STANDARDS AND SPECIFICATIONS FOR METALS AND METAL PRODUCTS

NATIONALLY RECOGNIZED STANDARDS AND SPECIFICATIONS
FOR ORES, METALS, AND MANUFACTURES
EXCEPT MACHINERY, VEHICLES, AND ELECTRICAL SUPPLIES

MISCELLANEOUS PUBLICATION No. 120
[Issued March 11, 1933]

PREPARED BY GEORGE A. WARDLAW, UNDER THE DIRECTION OF
A. S. McALLISTER, CHIEF OF THE DIVISION OF SPECIFICATIONS

UNITED STATES
GOVERNMENT PRINTING OFFICE
WASHINGTON: 1933

This volume represents an attempt on the part of the Department of Commerce to collect and publish the substance of the standards and specifications relating to ores, metals, and manufactures (except machinery, vehicles, and electrical supplies) formulated by the national technical societies, the trade associations having national recognition, or other organizations which speak for industry or with the authority of the Federal Government as a whole.

Criticisms and suggestions are desired from all interested persons, so that the presentation of the information concerning the nationally-recognized specifications may be made most nearly universally satisfactory and that the collection of existing specifications and classification thereof may be kept as complete, accurate, and up to date as possible. All recommendations for improvement received will be given careful consideration when future editions are issued.

LETTER OF SUBMITTAL

DEPARTMENT OF COMMERCE,
BUREAU OF STANDARDS,
Washington, March 9, 1933.

SIR: I have the honor to submit herewith for publication the manuscript for a compilation relating to "Standards and Specifications for Metals and Metal Products."

In conformity to plans outlined by the Secretary of Commerce in 1923, there has been made under the joint auspices of the Bureau of Standards and the Bureau of Foreign and Domestic Commerce a review of the nationally-recognized standards, specifications, simplifications, and testing methods in use in this country. The material obtained as a result of this review, following recommendations of an advisory board composed of official representatives of 14 national organizations interested in the utilization of specifications, was divided into two distinct parts. One part, in the nature of an index, was first issued in 1925, and revised in 1932, as the National Directory of Commodity Specifications. The second part, under the recommendations, was to contain copies of actual specifications (or abstracts thereof) instead of descriptive titles.

The first step in the accomplishment of this second part of the work was achieved in 1927, with the publication of the volume, Standards and Specifications in the Wood-Using Industries. In 1930 there appeared a second volume, on Standards and Specifications for Nonmetallic Minerals and their Products.

The present compilation represents a further step in the fulfillment of the second part of the foregoing program, being the third of the series of publications dealing with standards and specifications in various industries, to be issued as rapidly as conditions permit.

The arrangement and distribution of standards and specifications presented in this compilation conforms with the decimal system of indexing made use of in the National Directory of Commodity Specifications. In certain cases, due to the expansion of standardization, it has been necessary to enlarge upon the system laid out in the volume referred to.

Respectfully,

LYMAN J. BRIGGS,
Acting Director, Bureau of Standards.

HON. DANIEL C. ROPER,
Secretary of Commerce.

SOCIETIES AND ASSOCIATIONS

Technical societies, trade associations, and other organizations issuing standards and specifications dealing with metals and metal products	1341
--	------

INDEX

Alphabetical list of commodities covered by standards and specifications	1343
--	------

INTRODUCTION

The preceding table of contents discloses the nature and extent of the material contained in this book. The subdivisions show that some commodity designations carry a number of specifications and standards, while other commodity designations carry only a few. Some commodity designations carry no specifications at all. In the latter case either there has not been sufficient demand to create a supply or else the requirements of these particular commodities are embodied in the specifications and standards of a related commodity.

Unlike the specifications and standards for commodities employed in the wood-using and nonmetallic-using industries, the specifications and standards of which have already appeared in the two preceding volumes of this series, the nationally recognized specifications and standards of the metal group do not possess the quality of detachment but appear to be interdependent. They lend themselves readily to comparison because of their more or less close relationship. One finds certain basic requirements to be inherent in a number of specifications and standards which treat of commodities of the same name though made of different material—for example, iron, steel, aluminum, brass, copper rods and bars, shapes and sheets. Again, commodities which seem to have nothing else in common, often approach uniformity in respect to chemical analysis. And regardless of the commodity or the organization producing the specification, it will be found that requirements covering finish, inspection, rejection, and reheating are in a measure all-embracing.

These intimate relationships among the specifications and standards attaching themselves to the metals are reflected in this book in the unusual number of cross references. In a word, this spells interchangeability. Common ground, too, is covered by several different organizations producing similar or even identical specifications on the same commodity, or on metallic commodity attributes, such as screw threads, gages, tests, test specimens. In respect to screw threads, identical data take on a thin disguise of originality by the device of applied permutations and combinations in the arrangement of headings and tabular columns. Ferrous and nonferrous pipe fittings and hardware have much in common in the way of specification phrasing. Numerous cross references also emphasize these facts, facts which are apparent to anyone who takes the trouble to examine this book in some detail.

These many similarities may, perhaps, prompt the suggestion from the metal-using industries that the cause of economy and efficiency might be well served by setting up a specification-sifting agency along the lines of the Simplified Practice Division of the National Bureau of Standards.

In preparing the manuscript for this volume use has been made of the latest available issue of current nationally recognized standards and specifications. Information concerning the exact wording employed, and such changes as may have been made in these standards and specifications at some later date, can be obtained from the headquarters of the technical societies, trade associations, and other organizations sponsoring the standards and specifications reproduced herein. The names and addresses of these organizations are set forth on page 1341.

STANDARDS AND SPECIFICATIONS FOR METALS AND METAL PRODUCTS

600-609

IRON AND STEEL

600. GENERAL ITEMS RELATING TO BOTH FERROUS AND NONFERROUS MATERIAL

600.0. COMMON BASIC REQUIREMENTS.

AMERICAN BUREAU OF SHIPPING RULES FOR BUILDING AND CLASSING STEEL VESSELS; MATERIALS FOR MACHINERY, BOILERS, AND PIPING, 1930

(This organization has prepared specifications relating to steel ship construction, including ship parts from keel to masts, boilers, propelling and other machinery, and electrical equipment. Specifications contained in the publication relating to ferrous and nonferrous metals have been placed in this compilation under their proper commodity headings, as follows):

Commodity designation	Material	Page
600.0.....	General.....	1
600.1.....	Testing requirements.....	7
603.1.....	Iron stays for boilers.....	135
603.21.....	Steel bars and stays for boilers.....	141
604.11.....	Steel plates for boilers.....	227
607.4.....	Steel pipes.....	436
608.4.....	Steel rivets for boilers.....	612

641.21.....	Copper plates and shapes.....	1176
642.23.....	Copper pipes and tubes.....	1182
644.21.....	Brass plates and shapes.....	1198
645.21.....	Brass castings.....	1250
645.23.....	Brass pipes and tubes.....	1216
645.24.....	Condenser tubes and ferrule stock.....	1219
646.41.....	Bronze castings.....	1250

GENERAL

(See also 600.1, p. —.)

1. Where the process of manufacture is prescribed by the rules, the manufacturer must adopt a system of marking ingots, billets, slabs, finished plates, and

forgings which will enable the material to be traced to its tests and original heat, and the surveyor must be given every facility for so tracing the material.

2. Three copies of the mill sheets or shipping invoices of all materials accepted by the surveyor should be furnished for his signature—one to be forwarded by the manufacturer to the purchaser, two to be retained for the use of the bureau. Before the mill sheets are signed the manufacturer must furnish the surveyor with a certificate guaranteeing that the material has been made by an approved process and that it had withstood satisfactorily the prescribed tests. The following form of certificate will be accepted if printed on each mill sheet with the name of the firm and initialed by the authorized representative of the manufacturer:

3. "We hereby certify that the material described herein has been made by the (describe process) process, and is that which has been satisfactorily tested in the presence of the surveyors in accordance with the tests of the American Bureau of Shipping."

4. Where steel is not produced in the works at which it is rolled, a certificate shall be supplied to the surveyor stating the process by which it was manufactured, the name of the manufacturer who supplied it, and the number of the heat from which it was made, for reference to the books of the manufacturer. The number of the heat shall be marked on each plate or bar for the purpose of identification.

BOILER MATERIAL

5. *Physical requirements.*—The structural steel used in the construction of boilers must be made by the open-hearth process. The finished material shall be free from defects and shall have a workmanlike finish. All boiler plates are to be surface inspected by the surveyor at the mills. The rolled surface should be retained on two opposite sides of the test specimens. For quench bend tests the specimens are to be heated to a light cherry red and quenched at once in water of a temperature of about 80° F. The physical characteristics of the material must be in accordance with the requirements specified under their respective commodity designations as given above.

6. All material which has satisfactorily passed the requirements must be clearly stamped by the manufacturers, as indicated in the following table, in at least two places on each finished plate or bar.

	Limits of tensile strength	Yield point	Minimum elong. in 8 inches	Bend without fracture 180°	Stamping
Shell plates, angles, and shapes ^{1 2}	60,000-70,000	50 per cent of T. S.	$\frac{1,500,000}{T. S.}$ 25 to 21 per cent	Radius of bend $1\frac{1}{2}$ times the thickness of material.	A. B.
Plates for flanging or welding and for furnaces and combustion chambers. ²	55,000-65,000	do	$\frac{1,500,000}{T. S.}$ 27 to 23 per cent	Radius of bend $1\frac{1}{2}$ times the thickness of material.	A. B. F.
Longitudinal stays ¹	60,000-70,000	do	$\frac{1,500,000}{T. S.}$ 25 to 21 per cent	Radius of bend $1\frac{1}{2}$ times the thickness of material.	A. B.
Combustion chamber stays	58,000-68,000	do	$\frac{1,500,000}{T. S.}$ 26 to 22 per cent	Radius of bend $1\frac{1}{2}$ times the thickness of material.	A. B.
Steel rivet bars	55,000-65,000	do	$\frac{1,500,000}{T. S.}$ 27 to 23 per cent	Not required (see under rivets)	A. B.
Iron stays and rivet bars	48,000-53,000	do	$\frac{1,500,000}{T. S.}$ 31 to 28 per cent	Flat on itself	A. B.

¹ Materials other than those specified, within the limits of 58,000 to 78,000 pounds T. S. will be approved, provided the range of tensile strength of the materials used in any one construction does not exceed 10,000 pounds per square inch.

² For plates over three-fourths inch in thickness, a deduction from the specified elongation of 0.125 per cent may be made for each increase of one thirty-second inch of the specified thickness above three-fourths inch, to a minimum of 20 per cent.

AMERICAN BUREAU OF SHIPPING RULES FOR BUILDING AND CLASSING STEEL VESSELS; QUALITY AND TESTING OF MATERIALS—SHIP CONSTRUCTION, 1930

(This organization has prepared specifications relating to steel ship construction, including ship parts from keel to masts, boilers, propelling and other machinery, and electrical equipment. Specifications contained in the publication relating to ferrous and nonferrous metals have been placed in this compilation under their proper commodity headings, as follows):

Commodity designation	Material	Page
600.0	General	2
603.1	Round and flat iron bars	135
603.21	Steel rivet bars	141
603.42	Steel wire ropes	159
603.52	Iron and steel chains	201
603.53	Cast steel stud-link chain	204
603.57	Shackles and shackle pins	213
604.14	Iron plates and angles	234
605.15	Steel plates, angles, bulb angles, channels, etc.	268
608.4	Steel and iron rivets	612
611.3	Iron forgings	704
611.3	Forged wrought iron anchors	704
611.41	Steel castings	706
611.49	Cast steel anchors	742
611.51	Ingot steel and welded steel forgings	750
611.59	Ingot steel anchors	814

GENERAL

1. The committee is prepared to consider proposals from owners or builders in cases where it may be desired to use materials of other tenacity than is provided for in the following rules:

2. Where materials are not required to be in accordance with the rules of the American Bureau of Shipping, the committee will approve of their surveyors testing any such materials to suitable specifications other than those stated in the rules, provided these are mutually agreed upon by the manufacturers and purchasers. Materials tested under these conditions must not be stamped A. B., as this mark is reserved exclusively to signify that the materials have satisfactorily complied with the tests required by the rules of the American Bureau of Shipping, and have been tested in the presence of the surveyor.

3. The whole of the steel to be used in the construction of steel vessels shall be made by the open-hearth process, and the finished materials shall be free from injurious defects and shall have a workmanlike finish. The name or brand of the manufacturer and the melt number shall be legibly rolled or stamped on all finished material. The melt number shall be legibly stamped on each test specimen. Specimens are to be selected in such numbers as the surveyor may consider necessary, and tested in his presence at the place of manufacture prior to dispatch.

SOCIETY OF AUTOMOTIVE ENGINEERS, IRON AND STEEL SPECIFICATIONS, S. A. E. STANDARD, 1928

INTRODUCTION

1. The steel compositions included in this standard are considered adequate for practically all parts made of ferrous metals that are necessary for the production of automotive apparatus, and include grades that have been found commercially available and technically adequate for the service required of such parts. In cases where very special requirements or exceptional quality make it necessary, grades containing less phosphorus and sulphur and narrower ranges of carbon and manganese are available, but such steels should be obtained by special arrangement between the mill and the purchaser.

SPECIFICATION NUMBERS

2. A numerical index system is used for the specifications contained in this report, which makes it possible to use specification numerals on shop drawings and blue prints that are partially descriptive of the quality of material covered by such numbers. The first figure indicates the class to which the steel belongs; thus "1-" indicates a carbon steel; "2-" a nickel steel; and "3-" a nickel-chromium steel. In the case of alloy steels, the second figure generally indicates the approximate percentage of the predominant alloying element. Usually the last two or three figures indicate the average carbon content in "points," or hundredths of 1 per cent. Thus 2340 indicates a nickel steel of approximately 3 per cent nickel (3.25 to 3.75) and 0.40 per cent carbon (0.35 to 0.45); and 71360 indicates a tungsten steel of about 13 per cent tungsten (12 to 15) and 0.60 per cent

carbon (0.50 to 0.70). The basic numerals for the various qualities of steel specified are:

Carbon steels.....	1
Nickel steels.....	2
Nickel-chromium steels.....	3
Molybdenum steels.....	4
Chromium steels.....	5
Chromium-vanadium steels.....	6
Tungsten steels.....	7
Silico-manganese steels.....	8

3. Steels should be purchased on the basis of requirements as to chemical composition, and the specifications provided herein should be used in the purchase of the grades and types of steel covered by each. (For chemical composition of the various classes of steel enumerated above see the respective commodity designations of the several classes as follows:

Carbon steels.....	603.27 (p. 150)
Screw stock.....	603.21 (p. 145)
Steel castings.....	611.41 (p. 711)
Nickel steels.....	621.31 (p. 1124)
Nickel-chromium steels.....	621.31 (p. 1124)
Molybdenum steels.....	621.31 (p. 1124)
Chromium steels.....	621.31 (p. 1124)
Chromium - vanadium steels.....	621.31 (p. 1124)
Tungsten steels.....	621.35 (p. 1129)
Silico-manganese steels.....	621.34 (p. 1128)

4. Requirements as to physical properties have been omitted for all steels except steel castings, because the majority of steels for automotive purposes are either worked or given special heat treatments by the purchaser.

(Comments not included in S. A. E. standard specifications, covering the characteristics and uses of a large variety of automotive steels, will also be found in the handbook.)

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR RODS, WELDING, NONFERROUS, FOR GAS WELDING, QQ-R-571, MAY 3, 1932.

NONFERROUS WELDING RODS FOR GAS WELDING

GENERAL SPECIFICATIONS

1. United States Government General Specification for Metals, Federal Specifications Board specification 339a (current designation: QQ-M-151) or latest revision thereof, in effect on date of invitation for bids, shall form part of this specification. (See 339a, below.)

TYPES

2. Nonferrous welding rods shall be of the following types as specified under their respective commodity designations:

Type A, manganese bronze.....	(See 647.23, p. 1266)
Type B, naval brass.....	(See 645.11, p. 1205)
Type C, copper.....	(See 642.11, p. 1180)
Type D, aluminum.....	(See 631.31, p. 1157)
Type E, aluminum alloy.....	(See 631.31, p. 1157)
Type F, copper-nickel alloy.....	(See 654.53, p. 1285)

MATERIAL

3. The material for the various grades shall be as specified under their respective commodity designations as given above.

GENERAL REQUIREMENTS

4. All rods shall be of homogeneous composition throughout, true to form, clean, smooth, of uniform color, quality, size, and free from all injurious defects. Rods furnished in bundles shall be straight, and rods furnished in coils shall be free from kinks. Cast rods shall be pickled or rattled if necessary to obtain a clean surface.

DETAIL REQUIREMENTS

(For chemical requirements and diameter in inches of the several types of nonferrous welding rods covered by this specification, see under their respective commodity designations as given above.)

5. Drawn welding rods shall be furnished in straight lengths or coils as may be ordered. When furnished in straight lengths, drawn rods shall be in 36-inch lengths, and cast rods in 12 to 20 inch lengths.

METHOD OF INSPECTION, TESTS, AND CHEMICAL ANALYSIS

6. Welding rods shall demonstrate good weldability and shall flow smoothly and evenly without any unusual characteristics in flat and overhead positions. Sample rods may be selected by the inspector and forwarded to any Government laboratory for this test.

7. Check chemical analyses may be made by the inspector or through him by any Government laboratory or other designated representative and without cost to the contractor. The chemical composition thus determined shall conform to the requirements specified in the tables for the types ordered.

8. If check chemical analyses are made, the inspector shall obtain a composite sample of not less than 4 ounces from each 1,000 pounds or less of the same type. At least one wire from every size in each 1,000 pounds or less shall be selected. Where the 1,000 pounds or less consists of but one size, one wire from each of five bundles shall be selected. Samples shall consist of fine particles obtained by clipping, sawing, or drilling, depending on the size of the wire.

PACKING AND MARKING OF SHIPMENTS

9. When welding rods are ordered in lengths or coils they shall be securely wired and wrapped in heavy waterproof paper and burlap, or wrapped in heavy waterproof paper and boxed.

NOTES

10. Requisitions for welding rods should state the type, diameter, whether drawn or cast, and whether rods are desired in straight lengths or coils.

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATIONS FOR METALS NO. 339a, JANUARY 25, 1929. (CURRENT DESIGNATION: QQ-M-151)

GENERAL SPECIFICATION FOR METALS

PART I

NOTE.—A revision of this specification which appeared too late for incorporation in this publication includes additional provisions to those given below. New requirements are given concerning the use of purchaser's patterns on contracts for furnishing castings; samples destroyed are to be in addition to the quantities called for in the contract; new requirements on the forms and dimensions of test specimens for tubing and sheet material; form and dimensions of bend test and impact test specimens; requirements on hardness test procedure; and determination of elastic limit, proof stress, and yield strength by use of extensometer.

2. *Subtechnical requirements.*—This specification covers certain requirements which are common to all detail specifications for metals unless specifically excepted in the detail specifications. Strictly technical requirements which describe the material or articles are given in the detail specifications. The requirements of this specification do not describe the material or articles, but provide means for determining whether the technical requirements are being met.

3. *Technical requirements.*—While it is mandatory that the technical requirements of the specifications of any particular department of the Federal Government conform in detail to the technical requirements of Federal specifications, there is no compulsion requiring conformity with other than the technical requirements. However, the adoption of the provisions of this specification is strongly urged on all departments so that there may be greater uniformity among the various departments in their procurements.

4. *Extent of application.*—It is to be presumed that it will be desirable to make exceptions in certain detail specifications to certain of the requirements stated herein. The use of this specification avoids the repetition of most of its provisions in each detail specification.

PART II

II. GENERAL

5. *Detail specifications.*—This specification shall form a part of each detail specification for metals issued by the Federal Specifications Board.

6. *Precedence.*—Should any conflicts exist between the requirements of this specification, the detail specifications, the drawings or the contract; the requirements of the contract, the drawings, the detail specifications, and this specification shall prevail in the order named unless a different order of precedence be specifically indicated.

III. MANUFACTURE

7. *Responsibility for subcontracts.*—Contractors will be held responsible for the compliance by their subcontractors with all the requirements of the contract, drawings, and specifications.

8. *Manufacturing methods.*—When not specified in the contract, drawings, or detail specifications, the means and methods for executing the work will be determined by the contractor, but the obligation is on the contractor to satisfy the inspector as to full compliance with the requirements of the specifications, drawings, and contract.

IV. HEAT TREATMENT

9. *Equipment.*—Materials that are subjected to heat treatment as a process of manufacture, or as a final operation, shall be heat treated by methods, and in equipment, suited to the purpose.

V. INFORMATION AND FACILITIES

10. *Information furnished by contractor.*—As soon as practicable after receiving an order under this specification, the contractor shall, if requested by the inspector, inform the latter when work will be commenced, and of the general plans and methods that he intends to follow. During the progress of the work, the contractor shall, if requested, furnish the inspector or such of his assistants as he may designate, the following:

(a) A copy of the results of chemical analyses for all material for which chemical requirements are stated in the detail specifications.

(b) Notification of the time when each operation which the specifications require the inspector to witness is to take place.

(c) Such other notifications as may be required to insure that the inspector has the opportunity to witness any particular part of any operation which he may specify.

11. *Facilities furnished by contractor.*—The contractor shall furnish the inspector, free of cost, such facilities, including suitable office space and office furniture, as may be necessary for the performance of his work.

12. *Inspector's access to plant.*—The inspector and his assistants shall have free access at all times to all parts of any manufacturing plant which directly concern the manufacture of the material ordered.

13. *Contractor's expense in connection with tests.*—All handling of material, sampling, preparation of test specimens, and testing thereof, except inspection analyses, shall be performed or furnished by the contractor without expense to the Government. Where the manufacturer has no facilities for making tests or analyses required by specifications, they will be made at some suitable place in the vicinity at the contractor's expense. Physical tests shall be made in the presence of the inspector.

14. *Identity.*—When material is inspected by melt or lots, the contractor shall so arrange his working, handling, and marking of the material that the inspector, at all times throughout its manufacture and inspection, may identify with certainty any or all portions of each heat, melt, or lot. In case the inspector can not satisfy himself as to the identity of the heat, melt, or lot from which a piece is made, each such piece may be tested singly, at the expense of the contractor.

15. *Samples for Government inspection analysis.*—(a) Samples of material for inspection analysis shall be so taken as to represent the quality of material offered for inspection.

(b) All drillings, turnings, or cuttings of material shall be fine, clean, dry, and free from foreign substance. They shall be taken at slow speed and shall not be oxidized. Where surfaces are contaminated by foreign material or are otherwise not representative of the quality of the articles or material, surface chips shall be discarded.

(c) In addition to such analyses as are required to be made by the contractor, the inspector may have an analysis made from finished material representing each melt in cases where he may deem it necessary. The inspector may have the samples taken from the test coupons, test specimens, or from any part or parts of the material concerned, provided the serviceability of the part or parts is not destroyed. The sample taken shall be of sufficient size to permit five analyses to be made.

16. *Check analysis.*—(a) In case of dissatisfaction with results of the inspection analysis, the contractor may make claim for a check analysis, in which case the chemical composition shall be determined by a Government laboratory.

(b) Part of any sample taken for the above analysis shall be furnished the contractor if he so requests the inspector at the time the sample is taken.

17. *Physical test specimens.*—(a) The inspector shall select test coupons or test pieces and apply his stamp or other marks to them for future identification. Test coupons or pieces from which test specimens are to be prepared are to be subjected to the same treatment and identical processes which are applied to the material which they represent. Coupons or test pieces shall not be cut off or otherwise removed from the individual pieces or material until these pieces have received their final annealing or other treatment. Any marks applied by the inspector or his assistants shall remain on the coupons or test specimens until the pieces are tested and necessary record made. Before the inspector's stamp or other identification marks are effaced or removed from one place, they shall be transferred to

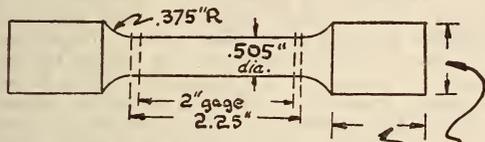

another place by the inspector. The Government may waive any or all of the requirements of this paragraph in cases where they are impracticable of application, wholly or in part.

(b) Test coupons or pieces, or the test specimens taken therefrom, shall receive no further or special working or treatment other than necessary machining after their removal from the individual pieces of material represented.

18. *Tension specimens.*—(a) Standard specimens, types 1, 2, and 3, as shown in Figures 1, 2, and 3, respectively, indicate standard tension test specimens which shall be used when practicable, unless otherwise provided in detail specifications. Type 1 is circular in cross section. Type 2 is rectangular in cross section and may be used for tests requiring either a 2 or an 8 inch gage length. Type 3, which is also rectangular in cross section, shall be used only where it is impracticable to use type 2. A variation of 5 per cent above or below the standard area of cross section shall be allowed in test specimens of type 1.

(b) All rods, bars, and shapes shall be pulled in full size when practicable.

(c) *Subsize specimens.*—When it is not possible to obtain from forgings or other shapes tension-test

These dimensions to suit fixture in testing machine in such a way that the load shall be axial.

FIGURE 1.—Standard test specimen, type 1

specimens that conform to type 1 or to such other dimensions as may be provided in the respective detail specifications, round subsize tension-test specimens as shown in type 4 (see fig. 4) shall be used. A variation of 5 per cent above or below the standard area of cross section shall be allowed in test specimens of type 4.

19. *Bend-test specimens.*—Whenever machined bend-test specimens are required by detail specifications, unless otherwise specified the specimen shall be from 6 to 8 inches long, about 1 inch wide or the full width of the material if it be less, and about one-half inch thick or the full thickness of the material if it be less. The long edges will be rounded to about one-sixteenth inch radius.

20. *Retests.*—(a) If any test specimen shows defective machining or obvious lack of continuity of metal it may be discarded and replaced by another specimen selected by the inspector.

(b) If the percentage of elongation of any tension-test specimen is less than that specified, and any part of the fracture is outside of the gage length, or within the gage length and less than 25 per cent of the gage length from either datum point, as indicated by scribe marks made on the specimen before testing, the inspector shall select another specimen in its stead and a retest shall be allowed.

(c) If any of the test specimens selected fail to meet the requirements specified and the Government permits a retest, at least twice the number of specimens that failed shall be selected by the inspector for replacement, all of which shall meet requirements.

21. *Test methods.*—(a) All tension and compression tests shall be made with a testing machine of standard make, maintained in good condition. All knife-edges shall be sharp and free from oil or dirt.

Such a machine shall be sensitive to a variation of one two-hundred-and-fiftieth of any registered load.

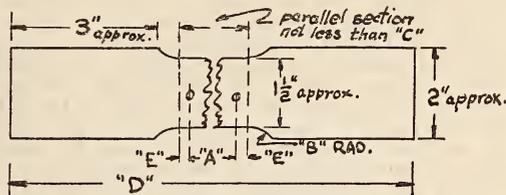

FIGURE 2.—Standard test specimen, type 2

When $A=2$ inches, $B=0.25$ inches, $C=2.25$ inches, $D=9$ inches, $E=0.125$ inches.

When $A=8$ inches, $B=1$ to 3 inches, $C=9$ inches, $D=18$ inches, $E=0.5$ inches.

They shall be accurate within their loading ranges to 1½ per cent plus or minus. Machines shall be calibrated at least once every 12 months, using approved standard methods.

(b) During the conduct of the tests, the speed of the testing machine shall be such that the beam of

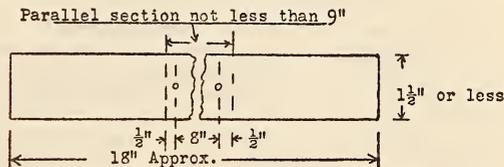

FIGURE 3.—Standard test specimen, type 3

NOTE.—In types 2 and 3, the thickness shall not exceed the width of the parallel section.

the machine can be kept balanced, but in no case shall the values given in the following table be exceeded.

Specified minimum tensile strength of material (in pounds per square inch)	Gage length	Maximum cross-head speed (in inches per minute)	
		Up to yield point	Above yield point
80,000 or under.....	Inches 2	0.50	2.0
	8	2.00	6.0
	2	.25	1.0
Over 80,000.....	8	.50	2.0

(c) In determining the proportional limit or proof stress, the cross-head speed shall not exceed 0.025 inch per inch of gage length per minute.

VI. CORRESPONDENCE AND REPORTS

22. *Channels.*—All communications between the contractor and the department involved shall be through the inspector, and shall be forwarded in triplicate. All important communications between the contractor and the inspector shall be in writing, and shall be forwarded in duplicate. All correspondence shall refer to the contract or purchase order applicable.

23. *Report forms.*—All reports covering details of manufacture, heat treatment, tests, etc., shall be submitted on forms approved by the department concerned.

VII. PACKING AND MARKING OF SHIPMENTS

24. *Normal packing.*—Unless otherwise specified in the contract, purchase order, or detail specifications, the material or articles shall be packed, boxed, or crated, and marked in accordance with standard commercial practice for similar material or articles, the cost of such special or commercial packing, boxing, crating, or marking being included in the bid.

25. *Packing for ocean shipment.*—In all cases where material is purchased to be packed for ocean shipment, such packing shall be witnessed by the inspector, and the quantity, weight, etc., checked, and such other inspection conducted as will permit

it to be final; and proper notation thereof shall appear on the shipment report.

PART III

VIII. INSPECTION AND TESTS

26. *Inspector.*—The term "Inspector" refers to the representative of the Government assigned to the duty of inspecting the materials or articles involved.

27. *Commercial quality.*—Material specified as "Commercial quality," will not ordinarily be subject to tests or analyses; however, the right is reserved to make such tests as the inspector deems necessary.

28. *Contractor's design.*—Where approval of a manufacturer's plans and specifications by the Government is required, inspection will not be completed nor shipment authorized, except at the contractor's risk, in advance of the receipt of copies of such approved plans and specifications by the inspector.

29. *Inspection at place of manufacture.*—All material shall, as far as practicable, be inspected, tested, and accepted at the place of manufacture. Procedure as to inspection at place of manufacture divides itself into three general groups or conditions, as follows:

Condition 1.—When it is possible to conduct all required inspection and tests prior to shipment, acceptance at destination will be based on certification of inspection. Inspection will be conducted at destination for the purpose or checking the quantity, ascertaining damage in transit, and properly identifying the material. Rejections will not be made at destination unless substitutions have oc-

curred, fraud exists, or material can not be properly identified as that covered by the shipping report.

Condition 2.—When for any reason material, furnished under contracts or orders requiring delivery f. o. b. carrier at works or point of shipment, is not given final inspection before shipment, it is agreed that title will pass to the Government at point of shipment with the understanding that final inspection will be made at destination and that the contractor will furnish the inspector with a written guarantee that the material is in accordance with the specifications. If the material is rejected at the point of delivery, title will revert to the contractor at the point of delivery, and he will be required to replace same with acceptable material, the expense of removing rejected material and the cost of transportation of replacement material being borne by the contractor. If the contractor declines to furnish the guarantee, shipment will not be authorized and the inspector will refer the matter to the department concerned, for instructions.

Condition 3.—When material which has been inspected, tested, and accepted contains inherent defects subsequently exposed, the contractor may be required to replace the defective material without expense to the Government.

30. *Inspection at destination.*—Inspection at place of manufacture shall be waived when the contract specifies inspection at destination. Inspection at the place of manufacture may be waived by the department concerned and the right to do so is hereby expressly reserved in the case of orders where the value of the material is small, or where the distance to be traveled by the inspector is so great that the cost of inspection at the place of manufacture would not be warranted, or where for other reasons inspection at the point of delivery or at destination can be more satisfactorily made. In such cases, the manufacturer shall ship the material at his own risk, subject to final acceptance or rejection after delivery at destination, however, waivers of any part of inspection or test of material purchased f. o. b. contractor's works without first having obtained the consent of the department involved are not authorized.

31. *Inspection at subcontractor's plant.*—The inspection of material purchased by the contractor may, at the option of the department involved, be at the works of the subcontractor, to whom all of the provisions of this specification, not in their nature inapplicable, shall apply.

Nothing contained herein shall operate to relieve the contractor of his responsibility for furnishing material conforming strictly with the requirements of the prescribed contract, drawings, and specifications.

32. *Provisional acceptance.*—The inspector may decide on the provisional acceptability of all manufactured material to be used by the contractor for the work covered by his order, but such acceptance shall not operate to transfer title to the United States, and shall not preclude subsequent rejection for discovered or developed defects. The inspector shall promptly notify the contractor or subcontractor of the existence of any defect which, in his opinion, will probably make the material unsuitable.

33. *Inspector's stamps.*—(a) In the case of small articles packed in bulk, or in the case of material which would be injured by stamping, the necessary stamp marks shall be applied by the inspector to the boxing or packing material of the article, or to tags securely wired or attached thereto.

(b) The removal of any inspector's official stamped markings or any other Government markings from material prior to its final acceptance, without the authority or permission of the inspector, shall be a sufficient cause for the rejection of such material.

IX. DEFINITIONS

34. *Definition of tension test terms.*—The following definitions and explanations of terms used in tension tests shall apply:

(a) The "elastic limit" is the greatest load per unit of original cross section which does not produce a permanent set.

(b) The "proportional limit" is the load per unit of original cross section at which the deformation ceases to be directly proportional to the loads.

(c) The "yield point" is the load per unit of original cross section at which a marked increase in the deformation of the specimen occurs without increase of load. It is usually determined by the drop of the beam of the testing machine or by the use of dividers.

(d) The "tensile strength" is the maximum load per square inch of original cross section.

(e) The "elongation" is the percentage difference between lengths laid off between gage marks before being subjected to any stress, and after rupture.

(f) The "reduction of area" is the percentage difference between the area of the bar before being subjected to stress and the area of the bar after rupture. The latter will be determined by measurements taken at the point of rupture.

35. *Definition of heat-treating terms.*—In general, heat treatment, when applied to steel, will consist of one or more of the following operations or combinations thereof:

(a) *Normalizing.*—Material ordered normalized shall be uniformly heated to and held at a temperature sufficiently above the critical range for a time sufficient to produce refining of the grain, after which it shall be allowed to cool freely in the air.

(b) *Annealing.*—Material ordered annealed shall, unless otherwise approved, be uniformly heated to and held at a temperature sufficiently above the critical range for a time sufficient to insure that the section has been soaked through and the grain refined, then allowed to cool slowly as desired.

If the contract or purchase order specifies a Brinell hardness or other physical requirement that necessitates a spheroidizing anneal, the contractor may perform such anneal at a temperature below the lower critical temperature, but such low temperature shall not be used for the usual annealing treatment to refine the grain.

(c) *Heating and quenching.*—Material ordered to meet physical requirements that necessitate heating and quenching shall be uniformly heated to and held at a temperature sufficiently above the critical range for a time sufficient to insure that the section has been thoroughly soaked through and the grain refined, then rapidly cooled in a suitable quenching medium. The heating and quenching operations may be preceded by a normalizing or annealing operation, or both, depending upon the character and condition of the steel, and the particular properties required.

(d) *Tempering.*—All hardened or quenched parts shall receive a tempering heat, which shall consist of uniformly reheating to some temperature below the lower critical temperature, holding at heat for a time sufficient to insure that the section has been soaked through, and then cooling as may be desired. Quenching from the tempering heat may be necessary with certain alloy steels in order to avoid so-called "temper brittleness."

600.1 TESTING OF METALS.

METHODS OF TEST

(In the ferrous and nonferrous metals group a test method that covers several items will be found under

the commodity designation 600.1. Reference to this test method is then inserted under the commodity designation of each item. For example, tentative methods of tension testing—and also of compression testing—of metallic materials appear below. References to these test methods will be found under commodity designations 621.30, 631.0, 640.1, 650.1, 680.1, and 692.0. But when a test method is confined to a specific item, the test method is inserted under the commodity designation attached to that item. For example, chemical analysis of alloy steels will be found under 621.30; under 693.3 will be found chemical analysis of silver solders.)

(Federal Specification Board specification No. 339a (current designation, QQ-M-151) includes general requirements for tests which apply to a number of the Federal specifications. These test requirements will be found under 600.0, p. 3.)

AMERICAN BUREAU OF SHIPPING, RULES FOR BUILDING AND CLASSING STEEL VESSELS; MATERIALS FOR MACHINERY, BOILERS, AND PIPING, 1930

TESTING REQUIREMENTS

1. All materials subject to tests and inspection are to be tested and inspected by the bureau's surveyors in accordance with the following requirements: Materials of different characteristics than prescribed herein require the special approval of the committee. Such materials satisfactorily tested and inspected shall be stamped **A. B.**, signifying that the material has satisfactorily passed the required test and inspection.

2. Where materials are not required to be in accordance with the rules, the same may be tested by the surveyors to the bureau, upon request, to specifications agreed upon by the purchaser and manufacturer. Such materials are not to be stamped **A. B.**

3. All materials subject to test and inspection are to be free from defects. Welding or dressing for the purpose of remedying defects is not permitted without the previous sanction of the surveyor. Where materials have been so treated the surveyor may prescribe additional tests, and the part treated must be stamped with the surveyor's identification mark and surrounded with a ring of paint.

4. All test specimens shall be selected by the surveyor and must not be detached until stamped with his identification mark and until the material has received its final treatment. The yield point is to be determined by the drop of the beam. In the event of any test specimen failing to meet the requirements, unless two further specimens prove satisfactory, the particular material from which such test specimens have been taken shall be rejected. Further tests of specimens taken from the same heat shall then be made, and if these fail the whole of the material produced from that heat is to be rejected. Should a tension test piece break outside the middle half, the test piece may, at the manufacturer's option, be discarded and a new specimen substituted. All tests are to be conducted in the presence of the surveyor at the place of manufacture prior to shipping.

5. Any material proving unsatisfactory in the process of being worked shall be rejected notwithstanding any previous certificate of satisfactory testing.

STANDARD TEST PIECES

6. The test pieces should be made to the following dimension, as shown in Figure 5, on page 8.

AMERICAN ASSOCIATION OF STATE HIGHWAY OFFICIALS, TENTATIVE STANDARD METHODS OF SAMPLING AND TESTING HIGHWAY MATERIALS. UNITED STATES DEPARTMENT OF AGRICULTURE, BULLETIN NO. 1216, 1928

SAMPLING AND TESTING HIGHWAY MATERIALS

(This publication includes reprints of American Society for Testing Materials specifications Nos. E4-27, E8-27T, E9-27T, and E10-27, all of which, with certain cross references, are given below.)

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, PROOF TESTING OF FORGINGS TO DETERMINE THEIR SOUNDNESS AFTER QUENCHING AND TEMPERING, SERIAL NO. E108-25, 1925

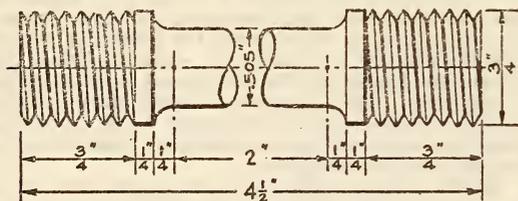

PROOF TESTING OF FORGINGS

Up to the present time proof testing has been mostly confined to locomotive driving axles and the

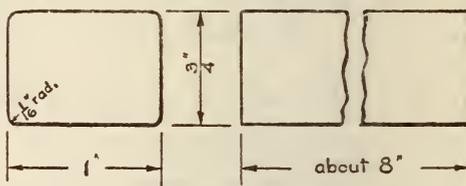

The accompanying table has been prepared to give a suitable height of drop uniform for both ends of each size of axle, but increasing with the size, and includes heights of drop for both 1,640 and 2,000 pound tups, for reasons given later in this report. This table is based on the formula above given, with compensation made for the varying cross section of axles, and was calculated for the rough turned sizes of association's standard axles, allowing one-fourth inch on the diameter for finishing.

It is recommended that wherever practicable the proof tests be made after the rough turning of forging.

Due to the many variables governing a test of this kind, some of which can not be ascertained with any degree of accuracy, it is impossible to calculate the proper height of drop for a definite fiber stress. The ideal proof test is one that subjects all parts of the forging to a stress slightly under its elastic limit, and under no circumstances should the elastic limit of the material be exceeded; therefore when it is considered that the stress due to a drop test is dependent on not only the weight of tup, height of drop, and distance between supports, but also on the hardness of the material, the relation between the mass of the forging tested and the anvils upon which it rests, the capacity and flexibility of springs

FIGURE 5.—Standard test pieces

(See specification on p. 7)

distance between supports usually placed at 3 feet, with height of drop generally based on the following formula:

$$H = \frac{d^3}{100}$$

Wherein

H=Height of drop in feet

and

d=Diameter of axle in inches.

Testing machine.—Standard M. C. B. with spring supported anvils.

Weight of tup.—1,640 pounds.

So far as can be learned, these tests were established through experiments conducted to determine the blow required to produce permanent set, and the theory developed for the M. C. B. car axle drop test with the modifications necessary to change from a destructive to a proof test.

which support the anvils, and other details of the testing apparatus, it can be readily seen that the ideal test can only be approximated, and the table given under Figure 6 should be taken, therefore, as a guide in indicating what has been found from actual use to fulfill as nearly as possible the requirements.

While a 1,640-pound tup has been generally used in the past in the standard proof testing machine, we are informed that the M. C. B. Association is considering adopting a tup weighing 2,000 pounds on account of the lighter weight not being sufficient for a destructive drop test with the present height of testing machine and the largest standard car axles, and in order that it shall not be necessary to change weight between the different tests, it has been suggested that the newly proposed standard weight of tup of 2,000 pounds be used for proof testing, with a corresponding reduction in height of drop.

It is the usual practice to turn the forging after each test so as to provide drop test on two opposite sides. Any drop test of this sort should not cause permanent set in sound forging, and provision should be made in the agreement with the manufacturer that permanent set in forging shall be cause for rejection. A suggestion for gage to determine the set in forgings is shown in Figure 7.

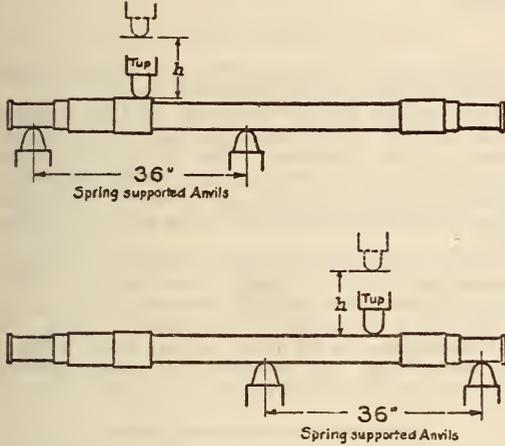

Table showing height of drop "h"

Axle		Drop with 1,640-pound tup	Drop with 2,000-pound tup

AMERICAN SOCIETY OF MECHANICAL ENGINEERS, GENERAL RULES FOR INSPECTION AND TESTS, BOILER CONSTRUCTION CODE, 1927

INSPECTION AND TESTS

(In respect to inspection, rejections, and reheating, this specification is identical with pars. 7, 8, and 9 of the standard specifications for steel of the American Society for Testing Materials (see 605.0, p. 247.) Additional provisions are as follows:)

Ladle analyses.—The manufacturer shall make an analysis of each melt of steel, from a test ingot taken during the pouring of the melts, to determine the percentage of carbon, manganese, phosphorus, and sulphur. The results of analysis shall conform to requirements, and shall be reported to the purchaser or his representative.

Check analyses.—The purchaser may make an analysis from finished material representing each melt. The chemical composition thus determined shall conform to the requirements.

Physical tests.—The yield point shall be determined by the drop of the beam of the testing machine. For determination of the yield point the speed of the

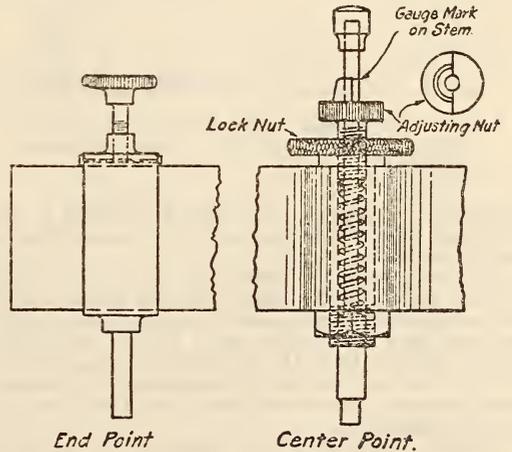

crosshead of the machine shall not exceed one-half inch per minute when the elongation is taken in 2 inches, nor exceed 2 inches per minute when the elongation is taken in 8 inches. After the yield point has been passed, the speed of the machine may be increased to not more than 2 inches per minute when the elongation is taken in 2 inches, nor more than 6 inches per minute when the elongation is taken in 8 inches.

[Approved by the American Standards Association, January, 1932]

ENGINEERING SYMBOLS

(This pamphlet contains the approved symbols for 69 different items which appear with varying frequency in publications related to the practice of engineering. Seven of these items—angular distance, angular velocity, angular acceleration, radius of curvature, deflection of a panel point of a truss, density, and the unit of elongation—are represented

Axle	A
Inches	Inches
3¾ by 7	41¼
4¼ by 8	41¾
5 by 9	42¾
5½ by 10	43¾

FIGURE 7.—Suggested design of gage for determining if axles take set in proof testing

by Greek letters. English capitals and lower case letters represent the others. Capital T covers four different items, including harmonic motion period, torque, and absolute temperature.)

NOTE.—Sponsor organizations: American Association for the Advancement of Science, American Institute of Electrical Engineers, American Society of Civil Engineers, American Society of Mechanical Engineers, and Society for the Promotion of Engineering Education.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD METHODS OF CHEMICAL ANALYSIS OF PLAIN CARBON STEEL, SERIAL DESIGNATION A33-24, 1924

CHEMICAL ANALYSIS OF PLAIN CARBON STEEL

DETERMINATION OF CARBON BY THE DIRECT COMBUSTION METHOD

(Substantially the same as in A64 (see 601.20, p. 119), except for the alternative method of absorbing the carbon dioxide by means of barium hydroxide solution, given below, and that nickel boats should not be made of sheet nickel containing more than 0.3 per cent of carbon instead of 0.15 per cent as in A64.)

DETERMINATION OF CARBON (CARBON DIOXIDE ABSORBED IN BARIUM HYDROXIDE SOLUTION)

Special Apparatus

Purifying train.—This method eliminates the necessity of a purifying train following the furnace, inasmuch as no precautions are necessary to prevent access of water vapor or oxides of sulphur from the

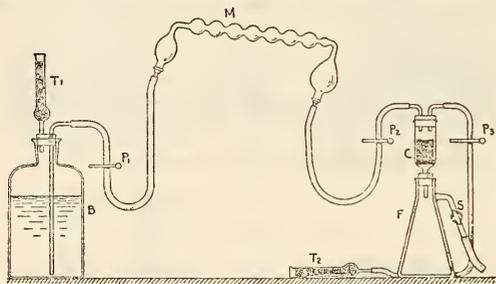

FIGURE 8.—Apparatus for filtration in determination of carbon by the direct-combustion method

absorbing apparatus. All that is needed is the purifying train before the combustion apparatus as mentioned above.

The train after the combustion apparatus.—This consists merely of the Meyer tube for absorption of the carbon dioxide, protected by a soda-lime or soda-asbestos tube at the far end. Meyer tubes with 7 to 10 bulbs of 10 to 15 c c capacity each, and large bulbs at the ends, having volumes equal to the combined capacity of the small bulbs, have been used and found satisfactory.

Filtering apparatus.—In filtration for accurate work, care should be taken to protect the solution from access of extraneous carbon dioxide. This is accomplished in the apparatus shown in Figure 8. For work requiring less accuracy, the barium carbonate may be filtered off on a filter made by fitting a carbon funnel with a perforated porcelain disk and filtering by suction. The precipitate is then washed with distilled water from which the carbon dioxide has been removed by boiling.

Reagents

Tenth-normal hydrochloric acid.—This may be standardized by any of the accepted methods, or as follows: Measure out 20 c c of the approximately 0.1 N acid (free from chlorides) with a pipette, and precipitate the silver chloride by an excess of silver-nitrate solution in a volume of 50 to 66 c c. After digesting at 70° to 80° C., until the supernatant liquid is clear, filter off the chloride on a tared Gooch filter and wash with water con-

taining 2 c c of HNO₃ (specific gravity 1.42) per 100 c c of water until free from silver nitrate. After drying to constant weight at 130° C., note the increase of weight over the original tare and from this weight, corresponding to the silver chloride, calculate the strength of the hydrochloric acid, after which adjust it to the strength prescribed. The standardization should be based upon several concordant determinations using varying amounts of acid.

$$1 \text{ cc } 0.1 \text{ N HCl} = 0.0006 \text{ g carbon}$$

Methyl orange.—Dissolve 0.02 g of methyl orange in 100 c c of hot distilled water and filter.

Tenth-normal sodium hydroxide solution.—Standardize against the hydrochloric acid. Use methyl orange as the indicator. The sodium hydroxide solution should be stored in a large bottle from which it may be driven out by air pressure, protecting against carbon dioxide by soda-lime or soda-asbestos tubes.

Barium hydroxide solution.—Filter a saturated solution and store in a large reservoir from which it is delivered by air pressure, protecting from carbon dioxide by a soda-lime or soda-asbestos tube. In each determination fill three or four small bulbs of the Meyer tube, and add CO₂-free water until the remaining small bulbs are filled.

Apparatus and Procedure for Filtration

The apparatus is shown to approximately one-tenth size in Figure 8, which is self-explanatory. The stopcock is a 3-way cock connected to the suction pipe. The rubber tubing connected to the Meyer tube should be of best-grade black rubber, and the lengths used should be so chosen as to permit of easy manipulation of the tube. The Meyer tube is connected or disconnected by the rubber stoppers which are left always attached to the rubber tubes. The carbon tube C is fitted with a perforated porcelain plate sliding easily.

The funnel is prepared for filtration by making on the porcelain disk a felt of asbestos about one-sixteenth to one-eighth inch in thickness, using amphibole (not serpentine) asbestos which has been carefully digested with strong hydrochloric acid for several hours and washed with water until it gives no acid reaction. On top of the asbestos pad is placed a layer of similarly treated quartz, mixed with asbestos, of the height shown. A mixture of quartz grains of various sizes (approximately 50 per cent passing a 20-mesh sieve and 50 per cent passing a 10-mesh and remaining on a 20-mesh sieve) is suitable. The mixture of quartz and asbestos may be obtained by filling the funnel from a beaker (directing against it a stream from a wash bottle) while maintaining a gentle suction. In this way the asbestos is properly mixed with the quartz. A little experience and attention to these details will enable one to prepare the quartz bed in a manner that will greatly expedite filtration. The stopper is now inserted in the funnel, the Meyer tube connected as shown, and the liquid and precipitate sucked into the funnel. Only a gentle suction should be used. When necessary P₂ is opened to admit air back of the column of liquid in the Meyer tube. When the contents of the Meyer tube have been transferred, the large bulb nearest B is half filled with water by opening P₁; the stopcock S is operated during this and subsequent operations so as to maintain a gentle suction all the time. M is now manipulated so as to bring the wash water in contact with all parts of the interior, after which the water is sucked through C; P₂ is left open during this and subsequent washings. After eight washings as directed, allowing the wash water to drain off thoroughly each time before adding more, M may

be detached, the stopper removed from the funnel, and the washings completed by filling *C* to the top with CO₂-free water, draining completely and repeating the operation once. With care the washing may be done with 150 c c of water. Air is now admitted through the side opening of *S*, *C* is removed, and the porcelain disk carrying the asbestos, quartz, and barium carbonate is thrust, by means of a long glass rod, into a flask, removing any adhering particles from the sides of *C*, by a stream of water from a wash bottle. An excess of the standard acid is now added from a burette or pipette, using a portion to wash out *M*, and after the contents of the flask have been thoroughly agitated by shaking, the excess of acid is titrated against the standard alkali, using three drops of the methyl-orange indicator.

NOTES.—The operation of filtering can be carried out very rapidly after a little practice.

Glass wool should on no account be used as a substitute for the quartz, on account of the probability of errors arising from its attack by the alkali or acid.

It is well to wash out the rubber tubes connected to the Meyer tube with a little water each day before beginning work.

Method

After having properly set up and tested the apparatus, place 2 g of steel (note 1) in the form recommended above, in a moderately packed condition on the bed material and introduce the boat into the combustion apparatus, already heated to the proper temperature. After one-half to one minute, admit oxygen somewhat more rapidly than it is consumed, as shown by the rate of bubbling in the Meyer tube (note 2). A rate of 200 c c per minute is satisfactory. The sample burns completely in one or two minutes, and all that is now necessary is to sweep all the carbon dioxide into the absorption apparatus. This is accomplished in 5 to 10 minutes by passing about 1 or 2 liters of oxygen. Detach the Meyer tube (note 2) and filter and wash the barium carbonate, using the special filtering apparatus shown. After solution in a measured excess of standard hydrochloric acid (the Meyer tube being washed out with a portion of the acid to remove adhering barium carbonate), titrate the excess of acid against alkali and from the data thus obtained calculate the percentage of carbon.

NOTES.—1. When working with steels high in carbon (above 1 per cent) it is advisable not to use more than 1 g in order that filtration may be sufficiently rapid.

2. As a precaution against error resulting from too rapid passage of the gases, it is well to attach a second barium-hydroxide tube to retain any carbon dioxide that may pass the first.

3. For the most accurate work the Meyer tubes should be washed with dilute acid before beginning work each day. After a determination is finished, the tube should be completely filled two or three times with tap water, then rinsed with distilled water, in order to remove the carbon dioxide liberated when dissolving the carbonate from the previous determination.

4. The flask containing the carbonate should be thoroughly agitated after adding the acid, since the carbonate sometimes dissolves rather slowly if this is not done; this is particularly the case if it has packed much during filtration.

DETERMINATION OF MANGANESE BY THE BISMUTHATE METHOD (ABSENCE OF COBALT)

Solutions Required

(Dilute nitric acid (1:3), dilute nitric acid (3:97), ferrous ammonium sulphate solution, standard potassium permanganate solution, and standard sodium arsenite solution—all conform to like solutions in the determination of manganese by the bismuthate method in A64 (see 601.20, p. 119).)

Method

In a 300 c c Erlenmeyer flask dissolve 1 g of steel in 50 c c of dilute HNO₃ (1:3), and boil to expel the oxides of nitrogen. Cool, and add about 0.5 g of sodium bismuthate and heat for a few minutes, or until the pink color has disappeared, with or without

precipitation of manganese dioxide. Add small portions of ferrous sulphate (or any suitable reducing agent) in sufficient quantity to clear the solution, and boil to expel the oxides of nitrogen. Cool to 15° C., add an excess of sodium bismuthate and agitate for a few minutes. Add 50 c c of dilute HNO₃ (3:97), filter through an alundum filter or asbestos pad, and wash with the same acid. Titrate by method (a) or (b) below.

(a) *Ferrous sulphate-permanganate titration* (less than 0.05 per cent chromium). (Same as in A64 (see 601.20, p. 119).)

(b) *Arsenite titration* (more than 0.05 per cent chromium).

Titrate immediately with the standard sodium arsenite solution to the clear green color used as an end point in the standardization of the solution.

Allowable error.—Percentages of manganese determined by the above method should be accurate to $\pm [0.01 + (0.02 \times \text{the percentage of manganese found})]$.

NOTES.—In the method, the preliminary treatment with sodium bismuthate has been found by a number of investigators to be apparently unnecessary; however, the available data to confirm this position are not considered sufficient to warrant its omission.

In making the asbestos filter pad it is advisable to have a thin bed, and as much surface as possible. This insures rapid filtration, and the filter may be used until it becomes clogged with bismuthate.

The filtrate must be perfectly clear, since the least particle of bismuthate carried through the filter will vitiate the results.

This method can not be used in the presence of cobalt.

In the arsenite titration, permanganic acid does not react in accordance with the ratio Mn₂O₇:2 MnO, but more nearly as indicated by the ratio Mn₂O₇:Mn₂O₃. Consequently the theoretical titre of the arsenite can not be used and the manganese titre must be obtained by titration of material of known manganese content under the conditions that obtain in the method.

DETERMINATION OF MANGANESE BY THE PERSULPHATE METHOD (ROUTINE AND IN THE PRESENCE OF COBALT)

Solutions Required

(Conform to like solutions in the determination of manganese by the persulphate method in A64 (see 601.20, p. 119).)

Method

In a small Erlenmeyer flask or large test tube (8 by 1 inch) dissolve 0.1 to 0.3 g of steel, depending on the manganese content of the sample, in 15 c c of dilute HNO₃ (specific gravity 1.20) with the aid of heat from a hot-plate or water bath. The solution of carbon may be hastened by the addition of 1 c c of the ammonium persulphate solution (10 per cent). When solution is complete and the liquid is clear, add 15 c c of AgNO₃ solution (0.133 per cent). (Then proceed as in the determination of manganese by the persulphate method in A64 (see 601.20, p. 119).)

DETERMINATION OF PHOSPHORUS BY THE MOLYBDATE-MAGNESIA METHOD

Solutions Required

Dilute nitric acid (specific gravity 1.20).—Mix 380 c c of HNO₃ (specific gravity 1.42) and 620 c c of distilled water.

Dilute nitric acid (2:100).—Mix 20 c c of HNO₃ (specific gravity 1.42) and 1,000 c c of distilled water.

Potassium permanganate (2.5 per cent).—Dissolve 25 g of KMnO₄ in 1,000 c c of distilled water.

Dilute ammonium hydroxide (1:2).—Mix 300 c c of NH₄OH (specific gravity 0.90) and 600 c c of distilled water.

Dilute ammonium hydroxide (1:19).—Mix 100 c c of NH₄OH (specific gravity 0.90) and 1,900 c c of distilled water.

Ammonium bisulphite (3 per cent).—Dissolve 30 g of ammonium bisulphite in 1,000 c c of distilled water.

Ammonium molybdate.—(Same as B28 (see 646.0, p. 1243).)

Magnesia mixture.—Dissolve 50 g of $MgCl_2 \cdot 6H_2O$ and 125 g of NH_4Cl in 750 c c of distilled water, and then add 150 c c of NH_4OH (specific gravity 0.90).

Method

In a 300 c c Erlenmeyer flask dissolve 5 g of steel in 75 c c of dilute HNO_3 (specific gravity 1.20). Heat to boiling; while boiling add about 12 c c of the potassium permanganate solution, and continue boiling until manganese dioxide precipitates. Dissolve this precipitate by additions of ammonium bisulphite or ferrous sulphate solution, boil until clear and free from brown fumes, and cool to 80° C. Add 100 c c of the ammonium molybdate solution at room temperature, shake or agitate for five minutes, allow to settle, filter on a 9 cm paper, and wash the flask and precipitate at least three times with the dilute HNO_3 (2 : 100), to free from iron.

Dissolve the precipitate on the filter with dilute NH_4OH (1 : 2), letting the solution run into the original flask and avoiding the use of more than 10 to 20 c c of the reagent. Pour a solution of 0.5 g of citric acid in 15 c c of water and 10 c c of HCl (specific gravity 1.19) through the filter in order to dissolve any ferric phosphate on the paper and render acid the ammoniacal solution of the phosphate. Transfer the solution to a 100 c c beaker, add 10 c c of the magnesia mixture and precipitate the phosphate by adding NH_4OH (specific gravity 0.90) slowly and with constant stirring, until a crystalline precipitate is formed or the solution is alkaline. Finally add 10 per cent by volume excess and set aside in a cool place for two to six hours. Filter, wash with dilute NH_4OH (1 : 19), ignite, and weigh. Dissolve the precipitate of magnesium pyrophosphate in 5 c c of dilute HNO_3 (5 : 6), and 20 c c of distilled water, filter, and wash with hot water. Ignite and weigh. The difference in weights represents pure magnesium pyrophosphate containing 27.87 per cent of phosphorus.

Allowable error.—Percentages of phosphorus determined by the above method should be accurate to $\pm[0.002 + (0.02 \times \text{the percentage of phosphorus found})]$.

NOTES.—The ammonium molybdate solution should be kept in a cool place and should always be absolutely clear before using.

If arsenic is present in the steel, it will come down in part with the phosphomolybdate and contaminate the pyrophosphate. In very accurate work, or where arsenic is present in appreciable amount steps must be taken for its removal before precipitation with magnesia mixture.

DETERMINATION OF PHOSPHORUS BY THE ALKALIMETRIC METHOD (ROUTINE)

Solutions Required

(Dilute nitric acid (specific gravity 1.20), dilute nitric acid (2 : 100), potassium permanganate, and ammonium bisulphite—all identical with molybdate-magnesia method given above. Ammonium molybdate, potassium nitrate (1 per cent), phenolphthalein indicator, standard sodium hydroxide, and standard nitric acid—all identical with B28 (see 646.0, p. 1243).)

Method

In a 300 c c Erlenmeyer flask dissolve 2 g of steel in 50 c c of dilute HNO_3 (specific gravity 1.20). Heat the solution to boiling and while boiling add about 6 c c of the $KMnO_4$ solution and continue boiling until manganese dioxide precipitates. Dissolve this precipitate by additions of ammonium bisulphite or ferrous sulphate solution, boil until clear and free from brown fumes, cool to 80° C., add 50 c c of the ammonium molybdate solution at room temperature, shake or agitate for five minutes, allow to settle, and filter on a 9 cm paper. Wash the flask and precipitate three times with dilute

HNO_3 (2 : 100) to free it from iron, and continue the washing with the 1 per cent potassium nitrate solution until the paper, precipitate, and flask are free from acid.

Transfer the paper and precipitate to the flask, add 20 c c of distilled water, 5 drops of phenolphthalein solution as indicator, and an excess of standard sodium hydroxide solution. Insert a rubber stopper and shake vigorously until solution of the precipitate is complete. Wash off the stopper with distilled water and determine the excess of sodium hydroxide solution by titrating with standard nitric acid solution. Each cubic centimeter of standard sodium hydroxide solution represents 0.01 per cent of phosphorus.

NOTES.—The ammonium molybdate solution should be kept in a cool place and should always be absolutely clear before using.

All distilled water used in titration should be freed from carbon dioxide by boiling or otherwise.

Appropriate Bureau of Standards standard steels are recommended for the standardization of the sodium hydroxide solution.

The composition of phosphomolybdate varies with changes in conditions such as acidity, temperature, and concentration of the molybdate reagent; consequently care should be taken to keep conditions alike in standardization and in analysis. The ratio 23 molecules of sodium hydroxide to 1 atom of phosphorus represents the reaction very closely if the phosphomolybdate is precipitated at 35° to 45° C.

DETERMINATION OF SULPHUR BY THE OXIDATION METHOD

Solutions Required

Dilute hydrochloric acid (2 : 98).—Mix 20 c c of HCl (specific gravity 1.19) and 980 c c of distilled water.

Barium-chloride solution (10 per cent).—Dissolve 100 g of $BaCl_2 \cdot 2H_2O$ in 1,000 c c of distilled water.

Barium chloride-hydrochloric acid washing solution.—Mix 10 c c of the above solution, 10 c c of HCl (specific gravity 1.19), and 1,000 c c of distilled water.

Method

Dissolve 4.57 g of the sample in 50 c c of HNO_3 (specific gravity 1.42) in a covered beaker or flask. In case solution is slow or difficult, HCl (specific gravity 1.19) may be added dropwise at intervals. When solution is complete, add 0.5 g of Na_2CO_3 , evaporate to dryness and bake for 1 hour on the hot plate. Add 30 c c of HCl (specific gravity 1.19), and repeat the evaporation and baking. Add another 30 c c of HCl (specific gravity 1.19), and evaporate to sirupy consistency. Add 5 c c of HCl (specific gravity 1.19), 20 c c of water, 5 g of 20 to 30 mesh zinc (free from sulphur) and warm on the steam bath until the iron is reduced to the ferrous state and the evolution of hydrogen has nearly ceased. Filter, by decantation on a small filter, from the silica and undissolved zinc, wash with small portions of approximately 75 c c of dilute HCl (2 : 98), warm to 60° to 70° C., and add 10 c c of $BaCl_2$ solution (10 per cent). Let stand for 18 to 24 hours, filter on a paper of close texture, and discard the filtrate. Wash with hot $BaCl_2$ - HCl washing solution until free from iron and then with hot water until free from chlorides. Reserve the paper, and precipitate and evaporate the washings to dryness. Dissolve the slight residue in 50 c c of hot dilute HCl (2 : 98), add 1 c c of $BaCl_2$ solution (10 per cent), and digest at 70° to 80° C. for an hour or so, avoiding any undue evaporation. Filter on a small paper of close texture, wash with hot $BaCl_2$ - HCl washing solution until free from iron and then with hot water until free from chlorides. Ignite both papers in a tared platinum crucible, and treat with one drop of dilute H_2SO_4 (1 : 1) and 1 c c of hydrofluoric acid. Evaporate to dryness, ignite, and weigh. A blank should be carried through all steps of the determination and any $BaSO_4$ found deducted. The corrected weight

of the ignited BaSO₄ multiplied by 3 represents the percentage of sulphur.

Allowable error.—Percentages of sulphur determined by the above method should be accurate to $\pm [0.002 + (0.02 \times \text{the percentage of sulphur found})]$.

Notes.—The precipitation of BaSO₄ must not be carried out in a solution containing more than 2 c c of HCl (specific gravity 1.19: per 100 c c).

The recovery of BaSO₄ which is obtained ordinarily represents approximately 0.001 per cent of sulphur.

Precipitation of BaSO₄ in unreduced iron solutions of carefully regulated acidity gives low values of the order of 0.001 to 0.002 per cent of sulphur.

DETERMINATION OF SULPHUR BY THE EVOLUTION-TITRATION METHOD (ROUTINE)

(In respect to diagram illustrating apparatus, solutions required, and method, this specification is identical with A64 (see 601.20, p. 119), except that in A64 the potassium iodate solution includes the chemical reactions, the starch solution in A64 is replaced by the starch indicator given below, and for the notes in A64 are substituted the following notes:)

Starch indicator.—(1) To 1,000 c c of boiling distilled water add a cold suspension of 6 g of starch in 100 c c of water, and boil vigorously for five minutes. Cool the solution, add 6 g of ZnCl₂ dissolved in 50 c c of cold water, thoroughly mix, and set aside for 24 hours. Decant the clear supernatant liquid into a suitable container, add 3 g of KI, and mix thoroughly. (2) (Optional.) Prepare an emulsion of 6 g of soluble starch in 25 c c of water, add a solution of 1 g of NaOH in 10 c c of water, and stir the solution until it gelatinizes. Dilute to 1,000 c c, add 3 g of KI, and mix thoroughly.

Notes.—This method succeeds best when the evolution of gas is rapid and the conditions are kept constant.

Some analysts prefer to add the dilute HCl at a temperature of 80° to 90° C. and to heat the flask on an electric heater instead of over gas. The use of concentrated HCl necessitates a condensing arrangement and does not offer any general advantages over the diluted acid.

With most plain carbon steel the results for sulphur which are obtained by the evolution method and the use of the theoretical sulphur titre check the gravimetric results within ± 0.002 per cent. Some steels dissolve too slowly, and some, as, for example, certain steels containing high sulphur and carbon, do not yield all of their sulphur. In such cases the samples must be annealed as follows:

Transfer 5 g of drillings to a 12.5 cm filter paper, and wrap the sample securely in the paper so that at least three thicknesses of paper cover the steel. Place the package in a 25 c c porcelain crucible, cover the crucible tightly so that no air can enter, and heat for 20 minutes at a bright-red heat over a burner or preferably in a muffle. The filter paper should be charred but not burned. Cool, and proceed as in the regular method.

DETERMINATION OF SILICON BY THE NITROSULPHURIC METHOD

Solutions Required

Nitrosulphuric acid.—Mix 1,000 c c of H₂SO₄ (specific gravity 1.84), 1,500 c c HNO₃ (specific gravity 1.42), and 5,500 c c of distilled water.

Dilute hydrochloric acid (5:95).—(Same as in A64 (see 601.20, p. 119).)

Method

(Identical with A64 (see 601.20, p. 119), except that 80 c c of the nitrosulphuric acid is added cautiously to 4.676 g of steel, and that the difference in weights in milligrams divided by 100 equals the percentage of silicon instead of being divided by 50 as in A64.)

Allowable error.—Percentages of silicon determined by the above method should be accurate to $\pm [0.005 + (0.02 \times \text{the percentage of silicon found})]$.

Note.—A blank determination on all reagents used should be made and the results corrected accordingly.

DETERMINATION OF SILICON BY THE SULPHURIC-ACID METHOD (OPTIONAL)

(Identical with A64 (see 601.20, p. 119), except that here 2.338 g of steel is substituted for the 2.336 g of iron specified in A64.)

DETERMINATION OF COPPER

(Identical with A64 (see 601.20, p. 119) except for the addition of the following clause in the method of precipitation by hydrogen sulphide:)

Dissolve the cooled melt in the crucible in 1 or 2 c c of HCl (specific gravity 1.19) and a few cubic centimeters of water, transfer to a 200 c c beaker, dilute to 100 c c, and add NaOH (5 per cent) solution in slight excess.

DETERMINATION OF COPPER (ROUTINE)

(Substantially the same as in A64 (see 601.20, p. 119).)

DETERMINATION OF NICKEL

See the determination of nickel in nickel steel by the gravimetric dimethylglyoxime method in A55 (621.30, p. 1107); also the determination of nickel in nickel steel by the cyanide titration method (routine) in A55 (621.30, p. 1107).

DETERMINATION OF CHROMIUM

(Same as the determination of chromium in chrome-nickel steel by the persulphate oxidation method in A55 (see 621.30, p. 1107) except in solutions required, where dilute nitric acid (specific gravity 1.20) is the same as in the determination of manganese by the persulphate method in A64 (see 601.20, p. 119), and standard ferrous-sulphate and standard permanganate solution are the same as in the determination of manganese by the bismuthate method in A64 (see 601.20, p. 119).)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD METHOD OF TEST FOR MAGNETIC PROPERTIES OF IRON AND STEEL, DESIGNATION A34-28, 1928

TESTING MAGNETIC PROPERTIES OF IRON AND STEEL

A. NORMAL INDUCTION AND HYSTERESIS

Definitions

1. (a) *Normal induction.*—The induction, produced under a given magnetizing force, in a substance which has been previously demagnetized and then subjected to a sufficient number of reversals of the given magnetizing force to bring it to a cyclic condition.

Both the induction and magnetizing force shall be expressed in terms of the cgs electromagnetic units (gauss and gilbert per centimeter respectively).

(b) *Magnetic permeability.*—The ratio of the normal induction to the magnetizing force which produces it. Thus:

$$\text{Permeability} = \frac{\text{Gausses}}{\text{Gilberts per centimeter}}$$

(c) *Residual induction.*—The magnetic induction which exists in a substance after the magnetizing force has been reduced to zero.

Note.—If the induction has been reduced from a point on the normal induction curve it is called the normal residual induction.

(d) *Coercive force.*—The negative value of magnetizing force required to reduce the induction in a substance to zero.

Note.—If the induction has been reduced to zero from a point on the normal induction curve the coercive force is called the normal coercive force.

Test Specimens

2. (a) Test specimens may consist of rings, straight bars, or strips of uniform cross section.

(b) Ring specimens shall be continuous, having no joints or welds. The ratio of mean diameter to radial width shall be not less than 10.

(c) Sharp shears or dies shall be used in the preparation of specimens of sheet material. If the radial width of ring specimens or the width of straight strips of sheet material is less than 3 cm ($1\frac{1}{16}$ inch), the punching or cutting strains shall be removed before testing by an annealing process acceptable both to manufacturer and to purchaser.

(d) Test specimens of sheet material consisting of straight strips shall be cut half parallel and half at right angles to the direction of rolling, and in types of test requiring companion samples each half shall contain an equal number of each kind of strips.

3. (a) Test specimens of sheet material shall have a cross-sectional area of not less than 2 cm² (0.31 square inch) nor more than 4 cm² (0.62 square inch) and shall be so selected from not less than two sheets that their properties shall represent as nearly as practicable the average properties of the sheets. (See figs. 9 and 10.)

(b) The cross section of specimens of sheet material shall be calculated from measured values of length and mass and measured or assumed values of density.

(c) For silicon steels, a density of 7.7 g per cubic centimeter shall be assumed if the silicon content is 2 per cent or less and a density of 7.5 g per cubic centimeter shall be assumed if the silicon content is over 2 per cent.¹

(d) For nickel-iron alloys the density shall be assumed from the nickel content as given by the straight lines joining the points defined as follows.²

Nickel	Density
<i>Per cent</i>	<i>g/cm³</i>
0	7.85
30	8.00
100	8.90

(e) For other alloys, a density corresponding to the actual measured or estimated value shall be used.

