**NATIONAL BUREAU OF STANDARDS**

## THE NATIONAL BUREAU OF STANDARDS

The National Bureau of Standards is a principal focal point in the Federal Government for assuring maximum application of the physical and engineering sciences to the advancement of technology in industry and commerce. Its responsibilities include development and maintenance of the national standards of measurement, and the provisions of means for making measurements consistent with those standards; determination of physical constants and properties of materials; development of methods for testing materials, mechanisms, and structures, and making such tests as may be necessary, particularly for government agencies; cooperation in the establishment of standard practices for incorporation in codes and specifications; advisory service to government agencies on scientific and technical problems; invention and development of devices to serve special needs of the Government; assistance to industry, business, and consumers in the development and acceptance of commercial standards and simplified trade practice recommendations; administration of programs in cooperation with United States business groups and standards organizations for the development of international standards of practice; and maintenance of a clearinghouse for the collection and dissemination of scientific, technical, and engineering information. The scope of the Bureau's activities is suggested in the following listing of its three Institutes and their organizational units.

**Institute for Basic Standards.** Applied Mathematics. Electricity. Metrology. Mechanics. Heat. Atomic Physics. Physical Chemistry. Laboratory Astrophysics.\* Radiation Physics. Radio Standards Laboratory:\*\* Radio Standards Physics; Radio Standards Engineering. Office of Standard Reference Data.

**Institute for Materials Research.** Analytical Chemistry. Polymers. Metallurgy. Inorganic Materials. Reactor Radiations. Cryogenics.\* Materials Evaluation Laboratory. Office of Standard Reference Materials.

**Institute for Applied Technology.** Building Research. Information Technology. Performance Test Development. Electronic Instrumentation. Textile and Apparel Technology Center. Technical Analysis. Office of Weights and Measures. Office of Engineering Standards. Office of Invention and Innovation. Office of Technical Resources. Clearinghouse for Federal Scientific and Technical Information.\*\*

Send orders with remittance to Superintendent of Documents, U.S. Government Printing Office, Washington, D.C., 20402. Remittances from foreign countries should include an additional one-fourth of the purchase price for postage.

Those wishing to be notified of future issues should send mailing address to the Government Printing Office.

# STANDARD X-RAY DIFFRACTION POWDER PATTERNS

## Section 4—Data for 103 Substances

Howard E. Swanson, Marlene Cook Morris,<sup>1</sup> and Eloise H. Evans<sup>1</sup>

Standard x-ray diffraction powder data are presented for 103 substances. Thirty-two of these patterns represent experimental data and 71 are calculated. Ten experimental patterns replace eleven cards already in the X-ray Powder Diffraction File published by the American Society for Testing and Materials; twenty-two experimental patterns and seventy-one calculated patterns are for substances not previously included in the File. The experimental x-ray powder diffraction patterns were made with a Geiger counter x-ray diffractometer, using samples of high purity. All *d*-values were assigned Miller indices determined by comparison with theoretical interplanar spacings and from space group extinctions. The densities and lattice constants were calculated, and the refractive indices were measured whenever possible. The calculated x-ray powder diffraction patterns were obtained from single crystal structure data. The reported peak height intensities for calculated patterns were converted from integrated intensities.

Accurate cell determination measurements for the internal standards were obtained by using a flat-plate back reflection focusing camera.

**Key Words:** standard, x-ray, diffraction, powder, patterns, crystal, structure, measurements, lattice, constants

## INTRODUCTION

The X-ray Powder Diffraction File [1]<sup>2</sup> is a compilation of diffraction patterns from many sources and is used for the identification of unknown crystalline materials by matching spacing and intensity measurements. The National Bureau of Standards in its program<sup>3</sup> for the revision and evaluation of published x-ray data for the X-ray Powder Diffraction File presents data in this report for 103 compounds. This compilation is the fourteenth of a series of "Standard X-ray Diffraction Powder Patterns."<sup>4</sup> The designation "Circular 539" used for the first ten volumes has been discontinued in favor of the series, "Monograph 25." This compilation is the fourth section of the series Monograph 25. Included are patterns recommended to replace data on 11 cards now present in the File. The other patterns are for 93 compounds not included in the File. In this group of compounds, 22 patterns are experimental and 71 are calculated.

### Experimental Powder Patterns

**Powder data cards.** Under this heading are given the Powder Diffraction File Card numbers and the literature reference for each card. Cards listed through the 1964 index to the Powder Diffraction File are included in the table.

**Additional published patterns.** Literature references for patterns that have not been published as Powder Diffraction cards are listed.

**NBS sample.** Many of the samples used to make NBS patterns were special preparations of high purity obtained from a variety of sources or prepared in small quantities in our laboratory. Unless otherwise noted, the spectrographic analyses were done at NBS after preparation of the sample was completed. The limit of detection for the alkali elements was 0.05 percent for the spectrographic analyses. A microscopic inspection for phase purity was made on the nonopaque materials during the refractive index determination. Another check of phase purity was usually provided by the x-ray pattern itself, when it was indexed by comparison with theoretical *d*-values. Treating the sample by appropriate annealing, recrystallization, or heating in hydrothermal bombs improved the definition of most of the patterns. The refractive index measurements were made by grain-immersion methods in white light, using oils standardized in sodium light, and covering the range 1.40 to 2.00.

**Structural data.** For cubic materials a value for the lattice constant was calculated for each *d*-value. However, the constant reported is that obtained by averaging the constants for the last five lines because of the greater accuracy of calculation in the large-angle region of the pattern. The unit cell values for noncubic substances were determined by means of a least-squares calculation made on the IBM 7094, using those *d*-values for which only one set of Miller indices could be assigned. The number of significant figures reported for the *d*-values in the NBS patterns varies slightly with the symmetry and crystallinity of each sample. A portion of the indexing and cell

<sup>1</sup> Research Associate at the National Bureau of Standards sponsored by the Joint Committee on Chemical Analysis by Powder Diffraction Methods.

<sup>2</sup> Figures in brackets indicate the literature references at the end of each section of this paper.

<sup>3</sup> This project is sponsored by the Joint Committee on Chemical Analysis by Powder Diffraction Methods. This committee is composed of members from the American Society for Testing and Materials, the American Crystallographic Association, and the British Institute of Physics. Financial support is also provided by the National Bureau of Standards.

<sup>4</sup> Other volumes were published as follows: Circular 539 Vol. 1 and Vol. 2, June 1953; Vol. 3, June 1954; Vol. 4, March 1955; Vol. 5, October 1955; Vol. 6, September 1956; Vol. 7, September 1957; Vol. 8, April 1959; Vol. 9, February 1960; Vol. 10, September 1960; Monograph 25, Section 1, March 1962; Section 2, May 1963; and Section 3, July 1964.

refinement calculation was performed on a Burroughs B 220 computer at the United States Geological Survey using a program developed by H. T. Evans, Jr., D. E. Appleman, and D. Handwerker [2]. Lattice constant errors are given only for data refined on that program and are based on least squares refinement of the variance-covariance matrix derived from the unweighted  $\Delta\theta$  residuals.

Published unit cell data in kX units and data given in angstrom units prior to 1947 were converted to angstrom units using the factor 1.00202 as recommended by an international conference of crystallographers [3].

The space groups are listed with both the Schoenflies and short Hermann-Mauguin symbols as well as the space group numbers given in the International Tables for X-ray Crystallography [4].

Orthorhombic cell dimensions are presented according to the Dana convention  $b > a > c$  [5].

The densities calculated from the NBS lattice constants are expressed in grams per cubic centimeter and are computed with atomic weights based on carbon 12 [6], and the Avogadro number ( $6.02252 \times 10^{23}$ ).

**Intensity measurements.** At least three patterns for intensity measurements were prepared to check reproducibility. Samples that gave satisfactory intensity patterns usually had an average particle-size smaller than  $10 \mu$  [7]. In order to avoid the orientation effects which occur when samples are packed or pressed, a sample holder was made that had an extended rectangular cavity opened on its top face and at the end. To prepare the sample, a glass slide was clamped over the top face to form a temporary cavity wall (see fig. 1). The powdered sample was then drifted

into the remaining end opening while the holder was held in a vertical position. With the sample holder returned to a horizontal position, the glass slide was carefully removed so that the sample surface could be exposed to the x-ray beam (as shown in fig. 2). To powders that did not flow readily, or were prone to orient excessively, approximately 50 volume percent of finely ground silica-gel was added as a diluent. The intensities of the diffraction lines were measured as peak heights above background and were expressed in percentages of the intensity of the strongest line.

**Interplanar spacings.** Specimens for the interplanar spacing patterns were prepared by packing into a shallow holder a sample containing approximately 5 wt percent tungsten powder that served as an internal standard. When tungsten lines were found to interfere, 25 percent silver was used in place of tungsten. If the internal standard correction varied along the length of the pattern, linear interpolations were used for the regions between the peaks of the standard. For low values of  $2\theta$ , the pattern peak was measured in the center, at a place averaging about 75 percent of the peak height. For higher values of  $2\theta$ , where the  $\alpha_1$  and  $\alpha_2$  peaks were separated, the  $\alpha_1$  peak was measured in the same way. The internal standard correction appropriate to each region was then applied to the measurement of  $2\theta$ . The internal standard lattice constants used were 3.1648 Å for tungsten and 4.0861 Å for silver at 25 °C, as determined by Jette and Foote [8]. All of the NBS patterns, unless otherwise noted, are made at 25 °C using either filtered copper or cobalt radiation ( $K\alpha_1$ ), having the wavelengths 1.5405 Å, and 1.7889 Å, respectively.

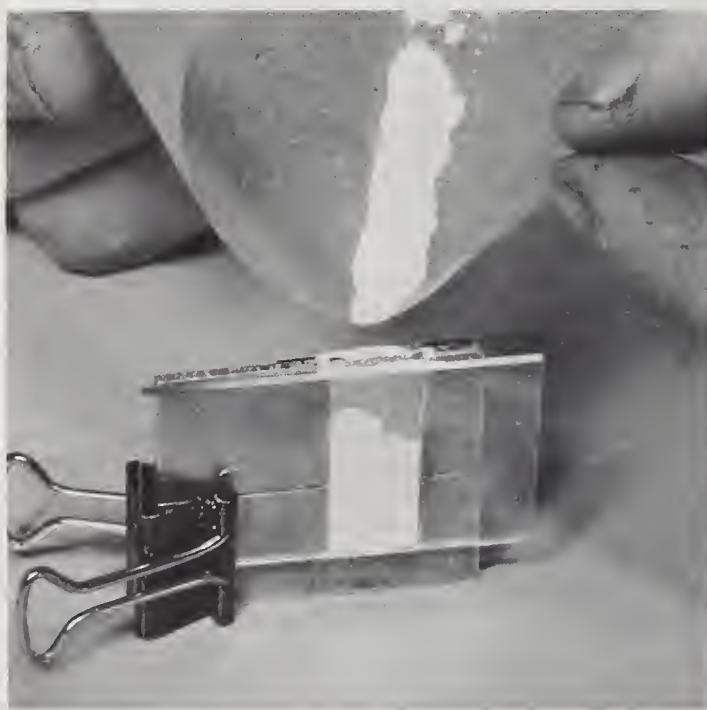

FIGURE 1

FIGURE 2

## Calculated Powder Patterns

Some substances are not readily available for experimental powder measurements. Therefore, patterns were calculated from single crystal structure data, using a FORTRAN program developed by Smith [9].

Scattering factors were obtained from The International Tables [10].

Intensity calculations were based upon copper wavelength, 1.5405 Å. The integrated intensities were converted to peak height values by means of a graph [11]. Data with peak height intensities less than 0.1 were omitted. Peak height intensities from 0.1 to 0.9 were recorded as <1. Those intensities with *d*-values close enough to be unresolved were summed.

No temperature corrections were included.

Literature references are compiled at the end of the section of calculated patterns.

The authors are indebted to H. F. McMurdie for measurement of indices of refraction and for his continuous interest and supervision in this work, to J. H. deGroot for the preparation of many of the samples used, and to S. J. Carmel for his assistance on the work using the back reflection camera.

## Cell Determination for Internal Standards

In the search for new sources of supply for silver and tungsten which we have used to reference  $2\theta$  measurements, we became interested in obtaining lattice values of the various samples of high purity silver and tungsten. The cell values for these internal standards, adopted by this laboratory in 1950, will be changed after this issue from 3.1648 to 3.16504 Å for tungsten, and from 4.0861 to 4.08625 Å for silver. The greater change in tungsten is due to higher purity (four 9's) of the newer tungsten sample. The purity of the old tungsten sample is approximately three 9's.

