", Rose A. Ryntz, Visteon Automotive Systems, Dearborn, MI

Dr. Ryntz talked about crystallization in the presence of fillers. As in the previous toughening problem, the filler particles here are elastomers as well. It was also of interest to study effects of metallocene impact modifiers on cohesive strength of thermoplastic olefins (TPOs). The study involved stability and structure of coatings and the influence of the skin-sublayer interface. Typical measurements involved utilizing compressive shear tests. Also of interest was the effect of having a filler in the presence of two-polymeric components. In Dr. Ryntz's view, for the fillers and nanocomposites area to develop significantly, a knowledge of the mechanical behavior of multicomponent (more than 2) systems was deemed critical. Dr. Ryntz also stated that the needs for the area are interphase characterization and crystallization effects.

"*Blends of Brominated Isobutylene Paramethylstyrene Copolymer (BIMS) and carbon Black*", Mun Fu Tse, K.O. McElrath, H.-C. Wang, Exxon Chemical Co., Baytown, TX

In his talk, Dr. Tse discussed the determination of polymer-filler interactions from bound rubber fraction measurements. In these measurements involving carbon black fillers, there is a surface area and concentration dependence. Solvent extractions methods are used to determine the bound rubber content. It was found that the amount of bound rubber is a function of the filler concentration. Blends of a number of different brominated isobutylene paramethylstyrene copolymers (BIMS elastomers) with different types of carbon black were studied. The BIMS elastomers have different levels of BrPMS (bromo-paramethylstyrene) and PMS structure levels. These polymer/filler blends are characterized by solvent extraction at different temperatures (bound rubber fraction), viscoelasticity and stress-strain behavior. It has been found that BIMS elastomer interacts strongly with carbon black, as indicated by bound rubber

measurements. These interactions increase approximately with the specific area of the carbon black, and with the BrPMS and/or PMS content in the BMS elastomer. In some cases, the structure level of the carbon black produces some subtle effects on the stress-strain behavior of the BIMS/carbon black blends.

Discussion- Question concerning whether studies of small molecule model compounds have been done to correlate bound rubber and adsorption / desorption behavior. Also whether calorimetric studies have been done to look at polymer-surface interactions; the need to determine the nature of the binding - whether it is chemical (covalent) or physical.

"Investigations of Filler - Polymer Interactions" A.J. Dias, Exxon Chemical Co., Baytown, TX

Dr. Dias stated that 85 % of elastomers produced are used in tires. Therefore, any incremental improvement impacts a major market segment. In their studies, the driving force behind migration of fillers was investigated. Does the filler move to a specific polymer phase or does the polymer move to the filler were some of the questions being asked. Apparently the filler particles migrated rapidly within and between viscous media, but it was unclear on what the mechanism and driving forces were. In his talk Dr. Dias stressed the importance of studying multicomponent polymer mixtures with filler. He explained that it was not possible to predict properties of networks from structural knowledge because of the range and effects of fluctuations. As an alternate technique to the bound rubber extraction, it was possible to follow adsorption of polymer to filler surfaces from polymer solutions using NMR. The order of addition of the polymers was important, implying the binding may be covalent. Further, he expressed the need to understand the diffusion behavior of polymers near surfaces. In their thin film studies they found that the polymer chains slowed down dramatically in thin films of thickness 20 nm. Additionally, he stated the need to understand the mechanics of deformed filled elastomers. Presently, a model by Lipizzera exists but further extensions and generalizations to filled systems are necessary.

Fig. 5

"Evolving Structure/Property Relationships for Precipitated Silica", <u>Jo-Ann Bice</u>, PPG Industries, Inc., Monroeville, PA

This talk was focussed on precipitated silicas rather than fumed silicas. The motivation for the studies were that recent studies indicated that silica particles in rubber improved properties of tire-wear resistance and moves forward in the step towards "green" technology. The processing conditions of filled systems dictate final properties, but the final properties are difficult to predict a priori. For these processes, in situ analysis techniques are therefore preferred. Determination of the microporous structure can be done by mercury porosimetry or oil (DBP) absorption. Determination of contact angle is however a more difficult problem. Residual porosity is found to affect the density measurements, and the poor determination of density is a big problem. Precipitated silica surface area can be determined by adsorption techniques, as enumerated by other speakers.

Surface preparation is important, since the chemistry of the surface determines the nature of the interactions with polymers as well as other additives. This is also related to wettability issues. Titration and spectroscopy are not useful in this regard. Other techniques give average values, but are not geometry specific (Same as with the density problem). Impurities are found to have a profound influence on surface chemistry.

Discussion- Any quantitative measure for energy required to disperse filler? (A: Not really).

