Preface

A second edition of the NBS Tables of Spectral-Line Intensities (Part I, Arranged by Elements and Part II, Arranged by Wavelengths) has been prepared. New classifications have been provided for 8500 previously unclassified lines, improved wavelengths are given for about 9000 lines and some revision of the intensity scale has been made. (Supersedes NBS Monograph 32, Parts I and II and its Supplement.)

Key words: Classification of spectral lines; intensities of spectral lines; spectral-line intensities; tables of spectral-line intensities; wavelengths of spectral lines.

This new edition of the NBS Tables of Spectral-Line Intensities incorporates three improvements on the original edition of 1961. In the original edition only about 25 000 of the 39 000 lines in the tables had been classified. In the ensuing thirteen years, about 8500 more lines (chiefly rare-earths) have been classified and the new classifications are here incorporated.

Furthermore in the course of spectroscopic research during that period, many spectra have been remeasured. About 9000 improved wavelength values have been adopted here. Many of the new values are accurate to somewhat better than two decimal places but in most cases there remains some uncertainty in the third place. We have therefore printed only two decimal places in this edition.

The third improvement to be found in this edition is in the intensity scale. Three changes have been made. The calibration of the region below 2450 Å, which was published by Corliss [1967], has been incorporated in the new edition. Secondly, a slight error in the original reduction of the intensity data from the overlapping regions of the plates has been corrected. In the original reduction the duplicate observations in the overlapping regions were simply averaged. This was a theoretically correct procedure since the observations had already been normalized to the intensity scale of the copper matrix. However, it was observed that this normalization did not produce identical scales on each plate. A more practical procedure would have been to have adjusted each plate to a common scale determined by the mean intensity level of all the plates. This was pointed out by J. L. Tech [1971] who has now applied this correction to all of the complex spectra in the tables. The elements with less than 100 lines (simple spectra) remain uncorrected for this relatively minor error because there are not enough lines in the overlapping regions to determine correction factors.

Finally, the whole scale of relative intensity numbers has been multiplied by ten to eliminate numbers less than unity. The intensity numbers now range from 1 to 90 000.

For the convenience of the user, the tables are presented in two separate parts, in the same way as the original edition. Part I is arranged by element in alphabetic order of chemical name. In Part II all observed lines are consolidated in a single table arranged in order of increasing wavelength and in a supplementary table of selected strong lines.

The values of ionization potentials for many of the elements are taken from the compilations of C. E. Moore but those for the lanthanides, actinides and Hf are taken from the compilation of W. C. Martin, Lucy Hagan, Joseph Reader and Jack Sugar (*J. Phys. Chem. Ref. Data*, Vol. 3, No. 3, 1974). The values of atomic weights are taken from the 1969 Report of the International Commission on Atomic Weights.

Tables of Spectral-Line Intensities — Part I

Arranged by Elements

The relative intensities, or radiant powers, of 39 000 spectral lines with wavelengths between 2000 and 9000 Ångströms have been determined on a uniform energy scale for seventy chemical elements. This was done by mixing 0.1 atomic percent of each element in powdered copper, pressing the powder-mixture to form solid electrodes which were burned in a 10 ampere, 220 volt direct-current arc, and photographing the spectra with a stigmatic concave grating while a step sector was rotating in front of the slit. The sectored spectrograms facilitated the estimation of intensities of all element lines relative to copper lines which were then calibrated on an energy scale provided by standardized lamps, and all estimated line intensities were finally adjusted to fit this calibration. Comparisons with other intensity measurements in individual spectra indicate that the National Bureau of Standards spectral-line intensities may have average errors of 20 percent, but first of all they provide uniform quantitative values for the seventy chemical elements commonly determined by spectrochemists. These data are presented by element in part I, and all 39 000 observed lines are given in order of wavelength in part II.

Key words: Classification of spectral lines; intensities of spectral lines; spectral-line intensities; tables of spectral-line intensities; wavelengths of spectral lines.

1. Introduction

Spectrochemistry was born a century ago when Kirchhoff and Bunsen [1]¹ definitely demonstrated that chemical elements were uniquely identified by spectral radiations, or lines as seen in a spectroscope provided with a slit. This led immediately to the identification of many chemical elements in the sun and to the discovery of several new elements, but no quantitative chemical analyses were made until much later.

In 1874, Lockyer [2] stated that "while the qualitative spectrum analysis depends upon the *positions* of the lines, the quantitative analysis depends not upon their position but upon their *length, brightness, thickness, and number* as compared with the number visible in the spectrum of a pure vapor". Thus, position (or wavelength) and brightness (or intensity) are recognized as being the two most important properties of spectral lines; wavelengths identify chemical elements and intensities indicate the concentrations of identified elements in mixtures or chemical compounds.

During the past century there has been spectacular improvement in the accuracy of spectral wavelength determinations; the early ones were limited to 3 or 4 figures, the later use of diffraction gratings and wavelength standards permitted the specification of 5 or 6 figures. Since 1900 the application of interferometers and better gratings has refined many wavelengths to 7 figures, and recently some 8-figure values of wavelength standards have been provided.

Unfortunately during this past century very little progress has been made in assigning uniform quantitative intensity values to spectral radiations. The great bulk of spectral observations have been made photographically because photographic emulsions provide detailed, permanent records of spectra not only in the visible but also in the invisible ultraviolet and infrared regions. But even if the light source is reproducible and standardized it is not easy to evaluate the spectral efficiencies of spectrographs and photographic emulsions so the usual procedure has been to make subjective visual estimates of relative intensities of spectral lines on an arbitrary scale based on the relative blackness and/or width of spectral-line images appearing on a developed photographic plate. Consequently, in thousands of individual papers and in numerous comprehensive compilations of spectral data we find only qualitative data on intensities which may have some meaning for adjacent lines in a given spectrum but none at all when comparing widely spaced lines, or lines of different spectra of the same element or of different chemical elements.

In the beginning, most intensity data were reported on an arbitrary scale of 10 steps, weak lines being assigned an intensity of 1, and the strongest line intensity 10. Even as late as 1945 extensive new spectral tables prepared by Gatterer and Junkes [3] displayed estimated intensities on this limited 1 to 10 scale. Since 1910 some spectroscopists have arbitrarily expanded this arbitrarily compressed

¹Figures in brackets indicate the literature references on page xiv.

scale. For example, in the very extensive spectral tables published by Exner and Haschek [4] the estimated intensities range from 1 to 1000. In wavelength tables compiled by Twyman and Smith [5] the maximum intensity is 20, in the compilation of Kayser and Ritschl [6] estimated intensities rise to 4000, and in the well-known M.I.T. Wavelength Tables [7] they soar to 9000. The most recent compilation of Tables of Spectrum Lines by Zaïdel, Prokof'ev, and Raiskií [8] quotes data from the M.I.T. Tables and more modern sources but adds nothing new on spectral line intensities.

In or about the year 1925, microdensitometers were developed for the purpose of quantitative measurement of relative intensities among related lines in multiplets to test the sum rules derived from the quantum theory of spectral structure, but no general applications were made. Since then thousands of spectrochemists have applied microdensitometers to quantitative chemical analyses by calibrating intensity ratios of analysis- and internal-standard lines but such measurements have contributed nothing to the basic data on spectral line intensities. Likewise, with few exceptions, the modern substitution of electronic photodetectors for photographic emulsions has added nothing to our knowledge of true line intensities over long ranges of different spectra of many chemical elements.