4. Specimens of magnet steel shall be hardened previous to testing in accordance with a procedure acceptable to both manufacturer and purchaser.

Standard data

5. (a) The standard normal-induction data for all magnetic materials shall consist of corresponding values of normal induction and magnetizing force at suitable intervals within the range of values agreed upon by the manufacturer and purchaser.

(b) Residual-induction and coercive-force values for transformer-core material and material of the type used for electromagnet cores shall be determined from a maximum normal induction of 10,000 gauss.

(c) For permanent magnet steel, the residual induction and coercive force shall be determined from the maximum normal induction corresponding to a magnetizing force of 200 gilberts per centimeter unless the maximum permeability is less than 100, in which case the maximum magnetizing force shall be not less than two and one-half times the value of the magnetizing force at which this maximum permeability occurs and shall be some multiple of 200.

Methods of test

6. The tests may be made by means of one of the following methods:

The Rowland ring method.—This method may be used for any material and any magnetizing forces.

The Burrows compensated double yoke.—This type of apparatus is suitable for tests at magnetizing forces up to 300 gilberts per centimeter. For higher magnetizing forces, serious difficulty due to heating

may be encountered unless special temperature control is provided.

The magnetizing coils shall be not less than 20 centimeters ($7\frac{1}{2}$ inches) in length and the ratio of the area of the test coil to that of the specimen shall be such that the air-correction factor shall be not greater than 5. This air correction may be applied by calculation or eliminated by means of an adjustable mutual inductance having its primary in series with the main permeameter magnetizing winding and its secondary in series with the main test coil. This mutual inductance shall be set to such a value that the flux in the space between the sample and the test coil shall be automatically compensated for. If desired, the two main magnetizing coils may be connected in series and the average values for the whole sample³ determined by connecting the two middle test coils in series and using them as one. In this arrangement, four auxiliary test coils near the ends of the specimens are connected in series and used as one coil for adjusting the current in the compensating magnetizing coils.

The Fahy simplex permeameter.—This type of apparatus is suitable for tests at magnetizing forces up to 300 gilberts per centimeter without difficulties due to heating. For higher values of magnetizing force, the high magnetization adapter may be used.

Isthmus method.—This method, as described in Bureau of Standards Scientific Papers Nos. 361 and 383, is suitable for tests at magnetizing forces exceeding 200 gilberts per centimeter.

Accuracy

7. (a) The accuracy of the results of magnetic tests depends not only upon the method or apparatus used but also upon the nature of the specimen. The most common sources of error are (1) lack of uniformity in permeability along the length of the specimen, (2) mechanical strain, and (3) temperature variations. Errors due to these causes are indeterminate and may be large.

(b) For specimens having a satisfactory degree of uniformity, clamped so as to be free from mechanical strain and kept at a constant temperature within 5° C., the methods specified above may be expected to give the following accuracy: For normal induction, the values of magnetizing force corresponding to inductions up to an induction equal to two-thirds of that corresponding to the maximum magnetizing force specified in section 5 (c) should be accurate within 3 per cent, provided the permeability does not exceed 10,000. This permeability limitation does not apply to the ring method. Values of induction greater than the above should be accurate within 1 per cent. For residual induction, values should be accurate within 2 per cent and for coercive force within 5 per cent.

B. CORE LOSS

Definitions

8. (a) *Core loss.*—The power consumption in electrical sheet steel when subjected to an alternating magnetization.

(b) *Standard core loss.*—The total power in watts consumed in each kilogram of material at a temperature of 25° C. when subjected to a harmonically varying induction having a maximum of 10,000 gauss and a frequency of 60 cycles per second, when determined in accordance with definite prescribed methods. It is represented by the symbol $W\%$.

NOTE.—If the loss corresponding to a higher induction is desired, the sample should be subjected to a harmonically varying induction having a maximum of 14,000 gauss. The corresponding symbol will be $W\frac{1}{2}\%$.

¹ For silicon steel having a 2 per cent silicon content the electrical resistance is 2.6 ohms per meter gram.

² For 50 per cent nickel content the density is 8.26 g/cm³. For 80 per cent nickel content the density is 8.64 g/cm³.

³ The limits of cross-sectional area given in section 3 (a) shall apply to each half of the whole sample.

(c) *Aging coefficient.*—The percentage change in the standard core loss after continued heating at 100° C. for 600 hours.

Procedure

9. The standard core loss shall be measured under the following conditions:

(a) The magnetic circuit shall consist of 10 kg (22 pounds) of the test material, cut with a sharp shear into strips 50 cm (19¹¹/₁₆ inches) in length and 3 cm (1¹/₁₆ inches) in width, one-half parallel and one-half at right-angles to the direction of rolling, made up into 4 equal bundles, 2 containing material parallel and 2 containing material at right angles to the direction of rolling, and finally built into the

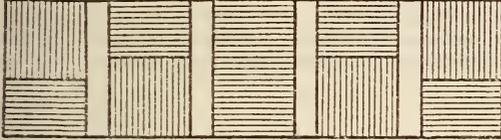

FIGURE 9

4 sides of a square with butt joints and opposite sides consisting of material cut in the same manner. No insulation other than the natural scale of the material (except in the case of scale-free material) shall be used between laminations, but the corner joints may be separated by tough paper 0.1 mm (0.004 inch) in thickness.

(b) The magnetizing winding shall consist of four solenoids surrounding the four sides of the magnetic circuit and joined in series. A secondary coil shall be used for energizing the voltmeter and the potential coil of the wattmeter.

These solenoids shall be wound on a form of any nonmagnetic nonconducting material of the following dimensions:

Inside cross-section.....	4 by 4 cm.
Thickness of wall.....	Not over 0.3 cm.
Winding length.....	42 cm.

The primary winding on each solenoid shall consist of 150 turns of copper wire uniformly wound over

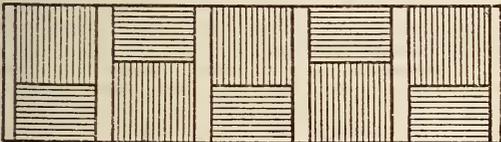

FIGURE 10

the 42 cm length. The total resistance of the magnetizing winding shall be between 0.3 and 0.5 ohm. The secondary winding of 150 turns of copper wire on each solenoid shall be similarly wound beneath the primary winding. Its resistance shall not exceed 1 ohm.

(c) A voltmeter and the voltage coil of a wattmeter shall be connected in parallel to the terminals of the secondary winding of the apparatus. The current coil of the wattmeter shall be connected in series with the primary winding.

(d) An electromotive force having a wave form approximating a sine curve shall be applied to the primary winding and adjusted until the voltage of the secondary circuit is given by the equation:

$$E = \frac{4fNnBM}{4ID10^3}$$

in which

- f = form factor of primary emf..... = 1.11 for sine wave.
- N = number of secondary turns..... = 600
- n = number of cycles per second..... = 60
- B = maximum induction, gauss..... = 10,000.
- M = total mass in grams..... = 10,000.
- l = length of strips in centimeters..... = 50.
- D = density, g per cu. cm..... = $\begin{cases} 7.5 \text{ for high-resistance steel.} \\ 7.7 \text{ for low-resistance steel.} \end{cases}$
- E = $\begin{cases} 106.6 \text{ volts for high-resistance steel for sine voltage.} \\ 103.8 \text{ volts for low-resistance steel for sine voltage.} \end{cases}$

NOTE.—For the 14,000-gauss test the voltages will be as follows:

E =	149.2 volts for high-resistance steel for sine voltage
	145.2 volts for low-resistance steel for sine voltage.

The form factor of the applied electromotive force shall not depart more than 1 per cent from the value of 1.11. As an alternative to the use of a sine wave, the correct value of the voltage may be determined by applying it to an Epstein apparatus containing a sample which has been standardized by means of a sine wave electromotive force. The wattmeter is brought to the correct reading for the standard sample. The corresponding voltage is the correct one to use.

10. (a) For silicon steels, a density of 7.7 g/cm³ shall be assumed if the silicon content is 2 per cent or less and a density of 7.5 g/cm³ shall be assumed if the silicon content is over 2 per cent.⁴

(b) For nickel-iron alloys the density shall be assumed from the nickel content as given by the straight lines joining the points defined as follows:⁵

Nickel	Density
<i>Per cent</i>	<i>g/cm³</i>
0	7.85
30	8.00
100	8.90

(c) For other alloys a density corresponding to the actual measured or estimated value shall be used.

11. The wattmeter gives the power consumed in the iron and the secondary circuit. The loss in the secondary circuit is given in terms of the total resistance and voltage. Subtracting this correction term from the total power gives the net power consumed in the steel as hysteresis and eddy-current loss. Dividing this value by 10 gives the core loss in watts per kilogram.

12. The core-loss material shall be cut from two or more sheets taken at random from shipment. The strips should be distributed symmetrically over the sheet, as nearly as may be practicable. (See figs. 9 and 10.)

It is recommended that a test sample shall represent not more than 5,000 kg (11,000 pounds.)

13. (a) Cut the test material into strips 3 by 50 cm as indicated in section 9 (a).

(b) Place on the balance a pile of strips weighing 2.5 kg. Add a second pile of the same kind, bringing the weight up to 5 kg. In each case the weight shall be taken to the nearest strip. Add in suc-

⁴ For silicon steel having a 2 per cent silicon content the electrical resistance is 2.6 ohms per meter gram.

⁵ For 50 per cent nickel content the density is 8.26 g/cm.³ For 80 per cent nickel content the density is 8.64 g/cm.³

cession two piles of 2.5 kg each, of the other kind of strips, bringing the weight up to 7.5 kg and 10 kg, respectively.

(c) Insert in the apparatus as indicated.

NOTE.—If desired, for convenience, the bundles may be loosely secured by tape or string (not wire).

(d) Apply the alternating voltage to the primary coil and tap the joints together until the current has a minimum value, as shown by an ammeter in

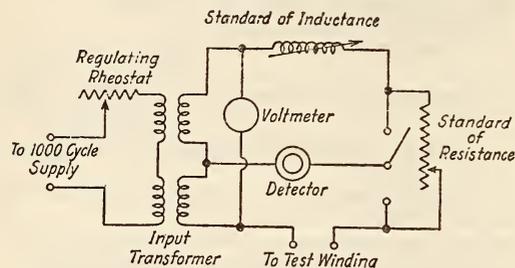

FIGURE 11.—Connections for balanced transformer method for magnetic properties at low inductions

series. Then clamp the corners firmly by some suitable device.

(e) Shunt the ammeter and adjust the primary current until the voltmeter indicates the proper value. This adjustment may be made by an auto-transformer, by varying the field of the alternator, or by both, but not by the insertion of resistance or inductance in the primary circuit. Simultaneously the frequency must be adjusted to 60 cycles.

(f) Read the wattmeter.

(g) *Calculations.*—Subtract from the wattmeter reading the instrument losses, which will be con-

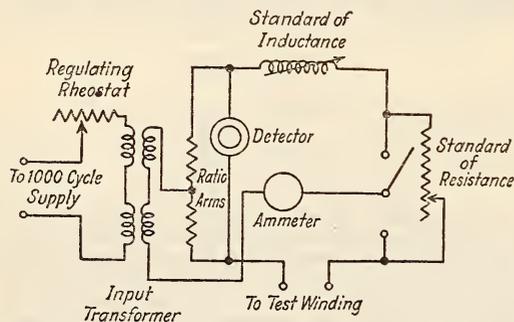

FIGURE 12.—Connections for ratio arm method for magnetic properties at low inductions

stant for any set of instruments and voltage, and divide by 10. The result is the standard core loss.

NOTE.—If desired, a 5 kg sample may be used for routine acceptance tests, provided it is cut from at least two sheets, except in case of a dispute between the manufacturer and purchaser when the 10 kg sample shall be used.

C. PROPERTIES AT LOW INDUCTIONS AND AUDIO-FREQUENCIES

14. This method provides for the determination of the alternating-current permeability and core loss of magnetic materials at low inductions and audio-frequencies. These properties are indicative of the effect of the material on the impedance and loss characteristics of audio-frequency apparatus. Standard values are those for the standard low induction of 10 gauss and the standard audio-frequency of 1,000 cycles.

Test Specimens

15. (a) Test specimens shall preferably be of the ring form. Ring specimens shall conform to the requirements specified in sections 2 and 3.

(b) If mutually agreed upon by the manufacturer and purchaser, the rings may be sheared at one point to facilitate insertion of the specimen into form-wound coils. If this method of preparation is used, the slits shall be staggered so as to come at different points in the magnetic circuit.

(c) As an alternative, test specimens of sheet material not exceeding 0.05 cm (0.0197 inch) in thickness may be of the form described in section 9 (a), except that the four bundles of strips shall be assembled so that at each corner consecutive layers mutually overlap the butt joints occurring in each single layer.

16. When testing for core loss, the separate laminations comprising each form of specimen shall be effectively insulated from each other.

Apparatus

17. (a) The apparatus shown in Figures 11 and 12 shall conform to the requirements specified in paragraphs (b) to (j), inclusive. The apparatus shall be connected for the balanced-transformer method as shown in Figure 11 or for the ratio-arm method as shown in Figure 12.

(b) *Test winding.*—Continuous ring specimens shall be wound with a toroidal test winding distributed uniformly around the circumference of the ring. If the sheared ring specimen is used, the windings may be applied in sections, provided the sections are of equal numbers of turns and uniformly spaced to cover at least 75 per cent of the mean circumference of the ring. The number of turns should be such that an inductance not less than 0.03 henry nor more than 0.15 henry is obtained. The winding conductor shall not be smaller than No. 23 nor larger than No. 20 A. W. G. Care shall be taken to prevent any electrical contact between turns or to the core. It is recommended that double-cotton-insulated wire be used. The test winding for the strip form of specimen shall be the secondary winding of the solenoids described in section 9 (b), care being taken that the primary winding is open circuited during the test.

(c) *Power supply.*—The supply voltage shall be of approximately a sine-wave form, having not more than 10 per cent of total harmonics present.

(d) *Transformer.*—The input transformer shall have a core formed from magnetic sheet material which is not more than 0.038 cm (0.015 inch) in thickness and which has a standard low induction permeability of not less than 400.

NOTE.—This corresponds to good quality 4 per cent silicon steel.

The primary and secondary windings shall have self and mutual inductance characteristics suited to the efficient transmission of power under the test conditions from the source to the test circuit. For the balanced-transformer method (fig. 11) the secondary winding shall have a tap at its electrical mid-point. The two half-windings so formed shall be closely balanced with respect to each other and with respect to mutual effects to the primary. The degree of balance will be satisfactory if, upon reversal of the complete secondary with respect to the test coils and standards, the readings of the standards are not changed for the new condition of balance by more than 0.02 ohm in resistance or 1 per cent in inductance. For the ratio-arm method (fig. 12) a balanced secondary winding is not required.

NOTE.—A satisfactory degree of balance can be obtained by winding two conductors together on the core and taking each of the coils thus formed as one-half of the double secondary.

(e) *Ratio arms.*—The ratio arms used in the ratio arm circuit (fig. 12) shall be balanced nonreactive resistors, the resistance of each of which may be of any value from 500 to 1,000 ohms. The degree of balance shall be equal to that specified for the secondary winding of the transformer used in the balanced-transformer method as specified in paragraph (d).

(f) *Standard of resistance.*—The adjustable standard of resistance shall have a range of from 0 to at least 100 ohms, the smallest step being not more than 0.1 ohm. The resistance values for each decade shall be correct to within $\pm(0.1$ per cent $+0.005$ ohm). The effective inductance for any setting shall not exceed 0.0001 henry.

(g) *Standard of inductance.*—The adjustable standard of inductance⁶ shall have a range of from 0.03 to 0.15 henry and shall be capable of being read to at least 0.0005 henry. It shall be wound with a stranded conductor, each strand of which shall not be larger than No. 35 A. W. G. and insulated from all other strands. The direct-current resistance shall not exceed 50 ohms. The inductance values shall be accurate, to within $\pm(0.5$ per cent $+0.00025$ henry).

(h) *Detector.*—Any zero-current detector having the desired sensitivity may be used. A telephone receiver having an impedance between 300 and 500 ohms at a frequency of 1,000 cycles is recommended.

(i) *Voltmeter.*—Any voltmeter capable of reading the output voltage at the test frequency with an accuracy of at least ± 2 per cent may be used. A vacuum-thermocouple type having a full scale of 10 volts is recommended.

(j) *Ammeter.*—Any ammeter capable of reading the bridge current at the test frequency with an accuracy of at least ± 2 per cent may be used. A vacuum-thermocouple type having a full scale of 0.020 ampere is recommended.

Procedure

18. (a) The test specimen shall be thoroughly demagnetized before testing.

(b) The apparatus having been connected in circuit as shown in Figure 11 or Figure 12, the standard of resistance shall be set at zero and the standard of inductance at approximately mid-scale. The output of the transformer shall then be adjusted by means of the regulating rheostat to give approximately the standard induction in the test specimen.

NOTE.—In this determination the following relations between the bridge voltage or current and the induction in the test specimen shall be used:

$$E = 8.88 f NAB \times 10^{-3} \text{ for the balanced-transformer method. (Fig. 11.)}$$

$$I = \frac{1.414 NAB \times 10^{-3}}{L} \text{ for the ratio-arm method. (Fig. 12.)}$$

where

- E = the secondary voltage (r. m. s. value);
- I = the bridge current (r. m. s. value);
- f = the test frequency in cycles per second;
- N = number of turns in the test winding;
- A = cross-sectional area of the test specimen in square centimeters;
- B = maximum induction in gaussses; and
- L = inductance of the test coil in henrys.

The standards of resistance and inductance shall then be alternately adjusted and, if necessary, the regulating rheostat readjusted until, with the meter reading the voltage or current corresponding to the standard induction, the detector indicates zero difference of potential between its terminals. The readings of the standards shall be noted and the

transformer secondary or ratio arms reversed and a second balance obtained. The mean of the two inductance readings shall be taken as the inductance of the test coil. The resistance readings shall be added to or subtracted from the resistance of the standard inductance, as indicated by the connection, and the mean of these resultants taken as the effective resistance of the test coil. Subtracting from this value the direct current resistance of the test winding gives the effective resistance due to the core loss in the test specimen.

Calculations

19. (a) *Permeability.*—The standard low induction permeability shall be calculated from the inductance value of the test coil determined as described in section 18 (b) by means of the following formulas:

(1) For ring specimens:

$$\mu_{z/1,000} = \frac{L \times 10^9}{2 N^2 h \log \frac{D}{d}}$$

or

$$\mu_{z/1,000} = \frac{L \times 10^9 (D+d)}{8 N^2 A}$$

(2) For straight-strip specimens:

$$\mu_{z/1,000} = \frac{41,600 L}{A}$$

where

$\mu_{z/1,000}$ = standard low induction permeability (permeability at 10 gaussses and 1,000 cycles);

L = inductance of the test coil in henrys;

N = number of turns in the test winding;

h = net axial height of the core in centimeters (see note);

D = outer diameter of the core in centimeters;

d = inner diameter of the core in centimeters; and

A = cross-sectional area of the test specimen in square centimeters.

NOTE.—The net axial height and cross-sectional area of the core shall be determined from measured values of the diameters and weight and standard values of density.

(b) *Core loss.*—The standard low induction core loss shall be calculated from the measured effective resistance due to the core loss in the test specimen determined in section 18 (b) by means of the following formula:

$$W_{z/1,000} = \frac{R_1 E^2 \times 10^3}{16\pi^2 f^2 L^2 M} \text{ for the balanced-transformer method. (Fig. 11.)}$$

$$W_{z/1,000} = \frac{R_1 I^2 \times 10^3}{4 M} \text{ for the ratio-arm method. (Fig. 12.)}$$

where

$W_{z/1,000}$ = the standard low induction core loss in watts per kilogram;

R_1 = the effective resistance due to the core loss in the test specimen;

M = weight of the test specimen in grams;

E = the bridge voltage (r. m. s. value);

f = the test frequency in cycles per second;

L = the inductance of the test coil in henrys; and

I = the bridge current (r. m. s. value) in amperes.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD METHODS OF CHEMICAL ANALYSIS OF ALLOY STEELS, SERIAL DESIGNATION A55-24, 1924

CHEMICAL ANALYSIS OF ALLOY STEELS

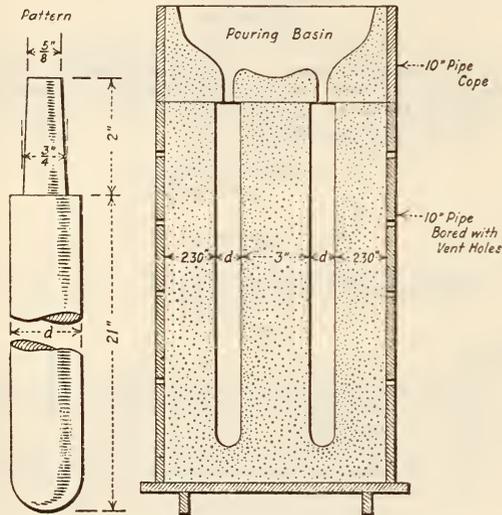

(See 621.30, p. 1107.)

⁶ A general form of construction suitable for this instrument is described in Bureau of Standards Scientific Paper No. 290, Oct. 12, 1926.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR THE ARBITRATION TEST BAR AND TENSION-TEST SPECIMEN FOR CAST IRON, DESIGNATION A124-29, 1929

CAST-IRON TEST SPECIMENS

1. These specifications cover the arbitration test bar for cast iron, 1.20 inches in diameter, intended

NOTE: The dimension "d" shall be made such that the casting shall measure approximately 1.20 in. in diameter at the mid point.

FIGURE 13.—Mold for arbitration test bar

for transverse testing placed horizontally upon supports 18 inches apart with a centrally applied load; and the tension-test specimen for determining the tensile strength of cast iron. The arbitration test bar represents the metal in the ladle and not in the casting.

ARBITRATION TEST BAR

2. The form and dimensions of the pattern and mold for the arbitration test bar shall conform to

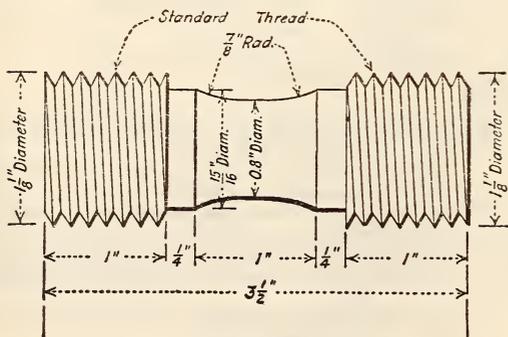

FIGURE 14.—Tension test specimen

those shown in Figure 13. The mold may be made in cores or in dry sand. The bottom of the bar shall be 0.05 inch smaller in diameter than the top, to allow for draft and for the strain of pouring. The pattern shall not be rapped before withdrawing. The flask shall be rammed-up with green molding sand, a little damper than usual, well mixed and

put through a No. 8 sieve, with a mixture of 1 to 12 bituminous facing. The mold shall be rammed evenly and fairly hard, thoroughly dried, and not cast until it is cold. The test bar shall not be removed from the mold until cold enough to be handled. It shall not be rumbled or otherwise treated, being simply brushed off before testing.

3. The patterns shall be made of such size that the arbitration test bar will have a diameter of 1.20 inches at the center.

4. (a) In case the transverse test bar varies from the specified diameter of 1.20 inches, a correction factor conforming to that shown in the table shall be applied.

Diameter of arbitration test bar (in inches)	Correction factor	Diameter of arbitration test bar (in inches)	Correction factor
1.10	0.770	1.21	1.025
1.11	.791	1.22	1.051
1.12	.813	1.23	1.077
1.13	.835	1.24	1.103
1.14	.857	1.25	1.130
1.15	.880	1.26	1.158
1.16	.903	1.27	1.185
1.17	.927	1.28	1.214
1.18	.951	1.29	1.242
1.19	.975	1.30	1.271
1.20	1.000		

If the test bar is not round the correction factor can not be obtained from the preceding table and shall be calculated as follows: Square the depth of the bar measured at point of application of load, multiply by the width, and divide the product by 1.728.

(b) In order to correct to a diameter of 1.20 inches the breaking load, obtained in testing the bar, shall be divided by the correction factor.

TENSION-TEST SPECIMEN

5. The tension-test specimen shall be machined from one of the broken pieces of the arbitration test bar, and shall conform to the dimensions shown in Figure 14.

AMERICAN SOCIETY FOR TESTING MATERIALS, TENTATIVE DEFINITIONS OF TERMS, WITH UNITS AND SYMBOLS, RELATING TO MAGNETIC TESTING, DESIGNATION A127-31T, 1931

MAGNETIC TESTING DEFINITIONS

In the following list of definitions the term defined is given first followed in parenthesis by any optional alternative terms which may be used when the context clearly indicates the intended conception. The symbol for the quantity is then given wherever such symbol is in use, followed by the definition of the standard term.

The name of the unit employed is included, together with the definition of the unit.

BASIC CONCEPTIONS

Magnetic field (field).—The region in space in which a magnetic state exists.

UNIT.—None.

Magnetic circuit.—A closed path of magnetic flux.
Magnetic flux (flux), Φ.—The magnetic quantity which by its variation is capable of producing in an

associated electric circuit an electromotive force proportional to its time rate of variation.

UNIT: *Maxwell*.—The maximum value of the magnetic flux, the uniform variation of which between zero and its full value in one second induces one cgs. unit of electromotive force in a single turn electric circuit enclosing the flux.

Magnetomotive force, \mathcal{F} .—The total magnetizing influence acting on any part of a magnetic circuit.

UNIT: *Gilbert*.—The magnetomotive force resulting from a current in an electric circuit of any number of turns linked with the magnetic circuit when the product of the current in amperes by the number of turns is $\frac{1}{0.4\pi}$.

NOTE.—When a current of I amperes is flowing in a circuit of N turns, $\mathcal{F} = 0.4\pi NI$.

DERIVED CONCEPTIONS

Magnetic force (magnetizing force, field intensity), H .—The space rate of variation of magnetomotive force at any point in the magnetic circuit.

UNIT: *Oersted*.—The magnetic force of one Gilbert per centimeter.

NOTE.—At the center of an infinitely long solenoid having n turns per centimeter in which a current of I amperes is flowing, $H = 0.4\pi nI$.

Magnetic potential difference.—The magnetomotive force between two points.

Induction (flux density), B .—The flux per unit area normal to the direction of the flux.

UNIT: *Gauss*.—An induction of one Maxwell per square centimeter.

Normal induction, B_n .—The induction in a magnetic material corresponding to a given magnetic force when the material is in a symmetrically cyclic magnetic condition with respect to the given magnetic force.

UNIT: Same as for *Induction*.

Intrinsic induction (ferric induction), B_i .—The excess of the normal induction over that corresponding to the same magnetic force in empty space.

UNIT: Same as for *Induction*.

Saturation induction, B_s .—The maximum intrinsic induction possible in a material.

UNIT: Same as for *Induction*.

Permeability, μ .—When used without a qualifying adjective, understood to be the normal permeability as defined below.

UNIT: None.

Normal permeability, μ_n .—The ratio of the normal induction to the corresponding magnetic force.

UNIT: None.

Initial permeability, μ_o .—The normal permeability when both the magnetic force and the induction are vanishingly small.

UNIT: None.

Differential permeability, μ_d .—The ratio of the positive increase of normal induction to the positive increase of magnetic force when these increases are vanishingly small.

UNIT: None.

Incremental permeability, μ_Δ .—The ratio of the cyclic change in induction to the corresponding cyclic change in magnetic force when the mean induction differs from zero.

UNIT: None.

Reversible permeability, μ_r .—The incremental permeability when the change in induction is vanishingly small.

UNIT: None.

Intrinsic permeability, μ_i .—The ratio of the intrinsic induction to the corresponding magnetic force.

UNIT: None.

Permeance, Φ .—The property of any part of a magnetic circuit which determines the flux corresponding to a given magnetomotive force.

NOTE.—Permeance = $\frac{\Phi}{\mathcal{F}}$ equivalent to $\frac{\mu A}{l}$ for uniform μ .

where

μ = permeability;
 A = area in square centimeters; and
 l = length in centimeters.

UNIT: None.

Reluctivity.—The reciprocal of permeability.

UNIT: None.

Reluctance, \mathcal{R} .—The reciprocal of permeance.

NOTE.—Reluctance = $\frac{\mathcal{F}}{\Phi} = \frac{l}{\mu A}$ for uniform μ .

UNIT: The reluctance of a portion of an empty space 1 centimeter in length and having a cross section of 1 square centimeter.

Remanence.—The magnetic induction which remains in a magnetic circuit after the removal of an applied magnetic force.

NOTE.—If there is an air gap in the magnetic circuit, the remanence will be less than the residual induction.

UNIT: Same as for *Induction*.

Residual induction, B_r .—The magnetic induction which remains in a magnetic material when the effective magnetic force has been reduced to zero.

NOTE.—When the material is in a symmetrically cyclic magnetic condition, the residual induction is called the *normal residual induction*.

UNIT: Same as for *Induction*.

Retentivity.—The property of a material measured by the normal residual induction remaining after the removal of an applied magnetic force corresponding to the saturation induction for the material.

UNIT: Same as for *Induction*.

Coercive force, H_c .—The reversed magnetic force that is just sufficient to reduce the residual induction in a material to zero.

NOTE.—When the residual induction is the *normal residual induction*, the coercive force required is called the *normal coercive force*.

UNIT: Same as for *Magnetic force*.

Coercivity.—The property of a material measured by the coercive force required to reduce to zero the induction remaining after the removal of an applied magnetic force corresponding to the saturation induction for the material.

UNIT: Same as for *Magnetic force*.

Core loss (iron loss), W .—The power expended in a magnetic material subjected to a varying induction.

Eddy current loss, W_e .—The part of the core loss due to currents circulating in the magnetic material as a result of electromotive forces induced by the varying induction.

Hysteresis loss, W_h .—That part of the core loss due to so-called hysteresis effects.

Standard core loss, $W_{B/f}$.—The total power in watts per kilogram expended in the magnetic material which is subjected to a harmonically varying induction of a specified maximum value B and of a specified frequency f .

Ageing (of magnetic materials).—The normal or accelerated change in magnetic properties of a

magnetic material under continued normal or specified artificial aging conditions. When used in reference to core loss this term, unless otherwise modified, implies an increase in loss. When used in reference to permeability or remanence the term, in a positive sense, indicates a decrease in these quantities.

Dia-magnetic.—Having a magnetic permeability less than unity.

Para-magnetic.—Having a magnetic permeability slightly greater than unity and approximately independent of the magnetic induction.

Ferromagnetic.—Having a magnetic permeability considerably greater than unity.

Linkage.—The product of the flux in maxwells by the number of turns in a coil or winding linked therewith.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD METHODS OF SAMPLING ROLLED AND FORGED STEEL PRODUCTS FOR CHECK ANALYSIS, DESIGNATION A130-30, 1930

SAMPLING ROLLED AND FORGED STEEL PRODUCTS

SAMPLING

Different parts of a piece of steel vary in composition. For this reason, a sample from a single piece

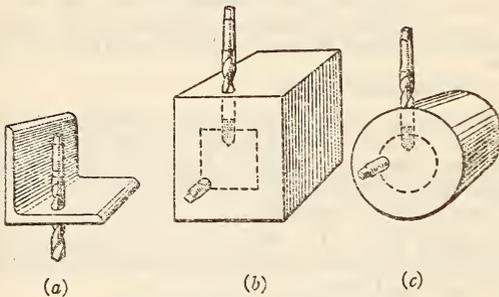

FIGURE 15.—Location of samples for check analysis

must be carefully selected if it is to be representative of that piece. If the analysis is to be representative of the melt, a number of representative pieces should be sampled and analyzed separately. In any case, the sample should be so selected as to be thoroughly representative, and large enough to suffice for all of the required determinations.

It should be remembered that the composition of the steel is changed by certain operations and that samples should be taken from the steel in its original condition.

PREPARATION OF SAMPLES

Samples shall consist of drillings or chips cut by some machine tool without the application of water, oil, or other lubricant, and shall be free from scale, surface metal, grease, dirt, or other foreign substances. If the samples are taken by drilling, a drill not less than one-half nor more than three-fourths inch in diameter shall be used. Samples shall be uniform, thoroughly mixed, and free from dust. Chips too coarse to pass a No. 20 sieve are not recommended, nor shall long curly drillings which will not pack closely for the carbon determination be used.

In referring samples to other analysts for check analyses, pieces of the original full-size section,

when possible, should be submitted rather than cuttings, unless the latter are specifically requested.

LOCATION OF SAMPLES

Large sections.—For large sections, including blooms, billets, slabs, rounds, squares, shapes, etc., samples shall be taken at any point midway between the outside and the center of the piece by drilling parallel to the axis. In cases where this is not practicable, the piece shall be drilled on the side (see figs. 15 (b) and (c)), but the drillings shall not be collected until they represent the portion midway between the outside and the center. The tension-test specimen may be used for sampling if it conforms to the above conditions.

Bored forgings.—For bored forgings, samples shall be taken midway between the inner and outer surface of the wall.

Thin material.—For thin material or material of small cross section, such as plates, shapes, bars, etc., if the method described above for large sections is not applicable, the sample shall be taken by machining off the entire cross section or, if this is not possible, by drilling entirely through the material at a point midway between the outside and the center. (See fig. 15 (a).)

Sheets rolled longitudinally.—For sheets rolled from slabs or bars longitudinally, the specimen for sampling shall be cut 2 inches in width and across the full width of the sheet as rolled. The specimen shall be cleaned by pickling or grinding and then folded once or more by bringing the ends together and closing the bend. The sample for analysis shall be taken in the middle of this length by milling the inside sheared edges or drilling entirely through from the flat surface. Sampling by milling is preferable. For sheets of a light gage more than one specimen may be taken and stacked together before folding.

Sheets rolled transversely.—For sheets rolled from slabs or bars transversely, the specimen shall be cut from the side of the sheet, half way between the middle and end as rolled, 2 inches in width and 18 inches in length. If the sheet is No. 20 gage (24 ounces per square foot or 0.037 inch in thickness) or lighter, the specimen shall be cut from the full length of the sheet as rolled. The specimen selected shall be cleaned by pickling or grinding and then folded once or more by bringing the ends together and closing the bend. The sample for analysis shall be taken in the middle of this length by milling the inside sheared edges or drilling entirely through from the flat surface. Sampling by milling is preferable.

Sheets not of the full size rolled.—Sheets cut from larger sheets and not of the full size rolled shall be sampled by milling or drilling the sheet in a sufficient number of places so that the sample is representative of the entire sheet. The sampling may be facilitated by folding the sheet both ways.

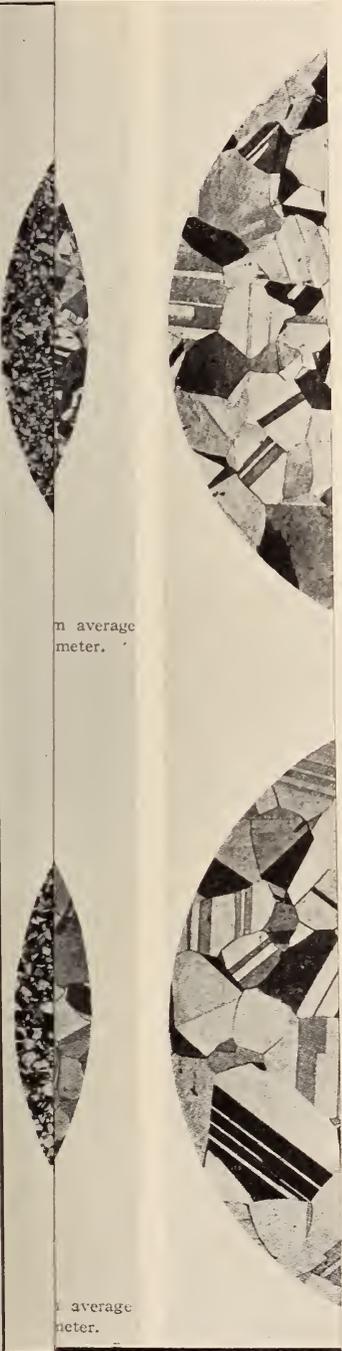

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD RULES GOVERNING THE PREPARATION OF MICROGRAPHS OF METALS AND ALLOYS, DESIGNATION E2-30, 1930

MICROGRAPH WORK

STANDARD MAGNIFICATIONS

1. The standard magnifications for general use in making micrographs, expressed in diameters, shall be as follows:

10, 25, 50, 75, 100, 200, 500, 1,000

m average
meter.

average
meter.

ularly nonferrous alloys, such
peroxide. ($\times 75$.)

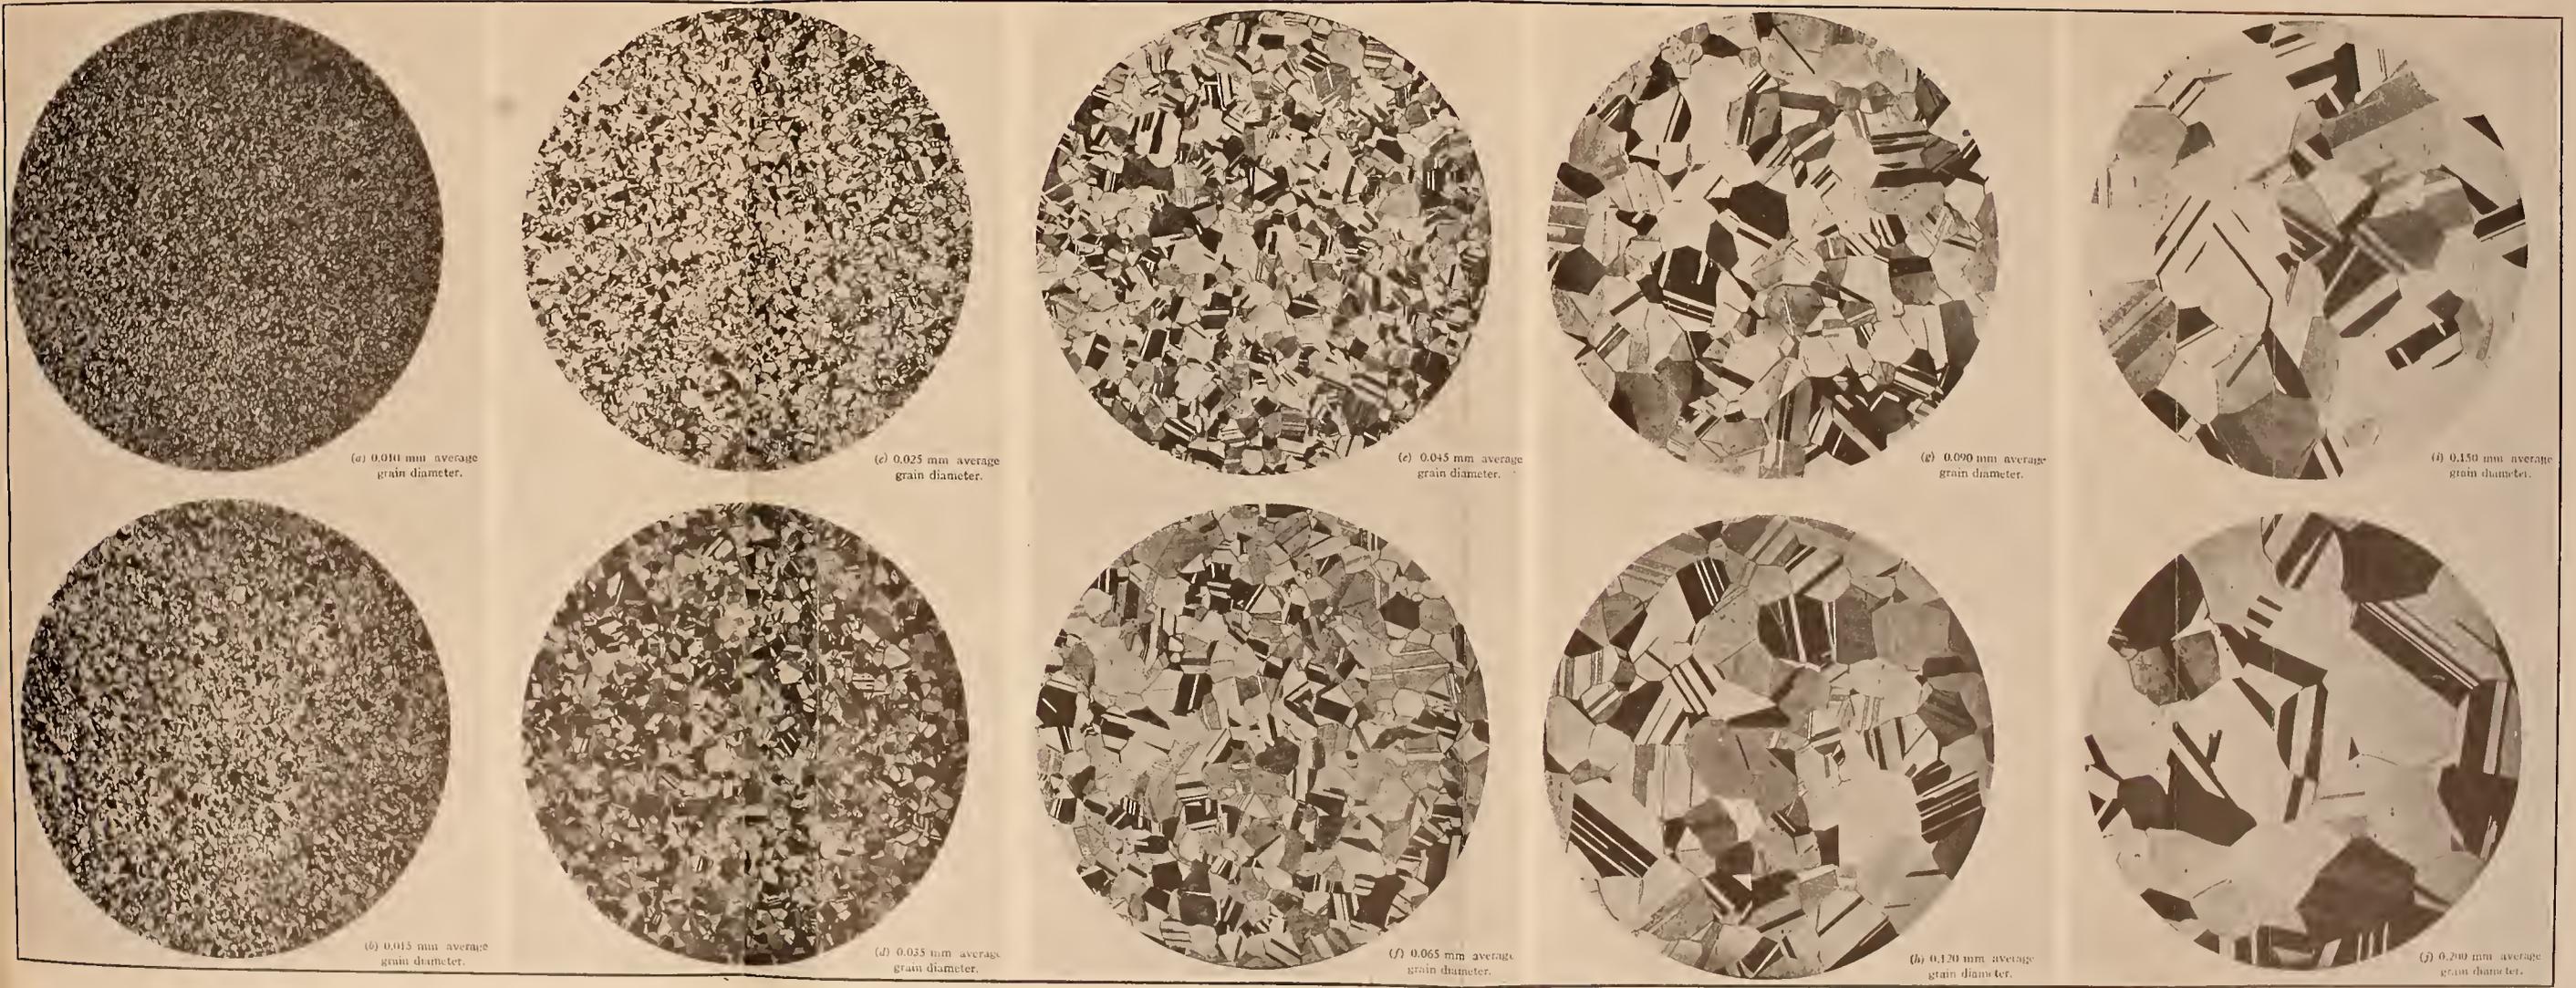

FIGURE 16. Grain size standards for the estimation of the diameter of average grain of annealed materials, particularly nonferrous alloys, such as brass, bronze, and nickel-silver. The micrographs are of 70-30 copper-zinc alloy etched by ammonia and hydrogen peroxide. ($\times 75$)

2. For general use in society reports, and for showing grain size, the following magnifications are recommended:

Material	Cast	Wrought
Steel, and ferrous materials.....	100	100
Copper.....	50 and 100	75
Copper-zinc alloys.....	50 and 100	75
Copper-nickel alloys.....	50 and 100	200
Copper-nickel-zinc alloys.....	50 and 100	200
Lead-tin-antimony alloys ¹	50 and 200	

¹ Including those containing small percentages of copper.

3. (a) Reproductions of micrographs in publications shall be made of exact standard magnifications except in those special cases where the details of structure are to be illustrated.

(b) If micrographs submitted for publication are not of standard magnification, they shall be enlarged or reduced to the nearest standard size. The actual magnification appearing in print shall be stated under the micrograph. (See par. (d).)

(c) To facilitate the reproduction, authors should be advised that their micrographs should be of proper size to fit the printed page, and in order to conserve space that micrographs be printed in the form of squares.

(d) With each micrograph shall be printed an explanatory title, together with actual magnification, etching medium, treatment, etc., indicating what the author intends to show, so that it will not be necessary to search the text for general information. With micrographs at magnifications of approximately 500 diameters and above, the numerical aperture of the objective and the type of illuminator shall be given.

(e) Photographs in which the magnification is less than 10 diameters are usually made with photographic lenses or single magnifiers. These will be considered as "macrographs."

With each macrograph should be printed an explanatory title, together with the actual magnifications, method of illumination, and general treatment indicating what the author desires to illustrate, so that it will not be necessary to refer to the text for general information.

LENSES

4. For obtaining the magnifications recommended, the following types of lenses are suggested as suitable for general commercial work:

(a) For magnifications from 20 to 30: A photographic lens of approximately 35 mm focal length, to be used without ocular.

(b) For magnifications from 30 to 75: A 32 mm objective with Huyghens ocular (approximately $\times 5$).

(c) For magnifications from 75 to 150: A 16 mm objective with Huyghens ocular (approximately $\times 5$).

(d) For magnifications from 250 to 500: A 4 mm objective (preferably apochromatic) with projection ocular.

5. (a) All objectives should be corrected for use without cover glasses.

(b) In using one of the lens combinations given above, the length of the camera bellows may be adjusted to give the exact magnification desired.

It should be borne in mind, however, that increasing the magnification by increasing the length of the camera bellows adds nothing to the detail of the micrograph. This depends mainly upon the resolving power of the objective used.

(c) The magnification shall be determined by accurately measuring the image of a stage microm-

eter scale, and not by estimation from lens combinations, or microscope or camera adjustments.

GRAIN SIZE

6. (a) Alloys consisting of but one type of crystals (for example, copper, alpha brass, etc.).—In counting individual grains the original crystal, including the twinned layers, shall be called one grain.

(b) Alloys consisting of two metallographic components (for example, steels, Muntz metal, etc.).—The original grain which has given rise to the aggregation of the two components shall be taken as the unit when determinable and the individual component in other cases.^a When grain size is included in actual specifications, the term should always be defined in such specifications.

7. For measuring grain size, two methods (see note 1) are recommended depending upon the condition of the material:

(a) For material in which the grains are equi-axed (for example, most metals in the cast and in the annealed state).—The planimetric method as modified by Jeffries (see note 2) is recommended for use as being very accurate and rapid. It is recommended that the circular area used should always include at least 50 grains.

(b) When the grains are not equi-axed (for example, in strained materials).—Heyn's intercept method should be used, the average grain size being determined by counting the number of grains at a given magnification along a line of known length on two axes at right angles to each other, one axis being parallel to the direction of rolling. In some cases a third count along a line perpendicular to the other two may be desirable. This will necessitate the preparation of another polished surface.

8. The grain size as determined by the planimetric method, section 7 (a), should be expressed as the number of grains per unit area (square inch or square centimeter). This may also, but less preferably so, be expressed as the average grain area; or the average linear dimension of the grain may be given. The grain size as determined by the intercept method, section 7 (b), should be expressed by giving the average number of grains per linear unit in the two directions; or the average number per unit area together with the ratio of length to breadth of grain (L/B) may be given.

9. If grain size is to be included in specifications, it should be expressed as the maximum or minimum allowable as determined above. It is recommended that only in extreme cases should grain size be made the sole basis of rejection of material.

NOTE 1.—Standard micrographs for comparison of grain sizes.—The direct comparison of a micrograph or projected image with the standard micrographs shown in Figure 16, will facilitate inspection of non-ferrous material magnified 75 \times and for most purposes will be found a sufficiently precise method of obtaining the grain count of a specimen.

NOTE 2.—Jeffries' method for grain-size measurements.⁷—A circle 79.8 mm in diameter is drawn on the rough side of a ground-glass screen, the center of the circle being near the center of the rectangular section of the screen. This ground glass is mounted in a frame which fits a metallographic camera, the smooth side of the glass being on the outside. When the image of the specimen for grain-size determination is focused on the screen, the circle will be plainly visible and its circumference should be well within the image.

When the image is properly focused the grains intersected by the circumference of the circle are checked and counted. Since the check marks must be made on the smooth side of the glass, a soft red pencil, such as is used in laboratories for marking beakers and flasks, will be found satisfactory. The marks used to indicate the boundary grains are usually short, straight lines intersecting the circumference of the circle and perpendicular to it. The completely included grains are next checked and counted, after which the red marks are erased from the glass with a dry cloth. The specimen can then be moved and other measurements made as desired.

^a See U. S. Navy specifications, 40-S-2-c., p. 7.
⁷ This method has been condensed from the paper by Zay Jeffries appearing in Chemical and Metallurgical Engineering, Vol. XVIII p. 185, 1918.

One-half the number of grains intersected by the circumference of the circle, added to the number of completely included grains, gives the number of equivalent whole grains within the circle. If the equivalent number of whole grains within the circle measured at a certain magnification be multiplied by the number in the third column in the following table opposite the magnification used, the product will be the number of grains per square millimeter.

Magnification used (= <i>m</i>)	Diameter of circle	Multiplier to obtain grains per square millimeter (= <i>f</i>)
	<i>mm</i>	
Full size.....	79.8	0.002
10.....	79.8	.02
25.....	79.8	.125
50.....	79.8	.5
75 ¹	79.8	1.125
100.....	79.8	2.0
150.....	79.8	4.5
200.....	79.8	8.0
250.....	79.8	12.5
300.....	79.8	18.0
500.....	79.8	50.0
750.....	79.8	112.5
1,000.....	79.8	200.0
1,500.....	79.8	450.0
2,000.....	79.8	800.0

¹ At 75 diameters, if a circle 84.5 mm in diameter, or a rectangle having an area of 5,625 mm² is used, the factor *f* becomes unity.

A circle 79.8 mm in diameter has an area of 5,000 mm². If it is desired to use a rectangle of the same area in place of a circle for the determination, convenient sizes are given as follows:

70.7 by 70.7 mm
 65 by 77 mm
 60 by 83.3 mm
 55 by 91 mm
 50 by 100 mm

Since each of these rectangles has an area of about 5,000 mm², the multipliers given in the table can be used for any one of them, or any other rectangle having an area of 5,000 mm². To make a grain-size determination with a rectangular in place of a circular area, the grains intersected by the periphery of the rectangle should be counted, one-half the number added to the completely included grains and the result will be the number of equivalent whole grains within the rectangle. If the determination is made at one of the magnifications given in the table the number of grains per square millimeter can be obtained by multiplying the equivalent number of whole grains within the area by the multiplier (*f*) opposite the magnification used. The rectangle could be used on a ground glass as described above for the circle, or it could be used on a micrograph.

Some metallographists prefer to refer to the grain size in terms of the diameter of the average grain in millimeters, or the area of the average grain in μ^2 . The following simple formulas will be found helpful in these cases:

$$x = \frac{1}{2} w + z$$

$$f = \frac{m^2}{5,000}$$

$$n = fx$$

$$d = \frac{1}{\sqrt{n}}$$

$$a = \frac{1,000,000}{n}$$

where

w = number of boundary grains;

z = number of completely included grains;

x = equivalent number of whole grains in 5,000 mm² (circle 79.8 mm in diameter or rectangle having area of 5,000 mm²);

m = magnification used;

f = multiplier to obtain number of grains per square millimeter;

n = number of grains per square millimeter;

d = diameter of average grain in millimeters; and

a = area of average grain in μ^2 .

After considering various criticisms, owing to the fact that 75 diameters has become an established practice for use in illustrating the structure and grain size of wrought copper and the copper-zinc alloys, and that a large volume of work has been done using this magnification, it seems advisable to retain a magnification of 75 diameters for this class of material.

(Recommended practice for photography as applied to metallography is added to this specification. It is considered under the following sections: Magnification, lenses, illumination of specimens, and photographic materials. An appendix treats of the care of the eyes when using a metallographic microscope.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD METHODS OF METALLOGRAPHIC TESTING OF IRON AND STEEL, DESIGNATION E3-24, 1924

METALLOGRAPHIC TESTING

MACROSCOPIC EXAMINATION

Preparation of Surface

In order to show up both chemical and crystalline heterogeneity, sections of iron and steel are more or less deeply etched in order to bring out their macrostructure. In this way the persistence of the dendritic structure of castings, even after much heat treatment and mechanical working, physical unsoundness such as blowholes, gas cavities, porosity; fine internal cracks and flakes; discontinuities of structure such as found in welding; flow of metal as in riveting, punching, hot pressing and forging; etc., are brought out.

Suitable sections are cut, smoothed, and then ground on various grades of emery paper in order to obtain a smooth flat surface. In some cases it is necessary to continue polishing through Nos. 0 and 00 French emery papers. The sample ought to have a surface free from grease and dirt; if necessary it is then freed from all grease by cleaning with gasoline and then alcohol when it is ready for immersion in the solution.⁸

Solutions Used in Etching

Macroscopic etching of iron and steel was used as early as 1783 by Bergman. Many different solutions have been used and many of them are given by Campbell⁹ and more recently by Rawdon.¹⁰

Of the following solutions 1 (a) and 2 are recommended.

⁸ For large sections various methods have been devised depending on the material. Surface grinding when carefully done gives excellent results.

⁹ Proc., Am. Soc. Testing Mats., Vol. XV, Pt. II, p. 96, 1915.

¹⁰ "Structure and Related Properties of Metals," Bureau of Standards Circular No. 113.

1. To show up segregation and the like:
 (a) Hot concentrated hydrochloric acid used at about 100° C. A deep-etched specimen may be printed with printer's ink.

(b) Etching for 4 to 5 hours with 5 per cent picric acid in alcohol.

2. To show up variations in crystalline structure as well as segregation:

One to two grams of ammonium persulphate in 10 c c of water. This is probably the best reagent for developing this phase of the structure in iron and steel.¹¹

3. To show up the distribution of phosphorus:
 Various reagents containing copper chloride are used. The copper coats those portions which are low in phosphorus and leaves the high phosphorus areas bright. It has recently been shown that nickel and other alloys give similar effects, also that oxide of iron acts in the same way. The accompanying list shows the various solutions which have been recommended:

Heyn.—Copper-ammonium chloride.....	g..	10
Water.....	c c..	100

A somewhat weaker solution is better, the specimen being etched two or three times in fresh solution if necessary. The liquid is gently agitated. The coating of spongy copper forming on the face of the specimen is easily removed with a swab of wet cotton. Portions high in carbon, sulphur and phosphorus will have darkened. If the copper film adheres, a 0.5 per cent solution of ammonium persulphate will facilitate its removal.

Stead.—CuCl ₂	g..	10	Dissolve salts in smallest possible amount of hot water and make up to 1,000 c c with absolute alcohol.
MgCl ₂	g..	40	
HCl.....	c c..	10	
H ₂ O.....	c c..	20	
Alcohol to.....	c c..	1,000	

For small specimens the reagent is applied drop by drop until structure is developed. The specimen is then washed with boiling water and then alcohol.

Another method is to wash off the deposited copper with ammonia and so increase the contrast.

Le Chatelier and Lemoine.—CuCl ₂	g..	10
MgCl ₂	g..	40
HCl.....	c c..	20
H ₂ O.....	c c..	180
Alcohol.....	c c..	1,000

Applied like Stead's reagent. Contrast can be increased by electrolysis, using a single battery cell, keeping the current below 50 milliamperes.

Rosenhain and Haughton.—		
Fe ₂ Cl ₆	g..	30
HCl.....	c c..	100
CuCl ₂	g..	10
SnCl ₂	g..	5
H ₂ O.....	c c..	1,000

The copper adheres firmly. Pearlite areas remain bright. Ferrite darkened by deposited copper, the purest parts darkening the fastest. Pitting can be avoided by diluting the reagent.

Le Chatelier and Dupuy.—		
Ethyl alcohol.....	c c..	100
H ₂ O.....	c c..	10
CuCl ₂	g..	1
Picric acid.....	g..	5
HCl (concentrated).....	1.3 to 2.5 c c, varying with material.	

Oberhoffer.—		
Ethyl alcohol.....	c c..	500
H ₂ O.....	c c..	500
SnCl ₂	g..	5
CuCl ₂	g..	1.0
Fe ₂ Cl ₆	g..	30
HCl.....	c c..	50

Humfrey.—		
Emery paper finish may be used for specimen.		
Copper ammonium chloride.....	g..	120
HCl (concentrated).....	c c..	±50
H ₂ O.....	c c..	1,000

The addition of HCl causes the copper deposit to adhere. Etching is therefore started with the neutral solution and continued until all traces of the scratches have disappeared. Then in successive applications the acidity of this solution is gradually increased up to the maximum. Alloy steels etch better with solutions of weaker acidity. After wiping away the deposited copper and drying the surface is lightly rubbed with fine emery paper and the relief portions brought out in strong contrast. The section may be printed with ordinary printer's ink applied to the surface by means of a roller.

Dickenson.—		
First etch with 10 per cent HNO ₃ . Then reetch with —		
Fe ₂ Cl ₆	g..	40
CuCl ₂	g..	3
HCl.....	c c..	40
H ₂ O.....	c c..	500

4. For etch tests to distinguish between wrought iron and steel, to develop the structure of welds, etc., the following rapidly acting reagents are recommended, the percentages given being by volume:

	Per cent
(a) Hydrochloric acid (specific gravity 1.19).....	10
Sulphuric acid (specific gravity 1.84).....	30
Water.....	60
(b) Nitric acid (specific gravity 1.42).....	25
Water.....	75

Methods for Indicating Distribution of Sulphur

The distribution of sulphur is usually shown by the sulphur-print method. A solution of 2 to 3 c c of concentrated H₂SO₄ in 100 c c of water is used to moisten a sheet of matte-finish photographic paper. The specimen, with its surface smoothed either with a fine file or grinding wheel, is pressed firmly on the paper on which a brown mark will indicate the sulphur-rich areas. About 60 seconds is usually sufficient to give a good print. The paper is then washed and fixed in hyposulphite solution.

With larger sections the paper is placed on their polished surface with care so that no air pockets occur. If a very dilute solution is used and a longer "etch," several prints can be obtained. Fresh solution can be added with absorbent cotton should the paper tend to become dry.

Methods Used for the Location of Minute Cracks Before Deep Etching

Considerable difference of opinion has arisen as to the meaning of the results obtained by deep etching in transversely fissured rails, etc., because the presence of cracks in the material previous to etching had not been demonstrated. The following method, however, can be used to locate them. The sample, after careful polishing, is magnetized and then immersed in kerosene or a similar liquid containing very fine iron dust in suspension. The particles of iron dust collect upon the face of the specimen and orient themselves to correspond to the shape of the cracks because of discontinuity in the metal which causes a change in the density of the magnetic flux. The samples are then washed in clean kerosene to remove as much as possible of the excess iron dust which clings to the surface.¹²

According to several authorities, their existence has been proven by annealing the specimens prior to etching, because a pronounced decarburized area then occurs around these cracks.

Method of Photographing

The camera should be arranged so that the specimen is illuminated by vertical light. After certain

¹¹ Rawdon, "Macro-etching with Ammonium Persulphate," Scientific Paper No. 402, Bureau of Standards, 1920.

¹² Rawdon and Epstein, Technologic Paper No. 165, Bureau of Standards, 1920.

kinds of etching, for example, ammonium persulphate, the surface should be immersed in water, alcohol, or light oil. For large specimens the surface may be covered with oil or glycerin.

Printing the Surface

The surface obtained by deep etching may be printed with printer's ink applied with a roller. The printing can be done on a glossy paper in a letter press. For small samples of wrought iron deeply etched a reproduction can be made using an ordinary ink pad and applying the specimen as in block printing.

MICROSCOPIC EXAMINATION

Location of Test Pieces

The location of the test piece for microscopic examination is of prime importance. In the case of a casting of steel or cast iron, the section should be cut perpendicular to the surface so as to show the variation of structure from the outside to the interior. In the case of forged and rolled metal both cross and longitudinal sections should be examined, their location being determined by the nature of the forging, etc. For crankshafts, definite locations are given with reference to the tension-test specimens. For guns, tangential specimens are required and for microstructure these should be cut parallel to the axis, etc. No one specimen is, of necessity, representative. The usual method of taking a cross section from rods and bars while showing segregation of the constituents fails to reveal the usual lamination in such material for which a longitudinal section is necessary. The location of test specimens may be determined by a preliminary macroscopic examination.

In defective material, the sample should be cut adjacent to the fracture or defect. When necessary the fracture can be protected during grinding and polishing by coating it with a heavy deposit of electrolytic copper, molten lead-tin solder or a mixture of litharge and glycerin. For hardened steel and other material liable to be tempered, fusible metals such as Rose's or Wood's alloys may be used.

Method of Polishing

The method used for polishing specimens will depend primarily on the material to be examined and on the polishing equipment. In general, samples should not be over 1 inch square and their thickness should be less than the smallest dimension of the polished surface; otherwise there is a tendency to round off the edges during the process.

The softer material can be cut with a saw while harder metal may be cut with an emery disk or broken off with a hammer. A flat surface is at first obtained either by rubbing on a file held in a vise or by grinding on an emery wheel. In both cases it is necessary to avoid tearing the surface of the metal or causing it to flow. Perfectly smooth surfaces can be obtained by commercial surface-grinding machines.

Having obtained a flat surface in this way, the sample is next rubbed down on a series of emery papers, usually starting with No. 00 commercial followed by Nos. 0 and 00 French emery. These papers may conveniently be mounted on revolving disks. Rubbing on one paper is stopped as soon as the scratches from the last operation have been taken out. From the No. 00 French emery the specimen may be taken to a revolving disk covered with broadcloth, preferably running in a horizontal position at such a speed that the polishing powders are not unnecessarily thrown off. For ordinary work, two such disks will be sufficient, the first

armed with well-washed carborundum, 65 or a similar grade, while the second may be armed with well-washed alumina. This is preferable to rouge because it is much cleaner.

To obtain a fine polish it is a mistake to try to save time by hurrying through the papers because if this is done, when the specimen is etched, innumerable fine lines will be revealed in the ferrite. In some cases the appearance of the ferrite is actually blurred because the metal distorted in the grinding and by the coarse grades of emery has not been subsequently removed. Under no conditions should buffing be tried, because this causes an actual flow of the metal and the structure is thereby obliterated.

No general rules can be laid down as to the method to be pursued, but common sense will tell what is right and what is wrong. For example, in grinding on the emery wheel a copious flow of water must be maintained, otherwise the surface of the sample will heat up and the structure of the metal will be modified thereby.

For material of small size, such as sheet and wire, numerous methods of mounting have been devised. For wire, various mounting media such as wax, a mixture of litharge and glycerin, fusible metals and the like can be used in a small brass container. For sheet metal, a pack can be built up of pieces of the sample with alternate layers of red fiber board, bakelite, or other resistant material, the whole being held together by two brass end pieces and two screws. The whole can then be polished down.

Methods of Etching

The sample ought to be examined as polished in order to show up the nonmetallic inclusions as well as cracks and other defects. In order to show up the structure of the metallic matrix various etching reagents have been used depending on the material being examined. For general work, a 4 per cent solution of picric acid in ethyl alcohol is recommended. This darkens the pearlite in steel and leaves the ferrite or cementite bright, as the case may be. Long etching with picric acid in alcohol will develop the grain structure in very low carbon steel and in wrought iron. This may be done more rapidly with a 2 to 4 per cent solution of nitric acid in ethyl alcohol (95 per cent). For showing up pearlite alone, picric acid in absolute alcohol is best.

To distinguish between ferrite and cementite in high-carbon steels, the usual method is to boil in the sodium picrate solution, which darkens the cementite.

For hardened and tempered steel, picric acid may be used, but after etching, washing under the tap, and flooding with alcohol, the specimen should be dried by an air blast or if this is not available by shaking it in air. If the usual method of mopping on a soft towel be tried, the etching film will be spoiled.¹³

For the study of hardened and tempered steels under high magnifications other reagents have been devised such as those of Kourbatoff.

For distinguishing between cementite and phosphide of iron in cast iron, either heat tinting, or boiling with sodium picrate may be used, as recommended by Matweiff. This attacks the iron phosphide, but leaves the cementite unattacked.

For revealing the segregation of the phosphorus in steel, various reagents have been used, depending on the deposition of copper from a copper chloride solution.

¹³ To dry specimens without the use of alcohol: After etching, wash in very hot water and dry in an air-blast. With this method the results obtained are as good as with the older method of using alcohol after washing in water. After etching with dilute nitric acid solutions, steels in the unhardened condition do not show the stains which generally appear after drying with alcohol.

Certain alloy steels, especially those high in the alloying elements, are very resistant to etching. For these, special solutions have been devised such as ferric chloride for high-nickel material, and caustic soda solution of hydrogen peroxide, etc., for high-speed steels.

In many cases after etching, the ferrite or cementite may be found to be more or less stained or colored. This can often be remedied by a light polish on a chamois-skin pad. While this brightens up the ferrite or cementite, as the case may be, it markedly alters the appearance of the pearlite, giving it an abnormal structure, and therefore when this method is used, photographs should be so marked.

(Supplementing these methods are numerous references to the art of metallography; and a list of reagents for etching, including solutions for iron and plain-carbon steels, solutions for hardened steels, solutions for carbides, and solutions for alloy steels. Information on methods of identifying nonmetallic inclusions is added, also a bibliography on etching.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD METHOD OF VERIFICATION OF TESTING MACHINES, DESIGNATION E4-27, 1927

VERIFYING TESTING MACHINES

DEFINITIONS

1. (a) *Testing machine (load applying).*—A mechanical device for applying a load (force) to a specimen.

NOTE.—Usually the magnitude of the load can be changed at the will of the operator. Many testing machines are arranged to measure the load, but this is not always the case, especially with impact machines and machines for testing ductility.

(b) *Error.*—In the case of a testing machine, the value obtained by subtracting the correct value of the quantity measured (usually load) from the indicated value as given by the testing machine.

NOTE.—The error may be positive or negative.

(c) *Percentage of error.*—In the case of a testing machine, the ratio, expressed in per cent, of the error to the correct value of the quantity measured.

(d) *Correction.*¹⁴—In the case of a testing machine, the value obtained by subtracting the indicated value from the correct value of the quantity measured.

NOTE.—The correction has the same magnitude as the error but the opposite sign.

(e) *Tolerance.*—In the case of a testing machine, the maximum allowable error in the value of the quantity indicated.

NOTE.—It is convenient to express tolerance in terms of percentage of error. The numerical value of the tolerance for a testing machine is so stated hereafter in these methods.

The word "accurate" applied to a testing machine shall be used without numerical values. The word "error" shall be used with numerical values. For example: "An accurate testing machine was used for the investigation"; but "the error of the testing machine at a load of 30,000 pounds was 15 pounds." A testing machine is said to be accurate if the indicated load is within the specified tolerance of the actual load.

The accuracy of a testing machine should not be confused with sensitiveness. For example, a testing machine might be very sensitive—that is, it might indicate quickly and definitely small changes in

the load—but, nevertheless, be very inaccurate. On the other hand, the accuracy of the results is, in general, limited by the sensitivity.

(f) *Loading range.*—In the case of a testing machine, the range of indicated loads for which the testing machine gives results within the specified tolerances. The loading range shall not include loads either greater than the largest load or less than the smallest load applied in verifying the testing machine.

METHODS FOR VERIFYING TESTING MACHINES THAT MEASURE LOAD

2. Wherever practicable, testing machines shall be verified by applying standard weights directly to the weighing mechanism of the testing machine, or by the use of standardized proving levers in connection with standard weights. The test loads selected shall be applied in both ascending and descending order, and the indications for both the ascending series and the descending series of loads shall be considered in the application of tolerances.

NOTE.—For machines in which the load-indicating device is actuated by a Bourdon pressure tube, a hydraulic (or steam-engine) indicator spring, or other device depending on the elastic properties of a material, the tolerances for the descending load shall be applied to differences in the indication for the corresponding ascending and descending readings. In such testing machines the test for ascending load shall be applied as rapidly as practicable after the testing machine has remained unloaded for at least six hours, and the time of applying the ascending series of loads shall not exceed thirty minutes. The descending load test shall be made after the maximum test load has remained on the machine for one hour, and the readings for descending loads shall be taken as rapidly as possible, and in any event the descending load test shall be completed within a period of twenty minutes.

3. For any loading range, the testing machine shall be verified by at least four test loads. It is recommended that the test loads used be 10, 20, 50, and 100 per cent of the maximum capacity at which the testing machine is to be used.

NOTE.—Where a large amount of testing of small specimens is to be done on a large-capacity machine, it is recommended that the verification outlined above be supplemented by a series of smaller test loads selected in reference to the light work to be done on the testing machine.

(A) Method of Verification by Standard Weights

4. Standard metal weights of suitable design, finish, and adjustment shall be placed on the weighing platform of the testing machine or upon trays or other supports suspended from the load-measuring mechanism in place of the specimen. The weights shall be applied in increments and removed in the reverse order. They shall be arranged symmetrically with respect to the weighing platform, so that the center of gravity of the load lies in the vertical line through the center of the platform. The applied load and the indicated load shall be recorded for each test load applied, and the error computed from these data.

NOTE.—The method of verification by standard weights can be used only on vertical testing machines. The total load is limited by the size of the platform and the number of weights available. Often 20 weights of 50 pounds each are used, a total of 1,000 pounds.

This method of verification is seldom used for any but small testing machines, as the loading range does not include the loads for which large machines are used.

(B) Method of Verification by Standardized Proving Levers

5. The arrangement of proving levers for verifying testing machines is shown in Figure 17. The two levers rest on supports on the weighing platform of the testing machine. These supports shall move easily in a horizontal direction, which insures that the forces at each of the knife-edges shall be very nearly vertical. The inner knife-edges in each lever bear against a suitable block in the movable head of the testing machine. Weight trays or hangers are suspended from each of the outer knife-edges

¹⁴ It is recommended that, except for special cases, no corrections be used on machines tested and found to have errors within the tolerances given in these methods.

and these trays or hangers are loaded with standard weights. The increment of load put on the testing machine by the standard weights is the amount of standard weights multiplied by the lever ratio m/n , Figure 17.

6. The knife-edges, as well as their supports, shall be of hardened tool steel. The knife-edges shall be

from the end knife-edges. Standard weights shall then be applied to the trays in three steps, corresponding approximately to 50, 75, and 100 per cent of the weights available, and the proving lever shall then be brought to a balance by the use of small weights and by observations of the freely swinging proving lever. From the weights in the two weight trays the lever ratio shall be computed.