2.4 Nanocomposites Session

"Structure and Dynamics of Polymer Nanocomposites", <u>Emmanuel P. Giannelis</u>, Dept. of Materials Science and Engineering, Cornell University, Ithaca, NY

Composites with dimensions in the range of 1 nm to 100 nm, so-called nanocomposites, are the subject of intense current research and development. In particular, nanocomposites synthesized by intercalation of polymers in layered silicates exhibit many advantages including improved mechanical properties, outstanding diffusional barrier properties as well as flame resistance and self-extinguishing characteristics. The talk reviewed the physical and mechanical properties of nanocomposites and discussed them in terms of their static (neutron scattering and computer simulations) and dynamic (including NMR and dielectric relaxation) properties.

*"**Montmorillonite Clay Structures and Intercalation Chemistries Based on Dipole Moment Interactions**", <u>Gary Beall</u> and Karl Kamena, Nancore, Inc., Arlington Heights, IL*

A new approach to montmorillonite clay surface modification has been developed to compatibilize clays with polymers to prepare nanocomposites. Dr. Beall explained that this new technology was referred to as ion-dipole treatment. The treatment method was described in some detail as well as its implications for nanocomposites. Two issues were discussed that have exhibited significant effects on nanocomposite properties and performance. The first involves the issue of clay purity. Data indicated that clay purity has a strong effect on engineering properties of nanocomposites, especially elongation and impact resistance. The second concerns the effect of clay on permeability. The traditional explanation for the improved barrier of nanocomposites is one of tortuous path. The effect of clay purity level was examined as well as intercalation chemistries that complicate permeability predictions and permanent properties and long term behavior.

*"**Dispersion in a Clay Nanocomposite; Application of Radiation Scattering**", <u>Chris D. Muzny</u>, B.D. Butler and H.J.M. Hanley, NIST, Boulder, CO*

The potential of using clay as the filler in a polymeric organic/inorganic composite is well understood and appreciated. The properties, however, of the resulting composite are most influenced when the largest possible clay surface area is presented to the polymer matrix. Ideally, then, the clay should be fully dispersed (exfoliated) into its constituents- negatively charged platelets about 1 nm thick and 20 nm to 200 nm in diameter – and bonded to the matrix using an appropriate cationic organic intermediary. Unfortunately, clay platelets tend to form large aggregates in the presence of organics, so they normally will not disperse. A proposed route to prevent clay aggregation by forming platelet-surfactant micelles was presented. The procedure is based on performing a cation exchange reaction between the clay and a surfactant monomer and then adding sufficient excess monomer to give clay-micelle complexes. From chemical analyses of the samples, combined with light and small angle neutron scattering, the estimated excess monomer corresponded to four cation exchange equivalents. In the preliminary work, the complex was then polymerized with acrylamide. Dispersion of the clay was verified by following the synthesis using dynamic light scattering , X-ray scattering, and electron microscopy. It was argued that proof of dispersion is well demonstrated from dynamic light scattering data, thus indicating the potential of the technique of dynamic light scattering as a tool to monitor a synthesis process involving particulates. Problems arising from dispersing a nanometer scale clay mineral in a polymer matrix were discussed.

Some of the issues which needed to be addressed were: 1) Can clay be dispersed in organic solvents? 2) Which is preferred for better properties - homogeneous dispersion or delamination? 3) How can clay content be increased in solvent? 4) How to prove covalent bonding to the surface of the clay occurs? 5) Is crosslinking important? Discussion- Crosslinking is important for compressive strength in composites, therefore, it is probably an important issue here.

"Nanocomposites from Polymers and Layered Minerals", <u>Leon H. Gielgens</u>, H. R. Fischer, T. P. M. Koster, Tno-Tpd Institute of Applied Physics, Materials Division, P.O. Box 595, 5600 AN Eindhoven, The Netherlands

In his talk, Dr. Gilgens discussed block copolymer modified clays. He introduced nanocomposite materials as consisting of polymeric matrix materials and natural or synthetic layered minerals like clays prepared by using special compatibilizing agents between the two intrinsically non-miscible materials. In their approach, these compatibilizers were block- or graft copolymers, with the idea of combining one part of the polymer identically and/or completely miscible with the organic polymer (matrix compound) and another part compatible/miscible with the natural mineral. The interaction between the first part of the compatibiliser is preferentially an ionic interaction or an interaction via H-bonds. This interaction leads to a separation of the mineral into single sheets and a subsequent homogeneous incorporation of these sheets into the polymer matrix material. The aim of the investigation was to provide a general process for the manufacturing of nanocomposite materials consisting of polymeric matrix materials and homogeneously dispersed layered crystalline inorganic materials. He stated needs in mechanical property evaluation, diffusion data, chemical resistance, high temperature behavior and needs in cost and safety evaluation.

Discussion- Comments include emphasis on cost and the balance between increased modulus but decreased toughness. Suggestion that traditional rubber toughening methods should be successful in these systems to improve brittleness and that complete exfoliation is not always needed.