How may one hope to obtain, with a reasonable amount of labor, quantitative intensity data on the same scale for thousands of spectral lines representing practically all of the metallic elements? A hint was given in 1874 by Lockyer [2] who observed that "the lines of any constituent of a mechanical mixture disappeared from the spectrum as its percentage was reduced." Acting on this suggestion, Hartley [9], in 1884, began to study the spark spectra of metals in solutions with concentrations of 1 percent, 0.1 percent, 0.01 percent, and 0.001 percent, and proposed a method of quantitative spectrochemical analysis based on the lines that could be detected at each dilution. Similar studies were later made by Pollok and Leonard [10], by de Gramont [11], and by Löwe [12], all showing that with progressive dilution of an element its spectral lines weakened and vanished until only the most sensitive line remained to reveal its presence. In all these works the principle of quantitative spectrochemistry appeared to rest on the *number of lines* detectable rather than on their individual *intensities*. Casual observation must have shown lines of equal strength in spectra of solutions differing 1000 fold in concentration but no one mentioned it. It is difficult to understand why these early studies of residual spectra in quantitatively prepared mixtures or solutions did not suggest a method for obtaining physical intensities, but it is a fact that before our work had begun no one had attempted to express spectral line intensities as directly proportional to the number of radiating atoms or concentration of the element. The present monograph reports such an attempt [13].

Our method of deriving line intensities from arc spectra of elements diluted in copper was recently adopted by Allen [14, 15] to obtain oscillator strengths of some radiations from 3200 to 5400 Å representing nine elements.

At various times since 1932 we have photographed the arc spectra of 70 chemical elements diluted in silver or in copper, and determined the line intensities of the diluted elements relative to selected lines of the matrix. An energy calibration of the latter finally led to physical intensities of 39,000 spectral lines representing 70 elements, all on the same energy scale. These experiments and results are based on the following propositions, regarded as fundamental for the quantitative description of residual spectra of diluted elements excited in ordinary d-c arcs.

1. *The limiting detectability of any line is defined as the atomic concentration that ensures positive detection of the line.* This limit is determined mainly by unavoidable background on a fully exposed spectrogram. The spectrum of an arc burning in air consists of discrete lines due to atoms, and of more or less extensive band systems from transient compounds (usually monoxides), all superposed on a continuous background arising from thermal radiation of incandescent oxides, from transitions in the continuum, and possibly from scattered light. This background sets a limit to the exposure for faint lines that may be given by any actual spectrograph. If this were not true, the exposure could be increased indefinitely to compensate for unlimited reduction in concentration, and detectability would always be infinite. Faint lines are not recorded by underexposure, and they cannot be recognized on a very dense background produced by overexposure. In order to guarantee positive recognition and unambiguous chemical identification a spectral line should be sufficiently well defined to permit accurate wavelength measurement. Experience shows that the minimum photographic density that meets this requirement is of the order of 0.05 above that of the background.

2. *The limiting detectability of any element in an arc depends on the matrix in which the element finds itself.* There is no doubt that in the conventional arc relative volatilities of the chemical elements as well as relative ionization potentials affect the relative strengths of their mixed spectra. In general, the elements with high-vapor pressure and/or low-ionization potential will be favored in spectral excitation, but elements with either high or low volatility may be underestimated if not uniformly present during the exposure, and easily ionized elements may appear less sensitive because of more complete ionization. In this connection it must be noted that large differences in apparent detectability are possible if concentrations are expressed in relative weights instead of numbers of atoms. Thus,

0.01 atomic percent of boron in uranium is equal to < 0.0005 weight percent since the uranium atom is 22 times heavier than the boron atom.

3. *The primary substance (matrix) has no important effect on the relative intensities of lines due to a secondary substance.* It is conceded that the relative intensities of analogous spectra of different elements, and of successive spectra of the same element, may vary with the composition of the samples and/or with the type, or portion, of light source from which radiation is taken, but there is no evidence that the relative intensities of lines in any particular spectrum of a given element are thereby greatly changed. It may be expected, therefore, that the relative intensities of lines observed in one metal arc will remain valid in any other metal arc, provided the arcs are at approximately the same temperature. The absolute intensities and the relative strengths of successive spectra may be altered by excitation conditions. For example, silicon may be more sensitive in carbon than in calcium, and it is well known that when easily ionized alkalies are present in sufficient quantity to influence discharge conditions they reduce the intensity of other spectra, especially those characteristic of ionized atoms.

4. *The order of lines arranged according to decreasing detectability in progressive dilution is the same as the order of decreasing intensity in the spectrum of the pure element.* In other words, emission line intensities in residual arc spectra (barring self-absorption) are proportional to the number of radiating atoms; and relative intensities may therefore be derived from concentrations at which different lines show the same intensity or limiting detectability.

Arc spectra usually exhibit a variety of lines, sharp or narrow ones, diffuse or wide ones (including band heads), strong ones accompanied by photographic spreading of developed images, others wide on account of hyperfine structure, and some partially reversed. All of these types, except the last, appear in residual arc spectra at low concentrations, and it may be questioned if it is possible to place them on a uniform intensity scale. It may be assumed that if total blackening integrated over the width of the line when recorded at a moderate level of density be con-

sidered in estimating relative intensities these will be on a uniform scale within the limits of precision in making such estimates on lines of different types.

5. *The order of spectral lines arranged according to decreasing intensity is the same when the intensities are decreased by rotating stepped sectors as when the intensity reduction is produced by successive dilution of the element in a matrix.* This was recognized by Löwe [12] who published an atlas of spark spectra of 44 elements diluted from 1 percent to 0.001 percent and later obtained practically the same results by observing spectra with stepped exposure times [16]. In our experiments the labor of preparing samples of 70 elements in four or more dilutions was greatly reduced by adopting only one dilution (0.1 atomic percent) and then producing further reductions of spectral-line intensities by means of rotating step sectors.

6. *Limiting detectability (as defined in 1.) may be adopted as a physical scale of intensities.* Such intensities may be fixed as follows: In a fully exposed spectrogram of copper containing 0.1 atomic percent of another element any faint but unmistakable line at a given wavelength is assigned unit intensity. Any similar line appearing with unit intensity in a spectrogram when the energy, or concentration, is reduced to $\frac{1}{5}$ is said to be 5 times as strong. Thus, all lines can be assigned relative intensities proportional to their limiting detectabilities by determining either the energy reduction or the concentration reduction at which the stronger lines finally show unit intensity. The atomic percent concentration at which any line will show unit intensity then results from dividing 0.1 by its required energy or concentration reduction. For example, a line of intensity 10 should show plainly at 0.01 atomic percent, while one of intensity 1000 should be easily seen at 0.0001 atomic percent (one in a million). Assuming the ratio concentration/intensity to be constant, the maximum intensity at 100 percent is easily obtained. Thus, a line of intensity 1000 at 0.1 atomic percent will have an intensity value of $1000 \times 100/0.1 = 1,000,000$ at 100 percent. This indicates a much larger range of spectral intensities than mentioned heretofore, but it is not unrealistic.

2. Experiments

Whereas all earlier experiments on residual spectra of diluted elements involved spark excitation of solutions or fused salts, we decided to employ d-c arc excitation for the following reasons. It has been shown [17] that the first ionization potentials of some seventy metallic elements range from 4 to 11 V and the strongest spectral lines of most of these elements have wavelengths between 2000 and

9000 Å, which is the spectral region covered by the present investigations. Furthermore, it is known [18] that the second ionization potential of these elements ranges from 10 to 75 V and that the strongest lines of singly ionized atoms generally have shorter wavelengths than those of neutral atoms, nearly half of them being shorter than 2000 Å so that they can be detected only in vacuum spectrographs.