8. The proving levers shall be placed symmetrically in the testing machine to be verified and both levers brought as near to a horizontal position as is feasible, after applying each increment of load, by means of the movable head of the testing machine. The testing machine shall be balanced with the levers in place and the weight trays empty. Standard weights shall be applied in increments, half an increment in each tray, and they shall be removed in the reverse order. The weights shall

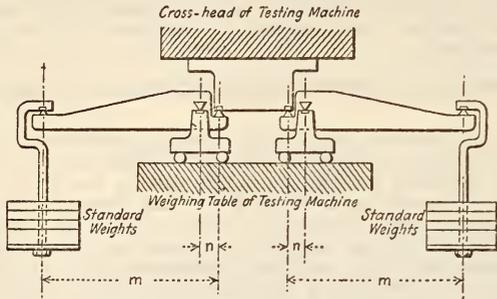

FIGURE 17.—Proving levers

ground sharp with an angle of 90°. The load on any knife-edge shall not exceed 7,000 pounds per linear inch. The three knife edges in each lever shall be parallel, and their edges shall lie in a plane. Each lever shall have machined surfaces in this or in

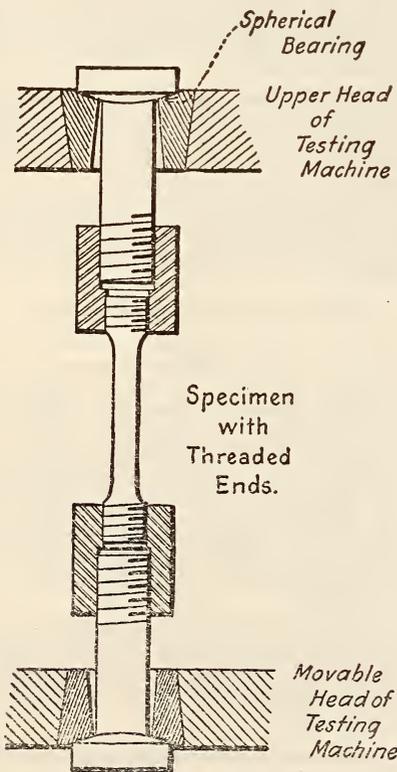

FIGURE 18

some parallel plane, upon which a spirit level can be placed.

7. The lever ratio of a proving lever shall be determined by the use of at least three test loads; the amount of weights used shall not be less than the maximum load applied upon one of the arms of a lever in using the levers to verify testing machines. The proving lever shall be balanced over its center knife edge with suitable weight trays suspended

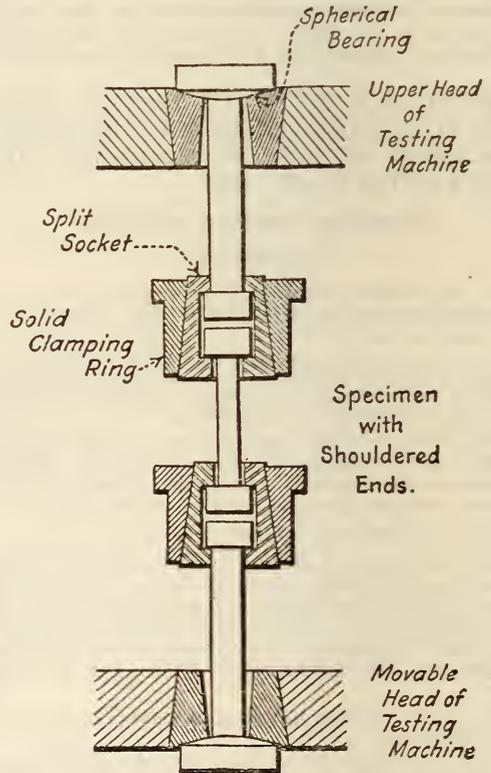

FIGURE 19

be placed symmetrically on the weight trays, with the center of gravity of the weights over the center of the tray. The applied load and the indicated load shall be recorded for each test load applied, and the error computed from these data.

NOTE.—The method of verification by standardized proving levers is used, at the present time, only on vertical testing machines. It is often used up to loads of 10,000 pounds.

(C) Method of Verification by Means of an Elastic Calibration Device

9. In this method the testing machine to be verified is tested by comparing its load indications with the amount of elastic deformation of a calibration device, the deformation being measured with a delicate strainometer.

10. The calibration device may be a bar tested in tension or in compression, or an elastic loop or other shape whose elastic deformation can be measured, and if a tension or compression bar is used it shall be fitted with spherical-seated shackles or with

a spherical-seated bearing block to insure as nearly axial loading as is possible. The arrangement shown in Figure 18 or Figure 19 is suggested for tension bars and the arrangement shown in Figure 20 is suggested for compression bars.

11. (a) The calibration device shall be of such size that under the greatest load for which the device is to be used (called its full load) the stress on any cross section will not be more than 80 per cent of the elastic limit of the material, as determined in accordance with Method II for the Determination of Elastic Limit as described under the definition of the term "Elastic Limit" of the Tentative Definitions of Terms Relating to Methods of Testing (A. S. T. M. Designation: E6-30T) of the American Society for Testing Materials on a test specimen cut from the bar, forging, or casting for the device after its final heat treatment. (See below.)

(b) Before the calibration device is first used for verification purposes, it shall be loaded to its full load at least six times, and between successive loadings it shall be heated to a temperature of 100° C. (212° F.) for a period of 30 minutes or shall be allowed to rest for a period of 24 hours. The object of this treatment is to adjust the device to its bearings and to relieve internal strain.

12. The loading range of a calibration device is the range of indicated loads for which the device gives results within specified tolerances. Obviously the loading range may not include loads either greater than the largest load or less than the smallest load applied in verifying the calibration device.

13. (a) The loading range of a calibration device shall be determined by verifying its indications by the use of standard weights or by standard weights and proving levers. In verifying the indications of the device, an initial load of 1 per cent of its full load shall first be applied. All changes of strainometer reading and of applied load shall be reckoned from the readings at this initial load. Successive loads shall be applied, a recommended series of loads being 10, 20, 50, and 100 per cent of the full load of the device. Such a series shall be applied to the bar at least five times to determine the relation of applied load to strainometer reading, the shackles or bearing blocks being readjusted before each application of the series.

(b) The average of the five (or more) strainometer readings obtained in this way shall be taken for each load applied. The average of the differences (taken without regard to algebraic sign) between the individual strainometer readings for any load and the mean reading for that load constitutes the average deviation for that load. The lowest value of load for which the average deviation is not greater than 0.5 per cent of the strain for that load is the lower limit of the loading range of the calibration device.

NOTE.—If in taking five or more strainometer readings for any load the deviation of any one reading is more than 1 per cent from the mean reading, then this series of five or more readings shall be repeated.

14. The strainometer for elastic calibration devices, which employ elastic bars in axial tension or axial compression, shall be so designed as to indicate the average elongation or compression of the bar. For any elastic calibration device, it shall be sufficiently sensitive to indicate a change of 0.25 per cent of the minimum load in the loading range of the device. If the strainometer is not permanently attached to the calibration device, the strainometer shall be removed and replaced for each successive reading taken during the calibration of the device itself. This, of course, does not mean that the strainometer must be removed for each reading in the regular use of the instrument.

15. In using the calibration device it is important that just previous to taking any reading including,

the initial reading of a series, there shall be no reversal in the direction of motion of the indicating mechanism of the strainometer, because such reversal may introduce error due to backlash in the instrument. That is, when taking readings for a series of increasing loads the load should be brought up to each predetermined test load, and when taking readings for a series of decreasing loads the load should be brought down to each predetermined test load.

16. In using a calibration device made of steel, correction for variation in mean temperature during any calibrations made on different occasions should be made by allowing a diminution of 0.015 per cent ($1\frac{1}{2}/1000$ of 1 per cent) in the modulus of elasticity of steel for each 1° F. increase in temperature. During any calibration with an elastic calibration device, temperature conditions should be kept as uniform as is possible.

(D) Verification by Comparison Method

17. When the direct method of verification of a testing machine can not be carried out (as is the case at present with horizontal testing machines, for example) or when an elastic calibration device is not available, a comparison method of verification may

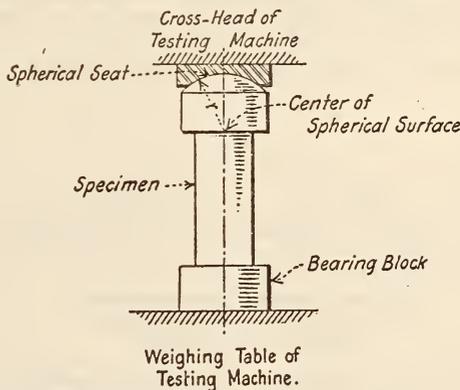

FIGURE 20

be used. In this method the machine to be verified is tested by comparing its indications with corresponding readings obtained under the same conditions by the use of another testing machine, especially tested and verified, as specified in section 18. The method of verification by comparison shall be carried out by the use of a series of companion specimens, half of which are to be tested in tension in the machine to be verified and half of which are to be tested in tension in the especially verified testing machine which serves as a standard machine. The general provisions respecting the application of the test loads and the loading range which are outlined in the direct method of verifying testing machines shall apply to the verification of testing machines by the comparison method, so far as is practicable.

NOTE.—The method of verification of a testing machine by standard weights (sec. 4) and the method of verification by standardized proving levers (secs. 5 to 8) are both regarded as superior to the method of verification by the use of companion specimens. If the results of a verification test of a testing machine by the comparison method fail to agree with the results of a verification by either the standard-weight method or the proving-lever method, the results of the verification by the comparison method shall be discarded.

18. (a) A testing machine which is to be used as the standard for verifying other testing machines shall itself be verified by a special test, in which the verification is carried out twice. The loading range shall be determined by the tolerance for new testing machines, namely, ± 1 per cent (sec. 22).

For the loading range established, the differences in indications found in the two tests of the standard machine shall not exceed 0.25 per cent.

(b) In verifying testing machines by the comparison method, corrections shall be applied to the indications of the standard machine and these corrections shall be based on the average correction obtained in the two tests used in its verification.

19. (a) For each test load, eight or more tension-test specimens shall be cut from soft rolled or drawn steel and numbered consecutively, as in Figure 21 (a).

(b) The tensile strength of the steel shall be determined by a preliminary test and the sets of specimens for the comparison test shall have such nominal cross-sectional areas as will give, approximately, the loads required. The form of the specimen shall be as shown in Figure 21 (b). The ends may be threaded, or otherwise machined, to fit holders, but it is recommended that those specimens shipped to another laboratory be left with cylindrical ends. The actual value of " d " (fig. 21) for each specimen shall be determined by means of a micrometer.

NOTE.—It should be noted that the standard tension-test specimen,¹⁵ 0.5-inch in diameter and having a 2-inch gage length, satisfies the requirements for a specimen for the verification of a testing machine by the comparison method.

20. (a) The specimens having odd numbers shall be tested in the machine to be verified and those

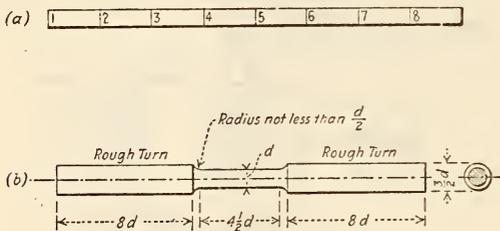

FIGURE 21.—Comparison specimen

(a) method of numbering specimens
(b) form of test specimen

having even numbers in the standard testing machine. The tensile strength only shall be determined.

(b) The speed of the testing machine, by which is meant the speed of the pulling head when the machine is running idle with no specimen in the machine, when testing verification specimens shall be approximately the same for both the standard testing machine and the machine being verified. The speed shall be the slowest speed that can be obtained on both machines; in any case the speed shall not exceed 1 inch per minute per inch of diameter of comparison specimen.

(c) When testing verification specimens, especial care shall be taken to maintain the weighing beam of the testing machine in equilibrium as the tensile strength of the specimen is approached. It is recommended that a mark be placed at the middle of the trig loop and that a pointer be placed on the beam for verification tests, and that the pointer be kept as nearly on the mark as possible.

21. (a) The average tensile strength (in pounds per square inch) of the odd-numbered specimens, multiplied by the nominal area of cross section, shall be considered a measure of the indicated load, and the average tensile strength of the even-numbered specimens, multiplied by the nominal area of cross section, shall be considered a measure of the applied load. The error shall be computed from these data.

(b) If the tensile strength (in pounds per square inch) of any verification specimen varies more than 1 per cent from the mean of the group with which it is tested, its tensile strength shall not be used in computing the error of the testing machine. If more than one specimen in the odd-numbered group or one in the even-numbered group exceeds the allowable variation in tensile strength, all the specimens shall be discarded and another set prepared.

TOLERANCES FOR TESTING MACHINES THAT MEASURE LOAD

22. All testing machines that measure load shall conform to the following tolerances:¹⁶

(a) *New machines.*—The error for loads in the loading range shall not exceed ± 1.0 per cent for new machines or for those which have had any of the knife-edges in the weighing mechanism repaired or renewed.

(b) *Used machines.*—The error for loads in the loading range shall not exceed ± 1.5 per cent.

23. The indicated load of a testing machine shall not be corrected either by computation or by the use of a calibration diagram to obtain values within the required tolerance.

TIME INTERVAL BETWEEN VERIFICATIONS

24. It is recommended that testing machines, when in constant use, be verified at intervals of six months and, when used intermittently, at intervals of two or three years. Testing machines shall, however, be verified immediately after making repairs or adjustments of the weighing mechanism, and whenever there is reason to doubt the accuracy of the results, without regard to the time interval since the last verification.

REPORTS AND CERTIFICATES

25. A clear and complete report shall be prepared of each verification of a testing machine. This report shall contain all data necessary to verify the accuracy of the report, and shall be filed for future reference. This report shall state clearly the method of verification used.

26. A certificate giving the maker's serial number and a brief description of the testing machine, the maker's name, the date of verification, and the loading range shall be signed by the person responsible for the maintenance of the testing machine, and this certificate shall be posted in plain view of a person operating the testing machine.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD METHODS OF METALLOGRAPHIC TESTING OF NONFERROUS METALS AND ALLOYS, DESIGNATION E 5-27, 1927

METALLOGRAPHIC TESTING OF NONFERROUS METALS

MACROSCOPIC EXAMINATION

In order to show up both chemical and crystalline heterogeneity, sections of metals and alloys should be more deeply etched than for microscopic examination. The dendritic structure in castings, dendritic shrinkage cavities, blowholes and other porosity, the flow of metal due to cold working, etc., are brought out.

¹⁶ It is believed that the tolerances given in this section may be made much smaller when more perfect methods of verification become generally available; and that the tolerances might well be materially reduced if there is available equipment for verifying testing machines by the use of standard weights (sec. 4) or by the use of standardized proving levers (secs. 5 to 8).

¹⁵ See Standard Specifications for Steel (605.0, p. 247).

After cutting the section, it is filed or ground smooth and flat, then rubbed on various grades of emery paper down to No. 00 French, so that all effects of surface cold working due to cutting are eliminated. After cleaning the surface of all grease it is ready for etching.

Etching Solutions

For macroscopic etching, most of the reagents used for microscopic examinations may be used, but the time of etching is usually much longer. Those solutions which give maximum grain contrast are usually to be preferred.

For copper and its alloys, a 50 per cent aqueous solution of nitric acid is recommended. Also an ammoniacal solution of copper ammonium chloride is very satisfactory.

The specimen is either immersed in the solution or flooded with it until the structure shows up strongly. It is then well washed with running water, flooded with alcohol, and dried. If the structure is to be recorded, it should be photographed immediately. The surface may be preserved for reference by covering with a thin coat of brass lacquer (a solution of gun cotton in amyl acetate) or similar preparation.

For aluminum and its alloys, a solution of HF-HCl (solution No. 2) is recommended. A 10 per cent aqueous solution of NaOH and a 10 per cent HF also give good results. In copper-bearing alloys the latter solution should be followed by a cleaning in cold concentrated HNO₃.

For lead and its alloys, 10 per cent of nitric acid in water is recommended. For lead ingots, acetic acid gives excellent results.

MICROSCOPIC EXAMINATION

Location of Test Pieces

In the case of castings, the sections should be cut perpendicular to the surface and show the variation of structure from outside to center. For rods, sheet, etc., transverse, longitudinal, and frequently oblique sections should be examined. For large forgings, the threaded ends of the tension test pieces can usually be used by cutting a longitudinal section about one inch in length. No one specimen is of necessity representative. As in iron and steel, the usual method of taking a cross section from rods and bars while showing segregation, fails to reveal lamination. Surface sections of sheet metal are usually taken, but for cold-worked metal, transverse, longitudinal, and frequently oblique sections are also necessary.

For material of small size, the methods of mounting recommended for iron and steel can be used as described in the standard methods of metallographic testing of iron and steel in A. S. T. M. E3-24, given above.

Method of Polishing

The methods of polishing recommended for iron and steel as described in the standard methods of metallographic testing of iron and steel in A. S. T. M. E3-24, given above, are applicable for the harder alloys. For soft metals and alloys, emery wheels can not be used. The sample is rubbed on a file held in a vise, care being taken that the surface is cut and not torn. The file must be kept free from embedded particles of metals or the surface is bound to be torn.

In using the emery papers, only very little pressure may be used or the surface is apt to flow. For soft metals, rubbing by hand is recommended. If revolving disks are used, low speed must be maintained to prevent spoiling the surface. From the No. 00 French paper the specimen may be taken to a revolving disk covered with broadcloth and armed

with well-washed alumina. Again, for soft metals, if the pressure is too great the surface is apt to be spoiled. Buffing can not be used. For very soft metals, such as lead and some of its alloys, even the most careful polishing leaves a film of "flowed" metal. Such samples can be etched fairly deeply with 10 per cent of nitric acid in water and then given a very light repolish with alumina, the surface of the disk being kept very moist. It is then washed free from polishing powder and dried with alcohol.

In the preparation of specimens of aluminum and its alloys, the same precautions must be followed which are recommended for other soft metals. It is further recommended that following the cut on the file, two coarse emery papers, No. 2 and No. 1, be used, preceding the use of the finer metallographic polishing papers. The papers should be prepared by applying a solution of paraffin in kerosene and working well into the surface. The polishing must be done by hand. The papers may be used either as so prepared or moistened with additional solution. It is not always necessary to use this solution on the coarse papers, No. 2 and No. 1. The hand polishing may be stopped at either No. 000 or No. 0000 paper and the polishing continued on a wheel revolving at approximately 200 r. p. m. For the first cut on the wheel, a coarse grade of broadcloth is used with a grade of abrasive similar to 65 F alundum. The next cut is made using a softer broadcloth and "heavy magnesium oxide," applied as follows: The pad is moistened with distilled water and approximately one teaspoonful of powder applied evenly to the surface and thoroughly rubbed in, all hard and coarse particles being brushed off with the hand. After the scratches left by the 65 F material have been removed the pad is washed clean and a smaller quantity of powder worked in as before. This time the cut is made at right angles to the first treatment. This procedure may be repeated several times until the specimen shows a brilliant, reflecting surface, and under the microscope the aluminum solid-solution matrix appears clear white and the constituents stand out in even colors, free from tarnish. Only distilled water should be used during the polishing with the magnesia powder, otherwise there is danger of forming particles of carbonate, which are harsh and scratch the specimen. It is good practice frequently to raise the specimen from the pad and revolve it 180° before replacing. The pressure and quantity of water to be used can only be determined after considerable practice and varies with the nature of the alloy.

Methods of Etching

The sample is first examined for nonmetallic inclusions, cavities, and the like. The structure is then developed by etching with a suitable reagent, a list of which is given below. No one reagent can be said to be the best for any alloy or group of alloys. Cast metal behaves quite differently from both hot and cold worked or annealed material.

For copper and its alloys a 50 per cent aqueous nitric acid solution is recommended. The sample is immersed until the structure shows up, then washed with water and dried with alcohol.¹⁷ This reagent, however, is liable to cause pitting.

For wrought brass, bronze, German silver, etc., the best reagent is ammonia and hydrogen peroxide. About 10 c c of strong ammonia are placed in a watch glass, 1 or 2 c c of peroxide (3.6 per cent) added and applied to the surface of the specimen with a small wad of cotton, rubbing gently till the grain structure appears.

¹⁷ To dry specimens without the use of alcohol: After etching, wash in very hot water and dry in an air-blast. With this method the results obtained are as good as with the older method of using alcohol after washing in water. After etching with dilute nitric acid solutions, steels in the unhardened condition do not show the stains which generally appear after drying with alcohol.

For cast gun metal, this method shows up the coring of the dendrites, but the eutectoid has little contrast with the saturated parts of the alpha. If the sample is then flooded with Grard's solution No. 1 until the alpha darkens slightly, the eutectoid still remains bright blue-white and shows up in marked contrast.

Nickel and its alloys frequently show a peculiar pitting. If a 50 per cent aqueous nitric acid solution be used, small pits appear with colored rings or halos. Merica's nitric-acetic acid gives much better results.

For wrought nickel alloys, concentrated hydrochloric acid is recommended. The action is very slow but the contrast is excellent.

The etching characteristics of copper and of nickel alloys are thoroughly dealt with by Rawdon and Lorentz.

Etching reagents for the identification of constituents in aluminum and its alloys are generally unsatisfactory. Reagents intended differentially to color specific constituents are uncertain and their action varies in different alloys and especially under different conditions of polishing. For this reason it is recommended that the specimens be carefully polished and examined in the unetched condition. If a light filter is used to give a source of light approximating daylight, the constituents will appear as described below:

Unetched characteristics

Constituent	Color	Usual shapes	Characteristics
Si	Slate	Irregular plates	Easily recognized.
FeAl ₃	Purplish gray	Needles	Tendency to purple tinge with relief polishing.
Other iron constituents.	do	"Chinese script" and needles.	Less tendency to purplish tinge. Occurrence due to other elements, notably Si. Composition uncertain.
CuAl ₂	Clear with pink tinge.	Gobs, stringers	Tendency to polish in relief and tarnish. Appears bright on passing out of focus.
MnAl ₃	Flat gray to watery	Angular plates, often hollow. Arrowheads.	Does not polish in relief, but prolonged polishing gives watery appearance. In high-manganese alloys shapes are very characteristic.
Mg ₂ Al ₃	Very faint watery	Gobs, stringers	Same form as CuAl ₂ but much softer. Sometimes difficult to distinguish from aluminum matrix.
NiAl ₃	Light gray	Needles	Difficult to distinguish from FeAl ₃ .
Mg ₂ Si	Slate gray to iridescent blue.	Skeletons and rounded particles. Angular primary particles.	Very careful polish gives even slate-gray particles which are easily tarnished and are turned black or eaten out by too much water in polishing.

With a little experience in the examination of specially prepared known standards, the identification of these constituents when they occur in sufficiently large particles is relatively simple, and etching reagents for distinguishing them are generally unnecessary. When the particles are smaller, the identification becomes extremely difficult, as etching reagents which satisfactorily color large particles fail to identify the smaller particles.

In studying a specimen containing very small particles, such as finely precipitated CuAl₂, there may be sufficient surface flow completely to obscure the particles. To guard against this condition and to reveal grain boundaries and other structural features, it is desirable to swab the specimen lightly with a soft cotton swab saturated with a dilute solution of HF (0.5 to 1 per cent preferred).

The white metals are usually easy to etch if properly polished. For the lead-tin alloys, however, the usual methods do not work so well. It is better to etch rather deeply with nitric acid and then very lightly to repolish on a chamois-skin pad until the structure shows up in marked contrast.

Reagents for Etching

(a) SOLUTIONS FOR COPPER AND COPPER ALLOYS.

Nitric acid.—50 c c nitric acid (concentrated).
50 c c water.

Ammonia.—10 c c ammonia (concentrated).
1 c c hydrogen peroxide (Marchand).

Grard No. 1.—5 g ferric chloride.
50 c c hydrochloric acid.
100 c c water.

Grard No. 2.—19 g ferric chloride.
6 c c hydrochloric acid.
100 c c water.

Ammonium persulphate.—10 per cent aqueous solution made just before use. This solution is improved materially by the addition of a few drops of ammonia.

Heyn's solution.—5 g copper ammonium chloride.
120 c c water.
Add ammonia until precipitate which forms redissolves.

(b) SOLUTIONS FOR NICKEL, MONEL METAL, CUPRO-NICKEL.

Merica's solution.—50 c c of 70 per cent nitric acid.
50 c c of 50 per cent acetic acid.

International Nickel Co.—20-40 c c nitric acid.
40-30 c c 75 per cent acetic acid.
40-30 c c acetone.

Hydrochloric acid.—(Concentrated).

(c) SOLUTIONS FOR ALUMINUM AND ALUMINUM ALLOYS

Solution No.	Reagent	Concentration	Specific use	Authority
1.	HF and HCl ^a	10 to 20 per cent alcoholic HF and concentrated HCl.	Macroscopic	Czochralski.
2.	HF and HCl ^a	10 parts HF, 15 parts HCl, 90 parts H ₂ O	do.	Flick.
3.	HF	0.1 to 10 per cent	General	Various.
4.	NaOH	do.	do.	Do.
5.	NaOH	0.1 per cent in 10 to 50 per cent of alcohol	do.	Merica.
6.	HNO ₃	1 per cent in alcohol	Mg ₂ Al ₃	Hanson.
7.	HNO ₃	10 per cent in alcohol	do.	Do.
8.	HNO ₃ ^b	20 per cent quench	CuAl ₂	Do.
9.	HNO ₃ ^b	25 per cent quench	"X" const. from FeAl ₃	Dix.
10.	Ferric sulphate	10 per cent	CuAl ₂ from FeAl ₃	R. J. Anderson.
11.	Picric acid	4 per cent in alcohol	CuAl ₂	A. Meyer.
12.	H ₂ SO ₄ ^b	10 per cent at 60° to 70° C	FeAl ₃	Do.

^a Czochralski originally etched for grain by using from 10 to 20 per cent of concentrated HF in 100 c c absolute alcohol, followed by dipping in concentrated HCl solution. Flick has very satisfactorily modified this etch by using a single solution prepared as follows: 10 c c of commercial HF and 90 c c of distilled water and 15 c c of concentrated HCl.

^b By the 20 and 25 per cent nitric acid quench is meant the procedure of heating the solution to exactly 70° C. and immersing the specimen for a period of from 2 or 3 seconds to 30 seconds and then immediately quenching the specimen in cold water. This same procedure may be used with the sulphuric acid etch, although the quench is not essential.

(d) SOLUTIONS FOR WHITE METALS (LEAD, TIN, OR ZINC BASE).

Nitric acid.—2 per cent alcoholic solution. For tin-rich alloys.

5 per cent aqueous solution. For lead-rich alloys.

Hydrochloric acid.—5 per cent aqueous solution. For zinc-rich alloys.

The above list gives the principal reagent used for etching the chief commercial alloys. Numerous other methods have appeared in the literature, each worker apparently preferring to develop his own method. The papers by Hudson, Czochralski, and Guertler covering etching reagents enumerate most of the ones which have had any vogue. Among these less-used reagents the following may be mentioned:

Gold, platinum, etc.—Aqua regia.

Zinc (Timofeff).—
 94 per cent nitric acid { A few drops added to
 6 per cent chromic acid { 100 c c of water be-
 fore use.

Tin.—5 per cent alcoholic solution of hydrochloric acid.

Magnesium and its alloys.—2 per cent nitric acid in water, 10 seconds.

Tungsten.—(1) Boil in ammonia and hydrogen peroxide or hydrogen peroxide alone.

(2) Electrolytic etch. 15 per cent NaOH. 20 milliamperes per square centimeter. About 5 minutes.

(3) 2.5 per cent water solution of potassium ferrocyanide to which a few drops of ammonia are added just before use. Broadcloth or rubber is moistened with the solution and the specimen gently polished on the surface so prepared.

Electrolytic Etching

Electrolytic etching has been advocated by many workers, notably Le Chatelier, for brass and other alloys. The newer methods, as, for example, ammonia with hydrogen peroxide, give better results. For certain materials, however, electrolytic etching gives excellent results, especially where the samples are very resistant to ordinary etching reagents: For example, tungsten, certain of the nickel chromium alloys, white gold, etc. A simple method is to connect two short platinum wires to the electric-light circuit of 110 volt (direct current) through a 4-candlepower lamp. Place the specimen on the anode wire so that its upper surface is perfectly

level. Drop on enough dilute sodium hydroxide to cover the whole surface and then dip the cathode wire into the electrolyte. In order to get a uniform etch, the end of the wire should be bent at right angles and moved back and forth above the surface of the specimen to be etched. As soon as the structure is visible to the eye, the sample may be washed and dried in alcohol in the usual way. This gives a quick although somewhat rough-and-ready method, but one which usually works very well.

The specimen is held face downwards by a flexible clip attached to the positive connection. The electrolyte is placed in a suitable dish in which the negative pole is immersed. The electrolyte surface is raised until it wets the surface of the specimen and then lowered slightly so as to produce a surface tension contact between the specimen and the solution. The results are very much superior to the old method of complete immersion of the specimen.

(Supplementing these methods are numerous references to the art of metallographic etching of nonferrous metals, including copper and copper alloys, nickel and nickel alloys, aluminum and aluminum alloys, brass, and bronze. There is also a bibliography of etching.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD DEFINITIONS OF TERMS RELATING TO METHODS OF TESTING, DESIGNATION E6-30, 1930

TESTING TERMS

Stress.—The intensity (measured per unit area) of the internal distributed forces or components of force which resist a change in the form of a body. Stress is measured in force per unit area (pounds per square inch, kilograms per square millimeter, etc.).

NOTE.—In examining the definitions given in various authoritative textbooks two definitions of the term "stress" were found. Textbooks in physics and some European textbooks in mechanics of materials gave a definition substantially as above. American textbooks in engineering mechanics define stress as a "force," measured in "pounds." They call the intensity of force (pounds per square inch) "unit stress," "intensity of stress," or "fiber stress." This use of the term "stress" is illustrated by the "stress sheet" of the bridge engineer which gives forces, measured in pounds.

In view of the fact that even in engineering textbooks the term "stress" is often used to denote intensity of force per unit of area, and in view of the fact that the physicists' definitions involve somewhat simpler terms, the physicists' definitions have been followed in these standards.

While it is important to have a clear definition for the term "stress" it is even more important to keep clearly in mind the units used in computations and test data for materials of construction. In fact, if the units are always given, there can be no misunderstanding as to the sense in which the term "stress" is used.

There are three kinds of stress: Tensile, compressive, and shearing. Flexure involves the combination of tensile stress and compressive stress. Torsion involves shearing stress.

It is customary to compute stress on the basis of the original dimensions of the cross section of the body.

Strain.—The change per unit of length in a linear dimension of a body, which change accompanies a stress. Strain is measured in inches per inch of length (millimeters per millimeter).

NOTE.—In American engineering textbooks the term "strain" is used in the sense of total deformation and is measured in inches. Change of dimension per unit length is called "unit strain," or "unit deformation." As in the consideration of the term "stress," the definitions given in textbooks in physics have been followed.

Under tensile stress or compressive stress, strain is measured along the dimension under consideration. Shearing strain is measured at right angles to the dimension under consideration. In torsion tests,

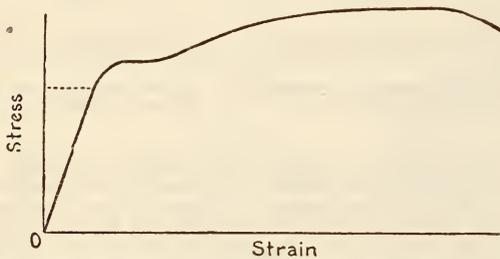

FIGURE 22.—A typical stress-strain diagram

which involve shearing stress, it is customary to measure the angle of twist, which may be translated into terms of strain.

Stress-strain diagram.—A diagram plotted with values of stress as ordinates and values of strain as abscissas.

NOTE.—The use of the term "stress-strain diagram" is frequently extended to cover diagrams plotted with values of applied load or applied moment as ordinates, and with values of stretch, compression, deflection, or twist as abscissas.

Figure 22 is an example of a stress-strain diagram.

Stress-strain diagrams are in some cases drawn directly by an autographic attachment to the testing machine. A more usual method of procedure consists in taking a series of load readings (from the balanced scale beam of the testing machine) with corresponding readings of the strain-indicating apparatus (extensometer, compressometer, deflectometer, or torsion indicator). The term "strainometer reading" will be used to denote the reading of any strain-

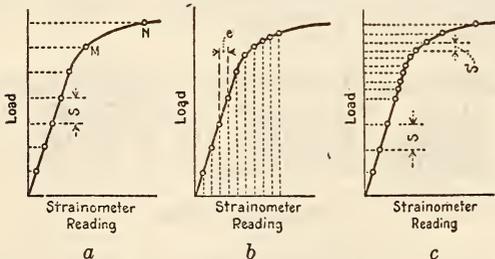

FIGURE 23.—Three methods of plotting load-deformation curves

(a), with equal increments of stress; (b), with equal increments of strain; (c) with two values of increments of stress.

measuring instrument. From these readings, or from values computed from them, there is plotted a diagram with stress-indicating values (load, flexural moment, twisting moment, or stress) as ordinates, and strain-indicating values (elongation, shortening, deflection, twist, or strain) as abscissas. In planning such a test it is necessary to decide on the increment of load or the increment of reading of strainometer to be used between successive readings.

In Figure 23 are shown three typical stress-strain diagrams. The material for all three tests is the same, and the test specimens are all of the same size, so that the diagrams should be the same. The diagram shown in Figure 23 (a) is plotted from points determined by taking increments of load S . In this diagram it is seen that owing to the shape of the curve, data for locating points between M and N are lacking. That particular portion of the curve (the "knee" of the curve) is the part for which it is especially desirable to locate several points on the diagram.

In Figure 23 (b) is shown a diagram plotted from points determined by taking increments of strainometer reading (e). It will be noted that for this diagram there are located several points near

the knee of the curve, and the shape of the diagram in this important region is much more definitely determined than for the curve shown in Figure 23 (a).

The custom of choosing increments of load rather than increments of strainometer reading is quite common in tests of materials and is followed because, in general, it is easier to compute increments of load than it is to compute increments of strainometer reading. An estimate of the load necessary to stress the specimen up to the knee of the curve is made and some fraction (frequently one-tenth) of this value is taken as an increment. The computation of the corresponding increment of strainometer reading is more complicated.

Sometimes the practice is followed of applying a few increments of load as determined above, and then applying load in much smaller increments S' until the knee of the curve is passed. Figure 23 (c) shows a diagram obtained in this manner. This method involves a marked increase in the number of readings necessary for a test and with unknown material there is always some danger that the knee of the curve will be reached before the use of small increments of load is begun.

The following method of choosing increments for a test is suggested: Estimate the load corresponding to the knee of the stress-strain diagram and choose a value for increment of load about one-tenth of this value. Apply this increment of load S once and note the corresponding change of reading for the strainometer e . Then for the remainder of the test, use for the increment of strainometer reading a value which corresponds to some convenient interval on the scale of the strainometer, and which is approximately equal to e .

Tensile strength.—The maximum tensile stress which a material is capable of developing.

NOTE.—In practice, it is considered to be the maximum stress developed by a specimen representing the material in a tension test carried to rupture, under definite prescribed conditions. Tensile strength is computed from the maximum load carried during a tension test and the original cross-sectional area of the specimen.

Compressive strength.—The maximum compressive stress which a material is capable of developing.

NOTE.—In the case of a material which fails in compression by a shattering fracture the compressive strength has a very definite value. In the case of materials which do not fail in compression by a shattering fracture the value obtained for compressive strength is an arbitrary value depending upon the degree of distortion which is regarded as indicating complete failure of the metal.

Modulus of elasticity.—The ratio, within the elastic limit of a material, of stress to corresponding strain.

NOTE.—As there are three kinds of stress, so are there three moduli of elasticity for any material: The modulus in tension, the modulus in compression, and the modulus in shear. The value of the modulus of elasticity in tension is nearly the same, for most metals, as the value of the modulus of elasticity in compression. The value of the modulus of elasticity in shear is smaller than the value of the modulus of elasticity in tension. The modulus of elasticity is expressed in pounds per square inch (kilograms per square millimeter).

AMERICAN SOCIETY FOR TESTING MATERIALS, TENTATIVE DEFINITIONS OF TERMS RELATING TO METHODS OF TESTING, DESIGNATION E6-30T, 1930

TENTATIVE TESTING TERMS

Elastic limit.—The greatest stress which a material is capable of developing without a permanent deformation remaining upon complete release of the stress.

NOTE.—In certain specifications of the society the term "elastic limit" is used to designate a value obtained by a test method which does not involve the release of stress during a test but which does involve the determination of a limiting load at which there occurs an appreciable change in rate of strain with respect to stress. This limit is frequently given the name "proportional limit" (or "proportional elastic limit"), and the following definition may be given:

Proportional limit.—The greatest stress which a material is capable of developing without a deviation from the law of proportionality of stress to strain (Hooke's law).

It is a matter of experience with many materials, especially with many metallic materials, that, using ordinary methods of testing, the values found for elastic limit by means of observations of permanent deformation (set) after release of stress do not differ widely from the values found for proportional limit. Since the determination of proportional limit is much more readily made than in the determination of elastic limit it is customary to accept the proportional limit as equivalent to the elastic limit for such materials.

Using any known method, the value determined either for proportional limit or for elastic limit is somewhat arbitrary; the value depends on various test conditions, among them precision of apparatus, the scales to which stress-strain diagrams may be plotted, and the tolerance allowed before it is judged that there exists an appreciable deviation from the law of proportionality of stress to strain or an appreciable permanent deformation (set) upon release of stress.

In connection with this note on elastic limit and proportional limit, it seems proper to consider the action of a material under steadily increasing stress, and to discuss briefly five stages which may be distinguished between the first application of stress and fracture of the metal. Not all materials show all five stages, and for a material the end of one stage and the beginning of the next stage are not always marked.

In the first stage (*OA*, fig. 24 (a)), with the use of measuring instruments of ordinary sensitiveness, deviations from the law of proportionality of stress to strain (Hooke's law) will not be detected, nor will there be detected set after release of stress.

In the second stage (*AB*, fig. 24 (a)) as stress increases there is detected an appreciable and growing deviation from the law of proportionality of stress to strain. This is usually accompanied by an appreciable and growing permanent deformation (set) after release of stress, although for some materials (for example, rubber) measurable permanent deformation may not occur after release of stress exceeding the proportional limit. Values for elastic limit and for proportional limit are found in this second stage.

The third stage (*BC*, fig. 24 (a)) is characteristic of ductile metals. In this stage, strain increases without any increase of stress and in some cases increase of strain is accompanied by an actual decrease of stress. The yield point is found at the beginning of this stage (at *B*, fig. 24 (a)).

In the fourth stage (*CD*, fig. 24 (a)) stress and strain both increase up to the maximum stress carried (*D*, fig. 24 (a)), which gives the tensile strength in a tension test of a material).

In the fifth stage (*DE*, fig. 24 (a)) strain increases while stress diminishes from the maximum value (*D*, fig. 24 (a)) to fracture

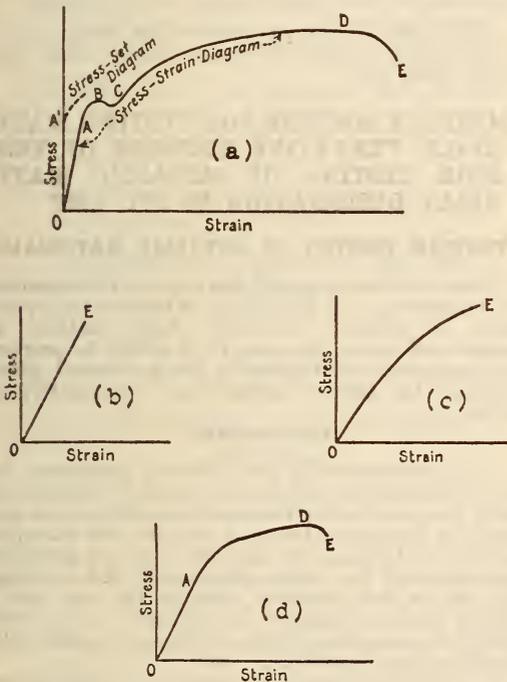

FIGURE 24.—Stress strain diagrams

(*E*, fig. 24 (a)). In considering each of these stages it is important to note that stress is computed on the basis of original cross section of specimen.

Many materials, especially brittle materials, do not exhibit all the above-mentioned stages. Some (for example, glass and fused quartz) show only the first stage. Figure 24 (b) gives a representative stress-strain diagram for such materials. Some materials (for example, cast iron) show only the second stage, and Figure 24 (c) shows a typical stress-strain diagram for such materials. Some materials (for example, medium-hard steel) do not show the third stage, and the second stage merges into the fourth stage. Figure 24 (d) shows a typical stress-strain diagram for such materials. The fifth stage is absent in many materials; it is, in fact, characteristic of ductile metals only.

The following methods of test are, strictly speaking, methods of determining proportional limit with various degrees of precision. However, the values determined by these methods may for certain materials, be regarded as satisfactory and reliable values for the elastic limit, and they are therefore so used in certain specifications of the society.

Method I. (For tension tests only, proposed by Committee A-1 on steel, and embodied in a number of specifications for steel.) The elastic limit shall be determined by an extensometer reading to 0.0002 inch. The extensometer shall be attached to the specimen

at the gage marks and not to the shoulders of the specimen nor to any part of the testing machine. When the specimen is in place and the extensometer attached, the testing machine shall be operated so as to increase the load on the specimen at a uniform rate. The observer shall watch the elongation of the specimen as shown by the extensometer and shall note, for this determination, the load at which the rate of elongation shows a sudden increase. The extensometer may then be removed from the specimen and the test continued to determine the tensile strength.

Method II (proposed by the late J. B. Johnson) is a somewhat more delicate method for locating the elastic limit than is Method I. In Method II, the elastic limit shall be taken as that stress at which the rate of deformation is 50 per cent greater than the initial rate of deformation. A stress-strain diagram is necessary for determining the elastic limit by Method II. Figure 25 illustrates the use of Method II. The initial rate of deformation is given by the ratio $mn : Om$. $nq = 0.5 mn$, and the slope of Oq represents a rate of deformation 50 per cent greater than the initial rate. $O'q'$ is drawn parallel to Oq and tangent to the stress-strain diagram. The point of tangency J locates the elastic limit. In using Method II the same precautions should be observed in attaching the strainometer as for the determination of the elastic limit by Method I. Method II, if used for tension tests of metals, gives lower values for the elastic limit than does Method I. It is recommended that in using Method II for tension tests the strainometer be of such sensitiveness that it will indicate a change of strain of 0.0001 inch per inch of gage length (0.0001 mm per millimeter of gage length) and that a corresponding degree of sensitiveness be required for strainometers used for compression tests, for flexure tests, and for torsion tests.

When it is desired to determine the elastic limit with a high degree of precision, it is suggested that the experimenter devise his own procedure, and in reporting his results describe the procedure in detail, including a statement of the limits of sensitiveness of the apparatus used and of the procedure used in plotting the stress-strain diagram from which the determination of elastic limit is made. It is to be remembered that the accurate determination of the elastic

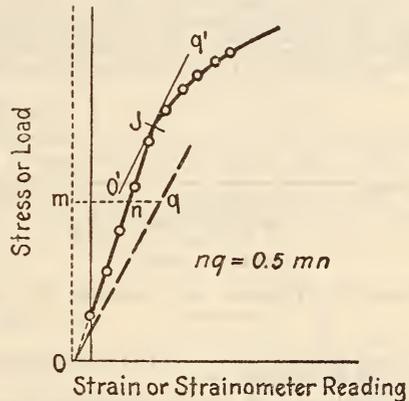

FIGURE 25.—Illustrating Method II for determining elastic limit

limit requires the use of accurate and sensitive instruments and the use of accurate methods of plotting test data.

Yield point.—The stress in a material at which there occurs a marked increase in strain without an increase in stress.

NOTE.—Some metals do not show a clearly defined yield point.

Two methods are in use for determining the yield point: (I) The "drop of the beam" method, and (II) the method by use of dividers. In Method I, load is applied to the specimen at a steady rate of increase and the operator keeps the beam in balance by running out the poise at a steady rate. At the yield point the increase of load stops, but the operator, running out the poise at a steady rate, runs it a trifle beyond the balance position, and the beam of the machine drops for a brief but appreciable interval of time. In a machine fitted with a self-indicating load-measuring device there is a sudden halt of the load-indicating pointer, corresponding to the drop of the beam. The load at the "halt" or the "drop" is recorded, and the corresponding stress is taken as the yield point. This method of determining the yield point requires only one man to conduct a test.

In Method II, an observer with a pair of dividers watches for visible elongation between two section marks on the specimens. When visible stretch is observed, the load at that instant is noted, and the stress corresponding to the load is taken as the yield point. When a strainometer¹⁸ is used in place of dividers a deformation of 0.01 inch over a gage length of 2 inches shall be regarded as indicating the yield point.

¹⁸ The determination of yield point with a strainometer is sometimes made in tests on nonferrous metals.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD DEFINITIONS OF TERMS RELATING TO METALLOGRAPHY, DESIGNATION E7-27, 1927

METALLOGRAPHIC TERMS

Alloy.—A substance, having metallic properties, consisting of two or more metallic elements, or of metallic and nonmetallic elements, which are miscible with each other when molten, and have not separated into distinct layers when solid.

NOTE.—Alloys when solid may be composed of eutectics, eutectoids, solid solutions, chemical compounds, or of aggregates of these components with each other or with pure metals. In the commercial sense, the term "alloy" would also include the case where some separation into distinct layers had occurred.

Alpha brass.—A copper-zinc alloy with a copper content greater than approximately 64 per cent. It is composed of but one type of crystals all of which are of the same composition.

Beta brass.—A copper-zinc alloy with a copper content of approximately 54 per cent, composed of but one type of crystals all of which are of the same composition.

NOTE.—At ordinary temperatures, the normal range of beta brass is from 51 to 55 per cent copper. Quenching from higher temperatures considerably broadens this range. Between 64 and 55 per cent copper, the copper-zinc alloys consist of mixed crystals of alpha and beta, the relative proportion of which depends upon the composition and heat treatment. Alloys of this type can be mechanically worked while hot and are frequently referred to as muntz metal. When rapidly cooled from high temperatures (that is,

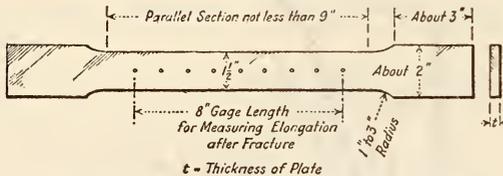

FIGURE 26.—Tension test specimen for plate material

from at or near the melting point) mixed alpha and beta may occur with copper as high as 70 per cent.

Etching reagent.—A reactive substance used to reveal the structure of a metal or alloy through the development of differences in the appearance of different constituent parts or different grains.

NOTE.—This substance is usually a solution of the reagent in water, acid, or alkali, but etching may in some cases be brought out by differential oxidation produced by "heat tinting."

Equi-axed grain.—A grain which has approximately equal dimensions in all directions.

NOTE.—This term is practically restricted to unstrained metals.

Grain.—A term used for an allotrimorphic crystal present in metals and in one-component alloys.

NOTE.—Although a crystal may show division by "twinning," etc., it is regarded as the grain rather than smaller subdivisions. In the case of alloys of more than one component, the crystal which, by its transformation, gave rise to these constituents is taken as the grain when its limits are still discernible; if the limits are not discernible the individual constituents are considered as grains.

Grain size.—This is preferably expressed as the number of grains per unit area of cross section. The average cross-sectional area of the grain may also be given or the average dimensions. Grain size of strained material is expressed by the average number per linear unit in two directions, or by the average number per unit cross-sectional area, together with the ratio of length to breadth (L/B).

NOTE.—By the intercept method for grain count, the number of grains and fractions of grains along a line of known length on two axes at right angles to each other are counted. By the planimetric method for grain count, the number of grains and fractions of grains within a definite area are counted.

Intercept method for grain count.—See note under Grain size.

Macrograph.—A graphic reproduction of any object which has not been magnified more than 10 diameters.

NOTE.—When it is desired to indicate that it is a photographic reproduction, the term "photomacrograph" may be employed.

Magnification.—The ratio of the size of the image to that of the object.

NOTE.—Magnification is generally expressed in diameters, thus $\times 100$ or 100 diameters.

Metal.—Any of the metallic elements, either of very high purity or of ordinary commercial grades.

NOTE.—Brass and many other alloys are metals in the commercial sense, but alloys in the scientific sense.

Metallography.—That branch of science which relates to the constitution and structure, and their relation to the properties, of metals and alloys.

Micrograph.—A graphic reproduction of any object magnified more than 10 diameters.

NOTE.—When it is desired to indicate that it is a photographic reproduction, the term "photomicrograph" may be employed.

Muntz metal.—See note under Beta brass.

Planimetric method for grain count.—See note under Grain size.

AMERICAN SOCIETY FOR TESTING MATERIALS, TENTATIVE METHODS OF TENSION TESTING OF METALLIC MATERIALS, DESIGNATION E8-27T, 1927

TENSION TESTING OF METALLIC MATERIALS

These methods deal with the form and dimensions, the machining, and the testing of tension-test specimens of metallic materials. Such matters as methods of taking samples from which to prepare test specimens are treated in the individual specifications for ferrous metals and for nonferrous metals.

TEST SPECIMENS

1. In recommending the following specimens for use in tension tests it is not intended to exclude entirely the use of other test specimens for special materials or for special forms of material; for example, in tests of tubing and pipe the form of specimen recommended for plate, shape, and flat material (fig. 26) is not generally suitable for use, and a special form of specimen is specified. It is, however, recommended that wherever feasible the specimens here specified be used.

2. Tension-test specimens of wire are of the full-size diameter as drawn, and tension-test specimens of rods of ductile metal are often of the full-size diameter as rolled. Tension-test specimens of pipe and of tubing are frequently of full size as manufactured, in which case the ends should be plugged with metal plugs which do not extend within the gage marks.

3. The tension-test specimen shown in Figure 26 is recommended for plate, shape, and flat material having a thickness of one-fourth inch or over.¹⁹

NOTE.—When it is desired to use a specimen with a gage length of less than 8 inches, the general proportions of Figure 26 should be followed. Specimens with a gage length of 2 inches are occasionally used. When it is not convenient to machine specimens to the standard shape shown in Figure 26, specimens may be used with edges machined parallel for the entire length of the specimen. If such specimens are machined with a tool cutting across the edges of the specimen it is important that the transverse tool marks be removed before the specimen is tested.

For thick plate material, it is usually preferable to use a machined specimen rather than to use a specimen the full thickness of the plate.

¹⁹ Attention is called to the fact that two types of specimen are applicable for material one-fourth inch in thickness, the plate specimen shown in fig. 26 and the thin sheet specimen shown in fig. 28.

The thickness of the specimen is that of the material tested.

4. For tension tests of wrought ferrous and non-ferrous metal in the form of plate, sheet, flat wire,²⁰ strip,²⁰ band,²⁰ and hoop²⁰ without respect to width,²⁰ length, grade, or method of manufacture, and having a thickness of from 0.01 to 0.250 inch, the test specimen described in sections 5 and 6 is recommended.

NOTE.—This specimen may also be used in tests of material cut from tubing.

5. The specimen blank shall be cut from the material to be tested, having its length in such direction relative to the material as may be specified.

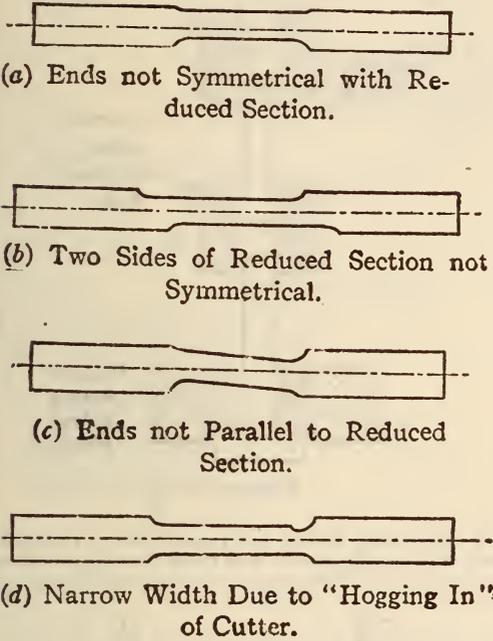

FIGURE 27.—Common errors in preparation of plate or sheet metal test specimens

The specimen blank shall conform to the dimensions shown in the following table:

Method of cutting long edges of blank	Nominal thickness of material (in inches)	Minimum width of blank
Sheared	Up to 1/8, inclusive	3/4
Sawed	Over 1/8 to 1/4, inclusive	1
	Up to 1/4, inclusive	3/4

¹ Or otherwise machined without severely straining the metal.

Blanks cut with a torch shall not be used unless all metal affected by such cutting is removed by machining.

6. Figure 28 shows the form of the finished specimen recommended for thin sheet metals. The reduced section of the specimen shall be machined in such a manner as to avoid leaving severe machining strains in the material. It is essential that the

²⁰ It is to be noted that the recommended specimen can not be used for flat wire, strip, band, or hoop material whose width is less than the end width of the specimen itself.

reduced section and the ends of the specimen be symmetrical with respect to the longitudinal axis of the specimen.²¹

In Figure 28, the 2-inch gage length should be laid off with a tolerance in length of ± 0.005 inch.

7. The tension-test specimen is identical with Figure 129 in A. S. T. M. standard specifications for steel (see 605.0, p. 247). The gage length for measuring elongation after fracture is 2 inches.

8. When it is necessary to cut specimens from material (other than plate, shape, and flat material) which is of such size that the standard test specimen

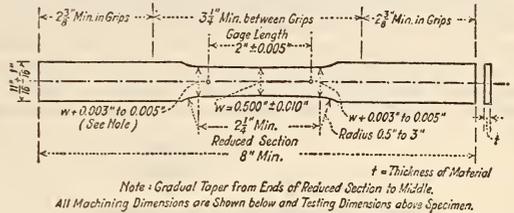

FIGURE 28.—Standard tension test specimen for thin sheet metals

referred to in the preceding paragraph can not be used, it is recommended that a specimen with dimensions proportional to those shown in Figure 129 be used, and that the specimen be made as large as feasible. In any such small-size specimen it is especially important that the gage length for measuring elongation be four times the diameter of the specimen.

9. In all tension tests of metals the actual dimensions of cross section of the test specimens shall be measured with a micrometer reading to 1/200 of the dimension measured, and the stresses shall be computed on the basis of the measured cross section; it should never be assumed that the dimensions of the

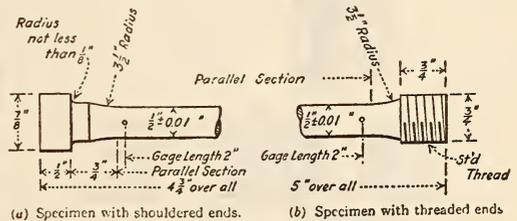

FIGURE 29

measured cross section are identical with the nominal dimensions.

NOTE.—It will be noted that the tolerance for diameter of specimens shown as Figure 129 in standard specifications for steel (see 605.0, p. 247) permits the use of specimens 0.505 inch in diameter.

10. The shape of the ends of the specimen shown in Figure 129 are not specified above. For specimens of brittle metal it is desirable that the diameter of the specimen be changed gradually along its length from the minimum section at the gage length to the diameter at the ends. Figure 29 shows two forms of end of specimen which have given satisfactory results in tests of brittle metals.

11. Specimens shall be finished so that the surfaces are smooth and free from nicks and tool marks. All ragged edges shall be smoothed.

²¹ For all specimens for flat metallic materials, both for thin sheet and for thick plate, it is important so to machine the specimen as to avoid the conditions shown in fig. 27.

GRIPPING DEVICES FOR TENSION-TEST SPECIMENS

12. For long bars of ductile metal and for the flat plate test specimen shown in Figure 26, wedge grips, bearing directly on the end of the test specimen, generally furnished a satisfactory means of gripping the specimens.

13. For short specimens and for specimens of brittle material, wedge grips are not a satisfactory means of holding test specimens; it is necessary to use machined specimens and to use special means for insuring that the specimen, when under load, shall be as nearly as possible in pure axial tension. Figure 30 shows a device for gripping tension specimens with threaded ends and Figure 31 shows a device for gripping specimens with shouldered ends. Both these gripping devices are attached to the heads of the testing machine through spherical-seated bearings. The distance between spherical

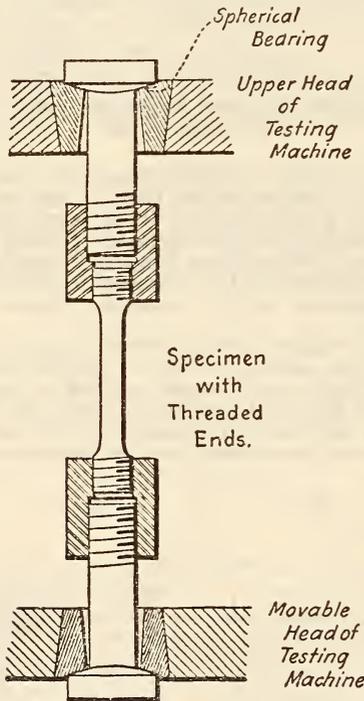

FIGURE 30

bearings should be as great as is feasible. For brittle materials, even the spherical-seated bearings shown in Figures 30 and 31 are not always effective in avoiding bending stress on the specimen. The gripping device shown in Figure 32 has proved satisfactory for testing such specimens, and is an excellent gripping device for any machined tension-test specimen.

14. For specimens cut from thin plate material and from sheet material, ordinary wedge grips are liable to cut the specimens near the edges, giving a tearing stress rather than an axial tension. The self-adjusting grips shown in Figure 33 have proved satisfactory for tests of thin sheet copper and aluminum.

15. For tests of specimens of wire, ordinary wedge grips are liable to cut the wire at the edges of the grips. This cutting has been found to be largely eliminated by the use of grips of the form shown in Figure 34.

16. In making tension tests, care shall be taken to see that the axis of the test specimen is located in the center line of the heads of the testing machine

and that the liners used behind wedge grips are of proper thickness. From time to time the openings in the heads of the testing machine shall be lined up

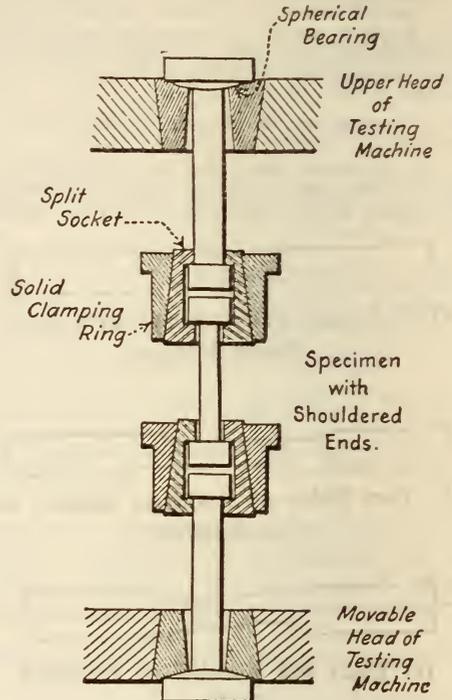

FIGURE 31

and the heads tested for parallelism. Deviations from correct alignment and from parallelism should not exceed 0.01-inch for any position of the movable

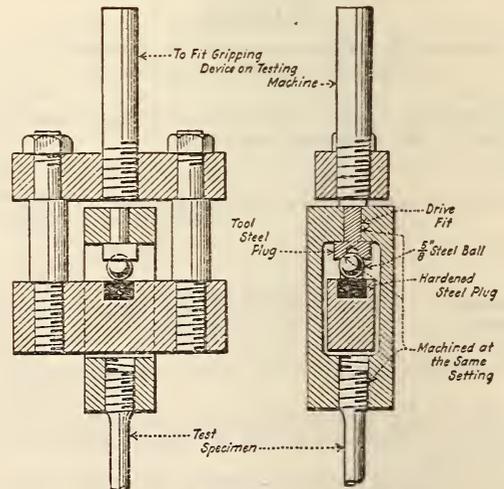

FIGURE 32

The gripping device is shown as used with threaded end specimens. A similar device fitted with split sockets would be used with shouldered specimens

head within the range of movement during test. The heads of the machine should be free from side-wise motion that is visible to the unaided eye as the machine is run at its fastest speed.

SPEED OF OPERATION OF TESTING MACHINE

17. The pulling speed has a marked influence on the tensile properties shown by materials tested, an increase in speed increasing the values found for yield point and tensile strength. In testing specimens of metallic materials in gage lengths of 2 and 8 inches, the speed of the machine, by which is meant the speed of the crosshead when the machine

is capable of developing without a permanent deformation remaining upon complete release of the stress.

NOTE.—The determination of the elastic limit as thus defined would logically involve the application and release of a succession of increasing loads on a test specimen until there was observed deformation after release of a load. This procedure is very slow and since for many materials experience does not indicate any appreciable difference between the elastic limit and the limit of proportionality of stress to strain (sometimes called the proportional limit), the determination of the stress at the limit of proportionality of stress to strain is regarded as an accurate determination of the elastic limit.

It is obvious that the values obtained in tests for determining the elastic limit will depend on the delicacy of methods and instruments used. It becomes necessary, therefore, that in any test the method used in obtaining the elastic limit be clearly stated. The following methods are in common use for determining a value designated as the elastic limit:

(Method I, Method II, and diagram, and methods of high precision for determining elastic limit are the same as A. S. T. M. E6-30T, given above. This is also true of Method I and Method II for determining the yield point.)

21. Some metals do not have a well-defined yield point.²³

(Definition of tensile strength is the same as in A. S. T. M. E6-30, given above.)

22. The conditions that must be prescribed in a tension test of metallic materials are the form of specimen, the method of gripping the specimen, and the rate of application of load. These are covered in foregoing sections. No further detailed discussion of methods of determining tensile strength is necessary, as there is involved merely the observing

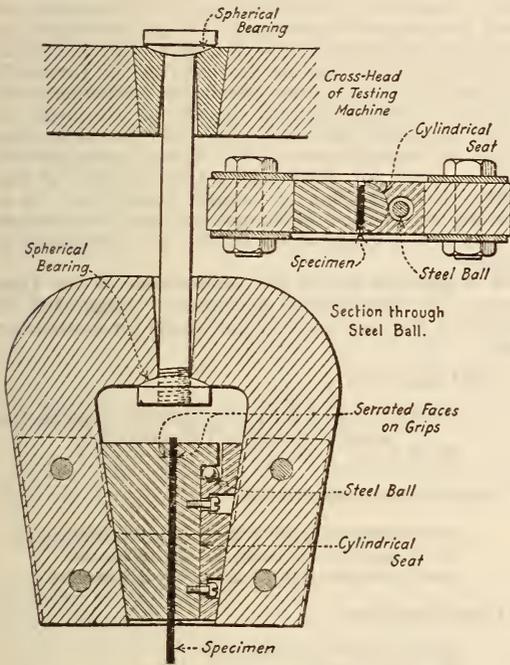

FIGURE 33

is running idle, shall conform to the following requirements:

The speed of head of the testing machine shall be such that the load can be accurately weighed, but in no case shall the speed be greater than the values given in the following table, which values represent the extreme of good laboratory practice for steel:²²

Specified minimum tensile strength of material (in pounds per square inch)	Gage length	Maximum cross-head speed	
		Yield point	Tensile strength
80,000 or under	2	0.50	2.0
	8	2.00	6.0
	2	0.25	1.0
Over 80,000	8	0.50	2.0

18. In determining the elastic limit in accordance with Method I, section 20 (see A. S. T. M. E6-30T, above) the crosshead speed for the 2-inch gage length shall not exceed 0.125 inch per minute.

19. In determining the elastic limit by Method II, section 20 (see A. S. T. M. E6-30T, above) the crosshead speed shall not exceed 0.025 inch per inch of gage length per minute.

DETERMINATION OF ELASTIC LIMIT, YIELD POINT, AND TENSILE STRENGTH

20. The term "elastic limit" is defined as follows: *Elastic limit*.—The greatest stress which a material

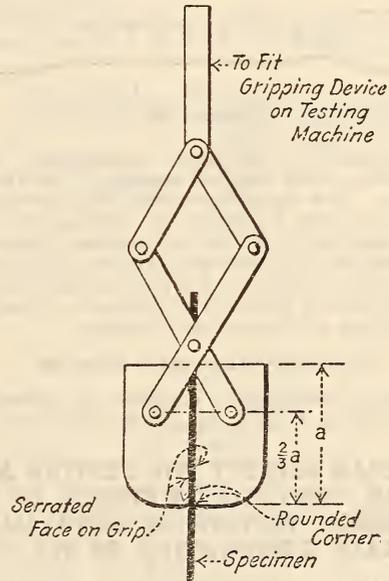

FIGURE 34

and the recording of the maximum load carried by the specimen during the test.

THE MEASUREMENT, AFTER FRACTURE, OF THE ELONGATION AND THE REDUCTION OF CROSS SECTION OF TENSION-TEST SPECIMENS

23. The measurement of the elongation after fracture of tension-test specimens can be made with sufficient accuracy by means of a pair of dividers and a scale. The elongation should not be reported for any tension-test specimen which breaks outside the middle third of the gage length.

²² The speeds given here are probably too high for satisfactory use in testing nonferrous metals.

²³ The determination of yield point with a strainometer is sometimes made in tests on nonferrous metals.

NOTE.—If only a few specimens are furnished for testing, it is recommended that in marking the gage length for measuring elongation after fracture it be divided into eight parts, and that if a specimen breaks inside the gage length but outside the middle third of the gage length the requirement in the foregoing paragraph be waived, and the elongation be measured and reported as follows:

1. If the specimen break in the middle half of the gage length (between *C* and *G*) (figs. 35 (a) and (b)) the elongation is measured directly over the stretched gage length (fig. 35 (b)).

2. If the specimen break between *A* and *C* (or between *G* and *I*), but nearer *B* than *A* (or nearer *H* than *I*), as shown in Figure 35 (c) the elongation from *A* to *C* (or from *G* to *I*) is measured, and to this is added twice the measured elongation from *C* to *F* (or from *D* to *G*).

3. If the specimen break within one-half a division of an end-gage mark (see fig. 35 (d)) the elongation from *A* to *E* (or from *E* to *I*) is measured and multiplied by 2.

The above method can be applied to specimens with any gage length, and to turned specimens as well as flat specimens.

This method is not applicable to brass specimens.

24. The measurement of reduction of the dimensions of the cross section of a tension-test specimen

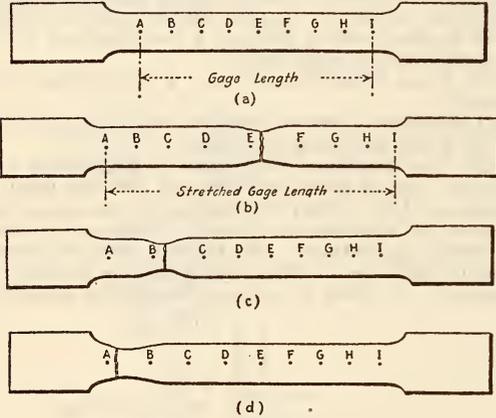

FIGURE 35

may be made by the direct measurement with a micrometer of the smallest section of the fractured specimen. For round specimens this measurement can usually best be made by holding the broken pieces together in a vise or between centers and then measuring the average diameter of the smallest cross section by means of a micrometer fitted with points so shaped that they will come in contact with the specimen at its smallest diameter.

PLOTTING STRESS-STRAIN DIAGRAMS

(Plotting stress-strain diagrams is substantially the same as in A. S. T. M. E6-30, given above.)

AMERICAN SOCIETY FOR TESTING MATERIALS, TENTATIVE METHODS OF COMPRESSION TESTING OF METALLIC MATERIALS, DESIGNATION E9-27T, 1927

COMPRESSION TESTING OF METALLIC MATERIALS

These methods deal with the form and dimensions, the machining, and the testing of compression-test specimens of metallic materials. Such matters as methods of taking samples from which to prepare test specimens are treated in the individual specifications for ferrous metals and for nonferrous metals.

TEST SPECIMENS

1. In recommending the following specimens for use in compression tests it is not intended to exclude entirely the use of other test specimens for special materials or for special forms of material. It is, however, recommended that wherever it is feasible the specimens here recommended be used.

2. It is recommended that standard compression specimens be in the form of circular cylinders. The ends of a specimen should be plane, as nearly as can be determined by the use of a straight-edge and the unaided eye. In most cases this requirement necessitates the turning or the grinding of the ends of the specimen.

3. There are recognized three classes of compression specimens for metallic materials, designated as short specimens, medium-length specimens, and long specimens, respectively. Short specimens are used for compression tests of such metals as bearing metals, which in service are used in the form of a thin plate or shell to carry load perpendicular to the surface. Medium-length specimens are used for determining the general compressive strength properties of metallic materials. Long specimens are best adapted for determining the modulus of elasticity in compression of metallic materials. In reporting the results of a compression test, it is important that the dimensions of the test specimen be given.

4. Figure 36 shows the proportions of the three classes of compression specimens. Suggested dimensions for compression specimens for general use are:

Short specimens:

$$d = 1\frac{1}{8} \text{ inches} \pm 0.01 \text{ inch (area of cross section is approximately 1 square inch)}$$

$$h = 1 \text{ inch;}$$

Medium-length specimens:

$$d = 0.798 \text{ inch} \pm 0.01 \text{ inch, } h = 2\frac{1}{2} \text{ inches, or}$$

$$d = 1 \text{ inch} \pm 0.01 \text{ inch, } h = 3 \text{ inches, or}$$

$$d = 1\frac{1}{8} \text{ inches} \pm 0.01 \text{ inch, } h = 3\frac{3}{8} \text{ inches.}$$

Long specimens:

$$d = 1\frac{1}{4} \text{ inches} \pm 0.01 \text{ inch}$$

$$h = 12\frac{1}{2} \text{ inches.}$$

5. In all compression tests of metallic materials, the actual dimensions of cross section of the test

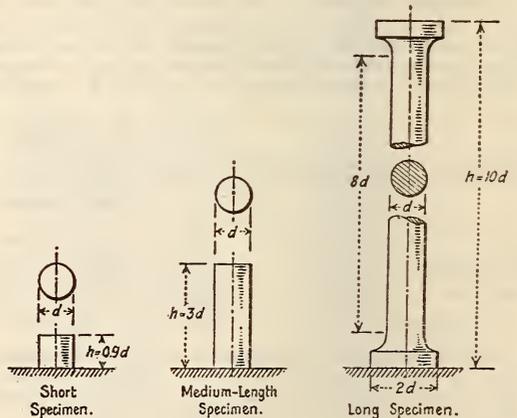

FIGURE 36

specimens shall be measured with a micrometer reading to $\frac{1}{200}$ of the dimension measured, and stresses shall be computed on the basis of the measured cross section. It should never be assumed that the dimensions of the cross section of the specimen are identical with the nominal dimensions.

6. Specimens shall be finished so that the surfaces are smooth and free from nicks and tool marks. All ragged edges shall be smoothed.

BEARING BLOCKS FOR COMPRESSION-TEST SPECIMENS

7. Both ends of a compression-test specimen shall bear on a carefully machined plane surface. The bearing blocks either shall be made of hardened steel or shall be faced with hardened steel.

8. One end of a compression-test specimen shall bear on a spherical-seated compression block.²⁴ Figure 37 shows a satisfactory arrangement of compression specimens and bearing blocks. It is desirable that the spherical-seated bearing block be at the upper end of the test specimen (for specimens tested with the axis vertical). It is important that the center of the spherical surface of the spherical-seated bearing block be in the flat face which bears on the specimen, otherwise lack of parallelism between faces of the specimen sets up a bending moment in the specimen.²⁵

9. It should be borne in mind that the object of a spherical-seated bearing block is to give the specimen as even a distribution of initial load as is possible. Owing to friction, the spherical-seated bearing can not be relied on to adjust itself to bending action which may occur during the test.

10. In making compression tests, care should be taken to preserve the alignment of the heads of the testing machine, and to center the specimen in the testing machine. From time to time the heads of the testing machine shall be tested for parallelism. Deviations from parallelism should not exceed 0.01 inch. The movable head of the machine should be free from sidewise motion that is visible to the unaided eye as the machine is run at its fastest speed.

SPEED OF OPERATION OF TESTING MACHINE

11. In making compression tests of specimens of metallic materials the speed of the machine, by which is meant the speed of the crosshead when the machine is running idle, shall be such that the load can be accurately weighed, but in no case, shall the speed be greater than the values given in the following table:

Length of specimen (in inches)	Maximum crosshead speed (in inches per minute)
1.00	0.05
3.00 or greater	.10

12. In making tests to determine the elastic limit in compression of metallic materials, the crosshead speed of the testing machine shall in no case exceed the allowable speed of head for the corresponding tension test of the material, as given in sections 18 and 19 of A. S. T. M. E8-27T given above.