"*Rheological Study of Macro- and Nano- Composites*", Ramanan Krishnamoorti, University of Houston, TX

Dr. Krishnamoorti reported on the rheological behavior of composite materials containing filler particles that led to macro and nanocomposites. The rheological properties of intercalated and exfoliated nanocomposites of a homopolymer were examined using oscillatory shear and the terminal regime flow characteristics were found to be distinctly different – the exfoliated nanocomposites exhibited liquid like behavior while the intercalated nanocomposites exhibited characteristics intermediate between a liquid and a solid. Dr. Krishnamoorti also reported on the linear viscoelastic, alignment characteristics and non-linear oscillatory shear behavior of an end-tethered nanocomposite. These were shown to be model melt-brush systems and exhibited extraordinary strain hardening characteristics. Finally, Dr. Krishnamoorti reported on structural and viscoelastic characteristics of a block copolymer based nanocomposite. The rheological properties in the terminal regime were found to be pseudo-solid like and consistent with the response from a "hairy-disc" object.

"Flammability Studies of Polymer Layered Silicate Nanocomposites", Jeffrey W. Gilman, Takashi Kashiwagi, Sergei Lomakin[†], National Institute of Standards and Technology, Gaithersburg, MD; Emmanuel P. Giannelis, Evangelos Manias Cornell University, Ithaca, NY; [†] Guest Researcher at NIST from the Russian Academy of Sciences, Moscow, Russia.

Dr. Gilman reported on the enhanced thermal properties and improved flammability properties of polymer-layered silicate (clay) nanocomposites. He showed that both delaminated and intercalated nanostructures have improved flammability properties. His collaborative research program with Dr. Giannelis at Cornell University has focused on demonstrating the generality of the flammability behavior and on studing the mechanism of the flame retardant effect of the nano-dispersed clay. XRD and TEM analysis was used to identify a nano-reinforced silicate/carbon-like char from the combustion residue. Dr. Gilman felt the presence of this high-performance char supports a physical rather than a chemical mechanism of flammability control. A NIST-Inductry Consortium has been formed to further study the flammability properties of nanocomposites.

Fig. 5

- The HRRs of thermoplastic and thermoset polymer layered silicate nanocomposites are reduced by 40 % to 60% in delaminated or intercalated nanocomposites containing a silicate mass fraction of only 2 % to 6 %. Furthermore, this system does not increase the carbon monoxide or soot produced during the combustion.

- Not only is this a very promising new method for flame retarding polymers, but it does not have the usual drawbacks associated with other additives. That is, the physical properties are not degraded by the additive (silicate); instead they are improved..

- The nanocomposite structure of the char appears to enhance the performance of the char layer. This layer may act as an insulator and a mass transport barrier slowing the escape of the volatile products generated as the polymer decomposes.

"Dynamics of polymers in confined geometries: Neutron studies of intercalated polymer-clay nanocomposites", Robert Ivkov, A. Karim, E. Amis, N. Malizsewskyi, P. Gehring, NIST; R. Krishnamoorti, Dept. of Chemical Engineering, Univ. of Houston, Houston, TX

Dr. Ivkov discussed the use of neutron scattering methods to characterize the structure and dynamics of polymers such as polyethylene oxide (PEO) intercalated into fluorohectorite clay. He described the filter-analyzer spectroscopy technique to characterize the high energy dynamical features, and neutron time-of-flight and spin-echo spectroscopy to characterize the low energy, larger spatial features of these materials. Intercalated materials were prepared by melt intercalation of 100,000 M_w polyethylene oxide (PEO) into fluorohectorite (FH) clay. Several samples were made with varying amounts of polymer mass fraction, 18 %, 25 %, and 30 %. The extent of intercalation was characterized by x-ray diffraction, and all samples were stored in a dessicator under vacuum until use. The samples were loaded into aluminum sample holders sealed with indium wire in an inert (dry He) atmosphere in a glove box immediately before use.

Neutron filter-analyzer spectra were obtained at a temperature of 10 K for all samples described above, and were compared with those obtained from bulk PEO and pure clay. The data reveal only subtle differences among the intercalated materials and the bulk PEO, suggesting that the vibrational motions of the hydrogens in the polymer do not experience a significantly different environment upon intercalation. Neutron time-of-flight data taken at 20 K below the glass transition of PEO (213 K) reveal significant differences between the intercalated materials and the bulk polymer. Bulk PEO displays several peaks that result from vibrational modes of the crystalline regions of the polymer. These features diminish with intercalation. Another prominent feature observed in the bulk PEO is the low energy plateau (-2 meV to -8 meV) common to the glassy state. With 30 % intercalation, the plateau becomes a shoulder and almost completely disappears in the 18 % PEO sample, suggesting that the intercalated polymer chains are not in the glassy state.

42

Discussion-Comment that extension of studies to examine slower molecular motion modes might be enlightening for fatigue and failure studies and long term stability of filled polymers.