A flat plate back reflection camera was specially constructed for these measurements. With this type of camera only one diffraction ring is in sharp focus with each setting. This tends to limit its use to cubic materials. For each sample, a radiation was selected which produced a back reflection ring between  $165^\circ$  and  $178^\circ$  ( $2\theta$ ). A micro focus tube was chosen partly because of the ease with which targets may be changed and partly because the small external tube dimension allowed the glass photographic plate to be close enough to the 0.1 mm X-ray target to satisfy focusing. The sample powders were mounted on a 5 cm diam rotating holder that was spherically shaped for the 50 cm focus. Samples of tungsten were run on a shorter focus of 25 cm with a shaped holder to fit a 25 cm sphere. The 10 in.  $\times$  2 in. photographic plates had a hole cut in the center prior to the emulsion coating.

An insulated box enclosed the camera and made possible the circulation of air or helium at  $25.00 \pm 0.02^\circ$  C. A steady cooling effect was obtained by using a fin containing  $18^\circ$  C water in a circulated air stream. The temperature was controlled by a proportioning device that allowed varying amounts of current to heat a 7W light bulb also in the air flow. Temperature was read from two Beckmann thermometers calibrated at  $25^\circ$  C. The diffraction ring recorded on the photographic plate was scanned with a densitometer driven manually by a comparator. Densitometer readings were plotted for the  $K\alpha_1$  portion of the peak and the center was chosen at the point where the center line intersected the top of the peak.

Measurements of the distance from sample to the photographic plate emulsion were made by an inside micrometer and end measuring rods. Calculation of *d*-values without sine tables was

possible using the formula  $d = \frac{\lambda}{2\sqrt{\frac{h+b}{2h}}}$

given:  $a = \frac{1}{2}$  diam of diffraction ring

$b$  = the distance from sample to the center of the plate

and  $h = \sqrt{a^2 + b^2}$ .

Samples of high purity tungsten and silver were obtained from several suppliers, but only three tungsten and four silver samples gave sufficiently sharp diffraction peaks for measurement of cell values. Since the variation of cell values for these samples was within the reproducibility of the equipment, it appears that most samples of tungsten or silver of four or five 9's purity and producing sharp diffraction peaks would be suitable for x-ray spacing reference standards.

Cadmium oxide was also considered and measured as a spacing standard, but the cell size was obtained from only one high purity sample.

New lattice measurements will be used with the recently obtained standard reference samples beginning with the next Section of this Monograph. These changes will increase  $d$ -values by a factor of 1.00004 compared to the  $d$ -values obtained with the older standard samples.

The following  $2\theta$  angles for high purity tungsten, silver, and cadmium oxide are computed using copper radiation  $K_{\alpha_1}=1.5405 \text{\AA}$  and the cell dimensions without index of refraction corrections.

### Barium Boron Oxide, high form, $\text{BaB}_2\text{O}_4$ (trigonal)

**Powder data cards.** No. 6-0220 and No. 6-0224, Levin and McMurdie [1] 1949. The data on card No. 6-0220 was taken at 700 °C. Card No. 6-0224 is for a lower temperature form of  $\text{BaB}_2\text{O}_4$ .

**Additional published patterns.** None.

**NBS sample.** The sample of barium boron oxide was prepared at NBS by C. E. Weir from barium carbonate and boric acid. It was heated at 1,000 °C, then alternately ground and reheated several times. Spectrographic analysis showed the following major impurities: 0.01 to 0.1 percent each of calcium, silicon, and strontium; and

0.001 to 0.01 percent each of aluminum, sodium, and nickel.

The sample is colorless and optically negative. The indices of refraction are  $N_e=1.530$  and  $N_o=1.658$ .

The  $d$ -values of the three strongest lines are 3.619, 3.324, and 5.98  $\text{\AA}$ .

**Structural data.** Block, Perloff, and Weir [2] in 1964 reported that there appear to be two polymorphic forms of barium boron oxide, the high form being trigonal having the space group  $\text{C}_{3v}^6$ —R3c (No. 161) or  $\text{D}_{3d}^6$ —R $\bar{3}$ c (No. 167) with 18 ( $\text{BaB}_2\text{O}_4$ ) per unit hexagonal cell.

# Barium Boron Oxide, $\text{BaB}_4\text{O}_7$ (monoclinic)

**Powder data card.** No. 6-0334, Levin and McMurdie [1].

**Additional published pattern.** None.

**NBS sample.** The sample of barium boron oxide was prepared at NBS from boric acid and barium carbonate, in a solid state reaction below the melting point of 910 °C. Spectrographic analysis showed the following major impurities: 0.1 to 1.0 percent silicon, and 0.01 to 0.1 percent each of aluminum, calcium, cobalt, and strontium.

The sample was colorless and optically positive with medium 2V. The indices of refraction are  $N_\alpha = 1.594 \pm 0.004$ ,  $N_\beta = 1.610 \pm 0.004$ , and  $N_\gamma = 1.666 \pm 0.004$ .

The  $d$ -values of the three strongest lines are 3.130, 3.805, and 4.908 Å.

**Structural data.** Block, Perloff, and Weir [2] in 1964 determined that barium boron oxide has the space group  $C_{2h}^5$ — $P2_1/c$  (No. 14) and 8( $\text{BaB}_4\text{O}_7$ ) per unit cell.

### Barium Fluosilicate, BaSiF<sub>6</sub> (trigonal)

**Powder data card.** No. 1-0534, Hanawalt, Rinn, and Frevel [1] 1938.

**Additional published patterns.** None.

**NBS sample.** The sample of barium fluosilicate was prepared at NBS from barium chloride and hydrofluosilic acid. The precipitate was dried at 60 °C. Spectrographic analysis showed the following impurities: 0.1 to 1.0 percent sodium; 0.01 to 0.1 percent each of aluminum, calcium, potas-

sium, magnesium, and strontium; and 0.001 to 0.01 percent each of iron, nickel, lead, titanium, and zirconium.

The sample was colorless. The refractive indices could not be determined because the sample was too fine-grained.

The *d*-values of the three strongest lines are 3.593, 1.953, and 3.055 Å.

Lattice constants

	1965 National Bureau of Standards, sample at 25 °C	<i>a</i>	<i>b</i>	<i>c</i>	$\beta$
		Å	Å	Å	
		6. 9596 ± 0. 0005	7. 1576 ± 0. 0005	6. 7378 ± 0. 0005	104°42. 7' ± 0. 3'

each of aluminum, iron, magnesium, and silicon. Rare-earth impurities were less than 0.1 percent of total rare-earth content.

The sample was colorless. The indices of refraction could not be determined because the sample was too fine-grained.

The *d*-values of the three strongest lines are 3.161, 2.966, and 3.688 Å.

**Structural data.** Schwarz [1] in 1963 reported that cerium arsenate is isostructural with hut-

tonite, with the space group  $C_{2h}^5$ —P2<sub>1</sub>/n (No. 14) and 4(CeAsO<sub>4</sub>) per unit cell.

The density of cerium arsenate calculated from the NBS lattice constants is 5.709 g/cm<sup>3</sup> at 25 °C.

### Cesium Fluoantimonate, CsSbF<sub>6</sub> (trigonal)

**Powder data cards.** None.

**Additional published patterns.** None.

**NBS sample.** The sample of cesium fluoantimonate was prepared at NBS by treating a mixture of antimony and cesium nitrates with hydrofluoric acid. The sample was dried at 100 °C. Spectrographic analysis showed the following major impurities: 0.1 to 1.0 percent rubidium; 0.01 to 0.1 percent each of aluminum and nickel; and 0.001 to 0.01 percent each of silver, calcium, copper, iron, potassium, sodium, silicon, and thallium.

The sample is colorless. It is optically positive with the indices  $N_o=1.400$  and  $N_e=1.406$ .

The *d*-values of the three strongest lines are 3.948, 3.534, and 2.192 Å.

**Structural data.** Schrewelius [1] in 1943 determined that cesium fluoantimonate has the space group  $D_{3d}^5$ —R̄3m (No. 166) and 3(CsSbF<sub>6</sub>) per unit hexagonal cell. The rhombohedral cell reported by Schrewelius has been converted to the equivalent hexagonal cell for comparison with the NBS values.

- [1] N. Schrewelius, X-ray analyses of thallium fluoantimonate TlSbF<sub>6</sub> and some isomorphous alkali compounds, Arkiv Kemi, **16B** No. 7, 1–6 (1943).

The density of cesium fluoantimonate calculated from the NBS lattice constants is 4.115 g/cm<sup>3</sup> at 25 °C.

## Cobalt, Co (cubic)

**Powder data cards.** None.

**Additional published patterns.** Hull [1] 1921, Sekito [2] 1927, and Hofer and Peebles [3] 1947.

**NBS sample.** The sample of cubic cobalt was prepared at NBS by heating cobalt oxalate in a stream of hydrogen at 800 °C for about 10 min. Spectrographic analysis showed the following major impurities: 0.1 to 1.0 percent each of nickel and antimony; and 0.01 to 0.1 percent each of aluminum and iron.

The sample was a dark grey opaque powder. The *d*-values of the three strongest lines are 2.0467, 1.7723, and 1.0688 Å.

**Structural data.** Hull [1] in 1921 determined that the cubic form of cobalt has the copper structure, the space group O<sub>h</sub><sup>5</sup>—Fm3m (No. 225) and 4(Co) per unit cell. There also exists a hexagonal close-packed form of cobalt and the forms commonly occur together.

hkl	Internal Standard W, $a = 3.1648 \text{ \AA}$ ; temp. 25 °C Co $\lambda 1.7889 \text{ \AA}$		
	<i>d</i>	<i>I</i>	<i>a</i>
111	2.0467	100	3.5449
200	1.7723	41	3.5446
220	1.2532	23	3.5446
311	1.0688	29	3.5448
222	1.0233	11	3.5448
Average value of last five lines-----		3.5447	

The lattice constant reported by Hull has been recalculated with a Mo wavelength of 0.711 Å. The lattice constant reported by Sekito could not be converted because the wavelength used for iron radiation was not given.

### Lattice constants

		Å
1921	Hull [1]	3.546
1927	Sekito [2]	3.558
1947	Hofer and Peebles [3]	3.546
1950	Taylor and Floyd [4]	3.5442
1965	National Bureau of Standards, sample at 25 °C	3.5447

The density of cubic cobalt calculated from the NBS lattice constant is 8.788 g/cm<sup>3</sup> at 25 °C.

## Cobalt Diarsenide, CoAs<sub>2</sub> (monoclinic), revised

**Powder data card.** The following pattern is the same pattern shown on No. 11–115 prepared in 1960 by NBS\*; however, it has been reindexed using recent data from the literature.

**Additional published pattern.** Quesnel and Heyding [1] 1962.

**NBS sample.** Minor corrections and additions were made to the original patterns.

**Structural data.** Quesnel and Heyding [1] in 1962 reported that cobalt diarsenide was isostructural with rhodium diphosphide, with the space group C<sub>2h</sub><sup>5</sup>—P2<sub>1</sub>/c (No. 14) and 4(CoAs<sub>2</sub>) per unit cell. However, the unit cell measurements reported by Quesnel and Heyding are not in close agreement with the indexing reported by them.

## Cobalt Silicate, $\text{Co}_2\text{SiO}_4$ (orthorhombic)

Powder data cards. None.

Additional published pattern. Gallitelli and Cola [1] 1954.

NBS sample. The sample of cobalt silicate was obtained from Alfa Inorganics Inc., Beverly, Mass. Spectrographic analysis showed the following major impurities: 0.1 to 1.0 percent aluminum, and 0.01 to 0.1 percent each of calcium, copper, iron, sodium, nickel, lead, titanium, and zircon.

The color of the sample was pink. The indices of refraction could not be determined because the sample was too fine-grained.

The *d*-values of the three strongest lines are 2.469, 2.790, and 3.516 Å.

Structural data. Gallitelli and Cola [1] in 1954 determined that cobalt silicate has the olivine structure, the space group  $D_{2h}^{16}$ —Pmnb (No. 62) and 4( $\text{Co}_2\text{SiO}_4$ ) per unit cell. Ringwood [2] in 1963 determined that the olivine form of cobalt silicate converts to a spinel form at 60 kilobars of pressure and over, at 700 °C.

The density of cobalt silicate calculated from the NBS lattice constants is 4.708 g/cm<sup>3</sup> at 25 °C.

# Cobalt Titanate, $\text{CoTiO}_3$ (trigonal)

**Powder data card.** No. 1-1040, New Jersey Zinc Co.

**Additional published pattern.** Barth and Posnjak [1] 1934.

**NBS sample.** The sample of cobalt titanate, obtained from Alfa Inorganics Inc., Beverly, Mass., was pressed into a pellet and heated  $4\frac{1}{2}$  hr at  $1,350^\circ\text{C}$ . Spectrographic analysis showed the following major impurities: 0.01 to 0.1 percent each of aluminum, calcium, copper, iron, nickel, and silicon.