THE DETERMINATION OF ELASTIC LIMIT, YIELD POINT, AND COMPRESSIVE STRENGTH

13. (a) The term "elastic limit" in compression is defined the same as in tension, as follows:

Elastic limit.—The greatest stress which a material is capable of developing without a permanent deformation remaining upon complete release of the stress.

²⁴ The device shown in Fig. 38 has been successfully used in compression tests of metallic specimens whose ends were machined with extreme care. It will be noted that this device does not involve a spherical seated compression block bearing directly on the test specimen. This device or one similar has been successfully used in the British National Physical Laboratory and in the laboratories of the U. S. Air Service at McCook Field, Dayton, Ohio.

²⁵ See Mont Schuyler, "Spherical Bearings," *Proc. Am. Soc. Testing Mats.*, Vol. XIII, p. 1004, 1913.

(b) The same general methods for determining elastic limit as given above in A. S. T. M. E8-27T (including the references in E8-27T to A. S. T. M. E6-30T) shall be used. For compression tests,

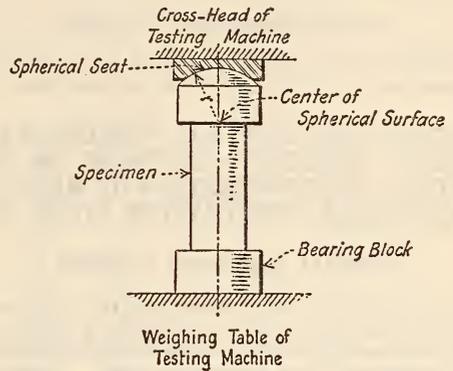

FIGURE 37

Method II or a still more precise method seems generally suitable.

14. (a) The term "yield point" in compression is defined the same as in tension, as follows:

Yield point.—The stress in a material at which there occurs a marked increase in strain without an increase in stress.

(b) The same methods for determining yield point as given above in A. S. T. M. E8-27T (including the

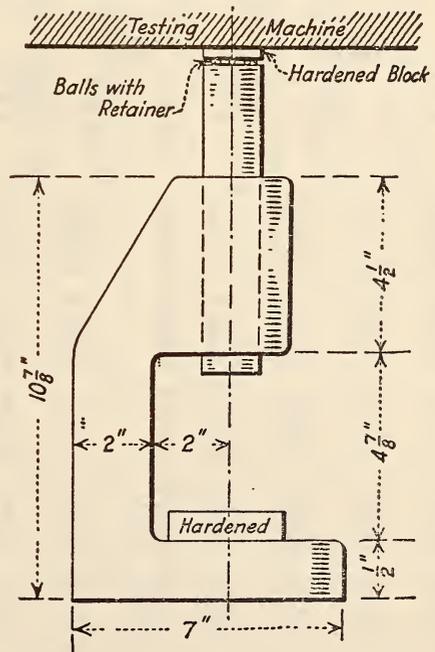

FIGURE 38

references in E8-27T to A. S. T. M. E6-30T) shall be used. The method by the use of dividers or by the use of a strainometer seems generally suitable for compression testing.

15. The term "compressive strength" is defined as follows:

Compressive strength.—The maximum compressive stress which a material is capable of developing.

NOTE.—In the case of a material which fails in compression by a shattering fracture the compressive strength has a very definite value. In the case of materials which do not fail in compression by a shattering fracture the value obtained for compressive strength is an arbitrary value depending upon the degree of distortion which is regarded as indicating complete failure of the metal.

PLOTTING STRESS-STRAIN DIAGRAMS

(Plotting stress-strain diagrams is substantially the same as in A. S. T. M. E6-30, given above.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD METHODS OF BRINELL HARDNESS TESTING OF METALLIC MATERIALS, DESIGNATION E10-27, 1927

BRINELL HARDNESS TESTING

The Brinell test for determining the hardness of metallic materials consists in applying a known load to the surface of the material to be tested through a hardened steel ball of known diameter. The diameter (or depth) of the resulting permanent impression in the metal is measured. The Brinell hardness number is taken as the quotient of the applied load divided by the area of the surface of the impression, which is assumed to be spherical. If *P* is the applied load (measured in kilograms), *D* is the diam-

eter of the steel ball (measured in millimeters), and *d* is the diameter of the impression (measured in millimeters), then:

$$B. H. N. = \frac{P}{\pi D \left(D - \sqrt{D^2 - d^2} \right)}$$

in which *B. H. N.* is the Brinell hardness number in kilograms per square millimeter.

If the steel ball were not deformed under the applied load and if the impression were truly spherical, then the above formula would be a general one, and any combination of applied load and size of ball could be used. As the impression is not quite a spherical surface (since there must always be some deformation of the steel ball and some recovery of form of the metal in the impression), for a standard Brinell test the size and characteristics of the ball and the magnitude of the applied load must be standardized. (A standard ball 10 mm in diameter and a load of 3,000 kg for hard metals and 500 kg for soft metals is standard practice. See secs. 3 and 6.)

In Table 1 is given the Brinell hardness number corresponding to various diameters of impression for both 500 and 3,000 kg load, making it unnecessary to compute for each test the value of the Brinell hardness number by the above formula.

TABLE 1.—Brinell hardness numbers

[Steel ball, 10 mm in diameter, pressures of 500 and 3,000 kg. Prepared by the Engineering Mechanics Section, Bureau of Standards]

The values given in this table for hardness numbers are merely solutions of the equation given in the introductory paragraphs. They do not imply that Brinell tests are feasible on materials of a hardness indicated by the highest values in the table

APPARATUS

1. The divisions on the micrometer scale of the microscope or other measuring device used for the measurement of the diameter of impression shall be such as to permit the direct measuring of the

diameter to 0.1 mm and the estimation of the diameter to 0.01 mm.

2. (a) The balls used in Brinell hardness testing shall be of hardened steel or other equally hard material.

(b) A ball to be suitable for use shall not show a permanent change in diameter greater than 0.0025

mm (0.0001 inch) when pressed with a force of 3,000 kg against a piece of steel having a Brinell hardness number of 500 or greater.²⁶

(c) If a ball is used in a test of a specimen which shows a Brinell hardness number greater than 500, the ball shall be remeasured after the test. Should the ball show a permanent change in diameter greater than that permitted in paragraph (b), the ball shall be unsuitable for further use in a standard test.²⁶

3. The standard ball for Brinell hardness testing shall be 10 mm (0.3937 inch) in diameter with a deviation from this value of not more than 0.01 mm (0.0004 inch) in any diameter, but the diameter of any ball measured at various points shall be constant within a tolerance of ± 0.0025 mm (0.0001 inch).

For testing very small specimens or very thin specimens it is sometimes necessary to make Brinell hardness tests with a ball less than 10 mm in diameter. For such tests (which are not to be regarded as standard Brinell tests) the relation between applied load, P , measured in kilograms, and diameter of ball, D , measured in millimeters, should be:

$$P = 3,000 \frac{D^2}{10^2} = 30 D^2 \text{ for iron and steel;}$$

and

$$P = 500 \frac{D^2}{10^2} = 5 D^2 \text{ for brass, bronze, and soft metals in general.}$$

For extremely soft metals the relation $P = D^2$ may be used.

Balls differing in size from the standard 10 mm ball shall conform to the requirements for the material and the tolerance in size of diameter as specified for the standard ball.

TEST SPECIMENS

Specimens used in Brinell hardness testing vary greatly in form since it is frequently desirable to make the impression upon a part to be used in the finished product rather than upon a sample test specimen.

4. The thickness of the piece tested shall be such that no bulge or other marking showing the effect of the load appears on the side of the piece opposite the impression. In any event the thickness of the specimen shall be at least ten times the depth of impression.

5. The surface on which the impression is to be made shall be filed, ground, machined, or polished with emery paper so that the edge of the impression shall be clearly enough defined to permit of the measurement of the diameter within 0.01 mm (0.0004 inch).

APPLICATION AND MAGNITUDE OF LOAD

6. The load in the standard Brinell test shall be 3,000 kg for iron and steel and 500 kg for brass, bronze, and soft metals generally.

NOTE.—For extremely soft metals a load of 100 kg is sometimes used. If for any reason it is necessary to use loads differing from those specified above, the load used should be specifically stated in the test report, conveniently as a subscript of the hardness numeral.

7. (a) The load shall be applied steadily to the specimen without jerk.

(b) The load shall be applied for at least 10 seconds in the case of iron and steel and for at least 30 seconds in the case of other metals.²⁷

(c) The center line of the applied load shall be far enough from any edge of the specimen so that when a straight-edge is applied to the edge after the load has been applied, the eye can detect no bulge in the edge due to the load and the resulting impression.

²⁶ In testing softer metals, it is not, of course, necessary to have balls of this extreme hardness. However, a ball to be suitable for use should withstand pressure against the hardest material to be tested without showing a permanent change in diameter greater than 0.0025 mm.

MEASUREMENT OF IMPRESSION

8. In the standard Brinell hardness test the diameter of the impression shall be measured.

9. When a micrometer microscope is used to measure the diameter of the impression the sharpness of definition of the edge of the impression can be increased by the use of a movable lamp for illuminating the specimen, placing the lamp so that the contrast of light and shade will bring first one edge of the impression, then the other into sharp definition. In testing very hard material, the sharpness of definition of the impression can be somewhat increased by the use of a ball lightly etched with nitric acid, or by the use of some pigment, such as Prussian blue, on the ball. In testing material in which there is considerable recovery of shape, the material may first be coated with a dull-black pigment, such as drawing ink or a mixture of graphite and alcohol. The edge of the impression is rendered clear on a surface so coated.

BRINELL HARDNESS TESTS IN WHICH DEPTH OF IMPRESSION IS MEASURED IN PLACE OF DIAMETER

When it is necessary to make Brinell hardness tests very rapidly, as is sometimes the case when the Brinell test is used as a control test for the output of a heat-treating furnace, the depth of impression under load or after the release of load can be measured more expeditiously than the diameter of impression. The depth of impression is usually determined from the relative motion of the plunger carrying the ball and the specimen. This method of determining Brinell hardness is not to be regarded as a standard method, and when requirements of speed necessitate its use the Brinell hardness number should not be determined from the geometrical relation of depth of impression to diameter, based on the assumption that the impression has a spherical surface. In such tests the relation between the Brinell hardness number and depth of impression may be determined with a fair degree of accuracy from tests on specimens of material of different degrees of hardness, several impressions being made on each specimen, and the depth under load, or the depth on release of load, and the diameter of impression after release of load being measured for each impression. By the use of a diagram or by interpolation, a table giving the Brinell hardness number for a given depth of impression can be prepared.

CALIBRATION OF BRINELL HARDNESS-TESTING APPARATUS

10. A load-measuring device which is in common use for Brinell hardness-testing machines involves the measurement of fluid pressure on a piston of known diameter working in a cylinder with so perfect a fit that packing is not necessary. To this piston is attached the ball. Other load-measuring devices use combinations of weights and levers. The use of dead weights acting on a small piston is to be preferred to the ordinary Bourdon gage for measuring the intensity of fluid pressure.

11. The load-measuring device of a Brinell hardness-testing machine may be calibrated by the use of dead weights, or by the use of dead weights and proving levers, or by an elastic calibration device or spring, in the manner described in the standard

²⁷ It was suggested in discussion that for magnesium and magnesium alloys the minimum time of application be two minutes. It was also suggested that for any given soft metal a definite time for holding the load be specified rather than a minimum time. See discussion of the Report of Committee E-1, Proc. Am. Soc. Testing Mats. vol. 24, Pt. I, pp. 729 and 730, 1924.

methods of verification of testing machines (serial designation E4) of the American Society for Testing Materials.²⁸ (See above.)

12. The load-measuring device of a Brinell hardness-testing machine may be calibrated by making a series of impressions on specimens of different degrees of hardness, measuring the diameters of the impressions, making a second series of impressions by the use of any standardized testing machine and standard steel ball, and, using the same measuring device as for the first series of impressions, measuring the diameters of this second series of impressions. The error of the machine under calibration can be determined by the relative average values of the hardness numbers determined by its use and by the use of the standardized testing machine.

13. When the above companion-impression method of calibrating a Brinell hardness-testing machine is used, it is recommended that the specimens used be approximately 1 by 1 by 12 inches in size and that specimens with as wide a range of hardness as is feasible be used. It is recommended that impressions made by the machine under calibration be spaced about 2.5 inches apart along the specimen, and that the impressions made by the standardized testing machine be spaced alternately along the length of the specimen with the impressions made by the machine under calibration.

14. If any determination of hardness, either for the machine under calibration or for the standard machine, differ by more than 2 per cent from the mean of the four determinations made with that machine, it is recommended that such determination be discarded. If two determinations differ more than 2 per cent from the mean, the whole series should be discarded.

15. A Brinell hardness-testing machine is acceptable for use over a loading range within which its load-measuring device is correct within 3 per cent.

16. The micrometer microscope or other device for measuring diameter of impression may be calibrated by using it to measure lengths on a standard steel or glass scale. The eyepiece of a micrometer microscope should be adjusted so that throughout the range covered the error of reading does not exceed 0.01 mm.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD DEFINITIONS OF TERMS RELATING TO SPECIFIC GRAVITY, DESIGNATION E12-27, 1927

SPECIFIC GRAVITY TERMS

1. *Absolute specific gravity (of solids and liquids).*—The ratio of the weight referred to vacuum of a given volume of the material at a stated temperature to the weight referred to vacuum of an equal volume of gas-free distilled water²⁹ at a stated temperature. It shall be stated thus:

(a) When the temperatures of the material and of the water are the same:

$$\text{Absolute specific gravity } x^{\circ} \text{ C., } \dots\dots\dots,$$

where x is the temperature of the material and the water.

(b) When the temperatures of the material and of the water are not the same:

$$\text{Absolute specific gravity } \frac{x^{\circ} \text{ C.}}{y^{\circ} \text{ C.}}, \dots\dots\dots,$$

where x is the temperature of the material and y the temperature of the water.

NOTE.—In the interest of standardization and simplification, the first form of statement of specific gravity (a) should be employed wherever practicable.

2. *Specific gravity (of solids and liquids).*—The ratio of the weight in air of a given volume of the material at a stated temperature to the weight in air of an equal volume of distilled water at a stated temperature. It shall be stated thus:

(a) When the temperatures of the material and of the water are the same:

$$\text{Specific gravity } x^{\circ} \text{ C., } \dots\dots\dots,$$

where x is the temperature of the material and the water.

(b) When the temperatures of the material and of the water are not the same:

$$\text{Specific gravity } x^{\circ}/y^{\circ} \text{ C., } \dots\dots\dots,$$

where x is the temperature of the material and y is the temperature of the water.

NOTE.—In the interest of standardization and simplification, the first form of statement of specific gravity (a) should be employed wherever practicable.

3. *Apparent specific gravity (of solids).*—The ratio of the weight in air of a given volume of the impermeable portion of a permeable material (that is, the solid matter including its impermeable pores or voids) at a stated temperature to the weight in air of an equal volume of distilled water at a stated temperature. It shall be stated thus:

(a) When the temperatures of the material and of the water are the same:

$$\text{Apparent specific gravity } x^{\circ}/x^{\circ} \text{ C., } \dots\dots\dots,$$

where x is the temperature of the material and the water.

(b) When the temperatures of the material and of the water are not the same:

$$\text{Apparent specific gravity } x^{\circ}/y^{\circ} \text{ C., } \dots\dots\dots,$$

where x is the temperature of the material and y is the temperature of the water.

NOTE 1.—In scientific circles, specific gravity and density determinations made in air (that is, uncorrected to vacuum) are frequently distinguished by the adjective apparent. Thus, the specific gravity defined by definition No. 2 would be designated as apparent specific gravity and that defined by definition No. 1 as specific gravity. But in industry, the terminology is more generally in accordance with that given in these definitions.

NOTE 2.—The terms permeable and impermeable can not be rigidly defined for general application. The exact meaning in a particular application is the conventional one inferred by the procedure specified for determining the specific gravity of the material in question.

NOTE 3.—In the interest of standardization and simplification, the first form of statement of specific gravity (a) should be employed wherever practicable.

4. *Bulk specific gravity (of solids).*—The ratio of the weight in air of a given volume of a permeable material (including both permeable and impermeable voids normal to the material) at a stated temperature to the weight in air of an equal volume of distilled water at a stated temperature. It shall be stated thus:

(a) When the temperatures of the material and of the water are the same:

$$\text{Bulk specific gravity } x^{\circ} \text{ C., } \dots\dots\dots,$$

where x is the temperature of the material and the water.

(b) When the temperatures of the material and of the water are not the same:

$$\text{Bulk specific gravity } \frac{x^{\circ} \text{ C.}}{y^{\circ} \text{ C.}}, \dots\dots\dots,$$

where x is the temperature of the material and y is the temperature of the water.

NOTE 1.—See note 2 under Apparent specific gravity.

NOTE 2.—In the interest of standardization and simplification, the first form of statement of specific gravity (a) should be employed wherever practicable.

AMERICAN SOCIETY FOR TESTING MATERIALS, TENTATIVE RECOMMENDED PRACTICE FOR THERMAL ANALYSIS OF STEEL, DESIGNATION E14-30T, 1930

THERMAL ANALYSIS OF STEEL

1. Thermal analysis is the process of determining the temperature at which physical changes accompanied by an abrupt change in heat content occur in metals by observing the aberrations which the heat content changes impose on the rate of temperature change of a specimen, situated in an environment whose temperature is changing at a constant rate. The essential units required for thermal analysis are: (a) A furnace which may be heated and cooled at a substantially constant rate, (b) a temperature measuring device, and (c) a means for measuring time. The specific apparatus chosen depends largely on which of the several possible methods of thermal analysis is adopted with the exception that electrical resistance furnaces and potentiometric measurement of thermocouple electromotive force are in general use for the type of furnace and a temperature measuring device, respectively, and are recommended when applicable.

METHODS

2. (a) The transformation data concerning steels usually required can be obtained with either the inverse-rate or differential method of thermal analysis. With the inverse-rate method, the time intervals required for the temperature to change through successive equal increments are observed and plotted against the mean temperatures of the temperature increments. With the differential method, the temperature difference between the specimen and a neutral body, that is, one undergoing no abrupt change in heat content over the temperature range concerned, is plotted against the temperature of observation. With both methods it is permissible and much more convenient to plot electromotive force readings of a thermocouple instead of actual temperatures.

(b) Both of the methods are recommended for steel. Choice between them depends on the purposes for which they are employed. The inverse-rate method using the Rosenhain type of furnace is superior for the detection of transformation at low temperatures (100° to 500° C.) and for the study of effects of rate of temperature change. The differential method has the advantage of being easily adaptable to autographic recording and high sensitivity is possible with it. A machined-test specimen is required in the differential method whereas with the inverse-rate method small test specimens of irregular shape may be used.

3. *Inverse-rate method.*—The modified type of Rosenhain furnace is recommended for obtaining inverse-rate thermal curves on steel. Details of construction can be obtained from the literature.

A specimen in the form of a disk about one-eighth inch in thickness and three-eighths inch in diameter mounted with the hot junction of a thermocouple at its center and in firm metallic contact with it is recommended. The axis of the specimen should coincide with that of the tube in which it is mounted.

Time intervals may be measured most conveniently by the double stop-watch method of Merica. For maximum precision, chronograph measurement of time intervals is required. Curves may be plotted autographically by the recording chronograph described by French.

4. *Differential method.*—An electric-resistance furnace having flexible control of the rate of temperature change is recommended. The thermal insula-

tion and heat capacity of the furnace must be reduced to a minimum to achieve this control.

The temperature of the specimen should be measured by a thermocouple, the hot junction of which is embedded in the specimen. For the measurement of temperature differences a differential thermocouple is required. The two lead-in wires should be of the same metal and their hot terminals should be connected by a wire of different composition. One of the hot junctions should be placed in the specimen and the other in the neutral body. The electromotive force generated by temperature difference between specimen and neutral body may be measured by galvanometer deflection. Temperature differences of 0.04° C. should be detectable.

The specimen and neutral body should be thermally and geometrically similar and symmetrically placed in the furnace. The preferred form of specimen is a cylinder. The thermocouple hot junctions need not come in metallic contact with the specimen or neutral body, but should be symmetrically placed with reference to the specimen and neutral body. Time measurements are necessary only to establish rates of temperature change for which purpose a watch or clock with second hand suffices.

PRECAUTIONS

5. The use of a high-vacuum environment (less than 0.01 mm mercury) for the specimen is desirable, but when not feasible it is recommended that precautions be taken to minimize decarbonization and convection currents. Thermocouples may be either of platinum-base or nickel-base alloys, and should be of moderate size (0.020 to 0.040 inch in diameter). The cold junctions should be kept at 0° C.; that is, in melting ice or a suitable cold-junction correction applied.

Thermocouples should be checked frequently to insure their accuracy, particularly nickel-base thermocouples used above 900° C. This may be done either by comparison with standardized couples or by the transformations in standard steel specimens. For the latter purpose the A_2 point of ingot iron is recommended when the inverse-rate method is used, and the A_{C1} point of unalloyed carbon tool steel when the differential method is used. The temperatures of these changes, taken when the rate of temperature change of the specimen is a minimum, may be taken as 768° and 733° C., respectively. The temperature of A_2 is practically independent of rate of temperature change, but that of A_{C1} corresponds to a rate of heating of 0.10° C. per second only.

The interpretation of thermal curves requires recognition of the fact that a peak on an inverse-rate curve does not represent the same stage of progress of the transformation as does one on a differential curve. The time ordinates of an inverse-rate curve are in effect the reciprocals of the slopes of the differential curve at corresponding temperatures and, therefore, the temperature of a minimum rate of change of heat content on a differential curve is that at which the curve has minimum slope with respect to the differential ordinate; that is, where its slope is most nearly perpendicular to the temperature ordinate. It is recommended that the interpretation and comparison of inverse-rate and differential curves be conducted on the basis outlined above.

In referring to temperatures of transformations, it is recommended that the stage of the transformation to which the temperature applies; for example, beginning, maximum, or end, be always stated.

RECORDS

6. It is recommended that the following data be recorded for every thermal curve taken:

(a) Source and composition of steel;

- (b) Method of thermal analysis;
- (c) Size and mounting of specimen;
- (d) Maximum temperature to which specimen is heated and time at that temperature;
- (e) Previous treatment of specimen, including number of times thermal curves have been taken previously on the same specimen;
- (f) The temperature of minimum rate of temperature change of the specimen at recognized and identified inflections, and the direction of temperature change;
- (g) The estimated rate of change of temperature of the furnace at the time of minimum rate of temperature change of the specimen for each inflection observed;
- (h) The temperatures at which the beginnings and ends of inflections can be definitely recognized;
- (i) The maximum and minimum temperatures of decalcescence and recalcescence in case either phenomenon is observed;
- (j) Any departures from the foregoing recommendations.

(Attached to this recommendation is a list of references in which will be found details of construction and operation of apparatus for obtaining thermal curves.)

AMERICAN SOCIETY FOR TESTING MATERIALS, RECOMMENDED PRACTICE FOR RADIOGRAPHIC TESTING OF METAL CASTINGS, DESIGNATION E15-29, 1929

RADIOGRAPHIC TESTING

GENERAL CONSIDERATIONS

On account of their very short wave lengths, X rays penetrate materials opaque to ordinary light. They are absorbed rapidly by heavy elements such as light is absorbed by fog. If X radiation is passed through metal that contains cracks, cavities, sand, or slag inclusions, the radiation that passes through the defects is absorbed to a less extent than that which passes through the adjacent sound metal. A photographic film placed to intercept the emergent beam will show, on development, regions of greater photographic density that may be definite images of the internal defects. Radiographic tests are concerned with the obtaining of such photographic indications of internal defects. They may be extended to the examination of various other hidden details of gross structure.

There are at present two important fields for application of metal radiography. One of these concerns the development of manufacturing technique in the foundry, the other the final inspection of the manufactured product.

In foundry development work pilot castings are examined, defects are studied, and changes made in casting technique to correct the defects. This study leads to a developed technique that may be relied on to produce dependably sound castings, the extent of the elimination of defects depending, to a certain extent, upon the service for which the casting is intended. An important by-product of such application is the education of foundry personnel. Interior defects are present in castings partly because there has been no easy method of detecting their presence and no particular effort has been made to overcome them because of this fact. Such application to manufacturing methods is probably the most economical use of radiographic tests. But on account of the fact that even with the most fully developed technique accidents or mistakes occur, there is still a possibility for defective castings.

For this reason, and also because very few castings are manufactured at present according to a

carefully developed technique, it is important to have a method of testing in final inspection that will reveal internal gross defects and that will not injure the casting. Radiography seems to offer the best solution to this problem. The method is expensive, but in cases where the possible failure of a casting would cause damage far in excess of the cost of the tests, radiographic examination becomes a matter of insurance and the question to be answered is often not whether such inspection can be afforded but rather whether it can be afforded not to make it. The rapid development of high-pressure steam installations, high-head hydraulic power, high-pressure oil-cracking systems, higher-power locomotives, aerial transportation, and various other lines of industrial activity presents increasingly numerous cases where such tests may be applied and where sometimes they will be found absolutely necessary.

Standards of soundness that must be met by castings in order to pass X-ray inspection can not be set up at the present time with any degree of fairness to consumer or manufacturer. This fact is due partly to the newness of this method of testing, partly to a lack of sufficient information as to the effects on strength or other properties of various types of defects, but mostly to the fact that each casting is a study in itself. Defects that would be injurious in some castings may not be serious in others and may be even advantageous in peculiar circumstances. It seems that castings must be regarded in this sense as structural units rather than as materials of construction. That they, in fact, have been so regarded, is illustrated by the way in which radiographic inspection tests have been handled. That is, revealed defects are usually considered with regard to known stress distribution or other conditions of service and rejections are made where the defects render the casting in question unfit for its particular service. It is probable that in the future foundries will be able to eliminate the more important casting defects. This will come about through intensive studies of casting technique. When this is accomplished the problem of final inspection will be simplified, but for many important cases will still remain a problem of individual study of individual castings.

DEFECTS THAT MAY BE REVEALED BY X RAYS

The more common defects found in castings by radiographic tests may be enumerated as follows:

1. Gas cavities:
 - (a) Due to gases liberated from the hot metal;
 - (b) Due to gases from the mold.
2. Sand inclusions.
3. Slag inclusions.
4. Pipe cavities.
5. Porosity:
 - (a) Due to small gas cavities;
 - (b) Due to small shrinkage cavities.
6. Cracks.
7. Metal segregations.

Most of these may be eliminated by improved manufacturing methods. Cracks, pipes, and porous sections are sometimes traceable to faulty design.

RADIOGRAPHIC EQUIPMENT

The apparatus needed for radiographic work depends to a certain extent on the nature of the materials to be investigated. For the study of steel castings whose sections do not exceed 3½ inches in thickness, the air-cooled Coolidge X-ray tube rated at 200 kv and 8 milliamperes has been found satisfactory. A finer-focus tube rated at 100 kv and 10 milliamperes is available for steel sections that do not exceed 1½ inches in thickness. The higher-powered tube will in general be more satisfactory. The accessory electrical equipment should include

a high-tension transformer that will deliver 10 milliamperes at 300 kv from the secondary, a rectifier for rectifying the output of the transformer, a milliammeter for measuring the current across the tube, a standard sphere gap for determining potentials across the tube, and a remote-control stand containing the operating controls.

The X-ray tube mounted in a flexible support to facilitate manipulation is preferably contained in a lead-lined operating chamber and the control stand in a separate chamber. Intensifying screens are required for metal sections greater than three-fourths of an inch. Mounted screens are used where possible, but a supply of unmounted screens of various sizes is desirable. A well-equipped photographic dark room completes the necessary equipment for making radiographs. In addition to the X-ray equipment, the laboratory should be supplied with a good 8 by 10 inch photographic camera and with facilities for handling heavy castings.

RADIOGRAPHIC TECHNIQUE

The procedure in the laboratory is somewhat as follows: A casting to be radiographed is given a superficial examination, and areas through which pictures are to be taken are charted. These areas are selected with a view to showing general conditions in the metal, and particular conditions in regions that, in service, are subjected to greater stresses or that for other reasons are of particular importance. The selected areas are numbered with white chalk or paint, after which the piece is photographed. The casting is now moved into the operating chamber and the X-ray tube arranged above one of the numbered areas. Lead numerals are placed over the painted ones. These show in the developed picture and serve to identify the areas and to permit exact orientation of the finished negative with the casting so that revealed defects may be charted on the surface of the metal. The special X-ray photograph film is placed in a paper holder or in a metal cassette between the intensifying screens and adjusted in as close contact with the metal as possible, to intercept the radiation that is to be passed through the selected area. Sheet lead is used to protect the film from all X radiation except that passing through the area under investigation. This protection is important. It is a peculiarity of X radiation that, when it encounters matter, secondary radiation is sent out from the material and this secondary radiation, coming from points remote from the target, may fog the X-ray film. Secondary radiation is given off by the atoms of the metal under test, but this radiation, being weaker than that of the primary beam, is absorbed by the metal and does not affect the film except that the radiation from the underside of the metal adjacent to the film is not absorbed, and does produce a certain amount of fog in the negative.

In many cases, pieces to be radiographed vary in thickness of section to such an extent that a proper exposure for the thicker portions would overexpose the portion of the photographic film under the thinner part. This difficulty may be overcome with large castings by first exposing for the thin section after which the thin portion is covered with lead sheet and the exposure continued for the thicker section. This difficulty may be overcome for small objects by immersing them in a liquid whose absorbing power for X radiation is nearly equal to that of the metal.²⁰ The exposure is then made through the liquid containing the pieces under investigation.

The method is excellent where it can be used. Metal radiography owes very much of its success to intensifying screens. As stated above, matter exposed to X radiation itself begins to radiate. This secondary radiation may be partly reflected primary radiation and partly radiation of a longer wave-length characteristic of the material itself. Also, the greater the intensity of the primary radiation, the greater is the intensity of the secondary. These facts are taken advantage of in the intensifying screen. The special X-ray photographic film, sensitized on both sides, is placed between two thin sheets of material, usually calcium tungstate, that reacts strongly to X rays. The resultant photographic density is due partly to the direct action of the primary X-ray beam, but mostly to the secondary radiation from the calcium tungstate. On account of the very intimate contact between film and screens there is no tendency for the radiation from the screen material to fog the film, although there is some spreading of the image with resultant loss in definition.

The same effects may be obtained with metal used in the place of the calcium tungstate except that the intensifying factor is much less. The use of lead foil for intensifying screens has some advantage over calcium tungstate. While the intensifying factor is less, the lead absorbs part of the secondary radiation from the underside of the metal being investigated, which, as stated above, tends to cause fog in the negative, and in cutting down fog it increases the contrast in the negative. Lead screens also give finer-grained images and consequently sharper definition. These screens have been found particularly useful in examining castings for fine cracks. Unfortunately, their intensifying factor is too low for them to be very useful with sections above 2 inches in thickness. A combination of lead and calcium tungstate has been found advantageous for sections up to 2¾ inches. In this case the lead screen is placed on the side of the film next to the metal to be investigated and the calcium tungstate on the remote side. Inasmuch as one of the present limitations in radiographing thick metal sections is the fogging of the negative by secondary radiation from the under side of the metal, it seems that metal screens may play an increasingly important part as tube power is increased and greater metal penetration obtained. Possibly the combination of screens, described above, with increase in tube power to offset the lower intensifying factor, will be found most advantageous.

FLUOROSCOPIC EXAMINATION

With present available tubes, X-ray visual examination for structural defects may be made where the thickness of section does not exceed about 1½ inches of steel, and where the contour of the metal is favorable. For this work the radiation after passing through the metal is caught on a screen that gives a visible fluorescence under the influence of X rays. Cavities or other defects stand out as brighter spots on the apple-green background of the fluorescing screen. The method is not so sensitive as the radiographic method, can not be used for as thick sections, does not give a permanent record, and is applicable only to metal pieces of relatively simple contours. The method is also open to the objection that it is more difficult to protect the operator from the injurious effects of the rays. There is an advantage in the method in that it is more rapid than radiography and consequently less expensive.

²⁰ Suggested by Ansel St. John.

ASSOCIATION OF AMERICAN STEEL MANUFACTURERS, STANDARD METHODS OF SAMPLING AND PERMISSIBLE VARIATIONS FOR CHECK ANALYSIS OF ROLLED AND FORGED STEEL PRODUCTS, 1928

SAMPLING AND CHECK ANALYSIS OF ROLLED AND FORGED STEEL PRODUCTS

(In respect to sampling, preparation of samples, and location of samples, this specification conforms to A. S. T. M. A130-30, given above. In addition, it provides that:)

METHODS OF ANALYSIS

Only well-known accurate methods of analysis shall be employed. Carbon shall be determined by the combustion method.

NUMBER OF CHECK ANALYSES

- (a) Material shall not be subject to rejection for any element or elements unless determinations have been made on the following minimum number of samples from each melt, except as provided in paragraph (b):
 - 3 for 5 tons or less;
 - 4 for over 5 tons to 10 tons;
 - 5 for over 10 tons to 15 tons; and
 - 6 for over 15 tons.
- (b) If the number of pieces of a melt is less than the number of samples specified in paragraph (a), one sample shall be taken from each piece.

STANDARD PERMISSIBLE VARIATIONS FROM ORDERED LIMITS

Ordinary Commercial Quality Material Without Special Discard

When check analyses are made of the material as furnished, the composition, based on the average of all the separate determinations made, may vary from that ordered to the extent permitted in the following table:

Permissible variations from ordered limits—average composition

Elements	Under minimum limit	Over maximum limit
Carbon—Maximum limits up to 0.80, inclusive.....	Per cent 0.02	Per cent 0.03
Carbon—Maximum limits over 0.80 to 1.15, inclusive.....	.03	.04
Carbon—Maximum limits over 1.15.....	.03	.05
Manganese.....	.02	.03
Phosphorus.....	.005	.005
Sulphur.....	.005	.005
Silicon.....	.02	.03
Copper.....	.02	.03

NOTE.—Variations both under and over apply only when a range is specified.

Forging Quality and Special Discard Material

When check analyses are made of the material as furnished, the composition, based on the average of all the separate determinations made, may vary from that ordered to the extent permitted in the following table:

Permissible variations from ordered limits—average composition

Elements	Under minimum limit	Over maximum limit
	Per cent	Per cent
Carbon.....	0.02	0.02
Manganese.....	.02	.02
Phosphorus.....	.005	.005
Sulphur.....	.005	.005
Silicon.....	.02	.03
Copper.....	.02	.03

NOTE.—Variations both under and over apply only when a range is specified.

The composition of individual samples may vary from that ordered to the extent permitted in the following table, except that the carbon, the manganese, and the silicon in the same melt may not vary both above and below the range ordered.

Permissible variations from ordered limits—individual samples

Elements	Under minimum limit	Over maximum limit
	Per cent	Per cent
Carbon—Maximum limits up to 0.25 inclusive.....	0.02	0.03
Carbon—Maximum limits over 0.25 to 0.60 inclusive.....	.03	.04

NATIONAL ENGINEERING INSPECTION ASSOCIATION, TENTATIVE METHODS OF PROCEDURE FOR INSPECTION OF MATERIALS, 1930

INSPECTION OF MATERIALS

(Covers general procedure, such as checking of order, witnessing of tests, surface inspection, marking, and reports for the following: Mill, shop, and field inspection of structural steel for buildings and bridges; inspection of T and girder rails, steel plate pipe, rolled or drawn steel and iron pipe, boiler and firebox steel, and cast-iron pipe.)

SOCIETY OF AUTOMOTIVE ENGINEERS, IRON AND STEEL SPECIFICATIONS, TEST SPECIMENS, MARCH, 1922

TEST SPECIMENS

1. S. A. E. steels shall be purchased on the basis of requirements as to chemical composition, and the

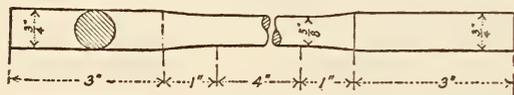

FIGURE 39.—Malleable iron tension test specimen

specifications provided herein should be used in the purchase of the grades and types of steel covered by each. When the steel user desires physical tests on forged parts, bars, or billets, the test specimens shall be selected and prepared in accordance with the following standards.

CONSTRUCTION

2. Tension and bend test specimens shall be taken from the rolled or forged material, except that in the case of irregularly shaped forgings they may be taken from a full-size prolongation. Test specimens shall not be annealed or otherwise treated, except as specified in the following paragraph. Bend tests shall be made cold.

3. Tension and bend test specimens for material that is to be annealed or otherwise treated before use shall, for rolled material, be cut from properly annealed or similarly treated short lengths of the full section of the piece and for forged material from the treated forgings.

4. The axis of tension and bend test specimens for rolled bars and forgings of uniform cross section of over 1½ inches thickness of diameter and for forgings of irregular sections shall, when practicable, be located at any point midway between the center and the outer surface when solid, and at any point midway between the inner and outer surfaces of the wall when bored, and shall be parallel to the axis of the piece in the direction in which the metal is most drawn out. Round tension test specimens shall be machined to the form and dimensions shown in Figure 129, A. S. T. M. 605.0, p. 247. The gage length and fillets shall be ground or lap polished free from scratches. The ends shall be of a form to fit the holders of the testing machine in such a way that the load shall be axial. Threaded ends or self-aligning ball ends are recommended.

5. The bend-test specimens shall be one-half inch square in section and not over 6 inches in length with corners rounded to a radius of not over one-sixteenth inch.

6. The axis of tension-test specimens for rolled bars and forgings of uniform cross-section 1½ inches

or under in thickness or diameter shall be machined concentrically from the specimen. Round tension-test specimens may be machined to the form and dimensions shown in Figure 129, A. S. T. M. 605.0, p. 247, or may be of larger dimensions provided the length of the pull section conforms to the formula

$$\text{gage length, } d = 4.5 \sqrt{\text{area of cross section.}}$$

The gage length and fillets shall be ground or lap polished free from scratches. The ends shall be of a form to fit the holders of the testing machine in such a way that the load shall be axial. Threaded ends or self-aligning ball ends are recommended.

7. Bend test specimens shall be one-half inch square in section and not over 6 inches in length with corners rounded to a radius of not over one-sixteenth inch.

8. Round tension-test specimens for rolled bars or forgings, of dimensions too small to permit the use of the standard full-size test specimen, may be machined to the dimensions of the proportional-size round test specimens shown in Figure 40 and the accompanying table. The gage length and fillets shall be ground or lap polished free from scratches. The ends shall be of a form to fit the holders of a testing machine in such a way that the load will be axial. Threaded or self-aligning ball ends are recommended.

9. Flat tension and bend test specimens for plates and shapes shall be of the full thickness of material as rolled and tensile-test specimens shall be machined to the form and dimensions shown in Figure 128 in A. S. T. M. 605.0, p. 247. The gage width of test specimens one-fourth inch or less in thickness should be equal to five times the thickness, except that in no case shall the width be less than three-fourths inch. The gage length should equal twenty-four times the thickness of the test specimen, except that in no case shall it be less than 2 inches. The gage length on test specimens shall be finished on all sides smooth and free from scratches.

10. Tension-test specimens for malleable castings as specified in that specification (see 611.21, p. 666).

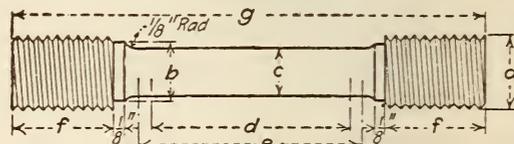

FIGURE 40.—Proportional-size round tension test-specimen

	Diameter of stock (inches)		
	½ to ¾	¾ to 1½	¼ to ¾
(a).....	Inches 0.500	Inches 0.375	Inches 0.250
(b).....	.391	.281	.172
Diameter over gage length (c).....	.375	.250	.125
Gage length (d).....	1.500	1.000	.500
(e).....	1.750	1.250	.750
(f) (approximately).....	.750	.500	.375
(g) (approximately).....	3.625	2.625	1.875

$$\text{Gage length, } d = 4.5 \sqrt{\text{area of cross section.}}$$

shall conform to the shape and dimensions shown in Figure 39 and shall not be machined.

NUMBER OF TESTS

11. Unless otherwise specified by the purchaser, one tension and one bend test shall be made from each melt; except that if material rolled from one

melt differs three-eighths inch or more in thickness, one tension and one bend test shall be made from both the thickest and the thinnest material.

12. If any test specimen shows defective machining or develops flaws, it may be discarded; in which case the manufacturer and the purchaser or his representative shall agree upon the selection of another test specimen in its stead.

13. If the percentage of elongation of any tension-test specimen is less than that specified and any part of the fracture is more than three-fourths inch from the center of the gage length of a 2-inch test specimen or is outside the middle third of the gage length of an 8-inch test specimen before testing, a retest shall be allowed.

SOCIETY OF AUTOMOTIVE ENGINEERS, IRON AND STEEL SPECIFICATIONS; SPECIFICATIONS FOR AUTOMOTIVE STEELS, S. A. E. STANDARD, AUGUST, 1922

AUTOMOTIVE STEELS

1. *Process*.—The steel shall be made by the Bessemer, openhearth, crucible, electric, or any other process approved by the purchaser.

2. *Discard*.—A sufficient discard shall be made from each ingot to secure freedom from injurious piping and undue segregation.

CHEMICAL PROPERTIES

3. The steel shall conform to the specified requirements as to chemical composition.

4. *Ladle analysis*.—An analysis of each melt of steel shall be made by the manufacturer to determine the percentages of the elements specified. This analysis shall be made from drillings taken at least one-fourth inch beneath the surface of a test ingot obtained during the pouring of the melt, and in as sound metal as possible. The chemical composition thus determined shall be reported to the purchaser or his representative, and shall conform to the requirements specified.

5. *Check analysis*.—Analyses may be made by the purchaser. The chemical composition thus determined shall conform to the requirements specified.

6. Drillings for analyses of bars, billets, or other regular shapes shall be taken parallel to the axis, at any point midway between the center and the surface.

7. Drillings or cuttings for analyses of irregularly shaped pieces shall be taken from both the thickest and the thinnest sections. Surface drillings shall be discarded.

8. Wire, tubing, sheets, and rods less than $1\frac{1}{4}$ inches thick shall be sampled through or across the entire section.

FINISH

9. *Defects*.—The material shall be free from injurious defects and shall have a workmanlike finish.

INSPECTION AND REJECTION

10. *Inspection*.—The inspector representing the purchaser shall have free entry at all times to all parts of the manufacturer's works that concern the manufacture of the material ordered while work on the contract of the purchaser is being performed. The manufacturer shall afford the inspector free of cost all reasonable facilities to satisfy him that the material is being furnished in accordance with these specifications. Tests and inspection at the place of manufacture shall be made prior to shipment.

11. The purchaser may make the tests to govern the acceptance or rejection of the material in his

own laboratory or elsewhere. Such tests, however, shall be made at the expense of the purchaser.

12. All tests and inspection shall be so conducted as not to interfere unnecessarily with the operation of the works.

13. *Rejections*.—Unless otherwise specified, any rejection based on tests made by the purchaser in its own laboratory shall be reported within 10 working days from the receipt of samples.

14. Material which shows injurious defects while being finished by the purchaser will be rejected, and the manufacturer shall be notified.

15. *Rejection tests*.—Samples tested by the purchaser in its own laboratory that represent rejected material shall be preserved for one month from the date of the test report. In case of dissatisfaction with the results of the tests, the manufacturer may make claim for a rehearing within that time.

SOCIETY OF AUTOMOTIVE ENGINEERS, IRON AND STEEL SPECIFICATIONS, S. A. E. RECOMMENDED PRACTICE, 1924

HARDNESS TESTS

BRINELL HARDNESS TEST

(The S. A. E. recommended practice for Brinell hardness testing is substantially the same as that of the American Society for Testing Materials in E-10-27, given above. Here and there in the table of hardness numbers appears a slight difference, a few tenths one way or the other, due to the omission from the S. A. E. table of all decimals.)

ROCKWELL HARDNESS TESTS

1. *Principle of test*.—The Rockwell tester measures hardness by determining the depth of penetration of a steel ball or diamond cone (Brale) in the material being tested, under conditions of load application. In elevating the work to testing position, the machine first applies a preliminary, or minor, load of 10 kg (22.046 pounds), which clamps and seats the piece being tested and allows the penetrator to break through the light scale and come in contact with the true material beneath. The direct-reading dial is set to zero penetration, directly after due application of the minor load. With the minor load applied and a zero penetration reading known, a final or major load is applied. This forces the penetrator into the metal being tested. The indication at this time on the direct-reading dial comprises not alone the depth of penetration but also the deformation of the testing-machine frame and components, and the work undergoing test. The true Rockwell hardness is read directly from the dial, after removing the major load. This automatically reinstates the 10 kg (22.046 pounds) minor load and removes the deformation of the machine and part under test. The result is the permanent deformation of the tested metal due to the penetrator and its major load. The Rockwell hardness readings are based on the depth to which the major load forces the penetrator below the point it was forced previously by the minor load.

2. *Preparation of surfaces*.—Concordant results are dependent on surface roughness being much less than the size of the impression. Surfaces that are ridged perceptibly to the eye by rough grinding or machining offer unequal resistance to the penetrator. The degree of surface preparation then, depends to some extent on the requirements of testing, whether they be production or research.

3. *Thickness of specimens*.—Practically any thickness in excess of 0.020 inch can be tested for comparative hardness. For true hardness, the piece must be of such thickness that the undersurface of

the specimen, after testing, does not show a point of compression. The minimum possible thickness of any specimen varies according to the hardness, the load applied, and the kind of test point or penetrator used. The hardest steels give true hardness readings if over 0.027 inch in thickness.

4. *Curved surfaces.*—The true hardness of parts having curved surfaces can be found if the radius of curvature of the surface at the point tested is three-sixteenths inch or more. If the radius is less than three-sixteenths inch only comparative results can be had. Data for hardness tests on a highly curved surface should be accompanied by a statement of the radius of curvature. In testing small rounds the effect of curvature can be eliminated by making a small flat spot on the specimen.

5. *Rockwell scales.*—Since 2 loads and 2 penetrators are used, 2 scales of hardness are placed on the dial of the machine. The black divisions and the letter *C* apply when the 120° diamond-cone penetrator or Brale and the 150-kg (330.693-pound) load are employed. The red divisions and the letter *B* apply when the 100-kg (220.462-pound) load and the one-sixteenth inch steel-ball penetrator are employed. All data should be prefixed by a letter showing whether the values are on the *C* or the *B* scale. Other loads and penetrators can be used, but only comparative results can be obtained. In recording such results all factors relating to them should be clearly stated—the load; the penetrator; the scale used; the thickness of the piece, if very thin; and the curvature of the surface.

6. *Penetrators and loads.*—The Rockwell scale being based on depth measurements, the Brale penetrator gives the more accurate readings on hard metals and the steel ball on soft metals. Hard metals require the 150-kg (330.693-pound) load. The diamond-cone penetrator of 120° angle with the point ground spherically to a definite radius is the standard Rockwell diamond cone or Brale.

7. If the readings are below C-20, it is preferable to test the material with the 100-kg (220.462-pound) load and the one-sixteenth inch steel ball (replaceable) and use the *B* scale. Readings on the *B* scale are not generally taken higher than B-100, when it is advisable to change to the *C* scale with the 150-kg (330.693-pound) load and the Brale penetrator.

8. Measuring hardness greater than B-100 is apt to deform the one-sixteenth inch steel ball, thus destroying its usefulness for testing softer materials.

9. On truly homogeneous material sublow readings are due to burrs on the undersurface of the material tested, causing a movement of the material on its chuck during application of the major load. Assuming that the machine checks correctly on its test blocks, too high readings can be secured only by testing on a spot previously tested, by testing too thin sections or by the penetrator being supported by two ridges caused by poor surface preparation, the last-named being a minor consideration in production testing.

10. In testing tubing or any shape that will deform under test, a blunt nose should be used in place of the penetrator, and the test conducted in the regular way to determine if the specimen takes a permanent set, that would invalidate the hardness test and necessitate consideration of another manner of chucking.

11. *Homogeneity of metals.*—The Rockwell tester measures the hardness of the specimen at the point of penetration, but the reading is also influenced by the hardness of the material under the impression. For example, in testing the hardness of carbon steels, when using the Brale penetrator and the 150-kg (330.693-pound) load, the actual depth of penetration is about 0.0027 inch while the effects of penetra-

tion extend to about 0.027 inch, and if any softer layer is located within 0.027 inch of the impression, the impression will be deeper and the apparent hardness less. Therefore, due regard for this condition must be given when testing material with a superficial hardness, such as cyanided or nitrogenized surfaces.

12. When testing bar stock and forgings, it will be found advisable to remove enough of the surface metal by machining or grinding that the penetrator will test the true metal underneath and the hardness reading will not be affected by the heavy scale and decarburization usually present.

13. Materials, such as cast iron with graphite particles and some nonferrous materials whose crystalline aggregates are greater than the area of the penetrator, must be tested, if possible, with a penetrator of sufficient size to overcome local or grain hardness in order to secure mass hardness.

14. *Conversion to other methods of hardness testing.*—Care should be used in converting readings from one method of hardness testing to another. The factors that cause erroneous conversions are: (a) Lack of true homogeneity in metals, (b) different depths from the surface at which various hardness tests operate, (c) different physical characteristics of various testing devices and the properties measured, and (d) different properties that are assumed by different metals under cold working.

15. No one conversion table is practical for close conversion on all metals. Tables and formulas have been compiled for some materials that can be used as guides. When conversion is necessary, it is advisable to make such conversion for each particular type of metal and each condition of heat treatment or mechanical work.

SHORE HARDNESS TEST

General Information

1. The Shore hardness number is the reading obtained on an arbitrary scale ranging from 0 to 120, by the rebound of a small diamond-pointed hammer dropped from a fixed height. Two types of instrument are in common use; one in which the rebound is read directly on a vertical scale, and the other on which the reading is registered by the instrument on a recording dial. It is suggested that, unless special means are used to compensate for the variations in mass, form, surface, composition, and physical condition of different specimens being tested, the user determine for himself the characteristic readings obtained on his particular product.

(The S. A. E. handbook for 1930 contains a number of charts on which are shown the scleroscope values obtained by the Shore tests.)

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, STANDARD SAMPLES, C25 AND SUPPLEMENT, 1927

STANDARD SAMPLES OF STEELS

ACID OPEN-HEARTH STEELS

(Standard samples No. 19c of 0.2C, No. 20c of 0.4C, No. 21c of 0.6C, No. 34a of 0.8C, and No. 35a of 1.0C are prepared and sold by the Bureau of Standards.)

BASIC OPEN-HEARTH STEELS

(Standard samples No. 15b of 0.1C, No. 11d of 0.2C, No. 12d of 0.4C, No. 13c of 0.6C, No. 14b of 0.8C, and No. 16b of 1.0C are prepared and sold by the Bureau of Standards.)

BESSEMER STEELS

(Standard samples No. 8d of 0.1C, No. 9c of 0.2C, No. 10d of 0.4C, and No. 22b of 0.6C are prepared and sold by the Bureau of Standards.)

ELECTRIC STEELS

(Standard samples No. 51 of 1.2C and No. 65a of acid electric steel are prepared and sold by the Bureau of Standards.)

(The above samples are sold to and used by industrial organizations and others for checking analyses of similar products. Each sample is accompanied by a certificate giving its analysis as regards the important constituents.)

600.2 CLASSIFICATION OF METALS.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, RECOMMENDED CLASSIFICATION OF SCRAP MATERIALS, PS100-29, 1929

CLASSIFICATION OF SCRAP MATERIALS

In order that a uniform selling method may be resorted to, the following conditions should be embodied in the bid or acknowledgment:

All ferrous scrap should be sold on a net-ton (2,000-pound) basis f. o. b. cars point of shipment, consignee to accept weights as invoiced which are based on railroad scale weights at shipping point. The question of cars being light weighed before loading and the cost of light weighing should be left to the judgment of each road.

Nonferrous scrap if shipped in carload lots should be sold f. o. b. cars point of shipment. If taken away by trucks it should be sold f. o. b. seller's plant.

Inspection of all scrap materials is to be made by bidder prior to making bid. It is understood that bid is made on materials as classified by seller and constitutes acceptance by purchaser. All bids should be opened at a specified date and time of day. No verbal bids should be accepted and no attention should be paid to bids unless they are addressed in the desired way.

To do away with the possibility of opening bids before the specified time it is suggested that special envelopes be provided with the bids.

Upon notification of award, purchaser is to send shipping instructions accompanied by certified check for the approximate amount of the purchase to the official designated.

If the sale involves a small amount it should be sold on "cash on delivery" basis.

Adjustment between the actual deposit and the actual amount shipped on each contract should be adjusted with the last billing.

In case of embargoes purchaser should arrange for permits for movement of cars.

If shipping instructions are not received by specified time the sale may be canceled at the discretion of the seller.

CLASSIFICATION OF FERROUS SCRAP

1. *Axles*—*Steel car axles*.—May include armature shafts.

2. *Brake shoes*.—To include steel-back brake shoes. Not to include wheel-truing shoes.

3. *Cast iron No. 1*.—To include pieces weighing more than 3 pounds but not over 150 pounds. Cast-iron parts of cars, automobiles, machinery, and miscellaneous castings; clean soil and water pipes. Must be cupola size, not over 24 by 30 inches in dimensions.

4. *Cast iron No. 2*.—Pieces weighing over 150 pounds. Otherwise same as No. 1 cast iron.

5. *Cast iron No. 4, burnt*.—To include grate bars, stoker castings, sand drying and other stove parts, rheostat grids, and also any other cast-iron pieces less than 3 pounds in weight.

6. *Galvanized scrap*.—To include all kinds of galvanized castings, pipe, wire, shapes, irrespective of size or weight.

7. *Malleable iron No. 1*.—All sizes. To include malleable parts of automobiles, cars, and miscellaneous track, and other malleable castings including malleable pipe fittings, reasonably clean. To be free from cast iron, steel, or galvanized pieces.

8. *Melting steel, No. 1, heavy*.—Steel scrap one-fourth inch and over in thickness, not over 18 inches in width and not over 5 feet long. No pieces to weigh less than 5 pounds. To include structural shapes, bars, rods and plates, angle bars, rail joints, rail braces, tie plates, short pieces of rail, couplers, drawbars, forgings, steel castings, heavy chain, steel gears and pinions, leaf and coil springs (all coil springs to be three-eighths inch or larger diameter), carbon tool steel, also cut boiler plates if practically clean and free from attachments. Individual pieces must be cut into such shape that they will lie reasonably flat in a charging box. All to be free from dirt, excessive rust, scale, or foreign material.

9. *Melting steel, No. 2*.—Plate scrap, such as car sides, automobile frame stock, tank scrap, steel parts from scrapped automobiles, including automobile springs (cut apart), bars, rods, shafts, links, brake drums and bands, wheel rims and wheel disks, etc., one-eighth inch and over in thickness. Maximum size 15 inches wide by 3 feet long excepting car sides and all light plates to be 15 by 15 inches or under and all light rods to be 12 inches and under in length. Any curved or twisted pieces to be sheared into such shape that they will lie flat in a charging box. All to be free from cast or malleable iron attachments.

10. *Pipe*.—To include all kinds of iron and steel pipe, tubing, conduit, trolley poles. To be free from galvanized material.

11. *Rail, steel girder*.—To include girder and guard rail 9 inches and under in height; also slot rail and contact rail from underground-conduit track construction. To contain no manganese steel scrap, cast welds, or attachments. Free from excessive rust, dirt, or concrete.

12. *Rail, steel T*.—Standard section, 40 pounds and heavier per yard, not less than 36 inches long, to be free from frog and switch rails not cut apart. To contain no manganese steel scrap, cast welds, or attachments and to be free from excessive rust, dirt, or concrete.

13. *Special track work, broken*.—Broken or cut to charging-box size. To include pieces not over 18 inches in width and not over 5 feet long. To contain no manganese steel scrap, cast welds, babbitt metal, or spelter and to be free from excessive dirt or concrete. (May be included as heavy melting steel by mutual agreement between buyer and seller.)

14. *Special track work unbroken*.—To include switches, frogs, and mates not cut apart. To be free from excessive dirt or concrete.

15. *Tool steel*.—To include all high-carbon-content tool steel irrespective of size.

16. *Turnings*.—Mixed steel or iron. To include drillings, borings, cuttings, turnings. To be free from excessive corroded material, oil, or foreign material.

17. *Wheels, steel*.—Solid rolled, forged, or cast-steel wheels 36 inches and under in diameter. Steel tires.

18. *Wheels, cast-iron.*—To include solid and spoked car wheels.

19. *Wrought No. 1.*—Wrought iron and soft steel over 6 inches in length. Flats to be one-fourth inch and over in thickness, rounds to be three-eighths inch and over diameter. To include bars, bolts, chain, tie rods, and similar material. To contain no riveted material and to be free from excessive rust or dirt.

20. *Wrought No. 2.*—Wrought iron and soft steel under 6 inches in length, any thickness. To include bolts, pins, rivets, nuts, washers, spikes, and similar material.

21. *Miscellaneous mixed iron and steel.*—To include sheets, car shapes, or any ferrous scrap, unsorted, irrespective of size, shape, or kind, which can not be considered in any of the accepted ferrous scrap classifications. To be free from galvanized material.

CLASSIFICATION OF NONFERROUS SCRAP

1. *Heavy copper.*—To include copper not less than one-sixteenth-inch thick, including field-coil wire, armature wire, bus bars, and copper clippings untinned. All to be free from insulation.

2. *Light copper.*—Less than one-sixteenth-inch in thickness. To include hair wire or any copper wire free from insulation, or sheets which are too light for heavy classification.

3. *Copper trolley wire.*—0000 and less in size, to be cut into suitable lengths as desired.

4. *Copper segments and fingers.*—Free from attachments. (This may be included in heavy copper.)

5. *Copper bonds.*—(This may be included in heavy copper.)

6. *Copper wire, insulated.*—To consist of armature wire, field wire, and other kinds of copper wire and cable from which the insulation has not been burned off.

7. *Brittle copper.*—To consist of miscellaneous copper wire which became brittle in burning off the insulation.

8. *Copper borings and turnings.*—To be free from all ferrous contents or babbitt.

9. *Bronze journal bearings.*—To be free from babbitt or lead.

10. *Bronze armature and axle bearings.*—To be free from babbitt or lead.

11. *Trolley wheels.*—To be free from bushings or screws.

12. *Heavy red brass or bronze.*—To include one-sixteenth-inch and over in thickness.

13. *Heavy yellow brass.*—To include one-sixteenth inch and over in thickness.

14. *Light brass.*—To include red and yellow brass which is too light for heavy classification.

15. *Brass or bronze borings and turnings.*—To include red and yellow brass or bronze.

16. *Aluminum.*—To include aluminum sheet, wire, castings, and pipe.

17. *Monel metal.*—To include sheet, clippings, and cast bars or rods free from iron.

18. *Babbitt dross, tin base.*—When the volume warrants it, such accumulation should be sold on the basis of random chemical analysis for metallic contents.

19. *Babbitt dross, lead base.*—When the volume warrants it, such accumulation should be sold on the basis of random chemical analysis for metallic contents.

20. *Heavy lead.*—To include sheet, pipe, etc. May be put in pig shape.

21. *Battery lead.*—To include dry battery plates, etc. To be free from wood, paper, and rubber.

22. *Zinc.*—To include sheet and castings.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, CLASSIFICATION OF MATERIALS AND SUPPLIES FOR ELECTRIC RAILWAYS, PS200-26, 1926

CLASSIFICATION OF MATERIALS AND SUPPLIES

This classification contemplates uniformity in the physical grouping of stock for more economical operation and provides a basis for statistics for control of investment and simplified accounting.

All requisitions for the purchase or delivery of material should show the class number. Separate requisitions are required for material in each class to facilitate shipment and accounting.

NOTE.—Each class shall embrace all parts and the appurtenances of the articles described therein unless they are otherwise specifically provided for.

(A) WAY AND STRUCTURES

3. *Rails.*—(a) Straight line, (b), special track-work, (c), relaying, (d), third rail.

4. *Rail fastenings.*—Includes splice bars, continuous joints, compromise joints, welded joints, braces, shims, tie plates, tie rods, tie plugs, track bolts, track spikes, boat spikes, clips, plate washers, etc.

5. *Special track work.*—Includes steam and street railroad crossings, crossovers, curves, switches, mates, tongues, frogs, run-offs, track switch boxes, electric switch boxes, etc., and their repair parts.

6. *Track tools, power and hand.*—Includes all kinds of track bars, adzes, mauls, tool handles, chisels, shovels, picks, electric track-drills, track wrenches, spike drivers, tamping machines, air compressors, welding outfits, and their repair parts, etc.

7. *Building and paving materials.*—Includes cast-iron pipe and fittings, gutter and down spouts, etc.

11. *Castings and forgings, rough and finished, not otherwise specified, for way and structures.*—Includes manhole covers, sewer drain boxes, escalator and turnstile parts, etc.

12. *Foundry supplies.*—Includes pig iron, crucibles, etc.

(C) EQUIPMENT

27. *Car wheels.*—All kinds.

28. *Car axles.*—All kinds.

29. *Brake shoes.*—All kinds.

30. *Drawheads, automatic couplers, and journal boxes complete.*—All kinds, complete units only. (Repair parts under castings and forgings.)

32. *Iron and steel bars, sheets, and shapes.*—Includes spring steel, tool steel, shaped steel, sheet iron and steel, chain, channels, I beams, etc.

33. *Pipe, conduits, and tubing.*—Iron and steel only, including trolley poles. (Copper and other metal tubing under class 34.)

34. *Metals.*—Includes brass, bronze, and copper in ingots, bars, sheets, tubes, etc.; Babbitt metals, lead, spelter, zinc, solder, aluminum, thermit, German silver, welding metals, etc.

35. *Castings, brass and other nonferrous metals.*—Includes rough and finished castings (rough castings which finish in a given class to appear there and not hereunder).

36. *Castings, malleable iron.*—Includes rough and finished castings (rough castings which finish in a given class to appear there and not hereunder).

37. *Castings, gray iron and steel.*—Includes rough and finished castings (rough castings which finish in a given class to appear there and not hereunder).

38. *Forgings.*—Includes forged side frames, brake levers, turnbuckles, and all forgings not otherwise specified.

39. *Springs*.—Includes all elliptical, helical, coil, body, truck, motor suspension, and other springs not otherwise specified. (Springs peculiar to air brakes, controllers, motors, or other equipment will be classed with that equipment.)

40. *Bolts, nuts, nails, etc.*—Includes flat washers, lock washers, rivets, pins, studs, lag screws, common nails, etc. (Flat-head nails, brads, cotters, tinners' rivets, and other package goods and screws under hardware, class 65.)

41. *Pipe and conduit fittings*.—All kinds for steam, air, water, etc., including condulets, valves, and cocks for same, etc. (Cast-iron sewer pipe and fittings under class 7.)

42. *Gears, pinions, and gear cases for railway-type motors*.—(Repair parts under class 45.)

43. *Bearings*.—For railway-type motors, armature, axle, and truck journal bearings, machined and finished, as well as rough castings to be used for these purposes.

(D) GENERAL

65. *Hardware and tinware*.—Includes screws, cotters, brads, stove bolts, buckets (water, coal, and sand—whether of tin, iron, or fiber), wire cloth, wire netting, wire fencing, barbed wire, metal drinking cups, oil cans, sprinkling cans, lanterns, torches, gasoline furnaces, fire extinguishers, sprocket chains, weather strip, stepladders, steel-wire rope, etc.

66. *Tools, all kinds, except machine and track tools*.—Includes hammers, wrenches (except only track wrenches), wire cutters, bolt cutters, pliers, soldering irons, files, saws, hatchets, axes, chisels, screw drivers, bits, glass cutters, lades, knives, blacksmith tools, twist drills, emery and buffing wheels, wheel dressers, stocks and dies, jacks and parts, putty knives, scrapers, etc.

71. *Scrap, nonferrous metals*.—Includes brass, copper, Babbitt, tin, German silver, lead, zinc, lead ashes, etc.

72. *Scrap, ferrous metals*.—Includes iron and steel scrap of all kinds, scrap rails, scrap wheels, scrap axles, etc.

(Other classification numbers, omitted here, include materials which have no place under ores, metals, and manufactures (except machinery and vehicles).)

AMERICAN RAILWAY ASSOCIATION, PURCHASES AND STORES DIVISION, STANDARD MATERIAL CLASSIFICATION, 1922

MATERIAL CLASSIFICATION

The object of this classification is to secure uniformity in all departments in the ordering of and accounting for materials, also in the preparation of inventories and the rendering of reports of material received, disbursed, and on hand.

1-A. Frogs, switches, and crossings, and parts of same.

1-B. Track fastenings, track bolts, spikes, etc.

1-C. Track and roadway tools, all kinds, miscellaneous track material and wire fencing.

6. Iron bridges, turntables, and structural steel, all kinds.

8-A. Rail, new.

8-B. Rail, secondhand, except scrap.

11. Bolts, nuts, washers, rivets, lag screws, pins, and studs.

12. Springs, helical and elliptical, all kinds, for locomotives and cars.

14. Brass, copper, and steel tubing; copper ferules; soft metals in bars, pigs, or sheets.

15. Bar iron and steel, spring steel, tool steel, unfabricated rolled shapes, wire netting and chain, except light coil.

16. Boiler, fire box, tank and sheet iron and steel, all kinds.

17. Forgings and pressed steel parts for locomotives, such as crank pins, piston rods, quadrants and levers, motion links, valve yokes, pressed steel grate side bars, front ends, cylinder and steam chest casing, etc.

18. Car forgings, iron and steel, and fabricated or shaped steel, for passenger and freight cars.

19. Locomotive and miscellaneous shop castings, gray iron, malleable and steel. Including cylinders and wheel centers, sand dryers, roundhouse stoves, etc., rough and finished.

20. Car castings, including gray iron, malleable and steel, all kinds, brake beams and parts, couplers and parts, metal bolsters, side frames, and metal car roofs.

21. Rough and finished brass castings and journal bearings.

29. Wheels, cast iron, steel tired and rolled steel, tires and axles, for locomotives and cars.

42. Pipe, iron and steel, and fittings, all kinds, for steam, air and water, valves and cocks for same.

45-A. Hardware, all kinds, including nails.

45-B. Hand and small machine tools, such as drills, taps, reamers, dies, chasers, including air tools and parts.

50. Scrap, all kinds, including scrap rail.

(Other classification numbers, omitted here, include materials which have no place under ores, metals, and manufactures (except machinery and vehicles).)

AMERICAN RAILWAY ASSOCIATION, PURCHASES AND STORES DIVISION, CLASSIFICATION OF SCRAP IRON AND STEEL, 1927

CLASSIFICATION OF SCRAP IRON AND STEEL

1. *Arch bars, iron*.—Railroad arch, transom and tie bars, and coupler yokes.

2. *Axles, steel*.—Solid car and locomotive, 5¼ inches diameter and over at center. (Free of axles with keyways between wheel seats.)

3. *Axles, steel*.—Solid car and locomotive under 5¾ inches diameter at center.

4. *Axles, steel*.—Hollow bored.

5. *Axles, iron*.—Railroad car and locomotive axles, A. R. A. and M. C. B. sizes. Free from defective or imperfect forgings.

6. *Angle and splice bars*.—Fish plates and patented joints, iron or steel.

7. *Boilers, fire boxes and tanks, uncut*.—All kinds, attached or separate. Specify whether with or without flues.

8. *Boilers, fire boxes, and tanks, cut up*.—Iron or steel boiler or tank plate cut into sheets and rings (with or without stay bolts).

9. *Bolsters and side frames*.—Cast steel.

10. *Busheling, No. 1*.—Clean iron and soft steel pipes and flues, tank and bands No. 12 gage and heavier, steel-plate punchings and clippings, soft steel and iron forgings and flashings. No dimensions over 8 inches. To be free from burnt material, hard steel, cast, malleable and metal-coated material of any kind.

11. *Busheling, No. 2*.—Netting, sheet and similar light material lighter than No. 12 gage. No dimension over 8 inches. To be free from hard steel, cast and metal-coated material of any kind.

12. *Cast, No. 1*.—Cast iron scrap, such as columns, pipes, plates, and castings of miscellaneous nature, but free from stove plate, brake shoes, and burnt scrap. Must be cupola size, not over 24 by 30 inches in dimensions, and no piece to weigh over 150 pounds. Must be free from foreign material.

13. *Cast, No. 2.*—Pieces weighing over 150 pounds, but not more than 500 pounds. Free from burnt cast.
14. *Cast, No. 3.*—Pieces weighing over 500 pounds; includes cylinders, driving wheel centers, and all other castings.
15. *Cast, No. 4.*—Burnt cast iron scrap, such as grate bars, stove parts, and any miscellaneous burnt scrap.
16. *Cast-iron brake shoes.*—Driving and car brake shoes of all types except composition filled shoes.
17. *Couplers and knuckles.*—Railroad car and locomotive steel couplers, knuckles and locks stripped clean of all other attachments.
18. *Frogs and switches, uncut.*—Steel and iron frogs and switches that have not been cut apart, exclusive of manganese.
19. *Flues, wrought-iron and steel.*—Two inches and $2\frac{1}{4}$ inches in diameter. 8 feet long and over, rattled.
20. *Flues, wrought-iron and steel.*—Five inches and over in diameter 8 feet long and over, rattled.
21. *Flues, tubes, and pipe.*—Wrought-iron and soft steel. Must be free from dirt, excessive corrosion or lime, and riveted seams. Fitting attached permitted.
22. *Limed iron and steel.*—All kinds of material from interior of boilers (except flues), which are encrusted with lime, such as crown bars, crown bar bolts, stay bolts, etc.
23. *Malleable.*—Malleable parts of automobiles, railroad cars, locomotives, and miscellaneous malleable castings. Must be free from steel and cast iron parts.
24. *Melting steel, No. 1.*—Steel scrap one-fourth inch and over in thickness, not over 18 inches in width, and not over 5 feet long. Individual pieces must be cut into such shape that they will be free from attachments and will lie reasonably straight in a charging box. Cut boiler plate must be practically cleaned of lime, free from stay bolts and not over 3 feet long. Smaller dimensions of scrap may be furnished upon mutual agreement between buyer and seller. May include structural shapes, plates, rods and bars one-half inch and heavier, steel castings, heavy chain, carbon tool steel, heavy forgings, forged butts, and similar heavy material. This grade may also include new mashed pipe ends (original diameter 4 inches and over, thoroughly flattened), sheet bars, billets, blooms, rail bends, railroad steel and wrought scrap such as angle and splice bars, couplers, knuckles, drawbars, cut cast-steel bolsters, and coil and leaf springs (all coil springs to be three-eighths inch or larger diameter). No needle or skeleton plate scrap agricultural shapes, annealing pots, boiler tubes, grate bars, cast iron, malleable iron, or curly or unwieldy pieces will be accepted. Must be free from dirt, excessive rust or scale, or foreign material of any kind.
25. *Melting steel, No. 2.*—Plate scrap, such as car sides one-eighth inch to one-fourth inch in thickness. Punchings one-fourth inch and over in thickness, heavy clippings, new unmashed pipe ends under 4 inches in diameter, and similar material. Car sides and all light plate to be sheared 15 by 30 inches or under and all light rods to be 12 inches and under in length. Any curved or twisted pieces must be sheared into such shape that they will lie reasonably flat in a charging box and not tangle in handling with a magnet; all to be free from cast iron, malleable iron, burnt scrap, dirt, or foreign material of any kind. Maximum size 15 inches wide by 3 feet long.
26. *Rail, iron.*—Standard section T rails, original weight 40 pounds per yard or heavier; free from frog, guard, and switch rails.
27. *Rail, steel No. 1.*—Standard section T rails, original weight 50 pounds per yard or heavier, 5 feet long and over. Suitable for rerolling. Free from bent and twisted rails; frog, switch, and guard rails, or rails with split heads and broken flanges.
28. *Rail, steel No. 2.*—Cropped rail ends under 3 feet long, 50 pounds and over standard section.
29. *Rail, steel No. 3.*—Standard section T and guard rails, not less than 36 inches long, to be free from frog and switch rails not cut apart, and to contain no manganese, cast welds, or attachments of any kind except angle bars. Free from concrete, dirt, or foreign material of any kind.
30. *Sheet scrap No. 1.*—Under one-fourth inch thick, consisting of cut stacks and stack netting hoops, band iron and steel, pressed steel, hand-car wheels, scoops and shovels (free of wood), and wire rope. Must be free from burnt or metal-coated material, cushion and other similar springs, and lime-encrusted pipe and flues from boilers.
31. *Sheet scrap No. 2.*—Includes netting (other than stack wire), galvanized or tinned material, composition brake shoes, gas retorts, and any other iron or steel material not otherwise classified.
32. *Steel, high-speed.*—Specify kind in offering.
33. *Steel, manganese.*—All kinds of manganese, rails, guard rails, frogs, and switch points, cut or uncut.
34. *Steel, spring.*—Coil and elliptical, made of material not less than three-eighths inch diameter or one-fourth inch thickness, not over 18 inches wide. May be assembled or apart.
35. *Structural wrought iron and steel, uncut.*—All steel or steel mixed with iron from bridges, structures, and equipment that has not been cut apart. May include uncut bolsters, brake beams, steel trucks, underframes, channel bars, steel bridge plates, frog and crossing plates, and other steel of similar character.
36. *Tires, No. 1.*—All locomotive or car tires 36 inches and over inside diameter, smooth inside, not grooved for retaining rings or lipped. Cut or uncut.
37. *Tires, No. 2.*—All tires not included in class 36, cut or uncut.
38. *Turnings, No. 1.*—Heavy turnings from wrought-iron and steel railroad axles or heavy forgings and rail chips, to weigh not less than 75 pounds per cubic foot. Free from dirt or other foreign material of any kind. Alloy steel scrap may be excluded from these specifications by mutual agreement between buyer and seller.
39. *Turnings, drillings, and borings No. 2.*—Cast, wrought, steel, and malleable-iron borings, turnings, and drillings mixed with other metals.
40. *Wheels, No. 1.*—Cast-iron car and locomotive wheels.
41. *Wheels, No. 2.*—Includes all kinds of built-up or steel-tired wheels 36 inches and under. (Specify kind in offering.)
42. *Wheels, No. 3.*—Solid cast steel, forged, pressed or rolled steel car and locomotive wheels, not over 36 inches diameter. (Specify kind in offering.)
43. *Wrought iron and soft steel, No. 1.*—Heavy wrought iron and soft steel from railroad shops and cars, 6 inches and longer, including iron links and pins. Flats one-fourth inch thick and over; rounds and squares three-eighths inch thick and over. Free from any riveted materials.
44. *Wrought iron and soft steel No. 2.*—Wrought-iron and soft-steel scrap from railroad shops and cars, under 6 inches long. May include tie plates, track bolts, spikes, and nuts. All to be free from steel shapes and plates.
45. *Destroyed steel cars and locomotive tenders.*—Includes underframes and bodies of steel cars cut apart sufficiently to load; excludes trucks and cast-steel underframes. (Specify kind in offering.)
46. *Aluminum.*—

47. *Brass No. 1.*—Locomotive bearing metals, such as driving crown and rod brass. Free from white metals; excluding car and tender bearings.