Select Figures
Fig. 1: Plots of neutron time-of-flight data obtained from samples at 193 K (20 K below the glass transition of bulk PEO) : a) pure fluorohectorite clay, b) pure polythylene oxide (PEO); c) 30 % PEO intercalated with fluorohectorite clay, and d) 18 % PEO intercalated with fluorohectorite clay. These reveal significant differences between intercalated materials and bulk polymer. Several features seen in bulk PEO get suppressed with intercalation. Together, the results suggest that intercalation of PEO into clay galleries significantly reduces interchain interactions to the point that the chains no longer retain their macroscopic properties.

2.5 Theory and Modeling Session

"Effect of fillers and their distribution on composite properties," <u>C.K. Hari Dharan</u>, Dept. of Mechanical Engineering, University of California, Berkeley, CA

Dr. Dharan stated the needs for gathering knowledge of local properties of the filler, elastic yield properties, interface strength, friction coefficients, and in-situ properties. Using homogenization techniques, certain effective properties of polymer composites can be derived from the volume fraction, distribution and properties of the reinforcing phase. Such approaches are useful for "designing" the composite so that desired properties can be obtained at desired locations. For these approaches to be useful, however, one needs to take a systems view, particularly a knowledge of the overall requirements of the structure. Thus, while so-called micromechanics approaches are used to homogenize the composite, the utility of the material depends upon component and application constraints which must be specified, requiring the materials designer to be cognizant of the application before the material can be designed.

This approach is illustrated by investigating the problem of an axisymmetric body subjected to thermal gradients. The desired distribution and properties of the reinforcement phase to minimize thermal stresses are obtained through the use of a homogenization scheme. Effective inhomogeneous material properties are obtained through the use of distribution functions that relate the concentration of the second phase with the coordinates of the structure. Using these properties, inhomogeneous eigenstrained media analyses are conducted for such axisymmetric bodies, and in this fashion, the desired shape and material properties of the reinforcement phase, and its close-optimal distribution, are determined. A similar approach was outlined for the case of a structure subjected to both internal and external pressure and to thermal gradients. Discussion- Areas requiring additional research, particularly the characterization of interfaces and in-situ properties in polymer composites, such as with a tensile stage for TEM.

"***Model for dispersion rheology***", <u>Jozef Bicerano</u>[1], Jack F. Douglas[2] and Douglas A. Brune[1]; [1]Dow Chemicals, Midland, MI; [2]Polymers Division, NIST, Gaithersburg, MD

A simple quantitative predictive model was developed for the shear viscosity η of dispersions of solids in liquids. The model is based on the fundamental physical concepts of universality and scaling. It does not involve empiricism; that is, calculations using the model do not require any pre-existing data for η(dispersion), either for calibration, interpolation, or for extrapolation. The model allows the calculation of η(dispersion) as a function of particle volume fraction, shape, polydispersity, fractal aggregation and flexibility, dispersing fluid viscosity, and shear rate and temperature.
Select Figures

OUTLINE

- Dilute regime (intrinsic viscosity [η] *versus* particle shape).

- Full volume fraction Φ range (η).

- Percolation threshold p_c *versus* particle shape.

- Maximum packing fraction Φ_m as key parameter.
    - Effects of particle shape for monodisperse rigid solid particles.
    - Shear rate (SR), absolute temperature (T), and flocculation effects.

- Examples of viscosity calculations as a function of:
    - Particle shape.
    - Shear rate (SR).
    - Absolute temperature (T).
    - Viscosity of dispersing fluid.
    - Number of particles (N) and fractal dimensionality (d) of aggregates in flocculated systems.

A_f DEPENDENCE OF $[\eta]$

- Isotropic average of $[\eta]$ for biaxially symmetric ellipsoids.
- A_f=(length of major axis c)/(length of minor axes a=b).
- $A_f>1$ for fibers, $A_f=1$ for spheres, $A_f<1$ for platelets.
- Squares indicate exact solutions of constitutive equations.
- The curve represents a fitting equation:

$$[\eta] \approx \frac{1012 + 2904A_f - 1855A_f^{1.5} + 1604A_f^{2} + 80.44A_f^{3}}{1497A_f + A_f^{2}}$$
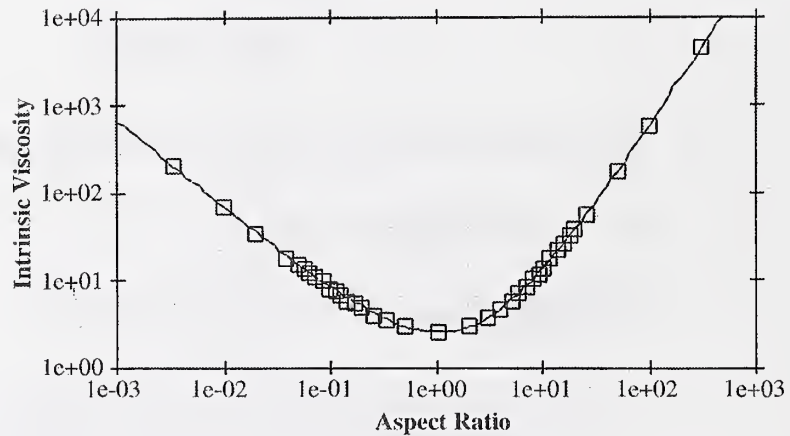