Because low-voltage arcs have less ionizing action than high-voltage sparks more atoms will remain in the neutral state and, in general, therefore, arc spectra will exhibit stronger lines and higher sensitivity than spark spectra.

The use of arc spectra in these experiments threatened to introduce errors on account of self-absorption of radiated energy in the arc aura or envelope which consists largely of unexcited neutral vapor atoms. In all spectra of arcs between metal electrodes this is the cause of conspicuous self-reversal of all lines involving the atom's ground state. However, this is a function of vapor density surrounding the arc and if this is reduced to 0.001, self-reversal is usually negligible (see fig. 2). This is our reason for making these experiments with individual elements diluted in copper in the ratio 1 to 1000. When ground-state lines of extraordinary intensity were suspected of some self-absorption, intensity ratios were checked or corrected by examining our earlier spectrograms made with this element diluted to 0.0002 atomic percent in silver.

2.1. Dilution in Silver

Our preliminary experiments, begun in 1932, can be described briefly as follows: solutions of known strength of the elements under investigation were prepared and proper amounts added to pure silver oxide, which was then reduced to metal by heating to make samples containing 8 definite atomic ratios extending from 0.05 to 0.0002 atomic percent of the element added to silver, with a factor of about 2 between 7 successive dilutions. In order to save time and labor, each series of silver samples incorporated 3 to 6 chemical elements, in addition to zinc which supplied internal standards. These samples were burned on pure copper electrodes of a 220 volt d-c arc with 10 amperes. An image of the arc was projected onto the slit of a stigmatic concave grating spectrograph by means of a fused-quartz lens. Each series of excited samples was exposed on successive segments of the slit, and was photographed in four spectral regions ranging from 2000 to 9000 Å (see fig. 1). A comparator was employed to measure wavelengths (relative to silver and copper lines) for the identification of the added elements, and relative intensities

sities of all lines belonging to residual spectra of diluted substances were estimated and related to concentration. These results were not satisfactory for the following reasons: The use of silver as a matrix and of copper for arc electrodes precluded the possibility of getting any data for these two elements or for any lines masked by silver and copper lines. Also the inclusion of 3 or more elements in each series of samples resulted in the blending of many lines, especially in complex spectra, so that it was not possible to assign proper intensities in these cases. Furthermore, the method of sample preparation and observing appeared to be unsuited to very volatile elements, or compounds, because no residual spectra could be recorded for them even at concentrations of 0.1 atomic percent.

2.2. Dilution in Copper

In 1941 these preliminary experiments were abandoned in favor of a modified procedure which led to satisfactory results. The chief changes in procedure came with the availability and use of pure metal powders, and a hydraulic press to form solid electrodes of mixed powders. Instead of reducing spectral line intensities to the limit of detectability by successive dilutions of the element in different samples only one dilution (0.1 atomic percent) was prepared and line intensities were reduced by observing through rotating step sectors. The successful procedure may be outlined as follows: An element under investigation was mixed with pure copper powder in the atomic ratio of 1 to 1000. These mixtures were pressed into solid electrodes, and burned in a 220-V, 10-A d-c arc which was imaged entirely on the collimator of a stigmatic grating spectrograph by a lens at the slit. A rotating step sector in front of the slit reduced the spectral intensities to one-fifth in each of four steps (see fig. 2). Spectral intensities of the element added to copper were estimated relative to those of selected copper lines, and this was done separately for each of 70 elements throughout the range of spectrum from 2000 to 9000 Å. The true intensities of the selected copper lines above 3300 Å that served as internal standards were then measured, by photographic photometry, relative to the known energy distribution in the spectrum of an incandescent tungsten-strip filament at a certain

temperature (see fig. 3). Between 2000 and 3300 Å a calibrated hydrogen lamp was used to determine the relative intensities of copper lines. Finally the apparent intensities of 39 000 spectral lines of 70 elements, relative to copper, were adjusted to fit the copper calibrations. These experiments thus provide empirically determined lists of the principal lines of all elements actually detectable under average conditions in arc spectra when their concentrations are 0.1 atomic percent, and the individual lines bear intensity numbers approximately proportional to their detectability or their relative energy. That these intensity numbers really represent physical intensities was proved by comparing them with earlier, accurately measured relative intensities of lines in multiplets and with published relative *f*-values or oscillator strengths of lines in different multiplets extending over a wide range of spectrum.

In order to provide intensity data for spectral lines that are partially or wholly obscured by copper lines a sectored spectrogram of the pure element excited with self-electrodes, or of a metallic compound or salt excited in a carbon arc, was photographed on every plate so that any lines blended with copper could be interpolated with proper estimates of their relative intensities. Comparison of relative intensities in copper and in carbon matrices also supplied new information on successive spectra, I and II, especially of rare-earth spectra. Similar data for copper itself were obtained by using pressed electrodes of pure silver powder to which 0.1 atomic percent of copper was added, plus the same quantities of gold and zinc to serve as internal standards.

Further details of experimental materials, apparatus, and procedure are given in the following paragraphs.

2.3. Arc Electrodes

For this investigation materials of high purity were acquired, preferably in the form of metal powders, although some elements, not available in pure powdered metal form, were obtained as oxides. In every case the proper amount was added to powdered copper to produce a mixture in which there was one atom of the added element to each 1000 atoms of copper. These mixtures were homogenized by mechanical shaking and then compressed into solid cylindrical pellets in an hydraulic press at 5000 psi. The pellets were $\frac{1}{4}$ in in diameter, $\frac{1}{4}$ in in length, and weighed about 1.5 g. Two of a kind were mounted in massive water-cooled clamps in an arc stand and a direct current of 10 A passed between them from a 220-V line with ballast resistance. A 3-mm gap was maintained between the electrodes during the exposures which varied in duration from 1 s to 5 min depending on spectrographic efficiency and sensitivity of photographic plates in different spectral regions.

The arc was imaged on the collimator of a concave grating spectrograph by means of a quartz lens immediately in front of the slit to obtain uniform illumination along its length and collect light from all parts of the arc. Rotating step sectors were operated immediately in front of the collecting lens, one with 5 to 1 ratio was used for all line-intensity spectrograms, but a 2 to 1 step was used for the energy calibration of copper lines.

2.4. Spectrograph

The dispersing apparatus was a 6-in grating with 15 000 lines per inch, and 22 ft radius of curvature in a Wadsworth-type mounting to give stigmatic images on photographic plates. All observations were made in the first-order spectrum in which the reciprocal dispersion was 5 Å/mm, and the practical resolving power about 50,000 with a slit width of $30\text{ }\mu$.

2.5. Photographic Plates

In order to determine, relative to copper, the intensities of all lines of 70 chemical elements diluted 1000 fold it was necessary to make many hundreds of spectrograms, and to employ 4 varieties of photographic plates to cover the wavelength range 2000 to 9000 Å. The spectral range 2000 to 3000 Å was recorded on Eastman² 103-0 Ultra-violet Sensitive plates, 2600 to 4900 Å on Eastman 33 plates, 4600 to 6900 Å on Eastman II-F plates, and 6600 to 9000 Å on Eastman I-N plates. Each plate was developed for 4 min in a rocking tray containing D-19 developer at 70°F.