The color of the sample was dark green. The indices of refraction could not be determined because the sample was too fine-grained.

The  $d$ -values of the three strongest lines are 2.727, 2.5340, and  $1.7114\text{\AA}$ .

**Structural data.** Barth and Posnjak [1] in 1934 determined that cobalt titanate has the ilmenite structure, the space group  $\text{C}_{3\bar{1}}^2$ — $\text{R}\bar{3}$  (No. 148) and  $6(\text{CoTiO}_3)$  per unit hexagonal cell.

The rhombohedral cell reported by Barth and Posnjak was converted to the equivalent hexagonal cell for comparison with the NBS values.

# Cobalt Tungstate, $\text{CoWO}_4$ (monoclinic)

**Powder data cards.** None.

**Additional published pattern.** Broch [1] 1929.

**NBS sample.** The sample of cobalt tungstate was obtained from Alfa Inorganics Inc., Beverly, Mass. Spectrographic analysis showed the following major impurities: 0.01 to 0.1 percent each of nickel and silicon, and 0.001 to 0.01 percent each of calcium, copper, iron, magnesium, manganese, lead, and vanadium.

The sample was a blue opaque powder.

The  $d$ -values of the three strongest lines are 2.916, 3.733, and  $3.608 \text{ \AA}$ .

**Structural data.** Broch [1] in 1929 determined that cobalt tungstate is isostructural with magnesium tungstate, with the space group  $\text{C}_{2h}^4$ — $\text{P}2/a$  (No. 13) and  $2(\text{CoWO}_4)$  per unit cell. Since monoclinic doublets were not seen in the NBS pattern, it was indexed as orthorhombic.

# Dysprosium Vanadate, $\text{DyVO}_4$ (tetragonal)

**Powder data cards.** None.

**Additional published patterns.** None.

**NBS sample.** The sample of dysprosium vanadate was prepared at NBS by adding hot sodium orthovanadate solution to a hot acidic solution of dysprosium chloride. After the sample was dried at 110 °C for 1 hr, it was heated for 20 min at 700 °C to improve the crystallinity. Spectrographic analysis showed the following impurities: 0.1 to 1.0 percent iron; 0.01 to 0.1 percent each of aluminum, calcium, and silicon; and 0.001 to 0.01 percent each of copper, manganese, and antimony. Rare-earth impurities were less than 0.1 percent of total rare-earth content.

The color of the sample was brown. The indices of refraction could not be determined because the sample was too fine-grained.

The  $d$ -values of the three strongest lines are 3.571, 2.675, and 1.837 Å.

**Structural data.** Milligan, Watt, and Rachford [1] in 1949 determined that dysprosium vanadate has the zircon structure, the space group  $D_{4h}^{19}$ — $I\bar{4}_1/a$  (No. 141) and 4( $\text{DyVO}_4$ ) per unit cell.

- [1] W. O. Milligan, L. M. Watt, and H. H. Rachford, X-ray diffraction studies on heavy metal orthovanadates, *J. Phys. Chem.* **53**, 227–234 (1949).

The density of europium(III) vanadate calculated from the NBS lattice constants is 5.316 g/cm<sup>3</sup> at 25 °C.

# Gadolinium Arsenate, $\text{GdAsO}_4$ (tetragonal)

**Powder data cards.** None.

**Additional published patterns.** None.

**NBS sample.** The sample of gadolinium arsenate was prepared at NBS from a water solution of gadolinium trichloride and arsenic pentoxide and heated for 30 min at 900 °C. Spectrographic analysis showed the following major nonrare-earth impurities: 0.01 to 0.1 percent each of aluminum and antimony, and 0.001 to 0.01 percent each of iron, magnesium, lead, silicon, and titanium. Rare-earth impurities were less than 0.1 percent of total rare-earth content.

The sample is colorless. The indices of refraction could not be determined because the sample was too fine-grained.

The  $d$ -values of the three strongest lines are 3.566, 2.689, and 1.8395 Å.

**Structural data.** Durif and Forrat [1] in 1957 determined that gadolinium arsenate has the zircon structure with the space group  $D_{4h}^{19}$ — $I\bar{4}_1/\text{amd}$  (No. 141) and 4( $\text{GdAsO}_4$ ) per unit cell.

# Holmium Vanadate, $\text{HoVO}_4$ (tetragonal)

Powder data cards. None.

Additional published patterns. None.

**NBS sample.** The sample of holmium vanadate was precipitated at NBS by adding hot sodium orthovanadate solution to a hot acidic solution of holmium chloride. The sample was first dried at 110 °C for 1 hr. To improve the crystallinity, the sample was heated at 600 °C for 2 hr. Spectrographic analysis showed the following major impurities: 0.01 to 0.1 percent each of iron and silicon, and 0.001 to 0.01 percent each of silver, aluminum, calcium, copper, magnesium, and antimony. Rare-earth impurities were less than 0.1 percent of total rare-earth content.

The color of the sample was dark brown. The indices of refraction could not be determined because the sample was too fine.

The  $d$ -values of the three strongest lines are 3.564, 2.668, and 1.8311 Å.

**Structural data.** Milligan and Vernon [1] in 1952 determined that holmium vanadate has the zircon structure, the space group  $D_{4h}^{19}$ — $I4_1/\text{amd}$  (No. 141) and 4( $\text{HoVO}_4$ ) per unit cell.

## Lattice constants

# Iridium Dioxide, $\text{IrO}_2$ (tetragonal)

**Powder data cards.** None.

**Additional published patterns.** None.

**NBS sample.** The sample of iridium dioxide was obtained from K&K Laboratories Inc., Jamaica, N.Y. It was heated in an evacuated sealed Vycor tube for 6 hrs at 900 °C. Spectrographic analysis showed the following major impurities: 0.01 to 0.1 percent each of sodium, lead, and platinum.

The sample was a black opaque powder.

The *d*-values of the three strongest lines are 3.178, 2.582, and 1.6960 Å.

**Structural data.** Goldschmidt [1] in 1926 determined that iridium dioxide has the rutile structure, the space group  $D_{4h}^{14}$ — $P4_2/mnm$  (No. 136), and 2( $\text{IrO}_2$ ) per unit cell.

*Lattice constants*

# Lead Boron Oxide, $\text{PbB}_4\text{O}_7$ (orthorhombic)

**Powder data cards.** None.

**Additional published patterns.** None.

**NBS sample.** The sample of lead boron oxide was prepared at NBS from lead oxide and boric acid. It was heated at temperatures below the melting point (768 °C), ground, and then alternately reheated and reground several times. Spectrographic analysis showed the following major impurities: 0.01 to 0.1 percent silicon and 0.001 to 0.01 percent each of aluminum, iron, magnesium, and nickel.

The sample was colorless. The indices of refraction could not be determined because the sample was too fine-grained.

The *d*-values of the three strongest lines are 2.673, 3.952, and 4.122 Å.

**Structural data.** Block, Perloff, and Weir [1] in 1964 determined that lead boron oxide has the space group  $C_{2v}^7$ — $Pnm2_1$  (No. 31) and 2( $\text{PbB}_4\text{O}_7$ ) per unit cell.

# Lithium Phosphate, low form (lithiophosphate), $\text{Li}_3\text{PO}_4$ (orthorhombic) revised

This compound was described in earlier work [1] from this laboratory. Recently the structure of the low form was determined by Keffer, Mighell, Mauer, Swanson, and Block [2]. The following pattern is intended to replace the earlier one in Monograph 25, Section 3.

**Powder data card.** No. 12-230, Fisher [3] 1958.

**Additional published patterns.** Matias and Bondareva [4] 1957 and National Bureau of Standards [1] 1964.

**NBS sample.** The sample of lithium phosphate was obtained from the City Chemical Co., New York, N.Y. Spectrographic analysis showed the following major impurities: 0.1 to 1.0 percent calcium; 0.01 to 0.1 percent each of aluminum, sodium, and strontium; and 0.001 to 0.01 percent each of barium, iron, magnesium, and silicon.

The sample was colorless. Two indices of refraction are  $N_\alpha = 1.550$  and  $N_\gamma = 1.538$ . It is optically negative with a large  $2V$ .  $N_\beta$  could not be determined because of the crystal shape.

The  $d$ -values of the three strongest lines are 3.973, 3.797, and 2.640 Å.

**Structural data.** Keffer, Swanson, Mighell, Mauer, and Block [2] in 1964 determined that low form lithium phosphate has the space group  $C_{2v}^7-\text{Pmn}2_1$  (No. 31) and 2( $\text{Li}_3\text{PO}_4$ ) per unit cell.

### Lithium Sulfate Monohydrate, $\text{Li}_2\text{SO}_4 \cdot \text{H}_2\text{O}$ (monoclinic)

**Powder data card.** No. 1-0425, Hanawalt, Rinn, and Frevel [1] 1938.

**Additional published patterns.** None.

**NBS sample.** The sample of lithium sulfate monohydrate was prepared at NBS from lithium metal and sulfuric acid, using enough heat to fume off the excess acid. Spectrographic analysis showed the following major impurities: 0.01 to 0.1 percent each of silver, calcium, sodium, and tungsten; and 0.001 to 0.01 percent each of aluminum, barium, iron, potassium, magnesium, silicon, and strontium.

The sample was colorless and optically negative. The indices of refraction are  $N_\alpha=1.460$ ,  $N_\beta=1.477$ , and  $N_\gamma=1.487$ ;  $2V$  is large.

The *d*-values of the three strongest lines are 5.084, 4.133, and 3.559 Å.

**Structural data.** Ziegler [2] in 1934 determined that lithium sulfate monohydrate has the space group  $C_2^2-P2_1$  (No. 4) with 2( $\text{Li}_2\text{SO}_4 \cdot \text{H}_2\text{O}$ ) per unit cell.

# Magnesium Aluminum Silicate (pyrope), $\text{Mg}_3\text{Al}_2(\text{SiO}_4)_3$ (cubic)

**Powder data cards.** None.

**Additional published patterns.** None.

**NBS sample.** The sample of pyrope was obtained from Dr. F. R. Boyd [5] at the Geophysical Laboratory, Carnegie Institute, Washington, D.C. The sample was prepared from magnesium silicate and aluminum silicate glasses at 40 kilobars of pressure and at 1,400 °C for 1 hr. Spectrographic analysis showed the following major impurities: 0.1 to 1.0 percent each of bismuth and iron; and 0.01 to 0.1 percent each of calcium, nickel, titanium and vanadium.

The sample was colorless. The index of refraction is 1.702.

The *d*-values of the three strongest lines are 2.562, 2.865, and 1.5312 Å.

**Structural data.** Menzer [1] in 1926 determined that pyrope was an end-member of the garnet group, having the space group  $O_h^{10}$ —Ia3d (No. 230) with  $8[\text{Mg}_3\text{Al}_2(\text{SiO}_4)_3]$  per unit cell.

The density of pyrope calculated from the NBS lattice constant is  $3.563 \text{ g/cm}^3$  at 25 °C.

## Magnesium Boron Oxide, $\text{Mg}_2\text{B}_2\text{O}_5$ (triclinic)

**Powder data cards.** No. 3-0841, Dow Chemical Co., Midland, Mich. This card is called magnesium metaborate,  $\text{MgO}\cdot\text{B}_2\text{O}_3$ ; however, the data is comparable to ours. Two other cards, Nos. 10-327 and 11-427, by Takéuchi [1] 1952 give patterns for a monoclinic and the triclinic form.

**Additional published patterns.** None.

**NBS sample.** The sample of magnesium boron oxide was prepared at NBS by C. E. Weir from a slurry of magnesium carbonate and boric acid in water. The sample was alternately fired and ground several times reaching a maximum temperature of 1,150 °C. Spectrographic analysis showed the following major impurities: 0.001 to 0.01 percent each of barium, beryllium, calcium, iron, silicon, and strontium.

The sample was colorless. The indices of refraction could not be determined because the sample was too fine-grained.

The  $d$ -values of the three strongest lines are 2.579, 2.536, and 2.009 Å.

**Structural data.** Block, Burley, Perloff and Mason [2] in 1959 determined that magnesium boron oxide is isomorphous with cobalt boron oxide having the space group  $C_1^1$ —P1 (No. 2) with  $2(\text{Mg}_2\text{B}_2\text{O}_5)$  per unit cell.

The density of magnesium boron oxide calculated from NBS lattice constants is 2.910 g/cm<sup>3</sup> at 25 °C.