Fig. 2

A_f, SHEAR RATE AND T DEPENDENCE OF $[\eta]$

A_f affects $[\eta]$ at all SR values, while SR and T dependences may occur for nonzero SR via dependence of $[\eta]$ on Pe.
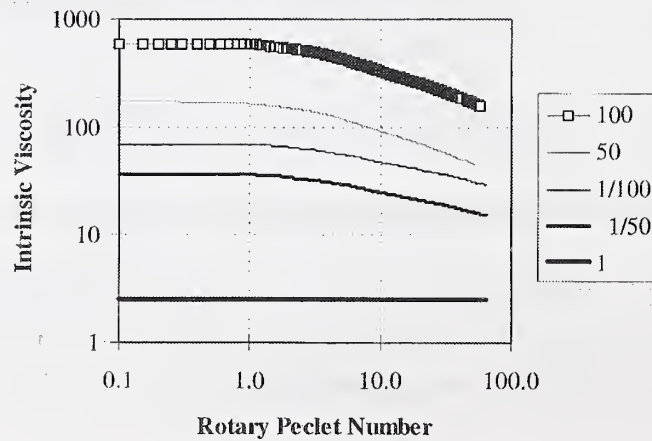

Fig. 3

"UNIVERSAL" EXPRESSION FOR η(relative)

- Dilute dispersion described by a "virial expansion":

$$\eta(\text{relative}) \equiv \frac{\eta(\text{dispersion})}{\eta(\text{dispersing fluid})} \approx 1 + [\eta]\Phi + k_H \cdot \Phi^2 + ...$$

- Concentrated dispersion described by the Maron-Pierce equation (a good semi-empirical expression), where k~1.

$$\eta(\text{relative}) \approx k \cdot \left(1 - \frac{\Phi}{\Phi_m}\right)^{-2}$$

- Our new "universal" expression is valid over full range of Φ values, and goes to following limits:
  - Second-order virial expansion in dilute regime.
  - Maron-Pierce equation with k=0.94 in concentrated regime.

$$\eta(\text{relative}) \approx \left(1 - \frac{\Phi}{\Phi_m}\right)^{-2} \cdot \left[1 - 0.4 \cdot \frac{\Phi}{\Phi_m} + 0.34 \cdot \left(\frac{\Phi}{\Phi_m}\right)^2\right]$$

Fig. 4

"UNIVERSAL" η EXPRESSION *VERSUS* DATA

- **Representative data from work of de Kruif *et al.*, for sterically stabilized hard silica spheres in cyclohexane.**

- **Also good agreement with data from many other sources, for particles of different shapes in different types of fluids.**

Fig. 5

51
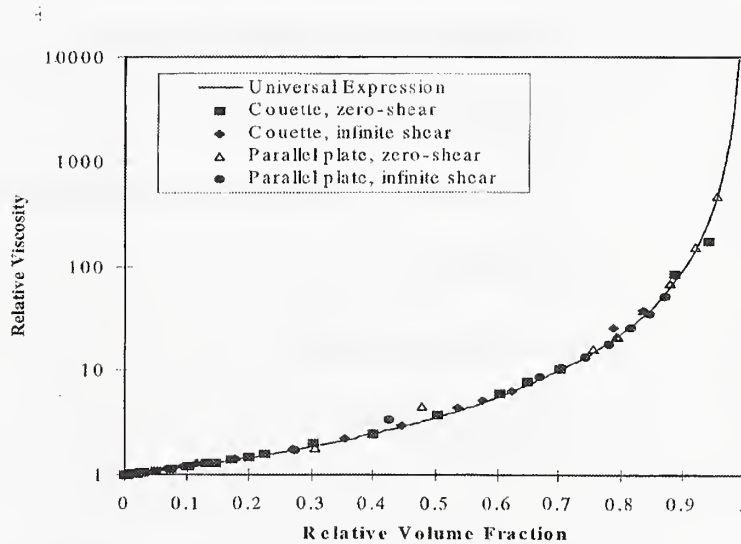

A$_f$ DEPENDENCE OF p$_c$

- Isotropically placed biaxially symmetric ellipsoids.
- A$_f$=(length of major axis c)/(length of minor axes a=b).
- A$_f$>1 for fibers, A$_f$=1 for spheres, A$_f$<1 for platelets.
- Squares indicate results of Monte Carlo simulations.
- The curve represents a fitting equation:

$$p_c \approx \frac{9.875A_f + A_f{}^2}{7.742 + 14.61A_f + 12.33A_f{}^{1.5} + 1.763A_f{}^2 + 1.658A_f{}^3}$$
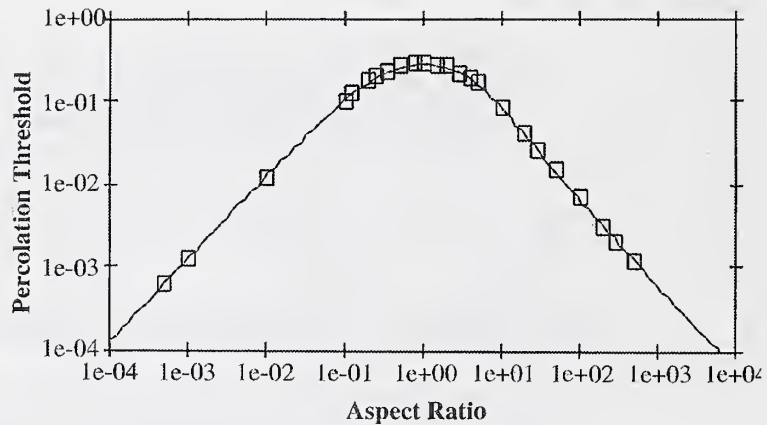

Fig. 6

- A quantitative predictive model was developed for dispersion shear viscosity relative to dispersing fluid, as a function of:

  - Volume fraction of dispersed particles.

  - Shape of dispersed particles.

  - Flocculation (size and fractal dimensionality of aggregates).

  - Shear rate.

  - Absolute temperature.

  - Particle flexibility.

- A computer program and a major manuscript were prepared.

Fig. 7

*"**Modeling the Behavior of Polymer/Clay Nanocomposites**"*, <u>Anna C. Balazs</u>, Chemical Engineering Department, University of Pittsburgh, PA

Dr. Balazs discussed the paucity of knowledge regarding thermodynamic properties of polymer/clay nanocomposites. It is well known that polymer-clay nanocomposites exhibit dramatic increases in tensile strength, heat resistance, and barrier properties as compared to the pure polymer matrix. Insights into these phenomena, and a better understanding of the properties of polymer/clay nanocomposites may by obtained by modeling their thermodynamics. By deriving the free energy for the system, phase diagrams for polymer/clay and polymer/solvent/clay mixtures were constructed. Dr. Balazs's results provided guidelines for fabricating thermodynamically stable nanocomposites with the desired morphology. Dr. Balazs also focussed on the interactions between surfactant-modified clay surfaces and a polymer melt. Using self-consistent field calculations, the various characteristics of the surfactants, polymers and clay surfaces were varied. From the calculations, the optimal conditions for promoting the penetration of the polymer between the organically-modified interfaces were isolated.

ATTENDEES RESPONSE

Surveys were conducted by brainstorming all research and technical needs in the area of fillers and nanocomposites and then ranking the needs by a voting scheme.

3.1 Results of Survey

CONCLUSIONS

4.1 Research and Technology Needs

The most important research and technological needs are summarized in the pie charts identified in the previous section. Some general observations are drawn from these results.

Filled Polymers

Research Needs

1. *Characterizing Polymer/Filler Interactions*

The polymer/filler interactions play an important role in the binding and adsorption of molecules at the filler surface, and these interactions determine many of the ultimate properties of filled materials. Control of interaction parameters can be therefore be vital for many filled systems. However, the nature of the polymer/filler interactions is ill-characterized in most filled polymeric systems. This is primarily because of the difficulty in applying measurement techniques suitable for filled polymer systems. Studies on model filler surfaces may be useful in this regard. Studies of blend phase separation in the presence of fillers using scattering and rheology is an approach being tested by the Blends and Processing Group at NIST. Results indicate that this can be used to characterize *relative* polymer/filler interactions in multicomponent filled systems. Absolute characterization of polymer/filler interactions is considerably more difficult, yet all important; an issue that should be addressed in future meetings and workshops.

2. *Dynamics at Filler/Polymer Interface*

While a number of rheological studies exist on measuring the bulk properties of filled systems, there is a paucity of information at the molecular level on dynamics of the polymer chains in filled systems. The volume in the vicinity of the filler is especially important in this regard. As with the polymer/filler interactions, these measurements suffer from technical difficulties in applying straight forward methods to measure local chain dynamics. Nuclear Magnetic Resonance (NMR) is perhaps the most successful technique to date. Inelastic neutron scattering is an equally promising technique for exploring the local chain dynamics in filled systems, especially since the measurements do not require costly deuterated polymers. This program was initiated by the Polymer Blends and Processing Group at NIST for investigating dynamics in nanocomposite materials, and is being extended more generally to filled materials in collaboration with industry.

3. *Surface Chemistry of Fillers (and Silane Coupling Agents)*

Control and characterization of filler surface chemistry is an important industrial approach for modifying polymer/filler interactions. For instance, silane coupling agents are widely used in many applications of filled polymers and therefore of significant interest to the filled polymers industry. Much of the knowledge on the modification and its effect is however at the empirical level. Development of characterization techniques for probing the chemical nature, homogeneity and roughness of the modified surface is deemed important. In addition, the effect of the surface modification in altering

polymer/filler interactions may be key to predicting properties of polymer materials containing surface modified fillers.