48. *Brass No. 2.*—Steam-metal brass, including valves and fittings, injector and lubricating bodies and parts, and check valves.

49. *Brass No. 3.*—Journal bearings free from babbitt.

50. *Brass No. 4.*—Brass or bronze borings, drillings, and turnings.

51. *Brass No. 5.*—Yellow-brass castings, including coach trimmings, light brass, hose couplings, pipe, tubes, etc.

52. *Copper, cable, insulated.*—Specify kind.

53. *Copper No. 1.*—Wire, free from insulation; flue ferrules, pipe, and tubes.

54. *Copper No. 2.*—Sheet, sheathing, and roofing, free from paint and nails.

55. *Copper No. 3.*—Sheathing and roofing with paint and nails.

56. *Copper No. 4.*—Battery.

57. *Copper No. 5.*—Dross and oxide. (Report separately.)

58. *Lead.*—Sheet, pipe, etc.

59. *Lead.*—Battery.

60. *Lead.*—Battery mud or sediment. (Specify wet or dry.)

61. *White metal No. 1.*—Including various mixtures of clean bearing or lining metals, such as babbitt, metallic packing, etc.

62. *White metal No. 2.*—All nonbearing white metals, such as lavatory basins, exclusive of aluminum.

63. *Zinc, battery or sheet.*—(Specify kind.)

Classifications as outlined above are for general use. Not necessary that all items specified in a particular classification be included. If, by separating, a higher price may be obtained, it is recommended that sale be made under the classification specifying as consisting of single item.

NATIONAL ASSOCIATION OF WASTE MATERIAL DEALERS (INC.), STANDARD CLASSIFICATION FOR OLD METALS, CIRCULAR L, 1930

CLASSIFICATION OF OLD METALS

1. *Delivery.*—(a) Delivery of more or less on the specified quantity up to $1\frac{1}{4}$ per cent is permissible. (b) If the term "about" is used, it is understood that 5 per cent more or less of the quantity may be delivered.

Upon request of the shipper, rejections shall be returnable to the seller on domestic shipments within one week and on foreign shipments within 30 days from the time notice of rejection is received by them and upon payment by them of 1 cent a pound on material rejected to cover cost of sorting and packing; the seller to be responsible for freight both ways.

(Additional requirements under "delivery" include damages for failure to make deliveries as specified, arbitration of claims, definitions of carload and ton, shipment for export, and adjustments of claims under differences in weight.)

2. *No. 1 copper wire.*—To consist of clean untinned copper wire not smaller than No. 16 B. & S. wire gage to be free from burnt copper wire which is brittle and all foreign substances.

3. *No. 2 copper wire.*—To consist of miscellaneous clean copper wire which may contain a percentage of tinned wire and soldered ends, but to be free of hair wire and burnt wire which is brittle; the tinned wire not to be over 15 per cent of the total weight.

4. *No. 1 heavy copper.*—This shall consist of tinned copper not less than one-sixteenth inch thick, and

may include trolley wire, heavy field wire, heavy armature wire, that is not tangled, and also new, untinned, and clean copper clippings and punchings, and copper segments that are clean.

5. *Mixed heavy copper.*—May consist of tinned and untinned copper, consisting of copper clippings, clean copper pipe and tubing, and copper wire free of hair wire and burnt and brittle wire; free from nickel-plated material.

6. *Light copper.*—May consist of the bottoms of kettles and boilers, bathtub linings, hair wire, burnt copper wire which is brittle, roofing copper, and similar copper; free from radiators, brass, lead and solder connections, readily removable iron, old electrotypes shells, and free of excessive paint, tar, and scale.

7. *Composition or red brass.*—May consist of red scrap brass, valves, machinery bearings and other parts of machinery, including miscellaneous castings made of copper, tin, zinc and/or lead, no piece to measure more than 12 inches over any one part or to weigh over 60 pounds; to be free of railroad boxes, and other similarly excessively leaded material, cocks and faucets, gates, pot pieces, ingots and burned brass, aluminum composition, manganese, and iron.

8. *Railroad bearing.*—Shall consist of railroad boxes or car journal bearings, must be old standard used scrap, free of yellow boxes, also iron-backed boxes, and must be free of babbitt, also free of excessive grease and dirt.

9. *Cocks and faucets.*—To be mixed red and yellow brass, free of gas cocks and beer faucets.

10. *Heavy yellow brass.*—May consist of heavy brass castings, rolled brass, rod brass ends, chandelier brass, tubing, not to contain over 15 per cent of tinned and/or nickel-plated material; no piece to measure more than 12 inches over any one part and must be in pieces not too large for crucibles. Must be free of manganese mixture, condenser tubes, iron, dirt, and excessively corroded tubing. Must be free of aluminum brass containing over 0.20 per cent aluminum.

11. *Yellow brass castings.*—Shall consist of brass castings in crucible shape, that is, no piece to measure more than 12 inches over any one part; must be free of manganese mixtures, tinned and nickel-plated material, and must be free of visible aluminum brass.

12. *Light brass.*—May consist of miscellaneous brass, tinned or nickel plated that is too light for heavy brass; to be free of gun shells containing paper, ashes, or iron; loaded lamp bases; clock works; and automobile gaskets. Free of visible iron unless otherwise specified.

13. *Old rolled brass.*—May consist exclusively of old pieces of sheet brass and pipe free from solder, tinned and nickel plated material, iron, paint and corrosion, ship sheathing, rod brass, condenser tubes and Muntz metal material.

14. *New brass clippings.*—Shall consist of the cuttings of new sheet brass to be absolutely clean and free from any foreign substances and not to contain more than 10 per cent of clean brass punchings to be not smaller than one-fourth inch in diameter.

15. *Brass pipe.*—Shall consist of brass pipe, free of nickel-plated, tinned, soldered pipes or pipes with cast-brass connections. To be sound clean pipes free of sediment, and condenser tubes.

16. *No. 1 red composition turnings.*—To be free of railroad car-box turnings and similarly excessively leaded material; aluminum, manganese, and yellow-brass turnings; not to contain over 2 per cent free iron; to be free of grindings and foreign material, especially babbitt. Turnings not according to this specification to be sold subject to sample.

17. *No. 1 yellow rod-brass turnings.*—Shall consist of strictly rod turnings, free of aluminum, manganese, composition, and Tobin and Muntz metal turnings; not to contain over 3 per cent free iron, oil or other moisture; to be free of grindings and babbitts; to contain not more than 0.30 per cent tin and not more than 0.15 per cent combined iron.

18. *No. 1 yellow-brass turnings.*—Shall consist of yellow-brass turnings, free of aluminum, manganese, and composition turnings; not to contain over 3 per cent of free iron, oil or other moisture; to be free of grindings and babbitts. To avoid dispute, to be sold subject to sample.

19. *Auto radiators (unsweated).*—All radiators to be subject to deduction of actual iron. The tonnage specification should cover the gross weight of the radiators unless otherwise specified.

20. *No. 1 pewter.*—Shall consist of tableware and soda-fountain boxes, but in any case must test 84 per cent tin. Siphon tops to be treated for separately.

21. *Zinc.*—Must consist of clean sheet and cast zinc, also cast batteries; to be free of loose oxide and dross, sal ammoniac cans and other foreign materials.

22. *Zinc dross.*—Must be in slabs and must contain a minimum of 92 per cent of zinc.

23. *Tin foil.*—Shall consist of pure foil free of lead compositions and other foreign ingredients and matters.

24. *Electrotype shells.*—Must be hand picked and free of loose dross and chunks of dross.

25. *Scrap lead.*—Should be clean, soft scrap lead.

26. *Battery lead plates.*—(a) Shall consist of dry battery lead plates, moisture not to exceed 1 per cent, allowance to be made for wood, rubber and paper and excess moisture, or (b) lead plus antimony content, dry basis, less a treatment charge.

NOTE.—Contracts covering this item should specify which method is to be used as a basis of settlement.

27. *New sheet aluminum clippings and new aluminum wire.*—Shall consist of new sheet aluminum, cuttings, and new aluminum wire. Must be free from oil, grease, and any other foreign substances. Must be guaranteed not less than 98 per cent pure aluminum and not to contain more than 10 per cent of clean aluminum punchings to be not smaller than one-quarter inch in diameter.

28. *Old aluminum wire.*—Shall consist of old aluminum wire guaranteed 98 to 99 per cent pure aluminum and must be free from iron cores, insulation, and any other foreign substance.

29. *Alloy sheet aluminum.*—To be sold on specification and sample.

30. *Painted sheet aluminum.*—Shall consist of painted sheet aluminum and must be absolutely free from iron, dirt, or any other foreign substance.

31. *Old sheet aluminum.*—Shall consist of old and manufactured sheet aluminum. Must be free from painted sheet aluminum, iron, dirt, and any other foreign substance.

32. *Aluminum castings.*—Shall consist of aluminum castings, free from iron, babbitt, brass, and any other foreign substance. Must not exceed 2 per cent of oil and grease. Free of pistons.

33. *Aluminum borings.*—To avoid dispute, should be sold subject to sample.

34. *Aluminum foil.*—Shall consist of pure aluminum foil, free from paper and any foreign ingredients.

35. *Babbitt metal.*—Shall contain bearing metal of all kinds. Shall not contain scrap hard metal, Allen metal (which is copper and lead alloy), die cast, ornamental metal, casket metal, zinc boxes, or type metal.

36. *Packages.*—Shall be good strong packages suitable for shipment, and each package shall be plainly marked with separate shipping marks and numbers and with the gross and tare weights so that the packages may reach their destination and their weights can be easily checked.

SOCIETY OF AUTOMOTIVE ENGINEERS, IRON AND STEEL SPECIFICATIONS, FEBRUARY, 1928

SPECIFICATION NUMBERS

(A scheme for classifying alloy steels so that at a glance one can tell the percentage of all alloying elements is detailed in 600.0, page 2. By these means partially descriptive specification numbers can be inserted on shop drawings and blue prints.)

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, SIMPLIFIED PRACTICE RECOMMENDATION R58-23, JANUARY, 1928

CLASSIFICATION OF IRON AND STEEL SCRAP

(Simplified practice recommended and accepted by industry establishing and defining various standard classes and grades of iron and steel scrap.)

SPECIFICATIONS FOR CLASSES OF SCRAP FOR USE IN BLAST FURNACES

1. *Pipe busheling scrap.*—Iron and steel pipe and flues (clean), bedstead tubing, and similar material cut 8 inches and under in length, free from galvanized material and foreign metals.

2. *Cast-iron borings.*—Clean cast-iron borings free from badly corroded material, lumps, scale, other metals, dirt, or foreign material of any kind.

3. *Shoveling turnings.*—Clean, short, steel and wrought-iron turnings, drillings, or screw cuttings; free from stringy, bushy, or tangled material, corroded or rusty lumps, excessive oil, scale, other metals, dirt, or foreign material of any kind. Alloy-steel scrap may be excluded from these specifications by mutual agreement between buyer and seller.

4. *Mixed borings and turnings.*—Clean, short, steel and wrought-iron turnings, drillings, screw cuttings, and cast or malleable iron borings and drillings; free from stringy, bushy, tangled, corroded material, lumps, excessive oil, scale, other metals, dirt, or foreign material of any kind. Alloy-steel scrap may be excluded from these specifications by mutual agreement between buyer and seller.

5. *Corroded borings and turnings.*—Corroded and lump borings, turnings, and similar stock; free from scale, other metals, dirt, or foreign material of any kind. No dimensions to exceed 9 inches. Alloy-steel scrap may be excluded from these specifications by mutual agreement between buyer and seller.

6. *Burnt iron scrap.*—Old annealing boxes, stools and pots, grate bars, and similar burnt iron. No dimension to exceed 9 inches, except brake shoes which may be included.

7. *Mill scale.*—Iron oxide produced in rolling-mill practice, from drop-forge hammers or from a busheling-mill squeezer. Should contain not less than 65 per cent metallic iron, and must be reasonably free from dirt, grease, and other foreign material. Scale from alloy steel may be excluded from these specifications by mutual agreement between buyer and seller.

8. *Mill cinder.*—Cinder from puddling furnaces, heating furnaces, and soaking pits. Should contain not less than 50 per cent iron, and be reasonably free from dirt and other foreign material. Cinder from alloy steel may be excluded from these specifications by mutual agreement between buyer and seller.

SPECIFICATIONS FOR CLASSES OF SCRAP FOR USE IN BASIC OPEN-HEARTH FURNACES

9. *No. 1 heavy melting steel scrap.*—Steel scrap one-fourth inch and over in thickness, not over 18

inches in width, and not over 5 feet long. Individual pieces must be cut into such shape that they will be free from attachments and will lie flat in a charging box. Cut boiler plate must be practically clean and free from stay bolts and not over 3 feet long and lie reasonably flat in charging box. Smaller dimensions of plate scrap may be required upon mutual agreement between buyer and seller. No piece to weigh less than 5 pounds.

May include structural shapes, angle bars and plates, steel castings, heavy chain, carbon tool steel, heavy forgings, forge butts, and similar heavy material.

This grade may also include new mashed pipe ends, original diameter 4 inches and over, thoroughly flattened, sheet bars, billets, blooms, rail ends, railroad steel, and wrought scrap, such as angles, splices, couplers, knuckles, short rails, drawbars, cut-steel bolsters, coil and leaf springs (all coil springs to be three-eighths inch or larger diameter).

No needle or skeleton plate scrap, agricultural shapes, annealing pots, boiler tubes, grate bars, cast iron, malleable iron, or curly or unwieldy pieces will be accepted.

Must be free from dirt, excessive rust or scale, or foreign material of any kind. Alloy-steel scrap may be excluded from these specifications by mutual agreement between buyer and seller.

10. *No. 2 melting steel.*—Plate scrap, such as car sides, automobile frame stock, tank and skelp crops, one-eighth inch and heavier; steel parts of agricultural implements, wagons, buggies, and scrapped automobiles; auto and buggy springs cut apart; rods and bars, one-half inch and heavier; punchings, one-fourth inch and over in thickness; heavy clippings; new unmashed pipe ends, under 4 inches in diameter; horseshoes; and similar material. Car sides and all light plates to be sheared 15 by 15 inches or under and all tires and light rods to be 12 inches and under in length. Any curved or twisted pieces must be sheared into such shape that they will lie flat in a charging box and not tangle in handling with a magnet, all to be free from cast iron, malleable iron, burnt scrap, dirt, or foreign material of any kind.

Maximum size 15 inches wide by 3 feet long, excepting car sides. Alloy steel scrap may be excluded from these specifications by mutual agreement between buyer and seller.

11. *Heavy shoveling steel scrap.*—Heavy, clean, wrought-iron and steel scrap, one-fourth inch and over in thickness, not exceeding 8 inches in breadth or length, and no piece to be less than the equivalent of one-half inch square by 3 inches long. May include clean horseshoes, railroad spikes, bolts, nuts, tie-plates, etc.; boiler, bridge, and structural punching and clippings; small bar and shafting crop ends; and other similar material.

To contain no burnt material, cast or malleable scrap, cut pipe and tank, skeleton stock, badly corroded material, or any twisted or tangled scrap. Must be free from foreign metals of all kinds, from galvanized, painted, enameled, or other coated stock, and from dirt and rubbish of all kinds.

Must be loaded in separate cars from other grades of scrap.

Alloy steel scrap may be excluded from these specifications by mutual agreement between the buyer and seller.

12. *Short shoveling flashings.*—Flashings or trimmings from iron or steel forgings to be 10 inches or under in length, suitable for hand shoveling, and to include no tangled or twisted material. Alloy-steel scrap may be excluded from these specifications by mutual agreement between the buyer and seller.

13. *Long flashings.*—Flashings or trimmings from iron or steel forgings, which have been strictly separated to a minimum length of 20 inches and not to

exceed a maximum of 36 inches. There must be a thickness in some section of each of these flashings of not less than three-sixteenths inch. Alloy-steel scrap may be excluded from these specifications by mutual agreement between the buyer and seller.

14. *Mixed flashings.*—Flashings or trimmings from iron or steel forgings, not over 36 inches in length. Alloy-steel scrap may be excluded from these specifications by mutual agreement between the buyer and seller.

15. *No. 1 busheling.*—Clean iron and soft-steel pipes and flues, tank, cut hoops and bands No. 12 gage and heavier, steel-plate punchings and clippings, soft-steel and iron forgings, and flashings; no dimension over 8 inches. To be free from burnt material, hard steel (cast, malleable), and galvanized, or metal-coated stock of any kind.

16. *No. 2 busheling.*—Cut hoops, netting, cotton ties, sheet, and similar material lighter than No. 12 gage, no dimension over 8 inches. To be free from hard steel (cast, malleable), and galvanized or metal-coated material of any kind.

17. *No. 1 selected rail scrap.*—Standard section T and guard rails, 40 pounds and heavier per yard, not less than 36 inches long, to be free from frog and switch rails not cut apart; and contain no manganese steel scrap or cast welds or attachments of any kind; or concrete, dirt, or foreign material of any kind.

18. *No. 1 selected shearing scrap.*—Angles from 2 inches up to 8 inches, structural shapes in single members from 4 inches up to 9 inches, bars one-half inch and over up to 4 inches diameter, and flats one-half inch to 2 inches thick and from 1 to 10 inches wide. To be in straight lengths and free from dirt and foreign material of any kind. Long-length girder rails free from cast welds and attachments may be included by mutual agreement between the buyer and seller.

19. *Axle turnings.*—Heavy, short first-cut turnings from wrought iron and steel railroad axles or heavy forgings, and rail chips, to weigh not less than 75 pounds per cubic foot, free from dirt or other foreign material of any kind. Alloy-steel scrap may be excluded from these specifications by mutual agreement between the buyer and seller.

20. *No. 1 machine-shop turnings.*—New, clean steel or wrought-iron turnings; free from lumps, badly tangled or matted material, cast-iron borings, other metals, excessive oil, dirt, or foreign material of any kind. Badly rusted or corroded stock will not be accepted.

21. *No. 2 machine-shop turnings.*—New, clean steel or wrought-iron turnings, curly, bushy stock; may contain tangled material, but must be free from badly rusted, lumpy, and corroded stock. To contain no cast-iron borings, other metals, excessive oil, dirt, or foreign material of any kind.

22. *Cast-iron borings.*—New, clean cast-iron borings and drillings; free from steel turnings and from badly corroded or rusty material, lumps, oil, scale, other metals, dirt, or foreign material of any kind.

23. *Hydraulically compressed sheet scrap.*—New, black steel sheet clippings, shearings, skeleton stamping scrap, side and end sheet and tin-mill scrap, hydraulically compressed into compact, rectangular packages not to exceed 20 inches longest dimension; weighing not less than 75 pounds per cubic foot; must be clean and free from excessive rust, paint, or protective coating of any kind. No detinned scrap, electrical sheets, or material over 0.50 per cent silicon will be accepted. Further limitation of silicon content may be made by mutual agreement between buyer and seller.

24. *Baled sheet scrap.*—New, black steel sheet clippings, shearings, skeleton stamping scrap, side and end sheet and tin-mill scrap; machine baled into angular or rectangular packages; tied with wire or

bands, or sufficiently compact not to come apart in handling with a magnet; not over 24 inches longest dimension; weighing not less than 45 pounds per cubic foot; must be clean and free from excessive rust, paint, or protective coating of any kind. No detinned scrap, electrical sheets, or material over 0.50 per cent silicon will be accepted. Further limitation of silicon content may be made by mutual agreement between buyer and seller.

25. *Hand-bundled sheet scrap.*—New, black steel clippings, shearings, skeleton stamping scrap, side and end sheet and tin-mill scrap; securely tied with not less than two wires or bands into packages not over 18 by 18 inches by 3 feet; weighing not over 125 pounds; to be bundled in such a manner that packages will not come apart in handling with a magnet; must be clean and free from excessive rust, paint, or protective coating of any kind. No detinned scrap, electrical sheets, or material over 0.50 per cent silicon will be accepted. Further limitation of silicon content may be made by mutual agreement between buyer and seller.

26. *Loose sheet clippings.*—New, black steel sheet clippings, shearings, and stampings; three-sixteenths inch and lighter; free from excessive rust, paint, or protective coating of any kind; to be not over 18 inches wide or long; or if edge trimmings or shearings, to be not over 12 inches by 5 feet long. No detinned scrap, electrical sheets, or material over 0.50 per cent silicon will be accepted. Further limitation of silicon content may be made by mutual agreement between buyer and seller.

27. *Galvanized or coated sheet scrap.*—New, clean steel sheet scrap, composed in whole or in part of material having a coating of zinc, paint, or protective material. Must be clearly specified as "galvanized or coated scrap" and be classified as stated above under 15, 16, 17, or 18, according to the manner in which it is prepared for shipment. No material over 0.50 per cent silicon will be accepted. Further limitation of silicon content may be made by mutual agreement between buyer and seller.

28. *Detinned sheet scrap.*—Sheet steel clippings and shearings, originally covered with a protective coating of tin, or lead and tin, but from which such foreign metals have been removed. Must be clean, contain no material over 0.50 per cent silicon and be free from badly rusted and corroded stock. Must be clearly specified as "detinned scrap" and classified as stated above under 15, 16, 17, or 18, according to the manner in which it is prepared for shipment. Further limitation of silicon content may be made by mutual agreement between buyer and seller.

29. *Electrical sheet scrap.*—New, clean steel sheet scrap, composed in whole or in part of material from 0.50 per cent to 1 per cent silicon. Must be clearly specified as "electrical sheet scrap" and be classified as stated above under 15, 16, 17, or 18, according to the manner in which it is prepared for shipment.

30. *High silicon sheet scrap.*—New, clean steel sheet scrap, composed in whole or in part of material over 1 per cent silicon. Must be clearly specified as "high silicon sheet scrap" and be classified as stated above under 15, 16, 17, or 18, according to the manner in which it is prepared.

31. *No. 1 cast-iron scrap.*—To contain all kinds of machinery and similar cast-iron scrap, nothing under 10 pounds or over 500 pounds in weight, nor over 48 inches long or 18 inches wide. To contain no brake shoes, cast-iron soil pipe or water pipe, stove scrap, or burnt iron of any description, and to be free from steel parts.

32. *No. 2 cast-iron scrap.*—To contain all kinds of agricultural implements of cast iron, free from steel parts, nothing under 10 pounds or over 500 pounds in weight, nor over 48 inches long or 18 inches wide. To contain no stove scrap or burnt iron of any description.

33. *No. 3 cast-iron scrap.*—To consist of cast-iron scrap with steel parts attached, nothing under 10 pounds or over 500 pounds in weight, nor over 48 inches long or 18 inches wide.

34. *Heavy breakable cast scrap.*—Heavy cast iron suitable for breaking under and with buyer's drop. Pieces not to exceed 10 tons in weight. Free from anvil blocks, hammer bases, and like material, over charging box size and containing no burnt iron.

SPECIFICATIONS FOR CLASSES OF LOW PHOSPHORUS AND LOW SULPHUR STEEL SCRAP FOR USE IN THE ACID OPEN-HEARTH FURNACES

35. *Billet and bar crops.*—Billet, bloom, axle, heavy forge, or bar crops not over 0.04 per cent phosphorus or sulphur, and not over 0.50 per cent silicon; free from alloys. Not less than 2 inches square or diameter, not over 18 inches wide and sheared to lengths not over 36 inches. No piece to weigh less than 10 pounds nor more than 500 pounds. Must be new material and free from excessive rust. Longer lengths may be allowed by mutual agreement between buyer and seller.

36. *Plate crops.*—Plate crops, or sheet-bar crops, not over 0.04 per cent phosphorus or sulphur, and not over 0.50 per cent silicon; free from alloys. Not less than one-fourth inch thick, not over 18 inches wide and sheared to lengths not over 36 inches. No piece to weigh less than 10 pounds or more than 350 pounds. To be free from needle and sliver stock. Must be new material and free from excessive rust. Longer lengths may be allowed by mutual agreement between buyer and seller.

37. *Structural and miscellaneous scrap.*—Bar ends, forging crops, structural crops, and plate shearings smaller and lighter than grades A and B, not over 0.50 per cent silicon, 0.04 per cent phosphorus, and 0.05 per cent sulphur; free from alloys. Not less than one-fourth inch thick, not over 18 inches wide or 36 inches long. To be fully described at time of sale and purchase. Must be clean and free from excessive rust. Longer lengths may be allowed by mutual agreement between buyer and seller.

38. *Tube scrap.*—Tube scrap, seamless or welded, not over 0.04 per cent phosphorus or sulphur, free from alloys. Not less than No. 12 gage thickness of wall; if over 6 inches inside diameter they must be mashed flat and sheared to lengths not over 36 inches. Must be only new material that has not been in use for any purpose, and free from excessive rust.

39. *Punchings.*—Punchings from plate and structural-steel scrap, not less than one-fourth inch thick and not less than one-half inch diameter, not over 0.04 per cent phosphorus or 0.05 per cent sulphur, not over 0.50 per cent silicon, free from alloys. Must be free from dirt and excessive rust or corrosion.

40. *Car wheels.*—Solid cast steel, forged, pressed, or rolled steel car and locomotive wheels, not over 36 inches diameter. (Specify kind when offering.)

41. *Spring-steel scrap.*—Coil and elliptic steel springs, made of material not less than three-eighths inch diameter or one-fourth inch thickness, not over 18 inches wide, and sheared to lengths not over 48 inches. May be assembled or cut apart.

42. *Couplers and knuckles.*—Railroad car and locomotive steel couplers, knuckles, and locks, stripped clean of all other attachments. Gates, heads, and risers may be included by mutual agreement between buyer and seller.

43. *Scrap tires.*—Steel tires from car and locomotive wheels, cut to not over 24 inches long.

44. *Car bolsters.*—Railroad car steel bolsters and side frames stripped clean of all iron attachments. Not over 24 inches wide and cut to lengths not over 48 inches.

45. *Medium silicon scrap.*—High silicon billet, bloom, bar crops, plate crops, or sheet-bar crops, not over 0.04 per cent phosphorus or sulphur, not less

than 0.05 per cent to 2 per cent silicon, free from other alloys, not less than one-fourth inch thick, not over 18 inches wide and 36 inches long, and no piece to weigh less than 10 pounds or more than 500 pounds. To be free from needle and sliver stock. Must be new material and free from excessive rust.

46. *High-silicon scrap.*—High-silicon billet, bloom, bar crops, plate crops, or sheet-bar crops, not over 0.04 per cent phosphorus or sulphur, not less than 2 per cent or over 4.5 per cent silicon, free from other alloys, not less than one-fourth inch thick, not over 18 inches wide and 36 inches long, and no piece to weigh less than 10 pounds or more than 500 pounds. To be free from needle and sliver stock. Must be new material and free from excessive rust.

47. *High-nickel scrap.*—Nickel-steel billet, bloom, bar crops, or other shapes of similar section and equal grade, not over 0.04 per cent phosphorus or sulphur, between 3 per cent and 3.5 per cent nickel (lower or higher in nickel content to be duly considered), free from other alloys. Not less than 2 inches square or diameter, not over 18 inches wide, and cut to lengths suitable for charging boxes of buyers, and no piece to weigh less than 25 pounds. Must be clean material.

48. *No. 1 chrome-nickel scrap.*—Chrome-nickel steel billet, bloom, bar crop, or other shapes of similar section and equal grade, not over 0.04 per cent phosphorus or sulphur, between 3 and 3.5 per cent nickel (lower or higher nickel content to be duly considered), not over 0.5 per cent chrome, free from other alloys. Not less than 2 inches square or diameter, not over 18 inches wide, and cut to lengths suitable for buyers' charging boxes, and no piece to weigh less than 25 pounds. Must be clean material.

49. *No. 2 chrome-nickel scrap.*—Chrome-nickel steel billet, bloom, bar crops, or other shapes of similar section and equal grade, not over 0.04 per cent phosphorus or sulphur, between 1.5 and 2.5 per cent nickel (lower or higher nickel content to be duly considered), between 0.5 and 1 per cent chrome, free from other alloys. Not less than 2 inches square or diameter, not over 18 inches wide, and cut to lengths suitable for buyers' charging boxes, and no piece to weigh less than 25 pounds. Must be clean material.

50. *Light chrome-nickel scrap.*—Nickel or chrome-nickel steel of the analyses and descriptions, as shown for grades 47, 48, and 49, except it may be lighter and of miscellaneous shapes. To be fully described at time of sale and purchase.

51. *Special chrome-nickel scrap.*—Nickel or chrome-nickel steel of the analyses and descriptions, as shown for grades 47, 48, and 49, except the phosphorus and sulphur may go up to but not over 0.05 per cent. To be fully described at time of sale and purchase.

52. *Nickel-steel turnings.*—Heavy, short first-cut turnings from nickel-steel forgings. Nickel and chrome content to be specified on each individual sale. To weigh not less than 75 pounds per cubic foot. To be free from dirt and other foreign materials.

SPECIFICATIONS FOR CLASSES OF SCRAP FOR USE IN ELECTRIC FURNACES

Alloy steel scrap may be excluded from these specifications by mutual agreement between buyer and seller.

53. *Punchings and clippings.*—Open-hearth steel punchings and clippings, one-fourth inch and heavier, 4 inches and under in length. Not over 0.04 per cent in phosphorus or sulphur and suitable for shovel charging. Must be clean and free from galvanized or coated stock, dirt, and excessive rust or corrosion.

54. *Guaranteed heavy scrap.*—Open-hearth steel plates, structural shapes, crop ends, shearings, broken steel tires, knuckles, tool steel, and spring

steel. To be not less than one-fourth inch thick, other dimensions subject to agreement. Not over 0.04 per cent in phosphorus or sulphur, clean, free from excessive rust and corrosion, and contain no foreign material.

55. *Unguaranteed scrap.*—Steel plate, shearings, nut and bolt punchings, short rails, and other similar material, not less than one-fourth inch in thickness and not over 12 inches in width or length. Not guaranteed under 0.04 per cent phosphorus or sulphur. To be suitable for hand charging. Must be free from galvanized and coated stock, foreign material, and excessive rust or corrosion.

56. *Guaranteed axle turnings.*—Heavy steel or iron axle or forge turnings, guaranteed not over 0.04 per cent in phosphorus or sulphur. To contain no foreign material and must be clean and free from excessive rust and corrosion. To weigh not less than 75 pounds per cubic foot.

57. *Unguaranteed turnings.*—Short, heavy shoveling steel or wrought-iron turnings or rail chips, not guaranteed under 0.04 per cent in phosphorus or sulphur. To contain no foreign material and must be free from excessive rust or corrosion. To weigh not less than 75 pounds per cubic foot.

SPECIFICATIONS FOR CLASSES OF SCRAP FOR USE IN GRAY IRON FOUNDRY PRACTICE

58. *No. 1 machinery cupola scrap.*—Clean, machinery cast-iron scrap. Must be cupola size, not over 24 by 30 inches in dimensions, and no piece to weigh over 150 pounds.

59. *No. 1 machinery breakable scrap.*—Clean, machinery cast-iron scrap, weighing over 150 pounds, which can be easily broken, by an ordinary drop, into cupola size.

60. *No. 1 standard cupola scrap.*—Clean cast-iron scrap, such as columns, pipes, plates, and castings of miscellaneous nature, but free from stove-plate and agricultural scrap. Must be cupola size, not over 24 by 30 inches in dimensions, and no piece to weigh over 150 pounds. Must be free from foreign material.

61. *No. 1 standard breakable scrap.*—Clean cast-iron scrap, such as columns, pipes, plates, and castings of miscellaneous nature, weighing over 150 pounds, which can be broken, by an ordinary drop, into cupola size.

62. *Burnt cast scrap.*—Burnt cast-iron scrap, such as grate bars, stove parts, and any miscellaneous burnt scrap.

63. *Stove plate scrap.*—Clean cast-iron stove plate. Must be free from malleable and steel parts, window weights, plow points, grates, burnt iron, etc.

64. *Agricultural scrap.*—Cast-iron parts of agricultural machinery including plow points. Must be free from steel, and malleable, and full-chilled iron.

65. *Cast-iron car wheels.*—Cast-iron car and locomotive wheels.

66. *Brake shoes.*—Driving and car brake shoes of all types, except composition-filled shoes.

67. *No. 1 radiator scrap.*—Broken radiator castings, cupola size, with all steel parts removed. Must be free from excessive scale, rust, and corrosion.

68. *No. 2 radiator scrap.*—Unbroken radiator castings. Must be free from excessive scale, rust, and corrosion.

69. *No. 1 malleable scrap.*—Malleable parts of automobiles, railroad cars, and miscellaneous malleable castings. Must be free from steel and cast-iron parts.

70. *No. 2 malleable scrap.*—Malleable parts of agricultural implements and other miscellaneous malleable castings. Must be free from steel and cast-iron parts. May include No. 2 rail steel, cropped rail ends under 3 feet long, 50-pound and over, standard section.

SPECIFICATIONS FOR CLASSES OF SCRAP FOR USE IN
BESSEMER CONVERTERS

71. *Mild steel converter scrap.*—Mild open-hearth steel scrap, such as structural shapes, rolling mill crop ends, forgings, and forge-crop ends. No piece to weigh over 150 pounds or less than 10 pounds, not under three-eighths inch section, and must not exceed 24 inches in any one dimension. Must be free from excessive rust or corrosion.

72. *High-carbon steel converter scrap.*—High-carbon or hard-steel scrap, such as steel rails and materials of similar analysis. No piece to weigh over 150 pounds or less than 10 pounds, and must not exceed 24 inches in any one dimension. Must be free from excessive rust or corrosion.

73. *Steel-spring scrap.*—Coil and leaf springs, made from stock three-eighths inch in thickness or heavier. Elliptical springs must be cut apart and must not exceed 24 inches in length. Must be free from plates and from excessive rust or corrosion.

SPECIFICATIONS FOR CLASSES OF MISCELLANEOUS SCRAP

74. *Crucible-steel scrap.*—Boiler steel punchings, under 0.04 per cent in phosphorus or sulphur. This is a basic classification for crucible-steel scrap. In the event any other material is specified, no piece shall exceed 5 inches in width or 8 inches in length. In the event that small, soft-steel castings are specified as crucible scrap, the weight shall not exceed 10 pounds per piece. Must be clean and free from dirt and excessive rust or corrosion.

75. *Chemical borings.*—Clean, fine, dry, cast-iron borings free from oil and grease. Shall contain no lumpy or rusty stock and be free from other metals.

600.3 COATING OF METALS.

AMERICAN ASSOCIATION OF STATE HIGH-
WAY OFFICIALS, METHODS OF DETER-
MINING WEIGHT OF COATING ON ZINC-
COATED ARTICLES, TENTATIVE METH-
OD T-65, 1930

WEIGHT OF ZINC COATING

(Same as A. S. T. M. A90-30, given below.)

AMERICAN ASSOCIATION OF STATE
HIGHWAY OFFICIALS, METHOD OF TEST
FOR UNIFORMITY OF GALVANIZING OR
SPELTER COATING ON WIRE, TENTA-
TIVE METHOD T-66, 1930

TESTING SPELTER COATING ON WIRE

(Same as A. R. A. signal section specification 2912, given below.)

AMERICAN ELECTRIC RAILWAY ENGI-
NEERING ASSOCIATION, STANDARD
SPECIFICATION FOR GALVANIZING OR
SHERARDIZING ON IRON AND STEEL,
D6-14, 1914GALVANIZING OR SHERARDIZING ON IRON OR
STEEL

(This specification is similar to that of the American Railway Association, signal section, specification 2912, given below, with the following additions and modifications:)

GENERAL DESCRIPTION

This specification shall apply to all galvanized or sherardized material.

COATING REQUIREMENTS

The coating shall consist of a continuous coating of pure zinc, zinc-iron alloy, or a combination of the two.

METHOD OF TEST

In the case of sherardized material the specimens must be vigorously brushed in running water after each dip.

In testing wire, the No. 12 B. W. G. and smaller sizes shall be required to stand three 1-minute and one ½-minute immersions.

In case the article has a cut screw, the thread shall be recut after galvanizing and shall stand at least one 1-minute immersion in the test solution. The rest of the article shall withstand the specified four immersions.

The threads of nuts shall be cut after the nut has been galvanized, and the threads shall not be required to stand the test.

INSPECTION

All material shall be inspected on receipt; samples shall be taken at random and submitted to tests hereinafter specified. The shipment will be accepted or rejected upon these samples.

REJECTION

Any material which fails to meet the requirements hereinabove specified may be rejected and returned at the expense of the contractor.

METHOD OF SHIPMENT

All material furnished under this specification shall be so packed for shipment that it will be suitably protected from injury. Each package shall be plainly marked, giving the kind of material and the number of the company's order on which the shipment was made.

NAL SECTION, SPECIFICATION 2211,
GALVANIZED E. B. B. BONDING WIRES,
1911

GALVANIZING E. B. B. BONDING WIRES

(In respect to coating, cleaning, solution, samples, test, and acceptance, this specification conforms to A. R. A. signal section, specification 2912, given below. Otherwise it provides as follows:)

GENERAL

(a) The intent of this specification is to provide for the furnishing of No. 8 B. W. G. galvanized E. B. B. wires for bonding rail joints of steam railroads where electric track circuits are to be used.

CONDUCTOR

(a) The wire must be cylindrical in form, free from scales, flaws, inequalities, splits, and all imperfections. The wires shall be cut and straightened to the length specified on order. The ends shall be sheared, cut, and free from burrs.

PROPERTIES

(a) The mechanical and electrical properties of the finished wire must be in accordance with the following requirements:

B. W. G.	Diameter	Breaking resistance	Per cent elongation in 10 inches	Resistance in ohms per mile at 68° F.
8.....	Mils 165	Pounds 975	15	12.05

The wire shall not vary more than 3 mils from the normal diameter.

GALVANIZING TEST

(a) A sufficient number of samples shall be taken from the wire submitted for inspection and shall be tested, these pieces being not less than 8 inches long and not more than seven pieces of wire shall be immersed in the specified quantity of solution.

INSPECTION AND TESTS

(a) The purchaser is to have the right to make such inspection and tests as he may desire of the wire at any stage of manufacture.

(b) The manufacturer must provide, at the mill, all apparatus and labor for making the required tests under the supervision of the purchaser.

(c) Tests shall be made at the mill on the wire before it is cut into lengths, or on samples submitted by the manufacturer, and may also be made on the wire upon its arrival at destination.

(d) If, upon arrival at destination, the wires do not meet the requirements of this specification they will be rejected and returned to the manufacturer, who shall pay all freight charges.

PACKING FOR SHIPMENT

(a) The wire shall be put up in bundles of 100 or 300, as ordered, well burlapped at ends and securely fastened in not less than three places.

TAGGING

(a) A tag shall be securely fastened to each bundle, having plainly and indelibly marked thereon the number of and length of the wires, the purchaser's order and inspection number, and the proper shipping address.

AMERICAN RAILWAY ASSOCIATION, SIGNAL SECTION, SPECIFICATION 2912, GALVANIZING FOR IRON OR STEEL, 1912

GALVANIZING FOR IRON OR STEEL

1. PURPOSE

(a) This specification gives in detail the tests to be applied to galvanized material. All specimens shall be capable of withstanding these tests.

2. COATING

(a) The galvanizing shall consist of a continuous coating of pure zinc of uniform thickness, and so applied that it adheres firmly to the surface of the iron or steel. The finished product shall be smooth.

3. CLEANING

(a) The samples shall be cleaned before testing; first with carbon tetrachloride, benzine, or turpentine and cotton waste (not with a brush), and then

thoroughly rinsed in clean water and wiped dry with clean cotton waste.

(b) The sample shall be clean and dry before each immersion in the solution.

4. SOLUTION

(a) The standard solution of copper sulphate shall consist of commercial copper sulphate crystals dissolved in cold water, about in the proportion of 36 parts, by weight, of crystals to 100 parts, by weight, of water. The solution shall be neutralized by the addition of an excess of chemically pure cupric oxide (CuO). The presence of an excess of cupric oxide will be shown by the sediment of this reagent at the bottom of the containing vessel.

(b) The neutralized solution shall be filtered before using by passing through filter paper. The filtered solution shall have a specific gravity of 1.186 at 65° F. (reading the scale at the level of the solution) at the beginning of each test. In case the filtered solution is high in specific gravity, clean water shall be added to reduce the specific gravity to 1.186 at 65° F. In case the filtered solution is low in specific gravity, filtered solution of a higher specific gravity shall be added to make the specific gravity 1.186 at 65° F.

(c) As soon as the stronger solution is taken from the vessel containing the unfiltered neutralized stock solution, additional crystals and water must be added to the stock solution. An excess of cupric oxide shall always be kept in the unfiltered stock solution.

5. QUANTITY OF SOLUTION

(a) Wire samples shall be tested in a glass jar of at least 2 inches inside diameter. The jar without the wire samples shall be filled with standard solution to a depth of at least 4 inches. Hardware samples shall be tested in a glass or earthenware jar containing at least one-half pint of standard solution for each hardware sample.

(b) Solution shall not be used for more than one series of four immersions.

6. SAMPLES

(a) Not more than seven wires shall be simultaneously immersed, and not more than one sample of galvanized material other than wire shall be immersed in the specified quantity of solution.

(b) The samples shall not be grouped or twisted together, but shall be well separated so as to permit the action of the solution to be uniform upon all immersed portions of the samples.

7. TEST

(a) Clean and dry samples shall be immersed in the required quantity of standard solution in accordance with the following cycle of immersions.

(b) The temperature of the solution shall be maintained between 62° and 68° F. at all times during the following test: (1) Immerse for one minute, wash, and wipe dry; (2) immerse for one minute, wash, and wipe dry; (3) immerse for one minute, wash, and wipe dry; and (4) immerse for one minute, wash, and wipe dry.

(c) After each immersion the samples shall be immediately washed in clean water having a temperature between 62° and 68° F., and wiped dry with cotton waste.

(d) In the case of number 14 B. W. G. galvanized iron or steel wire, the time of the fourth immersion shall be reduced to one-half minute.

8. ACCEPTANCE

(a) If, after the test described in section 7 (a) there should be a bright metallic copper deposit upon the samples, the lot represented by the samples shall be rejected.

(b) Copper deposits on zinc or within 1 inch of the cut end shall not be considered causes for rejection.

(c) In the case of a failure of only 1 wire in a group of 7 wires immersed together, of if there is a reasonable doubt as to the copper deposit, 2 check tests shall be made on these 7 wires and the lot reported in accordance with the majority of the sets of tests.

(A note appended to this specification enumerates the equipment necessary for conducting the tests outlined above.)

(Identical with A. R. A. signal section specification 2912, given above.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD METHOD OF DETERMINING WEIGHT OF COATING ON ZINC-COATED ARTICLES, DESIGNATION A90-30, 1930

WEIGHT OF ZINC COATING

SHOP WEIGHING TESTS

Select a pickled and washed sheet. Stand the sheet on edge and allow to drain for two minutes. The water remaining on the sheet will then amount to approximately 0.01 pound per square foot.

Weigh this sheet with an accuracy of 0.05 pound, and subtract the weight of the water to obtain the real weight of the uncoated sheet. After galvanizing, reweigh the sheet. The increase in weight represents the coating.

Where greater accuracy is desired, wash, dry, and weigh 10 sheets; then coat and reweigh.

To determine the weight of coating in ounces per square foot, divide the weight of coating in ounces by the area in square feet in the sheet or sheets.

SAMPLING

(a) *Sheets*.—The laboratory samples for determining the average weight of coating upon a galvanized sheet shall be taken as follows:

A 2½-inch strip shall be cut transversely or diagonally across the middle of the sheet with its ends approximately 1 inch from each edge. Three samples, 2¼ by 2¼ inches, shall be accurately cut from the middle and the two ends of this strip. These samples shall be cleaned with gasoline or benzol, then with alcohol and dried thoroughly before proceeding with the test.

The weight of coating in grams on a 2¼ by 2¼ inch piece (5.08 square inches) is numerically equal to the coating in ounces per square foot.

(b) *Wire*.—For determining the weight of coating on zinc-coated wire, the use of a sample of a specific length is not necessary, since the density of the steel (0.283 pound per cubic inch) is known, it is only required to determine the diameter of the stripped wire and the ratio of the weight of zinc to the weight of the stripped wire. The sample of galvanized wire may be of any length over 12 inches, but preferably about 24 inches.

HYDROCHLORIC ACID-ANTIMONY CHLORIDE METHOD
(Standard method)

Solutions Required

Antimony chloride solution.—Dissolve 20 g of antimony trioxide or 32 g of SbCl₃ in 1,000 c c of HCl (specific gravity 1.19).

Hydrochloric acid.—Concentrated HCl (specific gravity 1.19).

Method

(a) *Sheets*.—Cut three 2¼ by 2¼ inch laboratory samples, as described under Sampling, and weigh together³¹ after cleaning and drying. They should be immersed singly in 100 c c of hydrochloric acid (specific gravity 1.19) to which has been added 5 c c of antimony chloride solution, and allowed to remain therein until the evolution of hydrogen has ceased or until only a few bubbles are being evolved. This requires only about 15 to 30 seconds, except in the case of sherardized coatings which require a somewhat longer time. The same 100 c c of hydrochloric acid can be used for at least five samples, but 5 c c of the antimony chloride solution should be added before the immersion of each sample. After stripping, the samples should be washed and scrubbed under running water, dried with a towel and laid in a warm place for a short time. The samples should again be weighed together³¹ and the number of grams lost divided by the number of samples taken. Each gram then corresponds numerically to 1 ounce of coating per square foot.

(b) *Wire*.—

Solutions Required

Antimony chloride solution.—Dissolve 20 g of antimony trioxide or 32 g of SbCl₃ in 1,000 c c of HCl (specific gravity 1.19).

Hydrochloric acid.—Concentrated HCl (specific gravity 1.19).

Procedure

The sample shall be cleaned with gasoline or benzine and dried thoroughly and then carefully weighed to 0.01 g.

The sample shall then be stripped of the zinc coating by immersing in a solution made by adding 1 c c of the antimony chloride solution to 100 c c of the concentrated HCl.

As soon as the violent chemical action on the wire ceases, the wire shall be removed from the acid, washed thoroughly, and wiped dry.

The diameter of the wire shall then be determined to 0.001 inch by taking the mean of two measurements at right angles to each other. The stripped sample shall then be weighed to 0.01 g.

Calculation.—The original weight minus the weight of the stripped sample, divided by the weight of the stripped sample, gives the ratio of zinc to iron for the sample under test. The weight of coating in ounces per square foot of stripped wire surface is

³¹ If it is of interest to know the individual weight of coating on each piece, each must be analyzed individually instead of collectively as described.

determined by multiplying the constant 163 by the diameter in inches of the stripped wire by the above ratio. This calculation may be expressed by the following formula:

Ounces of zinc per square foot of stripped wire surface = $163 dr$ where d = the diameter in inches of stripped wire; and

$$r = \frac{\text{original weight} - \text{stripped weight}}{\text{stripped weight}}$$

BASIC LEAD ACETATE METHOD

(Alternate method)

Solutions Required

Lead acetate solution.—Dissolve 400 g of crystallized lead acetate in 1 liter of water. When dissolved, add 4 g of finely powdered litharge and after thorough agitation, allow the solution to settle and decant the clear portion for use.

Method

Cut three $2\frac{1}{4}$ by $2\frac{1}{4}$ inch laboratory samples, clean and weigh as described in the Hydrochloric acid-antimony chloride method.³² The samples should then be submerged separately in a tumbler containing sufficient lead acetate solution to cover the samples. The samples should be maintained in an upright position in order to enable the lead acetate to attack all portions.

After being immersed about three minutes, the sample should be taken out and the adherent lead carefully removed under running water in order that no burnishing action will cause the lead to plate onto the sample. Four immersions of three minutes each are usually sufficient to remove all zinc from the sample, when the bright surface of the iron will be exposed. The test pieces should then be washed in water, dried carefully, and weighed. The loss in grams divided by the number of samples represents the weight of coating in grams, which is numerically equal to the weight of coating in ounces per square foot.

SULPHURIC ACID PERMANGANATE METHOD

(Alternate method)

Solutions Required

Distilled water should be used in all cases where water is mentioned as a reagent.

Standard potassium permanganate, 0.1 N.—Dissolve pure, crystallized potassium permanganate in water in the proportion of 3.2 g per liter. Allow to stand at least two weeks and filter through asbestos. Standardize the solution in the following manner:

Weigh accurately 0.45 to 0.5 g of U. S. Bureau of Standards' sodium oxalate. Place in a 400 c c beaker and dissolve in 250 c c of water at 80° to 90° C. Add 10 c c of sulphuric acid composed of 5 c c of water and 5 c c of c. p. H_2SO_4 (specific gravity 1.84) and titrate the solution at once with the potassium permanganate solution, stirring the liquid vigorously and continuously. The permanganate must not be added more rapidly than 10 to 15 c c per minute and the last 0.5 to 1 c c must be added dropwise with particular care to allow each drop to be completely decolorized before the next is introduced. The solution should not be below 60° C. by the time the end point is reached. More rapid cooling may be prevented by allowing the beaker to stand on a small asbestos-covered electric hot plate during the titration. The use of a small thermometer as a stirring rod is most convenient.

³² If it is of interest to know the individual weight of coating on each piece, each must be analyzed individually instead of collectively as described.

Calculate the iron equivalent of the permanganate solution using the iron value furnished by the Bureau of Standards for the sodium oxalate used.

Sulphuric acid.—Mix 100 c c p. H_2SO_4 (specific gravity 1.84), with 900 c c of water.

Method

Carefully weigh the $2\frac{1}{4}$ by $2\frac{1}{4}$ inch piece, containing exactly 5.08 square inches.

After determining the weight of the plate, place the piece in a 250 c c beaker (Griffin form). Allow the piece to rest on or come in contact with a small piece of platinum foil. Add 125 c c or a sufficient amount of the sulphuric acid solution to cover the inclined piece. Cover the beaker with a watch glass and allow the zinc coating to dissolve. In from 10 to 20 minutes the zinc will be dissolved, as will be indicated by the cessation of the rapid evolution of gas, disregarding the small amount of gas coming mainly from the edges of the plate, due to the action of the acid on the base plate. Wash the plate with a jet of water from a wash bottle, allowing the washings to run into the beaker. Wipe the plate dry, and immediately titrate the solution in the beaker with the standard potassium permanganate solution and calculate the weight of iron dissolved with the zinc coating. Weigh the plate, and subtract this weight from the weight of the plate before removal of the coating. From the difference deduct the weight of iron found to have been dissolved with the coating, which will give the weight in grams of zinc coating on 5.08 square inches of the sample. The weight of the zinc coating in grams on the $2\frac{1}{4}$ by $2\frac{1}{4}$ -inch piece will be numerically equal to the weight of zinc coating in ounces per square foot.

APPENDIX

Field Tests for Determination of Zinc-Coated Articles

PREECE OR COPPER SULPHATE DIP TEST

The samples for the Preece test may be of any size, but should be free from as much cut surface as possible, and should be carefully cleaned before starting the test. The samples are then dipped into not less than 100 c c of copper sulphate solution maintained at a temperature of 18° C. The samples are allowed to remain exactly one minute in the solution. They are then washed in running water, and the copper deposit lightly rubbed off. Successive immersions of one minute each are continued, with the washing and cleaning of the sample between each one, until the appearance of bright adherent copper indicates that the iron beneath the coating has been exposed. Should a small amount of copper be coated adherently to the zinc coating, it must not be mistaken for the end point in which the copper plates-out onto the iron. The appearance of copper within 1 inch of a cut surface is likewise not considered to be the end point of the test.

The copper sulphate solution is prepared by dissolving 36 parts of commercial copper sulphate crystals in 100 parts of water, then adding enough cupric oxide to neutralize any free acid. The solution is filtered or allowed to settle and decanted, then diluted with water until its specific gravity is 1.186 at 18° C. It should always be used at this temperature.

When material is tested by the Preece or copper sulphate method, the number of 1-minute immersions which the sample shall withstand is specified.

The amount of coating removed by a 1-minute immersion in the copper sulphate solution is roughly between 0.20 and 0.25 ounce per square foot of actual surface, or double this per square foot of sheets.

This test is not as accurate in determining the average weight of coating upon a sample as is the

hydrochloric acid-antimony chloride method, but is useful, however, in determining which are the thinnest portions of the coating.

THERMAL METHOD³³

This method makes possible the determination of the zinc coating on iron and steel sheets and other articles without necessitating the use of an analytical balance. An accurately measured galvanized sample is immersed in a measured amount of acid, the maximum temperature rise being recorded. Each 0.1° C. rise in temperature is equivalent to a definite weight of zinc.

The apparatus necessary for conducting this test is as follows:

1. Testing jar, about 2½ inches in inside diameter, with a capacity of about 400 c c, flaring at the top if possible.
2. Thermometer, graduated in 0.1° C., with a range of about 50° C.
3. 300 c c graduated cylinder.
4. Glass-stoppered bottle containing concentrated HCl (specific gravity 1.19).
5. Rule for measuring.

The sample is cleaned with gasoline, dried and accurately measured. For testing zinc-coated sheet, the usual 2¼ by 2¼ inch specimen may be used, and for wire, suitable lengths may be used as given in the table under Sampling of wire.

A measured amount of hydrochloric acid (usually 200 c c) is poured into the testing jar. The temperature of the acid is recorded after stirring, and the sample is immersed in the acid, care being taken that the acid does not overflow the jar. During this time, and until the coating has been stripped from the piece, the temperature is watched until the highest point is reached and the temperature starts to decline. The rise in temperature is then recorded, and from a table of factors prepared for various quantities of acid, the amount of zinc may be calculated. From the number of grams of zinc and the area of the piece in square inches, the weight of coating may be calculated as follows:

$$\text{Coating, ounces per square foot, actual surface} = \frac{\text{Weight of zinc in grams} \times 5.08 \text{ square inches}}{\text{area, square inches}}$$

In this formula, the total area; that is, both sides of the sheet, is measured. To place this on the ordinary sheet basis, as expressed on zinc-coated sheet, the above figure should be doubled. For very light coatings (about 1 ounce per square foot) 100 c c of acid are sufficient. With coatings of 2½ ounces per square foot or heavier, 300 c c of acid should be used. To standardize the equipment, 5 or 6 zinc-coated specimens of any convenient gage or size are weighed, the rise in temperature determined for the apparatus, thermometer and volume of acid. The samples are washed, dried, and reweighed, and the difference in weight noted. The weight loss in grams is divided by the corresponding rise in temperature in degrees. When carefully determined, the average of the above five or six determinations will give a conversion factor which is reliable for the equipment used and for the volume of acid employed. Factors may be determined for any volume of acid in like manner.

EVOLUTION OF HYDROGEN METHOD

This method consists in measuring the hydrogen evolved from the action of hydrochloric acid containing antimony chloride upon a definite area of galvanized surface. By this method, it is not

required to cut any portion of the article to be tested, as with the Cushman coating tester, a 2½-inch ring is sealed to a portion of the surface. Acid is then added which attacks the coating within the area of the ring, and the evolved hydrogen is measured by a suitable gas burette. After removal of the spent acid, the stripped spot is washed, dried, and may either be painted or coated with a suitable metallic coating. The article is, therefore, not mutilated. A full description of the test is found in the 1920 Proceedings of the American Society for Testing Materials.³⁴

The results obtained by this method check very closely with those obtained by the regular hydrochloric acid-antimony chloride method. The main objection to this method is the fact that the coating upon only one side of a sheet is obtained, and as the coating upon galvanized sheets is not always exactly the same on each side; doubling the figures obtained on one side of the sheet will not always give the real amount of coating on both sides of the sheet.

This tester finds use, however, when it is necessary to test sheets or culverts already installed, and where it is desired that the articles shall not be mutilated as would be necessary in taking a regular sample.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD METHODS OF DETERMINING WEIGHT OF COATING ON TIN, TERNE, AND LEAD-COATED SHEETS, DESIGNATION A91-24, 1924

COATING ON TIN AND TERNE PLATE

SAMPLING

From each grade or shipment take one sheet for analysis. Cut four 2 by 2 inch pieces; one from each of the four sides of the sheet, parallel with and about one-half inch from the sides, and near the middle of each side—or cut similar samples from corner, middle, and opposite corner of the sheet, keeping in at least 1 inch from the edge in each case.

NOTE.—For more accurate work, 9 samples are cut, 3 from across the top, 3 across the middle, and 3 across the bottom of each sheet.

DETERMINATION OF WEIGHT OF COATING

Method

Clean the laboratory samples with chloroform, carbon tetrachloride, benzol, or gasoline and finally with alcohol, and dry thoroughly; then weigh accurately the four pieces together.

Wrap a stiff platinum or nickel wire about the 2 by 2 inch piece in such a manner that it may be held in the acid in a horizontal position. Using a 400 c c beaker, heat from 60 to 150 c c of sulphuric acid (specific gravity 1.84) to 250° C. Immerse the sample for about one minute in the hot acid, then remove and momentarily immerse in 50 c c of distilled water contained in a 600 c c beaker. Rub the surface with a "policeman," while washing with about 50 c c of distilled water from a wash bottle. If the coating has not been completely removed, again immerse in the acid and repeat the procedure. Treat all four samples in the same manner, using the same acid. Thoroughly dry and reweigh the samples. If desired, the samples may be retained for the analysis of the base metal.

The loss in weight represents the coating together with some iron.

Cool the sulphuric acid in which the samples were stripped and combine with the washings in a 600

³³ Described in paper by D. M. Strickland, "A Method for Determining the Spelter Coating on Iron and Steel Sheets by Measuring the Rise in Temperature of the Acid Employed," Proc. Am. Soc. Testing Mats., vol. 22, Pt. II, p. 227, 1922.

³⁴ Allerton S. Cushman, "A New Method of Testing Galvanized Coatings," Proc., Am. Soc. Testing Mats., vol. 20, Pt. II, p. 411, 1920.

c c beaker. Pour the solution into a 1,000 c c volumetric flask, and rinse the beaker with hydrochloric acid (specific gravity 1.12). Add rinsings to the flask and fill to the mark with hydrochloric acid of the same strength, again adjusting to the mark if necessary after cooling.

If it is desired to make a direct determination of the lead, the lead chloride should all be in solution. For heavy lead-coated sheets it may, therefore, be necessary to dilute the solution to 2,000 c c with hydrochloric acid (specific gravity 1.12), in order to have all the lead chloride in solution.

The solution may now be analyzed for iron, tin, lead, or any other elements.

DETERMINATION OF IRON

Method

Remove an aliquot portion of 200 c c from the 1,000 c c volumetric flask to a 600 c c beaker. Add 1 or 2 c c of a saturated solution of potassium permanganate to oxidize the iron and tin, and heat the solution to boiling. Cool and add a slight excess of ammonia. Filter the solution and wash the precipitate with hot water. Dissolve the precipitate in the original beaker with hydrochloric acid (specific gravity 1.12), and hot water. Evaporate with hydrochloric acid solution to a volume of about 10 c c and reduce with stannous chloride.

To the cooled solution add a mixture of 25 c c of a saturated mercuric chloride solution, 10 c c of phosphoric acid manganese sulphate solution and 400 c c of boiled distilled water. Titrate immediately with 0.1 N potassium permanganate solution. Calculate the amount of iron stripped from the four pieces, from the number of cubic centimeters of permanganate used.

Calculation of the Weight of Coating

From the loss in weight of the four 2 by 2 inch pieces, subtract the amount of iron found by the above test. This figure represents the weight of coating in grams on the four pieces.

Calculation Factors

The weight of coating in grams on the four 2 by 2 inch pieces

multiplied by 4.3210 = weight of coating in pounds per box of 112 sheets, 14 by 20 inches

multiplied by 8.6421 = weight of coating in pounds per case of 112 sheets, 20 by 28 inches

multiplied by 0.3175 = weight of coating in ounces per square foot.

Pounds of coating per case of 112 sheets, 20 by 28 inches, multiplied by 0.03673 = ounces per square foot.

Ounces per square foot multiplied by 27.22 = pounds per case of 112 sheets, 20 by 28 inches.

DETERMINATION OF TIN ON TERNE PLATE

Method

Remove an aliquot portion of 200 c c from the volumetric flask. Place in a 300 c c Erlenmeyer flask, and add 1 g of powdered antimony. Fit the flask with a 1-hole rubber stopper containing a glass tube bent twice at right angles, with the end of the short bend projecting through the stopper, the other end being long enough to reach almost to the bottom of a beaker placed on a level with the flask. This beaker contains about 300 c c of dilute sodium bicarbonate solution made up with boiled distilled water.

Place the flask on the hot plate, with the glass tube extending into the beaker of sodium bicarbonate solution. After boiling for about five minutes, substitute the beaker of dilute sodium bicarbonate solution with another containing about 50 c c of a

saturated solution of sodium bicarbonate dissolved in boiled distilled water, and remove both the beaker and flask to a cool place. This will cause a small amount of sodium bicarbonate to enter the flask and exclude the air. Finally bring the solution to a low temperature. Add several cubic centimeters of starch solution and titrate with 0.05 N iodine solution. It is desirable to run a duplicate analysis for tin, adding the iodine quickly to a point slightly less than the end point found in the previous determination, then finishing the titration.

From these determinations, calculate the percentage of tin in the coating. In the case of tin plate, the amount of tin can be calculated to pounds per box or pounds per case by factors given under Calculation of weight of coating.

DETERMINATION OF LEAD ON TERNE PLATE

Method

After ascertaining that all the lead chloride is in solution, remove an aliquot portion of 100 c c from the volumetric flask and place in a 400 c c beaker. Add 10 c c of sulphuric acid (specific gravity 1.84), cover, and evaporate to fumes of sulphuric anhydride. Cool and dilute to 300 c c with water. Allow to settle and then filter on a weighed Gooch crucible, washing with 5 per cent sulphuric acid solution. Dry and ignite at a dull red heat. Cool and reweigh. The gain in weight multiplied by 0.6331 equals the weight of lead, from which calculate the percentage of lead in the sample.

DETERMINATION OF TIN ON TIN-COATED SHEETS

Method

Bend or cut up each sample and place each in a separate Erlenmeyer flask and cover with about 40 c c of strong hydrochloric acid. Connect each flask through a rubber stopper with a source of pure oxygen-free carbon dioxide. Dissolve on a hot plate with carbon dioxide passing through to exclude air. Cool the flask in running water and titrate immediately with standard iodine solution, using starch indicator. The iodine solution is made up so that 1 c c is equivalent to 0.005786 g of tin, and is standardized against pure tin. The number of cubic centimeters of iodine used divided by 10 reads directly in pounds of tin per base box of plate.

NOTE.—A base box contains 112 sheets, 14 by 20 inches, and weighs 100 pounds.

When it is desired to analyze only a small number of samples, satisfactory results may be obtained by adding to the flask, with the sample, a small pinch of pure powdered antimony. Cover with a watch glass and dissolve at boiling temperature. As soon as solution is complete, insert a rubber stopper with glass tube extending just through the stopper, and bent twice at right angles, the long end extending approximately level with the bottom of the flask. Insert the long end of the tube into a dilute solution of sodium bicarbonate. Place the flask in cold running water, and as the flask cools, the bicarbonate solution is sucked into the flask, the carbon dioxide set free driving out the air. As soon as cool, titrate as above.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR ZINC-COATED (GALVANIZED) SHEETS, DESIGNATION A33-27, 1927

ZINC-COATED (GALVANIZED) SHEETS

(See 604.32, p. 244.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD METHODS OF TESTING ZINC-COATED (GALVANIZED) IRON AND STEEL WIRE AND WIRE PRODUCTS, DESIGNATION A110-30, 1930

TESTING GALVANIZED WIRE

SCOPE

1. These methods cover the testing of zinc coatings applied by the hot-dip and electrodeposition methods to iron and steel wire.

WEIGHT OF COATING

2. Weights of coating shall be determined by the hydrochloric acid-antimony chloride method as described in the standard methods of determining weight of coating on zinc-coated articles, A. S. T. M., A90, given above.

3. The classes of weights of coating per unit area on zinc-coated products shall be designated in accordance with the following illustrative scheme:

Class designation	Weight of coating, ounces per square foot
Weight 15-----	Minimum of 1.5
Weight 10-----	Minimum of 1.0
Weight 6-----	Minimum of .6
Weight 1-----	Minimum of .1

This classification may be extended or interpolated to provide a selection of classes as needed in preparing specifications for zinc-coated wire and wire products.

4. The weight of coating of any class of wire being found on inspection to be heavier than that defined for the class designated shall not constitute cause for rejection unless so specified on the purchase order.

UNIFORMITY OF COATING

5. The uniformity of zinc coatings shall be determined by the Preece test as described in the appendix to the standard methods of determining weight of coating on zinc-coated articles, A. S. T. M., A90, given above.

6. The requirements of zinc-coated wire in withstanding the Preece test shall be designated as 1 dip, 2 dip, 3 dip, 4 dip, etc., depending on the number of one-minute immersions in the standard Preece test solution that the coated wire is required to withstand. Fractional dip classes may be used, as 3½ dip, meaning 3 one-minute dips plus 1 half-minute dip.

7. There is a general relation between the weight of zinc coating and the number of dips in copper sulphate which the coating will withstand. Ordinarily a coating of weight 8 or heavier will withstand at least four immersions; one of weight 6, at least three immersions; one of weight 4, at least two immersions.

PHYSICAL PROPERTIES OF COATINGS

8. (a) Wrap tests of zinc-coated wire, performed to measure adherence of the coating, may be required in some specifications.

(b) When a wrap test is specified, the coating shall be tested by wrapping two turns around a cylindrical mandrel of the diameter specified at a rate of about 15 turns per minute, and a coating shall be considered as meeting the test requirements if, after wrapping, it does not flake and none of the coating can be removed from the wire by rubbing with the bare fingers.

9. The diameters of the test mandrels used shall be approximately even multiples of the diameter of

the wire tested. Mandrel sizes shall be designated as mandrel 1, mandrel 5, mandrel 12, etc., depending upon whether the mandrel diameters are 1, 5, 12, etc. times the diameter of the wire to be tested.

NOTE.—In general, wires carrying coatings of the higher weights and meeting higher dip-test requirements are used in the more severe conditions of exposure.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR ZINC-COATED (GALVANIZED) STEEL WIRE STRAND, DESIGNATION A122-30, 1930

GALVANIZED STEEL WIRE STRAND

(See 603.42, p. 181.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR ZINC (HOT-GALVANIZED) COATINGS ON STRUCTURAL-STEEL SHAPES, PLATES, AND BARS, AND THEIR PRODUCTS, DESIGNATION A123-30, 1930

[Approved as tentative American Standard by the American Standards Association, 1930]

ZINC COATINGS ON STEEL SHAPES

SCOPE

1. (a) These specifications cover the protective zinc coatings, applied on structural-steel shapes, plates, and bars, and their products (note 1) by dipping the articles in a molten bath of zinc (note 2).

(b) These specifications presuppose the use of steel of recognized manufacture conforming to standard specifications.

CHEMICAL PROPERTIES

2. The slab zinc used shall conform to the requirements of the standard specifications for slab zinc (spelter), A. S. T. M., B6 (see 683.1, p. 1310.), and shall at least be equal to the grade designated as "prime western."

3. The amount of lead or iron in the bath during actual galvanizing operations shall not exceed the limits allowed for "prime western" slab zinc (spelter) namely, lead 1.60 per cent and iron 0.08 per cent. The aluminum content shall not exceed 0.01 per cent.

4. (a) The analyses for impurities in the bath shall be made on specimens which are combinations of borings from at least three test ingots taken during actual operations. Samples for test ingots shall be taken on the center line of the pot, one at the middle and the other two at opposite ends of the pot, but not nearer the ends than one-half the width of the pot. The samples shall be taken from a depth of at least 2 inches below the surface of the zinc but not greater than 25 per cent of the depth of the zinc.

(b) The implements and molds used shall be of materials which will not change the proportions of lead, iron, or aluminum in the test ingot.

(c) The cost of analyzing samples of the zinc bath shall be paid by the purchaser.

PHYSICAL PROPERTIES AND TESTS

5. (a) The finished material shall not be embrittled. (Note 3.)

(b) The purchaser shall bear the expense of making all embrittlement tests and the responsibility for delays in shipment incidental thereto.

6. The weight of the zinc coating per square foot of actual surface shall not average less than 2 ounces, and no individual specimen shall show less than 1.8 ounces.

7. (a) Test specimens shall be selected from the material being galvanized and shall be galvanized at the same time, in the same manner, and in the same pot as the material whose coating characteristics they are intended to indicate. If the lot of material is of inconvenient lengths, pieces of the same shape but of convenient lengths for handling (at least 3 feet long) may be substituted as test specimens. (Note 4.)

(b) Three specimens may be required from each shift for carrying out the determination of the weight of coating as described in section 8.

(c) No test specimen shall be used for the determination of the weight of coating which would fail to conform to other requirements of these specifications.

8. (a) The weight of the zinc coating shall be determined by weighing one or more specimens after pickling and drying and again after coating.

(b) In the case of material manufactured without inspection, the weight of coating may be determined by stripping an entire piece in accordance with the standard methods of determining weight of coating on zinc-coated articles, A. S. T. M., A90, given above.

WORKMANSHIP AND FINISH

9. The zinc coating shall be adherent, smooth, continuous, and thorough. It shall be free from such imperfections as lumps, blisters, gritty areas, uncoated spots, acid and black spots, dross (note 5), and flux. The coating shall not be so loosely adherent as to be removable by any reasonable process of handling and erection. Light blows with a one-half-pound hammer shall not cause peeling of the coating adjacent to the area deformed by the hammer blow. The coating shall not interfere with the intended use of the material.