The exposure times in each spectral range were chosen by trial to obtain a suitable continuous background in the first step of the rotating step sector. Because of variations in spectral sensitivity of photographic materials and in spectrographic efficiency two exposures of the contaminated-copper arcs were usually made on each plate, with exposure durations in the ratio 2 to 1, and the sectored comparison spectrum of the contaminant was placed between them. Measurements were usually confined to the exposures which showed the optimum background in the first step of the rotating sector.

2.6. Energy Calibration of Copper Lines

In order to determine the factors necessary to convert the estimates of apparent intensities of the lines of 70 elements relative to copper into true relative intensities, it was necessary to determine the true relative intensities of selected reference lines in the spectrum of copper. The energy calibration of copper lines was performed as follows:

² Certain commercial products and instruments are identified in this paper in order to specify adequately the experimental procedure. In no case does such identification imply recommendation or endorsement by the National Bureau of Standards, nor does it imply that the products or equipment identified are necessarily the best available for the purpose.

A G.E. tungsten ribbon filament lamp (type F339-85, 30 A, 6V) equipped with a fused quartz window served as the reference standard of spectral energy distribution in the wavelength range 3300 to 9000 Å. The brightness temperature of the filament at 6500 Å was measured at two values of filament current by Henry Shenker in the National Bureau of Standards Pyrometry Laboratory. The true temperature T of the filament was determined from the brightness temperature by means of the following equation obtained from Wien's law

$$\frac{1}{T} = \frac{1}{T_B} + \frac{\lambda}{C_2} \ln A$$

where $C_2 = 1.438$ cm-deg and A is the product of the emissivity of tungsten (0.427) and the transmittance of the quartz window (0.916) at 6500 Å.

TABLE I. Temperature of tungsten lamp

Current	Brightness temperature	True temperature
A	K	K
38.00	2492	2787
40.00	2567	2881

The energy distribution from blackbodies operated at these temperatures was taken from tables prepared by Stair and Smith [19] in the 2300 to 3500 Å range, by Skogland [20] in the 3200 to 7600 Å range and by Lowan and Blanch [21] in the 7200 to 10 000 Å range. The data from these tables were adjusted to a common basis and multiplied by the emissivity of tungsten and the transmittance of fused quartz at intervals increasing from 50 Å in the ultraviolet to 200 Å in the infrared. The emissivity of tungsten was taken from a weighted mean curve of published values to which reference is made by Stair and Smith [19]. The transmittance of fused quartz was calculated from data on its index of refraction published by Sosman [22]. The final product, representing the relative energy distribution of the radiation emerging from the quartz window of the lamp, was plotted on a convenient scale to permit interpolation to any wavelength in the range 2300 to 10 000 Å.

Spectrograms of the pure copper arc and of the tungsten lamp were made under conditions identical with those described above except that for these a 2 to 1 step sector with 8 steps was used for closer calibration (fig. 3). Microphotometer measurements of transmittance were made in each step of the standard-lamp spectrum at intervals of 50 Å and a family of calibration curves of transmittance versus log exposure (hereafter referred to as $\log J$) was drawn up for each plate. The exposure of the standard-lamp J_s was read from the calibration curve

for each wavelength at a transmittance of 40 percent (where the curve is linear) and then divided by the calculated intensity I_s at that wavelength. I_s is the calculated intensity emitted by the standard-lamp. A standardization curve of $\log J_s/I_s$ versus λ was plotted for each plate. Calibration curves of transmittance versus $\log J$ were then drawn from measurements on each of the selected copper lines and the log exposure ($\log J_{Cu}$) of each copper line at a transmittance of 40 percent was read from each curve. $\log J_s/I_s$ was then subtracted from the average of numerous values of $\log J_{Cu}$ to give $\log I_{Cu}$ which is the log of the true relative intensity of the copper line. The values of $\log I_{Cu}$ from plates in adjacent wavelength regions were adjusted to a common basis by means of lines common to both plates. The plot of $\log J_s/I_s$ versus λ is the relative response function of the plate-spectrograph combination and as such was itself useful in the infrared where the copper spectrum lacks lines suitable for use as an intensity reference.

From 2 to 24 determinations were made on each of 202 lines of Cu I between 2800 and 8100 Å with an average of about 9 determinations per line. The values of I_{Cu} obtained by this procedure below 3300 Å were systematically low because of the rapid decline in intensity from the standard lamp in the direction of short wavelengths. The intensity from the lamp at 5500 Å is about 40 times the intensity at 3300 Å and about 300 times the intensity at 2800 Å. This fact introduces possible errors from scattered light of the intense visible radiation which tends to raise J_s and consequently depress I_{Cu} .

The spectrum of copper is composed of sharp lines and diffuse lines. Since the microphotometer measurements were made at the peaks of the lines rather than integrated over their widths, the measured intensities of the two groups of lines are on different relative scales, the scale of the diffuse lines being smaller than that of the sharp lines. The reference lines selected for calibration of the estimates of apparent intensity are all sharp lines.

The random error of the photometric procedure, including microphotometer error and irregularities of response of the "N" plates was determined from 92 measurements of apparent relative intensities in spectra of the standard lamp on two plates. The standard deviation of individual measurements from the mean was found to be about 1.5 percent. It is probable, therefore, that the uncertainties in these intensity measurements of the copper lines lie entirely in the systematic errors discussed above and in the random fluctuations of the arc under study.

Since the ribbon filament lamp was too faint in the region from 2000 to 3300 Å to serve as a standard, recourse was taken to a Hanovia hydrogen arc lamp. Output from this lamp was compared by R. Stair in the Radiometry Section of the Bureau with a standard tungsten-in-quartz lamp and a

standard mercury arc in the region from 2500 to 3800 Å; this provided an independent overlapping calibration which carried us down to 2500 Å.

The intensity numbers below 2500 Å become less accurate as the short wavelength limit is approached. Lacking any reliable energy calibration

for shorter waves, the intensity estimates from 2500 to 2000 Å were necessarily adjusted by judicious extrapolation, guided by the declining densities of background in the spectrograms, caused by the increasing absorption in the apparatus and in the air at shorter wavelengths.

3. Results

Because these relative intensities of 39,000 lines of 70 elements are based on empirical detectability they will be generally applicable to spectrochemical analysis provided that proper corrections are made on account of different excitation in different matrices. Chemical elements differ in volatility, electron emission, spectral excitation, and spectral background, and consequently their spectral detectability in different mixtures or matrices depends on certain controlling factors. One of the important factors is the atomic ionization potential which ranges from 3.9 V for Cs to 11.3 V for C, and for the investigated 70 elements has an average value of 7.3 V. By mixing these 70 elements with copper, which has an ionization potential of 7.7 V, we obtained excitation conditions very near the average for all. To convert our intensity numbers from copper to any other matrix would require the empirical determination of the proper conversion factor for each element.

It should be pointed out that sensitivity of detection in spectrochemical analysis is commonly given in percent by weight. In order to find the weight percent from the atomic percent given in the tables the following simple relation applies,

$$C_w = \frac{C_a A_x}{A_{Cu}}$$

where C_w is the concentration in percent by weight, C_a is the atomic percent (0.1 in this case), A_{Cu} is the atomic weight of copper, and A_x is the atomic weight of the element X .

Although our original intention was to determine the relative strengths of many spectral lines from different chemical elements for purposes of quantitative spectrochemical analysis we believe that the results may also interest theoretical spectroscopists and astrophysicists. For instance, if our intensity numbers, based on concentration detectability and relative energy calibration, actually express relative energies then all may be converted to oscillator strengths, or to relative gf -values, or even to absolute f -values, if the proper conversion factors can be found.