# Metaboric Acid, $\text{HBO}_2$ (cubic)

**Powder data cards.** None. Nos. 1-0409 and 9-15 are for other modifications of metaboric acid.

**Additional published patterns.** None.

**NBS sample.** The sample of cubic metaboric acid was prepared at NBS by Kilday and Prosen [1] 1964 by holding orthoboric acid in a vacuum with orthorhombic metaboric acid followed by heating at 180 °C. Spectrographic analysis of the starting materials showed no impurity greater than 0.001 percent.

The sample was colorless. The refractive index is 1.616.

The  $d$ -values of the three strongest lines are 4.442, 1.939, and 3.627 Å.

**Structural data.** Zachariasen [2] in 1963 determined that cubic metaboric acid has the space group  $T_d^4$ —P43n (No. 218) with 24( $\text{HBO}_2$ ) per unit cell. Three other forms of metaboric acid have been reported in the literature: a monoclinic, an orthorhombic, and a tetragonal.

## Neodymium Arsenate, $\text{NdAsO}_4$ (monoclinic)

**Powder data cards.** None.

**Additional published patterns.** None.

**NBS sample.** The sample of neodymium arsenate was precipitated at NBS from a water solution of arsenic pentoxide and neodymium trichloride. It was heated 1 hr at 930 °C. Spectrographic analysis showed the following major nonrare-earth impurities: 0.01 to 0.1 percent antimony and 0.001 to 0.01 percent each of aluminum, calcium, iron, lead, and silicon. Rare-

earth impurities were less than 0.1 percent of total rare-earth content.

The sample was colorless. The indices of refraction could not be determined because the sample was too fine-grained.

The *d*-values of the three strongest lines are 3.129, 2.941, and 3.331 Å.

**Structural data.** Schwarz [1] in 1963 determined that neodymium arsenate has the buttonite structure, the space group  $C_{2h}^5$ — $P2_1/n$  (No. 14), and 4( $\text{NdAsO}_4$ ) per unit cell.

# Neodymium Vanadate, NdVO<sub>4</sub> (tetragonal)

**Powder data card.** No. 6-0217, Milligan, Watt, and Rachford [1] 1949.

**Additional published patterns.** None.

**NBS sample.** The sample of neodymium vanadate was prepared at NBS by adding a hot solution of sodium orthovanadate to a hot acidic solution of neodymium chloride. After the sample was dried at 110 °C for 1 hr, it was heated for 20 min at 700 °C to improve the crystallinity. Spectrographic analysis showed the following major impurities: 0.1 to 1.0 percent silicon and 0.001 to 0.01 percent each of aluminum, calcium, copper, and magnesium. Rare-earth impurities were less than 0.1 percent of total rare-earth content.

The color of the sample was pale blue. The indices of refraction could not be determined because the sample was too fine-grained.

The *d*-values of the three strongest lines are 3.664, 2.732, and 1.881 Å.

**Structural data.** Milligan, Watt, and Rachford [1] in 1949 determined that neodymium vanadate has the zircon structure, the space group D<sub>4h</sub><sup>19</sup>—I4<sub>1</sub>/amd (No. 141) and 4(NdVO<sub>4</sub>) per unit cell.

## Lattice constants

# Potassium Acid Phthalate, C<sub>6</sub>H<sub>4</sub>(COOH)(COOK) (orthorhombic)

**Powder data card.** No. 1-0020, Hanawalt, Rinn, and Frevel [1] 1938.

**Additional published patterns.** None.

**NBS sample.** The sample of potassium acid

phthalate was obtained from J. T. Baker Chemical Co., Phillipsburg, N.J. Spectrographic analysis showed the following major impurities: 0.001 to 0.01 percent each of aluminum, sodium, and rubidium.

# Potassium Acid Phthalate, $C_6H_4(COOH)(COOK)$ (orthorhombic)—Continued

## Lattice constants

		<i>a</i>	<i>b</i>	<i>c</i>
1957	Okaya and Pepinsky [2]	9.61	13.26	6.47
1963	Bearden and Huffman [3]	9.62	13.3164	6.47
1965	National Bureau of Standards, sample at 25 °C	9.607	13.312	6.475

The sample is colorless and optically negative.

The refractive indices are

$$N_\alpha = 1.500, N_\beta = 1.653, N_\gamma = 1.660, 2V \approx 10^\circ.$$

The *d*-values of the three strongest lines are 13.32, 4.982, and 4.030 Å.

**Structural data.** Okaya and Pepinsky [2] in 1957 reported that potassium acid phthalate has the space group\*  $D_2^3$ — $P2_122_1$  (No. 18) with 4[ $C_6H_4(COOH)(COOK)$ ] per unit cell.

The density of potassium acid phthalate calculated from the NBS lattice constants is 1.638 g/cm<sup>3</sup> at 25 °C.

# Praseodymium Arsenate, $\text{PrAsO}_4$ (monoclinic)

**Powder data cards.** None.

**Additional published patterns.** None.

**NBS sample.** The sample of praseodymium arsenate was precipitated at NBS from a water solution of arsenic pentoxide and praseodymium trichloride. It was dried at 110 °C. Spectrographic analysis showed the following major impurities: 0.01 to 0.1 percent antimony and 0.001 to 0.01 percent each of calcium, iron, magnesium, lead, and silicon. Rare-earth impurities were less than 0.1 percent of total rare-earth content.

The color of the sample was light green. The indices of refraction could not be determined because the sample was too fine-grained.

The  $d$ -values of the three strongest lines are 3.141, 2.953, and 3.349 Å.

**Structural data.** Schwarz [1] in 1963 reported that praseodymium arsenate is isostructural with huttonite with the space group  $\text{C}_{2h}^5$ — $\text{P}2_1/\text{n}$  (No. 14) and 4( $\text{PrAsO}_4$ ) per unit cell.

The density of praseodymium arsenate calculated from the NBS lattice constants is 5.804 g/cm³ at 25 °C.

# Samarium Oxide, $\text{Sm}_2\text{O}_3$ (cubic)

**Powder data cards.** None. Nos. 9-201, 11-412, and 13-244 are for the monoclinic B form of samarium oxide.

**Additional published patterns.** Zachariasen [1] 1927.

**NBS sample.** The sample of samarium oxide was obtained from the Lindsay Chemical Co., West Chicago, Ill. The cubic form was obtained when the sample was heated at 800 °C for 19 hrs. The analysis by Lindsay Chemical Co. showed the rare-earth impurities to be less than 0.1 percent of total rare-earth content.

The sample was cream colored. The index of refraction is about 1.97.

The *d*-values of the three strongest lines are 3.155, 1.9317, and 2.731 Å.

**Structural data.** Zachariasen [1] in 1927 determined that the C-modification of samarium oxide has the manganese dioxide structure, the space group  $T_h^1$ —Ia3 (No. 206) with 16( $\text{Sm}_2\text{O}_3$ ) per unit cell.

### *Lattice constants*

		Å
1925	Goldschmidt, Barth, and Ulrich [2]	10.87
1927	Zachariasen [1]	10.89
1939	Bommer [3]	10.915
1954	Templeton and Dauber [4]	10.932
1954	Brauer and Gradinger [5]	10.928
1965	National Bureau of Standards, sample at 25 °C	10.927

The density of samarium oxide calculated from NBS lattice constant is 7.100 g/cm<sup>3</sup> at 25 °C.

# Scandium Arsenate, $\text{ScAsO}_4$ (tetragonal)

**Powder data cards.** None.

**Additional published patterns.** None.

**NBS sample.** The sample of scandium arsenate was prepared at NBS from a water solution of arsenic pentoxide and scandium trichloride. It was heated 30 min at 900 °C. Spectrographic analysis showed the following major impurities: 0.01 to 0.1 percent each of antimony, silicon, and vanadium; and 0.001 to 0.01 percent each of aluminum, chromium, copper, iron, magnesium, lead and tin.

The sample was colorless. The indices of refraction could not be determined because the sample was too fine-grained.

The  $d$ -values of the three strongest lines are 3.354, 2.569, and 1.742 Å.

**Structural data.** No reference to the structure of scandium arsenate was found, but it is apparently isostructural with yttrium arsenate with the space group  $D_{4h}^{19}$ — $I4_1/\text{amd}$  (No. 141) and 4( $\text{ScAsO}_4$ ) per unit cell.

# Strontium Boron Oxide, $\text{SrB}_4\text{O}_7$ (orthorhombic)

**Powder data cards.** None.

**Additional published patterns.** None.

**NBS sample.** The sample of strontium boron oxide was prepared at NBS from strontium carbonate and boric acid. It was heated to 1,000 °C, ground, and then alternately reheated and re-

ground several times. Spectrographic analysis showed the following major impurities: 0.01 to 0.1 percent each of barium, calcium, and silicon; and 0.001 to 0.01 percent each of aluminum, iron, and magnesium.

# Strontium Boron Oxide, $\text{SrB}_4\text{O}_7$ (orthorhombic)—Continued

The sample was colorless. The indices of refraction could not be determined because the sample was too fine-grained.

The  $d$ -values of the three strongest lines are 2.657, 2.015, and 2.729 Å.

**Structural data.** Block, Perloff, and Weir [1] in 1964 determined that strontium boron oxide has the space group  $\text{C}_{2v}^7$ — $\text{Pnm}2_1$  (No. 31) and 2( $\text{SrB}_4\text{O}_7$ ) per unit cell.

## Lattice constants

		$a$	$b$	$c$
1964	Block, Perloff, and Weir [1]	4.431	10.706	4.237
1965	National Bureau of Standards, sample at 25 °C	4.4263 $\pm 0.0002$	10.7074 $\pm 0.0005$	4.2338 $\pm 0.0002$

The density of strontium boron oxide calculated from the NBS lattice constants is 4.019 g/cm<sup>3</sup> at 25 °C.

# Tin Arsenide, SnAs (cubic)

**Powder data cards.** None.

**Additional published patterns.** Willott and Evans [1] 1934.

**NBS sample.** The sample of tin arsenide was prepared at NBS in a solid state reaction by heating a mixture of arsenic and tin in an evacuated Pyrex tube at 500 °C. Spectrographic analysis showed the following major impurities: 0.01 to 0.1 percent lead, and 0.001 to 0.01 percent each of aluminum, antimony, bismuth, copper, indium, iron, magnesium, nickel, and silicon.

The sample was a gray opaque powder.

The  $d$ -values of the three strongest lines are 2.862, 2.024, and 1.652 Å.

**Structural data.** Goldschmidt [2] in 1928 determined that tin arsenide has the sodium chloride structure, the space group  $\text{O}_h^5$ — $\text{Fm}3\text{m}$  (No. 225) and 4(SnAs) per unit cell.

## Lattice constants

# Ytterbium Arsenate, $\text{YbAsO}_4$ (tetragonal)

**Powder data cards.** None.

**Additional published patterns.** None.

**NBS sample.** The sample of ytterbium arsenate was precipitated at NBS from a water solution of arsenic pentoxide and ytterbium trichloride. It was dried 1 hr at 880 °C. Spectrographic analysis showed the following major nonrare-earth impurities: 0.01 to 0.1 percent each of antimony and titanium and 0.001 to 0.01 percent each of aluminum, calcium, iron, nickel, lead, and silicon. Rare-earth impurities were less than 0.1 percent of total rare-earth content.

The sample was colorless. The indices of refraction could not be determined because the sample was too fine-grained.

The  $d$ -values of the three strongest lines are 3.486, 2.6375, and 1.8004 Å.

**Structural data.** Durif and Forrat [1] in 1957 determined that ytterbium arsenate has the zircon structure with the space group  $D_{4h}^{19}$ —I4<sub>1</sub>/amd (No. 141) and 4( $\text{YbAsO}_4$ ) per unit cell.

### *Lattice constants*

The color of the sample was off-white. The indices of refraction could not be determined because the sample was too fine-grained.

The *d*-values of the three strongest lines are 3.206, 2.694, and 1.9509 Å.

**Structural data.** Stahl [1] in 1943 determined that zinc antimony oxide has the space group  $D_{4h}^{13}$ —P4/mbc (No. 135) with 4( $\text{ZnSb}_2\text{O}_4$ ) per unit cell.

**Additional published pattern.** Iandelli and Botti [8] 1937.

**Structural data.** Iandelli and Botti [8] in 1937 determined that antimony cerium is isomorphous with sodium chloride with the space group  $O_h^3$ —Fm3m (No. 225) and 4(CeSb) per unit cell. The atoms occupy the special positions:

Ce: 0 0 0  
Sb:  $\frac{1}{2}$   $\frac{1}{2}$   $\frac{1}{2}$ .

### Lattice constants

		<i>Å</i>
1937	Iandelli and Botti [8]	6.412
1963	Kuz'min and Nikitina [32]	6.41

The lattice constant used in this calculated pattern is  $a=6.412 \text{ \AA}$ .

No temperature correction was included.