10. After immersion in the molten zinc, the structural shapes, plates, or bars shall not be subjected to any process of scraping or wiping which will reduce the uniformity or the specified weight of the zinc coating.

11. The uniformity of the zinc coating shall be determined by visual inspection. If, in the opinion of the inspector, visual examination is not conclusive, he may use the Preece test as described in the appendix to the standard methods for determining weight of coating on zinc-coated articles, A. S. T. M., A90, given above. This test shall not be used to determine the weight of coating, and shall only be applied after the coating has been found to conform to the requirements of section 6. (Note 6.)

INSPECTION AND REJECTION

12. (a) (Inspection conforms to the requirements of A. S. T. M. standard specifications for steel, par. 7.) (See 605.0, p. 247.)

(b) The material shall be inspected at the manufacturer's plant during the process of manufacture. However, by agreement the purchaser may make the tests which govern the acceptance or rejection of the materials in his own laboratory or elsewhere; such tests shall be made at the expense of the purchaser.

13. (a) Visual inspection of materials ready for shipment shall be made to determine conformity with the requirements of section 9; when partial inspection warrants rejection of a lot, the manufacturer may re-sort the lot and submit it once again for inspection.

(b) If one specimen should fail to conform to the requirements specified in section 6 for the weight of

coating, a second and a third specimen shall be tested. Failure of either the second or third specimen to conform to the requirements shall be cause for rejection of the lot which the samples represent.

(c) Materials that have been rejected may be stripped and regalvanized and again submitted for test and inspection when they shall conform to the requirements of these specifications; otherwise the entire lot shall be rejected.

NOTE 1.—The use of the word "products" is not meant to imply an unqualified indorsement of the indiscriminate practice of applying zinc coatings on assembled parts.

NOTE 2.—The zinc coating on the materials covered by these specifications is too heavy to permit bending and other severe fabrication of the galvanized article without seriously damaging the coating.

NOTE 3.—Steels are encountered which are susceptible to embrittlement by the normal hot-dip galvanizing processes. Such embrittlement may depend on properties inherent in the steel, or on a method of cold working the material, or on the galvanizing processes.

The present state of the art being such that embrittlement can not be controlled and it being the belief that the causes and remedies can only be ascertained through cooperative research by the parties interested, these specifications do not unqualifiedly reject embrittled materials. Therefore, if, despite precautions taken by the manufacturers in the galvanizing and in the selection of the steel, embrittlement results, rejections are not to be enforced unless the liability is specifically provided for by contractual agreement between the purchaser and the manufacturer.

NOTE 4.—The use of convenient lengths of material for test specimens should not be interpreted to mean that small pieces of flat plate or odd shapes can be substituted for test specimens. Practice has shown that coupon specimens do not give true indications of the weight of coating on the shapes.

NOTE 5.—It is highly desirable to keep the materials being coated from coming in contact with the dross, and in all cases where practicable such contact should be avoided. Every practice tending to agitate the dross should be avoided.

NOTE 6.—Accepted experience indicates that the minimum weight of coating to be applied under these specifications will be removed in from 7 to 9 one-minute dips, and the average weight of coating in from 8 to 10 one-minute dips.

ASPHALT SHINGLE AND ROOFING INSTITUTE, NAILS, ACCELERATED CORROSION TEST, 1923

(For A. S. R. I. specifications on zinc-coated nails see 608.11, p. 558.)

CORROSION TEST

The salt-spray test shall be used for this purpose as described in circular No. 80, Bureau of Standards, Department of Commerce, Washington, D. C., issued October 4, 1919, page 24, which is as follows:

The test is made in a box with a glass cover, the construction of which is indicated in Figure 41.

The box is inclined so that drops of solution collecting on the cover will run down to the edge instead of dripping on the samples.

A 20 per cent solution (by weight) of commercial sodium chloride (20 g salt and 80 cm³ water, or 2 pounds salt and 1 gallon water) filtered if necessary, is used, and with an air pressure of about 6 or 7 pounds per square inch, a very fine mist is produced.

The compressed air is passed through a glass-wool or cotton plug and then through water to remove oil and dust, and to saturate the air with water vapor which prevents concentration of the salt solution and crystallization of the salt on the tips of the atomizer. The baffle plate prevents the salt spray from blowing directly against the test pieces.

The samples, after being washed with gasoline and ether to remove all grease, are placed in the spray box in a vertical position on the glass rods or strips. They are removed from the bath every 24 hours, washed with water, using a moderately stiff bristle brush, and after drying are carefully examined for the presence of red or yellow iron rust. The first appearance of rust indicates the conclusion of the test, but valuable information may be obtained by continuing the test and observing the extent of the corrosion produced by longer exposure.

ASPHALT SHINGLE AND ROOFING INSTITUTE, NAILS, ZINC IN PROTECTIVE COATING, 1921

(For A. S. R. I. specifications on zinc-coated nails see 608.11, p. 558.)

ZINC IN PROTECTIVE COATING

The hydrochloric acid-antimony chloride method is recommended for this purpose. Select 100 nails at random from the shipment. Weigh these in aggregate and calculate the average weight per nail. Select ten nails from the hundred taken, of which the weight per nail will not vary more than 2

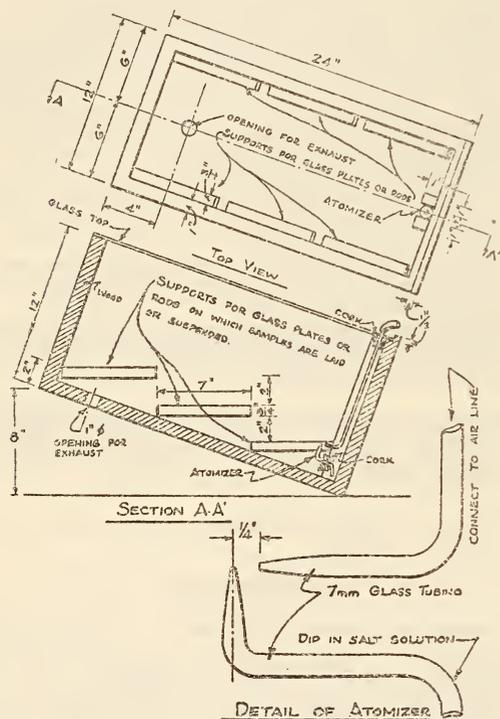

FIGURE 41.—Apparatus for salt spray test

per cent from the average calculated. Test these nails individually as follows:

Calculate the area of the nail's surface in square inches in the following manner:

If a represents the diameter of the nail head measured in inches; b the average length of the shank measured in inches; c the diameter of the shank measured in inches, then:

Area of nail's surface in square inches

$$= \frac{11}{7} a^2 + \frac{22}{7} bc$$

The apparatus as shown in Figure 42 consists of a separatory funnel (A) connected with the open end of a burette (B) by means of a stout rubber tubing (C) and rubber stopper (D) carrying a glass tube (E). The funnel should have a mouth sufficiently large to allow the nail to be introduced. This opening should be closed with a rubber stopper (F) through which passes a thistle tube (G) provided with a glass stopcock (H). The apparatus is connected up as follows:

Introduce the nail into the separatory funnel (A) and fill the apparatus with water to displace all the

air in the funnel (A), the rubber tubing (C) and the burette (B). Place in the thistle tube (G) a mixture of 30 c c of concentrated hydrochloric acid (specific gravity 1.20) and 3 c c of a 5 per cent solution of antimony chloride and allow about 10 c c to enter the funnel (A). As soon as hydrogen is generated, admit the rest of the mixture to the funnel. When the evolution of hydrogen ceases, or only a bubble of gas comes every few seconds, invert the burette to displace the hydrogen into the burette. The end-point is fairly sharp so that it is easy to distinguish the moment the zinc is all in solution and the iron or steel base begins to be slowly attacked by the acid. Return the funnel to its original position and allow the contents to cool to 20° C. Open the stopcock (H), bring the liquid in the funnel to the same level as the liquid in the burette, and read off the volume of hydrogen in the burette (B). Calculate the ounces of zinc per square foot nail surface from the following formula:

Ounces zinc per square foot =

$$\frac{H \text{ (in c c at } 20^\circ \text{ C. and } 760 \text{ mm)} \times 0.0138176}{\text{Area of nail's surface (square inches)}}$$

The method is claimed to be accurate to within 0.05 ounces per square foot. The average weight of zinc on the 10 nails examined should be reported as the average weight of zinc on the shipment under examination.

The committee is unconvinced of the value of lead in the protective coating and regards its pres-

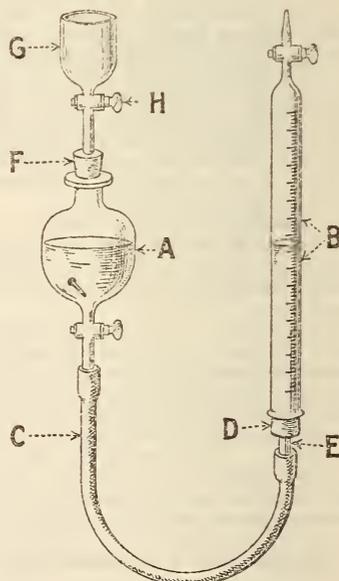

FIGURE 42.—Apparatus for determining zinc

ence with skepticism. The hydrochloric acid-antimony chloride method does not take into consideration any lead carried in the zinc coating and is favored for this reason:

**SOCIETY OF AUTOMOTIVE ENGINEERS,
ELECTRICAL EQUIPMENT; FLEXIBLE-
CONDUIT FERRULES, S. A. E. STAND-
ARD, AUGUST, 1928**

FLEXIBLE-CONDUIT FERRULES

(See 645.22, p. 1215.)

UNDERWRITERS' LABORATORIES, STANDARD FOR RIGID STEEL CONDUIT, APRIL, 1931

PROTECTIVE COATINGS

1. Both inside and outside surfaces of rigid steel conduit shall be protected against corrosion, and the character and appearance of the coating on the inside surface shall be such that conduit can be readily distinguished from ordinary commercial pipe commonly used for other than electrical purposes. Coatings other than enamel or zinc as described below shall be made the subject of special investigation before being used.

2. *Zinc coating.*—The zinc coating on either the interior or exterior surface of conduit shall be of standard weight and quality to afford protection against corrosion. If the interior surface does not have a standard zinc coating it shall have a standard enamel coating.

3. The protective zinc coating on rigid steel conduit is generally applied by the electroplating, by the sherardizing, or by the hot-dip process. The zinc is always applied to the outside surface, but the coating on the interior surface may be either zinc or enamel.

4. An additional coating of enamel, varnish, or other substance may be used in order to distinguish conduit from ordinary commercial pipe, as required in paragraph 1, when the interior surface has a zinc coating. When used for this purpose or for other reasons, the additional coating or coatings will not need to meet the requirements for standard enamel and shall not be considered as furnishing corrosion protection for the steel tube.

5. At any time up to one year from the time of manufacture the zinc coating on either the inside or outside of finished conduit shall be of uniform quality throughout, shall have a smooth and even appearance, and shall not soften at ordinary temperatures.

6. Compliance of conduit with the requirements of the preceding paragraph shall be determined by visual inspection.

7. *Elasticity.*—The zinc coating shall be sufficiently elastic to prevent its cracking or flaking at any time up to one year from the time of manufacture when a sample of finished ½-inch conduit is bent in a semicircle, the inner edge of which has a radius of 3½ inches.

8. Compliance of conduit with the requirement of the preceding paragraph shall be determined by means of a suitable form as shown in Figure 43, and when so tested the zinc shall not crack or fly off at any point on either the inside or outside surface of the conduit.

9. The requirement of paragraph 7 does not apply to enamel or other substance applied to an interior zinc coating for the purpose of distinguishing the conduit from ordinary commercial pipe, nor to additional coatings of enamel or other substance applied to either interior or exterior zinc coatings.

10. *Adequacy of zinc coating.*—The zinc coating shall be such that a sample of finished conduit will not show a fixed deposit of copper after the prescribed number of immersions or dips in a standard copper sulphate solution in accordance with the following table:

11. *Preparation of sample.*—A piece of finished conduit approximately 4 inches in length and free from abrasions is to be used. The end to be immersed is closed with a rubber stopper as shown in Figure 44. All grease and paraffin are removed by washing the sample in carbon tetrachloride or chloroform, and, when the zinc coating is covered with paint or varnish, this also is removed with a suitable solvent. Finally the sample is rinsed in water and dried with clean cheesecloth. The zinc surface is to be perfectly clean before the sample is immersed in the copper sulphate solution, due care being exercised to avoid contact of the cleaned surface with the hands or any foreign materials.

12. *Standard copper sulphate solution.*—The copper sulphate solution shall have a specific gravity of 1.186 ± 0.003 at 65° F. (approximately 18° C.), and shall be prepared according to the following directions:

13. Approximately 350 g of C. P. copper sulphate (CuSO₄·5H₂O) are weighed out for each liter of standard solution to be prepared. The required volume of distilled water is measured into a copper vessel and heated nearly to boiling. The weighed crystals of copper sulphate are then added slowly

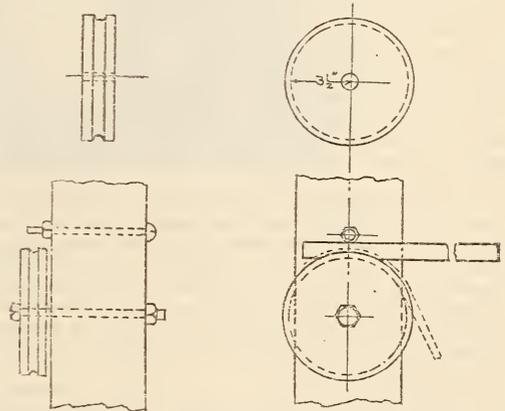

FIGURE 43.—Form for bending one-half inch conduit

and the solution stirred with a wooden rod. Approximately 1 g of cupric oxide (CuO) per liter of water used shall be added to neutralize any free acid. The solution is stirred until the crystals are dissolved and then allowed to cool for a few minutes. About 200 c c of the solution is filtered into a hydrometer cylinder, the temperature of the solution noted, and the specific gravity determined by means of a hydrometer. In case the temperature of the trial solution is somewhat above 65° F. when the hydrometer reading is taken, the specific gravity of the solution at 65° F. (approximately 18° C.) can be computed by reference to a specific gravity-temperature chart. From the specific gravity of the trial solution, the required amount of water to be added in order to obtain a solution of standard strength can be calculated according to the following formula:

$$X = 1.15 \frac{(A - 1.186) V}{0.186}$$

where

- X = number of cubic centimeters of water to be added;
- A = specific gravity of the trial solution at 65° F. (18° C.);
- V = number of cubic centimeters of water used in making up solution.

Kind of coating	Number of dips after which fixed copper deposit shall not show
Electroplated, with or without copper subcoat.	2
Sherardized.....	2
Hot-dipped and wiped.....	4

In case $V=35,000$ c c, a chart may be employed in calculating the volume of water to be added to obtain a solution of standard strength.

14. The calculated amount of water and the trial solution are added to the original solution, which is then thoroughly stirred, filtered, and tested again as described above. Not less than 24 hours should elapse between the addition of the cupric oxide and the final filtration of the solution. The solution is considered standard when its specific gravity is 1.186 ± 0.003 at 65° F. (18° C.). The standard solution is to be stored in glass-stoppered bottles labeled to show the specific gravity of the solution and the date of its preparation.

15. *Method of immersion.*—A glass vessel having a diameter approximately twice as great as the outside diameter of the conduit is filled with the standard solution to a depth sufficient to immerse $2\frac{1}{2}$ inches of the length of the sample, the temperature of the solution being approximately 65° F. The sample is then placed in a vertical position with the closed end at the bottom in the center of the vessel containing the solution, so that not less than 2 inches of the length is immersed. The sample is allowed to remain in the copper sulphate for a period of 60 seconds, during which time it is not to be removed, nor the solution stirred. At the end of the 60-second period the sample is removed from the vessel, immediately washed in a stream of running water, and rubbed with cheesecloth until any loosely adhering deposits of copper are removed. The sample is then dried with clean, dry cheesecloth, care being taken to avoid contact of the cleaned surface with foreign objects, particularly the hands.

16. The operation just described, including the immersion or dipping and the washing and wiping, is to be successively repeated, using the same copper sulphate solution, until a bright deposit of firmly adhering reguline copper remains on the sample. The sample is to be subjected to at least one more dip than the minimum number required for acceptable performance for the kind of coating in question as given in paragraph 10.

17. The fixed deposit of reguline copper generally occurs first at the weakest points in the zinc coating and increases in area upon successive dips, until the entire zinc coating disappears. After the dips have been completed on any one sample, the used copper sulphate solution is to be discarded and a fresh portion of the standard solution employed for any succeeding immersions.

18. *Test results.*—The results are to be expressed as an estimate of the percentage of the immersed surface which shows a fixed copper deposit after each dip—after the sample has been washed, rubbed, and dried. Failure is to be recorded for any sample on which the fixed copper deposit appears as the result of a number of dips equal to or less than the number given in paragraph 10 for the kind of coating in question.

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR ROPE, WIRE, NO. 297, 1925. (CURRENT DESIGNATION: RR-R-571)

WIRE ROPE

(See 603.42, p. 183, for galvanized wire rope.)

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR PLUMBING FIXTURES (FOR LAND USE), NO. 448, NOVEMBER 22, 1926. CURRENT DESIGNATION: FF-P-451)

(See also 617.73, p. 1062.)

PLUMBING FIXTURES (FOR LAND USE)

(i) *Nickel plating.*—The average thickness of nickel on articles subject to abrasion, such as faucet handles, toilet-door latches, coat hooks, etc., shall be not less than 0.0002 inch; and on articles not subject to abrasion, such as pipe, escutcheons, etc., shall be not less than 0.0001 inch. A tolerance of 10 per cent shall be permitted in these values to allow for uncertainties in measurement. These thicknesses are equivalent, respectively, to 0.144 ounce and 0.072 ounce per square foot, plating about one hour and one-half hour, respectively.

(j) *Test of nickel plating on brass.*—The area of the piece should be measured as closely as possible. It is then cleaned by immersion in an alkaline solution, rinsed, and hung in a solution containing about 10 per cent by volume of chemically pure concentrated hydrochloric acid. The article is connected as the anode and a strip of lead is made the cathode. A current is applied at 4 to 6 volts, until all the nickel is dissolved, usually in from one to two minutes. The resultant solution is diluted to a measured volume (for example, 250 c c) and a definite portion (for example, 10 c c) is used for the determination of the nickel content by the dimethylglyoxime method. If the area has been measured in square centimeters, the results can best be calculated to grams per 100 square centimeters or to thickness in millimeters, which may then be converted to ordinary units—

$$\frac{\text{Weight of nickel (g)}}{\text{Area of sample (cm}^2\text{)}} \times 100 = \text{g per 100 cm}^2 \text{ (g/dm}^2\text{)}$$

$$\text{g/dm}^2 \times 0.0115 = \text{thickness in millimeters.}$$

$$\text{Thickness (mm)} \times 0.039 = \text{thickness in inches.}$$

$$\text{g/dm}^2 \times 0.328 = \text{ounce per square foot.}$$

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR BUILDERS' HARDWARE (NONTEMPLATE), FF-H-101, AUGUST 19, 1930

BUILDERS' HARDWARE (NONTEMPLATE)

(For applicable Federal specifications; types, grades, and classes; material and workmanship; general requirements; detail requirements; packaging, packing, and marking; notes; and table of standard finishes; see 617.0, p. 978.)

(Specific commodities, such as locks, latches, hinges, door pulls, etc., will be found under their respective commodity designations. For a list of these commodities see under detail requirements in 617.0, p. 979.)

D-6. *Chromium plating.*—

D-6a. *Chromium plating on nonferrous metals.*—Chromium plating on nonferrous metals shall be applied over a coating of nickel. The specification for this procedure is as follows: Chromium plating

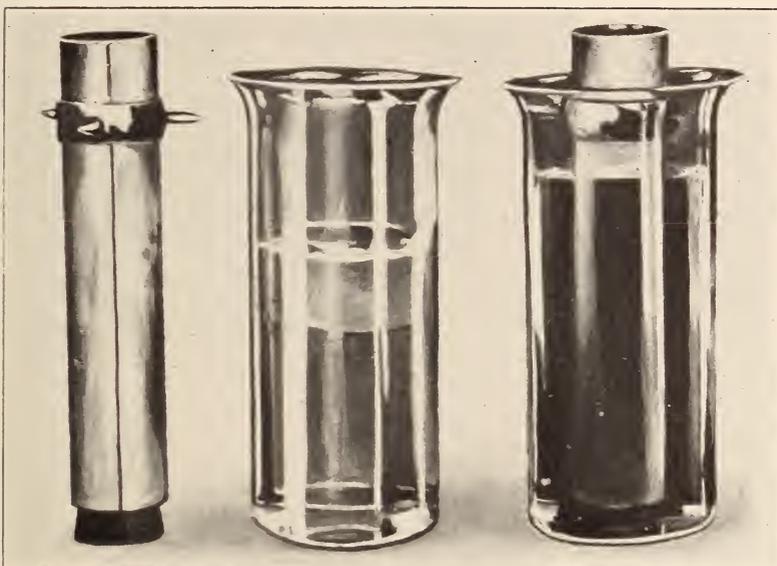

FIGURE 44.—Test sections of conduit before and during immersion in copper sulphate solution
(For specification see p. 69.)

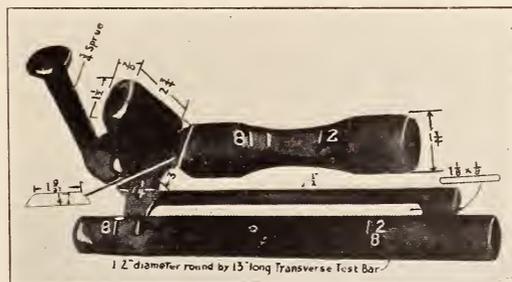

FIGURE 392.—Mold of tension and transverse test specimens
(For specification see A. S. T. M., A126, p. 637.)

over nickel plating on nonferrous metals. The nickel coating shall have an average thickness of at least 0.0001 inch (0.0025 millimeter) and the chromium coating of at least 0.00002 inch (0.0005 millimeter). These are equivalent, respectively, to 0.074 ounce per square foot (0.22 g/dm²) of nickel and 0.011 ounce per square foot (0.034 g/dm²) of chromium. A tolerance of 20 per cent shall be permitted on individual pieces, and of 10 per cent on the average of three or more samples from the same lot or shipment.

D-6b. Chromium plating on polished steel.—Chromium plating on polished steel shall be applied over a coating of nickel which has been applied over base plate of cadmium. The chromium and nickel shall be applied as required for plating on nonferrous metals. (See paragraphs D-6a and D-7a.) The requirement for cadmium plating is as follows: Cadmium plating on polished steel. The average thickness of cadmium shall be not less than 0.00013 inch. This thickness is equivalent to 0.11 ounce per square foot (0.34 g/dm²) of cadmium. A tolerance of 20 per cent shall be permitted on individual pieces and of 10 per cent on the average of three or more samples from the same lot or shipment.

D-7. Nickel plating.—

D-7a. Nickel plating on nonferrous metals.—The average thickness of nickel when plated on nonferrous metals shall be not less than 0.0001 inch. This thickness is equivalent to 0.074 ounce per square foot (0.22 g/dm²) of nickel. A tolerance of 20 per cent shall be permitted on individual pieces, and of 10 per cent on the average of three or more samples from the same lot or shipment.

D-7b. Nickel plating on polished steel.—Nickel plating on polished steel shall be applied over a suitable base plate, such as cadmium or copper. The combined thickness of nickel and the base plate shall be not less than 0.00015 inch. This combined thickness is equivalent to 0.107 ounce per square foot (0.33 g/dm²) of nickel. A tolerance of 20 per cent shall be permitted on individual pieces, and of 10 per cent on the average of three or more samples from the same lot or shipment.

D-8. Zinc coatings.—

D-8a. Zinc coatings on iron or steel—galvanized or sherardized.—The word "galvanized" where used in the detail specifications is intended to include the application of zinc by hot dipping, sherardizing, or zinc plating (electro galvanizing), provided that hot dipping and sherardizing shall not be applied on such alloy or heat-treated steels as will be injuriously affected at the temperatures employed. For such steels the zinc-plating process shall be used.

D-8b. The average thickness of zinc coating shall be not less than 0.001 inch or 0.60 ounce per square foot. On accurately dimensioned parts such as screw threads the average thickness of zinc coating shall not exceed 0.002 inch or 1.20 ounces per square foot.

D-9. Illustrations.—Illustrations in the specifications show only the type of the various devices. However, a construction other than that illustrated or described shall constitute a full commercial equivalent of the one shown in order to be acceptable. Illustrations precede the descriptions in every instance.

E. DETAIL REQUIREMENTS

(Sec. 617.0, p. 978.)

F. METHOD OF INSPECTION AND TESTS

F-2. Chromium plating.—

F-2a.—Test of chromium plating on brass or nickel-plated brass. The area of the piece should be measured as closely as possible. It is then cleaned by immersion in an alkaline solution, rinsed, thoroughly dried and weighed to the nearest milli-

gram for each square decimeter (about 16 square inches) of surface. It is then completely immersed in a solution containing about 10 per cent by volume of chemically pure concentrated hydrochloric acid, which has been warmed to about 50° C. (120° F.). When all the chromium has dissolved, as indicated by the ceasing of effervescence (usually in five minutes or less) the articles are removed, thoroughly rinsed, dried, and reweighed. The loss in weight is equal to the weight of chromium originally present.

Weight of chromium (g)
Area of sample (cm²) × 100 = g per square decimeter (g/dm²)

g/dm² × 0.0147 = thickness of chromium in millimeters.

Thickness (mm) × 0.039 = thickness in inches.

g/dm² × 0.328 = ounces per square foot.

F-2b.—After the chromium plating has been removed from nickel-plated brass, the nickel may be determined on the same sample by the method described below.

F-3.—*Nickel plating.*—

F-3a.—(Identical with test of nickel plating on brass in FF-P-451, given above.)

F-4.—Solid nickel-bronze trimmings and fittings will be acceptable in lieu of nickel-plated brass.

F-5. Zinc coatings.—Hydrochloric acid-antimony chloride method of determining thickness. The solution is prepared by adding 100 cubic centimeters concentrated hydrochloric acid (specific gravity 1.20) to 5 cubic centimeters of a solution made by dissolving 20 grams of antimony trioxide in 1,000 cubic centimeters of concentrated hydrochloric acid. A sufficient number of specimens should be used in each test to have an area not less than 25 square centimeters (4 square inches). The specimens are weighed carefully and then dipped in sufficient of the above solution to cover them completely. The samples are kept in the solution for one minute, or longer if necessary, to remove all of coating. They are then washed and scrubbed in running water to remove the deposited antimony. They are then dried and reweighed. The loss in weight represents the weight of the zinc coating, which is calculated directly to grams per square decimeter or to ounces per square foot (g/dm² multiplied by 0.328). On irregular-shaped parts the zinc may be expressed in grams per piece.

600.4 DEFINITIONS OF METALS.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD DEFINITIONS OF TERMS RELATING TO WROUGHT-IRON SPECIFICATIONS, DESIGNATION A81-30, 1930

WROUGHT-IRON SPECIFICATION DEFINITIONS

Wrought iron.—A ferrous material, aggregated from a solidifying mass of pasty particles of highly refined metallic iron with which, without subsequent fusion, is incorporated a minutely and uniformly distributed quantity of slag.

Busheling.—The process of heating to a welding heat in a reverberatory furnace, miscellaneous iron, steel, or a mixture of iron and steel scrap cut into small pieces.

Fagoting.—The making of a "fagot" or "box," the bottom and sides of which are formed of muck or scrap bars and the interior of miscellaneous iron scrap or a mixture of iron and steel scrap.

Muck bar or puddled bar.—Bar rolled from puddled balls, made wholly from puddled pig iron.

Common iron.—Iron made from rerolled scrap iron or a mixture of iron and steel scrap, no attempt being made to separate the iron and steel scrap.

Slab pile.—A pile built up wholly of flat bars of iron, all bars running the full length of the pile.

Box pile.—In manufacturing wrought-iron bars, a pile, the outside of which is formed of flat bars and the interior of a number of small bars, all bars running the full length of the pile.

Refined bar iron or refined wrought-iron bars.—Iron bars rolled from a muck bar pile or from a box pile, of muck bars and wrought iron scrap bars free from steel, all bars running the full length of the pile.

Double-refined iron.—Iron rolled from a slab pile or box pile of refined iron bars, all bars running the full length of the pile.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD DEFINITIONS OF TERMS RELATING TO METALLOGRAPHY, DESIGNATION E7-27, 1927

METALLOGRAPHY DEFINITIONS

(See 600.1, p. 34.)

SOCIETY OF AUTOMOTIVE ENGINEERS, IRON AND STEEL SPECIFICATIONS, GENERAL DEFINITIONS, JUNE, 1927

GENERAL DEFINITIONS

1. *Cold working.*—The operation of forming the metal, without the application of heat, by rolling, hammering, drawing, pressing, or other means, to obtain accurate size, fine finish, or increased strength.

2. *Hot working.*—The operation of rolling, hammering, pressing, or extruding metal which has been made plastic by heating.

3. *Yield point.*—The load per unit of original cross section at which a marked increase in the deformation of the specimen occurs without increase of load. It is usually calculated from the load determined by the drop of the beam of the testing machine or by use of dividers.

4. *Tensile strength.*—The maximum load per unit of original cross-sectional area obtained before rupture.

5. *Percentage elongation.*—The percentage of increase in length of a tension-test specimen after rupture.

6. *Percentage reduction of area.*—The percentage of decrease of cross-sectional area of a tension-test specimen after rupture.

7. *Shore hardness.*—The reading on a conventional scale determined by the rebound of the hammer of the Shore scleroscope on striking the surface of the specimen.

8. *Brinell hardness.*—The number obtained from the ratio between the load applied on and the spherical area of the impression made by a steel ball forced into the surface of the material tested.

600.5 HEAT TREATMENT OF METALS

AMERICAN SOCIETY OF MECHANICAL ENGINEERS, A BIBLIOGRAPHY ON EFFECT OF TEMPERATURE ON THE PROPERTIES OF METALS, 1928

TEMPERATURE AND METALS

(A pamphlet containing 307 separate items on the effect of temperature both on ferrous and on non-ferrous metals. In a subject index the effect of temperature is divided into two groups. In one

group the time factor controls, but has no part in the other group. Thus divided, both ferrous and nonferrous metals are considered in terms of tensile creep, elasticity, apparatus and methods, service tests and requirements, chemical action—theoretical and general. In addition, ferrous metals connote compression and shear, hardness, shock, expansion, and heat conduction.)

AMERICAN SOCIETY FOR STEEL TREATING, DEFINITIONS OF TERMS RELATING TO HEAT-TREATMENT OPERATIONS, 1929

HEAT-TREATMENT DEFINITIONS

(Same as A. S. T. M., A119-30, given below.)

AMERICAN SOCIETY FOR STEEL TREATING, TENTATIVE GENERAL RECOMMENDATIONS FOR THE HEAT TREATMENT OF TOOL STEELS, 1929

HEAT TREATMENT OF TOOL STEELS

Purpose.—Much of the general procedure for the heat treatment of one type of tool steel is applicable to others. These general instructions are to avoid repetitions in the Recommended practices.

General.—Often when correct temperatures are used, many hardening failures result from improper manipulation during heat treatment. The heat treatments given in the Recommended practices apply specifically to certain types of steels, the basic compositions of which are given. This does not imply that such steels are the only suitable ones. These practices are primarily for the purpose of recommending heat treatments.

If more specific information is desired on any type of steel, it should be obtained from the supplier of the material.

Rate of heating.—The rate of heating for carbon tool steels is given in the Recommended practices for the heat treatment of plain carbon tool steels.

The rate of heating for alloy tool steels is proportionally slower than for plain carbon steels as the alloying content increases.

Charging furnace.—Cold tools should be charged at comparatively low furnace temperature. Sudden changes in temperature should be avoided, except where steels, such as high-speed, are changed from preheating furnaces to high-heating furnaces to obtain rapid heating. It is especially important to avoid sudden changes when reheating hardened steel, as breakage may result.

The steel should be placed in the furnace so as to expose the maximum surface. It is often advisable to place supports under the tool to raise it from the furnace bottom, thus allowing better heat circulation. An intricate tool should be supported in such a manner as to avoid warping.

Large sizes.—A range of temperature is usually given in recommendations for hardening heats. This does not imply that satisfactory results can be obtained on any tool if held anywhere within that range. Generally the larger pieces are heated to the high side of the range while small pieces are heated to the low side.

Uniform heating of tools.—Cylindrical tools or intricate parts that have a tendency to heat non-uniformly should be frequently rotated.

Holding at heat.—Care should be taken to hold the tool at temperature long enough to insure uniform heating throughout the section of the piece.

Usually steel of higher alloy content will require more time, as noted in specific Recommended practices. This gives a better solution of the constituents, but may cause some grain growth and surface decarburization, particularly at temperatures well above the critical range.

For the time of holding high-speed steel at quenching heat, see the Recommended practice covering this steel.

Furnace atmosphere.—Proper control of furnace gases is important. As far as possible a reducing atmosphere should be maintained at all times. Flames should not strike the steel.

Effect of scale.—If tool steel is heated above a low red heat while in contact with scale, even though in a neutral or reducing atmosphere, it will be decarburized. Therefore, care should be taken to keep steel, furnace hearth, and containers as free from scale as possible.

Thermocouples.—The thermocouple should be so placed that the flames do not strike it and so located as to indicate as nearly as possible the temperature of the tool.

It is generally better to insert the thermocouple through the end or side of the furnace rather than in the top. For specific instructions on pyrometry see the A. S. S. T. Handbook.

COOLING

Quenching medium.—The quenching medium should vary with the kind of steel treated as well as the speed of cooling necessary for various types of tools. Sufficient bath volume should be provided to maintain the quenching medium at proper temperature for uniform results. The use of air as a means of agitation and cooling for liquid baths is not recommended.

Oils.—Oils generally give best results when used between the temperatures of 75° and 125° F. Some oils crack or otherwise deteriorate faster than others; consequently, should be replaced as found necessary.

Water.—Water should be held at a fairly constant temperature, usually between 70° to 110° F. Fresh tap water is often aerated and may produce soft spots, so that water which has been previously boiled, or has been used frequently, is recommended. A strong stream of water will produce better results and help to throw the scale, while a spray sometimes gives more uniform results.

Brine.—Tools quenched in brine will more readily throw their scale, producing a cleaner surface of more uniform hardness.

Air.—Certain types of tool steels require air cooling. When using an air blast, it should be applied through a properly designed device and care should be taken to avoid the presence of water in the air line. If tools are cooled naturally (without blast) they should be supported so as to allow uniform cooling.

Quenching.—Tools should be quenched in such a manner that warping is at a minimum. When immersing tools avoid the formation of gas pockets by vigorous agitation or by jets. It is important that the cooling medium come in contact with all parts of the work to be hardened. Tools should usually be removed before reaching the temperature of the quenching bath. For specific instances see the Tool Steel Recommended Practice, below.

TEMPERING

Strains.—Tools, after removal from the quenching bath and before tempering, are always in a highly and nonuniformly strained condition and danger of cracking is most pronounced. Tools should not become cold before tempering.

Uniform tempering.—Satisfactory tempering results are obtained by heating slowly and uniformly

in a freely circulating medium. If a liquid is used, the tools should be placed in a metal basket for immersion which prevents contact with the sides or bottom of the container.

Charging the tempering furnace.—When charging tools for tempering, the heating medium should be at a low temperature and the tools still warm.

Rate of heating tools.—Tools should be brought to heat slowly to prevent rapid release of hardening strains and warpage. Better results are obtained by holding at a lower temperature for a longer time. Generally the length of time should not be less than one hour at temperature, but for specific steels reference should be made to the Tool steel recommended practices.

Cooling from tempering.—Slow cooling from the tempering operation is recommended, since rapid cooling may induce strains in the steel.

Tempering by color.—Temper colors are the result of slight oxidation of the surface of steel when heated at low temperatures, and are dependent upon time as well as temperature. They are only indicative of the temperature of the surface and do not indicate that the steel has been heated uniformly throughout. Tempering by color is not conducive to uniformity. When necessity requires that tools be tempered by color they should be heated slowly as in other operations and the heat raised progressively to the point or color after which further tempering is usually stopped by quenching or withdrawing from the heating medium. The quenching should be done in the least drastic manner, preferably in oil.

NORMALIZING

Cementite segregates.—Normalizing implies heating steel far enough above the critical range to carry all cementite into solution and when this is done, it is followed by air cooling; cementite segregates may thus be broken up and a more uniform distribution obtained. This operation is more important on pieces that have been forged and should not be necessary on any material that has been annealed.

Rate of heating.—Heating tools for normalizing should be done in a manner similar to that of hardening.

Correct soaking time is proportional to the size of the piece. Prolonged soaking will coarsen the grain, rendering subsequent refinement difficult.

Rate of cooling.—The material is cooled from the normalizing temperatures in still air.

ANNEALING

Purpose.—Tool steel is annealed to soften it for machining, forming, and grain refinement.

Packing.—When the pieces are small it is advisable to pack them in charcoal to prevent scaling, decarburization, and too rapid changes of temperature. Care must be taken to keep the steel from contact with the container, and to avoid the presence of scale.

Heating.—Heat slowly and uniformly to the temperature desired. (See also specific Recommended practices.)

Holding at heat.—Hold at the annealing temperature long enough for complete penetration of heat and readjustment of grain. The time will increase with the weight of the charge and the alloy content of the steel.

Cooling.—Cool slowly, preferably in the furnace, or in mica or other good heat insulating material. In general, the slower the cooling, particularly through the critical range, the softer the steel. As the alloy content of the steel increases the slower the steel must be cooled.

Strain removal.—Heating is sometimes carried out at a temperature below the critical range for pur-

poses of strain removal. This operation is beneficial as a preparatory treatment for hardening tools on which considerable machining has been done. This treatment should be performed after the rough machining operations, but before heating for quenching.

Warping.—The amount of warping on hardening is dependent on the shape of the tool, the kind of steel, the conditions of heating, and the severity of the quench. In general, in water hardening, steels warp more than in oil hardening, and long, thin tools more than short, heavy ones.

Some causes of undue warp are improper tool design, the use of the wrong type of steel, nonuniform or too rapid heating, improper support of the steel while heating, heavy machining, cold-working strains, insufficient removal of surface, improper manner of quenching, nonuniform quenching, and nonuniform or too rapid tempering.

Soft spots.—Common causes of soft spots are decarburization, improper heating, quenching or bath agitation, gas pockets, tong contact, adhering scale, insufficient removal of surface, or defective furnace bottoms.

Straightening.—When necessary to straighten, the operation should be performed when quenching on the descending heat. The tool may change somewhat in the tempering operation, but the peening required will not be nearly as much as if the tools are straightened on the quenching heat. A continuous press should be available with an adjustable control and knife-edge rests, so that if one load does not satisfactorily straighten the tool another load can immediately be applied. For straightening on the descending heat, the tools should be withdrawn from the bath at a temperature from 500° to 600° F., which is just below the point where the oil ceases to flash, or in the case of water-quenched tools, just where the water steams or dries off the tools immediately.

AMERICAN SOCIETY FOR STEEL TREATING, RECOMMENDED PRACTICE FOR THE HEAT TREATMENT OF PLAIN CARBON TOOL STEEL, 1925

HEAT TREATMENT OF PLAIN CARBON TOOL STEEL

General.—This recommended practice covers the process to be followed in the heat treating of plain carbon tool steel.

NORMALIZING OF TOOL STEEL BEFORE HARDENING

Operations.—Heating and cooling.

Heating.—Place steel in furnace so as to expose maximum surface area. Heat uniformly to a temperature above the upper critical point, as given in Table 1, and hold at this temperature for sufficient time to obtain complete penetration of heat and for complete refinement of grain.

Cooling.—Remove from furnace and cool freely in air.

TABLE 1.—Normalizing temperature and carbon range

Carbon	° F.
0.65 to 0.80 per cent.	1,475-1,525
.80 to .95 per cent.	1,475-1,500
.95 to 1.10 per cent.	1,500-1,575
1.10 to 1.25 per cent.	1,575-1,650

CROSS SECTIONS, WEIGHT, AND TIME

Thickness of largest section of unit	Weight of unit in pounds (approximate)	Time of heating, in hours (approximate)	Time of holding, in hours (approximate)
Up to and including 1 inch.	Up to 100.....	$\frac{3}{4}$	$\frac{1}{2}$
Over 1 inch and including 2 inches.	Over 100 and including 300.	1 $\frac{1}{4}$	$\frac{1}{2}$
Over 2 inches and including 3 inches.	Over 300 and including 500.	1 $\frac{3}{4}$	$\frac{3}{4}$
Over 3 inches and including 4 inches.	Over 500 and including 1,000.	2 $\frac{1}{4}$	1
Over 4 inches and including 5 inches.	Over 1,000 and including 1,500.	2 $\frac{3}{4}$	1

HEAT TREATING OF PLAIN CARBON TOOL STEEL

Operations.—Heating for quenching, quenching, and tempering.

Heating.—Heat the steel uniformly to the temperature as given in Table 2.

Quenching.—Quench from this temperature in water, but do not cool below temperature of boiling water (212° F.).

TABLE 2.—Quenching temperatures

[Quenching temperature, water at 70° F.]

Carbon range, per cent.	0.65-0.80	0.81-0.95	0.96-1.10	1.11-1.25
Hardening temperature, °F.	1,550-1,450	1,460-1,410	1,300-1,430	1,380-1,420

Tempering.—Reheat immediately in oil, salt (NaNO₃), or furnace for the time and at the temperature specified in Table 3 and cool.

TABLE 3.—Tempering temperatures

Results desired	Tempering medium	Temperature
Relieving strains.....	Oil.....	° F. 350-375
Relieving strain and reducing brittleness.....	do.....	400-500
To relieve strains and to toughen.....	do.....	500-600

NOTES ABOUT THE PROCESS

General.—The recommended practice for the heat treatment of tool steel applies to the highest quality performance of tools for general purposes only. For specific applications, where special structural requirements seem to be necessary, deviation from the recommended practice must be left to the judgment of the individual.

Normalizing.—A normalizing treatment for all tool steels is recommended to obtain a uniform and refined grain structure, which enables the operator to predict the behavior and performance of the tool steel during heating and quenching for hardening.

The variation in temperature for the different carbon ranges becomes evident upon a careful examination of the critical-range diagram, as shown in Figure 45. A temperature very much in excess of that required to produce solid solution (austenite) is conducive to austenitic grain growth and intergranular weakness.

A low normalizing temperature for high-carbon steels (1.25 to 1.50 per cent carbon) which fails to

break up the massive cementite results in a brittle structure, since the rate of diffusion of the excess cementite depends upon the temperature. The solubility of carbide in iron being greater, or increasing as the temperature rises, the rate of this solubility is equivalent to the slope of the Ac_m line in the diagram. (Figure 45.)

The higher normalizing temperatures given in Table 1 apply to the lower carbon ranges and the lower temperatures to the higher carbon ranges for steel of the hypoeutectoid composition, or, in other words, "the normalizing temperature for hypoeutectoid steels varies indirectly as the carbon percentage rises or falls, and the normalizing temperature of hypereutectoid steels varies directly with the percentage of carbon."

Heating and quenching.—The wide range of temperature in the 0.65 to 0.80 per cent carbon steel is needed, as a number of tools, such as shear blades, arbor, mandrels, and others, are all around the low point, and because of mass and forms require somewhat higher temperatures for quenching.

The quenching temperatures given are at the lowest temperature range consistent with highest

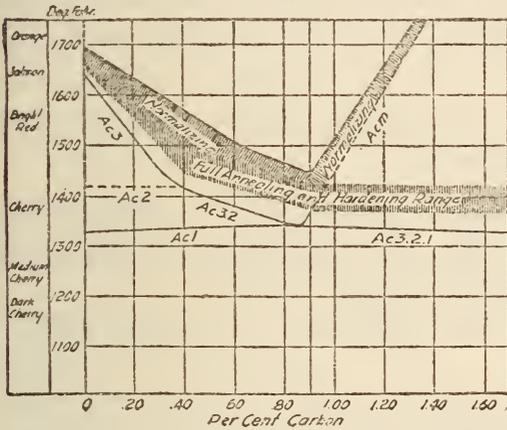

FIGURE 45.—Critical range diagram for iron-carbon alloys, showing normalizing, annealing, and hardening ranges

quality tools; deviations from it are not recommended, but may be practical for diverse reasons.

Quenching.—Water is the universal quenching medium and by varying its temperature and manner of application for the abstraction of heat, almost any degree of variation of structural conditions of the tool steel can be obtained. There are, however, special cases where oil may be a more suitable quenching medium.

CARBON STEELS SUITABLE FOR VARIOUS USES

Carbon content 0.65 to 0.85 per cent

Shear blades, boiler snaps and cups, hammers, stamping and pressing dies, mining drills.

Carbon content 0.81 to 0.95 per cent

Hot and cold sets, chisels, dies, shear blades, mining drills, smiths' tools, set hammers, swages, flatteners.

Carbon content 0.98 to 1.10 per cent

Small cold chisels, hot sets, small shear blades, large pinchers, large taps, granite drills, trimming dies, turning tools, planer tools, drills, cutters, slotting and milling tools, mill picks, circular cutters, threading dies.

Carbon content 1.11 to 1.25 per cent

Small cutters, small taps, drills, slotting and planing tools, wood-cutting tools, turning tools, razors, etc.

SUITABLE TEMPERING HEATS FOR VARIOUS TOOLS

Temperature 350° to 395° F.

Lathe tools for brass and copper alloys. Milling cutters for brass and copper alloys. Scraper and cutting tools for soft metals and micarta. Drawing mandrels, drawing dies, bone-cutting tools, hammer faces, steel engraving tools, wood-carving tools, cutting tools for iron and steel, hand tools, threading dies for brass.

Temperature 400° to 500° F.

Hand taps and dies, hand reamers, drills, bits, cutting dies, penknives, milling cutters, chasers, inserted sawteeth, press dies for sheet steel, rock drills, taps and dies, wire-drawing dies, dental and surgical instruments, twist drills.

Temperature 500° to 600° F.

Bending and forming dies, shear blades, chuck jaws, forging dies, drifts, gages, press dies, flat drills, reamers, chisels and tools for woodcutting, hammers and drop dies, axes, lathe tools for copper augers, cold chisels, coppersmiths' tools, grinders, screw drivers, molding and planing tools, hack saws, needles, butcher knives, saws.

AMERICAN SOCIETY FOR STEEL TREATING, RECOMMENDED PRACTICE FOR THE HEAT TREATMENT OF 18 PER CENT TUNGSTEN HIGH-SPEED STEEL, 1925

HEAT TREATMENT OF HIGH-SPEED STEEL

GENERAL

This recommended practice covers the process to be followed in the heat treating of high-speed steel.

ANNEALING

Heat slowly and uniformly to a temperature of 1,600° F. and hold for complete adjustment and for complete uniformity of grain. Cool in furnace, infusorial earth, mica, lime or any medium that will permit of uniform slow cooling.

HARDENING

(a) *Preheating.*—Heat slowly and uniformly to 1,500° F. in a furnace of sufficient size.

(b) *Heating for quenching.*—Transfer preheated steel to a high-temperature furnace that is maintained at a temperature of 2,250° to 2,400° F., depending on the type of tools being hardened.

In order to obtain the most satisfactory "red hardness" conditions, the steel should be brought rapidly to the higher temperature; but in many cases the character of the cutting edges of certain form tools, such as milling cutters, threading tools, etc., makes it inadvisable to use the higher temperatures owing to destruction of the delicate edges through blistering, pitting, etc. It is, therefore, usual to use the higher temperatures for tools such as rough lathe tools, while the finer class of tools is hardened at the lower temperatures.

High-speed-steel tools should not be held at the high heat longer than necessary, since holding at the high hardening temperatures causes excessive grain growth, with subsequent brittleness of the hardened tools.

Tools that can not be ground after hardening are often heated in a barium chloride or some such suitable salt bath.

Quench the steel in oil or air from the hardening temperature. It is advisable to maintain the oil quenching bath at a temperature of 150° to 200° F. to eliminate possibility of breakage with intricately shaped tools.

Tempering for secondary hardness.—Reheat uniformly in an open furnace, lead bath, or preferably in a sodium nitrate (NaNO₃) bath, or any other suitable salt bath, to a temperature of 1,050° to 1,150° F. for a sufficient length of time, and cool in air.

NOTES ABOUT THE PROCESS

Cooling from annealing.—Cooling in air should not be permitted, since air cooling from the annealing temperature is likely to result in partial hardening of the tool.

Heating for hardening.—It is the customary practice always to preheat for hardening in an open furnace, since preheating in a salt bath causes the salt to adhere to the tool, and the subsequent high temperature treatment causes unusual corroding from the adhering salt. Even preheating in lead is objectionable from small quantities of adhering lead. There is not much advantage to be gained in using a molten bath for the preheating, since the preheating temperature may vary over the comparatively wide range of 1,400° to 1,600° F., and an open furnace is invariably used in practice.

Quenching from tempering temperatures.—Quenching from the tempering temperatures is not advisable with high-speed steel.

AMERICAN SOCIETY FOR STEEL TREATING, RECOMMENDED PRACTICE FOR THE HEAT TREATMENT OF NONSHRINKING, NONDEFORMING, OIL HARDENING TOOL STEELS, 1928

HEAT TREATMENT OF TOOL STEELS

GENERAL

This recommended practice covers the process to be followed for the heat treatment of so-called nondeforming, oil-hardening steels. Because there are steels of other analyses used for nondeforming steels which require different heat treating temperatures, this recommended practice applies only to the steels given in Table 1.

TABLE 1.—Approximate chemical composition

Steel No.	C	Mn	Cr	W
-----	0.90-0.95	1.00-1.25	0.50	0.50
-----	0.90	1.50	-----	-----

ANNEALING OF STEEL AFTER FORGING AND BEFORE MACHINING

Place steel in furnace so as to expose maximum surface area. For steel No. 1 as listed in Table 1, heat slowly and uniformly to a temperature of approximately 1,475° F. and to 1,400° F. for steel No. 2. Hold the steels at these temperatures for sufficient time to obtain complete penetration of heat and to obtain complete refinement of grain.

Cool in furnace, infusorial earth, mica, lime, or any medium that will permit uniform, slow cooling.

HARDENING

Heat the steel very slowly but uniformly to a dark red heat of approximately 1,200° F., then raise

temperature more rapidly but uniformly to the quenching heat of 1,450° to 1,500° F. for steel No. 1 and to 1,400° to 1,475° F. for steel No. 2. Hold the steels at these temperatures for complete penetration of heat.

Quench from these temperatures in light oil, but do not cool below temperature of boiling water, 212° F.

Tempering.—For steels Nos. 1 and 2 reheat immediately in oil or other heating medium at a temperature of 325° to 400° F., hold for about one-half hour and cool from the tempering temperature in still air.

NOTES ABOUT THE PROCESS

Nonshrinking steels are essentially oil-hardening steels. The ratio of bath volume to mass of steel is a very important factor, and the heating up of the oil during prolonged and continuous quenching operation should be avoided.

Heating should be done very gradually and uniformly, preferably in a muffle furnace, the steel being out of contact with flame and furnace combustion gases.

The absorption of heat or its diffusion through these steels seems to be much slower than in ordinary carbon or alloy steels. Therefore, these steels should be heated more slowly and quenched less drastically.

USES

Taps; reamers; broaches; blanking-trimming-punching-forming and threading-dies; master-tools and gages.

AMERICAN SOCIETY FOR STEEL TREATING, RECOMMENDED PRACTICE FOR THE HEAT TREATMENT OF FINISHING STEEL, 1927

HEAT TREATMENT OF FINISHING STEEL

GENERAL

This recommended practice covers the process to be followed in the heat treatment of so-called fast-finishing steel, sometimes also referred to as semi-high-speed steel. This steel is fast finishing in comparison to carbon tool steel, but is not to be confused with high speed steel.

CHEMICAL COMPOSITION

There are various types of fast-finishing steels manufactured and it is not recommended that this is the most suitable steel to use, but simply points out that the heat treatments recommended refer to steels of the following approximate chemical composition:

Approximate Chemical Analysis

	Per cent
Carbon.....	1.35 to 1.50
Tungsten.....	3.50 to 5.00
Chromium.....	0.50 to 1.00
Vanadium.....	0.20 to 0.30

ANNEALING OF STEEL AFTER FORGING AND BEFORE MACHINING

Place steel in furnace so as to expose maximum surface area. Heat slowly and uniformly to a temperature of approximately 1,450° to 1,525° F. and hold at this temperature for a sufficient time to obtain complete penetration of heat and complete refinement of grain.

It is recommended that the steel be heated in a closed pipe or box containing a small amount of carbonaceous material, similar to regular tool steel practice.

Cool the steel in the furnace.

HARDENING

Heat the steel uniformly to 1,475° to 1,525° F. and hold for complete penetration of heat. Quench from this temperature in water.

TEMPERING

Reheat immediately in oil or other heating medium at a temperature of 300° to 500° F. according to the use to which the steel is to be put. For intricate or small sections quench in oil or air.

AMERICAN SOCIETY FOR STEEL TREATING, RECOMMENDED PRACTICE FOR THE HEAT TREATMENT OF TAPS AND MILLING CUTTERS, 1927

HEAT TREATMENT OF TAPS AND MILLING CUTTERS

GENERAL

This recommended practice covers the process to be followed in the heat treatment of taps and milling cutters made from plain carbon tool steel, 18 per cent tungsten high-speed tool steel, and 1.50 to 2 per cent tungsten tool steel, and must not be applied to taps and milling cutters having a chemical composition other than given below.

Approximate chemical composition

	Plain carbon tool steel	18 per cent tungsten high-speed steel	1.50 to 2 per cent tungsten tool steel
	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>
Carbon.....	1.00-1.30	0.65-0.75	1.00-1.30
Tungsten.....		17.50-18.50	1.50-2.00
Chromium.....		3.25-4.25	1.50
Vanadium.....		.75-1.25	1.25
Manganese..... maximum.....	.35	.35	.25
Phosphorus..... do.....	.030	.030	.030
Sulphur..... do.....	.030	.030	.030
Silicon..... do.....	.30	.35	.35

¹ Optional.

ANNEALING OF STEEL AFTER FORGING AND BEFORE MACHINING

Place the steel in the furnace on a charcoal-covered bottom (except high-speed steel) and heat slowly and uniformly to the temperature given in Table 1, and hold at this temperature for sufficient time to obtain complete penetration of heat and complete refinement of grain. It is recommended that the steel, especially the high-speed steel, be heated in a closed pipe or box containing some carbonaceous material.

Cool the steel in the furnace, infusorial earth, mica, lime, or any medium that will permit uniform, slow cooling and prevent excessive oxidation.

TABLE 3.—Heating and quenching of taps and milling cutters

Type of steel	Preheating		Heating medium or type of furnace	Heating for quenching		Quenching	
	Medium	Temperature		Temperature	Time	Medium	Temperature
Plain carbon.....		°F.	(1).....	1,425-1,450	1 hour per inch of diameter or thickness.	Water or brine.	Water, 70.
18 per cent tungsten, high speed.	Open furnace.	1,500-1,550	Open furnace.	2,250-2,300	(3).....	Oil.....	70.
1.50 to 2 per cent tungsten.				1,450-1,475	1 hour per inch of diameter or thickness.	Water or brine.	Water, 70.

¹ If a lead bath is used for heating, a higher temperature and shorter time should be used. When heating the steel in an open furnace either an indirect fired furnace (muffle) should be used or a smoky flame should be maintained.

² A temperature as high as 2,350° F., may be used provided the furnace design is correct and the atmosphere is suitable.

³ Hold shortest time possible to thoroughly heat through.

ANNEALING FOR RELIEVING MACHINING STRAINS

Place the taps and milling cutters in a box containing some carbonaceous material (except in case of high-speed steel). Place the box and contents in the furnace and heat to the temperature given in Table 2. Cool in furnace.

TABLE 1.—Annealing after forging and before machining

Type of steel	Method	Temperature	Time of heating to uniform temperature	Time of holding at temperature	Cool in—
Plain carbon.	Packanneal on charcoal bottom.	° F. 1,450	1 hour per inch of diameter or thickness. ¹	Hour ½	Furnace. ¹
18 per cent tungsten high speed.	Nonoxidizing atmosphere.	1,600-1,650do.....	½	Do.
.5 (to 2 per cent tungsten.	Packanneal on charcoal bottom.	1,475do.....	½	Do.

¹ When pack annealing, consider the container and contents as 1 unit.

² If lead bath or salt bath is used for heating, cool in lime, mica, or infusorial earth.

HARDENING

Heat the taps or milling cutters uniformly to the temperature given in Table 3 and hold for complete penetration of heat.

Quench from this temperature into water, brine, or oil as directed in Table 3, but do not cool below the temperature of boiling water, 212° F.

TEMPERING

After quenching, reheat immediately in oil, salt, or furnace for the time and temperature specified in Table 4.

TABLE 2.—Annealing for relieving machining strains

Type of steel	Temperature	Time of heating to uniform temperature	Time of holding at temperature	Cool in—
Plain carbon.....	° F. 1,400	1 hour per inch of diameter or thickness.	Hour ¼	Furnace.
18 per cent tungsten high speed.	1,500do.....	¼	Do.
1.50 to 2 per cent tungsten.	1,450do.....	¼	Do.

TABLE 4.—*Tempering of taps and milling cutters*

Type of steel	Results desired	Tempering medium	Tempering temperature	Time
Plain carbon 18 per cent tungsten high speed. 1.50 to 2 per cent tungsten.	(1)	Oil.....	°F. 325-500	½ to 1.
	(2)	Furnace...	1,050-1,150	
	(1)	Oil.....	325-500	½ to 1.

¹ Depending on degree of hardness or toughness desired.
² Development of secondary hardness and toughness.

NOTES ABOUT THE PROCESS

In the above practice it is assumed that the tap shanks are below the hardening temperature and are not fully hardened. If the shanks have been fully hardened they must be tempered in order to toughen them, especially the smaller sizes.

AMERICAN SOCIETY FOR STEEL TREATING, RECOMMENDED PRACTICE FOR THE HEAT TREATMENT OF DIES FOR DIE CASTINGS, 1930

HEAT TREATMENT OF DIE CASTINGS

INTRODUCTION

A die casting is a finished, or practically finished, casting made by forcing a liquid metal or alloy under pressure into a metallic mold or die. Little or no machining other than drilling for screws, bolts, and the removal of fins by dressing is required to put the casting in condition for use.

The essential feature in the die-casting process, which distinguishes it from other processes involving metallic molds, is that the alloy is forced into the die cavity by pressure; such pressure may be mechanical as a plunger working in a cylinder, or air pressure.

Die casting, as is the case with other processes involving metallic molds, is essentially a quantity production process. This is necessarily so because of the heavy expense involved in designing and preparing the dies. In small lots, the heavy die expense will be proportionately reflected in the cost of the castings.

The die-casting process is practical for tin, lead, zinc, and aluminum base alloys. Alloys of higher melting points, like the brasses and bronzes, can be die cast, but such alloys have so strong an erosive effect on ordinary die steels that the process is not practical for these alloys. The life of a die when casting brass is exceedingly short and at the present time the die-casting process is confined to alloys of relatively low melting points.

The die-casting process is especially applicable to the production of small interchangeable parts which are required to be well finished and with accurate dimensions. Die castings up to 8 and 10 pounds are being commercially produced to-day.

GENERAL

This recommended practice covers the process for the heat treatment of dies for die castings. There are other steels used for this purpose, but this recommended practice applies only to the steels listed in Table 1.

Die-casting dies for aluminum-alloy work are generally made of alloy steel.

CHEMICAL COMPOSITION

The approximate chemical compositions of the steels generally used for die casting dies are given in Table 1.

TABLE 1.—*Approximate chemical composition of steels for dies for die casting*

Steel No.	C	Mn	Si (maximum)	Cr	W	
1 ¹	0.20-0.50	Other elements vary				
2 ¹	.25-.35	0.60-0.70	0.30	0.65-0.75		
3 ¹	.20-.35	.50-.80	.30	With or without about 1.00		Al 1.00-1.50
4 ¹	.40-.55	.40-.80	.30	2.00-2.50		
5	.30-.45	.20-.35	.50-1.00	4.50-6.00	4.00-5.00	Co, with or without about 0.50
6 ¹	.25-.40	.20-.35	.35	2.75-3.50	3.50-10.50	

¹ Die steel for zinc, tin, and lead base alloys. The other steels are used for aluminum.

² Nickel range for this steel is 1 to 1.50 per cent.

³ Molybdenum range for this steel is 0.20-1 per cent. Steels containing low percentages of molybdenum, ordinarily contain chromium. When the chromium is not present the molybdenum is on the high side of the range.

⁴ Vanadium content for this steel is 0.20-0.30 per cent.

⁵ This steel may or may not contain vanadium. The range is 0.30-0.60 per cent vanadium.

HEAT TREATMENT

Steels Nos. 1 and 2, as listed in Table 1, do not require a heat treatment, but are used in the soft condition as received from the mill.

Unless otherwise stated, the heat treatments as outlined in this recommended practice refer to treatments as performed in a muffle or semimuffle type furnace.

NITRIDING STEELS

One of the more recent developments in die steels for die castings is the use of nitrided steels. This steel is finished machined and the impression polished before subjecting it to the nitriding process. Steel No. 3 in Table 1 shows the approximate composition of nitriding steels. These steels can be softened after nitriding for necessary alterations by a short anneal in a double chloride bath (50 per cent sodium chloride and potassium chloride) at a temperature of 1,400° to 1,500° F.

HEAT TREATMENT OF THE CHROMIUM-VANADIUM DIE CASTING STEEL

(Steel No. 4 in Table 1)

Normalizing after forging.—The chromium-vanadium steel (steel No. 4 as listed in Table 1) is usually normalized after forging by cooling from about 1,750° to 1,800° F. The steel is heated at the rate of about one hour per inch of diameter or thickness³⁵ and held at the normalizing temperature for one-fifth of the total heating time. The steel is cooled from this temperature in air.

Annealing after normalizing.—After the steel has been normalized it should be annealed by heating approximately one hour per inch of diameter or thickness to a temperature from 1,425° to 1,475° F. After holding the steel at the annealing temperature for one-fifth of the total heating time, it is cooled with the furnace. After this annealing the steel should have a maximum Brinell hardness number of 200.

Packing.—Instructions for packing are given at the end of this practice.

Hardening.—The dies are heated to the hardening temperature of 1,600° F. at a rate of approximately one and one-half hours per inch of greatest thickness. The dies are held at this hardening temperature for about one hour for every inch of diameter or thick-

ness. After holding the heat for the required time the dies are quenched into oil which should be at a temperature of 80° to 120° F. The dies should be removed from the oil when cooled just far enough so that the oil does not flash and catch fire on the die block after it comes out of the quenching bath.

For intricate dies, hold the hardening temperature at 1,600° F. for the full specified time, then drop the furnace temperature with the work to 1,500° F. and hold until this temperature is uniform throughout, then quench as above.

Tempering.³⁶—After quenching, the dies should be charged into the tempering furnace without being allowed to cool to room temperature. When the dies are charged into the tempering furnace, the furnace temperature should not be higher than 450° F. The temperature is then raised slowly and uniformly to 800° to 900° F. and held at this temperature for about one hour for every inch of diameter or thickness. A Brinell hardness number of about 444 is desirable.

HEAT TREATMENT OF THE TUNGSTEN-CHROMIUM DIE CASTING STEEL

(Steel No. 5 in Table 1)

Normalizing after forging.—The tungsten-chromium die steel (steel No. 5 as listed in Table 1) is usually normalized after forging by cooling from about 1,750° to 1,800° F. The steel is heated at the rate of about one hour per inch of diameter or thickness and held at the normalizing temperature for one-fifth of the total heating time. The steel is cooled from this temperature in air.

Annealing.—After the steel has been normalized it should be annealed by heating approximately one hour per inch of diameter or thickness to a temperature of 1,550° to 1,600° F. After holding the steel at the annealing temperature for one-fifth of the total heating time, it is cooled slowly with the furnace.

Packing.—Instructions for packing are given at the end of this practice.

Hardening.—The dies should be heated at the rate of approximately one and one-half hours for each inch of maximum thickness to a hardening temperature of about 1,800° F. The dies should be held at the hardening temperature approximately one-fifth of the heating time and then quenched into oil. For hardening large or intricate dies, quench into air from a temperature of about 1,875° F.

Tempering.—After quenching in either oil or air, the dies should be reheated immediately to a temperature not exceeding 1,075° F. The dies should be held at the tempering heat five hours with an additional one hour for each inch of diameter or thickness. A Brinell hardness number from 400 to 460 has been found satisfactory.

HEAT TREATMENT OF THE TUNGSTEN DIE CASTING STEEL

(Steel No. 6 in Table 1)

Annealing.—This steel should be annealed after forging and before machining. For this annealing treatment the steel is heated to a temperature of 1,600° to 1,650° F. at the rate of approximately one hour per inch of diameter or thickness and held at this temperature for a minimum time of one hour. From this temperature the steel is cooled with the furnace. The cooling is retarded at 1,450° to 1,400° F. for sufficient time (about one hour) to bring about a properly annealed structure.

Packing.—Instructions for packing are given at the end of this practice.

³⁵ This dimension is taken for all heat treatments at the largest section of the die.

³⁶ When a die must be machined after heat treatment to exact size, it may be desirable to temper this steel at 1,100° F. or higher in order to finish machining.

Preheating for hardening.—Before hardening, this steel is first preheated to a temperature of 1,500° to 1,550° F. and held at this temperature for about one hour for every inch of diameter or thickness.

Hardening.—After the dies have been preheated, they should be heated to a hardening temperature of approximately 1,800° to 1,900° F. and removed for cooling from the furnace as soon as this hardening temperature has been uniformly attained. The dies may either be cooled in still air or quenched into oil.

Oil quenching protects the surface but produces slightly greater movement than air cooling. Air cooling is usually resorted to when the permissible movement is at a minimum, and when the dies are air cooled the impression should be protected against excessive scaling.

When quenched into oil the dies should be withdrawn while still warm and immediately tempered.

Tempering.—After hardening, the dies should be reheated immediately to a temperature of 1,050° to 1,250° F. and held at this temperature for five hours with an additional one hour for each inch of diameter or thickness. A Brinell hardness number from 401 to 444 is desirable.

PACKING

Because of the high temperatures used in the heat treatment of steels Nos. 4, 5, and 6, it is necessary to protect the finished surface from scaling. The dies may be packed in cast-iron chips, spent charcoal, or other materials, which have proven satisfactory. However, when the dies are packed in these materials, excessive carburization may occur. It has been found that sealing the die in a box in which a mixture of charcoal with approximately 3 per cent by weight of soda ash surrounding the die, but not in contact with the die face, will produce a surface freer from carburization or decarburization than with the other methods and still prevent scale formation. Soda ash must not come in contact with the working face of the die.

NOTES ABOUT THE PROCESS

When die casting aluminum base alloy castings, first heat the dies uniformly to a temperature of approximately 350° F.

Dies for die casting are usually given a protective coating before going into service. This coating depends upon the alloy being cast.

AMERICAN SOCIETY FOR STEEL TREATING, TENTATIVE RECOMMENDED PRACTICES FOR THE HEAT TREATMENT OF PLAIN CARBON AND ALLOY-STEEL DIE BLOCKS, 1931

HEAT TREATMENT OF DIE BLOCKS

General.—This recommended practice covers the process to be followed in the heat treatment of die blocks made from plain carbon and alloy steels, but must not be applied to die blocks having chemical compositions other than those given in Tables 1 and 3.

It is not recommended that these steels are the most suitable for die blocks, because there are other steels used that are equally as satisfactory, but, of course, the heat treatments given in this recommended practice can not be applied.

Many die blocks are purchased from the manufacturer in the heat-treated condition. These blocks usually have a scleroscope hardness range of 40 to 57, according to the depth of impression. Shallow impressions usually require the higher hardness

Prior to any heat treatment, die blocks should have received hot forging on the six sides, in order to refine the grain and lessen the tendency toward directional structures.

When quenching die blocks, it is important that the quenching bath be sufficiently agitated to avoid the formation of gas pockets. When hardening with air, the blast should be dry and so directed as to strike the face of the block uniformly. The pressure of the air blast should be at least 12 ounces, and the volume should be adequate.

PLAIN CARBON STEEL DIE BLOCKS

(Cold and Hot Forming)

Chemical composition.—There are three classes of carbon steels generally used for die blocks. The chemical compositions of these steels are given in Table 1.

TABLE 1.—Approximate chemical composition for carbon-steel die blocks

Die block No.	Application or type	C	Mn	Si
1	Carbon-steel die block	0.50-0.65	0.60-0.80	0.15-0.30
2	do	.60-.75	.20-.40	.15-.30
3	Cold-forming dies; ordinary hammer die block	.75-.90	.20-.40	.15-.30

¹ This steel may or may not contain vanadium up to 0.30 per cent.

Normalizing after forging.—The normalizing temperatures and directions for heating and cooling are given in Table 2.

TABLE 2.—Heat treatments for carbon-steel die blocks—Cold and hot forming die blocks

No. as listed in Table 1	Normalizing ¹		Annealing and spheroidizing ²		Hardening ³
	Temperature	Temperature	Cool in— ⁴	Temperature	
	° F.	° F.		° F.	
1	1,450-1,500	1,300-1,350	Furnace	1,400-1,425	
2	1,475-1,550	1,350-1,375	do	1,450-1,500	
3	1,550-1,575	1,300-1,350	do	1,425-1,475	

¹ The time required to bring the blocks to normalizing heat should be 1 hour per inch of diameter or thickness. The time at the normalizing heat should be one-fifth of the total heating time. With large blocks, the time of holding at heat should be increased in order to refine the center of the block.

² It is assumed for this heat treatment that the die block was first normalized. Time heating is 1 hour for every inch of diameter or thickness plus 1 hour. Time at heat is 1 hour per inch of diameter or thickness.

³ Quench into water. After quenching, temper to desired hardness. Time heating 1 hour per inch of diameter or thickness. Time at heat one-fifth of heating time.

⁴ After this heat treatment, the scleroscope hardness should not be over 30.

TABLE 3.—Approximate chemical composition for alloy-steel die blocks

Die block No. ¹	Application or type	C	Mn	Cr	Ni	Mo	V	W
1	Drop hammer die block	0.50-0.70	0.40-0.80	0.60-1.30	1.00-2.00			
2	Drop hammer die blocks	.50-.70	.40-.80	.50-1.00	1.00-2.00	0.15-0.30	(?)	
3	Oil or air hardening die block ²	.50-.70	.50-.80	.75-1.00	1.00-2.00	.60-.90	(?)	
4	Hot-forming die block	.60-.70	.50-.80	.75-1.00		.60-.90		
5	Special hot-working die steel ⁴	.45-.65	.30-.80	.60-1.00			0.15-0.25	
6	Chromium hot-working die-steel	.80-1.05	.15-.35	3.00-4.50			(?)	
7	Header die steel	.40-.55	.20-.35	.50-1.50			.20-.40	1.50-2.00
8	Hot-working die steel	.30-.45	.25-.35	3.00-3.75			.30-.60	9.00-11.00

¹ The silicon content for these steels is 0.15 to 0.30 per cent.

² These steels may or may not contain vanadium.

³ When this steel is used for upsetters' tools, it is usually air hardened.

⁴ This steel is mainly used for inserts and forging-machine dies.

The temperature of the normalizing furnace should not be over 500° F. when the die blocks are charged into it. After normalizing, cool the blocks in air until they are below the lower critical point.

Annealing and spheroidizing.—The annealing and spheroidizing temperatures and directions for heating and cooling are given in Table 2.

From the annealing and spheroidizing treatment, cool the blocks slowly in the furnace until they become black.³⁷

Hardening.—The quenching temperature, the time required to bring the die blocks to heat, the time at heat, and the quenching medium used for these die blocks are given in Table 2.

The block is immersed from 1 to 2 inches below the deepest part of the impression³⁸ and held in the water until the block is cooled down to a temperature where reheating from the inside is not likely to occur to a sufficient degree to cause softening. This is determined by examining, with the hand, the deepest part of the impression. After quenching, the block is immediately placed in the tempering furnace, hot oil or salt bath, or transferred to a hot plate for tempering.