Because of the low concentration of each element in the copper arc from which the spectra were observed, the lines were extraordinarily free from

self absorption. This fact suggests that these emission intensities could be converted into relative gf -values, provided that a valid excitation temperature can be assigned to the copper arc.

The temperature of the copper arc can be determined by comparing the observed relative intensities of the lines of an element with the relative gf -values of those lines [23], provided that the arc can be shown to be in local thermodynamic equilibrium for the energy states under consideration. A preliminary investigation of this sort has been carried out by using relative gf -values determined by R. B. King and his coworkers for Ti I [24], Ti II [25], V I [26], Cr I [27], Fe I [28], [29] and Ni I [30] in the region above 3000 Å. Figure 4 is a typical example of the correlation of intensities and gf -values indicating the temperature of the copper arc. The comparison shows that our copper arc is sufficiently in equilibrium to yield a temperature which may be useful in calculating approximate gf -values of some utility from our intensity numbers. A preliminary value of $5000 \text{ K} \pm 300 \text{ K}$ has been obtained as the average temperature of the 10 Å, 220 V, copper arc.

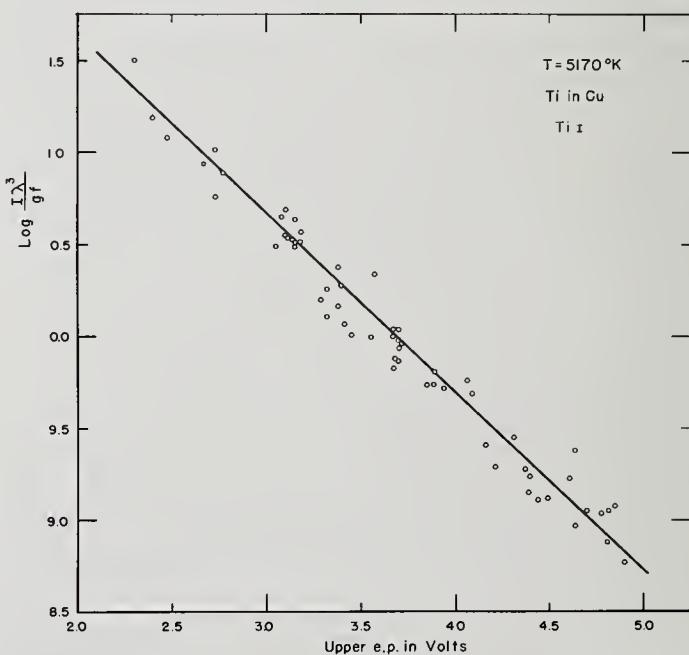

FIGURE 4. Plot of $\log \text{intensity } \lambda^3 \text{ over } gf$ versus upper excitation potential of Ti I lines.

The temperature of the arc is derived from the slope of the line which best fits the points.

Because our intensity data represent single (some times two) personal subjective estimates of photographic densities in sectored spectrograms there is no possibility of deriving statistically any probable errors or standard deviations for individual values. However, an estimate of the accuracy or reliability of our data may be obtained by comparing them with quantitative results published by other investigators. For example, figure 4 shows the ratios of our intensities to the relative *f*-values (or intensities) reported by King and King [24] who measured the total absorptions of Ti I lines in furnace absorption spectra; they stated [28] that "The average deviations of the individual intensity measures from the mean values vary from 4 to 15 percent for different lines" measured between 4 and 16 times on different plates. Each little circle plotted in figure 4 represents a Ti I multiplet of 1 to 12 lines. The average of 59 deviations from the mean of all is 25 percent.

A second indication of the reliability of our intensities is obtained by comparing our values with the relative intensities of lines in multiplets of five elements (Cr, Fe, Mn, Ti, V) measured with photographic densitometry by Frerichs [31] to test the sum rules. Such a comparison in 21 different multiplets indicates deviations ranging from 5 to 22 percent, with an overall average of 14 percent.

A third estimate of the errors in our data results from their comparison with photoelectric intensity measurements in the iron arc by Crosswhite [32], who claims an accuracy of the order of 1 percent. The average difference between intensities of 330 iron lines (3175 to 5658 Å) common to these two sets of observations is ± 27 percent, but some of this difference may be due to temperature if this is not the same in both arcs.

Other comparisons could be made but the above three are different and typical; they suggest that the average error of our spectral-line intensities within a spectrum of each element is probably between 15 and 25 percent. The uniformity of the intensity scale between the spectra of the various elements is more difficult to assess. Considerable care was taken to obtain spectrograms under comparable conditions for all of the elements; however, differences in volatilities of the elements or their oxides, and differences in ease of excitation may possibly result in shifts of intensity scales between elements. An inspection of the intensities of the strongest lines of the elements indicates that the values are generally in the same order as sensitivity of detection of the elements where these are known. Although no high precision was expected in our mass-production of intensities it is emphasized that reasonably uniform, quantitative values are now available for 39 000 lines emitted by 70 chemical elements.

The tables of spectral-line intensities resulting from this investigation are presented in two parts.

In part I the data are arranged by element in alphabetical order of chemical name. The heading of each table by element states the atomic symbol, atomic number, atomic weight, ratio of atomic weight to that of copper, the electron configuration and term symbol of the normal state of each spectrum and the corresponding ionization potential expressed in cm^{-1} . Following the heading is a selected list of references. Under *Wavelengths* are listed all of the sources from which the wavelengths used in the table were compiled. Under *Classification* or *Spectrum Assignments* are listed the sources from which the assignment of spectrum and energy levels were obtained. A few spectra showed bands of metallic oxides. References to data about these bands are given under *Molecular Spectra*.

Following the references there is abstracted from the main table a list of the strong lines arranged in order of decreasing intensity. These lists of the strong lines generally contain 2 percent or more of the lines in the main table.

Electron configurations and spectral term designations of quantum numbers are of unusual interest in the production of the strongest spectral lines, or *raies ultimes*. According to well-known rules governing the relative intensities of lines in multiplets, the strongest line arises from transitions between levels having the largest *J* and *L* values when $\Delta J = \Delta L = 1$. A rule relating to *raies ultimes* was expressed [33] a quarter of a century ago as follows: "A *raie ultime* in any spectrum originates with a simple interchange of a single electron between *s* and *p* states, usually preferring configurations in which only one electron occurs in such states." The above simple rules for the strongest lines appear to be valid for all spectra.

Then comes the main table, listing in order of wavelength, for every line of an element which appears on our plates, the intensity, character, wavelength, spectrum, and energy levels. The calibrated intensity numbers in the first column represent the relative radiant power emitted by our arc at each wavelength. Lines which differ in profile from a normal sharp symmetrical shape are described in the second column, with the notation suggested in the Transactions of the Joint Commission for Spectroscopy [34] as follows:

- b — band head,
- c — complex,
- d — unresolved double line,
- h — hazy,
- l — shaded longward,
- s — shaded shortward,
- w — wide.

The wavelengths in column 3 are taken from the places noted in the list of references and are given

to the nearest 0.01 Å. They are all normal air wavelengths, even those below 2000 Å. Column 4 gives the spectrum, I, II, or III (respectively from neutral, singly ionized and doubly ionized atoms) in which the line occurs or the molecule from which a band head originates and column 5 the numerical values, rounded off to the nearest wavenumber, of the levels between which the transition occurs. These data are taken from the *Classification* reference.