Technological Needs

1. *Measurements of transient morphology*

Most current measurement techniques involve measuring only the final state morphology of the filled polymer. However, in order to better control the final state morphology in a typical processing or extrusion, it is important to understand the morphological changes occurring during the different stages of processing. Advances in measurement technology for rapidly measuring transient morphologies is therefore important for the goal of reduction of industrial product development cycles.

2. *Low cost automated technique for dispersion characterization*

Development of an inexpensive technique for characterizing state of dispersion in filled polymers was a unanimous request by the fillers workshop participants. This would involve not only measuring the sample in its dispersed state, but also to quantify it in terms of useful parameters such as loading level, particle anisotropy, aspect ratio, etc. Development of advanced image analysis techniques in two and three dimensions is expected to be a necessary component to quantify dispersion as well. Mathematical tools and concepts such as Fourier transform of images, already in use by the Blends and Processing Group for quantifying morphology and kinetics during phase separation may possibly be applied to more generally characterize filler particle dispersed state. Due to the large number of parameters characterizing the dispersed state of a typical filler, developing a universal parameter defining dispersion is expected to be a non-trivial task.

3. *Online probes of filler distribution and process monitoring*

Related to the problem of measuring transient morphologies is the more general problem of measuring the in-situ state (such as dispersion, morphology, monitoring coupling agent level, etc.) of the filled polymer. Such in-situ measurements will enable incorporation of more efficient adaptive techniques for on-line process corrections. The use of on-line probes for process monitoring has been an ongoing project within the Blends and Processing Group using ultrasonic probes, and more recently using optical temperature probes with success on regular blends. An extension of these measurements to filled polymer systems would be a useful logical step. The monitoring of opaque filler particles is expected to place constraints on the applicability of the optical probe technique, however.

Nanocomposites

Research Needs

1. *Structure and dynamics in confined media*

The effects of confinement on polymer structure (such as chain dimensions, radius of gyration, isotropy, density etc.) can be significant given that the interlayer gallery spacing between clay sheets has the same order of magnitude dimensions as small molecule

polymer chains. Measurements of the polymer structure in confined media and how their dynamics are affected in intercalated and exfoliated clays versus bulk polymer should eventually be related to the ultimate material properties. Inelastic neutron scattering capabilities are expected to be exceptionally promising in accomplishing this goal. To this end, collaborative efforts are currently being forged with filler producers and manufacturing industries involved in this area of research.

2. *Characterization method for degree of intercalation*

The current most commonly used technique for demonstrating the degree of intercalation of polymer into the clay is transmission electron microscopy (TEM) and to a lesser extent, scattering methods. One of the problems with a technique such as TEM is that it does not readily yield the three dimensional (3-D) structure, but instead only a 2-D slice through an arbitrary plane. The results are therefore often dependent on sample preparation and slicing conditions. A more universal method for characterizing the degree of intercalation in nanocomposites in 3-D would be beneficial to obtain more complete structural information on dispersion in clays, especially since the clay sheets are not necessarily planar but mostly undulating.

3. *Characterization of thin film mechanics*

Many nanocomposite applications are expected to be in the area of thin film coatings, and thus an effort is required to characterize their novel mechanical properties. These novel mechanical properties should arise from the strong degree of anisotropy induced in the system due to the high aspect ratio clay platelets. Their orientation and degree of intercalation may strongly affect the mechanical integrity and stability of the coating. The use of atomic force microscopy (AFM) in conjunction with thin film shearing devices may be required for such characterization.

Technological Needs

1. *Characterize and control degree of exfoliation*

An understanding of the factors (e.g. enthalpic, entropic and geometric) controlling the degree of exfoliation is an important technological requirement for preparing nanocomposites with well defined degree of exfoliation. The importance arises from potential applications that may have requirements from nearly unintercalated state, to intermediate intercalated state, and finally to being in the exfoliated state. Characterization of the degree of homogeneity of the dispersed platelets in macroscopic samples is an additional requirement to fully predict and estimate the properties of bulk nanocomposites.

2. *Nanocharacterization utilizing functionalized AFM tips*

Measurements of interactions of clays with differently functionalized polymers may be simulated by performing AFM studies using tips with attached surface groups of different chemical functionality. Local modulus, friction and surface roughness are some of the measurable properties using the AFM. Development of theoretical models to predict such behavior would have to be developed as part of such an effort.

3. *Nanomechanics-real time measure of fracture, toughness*

The real-time measure of fracture and toughness on a local scale at the size of the clay platelets would yield useful insights into the mechanism governing macroscopic mechanical failure in nanocomposites, and means by which it can be avoided. Since the fracture typically occurs very quickly, measurement techniques such as AFM cannot be applied to do real time studies of fracture mechanics. Localized ultrasonic probes and dielectric spectroscopy approaches may be potentially more useful in this regard.