TEMPERING

1. **Tempering hot-forming die blocks.**—After quenching, the blocks are tempered immediately at a temperature from 450° to 1,000° F., depending upon the hardness desired.

A scleroscope hardness of 50 to 70 is suggested; the approximate Brinell hardness number is 331 to 495.

2. **Tempering cold-forming die blocks.**—After quenching, the blocks are tempered immediately at a temperature of 350° to 600° F., depending upon the hardness desired.

A scleroscope hardness of 70 to 80 is suggested; the approximate Brinell hardness number is 495 to 578.

ALLOY STEEL DIE BLOCKS

(See General Remarks)

Chemical compositions.—The chemical compositions of the alloy steel die blocks are given in Table 3.

Normalizing.—Directions for the normalizing of the die blocks (except No. 8, which is not normalized) are given in Table 4.

When the normalized die blocks become black or approximately 900° F., they should be charged back into the furnace for annealing or spheroidizing. Cool the blocks from the normalizing temperature in still air until they are below the lower critical point.

³⁷ To test the soundness of the steel (structural condition and imperfections) the block may be reheated to the hardening temperature and quenched completely after the normalizing and spheroidizing operations. The block is then annealed as directed in Table 2.

³⁸ Die blocks that are approximately a 6-inch cube or under may be quenched entirely in water and cooled to about 700° F. (slightly below a red heat). They are then withdrawn and cooled in oil to a temperature of approximately 200° F. and immediately tempered to desired hardness. When quenching the block, a strong geyser of water should be directed into the impression of the block. To prevent warping during quenching, the shank may be cooled to a black heat by pouring water on it.

The temperature of the normalizing furnace should not be over 500° F. when the die blocks are charged into it.

Annealing and spheroidizing.—For annealing and spheroidizing of the alloy blocks, heat to the temperatures given in Table 4 and hold at these temperatures for the time specified.

Hardening.—Unless otherwise stated, heat die blocks to the hardening temperatures given in Table 4 and hold at these temperatures for the time specified before quenching.

Preheating for hardening (die block No. 8).—Die blocks made from this steel should be preheated before hardening. They are heated to 1,500° to 1,550° F. and held at this temperature for 1 hour for every inch of diameter or thickness. The blocks are then heated quickly to the hardening temperature.

Hardening (die block No. 8).—When the die blocks have been thoroughly preheated, they are heated quickly to the hardening temperature shown in Table 4 and cooled in air or quenched into oil.

Hardening (die block No. 3).—For hardening, the die blocks should be heated to the temperature shown in Table 4 and held for the time specified. With intricate impressions, the blocks should be pack hardened and cooled with a blast of dry air. Cool to about 400° F. and temper at 1,000° F.

Tempering.—After quenching, the die blocks are tempered immediately at the proper temperature, depending upon the hardness desired. The object of most users of die blocks is to secure a hardness above the machinable range to increase production.

Before using a die of analysis No. 8, it should first be heated to approximately 200° F.

TABLE 4.—Heat treatments for alloy-steel die blocks

No. as listed in Table 3	Normal temperature ¹	Annealing and spheroidizing ²			Hardening			Quenching medium	Tempering
		Temperature ³	Time		Temperature	Time			
			Heating	At heat		Heating	At heat		
1	° F. 1,550-1,600	° F. 1,325-1,375	1 hour per inch of diameter or thickness plus 1 hour.	1 hour per inch of diameter or thickness.	° F. 1,500-1,550	1 hour per inch of diameter or thickness.	½ of heating time.	Oil ⁴ minimum temperature of 100° F.	° F. To desired hardness.
2	1,550-1,575	1,350-1,400	1¼ hours per inch of diameter or thickness.	1¼ hours per inch of diameter or thickness.	1,475-1,525	1¼ hours per inch of diameter or thickness.	do	Oil ⁴	Do.
3 (a)	1,600-1,650	1,350-1,400	do	do	1,600-1,650	do	do	Air	See text.
(b)	1,600-1,650	1,350-1,400	do	do	1,475-1,525	do	do	Oil	To desired hardness.
4	1,650-1,675	1,350-1,400	1¼ hours per inch of diameter or thickness plus 1 hour.	do	1,575-1,625	do	do	do ⁶	Do.
5 (a)	1,550-1,650	1,350-1,400	1¼ hours per inch of diameter or thickness.	do	1,525-1,575	do	do	Water	600-1,000.
(b)		1,450-1,500	1¼ hours per inch of diameter or thickness.	1¼ hours per inch of diameter or thickness.	1,550-1,650	do	do	Oil	800-1,000.
6		1,450-1,500	1¼ hours per inch of diameter or thickness.	1¼ hours per inch of diameter or thickness.	1,750-1,800	do	½ of heating time.	Mild air blast.	(8)
7		1,450-1,500	do	do	1,600-1,700	do	do	Oil	500-800.
8		1,600-1,650	1 hour per inch of diameter or thickness.	1 hour per inch of diameter or thickness.	1,800-2,200	do	do	Air or oil.	1,300 for 1 hour.

¹ For normalizing, heat at the rate of 1 hour per inch of diameter or thickness, and hold at temperature one-fifth of the heating time. Cool in air.

² It is assumed for this heat treatment that the die block was first normalized. After this treatment the scleroscope hardness should not exceed 35.

³ From these temperatures, cool slowly to a black heat in the furnace.

⁴ After quenching the block entirely in oil, it is sometimes customary not to allow the block to reach the temperature of the oil, but remove it while still hot enough, so that the oil smokes freely on the surface of the block, but does not flash. While smoking hot, the block is then put at once into the tempering furnace or hot plate. This is to prevent breakage of blocks.

⁵ For air quenching, heat to 1,550° to 1,600° F. The same rules for heating and holding at heat apply.

⁶ Small blocks of approximately a 6-inch cube or under should be quenched into oil which has first been heated to 150° F.

⁷ At high temperatures this steel is susceptible to grain growth. It is best to hold for a longer time at the lower temperature. If air cooling is employed, preheat at 1,500° F., then heat quickly to 1,700° F.

⁸ When air hardened, this die block may be tempered as high as 1,000° F.

⁹ This annealing operation of the blocks should be pack annealed. Retard the cooling at 1,350° to 1,400° F. for sufficient time to bring about proper annealing structure; this applies particularly to the higher carbon ranges.

¹⁰ See direction for preheating this die block in the text, under preheating for hardening.

AMERICAN SOCIETY FOR STEEL TREATING, TENTATIVE RECOMMENDED PRACTICE FOR THE HEAT TREATMENT OF BLANKING DIES AND PUNCHES, 1928

HEAT TREATMENT OF BLANKING DIES AND PUNCHES

General.—This is a tentative recommended practice for the heat treatment of blanking dies and punches, and must not be applied to blanking dies and punches with a composition other than given in Table 1. The steels considered in this practice

are in common use for blanking dies and punches, but are not the only steels used for this purpose. The heat treatments, therefore, apply only to those steels considered in this practice.

In this practice a blanking die is defined as consisting of two main parts—the stationary “die” and the movable “punch.”

Approximate chemical compositions.—The approximate chemical compositions of the steels generally used for blanking dies are given in Table 1.

Heat treatments.—The heat treatments for blanking dies and punches are given in Table 2.

Notes and general information.—Usually, but not always, both the punch and die are made from the

same steel. For dies of intricate design an oil-hardening steel should be used, but for a more simple design a water-hardening steel may be used.

TABLE 1.—Approximate chemical composition

Steel No.	Type of steel	Purpose	C	Mn max.	W	Cr	V
1	Plain carbon	Cold-work dies and punches.	{ 0.90-1.10 }	0.35	-----	-----	-----
2	C-V	do	{ 0.90-1.10 }	.35	-----	-----	0.25
3	Cr-V	do	{ 0.60-.80 }	.35	-----	0.90	.20
4	Oil hardening.	do	.95	² 1.15	0.50	.50	-----
5 ¹	Do	do	.90	² 1.50	-----	-----	-----
6 ³	Do	do	{ 1.10-1.30 }	.55	1.50	.50	.20
7	W-Cr-V	Cold-work punches.	.50	-----	2.00	1.25	.25
8	Cr	Hot-work dies and punches.	.85	.35	-----	3.50	-----
9	W	do	.40	.35	10.00	3.50	.40

11 ⁴	High carbon high Cr.	do	2.25	-----	-----	12.00	-----

¹ These steels may or may not contain vanadium.
² Approximately.
³ This steel may or may not contain vanadium to the approximate amount given.
⁴ The carbon content for this steel may be lower for special purposes.
⁵ This steel may or may not contain vanadium or cobalt.

TABLE 2.—Heat treatments for blanking dies and punches

Steel Nos. as listed in Table 1	Normalizing °F.	Annealing ¹ °F.	Hardening		Tempering temperature ² °F.
			°F.	Quenching medium	
1	1,500-1,575	1,375-1,425	1,400-1,450	Water	300-550
2	1,500-1,575	1,375-1,425	1,400-1,475	do	300-550
3	-----	1,400-1,450	1,425-1,475	do	350-600
4	-----	³ 1,425-1,475	1,450-1,500	Oil	300-550
5	-----	³ 1,375-1,425	1,400-1,475	do	300-550
6	-----	1,450-1,500	1,425-1,500	Water ⁴	325-600
7	-----	1,425-1,475	1,550-1,625	Oil	325-600
8	-----	1,500-1,550	1,600-1,675	do	400-600
9	-----	1,575-1,625	1,700-1,800	Air	900-1,100
10	-----	1,600-1,650	⁵ 1,850-2,150	Air or oil	1,000-1,250
11	-----	1,600-1,650	⁶ 2,200-2,325	do	1,050-1,200
			⁷ 1,950-2,200	do	1,050-1,200
			⁸ 1,850-2,100	Oil	1,000-1,100
			¹⁰ 1,725-1,800	do	400-1,000

¹ The degree of softness depends upon the rate of cooling from the annealing temperature. Up to a certain degree of softness, the slower the cooling the softer the material.
² After the steel has reached the desired tempering temperature, the tempering should be continued from 30 minutes to 1 hour. The tempering temperatures given must necessarily cover a wide range; however, for the major portion of blanking dies and punches, the tempering temperature is towards the lower side of the range given.
³ Steels Nos. 4 and 5 should be heated very slowly, but uniformly, to a dark-red heat of approximately 1,200° F., then raised more rapidly but uniformly to the hardening temperatures given in Table 2.
⁴ Oil quenching is considered preferable, but water quenching is sometimes used.
⁵ These steels should be preheated at 1,500° to 1,550° F.
⁶ Heat treatment for tools for cold work.
⁷ Heat treatment for tools for hot work.
⁸ Heat treatment for pack hardening. Charred sawdust or charred excelsior has been found best adapted for the packing material. Carburizing compounds should not be used. Care must be used in the use of this process that the steel does not become too highly carburized. Too high a carbon concentration on the surface will cause spalling or even an actual fusion of the surface of the die during hardening.
Do not hold longer than is necessary to assure that the die has reached the desired temperature.
⁹ This steel should be preheated at a temperature of 1,300° to 1,400° F.
¹⁰ This steel absorbs heat slowly, so, consequently, should be heated much more slowly than the other steels listed.
This steel is often pack-hardened to prevent a soft surface resulting from decarburization. For dies which do not admit of grinding after hardening, pack-hardening is recommended.

AMERICAN SOCIETY FOR STEEL TREATING, TENTATIVE RECOMMENDED PRACTICE FOR THE HEAT TREATMENT OF SHEAR BLADES, 1928

HEAT TREATMENT OF SHEAR BLADES

General.—This is a tentative recommended practice for the heat treatment of shear blades, and covers the steels that are generally used for cold and hot shearing. When other steels than those listed in Table 1 are used for shear blades, this recommended practice does not apply.

Chemical composition.—The approximate chemical compositions of the steels generally used for shear blades are given in Table 1.

Notes and general information.—The hardness of laid shear blades (steel No. 2) may have a scleroscope hardness from 70 to 85, but the majority of such blades have a scleroscope hardness over 75. For hot work, the scleroscope hardness should not be over 70, and preferably under 60.

When shearing very thin material, as well as hard steel, it is recommended that the blades be placed in close contact.

When quenching heavy and long shear blades, it is recommended that the bath be agitated to insure uniform cooling, otherwise the ends will cool before the center, resulting in nonuniform hardening.

Shear blades should be straightened, when quenching, on the descending heat. The blades may change somewhat in the tempering operation, but the peening required will not be anywhere near as much if the blades are straightened on the quenching heat. A continuous press should be available with an adjustable control and knife-edge rests, so that if one load does not satisfactorily straighten the blade another load can be immediately applied. For straightening on the descending heat, the blades should be withdrawn from the bath at a temperature from 500° to 600° F., which is just below the point where the oil ceases to flash, or in the case of water-quenched blades, just where the water steams or dries off the blades immediately.

Heat treatments for the shear-blade steels are given in Table 2.

TABLE 1.—Approximate chemical composition¹

Steel No.	Purpose of steel	Purpose of shears	C	Mn max.	Cr	V	W
			Per cent				
1	Carbon tool steel.	Shears for cold work on heavy materials. ²	0.80-.90	-----	-----	-----	-----
2	do	Laid and solid shear blades for cold work on light materials.	.90-1.10	0.35	-----	-----	-----
3	Cr-V shear blades.	Shears for cold work on heavy materials.	.40-.50	.35	0.90	0.20	-----
4	do	Shears for cold work on medium materials.	.40-.60	.35	.90	.20	-----
5	do	Shears for cold work on light materials.	.65-.75	.35	.90	.20	-----

¹ A steel that is finding some favor for hot shearing work is a chromium-nickel-molybdenum steel. Various compositions, of this steel may be used. The usual range is as follows: C, 0.35-0.60; Mn, 0.60-1.50; Si, 0.30-1.50; Ni, 1.00-2.75; Mo, 0.30-1.00; Cr, 0.60-2.75.
² By heavy material is meant stock above three-fourths inch in diameter or thickness; light material one-fourth inch and under; and medium material is thin stock up to three-fourths inch in thickness or diameter.

TABLE 1.—Approximate chemical composition—Con.

Steel No.	Purpose of steel	Purpose of shears	C	Mn max.	Cr	V	W
			Per cent				
6	W - Cr - V shear blades.	Shears for cold work; principally for medium and heavy materials.	0.50	0.35	1.25	0.25	2.00
7	Cr-steel for hot shearing.	Shears for hot rough shearing.	.85	.35	3.50	-----	-----
8	Tungsten hot working steel.	Hot shearing...	.40	.35	3.50	.40	10.00
9	High speed...	Cold shearing ^{3 4} for light materials.	.65	.35	4.00	1.00	18.00
10	High carbon high chromium.	Cold shearing ³ for light materials.	2.25	-----	12.00	-----	-----

³ For certain classes of work, these steels may be used for both light and heavy hot shearing.
⁴ With a lower carbon content, steel No. 9 is generally used for hot shearing.

TABLE 2.—Heat treatments for shear blades

Steel No. as listed in Table 1	Normalizing temperature	Annealing temperature ¹	Hardening temperature	Quenching medium	Tempering temperature ²	Scleroscope hardness
	°F.	°F.	°F.		°F.	
1	1,475-1,500	1,400-1,450	1,425-1,475	Water	425-650	60-80
2	1,500-1,575	1,400-1,450	1,400-1,450	do	425-650	370-85
3	-----	1,400-1,450	1,475-1,550	do	455-650	60-80
4	-----	1,375-1,450	1,450-1,525	do ⁴	450-650	65-85
5	-----	1,375-1,425	1,425-1,475	do ⁴	450-650	65-85
6	-----	1,500-1,575	1,500-1,575	Oil	450-650	60-75
7	-----	1,425-1,475	1,600-1,650	do	450-800	60-80
8	-----	1,475-1,525	1,600-1,650	Water	450-800	60-80
9	-----	1,500-1,550	1,700-1,800	Air	900-1,100	60-65
7	-----	1,575-1,600	1,850-2,150	Air or oil ⁸ or air	1,000-1,250	60-60
9 ⁷	-----	1,600-1,650	2,100-2,300	oil ⁸ or air	1,100-1,200	-----
10 ⁹	-----	1,600-1,650	1,750-1,850	Oil	500-1,000	-----

¹ After forging and for easy machining the steels are annealed at the temperatures given and cooled slowly.
² The tempering temperature depends upon the character of the work to which the shears are to be subjected. For carbon-steel blades, either solid or laid, a range of 425° to 650° F. covers the tempering range.
³ To shear very thin material the scleroscope hardness should be on the higher side of the range given.
⁴ With all chromium-vanadium steels, the shear blades should be removed from the water at about 500° F. and cooling continued in oil.
⁵ The hardness of chromium-vanadium shear blades is about the same as for plain carbon blades, but as chromium-vanadium blades are used because of their greater toughness, a somewhat lower hardness is often used.
⁶ For extreme hot work, the scleroscope hardness should not be over 60.
⁷ Before hardening these steels should be preheated at a temperature of 1,500° to 1,550° F.
⁸ For toughness, the blades are usually quenched in air. When oil-quenched, they should be removed from the bath at a temperature of approximately 400° F., and immediately tempered. If, however, the blades are to be straightened, they should be removed from the bath at approximately 900° F., straightened, allowed to cool in the air to a temperature of about 400° F., and then tempered.
⁹ Before hardening, this steel should be preheated at a temperature of 1,300° to 1,400° F.
¹⁰ This steel absorbs heat slowly, so time must be allowed for solution of the carbides. It should be held at temperature a much longer time than other steels. To prevent decarburization, it is often necessary to pack this steel in a suitable carbonaceous material.

AMERICAN SOCIETY FOR STEEL TREATING, TENTATIVE RECOMMENDED PRACTICE FOR THE HEAT TREATMENT OF CHISELS, 1928

HEAT TREATMENT OF CHISELS

GENERAL.—Chisels must meet severe fatigue stresses and retain good cutting edges. Various steels as well as heat treatments are employed to meet these conditions. Only the principal steels and simpler treatments are given here.

TABLE 1.—Approximate chemical composition

Steel No.	Type	C	W	Cr	V
		Per cent	Per cent	Per cent	Per cent
1	Carbon	0.70-0.95	-----	-----	-----
2	C-V	.70-.95	-----	-----	0.20
3	Cr-V	.45-.60	-----	0.80	.20
4	Cr	.55-.70	-----	.50	-----
5	W-Cr-V	.45-.55	2.00	1.25	.25

TABLE 2.—Heat treatment for chisels

Steel Nos. as listed in Table 1	Forging temperatures ¹	Hardening temperatures	Quenching media	Tempering temperatures
	° F.	° F.		° F.
1	1,600-1,400	1,400-1,475	Water	350-550
2	1,600-1,400	1,400-1,475	do	350-550
3	1,650-1,400	1,450-1,500	do	350-550
4	1,650-1,400	1,450-1,500	do	350-550
5	1,700-1,400	1,650-1,700	Oil	450-550
	1,700-1,400	1,550-1,600	Water	450-550

¹ The initial forging temperature depends upon the amount of work to be done upon the steel and in no case should the finishing temperature be below 1,400° F.
 NOTE.—With pneumatic chisels, various hardening methods are followed to put the shank in proper condition. Sometimes the chisel is treated as above and sometimes the shank is given a preliminary quench in oil from the temperatures given in Table 2, after which the cutting edge is hardened as given in Table 2, and the whole chisel tempered at the temperatures given.

AMERICAN SOCIETY FOR STEEL TREATING, RECOMMENDED PRACTICE FOR THE HEAT TREATMENT OF CARBON STEELS, S. A. E. SERIES, 1929

HEAT TREATMENT OF CARBON STEELS

GENERAL

This recommended practice covers the process for the heat treatment of carbon steels of the S. A. E. series. The heat treatments prescribed for the steels considered are applicable for bar stock or for articles fabricated from the particular steel as listed under "uses." The heat treatments, of course, may be applied to other articles fabricated from the same steel, but consideration should be given to the design and heat-treatment methods, because it is often necessary to alter the treatments to cope with designs, and local conditions.

CHEMICAL COMPOSITION

The chemical compositions of the steels considered in this recommended practice are given in Table 1.

TABLE 1.—Chemical compositions

S. A. E. steels	C	Mn	Phos. (maximum)	Sulphur (maximum)
	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>
1010.....	0.05-0.15	0.30-0.60	0.045	0.055
1020.....	.15-.25	.30-.60	.045	.055
1025.....	.20-.30	.50-.80	.045	.055
1030.....	.25-.35	.50-.80	.045	.055
1035.....	.30-.40	.50-.80	.045	.055
1040.....	.35-.45	.50-.80	.045	.055
1045.....	.40-.50	.50-.80	.045	.055

HEAT TREATMENT

The heat treatments are given in Table 2 and are prescribed to develop grain refinements, better physical properties, and better machining qualities. Carburizing and cyaniding treatments are purposely omitted from this recommended practice.

In all of these heat-treating operations, it is good practice to heat the steel 1 hour for every inch of diameter or thickness and to hold at temperature for at least one-fifth of the time required for heating.

STEEL NO. 1010

S. A. E. steel No. 1010 has low tensile strength in the annealed condition, but the strength can be greatly increased by heat treatment, especially in bolts, nuts, cap screws, and similar articles of diameters not greater than three-fourths inch. This treatment consists of heating the articles at or above the critical temperature range of the material and drastically quenching by means of suitable fixtures.³⁹ The proper result may require a quenching medium of water or soluble oil. The tensile strength of the smaller diameters, one-half inch and less, may be as high as 90,000 pounds per square inch with other desirable physical properties retained. The temperature generally used is 1,650° to 1,700° F. Quenching by this method in a 5 per cent soluble oil solution gives approximately 70,000 to 80,000 pounds per square inch tensile strength.

TABLE 2—Heat treatments for carbon steels—S. A. E. series

S. A. E. steel Nos.	Normalize ¹	Anneal	Quench	Quenching medium	Temperature of medium	Temper ²

				Water	-----	1,200

¹ From these temperatures cool in air.

² The tempering temperature depends upon the properties desired. See also the text for steels 1035 and 1040.

³ For a heat treatment to improve machining qualities, see text.

⁴ The oil for this quench is a 5 per cent soluble oil solution.

⁵ Many parts may be quenched into a 6 per cent sodium hydroxide solution.

⁶ With complicated sections, this steel should be quenched into oil.

⁷ See text.

³⁹ "Some Physical Properties of Low Carbon Steel," R. H. Smith, Trans., Am. Soc. Steel Treating, vol. 7, p. 569.

In the annealed condition, steel 1010 does not machine freely, but tears badly when turned, threaded, and broached. The machining qualities are improved by quenching from 1,700° F. into water; tempering is not required, as the hardness and strength are only slightly increased with this heat treatment.

Uses.—The heat treatments for S. A. E. steel 1010, as covered in this practice, are especially suitable for bolts, pins, cap screws, and similar parts.

STEEL NO. 1020

This steel is used where a trifle higher tensile strength is required. It responds more readily to heat treatment than steel 1010, especially if the carbon is around the upper limit.

High tensile strength bolts, pins, etc., are produced from this steel by drastically quenching from 1,450° to 1,525° F.⁴⁰ into a 5 per cent soluble oil solution, which also produces a rust-resisting coating.

When the carbon is near the middle of the range, the tensile strength is approximately 85,000 to 95,000 pounds per square inch, with an elongation of 25 per cent.

Steel 1020 machines better than 1010, but is improved by quenching into water from a temperature of 1,600° to 1,675° F. If the carbon is around 0.25 per cent, it is well to temper from 500° to 800° F., in order to produce a Brinell hardness number from 143 to 179, which is desirable for good machining qualities.

Uses.—The heat treatments for S. A. E. 1020 steel, as covered in this practice are suitable for the same articles as listed under 1010 steel, but where higher tensile strength is desired.

STEEL NOS. 1025 AND 1030

These steels are used to quite an extent in the untreated condition for unimportant forgings and for pressed and stamped parts. Heat treatment only slightly increases the physical properties, but greatly increases the toughness.

These steels machine fairly well in the annealed condition, but for best machining qualities the steel should be quenched, after normalizing, into water from a temperature of 1,575° to 1,625° F., then tempered from 600° to 1,100° F.

Uses.—The heat treatment for steels 1025 and 1030, as covered in this practice, are suitable for the following and similar articles:

Forgings; pressed or stamped parts (quenched after normalizing and annealing—where toughness is desired); frames; washing-machine parts; unimportant bolts.

STEEL NO. 1035

This steel responds readily to heat treatment and develops fair physical properties. It also machines readily.

When the carbon and the manganese are on the high side of the range, the quenching temperature should not exceed 1,550° F., and the quenching water or oil should be warm; otherwise quenching cracks are likely to be encountered. When the carbon and manganese are both low it is often necessary to quench from a temperature as high as 1,600° F. Even with this temperature, it is difficult to meet physical property requirements. For the heat treatment of small forgings, the low side of the quenching range should be used.

The quenching medium may be either oil or water. Higher physical properties are, of course, obtained with the water quench.

⁴⁰ When not drastically quenched, use temperature given in Table 2.

Uses.—The heat treatments for steel 1035, as covered in this practice, are suitable for the following and similar articles:

	Temper at—	Average Brinell No.
	° F	
Front automobile axles.....	900-1,100	207-241
Crankshafts.....	850-1,100	228-269
Large and small forgings, bolts, pins, cap screws.....	800-1,100	{ 1 217-321 2 196-241
Connecting rods.....	1,100-1,150	196-235
Wheel hubs.....	950-1,100	196-235
Brake-band anchors.....	850-1,000	241-286

¹ Water-quenched. ² Oil-quenched.

STEEL NO. 1040

Steel 1040, like 1035, responds well to heat treatment, develops good physical properties, and machines readily.

Forgings that are made in such a manner that portions of the parts receive only little work and are, therefore, quite coarse, should be normalized; otherwise normalizing can be dispensed with.

It is advisable to time-quench all parts quenched in cold water. When removed from the water the temperature of the pieces should be from 300° F. for heavy sections to 700° F. for light sections.

As breakage may occur if quenched into water, irregularly shaped pieces, that is, parts with a heavy section adjacent to a thin section with only small fillets, are usually quenched into oil.

Uses.—The heat treatments covered in this practice for steel 1040 are suitable for the following and similar articles:

	Temper at—	Average Brinell No.
	° F.	
Axle shafts.....	750- 950	241-321
Front axle centers.....	950-1,150	196-241
Washers.....	400- 500	Rockwell C-45-50
Railroad track bolts.....	700- 900	
Connecting rods.....		196-235
Torque-rod ends.....		187-223
Brake levers.....		187-223
Tie-rod ends.....		187-223
Stocker crankshafts.....		187-217
Propeller shafts (tubing).....		
Clutch plates.....		
Large gears.....		

STEEL NO. 1045

When steel 1045 is used for large forgings, it should be normalized and quenched. For this treatment the forgings are heated to 1,625° to 1,650° F., cooled in air, and reheated to 1,500° to 1,550° F., and quenched into oil. The tempering depends upon the properties desired; generally 750° to 900° F., is satisfactory.

When used for connecting rods, this steel is sometimes quenched into water from a temperature of 1,480° to 1,510° F. The temperature of the water is approximately 180° F.

When quenching this steel into cold water there is a tendency to develop cracks. It is, therefore, advisable to quench into oil wherever possible, especially with small, irregularly shaped pieces.

AMERICAN SOCIETY FOR STEEL TREATING, RECOMMENDED PRACTICE FOR THE HEAT TREATMENT OF CARBON-STEEL CASTINGS, 1929

HEAT TREATMENT OF CARBON-STEEL CASTINGS

GENERAL

This recommended practice covers the process to be followed for the heat treatment of carbon-steel castings and applies generally to commercial castings for ordinary construction purposes and not for special use.

CHEMICAL COMPOSITION

The chemical ranges for the steel castings considered in this recommended practice are given in Table 1.

TABLE 1.—Chemical composition

Carbon ¹	Manganese	Silicon
0.15-0.60	0.50-0.90	0.20-0.60

¹ The carbon content is subdivided in the tables where heat treatments are prescribed.

COOLING AND CLEANING CASTINGS AFTER POURING

After pouring, all castings should be allowed to cool to a temperature below the critical range, preferably in the mold.

After shaking out and before heat treating, the castings should be cleaned sufficiently to insure thorough and complete penetration of heat during the heat-treating operations.

After the castings have been cooled and cleaned, they are subjected to one or more of the heat treatments considered below.

SINGLE NORMALIZING OR SINGLE ANNEALING PRACTICES

The castings are placed in the furnace and heated slowly and uniformly to the temperature given in Table 2.

To obtain the correct structural condition throughout the castings, they should be held at temperature for approximately 60 minutes for each inch of thickness of the largest section of the castings.

To develop better ductility and relieve cooling strains, normalized castings may be reheated to a suitable temperature below the upper critical point. Usually reheating to about 1,200° F. is sufficient.

TABLE 2.—Single normalizing or single annealing

Carbon range	Temperature	For normalizing cool in—	For annealing cool in—
	° F.		
0.15-0.40	1,600-1,700	Still air.....	Furnace or other medium for cooling slowly. ¹
0.40-0.60	1,550-1,600do.....	Do. ¹

¹ The castings are cooled slowly until the temperature has dropped to 800° F. or below.

DOUBLE TREATMENT—NORMALIZING AND ANNEALING

Recent investigations indicate that where time and expense are minor considerations, but quality is of utmost importance, double annealing or normalizing treatments are often beneficial.

The first treatment is usually conducted at relatively high temperatures ranging from 1,600° to 2,000° F., while the second treatment is conducted at a temperature only slightly above the critical temperature range of the steel being treated. These treatments may be followed by a tempering or a spheroidizing treatment if so desired.

The mechanism of the above practice is based on the fact that, in the annealing of cast steel, two separate structural changes are involved. The first consists in breaking up or diffusing the dendritic segregation of metalloids as far as possible, so as to form a homogeneous, but not necessarily fine-grained, structure. Since this is a process of diffusion of the metalloids, and not of critical transformation, the temperature employed is not a definite one, but rather depends on the original degree of segregation. Generally stated, segregation increases with the section of casting, so that the homogenizing temperature will also depend somewhat on the thickness of the casting.

As a result of the severe homogenizing treatment, the grain structure will be relatively coarse, and a second treatment at a temperature only slightly above the critical temperature range is given to refine the grain.

OIL AND WATER QUENCHING STEEL CASTINGS

When exceptional physical properties, high degree of structural refinement, and resistance to wear are required, heating and quenching will greatly assist in producing the desired results. When the carbon content of the castings is above 0.30 per cent, quenching and tempering are especially effective in producing these requirements.

Castings should not be quenched unless they have first been thoroughly annealed.

When water is used as the quenching medium, the temperature of the water should preferably be maintained at 125° to 150° F., especially for the higher carbon contents. With carbon under 0.25 per cent the quenching may be more drastic.

When the size and design of the castings are such that quenching might cause cracking if kept in the water or oil until cold, the castings should be removed from the quenching bath when they have become black, but still hot enough to dry the water quickly or, in case of oil, the castings should be hot enough to cause the oil to smoke freely on the surface of the casting.

TEMPERING

After quenching, the castings should be tempered immediately. When the load is charged into the tempering furnace, the temperature of the furnace should be approximately the same temperature as the castings (about 700° F.). The tempering temperature ranges from 800° to 1,350° F., depending upon the physical properties desired. Where hardness is not a factor, it is recommended to temper in the neighborhood of 1,200° F. for the average commercial casting.

The quenching and tempering temperatures are given in Table 3.

NOTES ABOUT THE PROCESS

With some castings that have had considerable machine work performed on them, such as heavy-duty gears, it is often advisable to remove the ma-

chine strains by heating the castings slowly and uniformly to a temperature of 400° to 600° F., then cool in air.

Castings should be charged into the furnace in such a manner that lighter castings will be protected from the heat of the furnace by the heavier castings. Should the castings be of similar section, care must be exercised so as not to overheat those on the outside of the charge before the inner ones have reached the annealing temperature.

TABLE 3.—*Quenching and tempering of carbon-steel castings*

Carbon range	Quenching temperature ¹	Time at heat	Quenching medium and temperature	Tempering	
				Temperature	Time at heat
0.15-0.30	° F. 1,600-1,650	½ hour for every inch of diameter or thickness.	° F. Water at 70.	° F. 800-1,350	At least 3 hrs.
0.30-0.40	1,550-1,600	-----do-----	Water at 125.	800-1,350	Do.
0.40-0.60	1,500-1,550	-----do-----	Water at 125 or oil.	800-1,350	Do.

¹ These temperatures are based on the assumption that the castings were first annealed.

² See text for tempering.

When charging the furnace, the castings should be piled loosely so that the hot gases will have free circulation throughout the charge. To further insure free circulation of the gases, it is advisable to pile the castings loosely on perforated racks or other suitable fixtures which elevate the castings a few inches above the floor of the furnace and so permit free circulation of the hot gases. When cooling from the normalizing temperature, this practice of piling the castings on racks also insures free circulation of the air.

Sufficient number of thermocouples should be used and so arranged in the furnace and, if possible, in the charge of castings, that the desired temperature can be maintained at the top, center, bottom, and sides of the charge.

Steel castings should be grouped for heat treatment, so that the carbon content of the entire charge falls within one of the carbon ranges given in the recommended practice.

Castings of intricate design, or where a heavy and a light section are adjacent, should not be quenched, except with utmost care.

As a basis for determining the physical properties of the metal in the casting, it is commercial practice to use test coupons cut from separately cast blocks or attached to the castings. When attached to the casting they should be so placed that they are properly fed and represent, as nearly as possible, the condition of the metal in the casting. Test coupons should be heat treated with the castings they represent.

To check the heating operation and to obtain closer control of the temperature, it is advisable to distribute several test specimens, for fracture inspection, throughout the charge of castings. The cross-sectional dimensions of the specimens should represent the largest cross section of the castings, and the carbon content should be approximately the same as the castings being heat treated. After completion of the heat treatment, an examination of the fractures of the specimens for grain refinement indicates the uniformity of heat distribution without destroying a casting for fracture inspection.

AMERICAN SOCIETY FOR STEEL TREATING, RECOMMENDED PRACTICE FOR THE HEAT TREATMENT OF ALLOY-STEEL CASTINGS, 1929

HEAT TREATMENT OF ALLOY-STEEL CASTINGS

GENERAL

This recommended practice covers the process to be followed for the heat treatment of alloy-steel castings and applies generally to commercial alloy castings for ordinary construction purposes and not for special use.

CHEMICAL COMPOSITION

The chemical compositions of the steel considered in this recommended practice are given in Table 1.

COOLING AND CLEANING OF CASTINGS

Alloy castings should be cooled in the molds to a temperature below the critical range, but as the brittleness increases with the decrease of temperature they should be shaken out, preferably as soon as they become black, and cleaned while they are still warm.

Cleaning should be performed rapidly so that the castings can be placed in the annealing furnace while still as hot as possible, but the cleaning must be sufficient to insure a thorough and complete penetration of heat during the heat-treating operations.

Flame cutting of gates and risers must be done before heat treating and is somewhat dangerous unless the castings are hot. If the risers or gates are broken instead of cut, the operation should be performed while the castings are warm, otherwise stresses are set up and minute cracks are developed which show up in the quenching operation. To avoid cracks when cutting with a torch at least one inch of metal should be left between the torch cut and the body of the castings. When castings are placed in the furnace, the temperature of the latter should preferably be the same as the castings.

HEAT TREATMENT OF ALLOY CASTINGS

Heat treatments may be classified as follows: Normalizing, annealing, quenching, and tempering.

The heat treatments to be used depend upon the chemical composition of the castings and the physical properties desired. Quenching, followed by a suitable tempering treatment, develops highest combinations of properties and permits a wide range of adjustment in the balancing of properties to suit individual requirements. Normalizing, followed by tempering, usually is a cheaper process than direct quenching, and while the results will not equal those obtained by quenching and tempering, nevertheless this treatment may be considered to yield maximum improvement in physical properties per unit of cost. It is one of the most common of commercial treatments and is satisfactory for many applications. Tempering should follow rapid cooling as in normalizing and quenching, to relieve strains which otherwise might cause cracking. Full annealing increases the machinability of most steels, helps to break up the cast structure, and generally (though not always) induces maximum softness and ductility.

TABLE 1.—Approximate chemical compositions¹

Steel No.	Type of steel	C	Mn	Si	Cr	Ni	V
1	C-V	0.25-0.35	0.60-0.90	0.20-0.50	-----	-----	0.15-0.20

22	Mn	.25-.35	1.00-1.50	.20-.50	-----	-----	-----
23	Mn	.25-.35	1.50-1.75	.20-.50	-----	-----	-----
24	Mn	.35-.45	1.00-1.50	.20-.50	-----	-----	-----
25	Mn	.35-.45	1.50-1.75	.20-.50	-----	-----	-----

¹ Maximum sulphur, 0.060 per cent. Maximum phosphorus, 0.050 per cent.

² 0.20 to 0.30 per cent silicon preferred.

³ Molybdenum range, 0.25 to 0.35 per cent.

Normalizing.—The purpose of normalizing is to relieve cooling strains, refine the cast structure, and produce as high physical properties as are possible without liquid quenching. To accomplish this purpose, castings are placed in the furnace, preferably while they are still warm, as noted above, and heated slowly and uniformly to the normalizing temperatures as given in Table 2, after which they should be allowed to cool uniformly and as rapidly as possible in still air. (Air blast is not usually considered acceptable.)

Castings should be held at temperature approximately one hour for each inch of thickest cross section. Manganese steels, numbers 22 to 25, require a longer period of heating.

After normalizing, the castings should be further heat-treated by tempering, or by quenching and tempering as described later in this practice.

TABLE 2.—Normalizing treatments

Steel Nos. as listed in Table 1	Temperature	Cool in—
1, 2, 3, 22, 23, 24, 25	°F. 1,600-1,700	Air.
4 to 21	1,600-1,800	Do.

Full annealing.—Although full annealing of alloy steel castings is not generally recommended, it is essential for heavy sections and where machinability is desired. If full annealed, the castings should be further heat treated after machining to bring out the available physical qualities.

When the castings have had no preliminary treatment, they may be full annealed at the normalizing temperatures as given in Table 2, followed by furnace cooling.

If the steel has been previously normalized it may be annealed at lower temperatures as given in Table 3, holding at temperature a sufficient time to insure thorough soaking. The rate of cooling should be regulated to give the desired machining qualities.

TABLE 3.—*Annealing temperatures for alloy castings*

Steel Nos. as listed in Table 1	Temperature	Cool in—
1 to 3; 10 to 12; 16 to 18; 22 to 25.....	° F. 1, 500-1, 600	Furnace.
4 to 9; 13 to 15; 19 to 21.....	1, 550-1, 650	Do.

Double treatment—Normalizing and full-annealing.—For information on these treatments, refer to the practice for the heat treatment of carbon-steel castings.

Quenching.—Quenching should be employed where maximum physical properties are necessary.

After properly normalizing or annealing, the castings should be heated slowly and uniformly to the quenching temperature as given in Table 4. Before quenching, they should be held at temperature for at least 30 minutes for each inch of cross section.

TABLE 4.—*Quenching and tempering temperatures for alloy castings*

Steel Nos. as listed in Table 1	Type of steel	Quenching temperatures	Quenching medium ¹	Maximum tempering temperatures	Cool in—

¹ Air quenching is often made use of in the hardening of alloy steel castings of intricate design which would be likely to crack in the more drastic water or oil quench.

² The shock resistance is usually improved by oil quenching from the tempering temperature.

³ A long soak is required at the tempering temperature.

When water is used as the quenching medium, the temperature of the water should preferably be maintained at 125° to 150° F., especially for the higher carbon steels.

When the size and design of the castings are such that quenching might cause cracking, if kept in the water or oil until cold, the castings should be removed from the quenching bath while still hot enough to dry the water quickly, or in case of oil, the castings should be hot enough to cause the oil to smoke freely on the surface of the castings.

Tempering.—As soon as possible after normalizing or quenching, castings should be reheated for tempering. The temperature of the furnace receiving the charge should be approximately the same as that of the castings.

The purpose of tempering is to relieve the strains and brittleness caused by quenching or normalizing and to moderate the hardness; that is, to toughen the material. The temperature to be used depends upon the hardness and physical properties desired. Usually the higher the tempering temperature, up to the critical range, the softer and more ductile the steel. For maximum hardness and strength, a tempering temperature only sufficient to relieve strains is used. The maximum tempering temperatures recommended are given in Table 4.

Except in special cases, the time the material is held at the tempering temperatures should be at least sufficient to insure complete equalization of the heat throughout the heaviest section of the casting, and preferably an hour or more per inch of thickness.

USES

The alloy steels listed possess desirable combinations of hardness, strength, and toughness not obtainable with carbon cast steel. The castings are used for locomotive frames, gear blanks, dies, stamps, crusher jaws, pinions, car wheels, shovel-teeth racks, chain, valves and fittings, caterpillar treads, etc. The selection of the alloy depends upon the service required.

Due to their higher physical properties it is possible to obtain greater strength for a given cross section than with carbon steel castings. These alloys, therefore, find particular application where reduction of weight is important, and where high stresses are encountered.

NOTES ABOUT THE PROCESS

Castings should be charged into the furnace in such a manner that lighter castings will be protected from the heat of the furnace by the heavier castings. Should the castings be of similar section, care must be exercised so as not to overheat those on the outside of the charge before the inner ones have reached the desired temperature.

When charging the furnace, the castings should be piled loosely so that the hot gases will have free circulation throughout the charge. To further insure free circulation of the gases, it is advisable to pile the castings loosely on perforated racks or other suitable fixtures which elevate the castings a few inches above the floor of the furnace. When cooling from the normalizing temperature, this practice of piling the castings on racks also insures free circulation of the air, producing more rapid and uniform cooling.

Sufficient number of thermocouples should be used and so arranged in the furnace and, if possible, in the charge of castings that the desired temperature can be maintained at the top, center, bottom, and sides of the charge.

Steel castings should be grouped for heat treatment so that the carbon content of the entire charge falls within one of the carbon ranges in Table 1.

Castings of intricate design, or where a heavy and a light section are adjacent, should not be quenched. However, when quenching is necessary, utmost care should be exercised to avoid cracking.

Alloy-steel castings, in most cases, will harden appreciably if heated above the critical range and

allowed to cool in the air. Therefore, they should always be tempered after normalizing.

When the suggested methods of annealing are not effective, alloy castings may sometimes be appreciably softened by heating within the critical range and holding for a considerable length of time.

The physical properties obtained by heat treating alloy castings are destroyed by the local application of heat, such as in welding or hot straightening. These operations produce dangerous local disturbances of grain structure, hardness, and excessive strains. Castings should, therefore, be retreated after such practice.

The rate of cooling in the normalizing practice is merely relative, depending upon the size of the charge. The smaller the load, the more drastic the cooling, and, therefore, the higher the physical strength and the lower the ductility.

It is commercial practice to use test specimens cut from a separately cast block or from test coupons attached to the casting as a basis for determining the physical properties of the castings. Test pieces or test coupons should be heat treated with the castings which they represent.

AMERICAN SOCIETY FOR STEEL TREATING. RECOMMENDED PRACTICE FOR THE HEAT TREATMENT AND CARE OF SLING AND CRANE CHAIN, 1929

HEAT TREATMENT OF SLING AND CRANE CHAIN

INTRODUCTION

The reliability of chain depends upon the quality of the welded links and the metal from which they are made. It is of paramount importance to ascertain if the chain is of ample size to sustain the safe working load. The quality of the metal should be carefully and thoroughly tested by the chain manufacturer, both for chemical and physical properties, also a metallographic examination is considered desirable.

Wrought iron for chain usually has the following approximate chemical composition:

	Per cent
Carbon, under.....	0.05
Manganese, under.....	.10

The A. S. T. M. specification A56-24 limits the manganese to 0.10 per cent for the best grade of wrought iron for chain.

The average physical properties of wrought iron for chain are as follows:

Tensile strength.....	lbs./in. ²	46,000
Yield point.....	do.	23,000
Elongation in 8 inches.....	per cent.	26
Reduction of area.....	do.	49

Other tests that are often performed on wrought iron for chain are: Cold-bend, quench-bend, and drift tests. In addition, a cold feathering test may be applied by flaring the end of the bar under a hammer. This test is an aid in judging the workmanship put into the welded fagot. The results of these tests should show a high degree of ductility, and a fibrous, silky fracture free from bright spots.

Because mild steel requires different welding temperatures and methods than wrought iron, a satisfactory weld may not be obtained if the two materials are mixed in rolling or reheating processes. To determine if an admixture of wrought iron and steel has been used, metallographic examination should be resorted to.

Low-carbon steels are largely used for small chain, other than sling chain, but in large sizes there are welding difficulties which are not encountered with wrought iron. Most chain, therefore, above 1½ inch, is made of wrought iron.

NORMALIZING, TESTING, AND INSPECTING AFTER WELDING

Normalizing.—If the welding operation has been properly performed the welded portion may not need a normalizing treatment to refine the structure, but in the case of large chain, portions of the link adjacent to the welds have been heated to or near the welding temperature, and if not hot worked a weak, coarse, crystalline structure is developed which requires a normalizing treatment for refinement.

To normalize, the chain is placed in the annealing furnace, usually of the car-bottom type, and heated until the complete charge, top, center, and bottom is at a temperature of 1,750° F. The time for heating is about three hours. The charge is held at this temperature for 10 to 15 minutes, or until the heat has completely penetrated the work. The car, if the car-bottom type has been used, is then drawn out and the chain allowed to cool in the air. In other furnace types, the furnace doors may be opened or the chain removed from the furnace and allowed to cool on the shop floor.

Proof test and inspection.—After cooling, the chain is proof tested. The test consists of fastening one end of the chain to the head of the testing machine and the other end to the anchor crosshead. The required proof load is 50 per cent of the breaking load. Each link is then carefully inspected for flaws

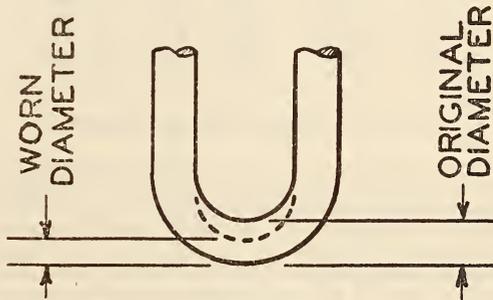

FIGURE 46

or other defects. Link measurements are made to determine if the chain has stretched beyond the specified dimensions. All chain suffers permanent elongation after the proof test.

After subjecting the chain to a proof test, it may be annealed and the yield point thereby lowered. This step makes overloading more evident and to that extent increases the factor of safety. Because of the increased cost, this operation is usually dispensed with, so the problem should be referred to the manufacturer before this particular annealing operation is specified.

CARE AND USE OF CHAIN

Overloading is probably the most serious service abuse to which chain is subjected. A new chain may be impaired by overloading the first few times it is used. The elasticity of the chain metal is sufficient to take care of the safe working load. If the chain has not been overloaded, or stressed beyond the yield point, the chain will regain normal shape as soon as it is relieved of its load. When stressed beyond the yield point by an overload the metal does not go back to its normal condition or shape after the load is removed. When the yield point of the metal is once passed by an overload, the metal is never as strong under impact as before it had been stretched. If the chain is carefully measured at frequent intervals, any elongation that is not the result of wear is sure proof of overload.

Improper application of the chain sets up stresses that are far in excess of those caused by the weight of the load lifted, and which are the cause of fatigue failure. These increased stresses may be caused by any of the following: (1) Sudden application of the load, shocks, and sudden jolts; (2) twisting of chain, kinks in chain, and crossing of chain; (3) bending of links around sharp corners; and (4) large angles between the branches or legs of a double-sling chain.

TABLE 1.—Safe loads in pounds for sling chains under different loading conditions

Diameter of chain stock (in inches)	Single chain when used straight	Double-sling chains when used to form base angles of—		
		60°	45°	30°
1/4	1,060	1,850	1,500	1,060
5/16	1,655	2,875	2,350	1,655
3/8	2,385	4,150	3,350	2,385
7/16	3,250	5,600	4,600	3,250
1/2	4,240	7,350	6,000	4,240
9/16	5,370	9,300	7,600	5,370
5/8	6,630	11,450	9,350	6,630
3/4	9,540	16,500	13,500	9,540
7/8	12,960	22,450	18,300	12,960
1	16,950	29,350	23,950	16,950
1 1/8	20,040	34,700	28,300	20,040
1 1/4	24,750	42,850	35,000	24,750
1 3/8	29,910	51,800	42,350	29,910
1 1/2	35,600	61,650	50,350	35,600
1 5/8	41,800	72,400	59,100	41,800
1 3/4	48,450	83,800	68,500	48,450
1 7/8	55,300	95,800	78,200	55,300
2	63,300	119,600	89,500	63,300

FAILURE CAUSED BY REPEATED LOADING

Chain may break without showing elongation if loaded below the yield point a sufficient number of times. Failure may take place by ordinary fatigue, but is much more likely to occur by the following mechanism: Through the repeated peening action of the chain links against each other and their being dropped and hit against stone or metal, the surface of the soft iron is given a work-hardened skin. Under impact loads, usually difficult to avoid, this skin is broken and the crack constitutes a notch which localizes stress and weakens the chain under conditions of further impact or repeated load. This hard skin may be removed and the impact strength of the chain maintained by periodic annealing. How often this is desirable depends on the particular service involved.

ANGLE OF SLING CHAINS

The angle between the legs of the branches of a double-sling chain should always be taken into consideration, especially when handling heavy loads. As this angle increases, the angle between the legs and the work decreases. This reduces greatly the safe working load of the chain, because as the angle between the two legs of the chain increases the tension in each leg is also increased. The safe load in pounds for double-sling chains, using different angles between the legs, is given in Table 1.

TABLE 2.—Reduced diameter of link stock in chain slings

(Original safety factor=7)

Chain size (in inches)	Reduced safety factors			
	6	5	4	3
	Reduced diameters			
	<i>Inches</i>	<i>Inches</i>	<i>Inches</i>	<i>Inches</i>
1/4	0.23	0.21	0.19	0.16
5/16	.35	.32	.38	.25
3/8	.47	.42	.38	.33
7/16	.58	.52	.47	.42
1/2	.70	.63	.57	.49
5/8	.81	.74	.66	.57
1	.93	.84	.75	.66
1 1/8	1.04	.95	.85	.73
1 1/4	1.17	1.05	.95	.82
1 3/8	1.28	1.16	1.04	.90
1 1/2	1.39	1.26	1.13	.98
1 5/8	1.50	1.37	1.22	1.06
1 3/4	1.63	1.47	1.32	1.15
1 7/8	1.73	1.58	1.42	1.23
2	1.86	1.68	1.51	1.31

Links to be measured at point of greatest wear.

Example.—A 1/2-inch chain is worn to about 0.40 inches in diameter. The remaining safety factor, full load, is (from table) about 4.5.

FACTOR OF SAFETY

Chain is always manufactured with a factor of safety sufficient to take care of a reasonable amount of abuse, but even this is of little avail with the careless handling which is given some chain.

The cold working caused from overloading will increase the breaking load, but decreases the ductility and resistance to shock, thereby reducing the factor of safety. Chain links are reduced in diameter, due to dirt, grit, and abrasives grinding between the links when the load is applied. As the diameter is reduced, the factor of safety is lowered. In Table 2 is given the factor of safety for reduced chain links caused by wear.

If properly carried out, annealing will automatically increase the factor of safety, except where the link is reduced in diameter by wear. Annealing should not be done periodically as a "cure all," but carried out in conjunction with careful inspection. Inspection and measurements of the chain will give notice of any abuse. Wear, however, will cause elongation of the chain, so it is necessary to distinguish between this effect and the elongation caused from overload.

Annealing can only restore ductility in the metal of the reduced cross section and does not restore the chain to its original condition because the effects of the permanent deformation to the links are unchanged. No chain should be used on heavy work after it has been badly overloaded and has, thereby, become deformed. The tensile strength may not be impaired but the deformation of the original links considerably reduces the reserve of shock resistance in the links.

RECOMMENDED PRACTICE FOR THE HEAT TREATMENT OF SLING AND CRANE CHAIN

General.—This recommended practice covers the process to be followed for the annealing of sling and crane chain.

Process.—The process of annealing chain consists of loading the furnace, heating, and cooling the chain.

Loading the furnace.—Place the chain in uniform layers on the furnace bottom so as to expose maximum surface area. To prevent scale from forming, a hood should be placed over the chain and the edges of the hood sealed with sand. The openings of the hood are sealed with fire clay.

TABLE 3.—Annealing treatment for iron sling and crane chains

Diameter of chain link (in inches)	Annealing temperature ¹	Time of holding at temperature	Cool in—
	° F.	Hours	
1/4 to 1/2	1,200-1,400	1/4	Air.
5/8 to 1 1/8	1,200-1,400	3/4	Do.
1 1/8 and above	1,200-1,400	2	Do.

¹ In case there is doubt as to whether the chain to be treated is iron or steel, a temperature of 1,600° to 1,650° instead of 1,200° to 1,400° F. should be used. This higher temperature is not required for iron, but will not injure it. The lower temperature is undesirable for steel.

Heating to this higher temperature and coming down again brings about a recrystallization and decreases the danger of excessive grain growth such as may occur below the critical range, especially if the chain had been severely strained in service.

Heating.—Heat to a temperature of 1,200° to 1,400° F., and hold at this temperature for the time specified in Table 3. The time required to bring the chain up to temperature, and whether the chain is charged into a hot or cold furnace have little influence on the result. The heat should thoroughly penetrate the work, and the top, center, and bottom of the charge should reach approximately the same temperature.

A sufficient number of thermocouples should be used to assure uniform temperature throughout the charge. A pyrometric record of the heating operation should be delivered with the annealed chain.

Cooling.—After the chain has been held at the annealing temperature for sufficient time, the charge is pulled onto the cooling platform, or onto the floor. The chain should be spread in single layers, with ample space between each chain, so as to allow it to cool rapidly and uniformly to room temperature.

AMERICAN SOCIETY FOR STEEL TREATING, RECOMMENDED PRACTICE FOR THE HEAT TREATMENT OF OIL-HARDENING ALLOY GEARS, 1929

HEAT TREATMENT OF ALLOY GEARS

GENERAL

This recommended practice covers the process to be followed in the heat treatment of oil-hardening gears. It is recognized that the size, composition, and type of gears govern entirely the heat-treating process. This recommended practice, therefore, pertains only to gears of approximately the size of a passenger-car sliding gear.

All the temperatures recommended in this practice refer to the temperature of the stock and not to the furnace temperature.

CHEMICAL COMPOSITION

The alloy steels most commonly used for gears, together with their chemical compositions, are listed in Table 1.

All the alloy steels for gears should be selected as closely as is commercially possible from the middle of the carbon range, as given in Table 1.

TABLE 1.—Approximate chemical composition

Steels, S. A. E. Nos.	C	Mn	P	S	Cr	V (minimum)	Ni
2345	0.40-0.50	0.50-0.80	0.04	0.05	—	—	3.25-3.75
3250	.45-.55	.30-.60	.04	.045	0.90-1.25	—	1.50-2.00

3150 ¹	.45-.55	.50-.80	.04	.045	.45-.75	—	1.00-1.50

¹ This is not an S. A. E. steel, but follows the S. A. E. numbering system.

HEAT TREATMENT AFTER FORGING AND BEFORE MACHINING

To eliminate forging structure and to obtain desirable machining properties, either with bar stock or gear blanks, the steel should be normalized, annealed, or quenched and annealed. The preliminary heat treatments are given in Table 2.

From the normalizing temperatures the steels are cooled in air. After the preliminary quenching, the steels are heated for at least one hour at the annealing temperature as indicated in Table 2, then cooled in the furnace to about 800° F. Below this temperature the steels may be cooled in air. After this heat treatment, the Brinell hardness number should be between 170 to 217, which produces desirable machining properties.

To assure uniformity of the product, it is good practice to test, after the preliminary heat treatment, a sufficient number of the gears for hardness.

TABLE 2.—Normalizing, preliminary quenching, and preliminary annealing after forging

S. A. E. No.	Normalizing		Preliminary quenching		Preliminary annealing	
	Temperature	Cool in—	Temperature	Quenching medium	Temperature	Cool in—
2345	° F. 1,525-1,575	Air...	° F. 1,500-1,525	Oil	° F. 1,400-1,425	Furnace at 20° to 40° F. per hour.
3250	1,525-1,575	Air...	1,500-1,525	Oil	1,400-1,425	Furnace at 40° F. per hour.

6150	1,550-1,600	Air...	—	—	1,500-1,525	Furnace at 30° to 50° F. per hour to 1,100° F.
3150 ¹	1,525-1,575	Air...	1,500-1,525	Oil	1,350-1,400	Furnace.

¹ This is not an S. A. E. steel, but follows the S. A. E. numbering system.

² When the quenching treatment is omitted, this steel should be annealed at 1,450° to 1,500° F.

HEAT TREATMENT OF FINISHED MACHINED GEARS

After machining and cutting the teeth, the gears are hardened and tempered.

Heating for quenching.—The gears are heated slowly and uniformly to the quenching tempera-

tures given in Table 3, and held for sufficient time to assure complete and thorough penetration of heat. The heating medium should be so selected that scaling is held to a minimum.

Quenching.—The gears are quenched from the quenching temperature into oil as indicated in Table 3. The quenching oil should flow through the tank in large volumes, and the quenching should be so performed that the quenching oil circulates freely between the gear teeth.

TABLE 3.—Heating, quenching, and tempering of gears

Steels, S. A. E. No.	Heating for quenching		Tempering temperature
	Temperature	Quenching medium	
	° F.		° F.
2345.....	1,425-1,475	Oil.....	400-450
3250.....	1,425-1,475	do.....	425-475
5150.....	1,475-1,525	do.....	425-475
6150.....	1,500-1,550	do.....	450-500
3150 ¹	1,450-1,500	do.....	425-475

¹ This is not an S. A. E. steel, but follows the S. A. E. numbering system.

Tempering.—After quenching, the gears are reheated to the temperature indicated in Table 3, and held for sufficient time to produce toughness. For tempering, either a liquid or circulating-air heating medium is satisfactory.

NOTES ABOUT THE PROCESS

Upset gear blanks produce teeth of uniform strength all the way around, whereas pegged out flats when drop tested usually reveal strong teeth on two sides of the gear and weak teeth on two sides between the strong teeth.

Inspecting and testing.—At least three teeth on every gear should be polished and tested for hardness. After quenching and tempering, the scleroscope readings should be 70 to 76, Rockwell hardness C-52 to C-57. Special fixtures are of advantage when obtaining the hardness tests.

Specimens should be broken periodically under a drop hammer to check up on the forging and heat-treating methods.

Cleaning.—Before grinding the holes and teeth of the gears, they should be subjected to a cleaning process, such as wire brushing or electric cleaning.

AMERICAN SOCIETY FOR STEEL TREATING, RECOMMENDED PRACTICE FOR THE HEAT TREATMENT OF PLAIN CARBON AND ALLOY SPRING STEEL, 1929

HEAT TREATMENT OF SPRING STEEL

General.—This practice covers the recommended process to be followed in the manufacture and heat treatment of springs, and is divided into three sections: A. Flat springs (watch springs, etc., not included); B. Helical springs—wire diameter one-half inch and over; and C. Helical springs—wire diameter under one-half inch.

DIVISIONS A AND B

Flat Springs and Helical Springs One-half Inch and Over

Hardness of steel as received from manufacturer.—The maximum hardness limit for flat springs will depend to a considerable extent upon the nature of any cold work to be performed upon them. A maxi-

mum Brinell hardness number of 321 is satisfactory for the thinner gages (less than five-sixteenth inch) where only the simple cold working operation, such as shearing, punching, and trimming are necessary. Heavier gages (five-sixteenths inch or over) should have a maximum Brinell hardness number of 302. A minimum hardness limit is necessary only in special cases.

All coil-spring bars one-half inch or over should be soft enough to permit shearing without breaking.

Imperfections.—The maximum decarburization should not exceed 0.003 of an inch carbon free metal or a total depth of 0.008 of an inch of total and partial decarburization, as measured with the microscope.

Where springs are subjected to a large number of load applications per minute or to heavy stresses, surface imperfections such as seams with a depth of only 0.005 of an inch, generally cause early failure. Quenching cracks, warping, and low-fatigue resistance are frequently encountered when considerable carbide is segregated.

Forging, forming, and coiling.—The lowest temperature at which the steel will work satisfactorily should be used. This temperature should not exceed 1,850° F., and the steel should be held at this temperature for only sufficient time thoroughly to heat throughout. The method of cooling after forging or forming is usually not important. When severe coiling or other severe forming operations are performed, the steel should be allowed to cool in the air until it becomes black.

Annealing.—When annealing is necessary for machining to relieve machining strains, to relieve cold working strains, or to relieve strains from local heating, the steel may be heated to the annealing temperatures given in Table 2. The rate of cooling to vary with requirements.

Chemical composition.—The steel listed in Table 1 are recommended for flat springs. The second carbon steel listed in this table is generally used for large helical springs, as alloy steels have proved successful only in special applications.

TABLE 1

Steel	C	Mn	P (maximum)	S (maximum)	Si	Cr	V (minimum)
C.....	0.70-0.80	0.50-0.80	0.040	0.040	-----	-----	-----
C.....	.90-1.05	.30- .50	.040	.050	-----	-----	-----
Cr.....	.45- .55	.80-1.00	.040	.045	-----	1.00-1.20	-----
Cr-V.....	.45- .55	.70- .90	.040	.040	-----	1.00-1.20	0.15
Si-Mn.....	.50- .60	.60- .90	.045	.045	1.80-2.20	-----	-----

¹ Used for flat springs one-eighth inch and under.

Heat treatment.—Specific heat treatments of steels for flat and large helical springs are given in Table 2. Variations in the heat-treatment operations are often due to the personnel, variations in the composition of the steel or manufacture, and changes in local conditions, such as the control and sensitiveness of heat-treating equipment.

TABLE 2

Steel (as listed in Table 1)	Annealing temperature,	Quenching temperature,	Tempering temperature, ¹	Brinell hardness
	° F	° F	° F	
C 0.70-0.80.....	-----	1,450-1,475	² 700- 850	-----
C 0.90-1.05.....	1,575-1,600	1,525-1,550	850-1,050	352-415
Cr.....	1,600-1,625	1,550-1,575	850-1,050	363-444
Cr-V.....	1,600-1,625	1,550-1,575	850-1,050	363-444
Si-Mn.....	1,600-1,625	1,575-1,600	850-1,050	363-444

¹ The tempering temperatures are to be used only as a guide to obtain the Brinell hardness numbers given in the table.

² Rockwell C40 to C50, depending upon use.

Quenching.—The steel should be heated uniformly to the temperature shown in Table 2 and quenched in thin oil. The time, in minutes, of heating in the furnace may be determined approximately by multiplying the diameter or thickness of the steel in inches by 60. More uniform results are obtained with good circulation of the quenching medium and with regulation of the temperature from 100° to 140° F.

Tempering.—The steel should be heated in a suitable tempering medium to the temperature shown in Table 2. It should be held at this temperature for sufficient time to permit complete penetration of the heat.⁴¹ The method of cooling after tempering is optional.

DIVISION C

Helical Springs Under One-half Inch

Hardness of steel as received from manufacturer.—Wires made of steels listed in Table 3 are purchased either pretempered or annealed. The Rockwell C-hardness of the pretempered wire is the same as shown in Table 4. For uniform coiling the annealed wire should have a Rockwell C-hardness of 15–25.

Imperfections.—The wire should be free from all evidence of decarburization. It is recommended that the alloy steels should be tested for defects by macroetching.

Forging, forming, and coiling.—Springs of this type are seldom formed or coiled hot.

TABLE 3.—Steels for helical springs under one-half inch diameter

Steels	C	Mn	P (maximum)	S (maximum)	Cr	V (minimum)
C.....	0.45-0.70	0.80-1.20	0.040	0.045	-----	-----
C.....	.50-.70	.60-.90	.040	.045	-----	-----
C.....	.60-.70	.30-.60	.040	.025	-----	-----
C.....	.80-.90	.30-.60	.040	.040	-----	-----
C.....	.90-1.05	.30-.50	.040	.040	-----	-----
Cr-V...	.45-.55	.50-.80	.040	.040	0.80-1.10	0.15

¹ This steel is furnished as "hard drawn" wire, and in small sizes the carbon is often lower.

² In "music" wire the manganese is often lower.

Chemical composition.—Steels listed in Table 3 are recommended for helical springs under 1/2-inch wire diameter.

Heat treatment.—Specific heat treatments of steels for helical springs under one-half inch are given in Table 4. Variations in the heat-treatment operations are often due to the personnel, variations in the composition of the steel or manufacture, and changes in local conditions, such as the control and sensitiveness of heat-treating equipment.

TABLE 4.—Heat treatments for helical springs under one-half inch in diameter

C range from Table 3	Quenching temperature,	Tempering temperature,	Rockwell hardness
	° F	° F	
0.45-0.70	Pretempered.....	450-600	1 40-45
.50-.70do.....	450-600	40-45
.50-.70	1,450-1,525.....	700-850	40-45
.60-.70	Pretempered.....	450-600	40-45
.80-.90do.....	450-600	40-45
.80-.90	1,425-1,500.....	800-850	40-45
.90-1.05	Cold-worked.....	325-375	(?)
.90-1.05	1,450-1,525.....	800-900	40-45
Cr-V...	1,575-1,625.....	850-950	40-45

¹ On cushion springs this may be 35-45.

² Music wire is brought to tensile properties, not hardness.

⁴¹ Flash tempering should never be resorted to.

Quenching.—The steel should be heated uniformly to the temperature shown in Table 4 and quenched in thin oil. More uniform results are obtained with good circulation of the quenching medium and with regulation of the temperature from 100° to 140° F.

Tempering.—The steel should be heated in a suitable tempering medium to the temperature shown in Table 4. It should be held at this temperature for sufficient time to permit complete penetration of the heat. The method of cooling after tempering is optional.

AMERICAN SOCIETY FOR STEEL TREATING, TENTATIVE RECOMMENDED PRACTICE FOR THE HEATING, FORGING, AND HEAT TREATING OF LOCOMOTIVE FORGINGS, 1931

LOCOMOTIVE FORGINGS

INTRODUCTION

This recommended practice is to be used as a guide in the manufacture and heat treatment of locomotive forgings, such as locomotive driving and trailer axles, crank pins, main and side rods, piston rods, and similar forgings.

HEATING BILLETS FOR FORGING

As rapid heating may produce internal ruptures, care must be taken to avoid rapid heating, particularly from the low temperatures. Ample time should also be given for the heat to penetrate uniformly and thoroughly into the billet before forging. The actual heating time required will depend on the type of steel and the equipment and methods used for heating.

Cold billets should not be charged into a hot furnace. Billets that have been stored out of doors, particularly during winter months, should be brought into the shop for a warming period of 10 to 12 hours before charging into the furnace for heating.

PREHEATING FORGING BILLETS

It is good practice to preheat the billets. This preheating is best done in a separate furnace or one with a preheating chamber. If such a furnace is not available, the billets can be charged into a forging furnace after the operations for the day are completed, and the furnace has been cooled down to a dull red. The billets will absorb the furnace heat and by the next morning will be preheated to a temperature of several hundred degrees Fahrenheit. The billets are then ready for direct firing, which should proceed slowly. When a separate furnace is available for preheating, the billets are charged into the cold furnace and brought up slowly and uniformly to a temperature of 1,100° to 1,200° F. The time required to heat to this temperature should be approximately three-quarters to 1 hour per inch of least thickness.

To avoid loss of heat the billets should be transferred quickly from the preheating furnace to the forge-heating furnace. As the danger of rupturing the billets has been practically eliminated by preheating, the forging furnace can be at considerably higher temperature than the preheated billets. Raising the preheated billets to the forging temperature is carried out with the usual precautions to insure uniform heating and thorough penetration of the heat. The minimum time required to bring preheated billets from a temperature of about 1,100° F. to the forging heat (2,100° to 2,200° F.) is approximately one-half to 1 hour per inch of least thick-

ness. For billets of various thicknesses, the following schedule is typical:

	Hours
8 by 8 inches.....	3
14 by 14 inches.....	6
12 by 6 inches.....	3
10 by 10 inches.....	4
16 by 16 inches.....	7
14 by 8 inches.....	4
12 by 12 inches.....	5
18 by 18 inches.....	9
20 by 8 inches.....	4

FORGING TEMPERATURES FOR BILLETS

The proper forging temperature for both carbon and alloy steel billets, of the types generally used for locomotive forgings, is from 2,000° to 2,200° F. which is very pale yellow, fading into white. Overheating and nonuniform heating must be avoided, as both are sources of forging ruptures. It is desirable to have the heating furnace under pyrometric control, preferably by thermocouples.

The temperature at which the forgings are finished will be determined by the initial forging temperature, and by the temperature lost during forging, which depend on the size of the forging and on the amount of work required to shape the forging from the billet. Generally they are finished at a temperature of 1,500° to 1,800° F. Lighter sections, such as connecting rods, are usually finished at the lower temperature, while heavy sections, such as driving axles, are finished near the higher temperature mentioned.

HEAT TREATMENT OF LOCOMOTIVE FORGINGS

After the forging operation is completed, the forgings should be allowed to cool to below the critical range under suitable conditions to prevent injury by too rapid cooling. To remove forging stresses and to refine the grain, an appropriate heat treatment should be given.

The heat treatment may consist of annealing, but it is usual practice for high-duty locomotive forgings, where better physical properties are required, to use a treatment consisting of normalizing followed by tempering.

When forgings are to be bored or rough machined, they may be annealed to improve the machinability, preliminary to normalizing and tempering.

ANNEALING

The purpose of annealing a forging is to refine the grain structure, to increase the ductility, or to soften it for ease of machining. Annealing consists of heating to a temperature above the critical range, holding a sufficient length of time at that temperature, and then cooling in the furnace or cooling under suitable conditions to secure uniform retarded cooling.

NORMALIZING AND TEMPERING LOCOMOTIVE FORGINGS

The purpose of normalizing locomotive forgings is to refine the grain structure of a forging and to secure the highest combination of physical properties without resorting to quenching in a liquid medium. The normalizing temperature is therefore above the critical range. The temperature must be held a sufficient time to permit complete grain refinement in the forgings.

Normalizing may consist of a single heating to a temperature above the critical range followed by cooling in the air, or of a sequence of such heatings and coolings. If a sequence of heatings and coolings is used, the temperature may vary. A decrease in temperature is usually made for each successive heating, but the temperature for each heating should be above the critical range. Normalizing should be followed by tempering.

To eliminate the lack of uniformity in the grain structure of forgings, resulting from variations in reduction and finishing temperatures, and to produce a homogeneous grain structure throughout the forgings which will respond uniformly to the usual normalizing temperature, it is often desirable particularly with large forgings, first to normalize the forgings at a temperature much above the upper critical (approximately 1,750° to 1,850° F.) temperature.

TEMPERING

The purpose of tempering is to remove strains set up in the forgings during the cooling from the normalizing temperature. The ductility of the forgings is increased by tempering, while the tensile strength may be slightly reduced. Tempering is not intended to change the grain size; therefore, the temperature is below the critical range. After tempering, the forgings may be cooled in the air, slowly with the furnace, or under conditions to secure uniform retarded cooling. The forgings should be held at temperature a sufficient time to insure complete penetration of the heat.

In annealing, normalizing, and tempering, choice as to the temperatures used, the number of normalizing treatments, the length of time that the forgings are held at temperature, and the method of cooling in annealing and tempering must be made according to experience, taking into account the type of steel, the size and character of the forgings, and the condition of the furnace used.

TEMPERATURES AND TIMES OF HEATING

In view of the large number of variable conditions involved, it is impossible to lay down exact rules of procedure for annealing, normalizing, and tempering, with stated temperatures and times of heating which will be applicable under all conditions. The following sections give general information regarding temperatures and times of heating which may be expected to give satisfactory results under favorable conditions. The information is given only as a guide and not as standard practice for all cases. Experience based on the actual conditions involved will sometimes show that better results are obtained by the use of other temperatures.

The rate at which forgings are heated to the normalizing and tempering temperatures must not be too rapid or the forgings may be injured. The proper rate will depend to a considerable extent on the design of the furnace. In general, the time allowed for each inch of diameter or thickness of the forging should be 45 minutes for raising to the normalizing temperature and 30 minutes for raising to the tempering temperature.

After the temperatures desired for normalizing have been reached, the forgings should be held at these temperatures a sufficient time to permit the desired changes in structure to be completed. In general, a holding time of one hour per inch of diameter or maximum thickness will usually be satisfactory.