The wavelength of a doubly classified line appears before the first pair of energy levels and the second pair follows immediately. In these tables all energy levels are given in vacuum wavenumber units, cm^{-1} , for which the name kayser (*K*) has been proposed [35]. For all spectral lines explained as transitions between energy levels this serves as a mutual check since the wavelengths in normal air, when converted to vacuum wavenumbers by a conversion table [36], will coincide within one unit with the difference between the two energy levels. Furthermore these numbers serve as an index to the term designation in "Atomic Energy Levels" [37] where electron configurations, quantum numbers, and magnetic splitting factors are given.

A comparison of the excitation energies of any two classified lines may be made by directly comparing their energy levels in cm^{-1} . This direct and simple procedure avoids the labor of converting all energy levels from cm^{-1} to electron volts by means of the relation one eV = 8065 cm^{-1} .

In part II the intensity data are arranged in two tables in order of increasing wavelengths. In table 1 the strong lines of each element which were ab-

stracted from the main tables in part I are here arranged in order of wavelength. Following this is table 2 in which the individual main tables of part I have been consolidated into a single table arranged by wavelength. This table contains about 39 000 lines of 70 elements. The intensities in the table are on a scale of relative radiant power and the scale is the same from element to element. Following the intensity numbers are given the wavelength, the element symbol, and the spectrum. The intensity of a double line appears before the first wavelength and the second wavelength follows immediately.

This investigation has extended over a period of 28 years, and represents a very considerable amount of intermittent labor contributed mainly by a relatively small number of individuals. The program was initiated by Meggers and Scribner; the latter prepared diluted-element mixtures, electrodes and spectrograms, while the former identified wavelengths, supplied many line classifications, and estimated relative intensities of some fifty thousand lines. In the production of the mixtures and the copper electrodes and spectrograms valuable assistance was given by Harriet E. Brown. Corliss contributed the copper calibration, the conversion of apparent intensities to relative radiant powers, and prepared the final tables. Mrs. Ruth Peterson carefully prepared and checked all the data on IBM cards so that it could be printed automatically. Valuable advice and assistance on the IBM machine operations was given by William Bozman. To all our able and reliable assistants the authors extend their sincere appreciation and thanks for cheerful and conscientious cooperation.

Calcium

$$\text{Ca, } Z = 20, M = 40.08, \text{ Ratio } \frac{\text{Ca}}{\text{Cu}} = 0.6307$$

Ca I Normal state of valence electrons $4s^2 \ ^1S_0 = 0$. I.P. = 49305 cm^{-1} .
Ca II Normal state of valence electrons $4s \ ^2S_{1/2} = 0$. I.P. = 95752 cm^{-1} .

Cesium

$$\text{Cs, } Z = 55, M = 132.9055, \text{ Ratio } \frac{\text{Cs}}{\text{Cu}} = 2.091$$

Cs I Normal state of valence electrons $5p^6 6s^2 S_{1/2} = 0$. I.P. = 31407 cm^{-1} .
Cs II Normal state of valence electrons $5p^6 1S_0 = 0$. I.P. = 186600 cm^{-1} .

Cobalt

$$\text{Co, } Z=27, M=58.9332, \text{ Ratio } \frac{\text{Co}}{\text{Cu}}=0.9274$$

Co I Normal state of valence electrons $3d^74s^2\ ^4F_{1/2}=0$. I.P. = 63430 cm^{-1} .

Co II Normal state of valence electrons $3d^8\ ^3F_4=0$. I.P. = 137572 cm^{-1} .

Copper

$$\text{Cu, } Z = 29, M = 63.546, \text{ Ratio } \frac{\text{Cu}}{\text{Cu}} = 1.0000$$

Cu I Normal state of valence electrons $3d^{10}4s^2S_{1/2} = 0$. I.P. = 62317 cm^{-1} .
Cu II Normal state of valence electrons $3d^{10}1S_0 = 0$. I.P. = 163666 cm^{-1} .

Dysprosium

$$\text{Dy, } Z = 66, M = 162.5, \text{ Ratio } \frac{\text{Dy}}{\text{Cu}} = 2.557$$

Dy I Normal state of valence electrons $4f^{10}6s^2\ ^5I_8 = 0$. I.P. = 47810 cm^{-1}
 Dy II Normal state of valence electrons $4f^{10}6s\ ^6I_{81/2} = 0$. I.P. = 94100 cm^{-1} .

Europium

$\text{Eu, } Z = 63, M = 151.96, \text{ Ratio } \frac{\text{Eu}}{\text{Cu}} = 2.391$

Eu I Normal state of valence electrons $4f^76s^2\ ^8S_{3/2}^o = 0$. I.P. = 45700 cm^{-1} .
Eu II Normal state of valence electrons $4f^76s\ ^9S_4^o = 0$. I.P. = 90660 cm^{-1} .

References

Wavelengths:

A. S. King, *Astrophys. J.* **89**, 377 (1939).

Classification:

Eu I, H. N. Russell and A. S. King, *Astrophys. J.* **90**, 155 (1939).

Eu II, H. N. Russell, W. Albertson, and D. N. Davis, *Phys. Rev.* **60**, 641 (1941).

Gadolinium

$$Gd, Z=64, M=157.2, \text{Ratio } \frac{Gd}{Cu} = 2.475$$

Gd I Normal state of valence electrons $4f^7 5d6s^2 {}^9D_2 = 0$. I.P. = 49500 cm^{-1} .
 Gd II Normal state of valence electrons $4f^7 5d6s {}^{10}D_{2 1/2} = 0$. I.P. = 97500 cm^{-1} .

Holmium

$$\text{Ho, } Z = 67, M = 164.9303, \text{ Ratio } \frac{\text{Ho}}{\text{Cu}} = 2.595$$

Ho I Normal state of valence electrons $4f^{11}6s^2\ 4I_{7/2}^o = 0$. I.P. = 48540 cm^{-1} .
 Ho II Normal state of valence electrons $4f^{11}6s\ 5I_8^o = 0$. I.P. = 95200 cm^{-1} .

References

Wavelengths:

Below 7000 Å;

A. Gatterer and J. Junkes, Spektren der Seltenen Erden (Specola Vaticana, Vatican, 1945).

About 50 wavelengths were measured on our plates, including all lines above 7000 Å.

Classification:

Ho I, J. Blaise, P. Camus, G. Guelachvili, J. Verges, and J. F. Wyart, C. R. Acad. Sc. Paris, Ser. B.275,81 (1972); 274,1302 (1972).

Ho II, J. Sugar, J. Opt. Soc. Am. **58**, 1519 (1968).

Spectrum Assignments:

From 3837 Å to 4661 Å: A. S. King, Astrophys. J. **72**, 221 (1930).

The rest of the assignments are from our plates.

Molecular Spectra:

HoO, A. Gatterer, Ricerche Spettroscop. **1**, 139 (1942).

Strong lines of holmium

Indium

$$\text{In, } Z = 49, M = 114.82, \text{ Ratio } \frac{\text{In}}{\text{Cu}} = 1.807$$

In I Normal state of valence electrons $5s^2 5p^2 P_{1/2}^o = 0$. I.P. = 46670 cm^{-1} .
 In II Normal state of valence electrons $5s^2 1S_0 = 0$. I.P. = 152195 cm^{-1} .

Iron

$$\text{Fe, } Z=26, M=55.85, \text{ Ratio } \frac{\text{Fe}}{\text{Cu}} = 0.879$$

Fe I Normal state of valence electrons $3d^6 4s^2$ $^5D_4 = 0$. I.P. = 63700 cm^{-1} .
Fe II Normal state of valence electrons $3d^6 4s$ $^6D_{4\frac{1}{2}} = 0$. I.P. = 130524 cm^{-1} .