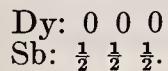

The calculated *d*-values of the three strongest lines are 3.21, 2.27, and 1.434 Å.

The calculated density is 6.598 g/cm<sup>3</sup>.

## Antimony Dysprosium, DySb (cubic)

### Calculated Pattern

Brixner [30] in 1960 determined that antimony dysprosium is isomorphous with sodium chloride with the space group  $O_h^5$ —Fm3m (No. 225) and 4(DySb) per unit cell. The atoms occupy the special positions:

Brixner [30] reports the lattice constant  $a=6.153\ \text{\AA}$ .

No temperature correction was included.

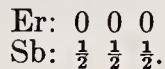

The calculated  $d$ -values of the three strongest lines are 3.08, 2.18, and 1.376  $\text{\AA}$ .

The density of antimony dysprosium calculated from the constant of Brixner is 8.104 g/cm<sup>3</sup>.

## Antimony Erbium, ErSb (cubic)

### Calculated Pattern

Brixner [30] in 1960 determined that antimony erbium is isomorphous with sodium chloride with the space group  $O_h^5$ —Fm3m (No. 225) and 4(ErSb) per unit cell. The atoms occupy the special positions:

Brixner [30] reports the lattice constant  $a=6.106\ \text{\AA}$ .

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 3.05, 2.16, and 1.365  $\text{\AA}$ .

The density of antimony erbium calculated from the constant of Brixner is 8.432 g/cm<sup>3</sup>.

## Bismuth Cerium, BiCe (cubic)

### Calculated Pattern

Additional published pattern. Iandelli and Botti, [10] 1937.

Structural data. Iandelli and Botti [10] in 1937 determined that bismuth cerium is isomorphous with sodium chloride with the space group  $O_h^5$ —Fm3m (No. 225) and 4(BiCe) per unit cell. The atoms occupy the special positions:

Bi: 0 0 0  
Ce:  $\frac{1}{2} \frac{1}{2} \frac{1}{2}$ .

The lattice constant used in this calculated pattern is  $a=6.500 \text{ \AA}$ , as reported by Iandelli and Botti [10].

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 3.25, 2.30, and 1.453  $\text{\AA}$ .

The calculated density is 8.443 g/cm<sup>3</sup>.

### Calculated Pattern

## Cobalt Iodide, CoI<sub>2</sub> (hexagonal)

### Calculated Pattern

Ferrari and Giorgi [4] in 1929 determined that cobalt iodide is isomorphous with cadmium iodide with the space group  $D_{3d}^3$ —P $\bar{3}$ m1 (No. 164) and 1(CoI<sub>2</sub>) per unit cell. The atoms occupy the special positions:

Ferrari and Giorgi [4] report the lattice constants  $a=3.97 \text{ \AA}$  and  $c=6.66 \text{ \AA}$ .

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 3.06, 2.39 and 1.98  $\text{\AA}$ .

The density of cobalt iodide calculated from the constants of Ferrari and Giorgi is 5.712 g/cm<sup>3</sup>.

### Calculated Pattern Copper $\lambda$

## Dysprosium Arsenide, DyAs (cubic)

### Calculated Pattern

Brixner [30] in 1960 determined that dysprosium arsenide is isomorphous with sodium chloride with the space group  $O_h^5$ —Fm3m (No. 225) and 4(DyAs) per unit cell. The atoms occupy the special positions:

$$\begin{array}{l} \text{Dy: } 0 \ 0 \ 0 \\ \text{As: } \frac{1}{2} \ \frac{1}{2} \ \frac{1}{2}. \end{array}$$

Brixner [30] reports the lattice constant  $a=5.780 \text{ \AA}$ .

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 2.89, 2.04, and 3.34  $\text{\AA}$ .

The density of dysprosium arsenide calculated from the constant of Brixner is 8.166 g/cm<sup>3</sup>.

### Calculated Pattern

# Lanthanum Arsenide, LaAs (cubic)

## Calculated Pattern

**Additional published pattern.** Iandelli and Botti [8] 1937.

**Structural data.** Iandelli and Botti [8] in 1937 determined that lanthanum arsenide is isomorphous with sodium chloride with the space group O<sub>h</sub><sup>5</sup>—Fm3m (No. 225) and 4(LaAs) per unit cell. The atoms occupy the special positions:

The lattice constant used in this calculated pattern is  $a=6.137 \text{ \AA}$ , as reported by Iandelli and Botti [8].

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 3.07, 2.17, and 1.372  $\text{\AA}$ .

The calculated density is 6.144 g/cm<sup>3</sup>.

## Calculated Pattern

## Lanthanum Nitride, LaN (cubic)

### Calculated Pattern

**Additional published patterns.** Iandelli and Botti [7] 1937, and Young and Ziegler [15] 1952.

**Structural data.** Iandelli and Botti [7] in 1937 determined that lanthanum nitride is isomorphous with sodium chloride with the space group  $O_h^5$ —Fm3m (No. 225) and 4(LaN) per unit cell. The atoms occupy the special positions:

La: 0 0 0  
N:  $\frac{1}{2} \frac{1}{2} \frac{1}{2}$ .

### Lattice constants

		$\text{\AA}$
1937	Iandelli and Botti [7]	5.286
1952	Young and Ziegler [15]	5.295
1956	Klemm and Winkelmann [24]	5.30
1963	Lyutaya and Samsonov [33]	5.302

The lattice constant used in this calculated pattern is the average value  $a=5.30 \text{ \AA}$ .

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 3.06, 2.65, and 1.87  $\text{\AA}$ .

The calculated density is 6.822 g/cm<sup>3</sup>.

### Calculated Pattern Copper $\lambda$

$hkl$	$d$	Peak height	
		$I$	
111	$\text{\AA}$		
111	3.06	100	
200	2.65	74	
220	1.87	46	
311	1.60	37

642	.810	17	
731	.789	2	

## Lutetium Nitride, LuN (cubic)

### Calculated Pattern

Klemm and Winkelmann [24] in 1956 determined that lutetium nitride is isomorphous with sodium chloride with the space group  $O_h^5$ —Fm3m (No. 225) and 4 (LuN) per unit cell. The atoms occupy the special positions:

$$\begin{array}{l} \text{Lu: } 0 \ 0 \ 0 \\ \text{N: } \frac{1}{2} \ \frac{1}{2} \ \frac{1}{2} \end{array}$$

Klemm and Winkelmann [24] report the lattice constant  $a=4.766 \text{ \AA}$ .

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 2.75, 2.38, and 1.685  $\text{\AA}$ .

The density of lutetium nitride calculated from the constant of Klemm and Winkelmann is 11.59 g/cm<sup>3</sup>.

### Calculated Pattern Copper $\lambda$

$hkl$	$d$	Peak height	
		$I$	
111	2.75 $\text{\AA}$	100	
200	2.38	67	
220	1.685	40

531	.806	20	
600	.794	16	

## Magnesium Bromide, MgBr<sub>2</sub> (hexagonal)

### Calculated Pattern

Ferrari and Giorgi [3] in 1929 determined that magnesium bromide is isomorphous with cadmium iodide with the space group  $D_{3d}^3$ —P3m1 (No. 164) and 1(MgBr<sub>2</sub>) per unit cell. The atoms occupy the special positions:

$$\begin{array}{l} \text{Mg: } 0 \ 0 \ 0 \\ \text{Br: } \frac{1}{3} \ \frac{2}{3} \ u; \ \frac{2}{3} \ \frac{1}{3} \bar{u} \end{array} \quad \text{with } u=0.25.$$

Ferrari and Giorgi [3] report the lattice constants  $a=3.822 \text{ \AA}$  and  $c=6.269 \text{ \AA}$ .

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 2.93, 2.28, and 1.91  $\text{\AA}$ .

The density of magnesium bromide calculated from the constants of Ferrari and Giorgi is 3.855 g/cm<sup>3</sup>.

### Calculated Pattern Copper $\lambda$

$hkl$	$d$	Peak height

300	1.103	3	

## Manganese Bromide, $\text{MnBr}_2$ (hexagonal)

### Calculated Pattern

Ferrari and Giorgi [3] in 1929 determined that manganese bromide is isomorphous with cadmium iodide with the space group  $D_{3d}^3$ — $P\bar{3}m1$  (No. 164) and 1( $\text{MnBr}_2$ ) per unit cell. The atoms occupy the special positions:

$$\begin{aligned}\text{Mn: } & 0 \ 0 \ 0 \\ \text{Br: } & \frac{1}{3} \ \frac{2}{3} \ u; \ \frac{2}{3} \ \frac{1}{3} \bar{u} \quad \text{with } u=0.25.\end{aligned}$$

Ferrari and Giorgi [3] report the lattice constants  $a=3.828 \text{ \AA}$  and  $c=6.200 \text{ \AA}$ .

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 2.92, 2.26, and 1.91  $\text{\AA}$ .

The density of manganese bromide calculated from the constants of Ferrari and Giorgi is 4.532 g/cm<sup>3</sup>.

### Calculated Pattern

Copper  $\lambda$

$hkl$	$d$	Peak height	
		$I$	
001	6.20 $\text{\AA}$	17

204	1.132	<1	
300	1.105	3	
301	1.088	<1	

## Manganese Iodide, $\text{MnI}_2$ (hexagonal)

### Calculated Pattern

Ferrari and Giorgi [4] in 1929 determined that manganese iodide is isomorphous with cadmium iodide with the space group  $D_{3d}^3$ — $P\bar{3}m1$  (No. 164) and 1( $\text{MnI}_2$ ) per unit cell. The atoms occupy the special positions:

$$\begin{aligned}\text{Mn: } & 0 \ 0 \ 0 \\ \text{I: } & \frac{1}{3} \ \frac{2}{3} \ u; \ \frac{2}{3} \ \frac{1}{3} \bar{u} \quad \text{with } u=0.25.\end{aligned}$$

Ferrari and Giorgi [4] report the lattice constants  $a=4.17 \text{ \AA}$  and  $c=6.83 \text{ \AA}$ .

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 3.19, 2.48, and 2.08  $\text{\AA}$ .

The density of magnanese iodide calculated from the constants of Ferrari and Giorgi is 4.984 g/cm<sup>3</sup>.

### Calculated Pattern

## Neodymium Arsenide, NdAs (cubic)

### Calculated Pattern

**Additional published pattern.** Iandelli and Botti [9] 1937.

**Structural data.** Iandelli and Botti [9] in 1937 determined that neodymium arsenide is isomorphous with sodium chloride, with the space group  $O_h^5$ —Fm3m (No. 225) and 4(NdAs) per unit cell. The atoms occupy the special positions:

Nd: 0 0 0  
As:  $\frac{1}{2} \frac{1}{2} \frac{1}{2}$ .

The lattice constant used in this calculated pattern is  $a=5.970 \text{ \AA}$ , as reported by Iandelli and Botti [9].

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 2.98, 2.11, and 1.335  $\text{\AA}$ .

The calculated density is 6.841 g/cm<sup>3</sup>.

### Calculated Pattern Copper $\lambda$

$hkl$	$d$	Peak height	$I$
		$\text{\AA}$

640	.828	9	
642	.798	18	

## Neptunium Nitride, NpN (cubic)

### Calculated Pattern

Zachariasen [14] in 1949 determined that neptunium nitride is isomorphous with sodium chloride with the space group  $O_h^5$ —Fm3m (No. 225) and 4(NpN) per unit cell. The atoms occupy the special positions:

Np: 0 0 0  
N:  $\frac{1}{2} \frac{1}{2} \frac{1}{2}$ .

Zachariasen [14] reports the lattice constant  $a=4.897 \text{ \AA}$ .

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 2.83, 2.45, and 1.731  $\text{\AA}$ .

The density of neptunium nitride calculated from the constant of Zachariasen is 14.20 g/cm<sup>3</sup>.

### Calculated Pattern Copper $\lambda$

$hkl$	$d$	Peak height	$I$
		$\text{\AA}$	
111	2.83	100

# Potassium Hydroxide, KOH, at 300 °C (cubic)

## Calculated Pattern

**Structural data.** Teichert and Klemm [13] in 1939 determined that potassium hydroxide at 300 °C is isomorphous with sodium chloride with the space group  $O_h^5$ —Fm3m (No. 225) and 4(KOH) per unit cell. The atoms occupy the special positions:

K: 0 0 0  
O:  $\frac{1}{2}$   $\frac{1}{2}$   $\frac{1}{2}$   
H: undefined.

The lattice constant used in this calculated pattern is  $a=5.79 \text{ \AA}$ , as reported by Teichert and Klemm [13].

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 2.90, 2.05, and 3.34  $\text{\AA}$ .

The calculated density is 1.920 g/cm<sup>3</sup>.