4.2 Summary and Future Outlook

The workshop discussions clearly suggest that there are significant technological and scientific opportunities in extending our knowledge of filled polymers and nanocomposites at a more fundamental scientific level of description. A steady increase in the demand for filled polymeric materials, yet with flexible or finely tunable and predictable properties, makes it imperative to understand key factors governing filled polymer behavior. Control of *molecular level interactions* and *polymer dynamics* at the filler interface have been identified as the most critical issues in filled polymers and nanocomposites in our workshop. Other important issues relate to developing inexpensive methods for characterizing online and in-situ processing studies, better dispersion control, developing a more universal definition for characterizing dispersion, and nano-characterization of filled material properties. The Polymer Blends and Processing Group at NIST has developed a program to study filled polymer and nanocomposites to address some of the most critical issues, in collaboration with industrial partners. Future efforts will focus on some of the other important issues identified through the workshop.

APPENDICES

Appendix I   Workshop Program Agenda

Thursday June 18, 1998
8:30 Registration, Refreshments
9:00 Welcome and Introduction- Leslie Smith, Director, MSEL
9:10 Outline and Introductions - Eric Amis and Alamgir Karim, NIST Polymers Division

Morning-Compounding, Reinforcement and Toughening (I)
9:30 Gary Burns (Dow Corning)- *Concepts in Rubber Chemistry: The Role of the Filler Particle*
10:15 Break
10:30 Henry Yang (Sid Richardson) - *Filler-Filler, Polymer-Polymer and Filler-Polymer interactions: Effects on Rubber Compounds Physical Properties*
11:00 Saad Khan (NC State)- *Flow-induced Microstructural changes in Filled Polymeric Liquids*
11:30 Moshe Narkis (Technion, Israel)- *Recent Industrial Developments: From Anti-Static Polymers to Artificial Marble*
12:00 Discussion
12:30 Lunch Break (NIST Cafeteria)

Afternoon-Compounding, Reinforcement and Toughening (II)
1:45   Albert Yee (U. of Michigan) - *A Comparative Study of Microstructure and Fracture Behavior of a Conventional Filled Polymer and a Nanocomposite: Possible Roles of Interfacial Constraint*
2:30 Rose Ryntz (Ford) - *Effect of Metallocene Impact Modifiers on Cohesive Strength of Thermoplastic Olefins*
3:00 Break
3:15 Mun Fu Tse (Exxon) - *BIMS Elastomer/Filler Interactions*
3:45 Jay Dias (Exxon) - *Investigations of Filler Polymer Interactions*
4:15   Jo Ann Bice (PPG) - *Evolving Structure/Property Relationships for Precipitated Silica*
4:45 Discussion of Needs and Priorities

Friday June 19, 1998
Morning -Nanocomposites
8:30 Emanuelle Gianellis (Cornell U.)- Structure and Dynamics of Polymer Nanocomposites
9:00 Karl Kamena (Nanocor) - Montmorillonite Clay Structures and Intercalation Chemistries based on Dipole Moment Interactions
9:30 Howard Hanley (NIST) - Dispersion in a Clay Nanocomposite; Application of Radiation Scattering
10:00 Break
10:15 Leon Gilgens (TNO netherlands) -Nano-Composites from Polymers and Layered Minerals

10:45 Ramanan Krishnamurthy (U. Houston) - Rheological Study of Macro and Nano Composites

11:15 Jeffrey Gilman (NIST) - Flammability Studies of Polymer Layered Silicate Nanocomposites

11:40 Robert Ivkov (NIST) - Dynamics of Polymers in Confined Geometries: Inelastic Scattering

12:00 Discussion

12:30 Lunch (NIST Cafeteria)

Afternoon-Theory and Simulations

1:45 C.K.H. Dharan (U. Berkeley) - Effect of Fillers and their Distribution on Composite Properties

2:15 Josef Bicerano and Jack Douglas (NIST) - The "Effective" Properties of Polymer-Filler Mixtures

2:45 Coffee Break

3:00 Anna Balazs (U. Pittsburg) - Modeling the Phase Separation of Polymer Clay Nanocomposites

3:30 Discussion of Needs, Priorities and Future Plans

Appendix II

Final Participants List

Workshop on Interactions of Polymers With Fillers and Nanocomposites

June 18-19, 1998
National Institute of Standards and Technology
Gaithersburg, MD

Eric Amis
NIST
Bldg. 224, Rm. B210
Gaithersburg, MD 20899-0001 USA
Telephone: 301/975-6681
Fax: 301/975-4924
Email: eric.amis@nist.gov

Anna Andrews
Ferro Corp.
7500 E. Pleasant Valley Rd.
Techanical Center
Independence, OH 44131 USA
Telephone: 216/641-8580 ext/ 7912
Fax: 216/524-0518