Lanthanum

$$\text{La, } Z = 57, M = 138.905, \text{ Ratio } \frac{\text{La}}{\text{Cu}} = 2.186$$

La I Normal state of valence electrons $5d6s^2\ 2D_{1\frac{1}{2}} = 0$. I.P. = 44981 cm^{-1} .

La II Normal state of valence electrons $5d^2\ 3F_2 = 0$. I.P. = 89200 cm^{-1} .

La III Normal state of valence electrons $5d^2D_{1\frac{1}{2}} = 0$. I.P. = 154675 cm^{-1} .

Magnesium

$$\text{Mg, } Z = 12, M = 24.305, \text{ Ratio } \frac{\text{Mg}}{\text{Cu}} = 0.3825$$

Mg I Normal state of valence electrons $2p^6 3s^2 \ ^1S_0 = 0$. I.P. = 61671 cm^{-1} .
Mg II Normal state of valence electrons $2p^6 3s^2 S_{1/2} = 0$. I.P. = 121268 cm^{-1} .

Mercury

$Hg, Z = 80, M = 200.6, \text{Ratio } \frac{Hg}{Cu} = 3.157$

Hg I Normal state of valence electrons $5d^{10}6s^2\ ^1S_0 = 0$. I.P. = 84184 cm^{-1} .
Hg II Normal state of valence electrons $5d^{10}6s^2\ ^2S_{1/2} = 0$. I.P. = 151280 cm^{-1} .

Molybdenum

Mo, $Z = 42$, $M = 95.9$, Ratio $\frac{\text{Mo}}{\text{Cu}} = 1.510$

Mo I Normal state of valence electrons $4d^5 5s^1 S_3 = 0$. I.P. = 57260 cm^{-1} .
 Mo II Normal state of valence electrons $4d^5 6S_{21/2} = 0$. I.P. = 130300 cm^{-1} .

Neodymium

$$\text{Nd, } Z = 60, M = 144.2, \text{ Ratio } \frac{\text{Nd}}{\text{Cu}} = 2.270$$

Nd I Normal state of valence electrons $4f^46s^2\ 5I_4 = 0$. I.P. = 44270 cm⁻¹.
 Nd II Normal state of valence electrons $4f^46s^6\ 6I_{3/2} = 0$. I.P. = 86500 cm⁻¹.

Nickel

$$\text{Ni, } Z = 28, M = 58.7, \text{ Ratio } \frac{\text{Ni}}{\text{Cu}} = 0.924$$

Ni I Normal state of valence electrons $3d^8 4s^2$ ${}^3F_4 = 0$. I.P. = 61579 cm^{-1} .
 Ni II Normal state of valence electrons $3d^9$ ${}^2D_{2\frac{1}{2}} = 0$. I.P. = 146532 cm^{-1} .

Niobium

$\text{Nb}, Z=41, M=92.9064, \text{Ratio } \frac{\text{Nb}}{\text{Cu}} = 1.462$

- Nb I** Normal state of valence electrons $4d^45s\ 6D_{1/2}=0$. I.P. = $55000\ \text{cm}^{-1}$.
Nb II Normal state of valence electrons $4d^4\ 5D_0=0$. I.P. = $115000\ \text{cm}^{-1}$.

Osmium

$\text{Os, } Z=76, M=190.2, \text{ Ratio } \frac{\text{Os}}{\text{Cu}}=2.993$

Os I Normal state of valence electrons $5d^66s^2\ 5D_4=0$. I.P.= $69000\ \text{cm}^{-1}$.

Os II Normal state of valence electrons $5d^66s\ 6D_{41/2}=0$.

Palladium

$$\text{Pd, } Z=46, M=106.4, \text{ Ratio } \frac{\text{Pd}}{\text{Cu}} = 1.674$$

- Pd I Normal state of valence electrons $4d^{10} 1S_0 = 0$. I.P. = 67236 cm^{-1} .
 Pd II Normal state of valence electrons $4d^9 2D_{21/2} = 0$. I.P. = 156700 cm^{-1} .

References

Wavelengths:

G. R. Harrison, Massachusetts Institute of Technology Wavelength Tables (John Wiley & Sons, New York, 1939).

Classification:

- Pd I, A. G. Shenstone, Phys. Rev. **36**, 669 (1930).
 Pd II, A. G. Shenstone, Phys. Rev. **32**, 30 (1928).

Rhenium

Re, Z = 75, M = 186.2, Ratio $\frac{\text{Re}}{\text{Cu}} = 2.930$

Re I Normal state of valence electrons $5d^56s^2\ ^6S_{21/2} = 0$. I.P. = 63530 cm^{-1} .

Re II Normal state of valence electrons $5d^56s\ ^7S_3 = 0$. I.P. = 134000 cm^{-1} .

Rhodium

$\text{Rh, } Z = 45, M = 102.9055, \text{ Ratio } \frac{\text{Rh}}{\text{Cu}} = 1.619$

- Rh I Normal state of valence electrons $4d^8 5s\ 4F_{41/2} = 0$. I.P. = $60197\ \text{cm}^{-1}$.
 Rh II Normal state of valence electrons $4d^8\ 3F_4 = 0$. I.P. = $145800\ \text{cm}^{-1}$.

Rubidium

$$\text{Rb, } Z=37, M=85.467, \text{ Ratio } \frac{\text{Rb}}{\text{Cu}} = 1.345$$

- Rb I** Normal state of valence electrons $4p^6 5s^2 S_{1/2} = 0$. I.P. = 33691 cm⁻¹.
Rb II Normal state of valence electrons $4p^6 1S_0 = 0$. I.P. = 220105 cm⁻¹.

Scandium

$\text{Sc, } Z=21, M=44.9559, \text{ Ratio } \frac{\text{Sc}}{\text{Cu}}=0.707$

Sc I Normal state of valence electrons $3d4s^2 \ ^2\text{D}_{1 \frac{1}{2}} = 0$. I.P. = 52920 cm^{-1} .

Sc II Normal state of valence electrons $3d4s \ ^3\text{D}_1 = 0$. I.P. = 103240 cm^{-1} .

Sc III Normal state of valence electrons $3d \ ^2\text{D}_{1 \frac{1}{2}} = 0$. I.P. = 199677 cm^{-1} .

Tellurium

$\text{Te, } Z = 52, M = 127.6, \text{ Ratio } \frac{\text{Te}}{\text{Cu}} = 2.008$

Te I Normal state of valence electrons $5s^2 5p^4 3P_2 = 0$. I.P. = 72667 cm^{-1} .
Te II Normal state of valence electrons $5s^2 5p^3 4S_{1/2}^0 = 0$. I.P. = 150000 cm^{-1} .

References

Wavelengths:

J. F. Ward, unpublished material (1969).

Classification:

Te I, O. Bartelt, Z. Physik **88**, 522 (1934).

Tellurium—all observed lines

Terbium

$$\text{Tb, } Z = 65, M = 158.9254, \text{ Ratio } \frac{\text{Tb}}{\text{Cu}} = 2.501$$

Tb I Normal state of valence electrons $4f^96s^2\ ^6H_{7/2}^o = 0$. I.P. = 47200 cm⁻¹.
 Tb II Normal state of valence electrons $4f^96s\ ^7H_8 = 0$. I.P. = 92900 cm⁻¹.

Supplemented by:

J. M. Eder, Sitzber. Akad. Wiss. Wien, Math. naturw. Kl. **131**, 199 (1922).

A. S. King, Astrophys. J. **72**, 221 (1930).

P. F. A. Klinkenberg and E. Meinders (see below).

About 70 lines above 7000 Å were measured on our plates.