## Calculated Pattern Copper $\lambda$

$hkl$	$d$	Peak height
		$I$
111	3.34	25

# Praseodymium Arsenide, PrAs (cubic)

## Calculated Pattern

**Additional published pattern.** Iandelli and Botti [8] 1937.

**Structural data.** Iandelli and Botti [8] in 1937 determined that praseodymium arsenide is isomorphous with sodium chloride with the space group  $O_h^5$ —Fm3m (No. 225) and 4(PrAs) per unit cell. The atoms occupy the special positions:

Pr: 0 0 0  
As:  $\frac{1}{2} \frac{1}{2} \frac{1}{2}$ .

The lattice constant used in this calculated pattern is  $a=6.009 \text{ \AA}$ , as reported by Iandelli and Botti [8].

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 3.00, 2.12, and 1.344  $\text{\AA}$ .

The calculated density is 6.607 g/cm<sup>3</sup>.

## Calculated Pattern Copper $\lambda$

# Praseodymium Sulfide, PrS (cubic)

## Calculated Pattern

**Structural data.** Iandelli [20] in 1955 determined that praseodymium sulfide is isomorphous with sodium chloride, with the space group  $O_h^5$ —Fm3m (No. 225) and 4(PrS) per unit cell. The atoms occupy the special positions:

Pr: 0 0 0  
S:  $\frac{1}{2} \frac{1}{2} \frac{1}{2}$ .

## Lattice constants

		$\text{\AA}$
1955	Iandelli [20]	5.739
1956	Picon and Patrie [25]	5.747

The lattice constant used in this calculated pattern is the average value  $a=5.743 \text{ \AA}$ .

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 2.87, 3.31, and 2.03  $\text{\AA}$ .

The calculated density is 6.065 g/cm<sup>3</sup>.

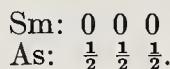

## Calculated Pattern Copper $\lambda$

## Samarium Arsenide, SmAs (cubic)

### Calculated Pattern

Iandelli [23] in 1956 determined that samarium arsenide is isomorphous with sodium chloride with the space group  $O_h^5$ —Fm3m (No. 225) and 4(SmAs) per unit cell. The atoms occupy the special positions:

Iandelli [23] reports the lattice constant  $a=5.921 \text{ \AA}$ .

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 2.96, 2.09, and 1.324  $\text{\AA}$ .

The density of samarium arsenide calculated from the constant of Iandelli is 7.208 g/cm<sup>3</sup>.

## Scandium Arsenide, ScAs (cubic)

### Calculated Pattern

Brixner [30] in 1960 determined that scandium arsenide is isomorphous with sodium chloride with the space group  $O_h^5$ —Fm3m (No. 225) and 4(ScAs) per unit cell. The atoms occupy the special positions:

Brixner [30] reports the lattice constant  $a=5.487 \text{ \AA}$ .

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 2.74, 1.940, and 1.227  $\text{\AA}$ .

The density of scandium arsenide calculated from the constant of Brixner is 4.820 g/cm<sup>3</sup>.

# Sodium Hydroxide, NaOH at 300 °C (cubic)

## Calculated Pattern

**Structural data.** West [5] in 1935 determined that sodium hydroxide at 300 °C is isomorphous with sodium chloride with the space group  $O_h^5$ —Fm3m (No. 225) with 4(NaOH) per unit cell. The atoms occupy the special positions:

Na: 0 0 0  
O:  $\frac{1}{2} \frac{1}{2} \frac{1}{2}$   
H: undefined.

The lattice constant used in this calculated pattern is  $a=5.01$  Å, as reported by West [5].

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 2.50, 1.77, and 1.45 Å.

The calculated density is 2.112 g/cm<sup>3</sup>.

620	.792	6	

# Strontium Telluride, SrTe (cubic)

## Calculated Pattern

Goldschmidt [1] in 1926 determined that strontium telluride is isomorphous with sodium chloride with the space group  $O_h^5$ —Fm3m (No. 225) and 4(SrTe) per unit cell. The atoms occupy the special positions:

Sr: 0 0 0  
Te:  $\frac{1}{2} \frac{1}{2} \frac{1}{2}$ .

Goldschmidt [1] reports the lattice constant  $a=6.660$  Å.

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 3.33, 2.35, and 1.489 Å.

The density of strontium telluride calculated from the constant of Goldschmidt is 4.839 g/cm<sup>3</sup>.

822	.785	10	

## Terbium Nitride, TbN (cubic)

### Calculated Pattern

Klemm and Winkelmann [24] in 1956 determined that terbium nitride is isomorphous with sodium chloride with the space group  $O_h^5$ —Fm3m (No. 225) and 4(TbN) per unit cell. The atoms occupy the special positions:

Tb: 0 0 0  
N:  $\frac{1}{2} \frac{1}{2} \frac{1}{2}$ .

Klemm and Winkelmann [24] report the lattice constant  $a=4.933 \text{ \AA}$ .

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 2.85, 2.47, and 1.744  $\text{\AA}$ .

The density of terbium nitride calculated from the constant of Klemm and Winkelmann is 9.568 g/cm<sup>3</sup>.

### Calculated Pattern Copper $\lambda$

531	.834	17	
600	.822	13	

## Thorium Arsenide, ThAs (cubic)

### Calculated Pattern

Ferro [19] in 1955 determined that thorium arsenide is isomorphous with sodium chloride with the space group  $O_h^5$ —Fm3m (No. 225) and 4(ThAs) per unit cell. The atoms occupy the special positions:

Th: 0 0 0  
As:  $\frac{1}{2} \frac{1}{2} \frac{1}{2}$ .

Ferro [19] reports the lattice constant  $a=5.972 \text{ \AA}$ .

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 2.99, 2.11, and 1.801  $\text{\AA}$ .

The density of thorium arsenide calculated from the constant of Ferro is 9.572 g/cm<sup>3</sup>.

## Ytterbium Nitride, YbN (cubic)

### Calculated Pattern

Klemm and Winkelmann [24] in 1956 determined that ytterbium nitride is isomorphous with sodium chloride with the space group  $O_h^5$ —Fm3m (No. 225) and 4(YbN) per unit cell. The atoms occupy the special positions:

Yb: 0 0 0  
N:  $\frac{1}{2} \frac{1}{2} \frac{1}{2}$ .

Klemm and Winkelmann [24] report the lattice constant  $a=4.786 \text{ \AA}$ .

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 2.76, 2.39, and 1.692  $\text{\AA}$ .

The density of ytterbium nitride calculated from the constant of Klemm and Winkelmann is 11.33 g/cm<sup>3</sup>.

### Calculated Pattern Copper $\lambda$

$hkl$	$d$	Peak height

## Yttrium Arsenide, YAs (cubic)

### Calculated Pattern

Brixner [30] in 1960 determined that yttrium arsenide is isomorphous with sodium chloride with the space group  $O_h^5$ —Fm3m (No. 225) and 4(YAs) per unit cell. The atoms occupy the special positions:

Y: 0 0 0  
As:  $\frac{1}{2} \frac{1}{2} \frac{1}{2}$ .

Brixner [30] reports the lattice constant  $a=5.786 \text{ \AA}$ .

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 2.89, 2.05, and 1.294  $\text{\AA}$ .

The density of yttrium arsenide calculated from the constant of Brixner is 5.617 g/cm<sup>3</sup>.

### Calculated Pattern Copper $\lambda$

$hkl$	$d$	Peak height	
		$\text{\AA}$	$I$

## Yttrium Telluride, YTe (cubic)

### Calculated Pattern

Brixner [30] in 1960 determined that yttrium telluride is isomorphous with sodium chloride with the space group  $O_h^5$ —Fm3m (No. 225) and 4(YTE) per unit cell. The atoms occupy the special positions:

$$\begin{aligned} \text{Y: } & 0 \ 0 \ 0 \\ \text{Te: } & \frac{1}{2} \ \frac{1}{2} \ \frac{1}{2} \end{aligned}$$

Brixner [30] reports the lattice constant  $a=6.095 \text{ \AA}$ .

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 3.05, 2.15, and 1.363  $\text{\AA}$ .

The density of yttrium telluride calculated from the constant of Brixner is 6.351 g/cm<sup>3</sup>.

### Calculated Pattern Copper $\lambda$

$hkl$	$d$	Peak height	
		$I$	
111	3.52 $\text{\AA}$	5	
200	3.05	100

## Zirconium Phosphide, ZrP (cubic)

### Calculated Pattern

Schönberg [17] in 1954 determined that zirconium phosphide is isomorphous with sodium chloride with the space group  $O_h^5$ —Fm3m (No. 225) and 4(ZrP) per unit cell. The atoms occupy the special positions:

$$\begin{aligned} \text{Zr: } & 0 \ 0 \ 0 \\ \text{P: } & \frac{1}{2} \ \frac{1}{2} \ \frac{1}{2} \end{aligned}$$

Schönberg [17] reports the lattice constant  $a=5.27 \text{ \AA}$ .

No temperature correction was included.

The calculated  $d$ -values of the three strongest lines are 2.63, 1.86, and 1.304  $\text{\AA}$ .

The density of zirconium phosphide calculated from the constant of Schönberg is 5.54 g/cm<sup>3</sup>.

### Calculated Pattern Copper $\lambda$

$hkl$	$d$	Peak height	
		$I$	
111	3.04 $\text{\AA}$	51

Calcium chromium germanate, $\text{Ca}_3\text{Cr}_2(\text{GeO}_4)_3$ -----	10	16	Cesium vanadium sulfate dodecahydrate, $\text{CsV}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ -----	1m	11
Calcium chromium silicate (uvarovite), $\text{Ca}_3\text{Cr}_2(\text{SiO}_4)_3$ -----	10	17	Chromium, Cr-----	5	20
Calcium fluoride (fluorite), $\text{CaF}_2$ -----	1	69	Chromium orthophosphate, alpha, $\text{CrPO}_4$ -----	2m	12
Calcium fluoride phosphate (fluorapatite), $\text{Ca}_5\text{F}(\text{PO}_4)_3$ -----	3m	22	Chromium orthophosphate, beta, $\text{CrPO}_4$ -----	9	26
Calcium formate, $\text{Ca}(\text{HCO}_2)_2$ -----	8	16	Chromium (III) oxide, $\text{Cr}_2\text{O}_3$ -----	5	22
Calcium gallium germanate, $\text{Ca}_3\text{Ga}_2(\text{GeO}_4)_3$ -----	10	18	Chromium silicide, $\text{Cr}_3\text{Si}$ -----	6	29
Calcium hydroxide (portlandite), $\text{Ca}(\text{OH})_2$ -----	1	58	Cobalt, Co (cubic)-----	4m	10
Calcium iron germanate, $\text{Ca}_2\text{Fe}_2(\text{GeO}_4)_3$ -----	10	19	Cobalt aluminum oxide, $\text{CoAl}_2\text{O}_4$ -----	9	27
Calcium iron silicate (andradite), $\text{Ca}_3\text{Fe}_2\text{Si}_3\text{O}_12$ -----	9	22	Cobalt arsenide (skutterudite), $\text{CoAs}_3$ -----	10	21
Calcium molybdate (powellite), $\text{CaMoO}_4$ -----	6	22	Cobalt (II) carbonate (sphero cobaltite), $\text{CoCO}_3$ -----	10	24
Calcium nitrate, $\text{Ca}(\text{NO}_3)_2$ -----	7	14	Cobalt diarsenide, $\text{CoAs}_2$ (revised)-----	4m	10
Calcium oxide, $\text{CaO}$ -----	1	43	Cobalt fluosilicate hexahydrate, $\text{CoSiF}_6 \cdot 6\text{H}_2\text{O}$ -----	3m	27
Calcium sulfate (anhydrite), $\text{CaSO}_4$ -----	4	65	Cobalt gallate, $\text{CoGa}_2\text{O}_4$ -----	10	27
Calcium sulfide (oldhamite), $\text{CaS}$ -----	7	15	Cobalt germanate, $\text{Co}_2\text{GeO}_4$ -----	10	27
Calcium telluride, $\text{CaTe}$ -----	4m	50	Cobalt iodide, $\text{CoI}_2$ -----	4m	52
Calcium tungstate, scheelite, $\text{CaWO}_4$ -----	6	23	Cobalt iron arsenide (safflorite), $\text{CoFeAs}_4$ -----	10	28
Carbon, diamond, C-----	2	5	Cobalt mercury thiocyanate, $\text{Co}[\text{Hg}(\text{CNS})]$ -----	2m	13
Cerium arsenate, $\text{CeAsO}_4$ -----	4m	8	Cobalt (II) oxide, $\text{CoO}$ -----	9	28
Cerium arsenide, $\text{CeAs}$ -----	4m	8	Cobalt (II, III) oxide, $\text{Co}_3\text{O}_4$ -----	9	29
Cerium (III) chloride, $\text{CeCl}_3$ -----	1m	51	Cobalt perchlorate hexahydrate, $\text{Co}(\text{ClO}_4)_2 \cdot 6\text{H}_2\text{O}$ -----	3m	28
Cerium (III) fluoride, $\text{CeF}_3$ -----	8	17	Cobalt silicate, $\text{Co}_2\text{SiO}_4$ (orthorhombic)-----	4m	11
Cerium, magnesium nitrate 24-hydrate, $\text{Ce}_2\text{Mg}_3(\text{NO}_3)_12 \cdot 24\text{H}_2\text{O}$ -----	10	20	Cobalt sulfate, beta, $\text{CoSO}_4$ -----	2m	14
Cerium niobium titanium oxide (eschynite), $\text{CeNbTiO}_6$ -----	3m	24	Cobalt titanate, $\text{CoTiO}_3$ -----	4m	13
Cerium nitride, $\text{CeN}$ -----	4m	51	Cobalt tungstate, $\text{CoWO}_4$ -----	4m	13
Cerium(IV) oxide (cerianite), $\text{CeO}_2$ -----	1	56	Copper, Cu-----	1	15
			Copper(I) bromide, $\text{CuBr}$ -----	4	36
			Copper carbonate basic, azurite, $\text{Cu}_3(\text{OH})_2(\text{CO}_3)_2$ -----	10	30
			Copper carbonate basic, (malachite), $\text{Cu}_2(\text{OH})_2\text{CO}_3$ -----	10	31

