SOUND ABSORPTION COEFFICIENTS OF THE
MORE COMMON ACOUSTIC MATERIALS.

The following figures have been obtained at the National Bureau of Standards for the sound absorption coefficients of a number of acoustic materials which are on the market. The bulk of the measurements are on materials submitted by the makers. The measurements on some of these materials were made several years ago. Technologic changes in manufacture, some induced by the war, may have caused differences between the coefficients of materials now on the market and those of materials originally tested. However, an attempt has been made to reduce the effect of variations in manufacture by including the coefficients only for those materials which the makers state are essentially the same as when the tests were made.

The inclusion of a material in this letter circular is not to be construed as a general approval. Each material should be judged on its merits in any particular case as there are other requirements besides sound absorption which must be considered, such as fire resisting qualities, light reflection, appearance, etc. Figures are also given for the absorption of an audience seated in chairs of different kinds. All the results have been obtained by the reverberation method on samples having an area of approximately 72 square feet.

The sound absorption coefficient of a material is defined as the fractional part of the energy of a sound wave that is absorbed at each reflection. Experimental figures such as are given here must be regarded as approximate only. This branch of applied science is new and in a state of development. The methods and formulas used in obtaining these figures are those which, while not entirely satisfactory, are open to the least objection. The uncertainty involved is such that all the coefficients are probably somewhat too large.

The "noise coefficient" given in the table is the average, to the nearest multiple of 0.05, of the coefficients for 256, 512, 1024, and 2048 cycles. It has been recommended by many consultants that such a coefficient be used when the problem is one of reducing the noise level, as in offices, restaurants, etc.

Many of the acoustic materials exhibit large variations in their sound absorption properties when the method of mounting is changed. In many cases the most important feature is the amount of air space

back of the material. The figures given in this letter circular apply only when the materials are mounted in the same manner as when tested. For this reason the exact method of mounting is given for each test.

Acoustic plasters require special skill in their application, as improper manipulation may reduce the coefficient. Particular attention is called to the fact that a dry base coat is used for most applications. Also, the sound absorption coefficients are affected quite materially by the time between the application of the first and second coats of acoustic plaster, the amount of moisture in the surface of the plaster when it is finally floated, or finished with a trowel or by other means; and other factors of this nature.

A number of materials have been painted and retested to determine the effect of painting. In every case the paint was applied so as to decrease the sound absorption as little as possible and still obtain a reasonably good paint job. Details of the manner in which the paint was applied on any particular material will be supplied upon application.

It is not necessarily the case that the materials of highest coefficient are the most advantageous. When there is room enough to apply the requisite quantity, a material of low coefficient will give better results than one of higher absorption, because of the more uniform distribution of material. Also, in comparing different materials it should be borne in mind that there is some variation in manufacture; hence, the sample which was measured may have more or less absorption than the material delivered on the job. Minor differences in coefficients, therefore, should be disregarded in choosing between materials.

For the foregoing reasons it is advisable in drawing up specifications for auditoriums to lay emphasis upon the reverberation time desired rather than upon coefficients of material. See National Bureau of Standards Circular C418 entitled "Architectural Acoustics," which may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C., at 5 cents per copy. Supplementary data on any of the materials mentioned in this letter circular will be furnished on application.

Additional information regarding the absorption coefficients of acoustical materials may be obtained from the Acoustical Materials Association, 120 South LaSalle Street, Chicago, Illinois.

CORRECTION SHEET

LC-714

1. p. 5, Item 10 under "Types of Mounting" should read "Nailed on 2 x 8's, 12' o. c., unless otherwise indicated."
2. p. 6, Cushiontone A-3, weight should be "1.27" and not ".95" as indicated.
3. p. 6, Temlok De Luxe 1/2", weight "1.18" should be deleted.