Classification:

Tb I, P. F. A. Klinkenberg and E. Meinders, Physica **32**, 1113, 1617 (1966); **37**, 197 (1967); **38**, 253 (1968); **42**, 213 (1969); **50**, 625 (1970); **57**, 594 (1972).

Tb II, E. Meinders, Physica **42**, 427 (1969) and unpublished material (1969).

Spectrum Assignments:

From 3837 to 4677 Å the assignment of spectrum is from A. S. King, Astrophys. J. **72**, 221 (1930).

The rest of the assignments are from our plates.

Thallium

$$\text{Tl, } Z = 81, M = 204.4, \text{ Ratio } \frac{\text{Tl}}{\text{Cu}} = 3.216$$

Tl I Normal state of valence electrons $6s^2 6p^2 P_{1/2}^o = 0$. I.P. = 49267 cm^{-1} .

Tl II Normal state of valence electrons $6s^2 1S_0 = 0$. I.P. = 164765 cm^{-1} .

Thulium

$$Tm, Z=69, M=168.9342, \text{Ratio } \frac{Tm}{Cu} = 2.658$$

- Tm I Normal state of valence electrons $4f^{13}6s^2\ ^2F_{3/2}^o = 0$. I.P. = 49880 cm⁻¹.
 Tm II Normal state of valence electrons $4f^{13}6s\ ^3F_4^o = 0$. I.P. = 97200 cm⁻¹.
 Tm III Normal state of valence electrons $4f^{13}\ ^2F_{3/2}^o = 0$. I.P. = 191000 cm⁻¹.

Tin

$$\text{Sn, } Z = 50, M = 118.7, \text{ Ratio } \frac{\text{Sn}}{\text{Cu}} = 1.868$$

Sn I Normal state of valence electrons $5s^2 5p^2 \ ^3P_0 = 0$. I.P. = 59232 cm^{-1} .
 Sn II Normal state of valence electrons $5s^2 5p \ ^2P_{1/2}^o = 0$. I.P. = 118017 cm^{-1} .

Titanium

$$\text{Ti, } Z = 22, M = 47.9, \text{ Ratio } \frac{\text{Ti}}{\text{Cu}} = 0.754$$

Ti I Normal state of valence electrons $3d^24s^2\ ^3F_2 = 0$. I.P. = 55138 cm^{-1} .

Ti II Normal state of valence electrons $3d^24s\ ^4F_{1/2} = 0$. I.P. = 109506 cm^{-1} .

Tungsten

$$W, Z = 74, M = 183.8, \text{ Ratio } \frac{W}{Cu} = 2.893$$

W I Normal state of valence electrons $5d^46s^2$ ${}^5D_0 = 0$. I.P. = 64400 cm^{-1} .

W II Normal state of valence electrons $5d^46s$ ${}^6D_{1/2} = 0$. I.P. = 143000 cm^{-1} .

Uranium

$$U, Z = 92, M = 238.029, \text{ Ratio } \frac{U}{Cu} = 3.746$$

U I Normal state of valence electrons $5f^36d7s^2\ ^5L_6^o = 0$. I.P. = 48800 cm⁻¹.
 U II Normal state of valence electrons $5f^37s^2\ ^4I_{4\frac{1}{2}}^o = 0$. I.P. = 96000 cm⁻¹.

 C. C. Kiess, C. J. Humphreys, and D. D. Laun, unpublished material (1946).

Spectrum Assignments:

C. C. Kiess, C. J. Humphreys, and D. D. Laun, unpublished material (1946).

Classification:

U I, C. C. Kiess, C. J. Humphreys, and D. D. Laun, J. Research NBS **37**, 1 (1946) RP 1723.
 U I and II, Z. Ben Osman, Thesis, Univ. of Paris (1966).
 F. Guyon, Thesis, University of Paris-Sud, Orsay (1972).
 D. W. Steinhaus, M. V. Phillips, J. B. Moody, L. J. Radziemski, K. J. Fisher, and D. R. Hahn, Los Alamos Report LA 4944 (1972).
 U II, J. C. van den Bosch, Physica **15**, 503 (1949).
 D. D. Laun, unpublished material (1969).

Strong lines of uranium

Vanadium

$$V, Z=23, M=50.941, \text{Ratio } \frac{V}{Cu}=0.8016$$

V I Normal state of valence electrons $3d^34s^2\ ^4F_{1\frac{1}{2}}=0$. I.P. = 54361 cm $^{-1}$.
 V II Normal state of valence electrons $3d^4\ ^5D_0=0$. I.P. = 118200 cm $^{-1}$.

Ytterbium

$\text{Yb, } Z = 70, M = 173.0, \text{ Ratio } \frac{\text{Yb}}{\text{Cu}} = 2.723$

- Yb I** Normal state of valence electrons $6s^2 \text{ } ^1\text{S}_0 = 0$. I.P. = 50441 cm^{-1} .
Yb II Normal state of valence electrons $6s \text{ } ^2\text{S}_{1/2} = 0$. I.P. = 98150 cm^{-1} .
Yb III Normal state of valence electrons $4f^{14} \text{ } ^1\text{S}_0 = 0$. I.P. = 201900 cm^{-1} .

Yttrium

$$Y, Z = 39, M = 88.9059, \text{ Ratio } \frac{Y}{Cu} = 1.399$$

- Y I Normal state of valence electrons $5s^2 4d^2 D_{1/2} = 0$. I.P. = 52000 cm^{-1} .
 Y II Normal state of valence electrons $5s^2 1S_0 = 0$. I.P. = 99000 cm^{-1} .
 Y III Normal state of valence electrons $4d^2 D_{1/2} = 0$. I.P. = 165000 cm^{-1} .

Zinc

$$\text{Zn, } Z = 30, M = 65.4, \text{ Ratio } \frac{\text{Zn}}{\text{Cu}} = 1.029$$

Zn I Normal state of valence electrons $3d^{10}4s^2\ ^1S_0 = 0$. I.P. = 75768 cm^{-1} .
Zn II Normal state of valence electrons $3d^{10}4s\ ^2S_{1/2} = 0$. I.P. = 144893 cm^{-1} .

16. ABSTRACT (A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here.) The relative intensities, or radiant powers, of 39 000 spectral lines with wavelengths between 2000 and 9000 Angstroms have been determined on a uniform energy scale for seventy chemical elements. This was done by mixing 0.1 atomic percent of each element in powdered copper, pressing the powder-mixture to form solid electrodes which were burned in a 10 ampere, 220 volt direct-current arc, and photographing the spectra with a stigmatic concave grating while a step sector was rotating in front of the slit. The sectored spectrograms facilitated the estimation of intensities of all element lines relative to copper lines which were then calibrated on an energy scale provided by standardized lamps, and all estimated line intensities were finally adjusted to fit this calibration. Comparisons with other intensity measurements in individual spectra indicate that the National Bureau of Standards spectral-line intensities may have average errors of 20 percent, but first of all they provide uniform quantitative values for the seventy chemical elements commonly determined by spectrochemists. These data are presented by element in part I, and all 39 000 observed lines are given in order of wavelength in part II.				
17. KEY WORDS (six to twelve entries; alphabetical order; capitalize only the first letter of the first key word unless a proper name; separated by semicolons) Classification of spectral lines; intensities of spectral lines; spectral-line intensities; tables of spectral-line intensities; wavelengths of spectral lines.