Rubidium fluoplatinate, $Rb_2PtF_6$ -----	6	48	Sodium magnesium aluminum boron hy- droxy silicate, dravite, $NaMg_3Al_2Si_5O_{27}(OH)_4$ -----	3m	46
Rubidium fluorosilicate, $Rb_2SiF_6$ -----	6	49	Sodium metaperiodate, $NaIO_4$ -----	7	48
Rubidium iodide, $RbI$ -----	4	43	Sodium molybdate, $Na_2MoO_4$ -----	1m	46
Rubidium perchlorate, $RbClO_4$ -----	2m	30	Sodium nitrate (soda-niter), $NaNO_3$ -----	6	50
Rubidium periodate, $RbIO_4$ -----	2m	31	Sodium nitrite, $NaNO_2$ -----	4	62
Rubidium sulfate, $Rb_2SO_4$ -----	8	48	Sodium orthotungstate (VI) dihydrate, $Na_2WO_4 \cdot 2H_2O$ -----	2m	33
Ruthenium, $Ru$ -----	4	5	Sodium perchlorate, $NaClO_4$ (orthorhombic)-----	7	49
Samarium arsenate, $SmAsO_4$ -----	4m	33	Sodium sulfate (thenardite), $Na_2SO_4$ -----	2	59
Samarium arsenide, $SmAs$ -----	4m	68	Sodium sulfite, $Na_2SO_3$ -----	3	60
Samarium chloride, $SmCl_3$ -----	1m	40	Sodium tetrametaphosphate tetrahydrate, alpha, $Na_4P_4O_{12} \cdot 4H_2O$ (monoclinic)-----	10	52
Samarium fluoride, $SmF_3$ -----	1m	41	Sodium tetrametaphosphate tetrahydrate, beta, $Na_4P_4O_{12} \cdot 4H_2O$ (triclinic)-----	2m	35
Samarium gallium oxide 3:5, $Sm_3Ga_2(GaO_4)_3$ -----	1m	42	Sodium trimetaphosphate, $Na_3P_3O_9$ -----	3m	49
Samarium oxide, $Sm_2O_3$ (cubic)-----	4m	34	Sodium trimetaphosphate monohydrate, $Na_3P_3O_9 \cdot H_2O$ -----	3m	50
Samarium oxychloride, $SmOCl$ -----	1m	43	Sodium tungstate, $Na_2WO_4$ -----	1m	47
Scandium arsenate, $ScAsO_4$ -----	4m	35	Strontium arsenate, $Sr_3(AsO_4)_2$ -----	2m	36
Scandium arsenide, $ScAs$ -----	4m	68	Strontium 1:1 borate, $SrO \cdot B_2O_3$ -----	3m	53
Scandium oxide, $Sc_2O_3$ -----	3	27	Strontium boron oxide, $SrB_4O_7$ -----	4m	36
Scandium phosphate, $ScPO_4$ -----	8	50	Strontium bromide hexahydrate, $SrBr_2 \cdot 6H_2O$ -----	4	60
Selenium, $Se$ -----	5	54	Strontium carbonate (strontianite), $SrCO_3$ -----	3	56
Selenium dioxide (selenolite), $SeO_2$ -----	1	53	Strontium chloride, $SrCl_2$ -----	4	40
Silicon, $Si$ -----	2	6	Strontium chloride hexahydrate, $SrCl_2 \cdot 6H_2O$ -----	4	58
Silicon dioxide, alpha or low quartz, $SiO_2$ (hexagonal)-----	3	24	Strontium fluoride, $SrF_2$ -----	5	67
Silicon dioxide (alpha or low cristobalite), $SiO_2$ (revised) (tetragonal)-----	10	48	Strontium formate, $Sr(CH_2O_2)_2$ -----	8	55
Silicon dioxide (beta or high cristobalite), $SiO_2$ (cubic)-----	1	42	Strontium formate dihydrate, $Sr(CH_2O_2)_2 \cdot 2H_2O$ (orthorhombic)-----	8	56
Silver, $Ag$ -----	1	23	Strontium iodide hexahydrate, $SrI_2 \cdot 6H_2O$ -----	8	58
Silver antimony telluride, $AgSbTe_2$ -----	3m	47	Strontium molybdate, $SrMoO_4$ -----	7	50
Silver arsenate, $Ag_3AsO_4$ -----	5	56	Strontium nitrate, $Sr(NO_3)_2$ -----	1	80
Silver bromate, $AgBrO_3$ -----	5	57	Strontium oxide, $SrO$ -----	5	68
Silver bromide (bromyrite), $AgBr$ -----	4	46	Strontium peroxide, $SrO_2$ -----	6	52

**CUMULATIVE INDEX TO CIRCULAR 539, VOLUMES 1, 2, 3, 4, 5, 6, 7, 8, 9, 10,  
MONOGRAPH 25, SECTIONS 1, 2, 3, AND 4—Continued**

	Vol. or sec.	Page		Vol. or sec.	Page
Strontium sulfate (celestite), $\text{SrSO}_4$ -----	2	61	Tin (II) oxide, $\text{SnO}$ -----	4	28
Strontium sulfide, $\text{SrS}$ -----	7	52	Tin (IV) oxide (cassiterite), $\text{SnO}_2$ -----	1	54
Strontium telluride, $\text{SrTe}$ -----	4m	69	Tin (II) telluride, $\text{SnTe}$ -----	7	61
Strontium titanate, $\text{SrTiO}_3$ -----	3	44	Titanium, Ti-----	3	1
Strontium tungstate, $\text{SrWO}_4$ -----	7	53	Titanium dioxide (anatase), $\text{TiO}_2$ (tetra-		
Strontium zirconate, $\text{SrZrO}_3$ -----	9	51	gonal)-----	1	46
Sulfamic acid, $\text{NH}_3\text{SO}_3$ -----	7	54	Titanium dioxide, brookite, $\text{TiO}_2$ (ortho-		
Sulfur, S-----	9	54	rhombic)-----	3m	57
Tantalum, Ta-----	1	29	Titanium dioxide (rutile), $\text{TiO}_2$ (tetragonal)-----	1	44
Tantalum Silicide, $\text{TaSi}_2$ -----	8	59	Titanium (III) oxide, $\text{TiO}_{1.515}$ -----	9	59
Tellurium, Te-----	1	26	Titanium silicide, $\text{Ti}_5\text{Si}_3$ -----	8	64
Tellurium (IV) oxide (paratellurite), $\text{TeO}_2$ (tetragonal)-----	7	56	Titanium sulfide, $\text{TiS}_2$ -----	4m	72
Tellurium (IV) oxide, paratellurite, $\text{TeO}_2$ (tetragonal)-----	10	55	Tungsten, W-----	1	28
Tellurium (IV) oxide, tellurite, $\text{TeO}_2$ (orthorhombic)-----	9	57	Tungsten sulfide (tungstenite), $\text{WS}_2$ -----	8	65
Terbium arsenate, $\text{TbAsO}_4$ -----	3m	54	Uranium dioxide (uraninite), $\text{UO}_2$ -----	2	33
Terbium nitride, $\text{TbN}$ -----	4m	70	Uranium telluride, $\text{UTe}$ -----	4m	73
Thallium aluminum sulfate dodecahydrate, $\text{TlAl}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ -----	6	53	Urea, $\text{CO}(\text{NH}_2)_2$ -----	7	61
Thallium (I) arsenate, $\text{Tl}_3\text{AsO}_4$ -----	2m	37	Vanadium (V) oxide, $\text{V}_2\text{O}_5$ -----	8	66
Thallium (I) bromate, $\text{TlBrO}_3$ -----	8	60	Ytterbium arsenate, $\text{YbAsO}_4$ -----	4m	38
Thallium bromide, $\text{TlBr}$ -----	7	57	Ytterbium arsenide, $\text{YbAs}$ -----	4m	73
Thallium (I) chlorate, $\text{TlClO}_3$ -----	8	61	Ytterbium gallium oxide 3:5, $\text{Y}_3\text{Ga}_2(\text{GaO}_4)_3$ -----		
Thallium (I) chloride, $\text{TlCl}$ -----	4	51	Yttrium, oxide, $\text{Y}_2\text{O}_3$ -----	1m	49
Thallium chloroplatinate, $\text{Tl}_2\text{PtCl}_6$ -----	5	70	Yttrium oxychloride, $\text{YOCl}$ -----	4m	74
Thallium chlorostannate, $\text{Tl}_2\text{SnCl}_6$ -----	6	54	Yttrium phosphate (xenotime), $\text{YPO}_4$ -----	2m	39
Thallium chromate, $\text{Tl}_2\text{CrO}_4$ -----	3m	54	Yttrium telluride, $\text{YTe}$ -----	4m	74
Thallium chromium sulfate dodecahydrate, $\text{TlCr}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ -----	6	55	Zinc, Zn-----	1	28
Thallium fluosilicate, $\text{Tl}_2\text{SiF}_6$ -----	6	56	Zinc aluminate (gahnite), $\text{ZnAl}_2\text{O}_4$ -----	1	16
Thallium gallium sulfate dodecahydrate, $\text{TlGa}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ -----	6	57	Zinc antimony oxide, $\text{ZnSb}_2\text{O}_4$ -----	2	38
Thallium (I) iodate, $\text{TlIO}_3$ -----	8	62	Zinc borate, $\text{ZnB}_2\text{O}_4$ -----	4m	39
Thallium (I) iodide, $\text{TlI}$ (orthorhombic)-----	4	53	Zinc carbonate, smithsonite, $\text{ZnCO}_3$ -----	1	69
Thallium (I) nitrate, $\text{TINO}_3$ -----	6	58	Zinc cyanide, $\text{Zn}(\text{CN})_2$ -----	5	73
Thallium (III) oxide, $\text{Tl}_2\text{O}_3$ -----	2	28	Zinc fluoride, $\text{ZnF}_2$ -----	6	60
Thallium (I) perchlorate, $\text{TlClO}_4$ -----	2m	38	Zinc fluosilicate hexahydrate, $\text{ZnSiF}_6 \cdot 6\text{H}_2\text{O}$ -----	8	70
Thallium (I) phosphate, $\text{Tl}_3\text{PO}_4$ -----	7	58	Zinc germanate, $\text{Zn}_2\text{GeO}_4$ -----	10	56
Thallium (III) phosphate, $\text{TlPO}_4$ -----	7	59	Zinc iodide, $\text{ZnI}_2$ -----	9	60
Thallium (I) sulfate, $\text{Tl}_2\text{SO}_4$ -----	6	59	Zinc orthosilicate (willemite), $\text{Zn}_2\text{SiO}_4$ -----	7	62
Thallium (I) thiocyanate, $\text{TlCNS}$ -----	8	63	Zinc oxide (zincite), $\text{ZnO}$ -----	2	25
Thallium (I) tungstate, $\text{Tl}_2\text{WO}_4$ -----	1m	48	Zinc pyrosilicate hydrate, hemimorphite, $\text{Zn}_4(\text{OH})_2\text{Si}_2\text{O}_7 \cdot \text{H}_2\text{O}$ -----	2	62
Thorium arsenide, $\text{ThAs}$ -----	4m	70	Zinc selenide, $\text{ZnSe}$ -----	3	23
Thorium oxide (thorianite), $\text{ThO}_2$ -----	1	57	Zinc sulfate (zinkosite), $\text{ZnSO}_4$ -----	7	64
Thulium arsenate, $\text{TmAsO}_4$ -----	3m	56	Zinc sulfate heptahydrate (goslarite), $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$ -----	8	71
Thulium arsenide, $\text{TmAs}$ -----	4m	71	Zinc sulfide, (wurtzite), alpha $\text{ZnS}$ (hexagonal)-----	2	14
Thulium nitride, $\text{TmN}$ -----	4m	71	Zinc sulfide, (sphalerite), beta $\text{ZnS}$ (cubic)-----	2	16
Thulium sesquioxide, $\text{Tm}_2\text{O}_3$ -----	9	58	Zinc telluride, $\text{ZnTe}$ -----	3m	58
Thulium telluride, $\text{TmTe}$ -----	4m	72	Zinc tungstate, (sanmartinitite), $\text{ZnWO}_4$ -----	2m	40
Tin, alpha, Sn (cubic)-----	2	12	Zirconium, alpha, $\text{Zr}$ -----	2	11
Tin, beta, Sn (tetragonal)-----	1	24	Zirconium iodate, $\text{Zr}(\text{IO}_3)_4$ -----	1m	51
Tin arsenide, $\text{SnAs}$ -----	4m	37	Zirconium phosphide, $\text{ZrP}$ -----	4m	75
Tin (II) fluoride, $\text{SnF}_2$ -----	3m	51	Zirconium silicate, zircon, $\text{ZrSiO}_4$ -----	4	68
Tin (IV) iodide, $\text{SnI}_4$ -----	5	71	Zirconium sulfate tetrahydrate, $\text{Zr}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$ -----	7	66