TYPES OF MOUNTING

1. Cemented to gypsum wall board. This is considered equivalent to cementing to plaster or masonry.
2. Nailed on 13/16" x 2" furring, 12" o.c., unless otherwise indicated.
3. Metal supports attached to 13/16" x 2" wood furring.
4. Laid directly on laboratory floor.
5. Nailed on 2 x 4's, 12" o.c., unless otherwise indicated.
6. Cemented to the floor of the reverberation chamber.
7. Back of sample covered with concrete.
8. Attached to metal suspension system. $\frac{1}{4}$ " air space back of tile, unless otherwise indicated.
9. Acoustic tile nailed to 13/16" x 2" furring, 18" o.c., space between furring filled with Rockwool.
10. Nailed on 2 x 8's, 12" o.c.
11. Laid on 24 gauge sheet iron, nailed to 13/16" x 2" furring, 24" o.c.

TABLE 2

Acoustic Materials for Plastic Application

Unless otherwise stated, each sample of acoustical plaster was mixed according to the specifications furnished by the manufacturers and supplied by a skilled plasterer on a false ceiling at the National Bureau of Standards. All samples of material applied with an air gun or blower were constructed at NBS unless otherwise stated. The panels were laid on the floor of the Reverberation Chamber for test.

Table 3

Absorption per person for an audience seated in
chairs of various types.

| *Seating | | 128 | 256 | 512 | 1024 | 2048 | Date |
|----------|---------------------------------|-----|-----|-----|------|------|------|
| A | Women without coats | 0.7 | 1.3 | 2.3 | 3.6 | 4.6 | 1930 |
| A | Women with coats | 1.3 | 2.4 | 4.0 | 5.8 | 6.7 | 1930 |
| A | Men without overcoats | 1.3 | 2.1 | 4.1 | 5.5 | 7.4 | 1930 |
| A | Men with overcoats | 2.3 | 3.2 | 4.8 | 6.2 | 7.6 | 1930 |
| B | Mixed audience | - | - | 3.9 | 4.7 | - | 1929 |
| B | Empty seat | - | 3.4 | 3.0 | 3.3 | 3.6 | 1929 |
| C | Mixed audience | - | 3.5 | 4.1 | 4.9 | 4.2 | 1930 |
| C | Empty seat | - | 3.0 | 2.5 | 2.9 | 3.1 | 1929 |
| D | Mixed audience | - | 2.7 | 3.3 | 3.8 | 3.6 | 1930 |
| | Plywood chair | - | 0.2 | 0.3 | 0.5 | 0.5 | 1930 |

The above absorption figures are numerically equal to the number of square feet of a material having an absorption coefficient of 1.00, which would absorb the same amount of sound energy.

*A cane seat chairs, open back.
*B theatre chairs, box spring seat, heavily padded back.
*C same as B, but single layer of padding on back.
*D church pews, seating five.

Suggestions Concerning the Proper Use
of Acoustical Material.

As there has been considerable misconception concerning the proper use of acoustical material it is considered desirable to call attention to two of the fundamental principles underlying the formulas which are used in acoustical design. It is assumed in all of the formulas that (1) the absorption is proportional to the area of the absorbing material, and that (2) there is a uniform distribution of sound energy. As a rule neither one of these assumptions is true.

It has been found from experiment when very small areas are used, such as the panels in a coffered ceiling having areas of from 1 to 4 square feet and separated from each other by a foot or more, that the effective absorption of the material in these panels is greater than when the material is installed in one large area. In fact, for materials having large coefficients, this effective absorption may be as much as 50 percent more than one would expect from the coefficient.

It has also been found when all of the acoustical material is applied on one surface of a relatively small room, say 50,000 cubic feet or under, that this creates a non-uniform distribution of sound energy in the following manner. Let us assume that the ceiling of a room is covered with a highly absorbent material. Under these conditions the sound energy which is traveling between the floor and ceiling is absorbed quite rapidly, while that traveling between the untreated wall surfaces, having very little to absorb it, may continue for some considerable time. This persistence of sound energy between the untreated surfaces may cause the measured reverberation time to be considerably longer than would be computed using the ordinary reverberation formula and the coefficient usually given. For this reason, it is essential in small rooms that the acoustical material be distributed on the side walls as well as on the ceiling, if the effective absorption of the material is to be anywhere near that which one would expect from the coefficient of the material. For further discussion of this problem see Circular C418.

We also wish to call attention to the fact that a proper distribution of the acoustical material should be worked out in the initial plans of a building, as it is frequently impossible to obtain a satisfactory distribution after the interior design has been completed without taking into account the acoustical treatment.