**CUMULATIVE MINERAL INDEX**

	Vol. or sec.	Page		Vol. or sec.	Page
Alabandite $\text{MnS}$ -----	4	11	Andradite, $\text{Ca}_3\text{Fe}_2\text{Si}_3\text{O}_12$ -----	9	22
Alum, $\text{KAl}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ -----	6	36	Anglesite, $\text{PbSO}_4$ -----	3	67
Ammonia-niter, $\text{NH}_4\text{NO}_3$ -----	7	4	Anhydrite, $\text{CaSO}_4$ -----	4	65
Anatase, $\text{TiO}_2$ -----	1	46	Aragonite, $\text{CaCO}_3$ -----	3	53

# CUMULATIVE MINERAL INDEX—Continued

	Vol. or sec.	Page		Vol. or sec.	Page
Argentite, $\text{Ag}_2\text{S}$	10	51	Mascagnite, $(\text{NH}_4)_2\text{SO}_4$ (revised)	9	8
Arcanite, $\text{K}_2\text{SO}_4$	3	62	Massicot, $\text{PbO}$ (yellow)	2	32
Arsenolite, $\text{As}_2\text{O}_3$	1	51	Matlockite, $\text{PbFCl}$	1	76
Aurostibite, $\text{AuSb}_2$	7	18	Metacinnabar, $\text{HgS}$	4	21
*Azurite, $\text{Cu}_3(\text{OH})_2(\text{CO}_3)_2$	10	30	*Millerite, $\text{NiS}$	1m	37
Barite, $\text{BaSO}_4$	3	65	Minium, $\text{Pb}_3\text{O}_4$	8	32
Berlinite, $\text{AlPO}_4$	10	3	Molybdenite, $\text{MoS}_2$	5	47
*Beryl, $\text{Be}_3\text{Al}_2(\text{SiO}_3)_6$	9	13	Molybdite, $\text{MoO}_3$	3	30
Bismite, (alpha) $\text{Bi}_2\text{O}_3$	3m	17	Montroydite, $\text{HgO}$ (revised)	9	39
Bismoclite, $\text{BiOCl}$	4	54	Mullite, $3\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2$	3m	3
Bismuthinite, $\text{Bi}_2\text{S}_3$	4	23	Nantokite, $\text{CuCl}$	4	35
Böhmite, $\text{Al}_2\text{O}_3 \cdot \text{H}_2\text{O}$	3	38	Niter, $\text{KNO}_3$	3	58
Bromellite, $\text{BeO}$	1	36	Nitrobarite, $\text{Ba}(\text{NO}_3)_2$	1	81
Bromyrite, $\text{AgBr}$	4	46	Norbergite, $\text{Mg}_2\text{SiO}_4 \cdot \text{MgF}_2$	10	39
*Brookite, $\text{TiO}_2$	3m	57	Oldhamite, $\text{CaS}$	7	15
Brucite, $\text{Mg}(\text{OH})_2$	6	30	Otavite, $\text{CdCO}_3$	7	11
Bunsenite, $\text{NiO}$	1	47	Oxammite, $(\text{NH}_4)_2\text{C}_2\text{O}_4 \cdot \text{H}_2\text{O}$	7	5
Calcite, $\text{CaCO}_3$	2	51	*Paratellurite, $\text{TeO}_2$	10	55
Calomel, $\text{Hg}_2\text{Cl}_2$	1	72	Paratellurite, $\text{TeO}_2$	7	56
Cassiterite, $\text{SnO}_2$	1	54	Partridgeite, $\text{Mn}_2\text{O}_3$	9	37
Celestite, $\text{SrSO}_4$	2	61	Periclase, $\text{MgO}$	1	37
Cerargyrite, $\text{AgCl}$	4	44	*Phenacite, $\text{Be}_2\text{SiO}_4$	8	11
Cerianite, $\text{CeO}_2$	1	56	Picrochromite, $\text{MgCr}_2\text{O}_4$	9	34
Cerussite, $\text{PbCO}_3$	2	56	Portlandite, $\text{Ca}(\text{OH})_2$	1	58
Cervantite, $\text{Sb}_2\text{O}_4$	10	8	Powellite, $\text{CaMoO}_4$	6	22
Chalcocyanite, $\text{CuSO}_4$	3m	29	Pyrite, $\text{FeS}_2$	5	29
Chloraluminite, $\text{AlCl}_3 \cdot 6\text{H}_2\text{O}$	7	3	Pyrope, $\text{Mg}_3\text{Al}_2(\text{SiO}_4)_3$	4m	24
Chrysoberyl, $\text{BeAl}_2\text{O}_4$	9	10	*Quartz, $\text{SiO}_2$ (alpha or low)	3	24
Cinnabar, $\text{HgS}$	4	17	Rammelsbergite, $\text{NiAs}_2$	10	42
*Claudetite, $\text{As}_2\text{O}_3$	3m	9	Retgersite, $\text{NiSO}_4 \cdot 6\text{H}_2\text{O}$	7	36
Clausthalite, $\text{PbSe}$	5	38	Rhodochrosite, $\text{MnCO}_3$	7	32
Cordierite, $\text{Mg}_2\text{Al}_4\text{Si}_5\text{O}_{18}$ (orthorhombic)	1m	28	Rutile, $\text{TiO}_2$	1	44
Cordierite, $\text{Mg}_2\text{Al}_4\text{Si}_5\text{O}_{18}$ (hexagonal)	1m	29	Safflorite, $\text{CoFeAs}_4$	10	28
Corundum, $\text{Al}_2\text{O}_3$	9	3	Sal-ammoniac, $\text{NH}_4\text{Cl}$	1	59
Cotunnite, $\text{PbCl}_2$	2	45	Sanmartinite, $\text{ZnWO}_4$	2m	40
Covellite, $\text{CuS}$	4	13	*Scheelite, $\text{CaWO}_4$	6	23
Cristobalite, (alpha or low) $\text{SiO}_2$ (revised)	10	48	Selenolite, $\text{SeO}_2$	1	53
Cristobalite, (beta or high) $\text{SiO}_2$	1	42	Sellaite, $\text{MgF}_2$	4	33
Cryptohalite, $(\text{NH}_4)_2\text{SiF}_6$	5	5	Senarmontite, $\text{Sb}_2\text{O}_3$	3	31
Cuprite, $\text{Cu}_2\text{O}$	2	23	Skutterudite, $\text{CoAs}_3$	10	21
*Diamond, C	2	5	*Smithsonite, $\text{ZnCO}_3$	8	69
*Diaspore, $\text{Al}_2\text{O}_3 \cdot \text{H}_2\text{O}$	3	41	Soda-niter, $\text{NaNO}_3$	6	50
*Dravite, $\text{NaMg}_3\text{Al}_6\text{B}_3\text{Si}_6\text{O}_{27}(\text{OH})_4$	3m	47	Sphalerite, $\text{ZnS}$	2	16
*Enstatite, $\text{MgSiO}_3$	6	32	Sphero cobaltite, $\text{CoCO}_3$	10	24
Epsomite, $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$	7	30	Spinel, $\text{MgAl}_2\text{O}_4$	2	35
Eschynite, $\text{CeNbTiO}_6$	3m	24	Stibnite, $\text{Sb}_2\text{S}_3$	5	6
Ettringite, $\text{Al}_2\text{O}_3 \cdot 6\text{CaO} \cdot 3\text{SO}_3 \cdot 31\text{H}_2\text{O}$	8	3	Stolzite, $\text{PbWO}_4$	7	24
Fluorapatite, $\text{Ca}_5\text{F}(\text{PO}_4)_3$	3m	22	Strontianite, $\text{SrCO}_3$	3	56
Fluorite, $\text{CaF}_2$	1	69	Struvite, $\text{MgNH}_4\text{PO}_4 \cdot 6\text{H}_2\text{O}$	3m	41
Forsterite, $\text{Mg}_2\text{SiO}_4$	1	83	Sylvite, $\text{KCl}$	1	65
Galaxite, $\text{MnAl}_2\text{O}_4$	9	35	*Tellurite, $\text{TeO}_2$	9	57
Galena, $\text{PbS}$	2	18	Tellurobismuthite, $\text{Bi}_2\text{Te}_3$	3m	16
Gahnite, $\text{ZnAl}_2\text{O}_4$	2	38	Tenorite, $\text{CuO}$	1	49
Geikielite, $\text{MgTiO}_3$	5	43	Teschemacherite, $\text{NH}_4\text{HCO}_3$	9	5
Gersdorffite, $\text{NiAsS}$	1m	35	Teschermigite, $\text{NH}_4\text{Al}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$	6	3
Goslarite, $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$	8	71	Thenardite, $\text{Na}_2\text{SO}_4$	2	59
Greenockite, $\text{CdS}$	4	15	Thermonatrite, $\text{Na}_2\text{CO}_3 \cdot \text{H}_2\text{O}$	8	54
Halite, $\text{NaCl}$	2	41	Thorianite, $\text{ThO}_2$	1	57
*Hemimorphite, $\text{Zn}_4(\text{OH})_2\text{Si}_2\text{O}_7 \cdot \text{H}_2\text{O}$	2	62	Tiemannite, $\text{HgSe}$	7	35
Hieratite, $\text{K}_2\text{SiF}_6$	5	50	*Topaz, $\text{Al}_2\text{SiO}_4(\text{F}, \text{OH})_2$	1m	4
Huebnerite, $\text{MnWO}_4$	2m	24	Trevorite, $\text{NiFe}_2\text{O}_4$	10	44
Humite, $3\text{Mg}_2\text{SiO}_4 \cdot \text{MgF}_2$	1m	30	Tungstenite, $\text{WS}_2$	8	65
Iodyrite, $\text{AgI}$	8	51	Uraninite, $\text{UO}_2$	2	33
Jacobsite, $\text{MnFe}_2\text{O}_4$	9	36	Uvarovite, $\text{Ca}_3\text{Cr}_2(\text{SiO}_4)_3$	10	17
Litharge, $\text{PbO}$ (red)	2	30	*Valentinite, $\text{Sb}_2\text{O}_3$	10	6
Lithiphosphate, $\text{Li}_3\text{PO}_4$	4m	21	Villiaumite, $\text{NaF}$	1	63
Loellingite, $\text{FeAs}_2$	10	34	Willemite, $\text{Zn}_2\text{SiO}_4$	7	62
Magnesite, $\text{MgCO}_3$	7	28	Witherite, $\text{BaCO}_3$	2	54
Malachite, $\text{Cu}_2(\text{OH})_2\text{CO}_3$	10	31	Wulfenite, $\text{PbMoO}_4$	7	23
Manganosite, $\text{MnO}$	5	45	Wurtzite, $\text{ZnS}$	2	14
Marshite, $\text{CuI}$	4	38	Xenotime, $\text{YPO}_4$	8	67
			Zincite, $\text{ZnO}$	2	25
			Zinkosite, $\text{ZnSO}_4$	7	64
			*Zircon, $\text{ZrSiO}_4$	4	68