Table 1 gives, for general guidance, the time for heating and holding a medium furnace charge of forgings.

TABLE 1

Thickness of largest section of forging	Time of heating (approximate) ¹	Time of holding (approximate) ¹
	Hours	Hours
Up to and including 5 inches.....	8	5
Over 5 inches and including 8 inches.....	8	8
Over 8 inches and including 10 inches.....	10	12
Over 10 inches and including 12 inches.....	12	16

¹ Medium charge.

NORMALIZING AND TEMPERING TEMPERATURES

Table 2 gives, for general guidance, temperatures which may be used in normalizing and tempering forgings of the various compositions indicated. The figures are based on a single normalizing treatment with slow cooling in the furnace from the tempering temperature. As previously stated, the tempera-

tures may require modification to meet individual requirements.

Annealing temperatures will usually be lower than the normalizing temperatures. The difference is approximately 50° F. lower for annealing the plain carbon steel, 25° F. for the nickel steels, and 100° F. for the vanadium steels.

TABLE 2.—Normalizing and tempering locomotive forgings

AMERICAN SOCIETY FOR STEEL TREATING, TENTATIVE RECOMMENDED PRACTICE FOR THE HEAT TREATMENT OF SPLINE SHAFTS, 1931

SPLINE SHAFTS

GENERAL

This recommended practice covers the processes to be followed for the heat treatment of spline shafts. A spline shaft is so constructed that it interlocks, either rigidly or sliding, with a part or parts, such as gears. Thus a spline shaft may have one or more keyways, or one or more keys, but it is not customary to have both keys and keyways on the same shaft. Spline shafts are used in two general classes of work—automotive parts and machine-tool parts. Short shafts are widely used in automotive parts, whereas long spline shafts are more common in machine tools. No arbitrary dimensions are set in distinguishing between long and short shafts but, in general, shafts not over 12 inches in length or over 1½ inches in diameter may be called "short" spline shafts.

DESIGN

As spline shafts in operation are subjected to alternating stresses, their endurance limit or resistance to fatigue is of importance. The shaft should be designed to eliminate unnecessary necks and sharp corners where stresses might be concentrated. Fillets and machined grooves in splines should always be gradually rounded up.

Stiffness is one of the necessary properties of some types of spline shafts, particularly long shafts. Shafts should be designed of sufficient section so that harmful deflection will not occur under the applied load. Where the design is incorrect, the shaft may twist, or bend, thus causing undesirable effects due to alternating stress, vibration, and the like, which will be felt in the gears or other moving parts as well as in the shaft. Heat treatment may raise the elastic limit of the steel, but it will not change the modulus of elasticity. For this reason,

heat-treated shafts may not be any stiffer than untreated shafts when operating below the elastic limit.

DISTORTION

Distortion is the trouble most commonly encountered in the heat treatment of spline shafts. To avoid distortion care must be exercised in all operations. The steel must be carefully selected and inspected. If much machining is performed on the shafts, the machining strains should be relieved by normalizing or annealing before subjecting the shafts to the final heat treatments.

The carburizing and heat-treating processes should all be carried out with extreme care. It may be necessary with some carburized spline shafts to omit the double treatment and to carburize at a lower temperature to avoid distortion.

There are many spline shafts made of bar stock which is either black hot-rolled finish, or bright cold-drawn finish. In either case this material is more prone to distortion than a properly normalized forging, and, therefore, where minimum straightening is essential, spline shafts made of bar stock should be normalized the same as forgings unless the straightening operation is considered absolutely necessary on the finished spline shaft. If hot-rolled or cold-drawn bar stock is used, it is essential that one sixty-fourth to one thirty-second of an inch should first be machined from the outer surface to insure a clean surface for hardening.

Keyways in a spline shaft may cause distortion in quenching. Unless designed with ample section, a shaft with a keyway has less stiffness than one carrying keys integral with the shaft. To minimize distortion in quenching, it is advantageous to have more than one integral key. These keys are equally spaced about the shaft to facilitate equal cooling and balance the section.

CHEMICAL COMPOSITION OF SPLINE SHAFT STEELS

Three types of steel are commonly used for spline shafts. These are the carburizing, water-hardening, and oil-hardening types. In Table 1 typical compositions are given, but no attempt has been made to include every steel that might be used for some specific purpose.

TABLE 1.—Chemical composition of spline shaft steels

CARBURIZING STEELS

SELECTION OF STEELS FOR SPLINE SHAFTS

Spline shafts which are not to be highly stressed can be satisfactorily made from steel No. 1020. To make the shaft sufficiently stiff, it is sometimes designed large enough so that this steel may be used instead of an alloy steel.

For small shafts which are to be carburized, steels Nos. 3115, 2512, 3312, and 2315 are satisfactory. If the diameter is over 1½ inches, the carbon can be increased slightly without encountering brittleness on quenching. For example, for large shaft steels Nos. 3415, 3120, or 2320 are satisfactory.

While the water-hardening steels can be used, it should be pointed out that water quenching may result in cracking, particularly if the design is such that the shaft will be susceptible to cracking. Steel No. 1045, although used for spline shafts, is not entirely satisfactory. It does not always respond uniformly to heat treatment.

The steels given in Table 1 designated as manganese A, B, and 1335 are representative of the manganese structural steels. Steels of this general type are used successfully in spline shafts. They machine freely, have excellent physical properties, and harden without difficulty.

In addition to these two manganese steels, steels Nos. 1340 and 1345 are used to some extent for

spline shafts. These steels contain carbon 0.35-0.45, 0.40-0.50 per cent respectively with 1.60-1.90 per cent manganese. These steels do not machine so readily as the manganese steels listed, but have excellent physical properties and are oil quenched.

The oil-hardening steels listed are in general quite satisfactory.

HEAT TREATMENT OF CARBURIZING STEELS

Normalizing and Annealing of Carburizing Steels

To normalize or anneal the carburizing steels as given in Table 1, heat openly, exposing maximum surface area, to a temperature of 1,650° to 1,750° F. Hold at heat only long enough for complete refinement of grain and complete penetration of the heat. Cool in air or at a rate to give the desired machining qualities.

Carburizing

Carburize to a depth to suit individual requirements. The conventional methods of carburizing, as given in the National Metals Handbook, may be followed. The carburizing temperatures and the heat treatments for carburized spline shafts are given in Table 2.

TABLE 2.—Carburizing and heat treating of carburized spline shafts

Steel No. as listed in Table 1	Carburizing temperature	Cool in—	Reheat	Quench in—	Reheat	Quench in—	Tempering temperature
	° F.		° F.		° F.		° F.
1020	1,600-1,700	Box	1,550	Oil	1,400-1,450	Water	350-425
2315	1,600-1,700	do	1,540	do	1,375-1,400	Oil	350-425
2320	1,600-1,700	do	1,540	do	1,375-1,400	do	350-500
2512	1,600-1,700	do	1,525	do	1,375-1,400	do	350-500
3115	1,600-1,700	do	1,550	do	1,400-1,425	do	350-425
3120	1,600-1,700	do	1,550	do	1,400-1,425	do	350-500
3312	1,600-1,700	do	1,525	do	1,375-1,400	do	350-500
3415	1,600-1,700	do	1,525	do	1,375-1,400	do	350-500
Manganese A	1,600-1,650	do	1,575	do	1,400-1,425	do	400

¹ Carburizing at the lower temperature causes less distortion, while at the higher temperature more rapid penetration is secured.

Single-Quenching Treatments for Carburizing Spline Shafts

A single quench, or single treatment, may be given where resistance to impact or shock is not important and where it is important to hold distortion to a minimum. This treatment consists essentially in cooling the material in the box, reheating sufficiently high to refine the case and partially refine the core in one operation, followed by a suitable quench. This treatment is suited particularly to S. A. E. Nos. 2315 and 2512.

It is advisable, when the single-quenching treatment is employed, to use the lower carburizing temperature, and after carburizing if the structure is coarse it is advisable to use the higher reheating temperature, as given in Table 3.

TABLE 3.—Single-quenching treatment for carburized spline shaft

Double-Quenching Treatment for Carburized Spline Shafts

A double quench as given in Table 2 is recommended for obtaining case and core refinement, maximum ductility, and resistance to shock and impact. The conventional carburizing process (packing the material in a carburizing compound in a box) is satisfactory. Long and short shafts should stand vertically in the box, but uniform heating is essential which, in some furnaces, may require horizontal heating at a sacrifice of straightness.

It is suggested for hardening that the spline shafts may be hung vertically from eyebolts in the furnace, and also quenched vertically from the same eyebolts on both single and double quenched shafts. Spline shafts are always out in relation to the keyway. Shafts can be quenched in a fixture or on a machine on the final heat, so that they will come straight enough to clean up on grinding when an ample amount of grinding stock is allowed. By this method, in many cases, the straightening operation may be unnecessary.

Spline shafts can also be heated in a horizontal position in a continuous furnace provided the supports are properly spaced. The shafts come out fairly straight although they usually require some straightening.

Tempering Carburized Spline Shafts

In tempering, the highest temperature should be used that will give the desired hardness.

HEAT TREATMENT OF WATER-HARDENING STEELS

Normalizing and Annealing

To normalize or anneal the water-hardening steels for spline shafts as given in Table 1, heat openly, exposing maximum surface area, to a temperature of 1,600° to 1,700° F. for steel No. 1045, and to 1,650° to 1,750° F. for steels Nos. 2320 and 4130. For this treatment the steels should only be

held at temperature long enough to insure complete penetration of heat. From these temperatures the steels may be cooled in the air or cooled at a rate to produce the desired machining qualities.

Hardening and Tempering

The quenching and tempering temperatures for the water-hardening steels are given in Table 4. Before quenching in water, it may be advisable first to quench these steels for a few seconds in oil. The shafts should always be removed from the water before they become cold.

TABLE 4.—Hardening and tempering of water-hardening spline shafts

Steel No. as listed in Table 1	Quenching temperature	Quench in—	Tempering temperature (° F.)
	° F.

4130.....	1,475-1,525	do.....	700-1,200 suggested.

HEAT TREATMENT OF OIL-HARDENING STEELS

Normalizing and Annealing

After forging, these steels should be normalized or annealed. The following is a form of normalizing suitable for steels Nos. 1335, 2345, 3250, 3450, 6150, and manganese B. This treatment produces good machining qualities.

Heat the steels slowly, while exposing maximum surface area, to temperature of 1,650° to 1,700° F. Hold at heat only long enough to insure thorough and uniform heating. Cool rapidly by opening furnace doors to 1,280° F. Cool slowly from 1,280° to 1,000° F. over a period from 6 to 10 hours for good machining.

Steel No. 3140 may be normalized by heating slowly and uniformly while exposing maximum surface area to a temperature of 1,575° to 1,625° F. and cooling from this temperature slowly in air.

Steel No. 4140 may be normalized by heating slowly and uniformly while exposing maximum surface area to a temperature of 1,650° to 1,700° F. and cooling slowly in air.

Hardening and Tempering

The quenching and tempering temperature for the spline shafts made from oil-hardening steels are given in Table 5.

TABLE 5.—Hardening and tempering oil-hardening spline shafts

Steel No. as listed in Table 1	Quenching temperature	Quench in—	Tempering temperatures	Approximate Brinell hardness
	° F.		° F.	
1335.....	1,500-1,525	Oil.....	900-1,000	217-255
3145.....	1,425-1,450	do.....	900-1,050	351-300
	1,525-1,550	do.....	650- 750	430-375
3250.....	1,475-1,500	do.....	475- 750	529-480
3450.....	1,475-1,500	do.....	750- 850	460-387
4135.....	1,525-1,550	do.....	550- 650	400-387
6150.....	1,575-1,600	do.....	700- 800	444-351
Manganese B.....	1,475-1,525	do.....	900-1,000	400-321

Hardening steel No. 3145 may be accomplished in two different ways, as indicated in Table 5. The method giving a high-tempering temperature con-

sists in hardening the shaft vertically, with the spline or keyway not cut, and leaving ample stock for grinding. The keyway is then milled after the heat treatment. If the steel has been properly normalized and carefully handled, straightening is rarely needed, but it can be done at the tempering heat if necessary. After tempering, the shafts are rough ground to 0.010 inch large, then the spline is milled, and the spline shafts are then finish ground.

This same sequence of operations may be followed for any of the steels listed in Table 5. The tempering temperature would then necessarily be higher than indicated in the table in order to make machining possible. By using this treatment on steels Nos. 3250 and 3450, more ductility may be obtained than is possible with steel No. 3145.

Spline shafts may be difficult to straighten after quenching. For example, shafts made with ample grinding stock from steel No. 3450 may be designed either to have two splines equally spaced or three integral keys which eliminate the unbalanced distortion. If steels Nos. 3250 and 3450 have to be straightened, it is done at the tempering temperature.

When steel No. 3145 is tempered at the lower temperature, the same method as outlined for steel No. 3450 is used. However, it may be possible to jig or machine quench this steel with a single spline, so that it will come within a reasonable grinding allowance.

Steel No. 6150 distorts in heat treating more than the steels previously discussed. However, it withstands abuse, has high strength, and high fatigue-resistance values.

AMERICAN SOCIETY FOR STEEL TREATING, TENTATIVE RECOMMENDED PRACTICE FOR THE HEAT TREATMENT OF RIVET SETS FOR HOT WORK, 1931

RIVET SETS FOR HOT WORK

GENERAL

This tentative recommended practice deals with two types of rivet dies; first, pneumatic rivet sets used in air guns, and, second, compression rivet dies which head by pressure rather than blows.

The approximate chemical compositions of the steels generally used for both types of rivet dies are given in Tables 1 and 3.

TABLE 1.—Approximate chemical composition for pneumatic rivet sets

Steel No.	Type	C	Si	Mn	W	Cr	V
1.....	Carbon.....	0.70-0.90	-----	0.30	-----	-----	-----
2.....	C-V.....	.70-.90	-----	.30	-----	-----	0.20
3.....	Cr-V.....	.45-.60	-----	.35	-----	0.80	.20
4.....	Cr-V.....	.45-.60	-----	.55	-----	.80	.20

7.....	1,800-1,600	1,600-1,700	1,475-1,525	1,550-1,625do. ³	550-700	52-57

¹ A 10 per cent brine solution is used.

² For this treatment, oil is the preferred quenching medium.

³ If this steel contains around 0.50 per cent molybdenum it may be quenched in oil by using a temperature approximately 25° to 50° F. higher than the temperature for water quenching.

QUENCHING AND TEMPERING

It is recommended that the rivet sets should be completely immersed while a stream of the quenching medium is being forced into the cup. When quenching, it is good practice to hold the rivet set with a special pair of tongs which keeps the water away from the ring, but at the same time permits uniform cooling of the cup and shank.

The sets should be tempered all over at the temperatures given in Tables 2 and 4.

AMERICAN SOCIETY FOR STEEL TREATING, RECOMMENDED PRACTICE FOR THE CARBURIZING AND HEAT TREATING OF CAMSHAFTS, 1929

HEAT TREATMENT OF CAMSHAFTS

GENERAL

This recommended practice covers the process to be followed in the carburizing and heat treating of camshafts.

CHEMICAL COMPOSITION

The steels listed in Table 1 may be used for camshafts and this recommended practice is not applicable to steels having any other chemical composition.

TABLE 1.—*Chemical composition*

Steels	C	Mn	P (maximum)	S (maximum)	Ni
S. A. E. 1015.....	0.10-0.20	0.30-0.60	0.045	0.055	-----

Cr-V ⁵10-.15	.30-.50	.040	.040	-----

¹ This steel is the one most commonly used for camshafts.
² The chromium content for this steel is 0.45 to 0.75 per cent.
³ The molybdenum content of this steel is 0.20 to 0.30 per cent.
⁴ The chromium content for this steel is 0.80 to 1.10 per cent and the vanadium content is 0.15 to 0.20 per cent.
⁵ The chromium content for this steel is 0.25 to 0.40 per cent and the vanadium content is 0.15 to 0.20 per cent.

ANNEALING AFTER FORGING AND BEFORE MACHINING

For annealing the S. A. E. steels Nos. 1015, 1020, 2320, 3120, 6120, the 0.50 per cent nickel, nickel-molybdenum, and the chromium-vanadium steels, place the steels in the furnace so as to expose maximum surface area. Heat slowly and uniformly to a temperature of 1,600° to 1,650° F., and cool at a rate to give the desired machinability.

For annealing the 5 per cent nickel steel (S. A. E. No. 2512), place in furnace so as to expose maximum surface area. Heat slowly and uniformly to 1,600° F., and hold at this temperature for about 1 hour. Cool slowly in furnace to 800° F., and then cool in air.

Before machining hollow camshafts, quenching and tempering operations, at the proper temperatures, are advisable to give the desired machinability.

PREPARATION OF CAMSHAFTS FOR CARBURIZING

Two methods are used for machining a camshaft that will straighten without breaking after hardening.

One method consists of copper plating the entire shaft prior to carburizing and removing the copper by grinding or turning from those areas which are to be carburized and hardened.

The second method consists of forging or machining the camshafts somewhat larger with an excess of metal between the cams and bearings. This excess metal is machined off after carburizing and before hardening.

Many companies are now finish-machining the camshafts before carburizing, and when hardening quench directly into a straightening machine.

CARBURIZING CAMSHAFTS

The carburizing operation should be carried out in containers and furnaces of suitable dimensions

and design to permit uniform heating throughout the charge. The carburizing temperatures for the various steels are given in Table 2.

The camshafts should be so packed that the areas to be hardened do not come in contact with each other or with the walls of the containers.

Sufficient compound should be used so that the camshafts are not exposed at any time during the carburizing and cooling operations; after carburizing, the camshafts are allowed to cool in the containers.

CASE DEPTH

The time required to attain the depth of case depends upon a number of factors, such as temperature of the furnace at time of loading, rate of heating, type of furnace, thickness of the containers, amount of stock left for grinding, etc. However, the carburizing time and the amount of stock left before grinding should be so regulated that the depth of case after grinding is at least 0.045 of an inch.

HEAT TREATING OF CAMSHAFTS AFTER CARBURIZING

Hardening.—The camshafts should be heated uniformly to the temperature given in Table 2, and held for complete penetration of heat. The heating medium should be of such a character that no decarburization will take place.

To prevent warpage, the shafts should be arranged properly in the heating medium and quenched either vertically or rolled horizontally into the quenching bath.

Tempering.—After quenching, reheat the camshafts in a suitable tempering medium to the temperature given in Table 2 and hold at this temperature for at least 1 hour to insure complete penetration of heat. The highest temperature that will not affect the hardness should be used. The hardness of the camshaft should not be below a scleroscope reading of 75.

TABLE 2.—*Carburizing and heat treating camshafts*

Steels	Carburizing temperature	Cool in—	Reheat to—	Quench in—	Tempering temperature
S. A. E. 1015.....	1,625-1,750	Box.....	1,425-1,450	Water or brine	350-400

S. A. E. 3120.....	1,625-1,675	Box.....	1,375-1,425	Water or oil...	250-450
S. A. E. 2512 ¹	1,600-1,650	Box.....	1,350-1,400	Oil.....	250-450
Ni-Mo.....	1,650	Box.....	1,475-1,525do.....	350
S. A. E. 6120.....	1,675-1,725	Box.....	1,425-1,475	Water or brine	400-450
Cr-V.....	1,675-1,725	Box.....	1,425-1,475do.....	400-450

¹ Use lowest possible temperature to produce maximum hardness.
² After rough machining anneal at 1,450° F., air cool, finish the machining, and then carburize.

NOTES ABOUT THE PROCESS

The mixture of the carburizing compound is left to the judgment of the individual. Some add only enough new compound to replace the amount used during carburizing, while others may vary the ratio from the above to a mixture of 50 per cent old and 50 per cent new.

There are several methods used for packing the camshafts. For example, a single shaft may be packed in a tube, or a number of shafts may be packed in a tube or a box of suitable size. The majority of the methods give good results if properly carried out.

When using the plain carbon steel (S. A. E. No. 1020), satisfactory results may be obtained without annealing or otherwise heat treating before machining, although by following the above practice the steel will be in a better condition.

When using a salt bath as a heating medium for hardening, the shafts are sometimes preheated at approximately 600° F., transferred to the salt bath in which they are suspended vertically to prevent warping, and maintained in the heating medium until they attain the proper hardening temperature. They are then quenched and tempered.

AMERICAN SOCIETY FOR STEEL TREATING, RECOMMENDED PRACTICE FOR THE CARBURIZING AND HEAT TREATING OF GEARS, 1929

HEAT TREATMENT OF GEARS

GENERAL

This recommended practice covers the process to be followed in the carburizing and heat treating of gears. The gears may be carburized by either the pack method or in retort furnaces, using either gas or a solid compound.

CHEMICAL COMPOSITION

There are steels used for gears of other analyses than those listed below, but they require different heat treatments and, therefore, this recommended practice does not apply to them. The chemical compositions of the steels generally used for gears are given in Table 1.

TABLE 1.—Approximate chemical composition of gear steels for carburizing

¹ For most uniform and satisfactory results the carbon content for these steels should be within a 5-point range.

ANNEALING AFTER FORGING AND BEFORE MACHINING

For annealing, place the steel in the furnace to expose maximum surface area, then heat slowly and uniformly to the temperature given in Table 2.

The 5 per cent nickel steel (steel No. 4 in Table 1) is heated to the annealing temperature as given in Table 2 and usually cooled with the furnace, allowing from five to eight hours for the steel to become cold.

To obtain the best conditions for machining and grain size, it is sometimes desirable to quench the 3½ and 5 per cent nickel steels from the annealing tem-

peratures into water or oil. Then anneal to give a Brinell hardness number from 163 to 179. The 5 per cent nickel steel also gives satisfactory results when air cooled from the annealing temperature.

CARBURIZING

The carburizing temperatures for the gear steels considered in this recommended practice are given in Table 3.

HEAT TREATMENT OF CARBURIZED GEARS

The quenching temperatures for the carburized gears are given in Table 3.

TABLE 2.—Annealing temperatures for carburizing gear steels—after forging and before machining

Steel No. as listed in Table 1	Heating medium	Time heating	Temperature	Method of cooling
1.....	Furnace	1 hour per inch of diameter or thickness.	° F. 1,525-1,575	Air or furnace.
2.....	do.....	do.....	1,500-1,550	Furnace.
3.....	do.....	do.....	1,500-1,550	Do.
4.....	do.....	do.....	1,600	Air or furnace. (See text).
5.....	do.....	do.....	1,500-1,550	Furnace.
6.....	do.....	do.....	1,500-1,550	Do.
7.....	do.....	do.....	1,500-1,550	Do.
8.....	do.....	do.....	1,475-1,525	Furnace. (Do not remove from furnace over 800.)

When bevel gears are quenched, the last operation should be done on a quenching machine with a properly designed die.

For large gears (larger than automobile gears), where surface hardness is required in excess of that obtained from quenching in oil, water is sometimes used for the last quenching operation. This is especially true for steel No. 2.

The heating medium considered in this recommended practice is the indirect-fired or muffle-type furnace.

TEMPERING

All gears should be tempered at 300° to 350° F., except clash gears, which are tempered at 350° to 400° F.

CARBON CONTENT OF CASE

The carburizing process should be so carried out that the carbon content of the outer portion of the case will be approximately 1.00 per cent. Care should, therefore, be exercised to avoid the use of badly spent carburizing compound.

DEPTH OF CASE

The depth of case on each side of the gear tooth should be about 15 per cent of the total thickness of the tooth, measured at the pitch line, until a case depth of 0.060 to 0.070 of an inch is reached. It is not considered practical to produce carburized cases of much greater depth, so this is about the limit of case depth even with gears having a greater total thickness of tooth.

COPPER PLATING

Where it is desired to keep a portion of the work soft after heat treatment, to permit machining or to assist in controlling distortion, copper plating to prevent the penetration of carbon is recommended.

TABLE 3.—Carburizing and heat treating of carburized gears

AMERICAN SOCIETY FOR STEEL TREATING, RECOMMENDED PRACTICE FOR THE CARBURIZING AND HEAT TREATING OF PISTON PINS, 1929

HEAT TREATMENT OF PISTON PINS

GENERAL

This recommended practice covers the processes to be followed in the carburizing and heat treating of piston pins made from plain carbon and alloy steels.

CHEMICAL COMPOSITION

The steels listed in Table 1 may be used for piston pins and this recommended practice is not applicable to steels having any other chemical composition.

TABLE 1.—Chemical composition of steels used for piston pins

S. A. E. steel No.	C, ¹	Mn	P (maximum)	S (maximum)

4615		1.50-2.00		0.20-0.30
6115	.80-1.10		0.15-0.20	

¹ Some users specify the carbon for these steels to be 0.08 to 0.14 per cent and 0.15 to 0.25.

PREPARATION OF PISTON PINS FOR CARBURIZING

Piston pins are generally made from either regular or special finish bar stock or tubing. If made from bar stock the hole may be drilled before carburizing. After drilling, the pins may be packed in the carburizing compound; but to prevent carburizing of the hole the pins may be strung on a rod, or they may be plugged. The pins may also be drilled after carburizing, which will leave the centers soft.

CARBURIZING OF PISTON PINS

The carburizing operation for piston pins may be carried out in containers and furnaces of suitable dimension and design to permit uniform heating throughout the charge, or in rotary retort furnaces using either gas or a solid compound. The carburizing temperatures for the various steels are given in Table 2.

To keep the areas to be hardened from coming in contact with each other, or with the walls of the containers, and to prevent the piston pins from being exposed at any time during the carburizing and cooling operations, at least three-eighths of an inch of carburizing compound should separate the pins from each other and from the walls of the containers.

To determine the actual depth of case before the containers are allowed to cool, a test piece may be attached to a wire, one end of which is exposed. The test piece can then be conveniently removed while the container is still hot and the depth of case checked.

TABLE 2.—Carburizing and heat-treating of piston pins

S. A. E. steel No.	Carburizing temperature	Cool in—	Reheat to—	Quench in—	Tempering
	° F.		° F.		° F.
1015	1,650-1,725	Box	1,425-1,450	Water or brine	275-375
2315	1,575-1,625	Box	1,400-1,450	Oil or water	375
2512	1,600-1,650	Box	1,350-1,400	do	250-450
3115	1,650-1,700	Box	1,400-1,450	Oil	350-400
4615	1,600-1,650	Box	1,475-1,525	Oil or water	350-400
6115	1,650-1,700	Box	1,425-1,475	do	350-400

CASE DEPTH

The carburizing time and the amount of stock left before grinding should be so regulated that the depth after grinding is at least 0.030 of an inch. From 0.008 to 0.010 inch is the amount of stock generally removed by grinding.

HEAT TREATING OF PISTON PINS AFTER CARBURIZING

Hardening.—For hardening, the piston pin should be heated uniformly to the temperature given in

Table 2, and held for complete penetration of heat. The heating medium should be of such a character that no decarburization takes place.

Before hardening the case, the piston pins are sometimes given a core-refining treatment, the hardening temperature for the case then being lowered. However, a single heat treatment is usually satisfactory.

Tempering.—After quenching, piston pins may be tempered by reheating to the temperature given in Table 2.

The hardness of the piston pin should not be below a scleroscope reading of 75, the approximate Rockwell being C-54.

alloys of the duralumin type, the silicon content may be definitely controlled. The iron content is ordinarily less than 1 per cent in all these products.

FORMS AVAILABLE

Each of the following fabricated forms is commercially available in some or all of the alloys mentioned: Plate, sheet (both flat and coiled), bar, rod, wire, seamless tubing (round, square, and oval), shapes (both rolled and extruded), stampings, forgings, rivets, and automatic screw machine products.

GRADES AND TEMPERS

Duralumin is supplied in at least two grades and 17S in four grades, produced by modifying the composition. The two standard grades of Baush duralumin are distinguished by the letters A and B, while the various modifications of 17S are designated 17S, A-17S, B-17S, and Special 17S. Each of the alloys is supplied in several tempers. The temper is determined by the condition as regards heat treatment or cold working. Like other metals, these alloys are hardened by cold working. If the alloy was in the hot rolled or annealed condition, as distinguished from the heat-treated condition, prior to cold rolling, the cold-rolled product is designated "hard" or "hard wrought."

In this condition the strength and hardness are fairly high and the elongation quite low. On heating the alloys to suitable temperatures and cooling, they are softened and the resulting temper is designated as the "annealed" temper.

The above statements concerning temper are applicable to all of the alloys mentioned. If any of these alloys be heated to a suitable temperature, then quenched, the strength and hardness are materially increased over the values characteristic of the annealed temper. The elongation is usually somewhat increased with respect to that of the annealed material, and is very markedly increased over that of the hard-wrought temper.

On standing at ordinary temperatures after the above quenching treatment, 17S and duralumin undergo a spontaneous change, commonly referred to as aging, which involves further increases in strength and hardness, with little change in elongation, but with a decrease in plasticity. This change is at first rapid, but proceeds at a gradually decreasing rate. The change is largely effected in the first few hours and is generally considered to be substantially complete in about four days. Heating the alloy to the temperature of boiling water increases the rate of aging, but has little effect on the mechanical properties attained after several hours. The aging process may be illustrated by the following data:

17S sheet, 0.064 inch quenched from 940° to 960° F.

AGED AT ROOM TEMPERATURE

Aging time	Tensile strength	Yield point	Elongation in 2 inches
	Lbs./in. ²	Lbs./in. ²	Per cent
1 hour	44,830	21,150	19.0
1 day	54,755	32,350	18.7
2 days	56,115	33,000	18.7
6 days	56,765	34,850	19.7
10 days	57,175	34,350	19.7

AGED IN BOILING WATER

1 hour	53,705	29,900	22.0
1 day	55,505	32,350	21.2
2 days	56,370	33,000	22.2
10 days	56,040	33,650	21.7

In order to discuss the properties of these alloys in various grades and tempers, it will be necessary to refer to them by their trade symbols, as follows:

AMERICAN SOCIETY FOR STEEL TREATING, HEAT TREATMENT OF WROUGHT ALUMINUM ALLOYS OF HIGH STRENGTH, RECOMMENDED PRACTICE, 1927

HEAT TREATMENT OF ALUMINUM ALLOYS

SUBJECT

These data sheets cover the heat treatment of wrought aluminum alloys capable of being hardened by heat treatment. The word "hardened" as here used indicates an increase in Brinell hardness, yield point, tensile strength, and a decrease in plasticity.

ALLOYS

There are many possible aluminum-alloy compositions which may be worked and whose properties may be greatly improved by heat treatment. The same general principles and methods of heat treatment would apply to these various alloys, although the temperatures and other details depend on the specific compositions. These principles and methods will be illustrated with reference to the high-strength aluminum alloys commercially manufactured in the United States. Since these alloys are not yet recognized by general names or specifications, it will be necessary to refer to them by their trade symbols or designations. The alloys include duralumin "A" and "B" and 17S, 25S, and 51S. These are fundamentally wrought alloys, and the statements here made concerning their properties and heat treatment apply to material which has received sufficient working to destroy the cast structure.

COMPOSITION

The alloys 17S and duralumin are characterized by containing both copper and magnesium. Manganese is nearly always present and sometimes a small amount of chromium. Typical specifications for these alloys contain the following composition limits:

	Per cent
Copper.....	3.5- 4.50
Manganese.....	.4- 1.00
Magnesium.....	.3- .75
Aluminum (minimum).....	92.00

The composition of commercial alloys of the duralumin type may, however, vary somewhat from these values. The manufacturer's tentative operating limits for 25S and 51S are as follows:

<i>Alloy 25S</i>		Percent
Copper.....		3.9- 5.0
Manganese.....		.5- 1.10
Silicon.....		.5- 1.10
Aluminum (minimum).....		92.00

<i>Alloy 51S</i>		Percent
Magnesium.....		0.45- 0.80
Silicon.....		.60- 1.20
Aluminum (minimum).....		96.50

Iron and silicon occur as impurities in all commercial aluminum alloys. In 25S, 51S, and some

MECHANICAL PROPERTIES

The actual mechanical properties of these alloys in their various tempers depend somewhat on their fabrication history, especially on the total reduction by mechanical working; and in the case of hard material, on the amount of cold working. Lack of sufficiently thorough mechanical working results in low strength and elongation. This influence is apt to become apparent in sheets heavier than about one-fourth inch in thickness, in bars larger than three-fourths inch in diameter, and in heavy forgings. In very heavy material the strength may be affected by as much as 5,000 pounds per square inch and the elongation in 2 inches by 4 per cent or more.

Another factor which affects the tensile properties is the form of the test specimen. In testing very thin metal specimens the elongation values are usually less than when measured over the same gage length on thicker specimens of material possessing the same inherent physical properties. This is due to the proportions of the specimen (ratio of cross section area to gage length) and not to inferior properties of thin sheet.

With these qualifications, the following properties are given by the manufacturers as characteristic of the alloys in various tempers:

17S, 25S, AND 51S

These alloys are seldom used in the cold-worked condition, being intended primarily to be hardened by heat treatment. The properties of work-hardened materials depend, of course, on the amount of cold work, which varies with the product. In general, a given percentage reduction by cold working gives roughly the same percentage increase in tensile strength. The yield point rises more rapidly, in per cent, than the tensile strength, and the elongation decreases rapidly. By way of example, it may be mentioned that certain samples of 17SH sheet (14 gage) which had been reduced in section 50 per cent by cold rolling after annealing had 37,625 pounds per square inch yield point, 39,400 pounds per square inch tensile strength, and 3 per cent elongation in 2 inches.

Material which has been quenched and aged is similarly hardened by cold work, but the reductions employed are relatively small. The figures for the material BH in the above table represent from 10 to 20 per cent reduction. While these properties are desirable for certain work, the field is limited as it is mainly in the case of sheet that any considerable cold work can be done on quenched and aged material without damage.

ELASTIC MODULUS

Young's modulus (*E*) is about 10,000,000 pounds per square inch for all of these alloys.

SPECIFIC GRAVITY

Approximate values are as follows:

	Alloy				
	Duralumin, 17S	25S, Special 17S	51S	A-17S	B-17S
Specific gravity.....	2.79	2.79	2.69	2.74	2.76
Weight (lbs./in. ³).....	.101	.101	.098	.099	.100

ELECTRICAL CONDUCTIVITY

The conductivities of heat-treated duralumin, 17ST and 25ST are approximately 30 to 35 per cent of the annealed copper standard, while for 51ST the values are approximately 40 to 45 per cent.

THERMAL CONDUCTIVITY

The thermal conductivities in cgs units are numerically very close to the above values for electrical conductivity.

HEAT-TREATMENT PROCESSES

The heat-treatment processes usually applied to the high-strength aluminum alloys are of three types:

1. Annealing

Normally applied to work-hardened metal with the object of softening and improving workability.

2. Solution Heat Treatment

A heat treatment at temperatures upward of 900° F. followed by quenching. Metallurgically, the object of this treatment is to bring the soluble constituents of the alloys into solid solution, and to retain this solid solution in a supersaturated condition by rapid cooling to room temperature. This produces a susceptibility to hardening by natural or "artificial" aging. Immediately after quenching, the alloys are harder than in the annealed condition but softer than in the quenched and aged condition.

3. Precipitation Heat Treatment

The hardening which takes place on aging at room temperature or at elevated temperatures is believed to be due to the formation of a very fine precipitate of the soluble constituents from the supersaturated solid solutions. Hence, any heat treatment designed to accomplish this result may be referred to as a "precipitation heat treatment."

ANNEALING

Ordinarily the object of annealing is to remove the hardening effects of cold work. To accomplish this result, it is necessary to heat the metal above its recrystallization temperature, as in the annealing of copper and brass. In the case of high-strength aluminum alloys, however, if the metal is heated to higher temperatures and cooled at any other than a very slow rate, some hardening will take place, as in the regular solution-heat treatment. It is, therefore, necessary to avoid heating to temperatures above that required to remove the work-hardening. This temperature varies with the composition of the alloy and the amount of cold working, from about 575° to 675° F. In general, a temperature of 650° F. is suitable for all of the alloys. The material should be left in the furnace for a sufficient length of time to make sure that all of the metal has reached the annealing temperature. Slow cooling to a temperature well below the annealing temperature is desirable, since this will tend to remove the hardening effect that would result if any part of the load had been overheated.

It is sometimes desired to anneal material which has been previously hardened by heat treatment (*W* or *T* temper). Heating to the usual annealing temperature, as described above, will soften such material to some extent but not sufficiently to produce the workability characteristic of the normal annealed temper. A special annealing treatment which has been found effective in such cases consists in heating for an hour or more at 800° F. and cooling very slowly to below 500° F. The longer the time at 800° F., and the slower the cooling, the more thoroughly will the material be annealed.

The condition of greatest softness in these alloys is attained when the work-hardening is removed by recrystallization and grain growth, and when the soluble constituents are precipitated from solid solution as completely as possible in the form of large particles. The drawing qualities can, however, be adversely affected by over-annealing, with the development of coarse grain.

SOLUTION-HEAT TREATMENT

Accurate temperature control is essential for the best results. The hardening effect increases gradually with the temperature of treatment until the maximum solution of soluble constituents is attained. If the heat-treating temperature is too low, the hardening will be incomplete, while if it is too high, partial melting of the alloy will take place with consequent loss of ductility and strength. This effect, known as "burning," should be carefully avoided. The damage done by burning increases gradually as the temperature of treatment and time of holding increase until finally the material is completely ruined. Badly burned material is characterized by a crystalline fracture, with or without discoloration; surface cracks are apt to appear on bending or stretching; the microstructure shows areas which have been fused. In its early stages, burning is fairly difficult to detect. Material once burned can not be completely restored by heat treatment.

The exact temperature at which burning will begin depends on the chemical composition, and perhaps also on the fabrication history of the alloy. It is apt, therefore, to vary a little from heat to heat of the same alloy. The temperature ranges recommended below are such that burning will not take place in any lot of material within the usual range of chemical composition.

Alloy	Temperature for solution heat treatment	
	Permissible range	Preferred temperature
	° F.	° F.
Duralumin, 17S, A-17S, B-17S.....	925-960	950
25S and 51S.....	950-985	970
Special 17S.....	910-930	925

The time required at heat depends somewhat on the amount of mechanical working the material has received; for ordinary well worked sections 15 to 30 minutes, after due allowance for the thorough heating of heavy sections and large masses of material, will usually be sufficient. Long soaking after the material is at heat is ordinarily not beneficial, unless the material has not been thoroughly worked. Practically, the type of heating equipment and its method of operation as well as the sections, mass, and distribution of the charge, determine the total time taken. For example, a single piece of thin sheet might be heated and quenched in 15 minutes, while several hours might be required properly to heat and quench a large batch of heavy forgings. The same exercise of judgment required in heat-treating varying sections and masses of steel will be sufficient in handling aluminum alloys.

After this treatment, the metal is cooled rapidly, as by quenching in water or oil. The time interval between the removal of the metal from the heating medium and its quenching should be as short as possible. The physical properties finally obtained are about the same whether the quenching medium is cold water, boiling water, or oil. Quenching from a nitrate bath into boiling water is apt to be accompanied by dangerous spattering, and operators should be protected by shields, goggles, etc. Good physical properties, with reduction of distortion, can also be obtained by cooling in a current of air—especially in the case of light sections. Another method of quenching may be described as die-quenching. The act of hot-forming some of these materials, such as 17S and duralumin, at substan-

tially the same temperatures that are used for the solution-heat treatment, results in a sufficiently rapid quench to produce substantially fully heat-treated material.

Although the quenching rate has very little effect upon the final mechanical properties of the material, the susceptibility to corrosion of quenched and aged material is affected to a much greater extent by this variable. It has been found that the resistance to salt-water corrosion, and to corrosion by chloride solutions in general, is better the more rapid the quenching. As a rule, cold-water quenching is recommended for materials which will be exposed to corrosive conditions, especially sheet material and structures fabricated from sheets or other thin sections. Since corrosion begins at the surface, its effect on the mechanical properties of the piece as a whole, is, of course, more serious the thinner the material. For articles of relatively large cross section, for example, forgings, the question of the corrodibility of the material, as affected by the rate of quenching is comparatively negligible.

The properties produced by the solution heat treatment are substantially independent of the initial condition of the material; that is whether hard, annealed or heat treated, except that in the case of material which has received a relatively slight degree of cold work, either locally or generally, there is some possibility of excessive grain growth. In such cases rapid heating and short time at heat usually tend to reduce grain growth.

AGING

It should be noted that temperatures much below room temperature (68°F.) will temporarily retard the normal age-hardening of duralumin and 17S, while extreme cold actually arrests aging. On return to normal room temperature, normal aging is resumed. In making tests, care should be taken that the aging has not been retarded by chilling. If there is any doubt as to rate of aging, hardness tests may be used as a check before pulling test bars.

PRECIPITATION HEAT TREATMENT

This type of heat treatment is ordinarily applied only to 25S, 51S, and special 17S, of the alloys mentioned above. (Duralumin and 17S ordinarily receive their "precipitation heat treatment" by aging at room temperature.) It is to be preceded by the solution heat treatment.

The general effects of this treatment are increased hardness, yield point, and tensile strength, and decreased plasticity. The per cent elongation in the tensile test may increase slightly during the first stages of the treatment, but decreases by the time maximum hardening is attained.

The most favorable range of temperature for the treatment is usually from about 250° to 320°F. The time required is greater the lower the temperature of treatment, and the greater the hardening effect desired. As a rule, better combinations of tensile strength and elongation can be obtained by a long treatment at a low temperature than by a short treatment at a high temperature.

As the treatment progresses, the hardness rises to a maximum and then, after prolonged heating at 250° F. or higher, begins to decrease slowly. In actual practice the precipitation treatment usually stops well short of this point.

To attain the physical properties given above for 25ST, 51ST, and special 17ST, the following precipitation treatments have been found suitable: For 25S, 8 to 15 hours at 285° to 295° F.; 51S, 18 hours at 310° to 320° F.; special 17S, 18 hours at 310° to 320° F.

Some experimentation may be required to determine the best treatment for any particular class of product.

The manner of cooling after the precipitation treatment is immaterial.

WELDING

It is not intended to discuss here in detail the welding of the strong aluminum alloys nor the properties of welded joints, but it is felt that a few general principles should be pointed out. To make a weld it is necessary to melt some of the metal. This molten metal solidifies rather rapidly after welding, and acquires the structure and properties of a more or less sound chill casting, rather than those of a wrought metal. The adjacent metal which actually has not been melted has been heated to various temperatures including those used for the precipitation treatment, for annealing, and for the solution heat treatment as well as that required for burning. The properties of the metal, accordingly, will vary with the distance from the weld.

Both the mechanical properties and corrosion resistance of welded joints can be improved materially by heat treatment after welding.

FORMING

The cold-forming properties of the various alloys are best in the annealed condition. Articles formed from annealed material must be given the solution heat treatment before the material will develop its full physical properties either on natural or artificial aging. Because of the high temperatures used in the solution heat treatment there may be more or less difficulty, depending on the shape of the article, from warping or distortion. To avoid this difficulty it is often desirable to carry out forming operations after the solution heat treatment. This can best be done immediately after quenching, especially in the case of alloys which age-harden materially at room temperature. Even then the operations which can be carried out are usually more limited than in the case of annealed material. The capacity for cold forming decreases as the material is age-hardened at room temperature, and still further on aging at elevated temperatures. In the case of the alloys to which aging treatments at elevated temperatures are applied (special 17S, 25S, and 51S), the material may be obtained in the quenched condition, formed and then further hardened by a precipitation treatment. It is some times possible to combine the solution heat treatment with the forming operation. Articles have been successfully made from 17S and duralumin sheet, for example, by hot pressing at about 900° F., the quenching effect of the dies being sufficient to produce nearly full development of physical properties in the finished article.

TECHNICAL METHODS OF HEAT TREATMENT

Uniformity of temperature distribution and accuracy of control are essential in the heat treatment of the strong aluminum alloys. These conditions can be realized satisfactorily in various types of heating equipment.

Annealing may be carried out in an air atmosphere, or in furnaces of either batch or continuous type, heated by electricity, gas, or oil. For the best results, close temperature control is desirable, but is not so vital as in the solution and precipitation treatments, especially if care is taken to cool very slowly from the annealing heat to 500° F. or below.

The solution treatment of articles of light section, such as sheet, may readily be carried out in a bath

of fused sodium nitrate heated with gas or oil so as to permit close regulation of temperature. It may be necessary to stir such a bath to avoid inequalities in temperature. This can be readily accomplished by alternately raising and lowering the load while it is being heated, making sure, however, that the metal is not raised above the surface of the bath. This will insure the circulation of the liquid between the different parts of the load.

For heavier sections, such as bars and forgings, or for large amounts of material, a furnace for treatment in an air atmosphere has certain advantages over nitrate baths and is preferred by some. Such a furnace must be so constructed and operated as to give proper uniformity and control of temperature. Standard gas and oil fired furnaces of several types, as well as electric furnaces with automatic temperature control, are in commercial use.

When metal is heated in a nitrate bath, it is necessary that the adhering nitrate be completely removed as, if left on, it may cause corrosion. Quenching in hot water facilitates the removal of nitrate. If the metal is allowed to cool slowly, the salt forms a sort of enamel that is very difficult to remove. For this reason the nitrate bath is not very suitable for the annealing treatment, from which the metal is preferably cooled slowly.

For the precipitation treatment, good temperature control and distribution can be obtained by the use of live steam, as in tanks employed for vulcanizing. This method insures rapid heating and the temperature can be controlled by a pressure-regulating device. The steam has some action on the surface of the aluminum, especially if the solution treatment has been carried out in niter. This surface action is more serious with thin than with heavy material. It is rather objectionable in the case of sheets, for example, and not of much consequence in the case of forgings.

The precipitation treatment may also be carried out in an oven heated by steam coils or electricity and provided with a fan for air circulation. When steam coils are used, the temperature can be varied by changing the pressure in the coils.

A circulated oil bath with automatic temperature control is, of course, ideal for the precipitation treatment from the standpoint of temperature distribution and freedom from chemical action on the aluminum, but may be uneconomical.

NITRATE HAZARD

Although fused nitrate baths are commonly used in the heat treatment of steel as well as aluminum, it is felt that attention may well be called here to certain dangers in their operation. Care should be taken to prevent contact of the fused salt with carbonaceous or organic material (wood, charcoal, coke, oil, cloth, etc.) or with red hot iron or steel. Articles to be heat treated, or sludge, should not be allowed to lie on the bottom of the tank, especially if the tank is underfired, as they are apt to cause the tank to become locally overheated and be burned through. The possibility of combustible gases accumulating around the tank should be guarded against, and it is desirable to have at some distance from the tank a gas or oil shut-off valve which can be operated in emergency. Care should be taken not to put anything wet into the nitrate bath. Extra sacks of nitrate should be stored in a dry place and at a distance from the tank. Care should be exercised in adding fresh salts to the bath if at all wet; this is best done when the bath is frozen. In melting a solid bath, the salt must melt freely at the sides of the tank before melting at the bottom, to avoid generation of pressure and possible explosion. In case of a nitrate fire, avoid the use of water or of any fire extinguisher containing water. Perhaps the best fire extinguisher is dry sand, a supply of which should be kept near the tank.

AMERICAN SOCIETY FOR TESTING MATERIALS, RECOMMENDED PRACTICE FOR ANNEALING OF MISCELLANEOUS ROLLED AND FORGED CARBON-STEEL OBJECTS, DESIGNATION A35-24, 1924

ANNEALING CARBON-STEEL OBJECTS

1. *Purpose and general procedure.*—The usual purpose in annealing miscellaneous forged or rolled carbon-steel objects is to remove existing coarseness of grain. This removal is brought about by heating the object to an annealing temperature, which varies with the carbon content of the metal. But the rate at which the object cools from this annealing temperature influences its properties very profoundly. Hence this rate of cooling should be suited to the duties which the object has to perform in service, and hence to the properties which we seek to give it.

Therefore these specifications first consider the annealing temperature to which the piece must be heated in order to remove existing coarse grain, and then the rate of cooling from that temperature.

Under certain special conditions an annealing is required in order to remove not coarseness of grain but the effects of rolling or otherwise working the metal at a temperature so low as to set up serious internal stress. Appropriate treatment for these conditions is given in section 14.

As these specifications are intended to apply to a great variety of miscellaneous objects, they are purposely made suggestive rather than mandatory in many respects, because no single set of rules can be applied rigorously to such widely varying classes of objects and purposes.

ANNEALING FOR REMOVING EXISTING COARSE GRAIN

2. *Method of heating.*—In the case of large objects, the heating of the interior of which lags behind that of the outside, the final approach to the annealing temperature aimed at should be slow, so that the interior may be brought fully up to it without carrying the exterior far beyond it, because in general any needlessly high temperature is injurious, and tends to re-coarsen the grain. The temperature should be held long enough at the annealing point to insure that the whole of the interior reaches that point, and that the refining of the grain may become complete. An exposure of 45 minutes should be long enough for each inch of thickness.

3. *Control of temperature—Pyrometers.*—For all important work in careful hands the use of some trustworthy pyrometer is strongly recommended. But most pyrometers should be checked frequently against some standard. For those who are unwilling to take this trouble it is safer to rely on a trained eye than on an unchecked pyrometer. The operator should have clearly before him the fact that no pyrometer indicates the temperature of the interior of the object heated, and that the temperature which most pyrometers indicate is one between the temperature of the outside of the object heated and the temperature of the flame which is supplying the heat. Wherever practicable the part of the pyrometer which is supposed to reach the temperature of the object heated should be in immediate contact with that object, and should be protected from the flame or other source of heat by a suitable insulation, as for instance by covering it with sand. In important cases the gas or other source of heat should be shut off for at least ten minutes before taking the observations.

4. *Control without the use of a pyrometer.*—In working without a pyrometer and relying on the eye, the light surrounding the furnace should be dull, and should be kept as nearly constant as practicable, in order that the eye may not be misled by the chang-

ing contrasts between the surrounding light and that of the object heated. In particular, direct sunlight should be excluded, and any arc or other strong lights should be so placed that neither they themselves nor any concentrated part of their light is in the field of the operator's sight when he is estimating by eye the temperature of the objects to be annealed. Allowance should be made for the brighter surroundings by day than at night, and on sunny than on dark days.

5. *Magnetic indications.*—The annealing temperature for steels containing between 0.50 and 0.90 per cent of carbon is that at which the metal suddenly ceases to be magnetic. This fact may sometimes be used for the purpose of fixing or verifying the annealing temperature.

6. *Annealing temperature.*—In general, the higher the carbon content the lower should be the annealing temperature. Hence different temperatures are given for different ranges of carbon content. Further, in order to bring the interior of large objects up to an effective annealing temperature, their outside may often be raised advantageously somewhat above that temperature. Hence for each range of carbon content a range of temperature is given. The upper limit of this range applied (1) to larger objects, and (2) to the lower part of the range of carbon content given.

The following ranges of temperature should be used for the several ranges of carbon content indicated. They refer to the usual moderate manganese content. For steels with a manganese content greater than 0.75 per cent, slightly lower temperatures suffice.

Range of carbon content	Range of annealing temperature
Less than 0.12 per cent.....	875° to 925° C. (1,607-1,697° F.).
0.12 to 0.29 per cent.....	840° to 870° C. (1,544-1,598° F.).
0.30 to 0.49 per cent.....	815° to 840° C. (1,499-1,544° F.).
0.50 to 1.00 per cent.....	790° to 815° C. (1,454-1,499° F.).

7. *Care in heating.*—Care should be taken that all parts of the object reach the same temperature. To that end it may be necessary to mask from the heat, by means of bricks, the thinner parts of objects of varying thickness. When the heating is nearly finished, these bricks may be removed. In particular the flame should never be allowed to touch any part of the object under treatment.

8. *Cooling.*—After the object has been held at the annealing temperature long enough to make its temperature nearly uniform throughout, and to complete the refining of the grain, it should be cooled in a way suited to its carbon content and to giving it the specific properties needed. The general principles are: First, the higher the carbon the slower should be the cooling; and second, the slower the cooling the softer and more ductile the metal will be, and the lower will be its tensile strength, elastic limit, and yield point. The greatest softness and ductility are obtained at a certain sacrifice of strength and elasticity, and the greatest strength and elasticity at a certain sacrifice of softness and ductility.

For most purposes neither of these extremes is desired, and it is not only sufficient as regards quality but also economical to remove the object from the furnace as soon as it has been thoroughly annealed, and to allow it to cool in air, always completely protected not only from rain and snow but from sharp drafts of air. Objects containing more than 0.50 per cent of carbon should cool more slowly till the color dies out, say, at 500° C. (932° F.), as for instance by leaving them in the furnace. They may then be removed and cooled in air. Further, thin objects containing between 0.25 and 0.50 per cent of carbon should be treated like those of 0.50 per cent of carbon, unless they can be so massed together that their collective bulk will retard their

cooling, so that they will collectively cool even in air with moderate slowness, like single large objects.

SPECIAL ANNEALING METHODS

9. The foregoing methods are economical because they release the furnaces early for further use. In case special qualities are desired the following methods may be used:

10. *To give the greatest softness and ductility* of which the metal is capable, even at a certain sacrifice of strength and elastic limit, for instance for ease of machining or to resist a small number of severe distortions, the metal should be cooled slowly, either within the furnace or, in the case of large objects, under a cover of lime, clay, or other slow conductor of heat. The slower the cooling and the lower the temperature to which slow cooling is carried, the softer and weaker will be the steel. But for most cases for which even unusual softness and ductility are required, it suffices to remove the object from the furnace when it has become dead black, and to cool it thenceforth in air.

11. *To give great tensile strength and high elastic limit* even at a certain sacrifice of ductility, the cooling should be more rapid, the rapidity to be governed by the thickness and carbon content of the object. Thin objects and those with high-carbon content can not stand so rapid a cooling as thick and low-carbon ones, lest their ductility be too far sacrificed. For instance, thick objects with less than 0.50 per cent of carbon may be cooled completely in air, of course protected from rain or snow. Objects with 0.50 per cent of carbon or more, and thin objects with from 0.30 to 0.50 per cent of carbon, may be cooled in air if their cooling is somewhat retarded, as for instance by massing them together, as happens in the case of rails.

12. *To give an unusually high combination of ductility with tensile strength and elastic limit.* *Water or oil quenching and annealing.*—This process needs great care and intelligence, and should in general be used only by those familiar with high-grade steels. After holding at the annealing temperature suited to the particular steel, as indicated in section 6, the object is quenched in oil, which should be kept in circulation. It may be quenched in water if its carbon content is so low and its shape so simple that it is not in danger of cracking or receiving permanently harmful stress. In any event the danger of such cracking and stress is lessened by removing the object from the oil or water before it has cooled completely, say when its temperature has fallen to 160° C. (320° F.). It should if possible not cool below 100° C. (212° F.) and certainly not below 20° C. (68° F.). The annealing should begin within a very few hours after the quenching and if possible without ever allowing the piece to cool below 100° C. (212° F.) and certainly not below 20° C. (68° F.).

The steel thus hardened should next be annealed by heating to a temperature suited for giving the properties needed. In general the higher this annealing goes the more ductile will the steel become and the lower will be its strength and elastic limit.

For very high elastic limit and tensile strength, anneal at 500 to 650° C. (932 to 1,202° F.). In this case the ductility will be low. Some steels, such as watch-springs and shafting, are annealed at 350° C. Little commercial annealing is done below 500° C.

For intermediate tensile strength, elastic limit, and ductility, best suited to the majority of cases, anneal at 600 to 650° C. (1,112 to 1,202° F.).

For the greatest ductility, with good strength and elastic limit, anneal at from 725 to 750° C. (1,337 to 1,382° F.).

The object should be held at this second annealing temperature long enough not only to allow its interior to reach it but also to relieve the stress

given in the water or oil quenching. For pieces of moderate thickness a 4-hour exposure should suffice.

13. *To give a moderate increase of strength and elastic limit above that given by a simple slow cooling without the full sacrifice of ductility which a simple air cooling would cause.*—After holding at the annealing temperature suited to the carbon content, as indicated in section 6, hasten the cooling till the object is at a dull red, say 650° C. (1,202° F.), and thenceforth cool slowly. The hastening of the cooling may be brought about in the case of thin objects in relatively shallow furnaces by opening the furnace door till the temperature falls to dull redness, or by running the objects out in the air on a movable car-bottom, and returning them to the furnace when they have cooled to dull redness. In cases in which such operations are to be performed frequently, special unfired chambers may be used for the final slow cooling, thus leaving the annealing furnaces properly available for their regular work. The results obtained in this way are not as good as those obtained with the method described in section 11.

14. *Special annealing to remove the effects of rolling or otherwise working the object in the cold or at any unduly low temperature.*—The object should be heated to about 775° C. (1,427° F.) and cooled with a slowness which should increase with the thickness that is, the least dimension of the piece. In the case of thin plates a mere heating to 725° C. (1,337° F.), followed immediately by slow cooling, should suffice. In the case of thick forgings, in which much time may be needed to allow severe stress to relieve itself, the sojourn at 775° C. (1,427° F.) may be prolonged for several hours, though always at the cost of superficial decarburizing.

Such annealing for steel containing less than 0.15 per cent carbon should be at 900° C. (1,652° F.). Large grain size may be caused by annealing very low carbon steel in the neighborhood of 700° C. (1,292° F.), after cold working.

AMERICAN SOCIETY FOR TESTING MATERIALS, RECOMMENDED PRACTICE FOR HEAT TREATMENT OF CARBON-STEEL CASTINGS, DESIGNATION A36-24, 1924

HEAT TREATMENT OF CARBON-STEEL CASTINGS

1. This recommended practice is intended solely for guidance, and is not to be construed as entering in any manner into specifications of the American Society for Testing Materials.

2. This recommended practice is intended to cover: (a) Annealing, (b) normalizing, (c) normalizing followed by a reheating, and (d) quenching followed by a reheating.

3. After pouring, the castings should be allowed to cool in the sand to a temperature below the critical range.

4. The castings should be sufficiently cleaned of adhering sand before heat treatment to insure thorough and uniform heating.

5. The temperatures recommended when treatment above the upper critical point is desired should vary with the carbon content, approximately as follows:

Carbon (per cent)	Temperature
Up to 0.40, inclusive.....	900° C. (1,650° F.)
Over 0.40 to 0.60, inclusive.....	850° C. (1,560° F.)
Over 0.60.....	830° C. (1,525° F.)

6. The use of pyrometers (preferably recording pyrometers) is recommended. Pyrometers should be checked frequently against a standard. Every precaution should be taken to procure due assurance that the castings throughout the furnace reach the required temperature.

7. After cooling as indicated in section 3, the castings should be heated slowly and uniformly to the desired temperature. Sufficient time should be allowed for the heat to accomplish the desired structural transformations throughout the mass of the castings. For these reasons it is necessary that each furnace containing castings be held for a prolonged period at the desired temperature after the castings have attained that temperature. It is recommended that this prolonged period should be not less than 60 minutes for each inch of thickness of the thickest casting segment in the charge.

8. To anneal castings properly, they should be heated as described in section 7 to one of the temperatures given in section 5. They should then be slowly cooled in the furnace until they reach a faint-red color, after which the cooling may be continued in air.

9. To secure finer structure (with probably less ductility than can be obtained by annealing as described in sec. 8) castings should be heated as described in section 7 to one of the temperatures given in section 5, and cooled in still air.

10. To secure fine structure, accompanied by great ductility, normalizing as described in section 9 should be followed by a reheating and subsequent cooling. In this reheating, the castings may be kept for a short time just above the lower critical point or they may be kept for several hours at a suitable temperature below the critical range. After this reheating, the castings should be cooled slowly in the furnace until they reach a faint-red color (provided they reach this color in the reheating), after which the cooling may be continued in air.

11. To secure maximum refinement of the structure coupled with the greatest possible combination of strength and toughness, castings should be heated as described in section 7 to one of the temperatures given in section 5, and quenched in water or oil. They should then be reheated. In this reheating, the castings may be kept for a short time just above the lower critical point or they may be kept for several hours at a suitable temperature below the critical range. After this reheating the castings should be cooled slowly in the furnace until they reach a faint-red color (provided that color was reached in the reheating operation), after which the cooling may be continued in air.

12. (a) Certain castings, which from their mass or design would crack on quenching if kept in the water or oil until completely cold, may be safely treated by removing them from the quenching bath when they have reached a black heat, immediately charging them into a furnace heated to approximately the same temperature as the castings, and reheating them as described in section 11.

(b) The advisability of attempting to quench and reheat any given casting must be considered with judgment in the light of experience; and to attempt to apply this method of heat treatment without taking the precautions demanded by the shape, size, and sections of each individual casting can only result in the loss of many castings through the development of cracks either in quenching, in reheating, or at some later time.

AMERICAN SOCIETY FOR TESTING MATERIALS, RECOMMENDED PRACTICE FOR CARBURIZING AND HEAT TREATMENT OF CARBURIZED OBJECTS, DESIGNATION A37-27, 1927

CARBURIZING

1. This recommended practice is intended solely for guidance, and is not to be construed as entering in any manner into specifications of the American Society for Testing Materials.

2. Carburizing is intended to increase the carbon content in the surface layers of low-carbon steel objects so they may be made hard and wear-resistant on the outside with a strong, tough, inner portion or core. This type of structure is suitable for parts which are required to stand considerable shock and friction. The process consists in heating the steel in contact with a carbonaceous material for a long time at temperatures above the critical temperature of the steel.

3. The primary factors governing the process are: (a) Chemical composition of the steel, (b) the carburizing operation, and (c) the hardening operation.

4. The steel should be selected according to the service requirements. A well-made carbon steel will be satisfactory for most ordinary purposes. The carbon content of simple and alloy steels should preferably be below 0.20 per cent. High manganese above 0.60 per cent is sometimes specified to obtain increased hardness and increased core strength. High phosphorus and sulphur contents improve the machineability but generally indicate a steel of poor quality. These elements are, however, often added intentionally to steels of good quality to improve their machining qualities.

In alloy steels, nickel tends to retard the grain growth at carburizing temperatures, depresses the critical temperature, and allows the steel to be hardened at lower quenching temperatures. Chromium is used alone in percentages up to 1.25 per cent and gives a greater abrasive hardness to the case. S. A. E. steel No. 3115, containing about 1.25 per cent nickel and 0.60 per cent chromium is recommended for general high-grade use. A molybdenum content of about 0.25 per cent or combined with about 1.75 per cent of nickel is used with good results. The use of molybdenum steel containing chromium is not recommended as this steel has an inherent tendency to distort in the carburizing operation.

5. Carburizing materials are divided into three general classes: Solids, liquids, and gases, the solid type being generally used. The recommendations given apply to this type only. Commercial compounds usually are better than those made by the user. One part of new solid compound to three parts of used compound is recommended as a shop mixture. The used compounds should be screened to remove the dust.

6. Packing pots are made from cast iron, cast and pressed steel, and special heat-resisting alloys. The latter are recommended. Comparisons are usually made on a heat-hour-cost basis, the life of the containers being determined by actual service and this figure divided into the cost of the pot which gives the cost per service-heat hour. The proportions of the pot in relation to the parts to be carburized is of primary importance as well as the proper distribution of metal in the walls, reinforcement ribs, legs, etc. A compromise in size is found between the very small containers which are expensive in handling practice and the large containers which have

a tendency to heat unevenly. The size of the pot should be governed by the size of the parts.

7. The effective temperature is the temperature inside the pot. The carburizing time should be designated as the number of hours at the carburizing temperature. The heating through of the pots is judged in two ways: By estimating with the eye, and by placing thermocouples inside the pot as shown in Figure 47. The latter method is recommended except on pots which are so small that it would be impracticable to place a thermocouple inside them.

8. The use of recording pyrometers is recommended. Where the method shown in Figure 47 is used, an extra couple should be placed in the furnace so that the furnace temperature may be more readily controlled, as otherwise excessive furnace temperatures or extremely variable heats may be obtained.

9. Quick heating to the carburizing temperature will cause more distortion of the parts than slow heating. The temperature in any pot must be comparable with the temperature inside any other. To

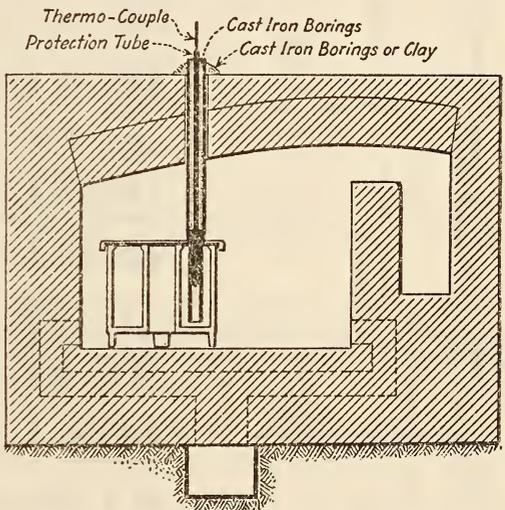

FIGURE 47

this end, the furnace must be designed to heat evenly and the pots must be spaced on the furnace hearth so that they will be heated evenly and uniformly.

10. The carbon content at the surface of the work increases with the carburizing temperature. The formation of free carbide at the grain boundaries is undesirable, as it leaves a very brittle surface exposed to the service stresses. The surface carbon should not exceed 1.15 per cent. This will be reduced by the finish grinding operation. The carbon content is governed by the carburizing compound and the temperature, while gradation depends upon the analysis of the steel and the rate of cooling. The allowable temperature depends upon the nature of the work. Temperatures of 941° to 954° C. (1,725° to 1,750° F.) may be used where speed and low expense are primary considerations. For general practice, 899° C. (1,650° F.) is recommended. The carburizing temperature should be lowered about 38° C. (100° F.) when the regenerative quench is not to be used. Thin cases, of 0.010 to 0.015 inch, are better obtained with a carburizing temperature of 843° C. (1,550° F.).

TABLE 1.—Recommended temperatures and cooling mediums to be used for carburizing and heat treatment of carburized objects

[The temperatures and cooling mediums given in this table are dependent upon and must be varied according to the instructions given in the main section of the recommended practice. Particular attention should be given to varying the regenerative quench with the size of the part and the degree of distortion which must be avoided]

S. A. steel No.	Composition				Preliminary heat treatments (use either A or B)										Carburizing				Refining and hardening treatments

¹ This steel is a chromium-vanadium steel, the vanadium requirement being 0.15 per cent minimum with a desired content of 0.18 per cent.

11. The "depth of case" shall be taken to be the depth of the refined case to be observed with the naked eye after carburizing, hardening at the temperature giving maximum case refinement, and breaking for fracture.

12. To obtain the best core condition, the part should be allowed to cool in the pots, outside the furnace, then reheated and quenched from a temperature which will refine the core and break up any undesirable structures of cementite. This is called a regenerative quench.

TABLE 2.—Common defects in carburized objects

Defect	Cause	Indication	Correction
Depth of case and carbon content outside specified limits.	A. Carburizing temperature not correct. A1. Furnace temperature uneven. Temperature of containers not uniform.	Results vary in the same furnace and from the same containers.	Redesign furnaces. Modify heating practice. Allow longer time for bringing furnaces to temperature.
	A2. Faulty pyrometer readings.	Entire furnace charges unsatisfactory.	Check pyrometer system.
	A3. Carburizing compound too weak or too strong.	Results from entire department vary from usual results.	Check carburizing compound before accepting shipment. Change time and temperature until desired results are obtained.
Soft spots obtained in hardening.	B1. Improper hardening. Temperature low or uneven.	File test.....	Raise hardening temperature.
	B2. Improper quench.	-----do-----	Use faster quench, brine or spray.
	B3. Surface decarburized.	File test. Determine whether decarburization occurred in carburizing or hardening furnace.	Correct carburizing practice. Correct heating practice for hardening.
Unsatisfactory fractures.	B4. Low carbon content or uneven penetration.	As above for B3.	Correct carburizing practice. Try other compound. Check pyrometers.
	C1. Too high hardening temperatures.	Fracture test..	Decrease or adjust hardening temperature.
	C2. High surface carbon (freckled edges).	-----do-----	Decrease hardening temperature. Use double quench with rather high temperature for regenerative quench. Use weaker compound.

13. The cooling of the carburized parts should take place in the containers, outside of the furnace. Where cost of production is vital, the parts may be quenched directly from the pot in either oil or water.

14. In determining the depth of case desired, sufficient allowance must be made for the metal which will later be removed by grinding. A tempering operation will tend to eliminate the tendency to the formation of grinding cracks.

15. The hardening temperature of the case is below the critical temperature of the core and the grain size produced in the core, by the carburizing temperature or regenerative quench, is not affected. The hardening temperature should be chosen as the temperature which gives the best fracture on several dummies or experimental pieces hardened from various temperatures. The figures given in Table 1 are the middle of the probable range of hardening temperatures.

16. The tendency to distort may be avoided by a preliminary heat treatment, either before or after the rough machining operation. The method of carburizing must be studied and the subsequent hardening operations carried on with extreme care as to the heating and cooling cycles. In many cases, the regenerative quench must be omitted as the high temperature of this operation causes too much warping. When omitted, the carburizing temperature should be lowered about 38° C. (100° F.).

17. Tempering may be carried on at low temperatures, for the relief of strains; or at high temperatures, for the increase of toughness and uniformity without materially decreasing the hardness. An oil bath is preferable to an open furnace for temperatures up to 316° C. (600° F.). For simple carbon steels, a softening of the surface is found when the tempering temperature exceeds 190° to 204° C. (375° to 400° F.). For maximum hardness the temperature should be kept below this figure.

18. Table 2 shows in condensed form the most common defects in carburized work together with the possible causes and methods for their identification and correction.

AMERICAN SOCIETY FOR STEEL TREATING, RECOMMENDED PRACTICES FOR THE HEAT TREATMENT OF SPRINGS, MAY 25, 1932

HEAT TREATMENT OF SPRINGS

(These recommended practices cover the heat treatment of small helical springs cold coiled from wire, large helical springs hot coiled from bars one-half inch or over in diameter, small flat springs cold formed from plates less than three-sixteenths inch in thickness, and large flat springs hot formed from plates three-sixteenths inch or over in thickness. It includes the chemical compositions of the various carbon and alloy steels usually used for these springs and the recommended physical characteristics. The recommended heat treatment for each of the steels is given, including the normalizing, quenching, and tempering temperature ranges, the quenching medium, and the approximate hardness of the resulting product.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR VALVES, FLANGES, AND FITTINGS FOR HIGH-TEMPERATURE SERVICE, DESIGNATION A95-29, 1929

CASTINGS FOR HIGH TEMPERATURES

For heat treatment (see 611.41, p. 709.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD DEFINITIONS OF TERMS RELATING TO HEAT-TREATMENT OPERATIONS (ESPECIALLY AS RELATED TO FERROUS ALLOYS), DESIGNATION A119-30, 1930

HEAT-TREATMENT DEFINITIONS ⁴²

In preparing the definitions included herein, the terms have been so defined, as most in keeping with present-day usage, that they shall mean definite

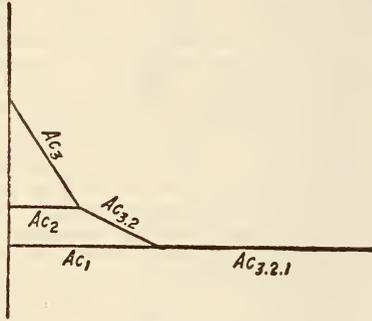

FIGURE 48

operations and shall not be considered as referring to the resultant structures or general conditions.

By "critical temperature range," as used in the definitions, is meant that temperature range illustrated in Figure 48, taken from Howe.

Heat treatment.—An operation or combination of operations involving the heating and cooling of a metal or an alloy in the solid state.

NOTE.—This is for the purpose of obtaining certain desirable conditions or properties. Heating and cooling for the sole purpose of mechanical working are excluded from the meaning of this definition.

Quenching.—Rapid cooling by immersion.

NOTE.—Immersion may be in liquids, gases, or solids.

Hardening.—Heating and quenching certain iron-base alloys from a temperature either within or above the critical temperature range.

Annealing.—A heating and cooling operation of a material in the solid state.

NOTE 1.—Annealing usually implies a relatively slow cooling.

NOTE 2.—Annealing is a comprehensive term. The purpose of such a heat treatment may be: (a) To remove stresses; (b) to induce softness; (c) to alter ductility, toughness, or electrical, magnetic, or other physical properties; (d) to refine the crystalline structure, and (e) to remove gases.

In annealing, the temperature of the operation and the rate of cooling depend upon the material being heat treated and the purpose of the treatment.

Certain specific heat treatments coming under the comprehensive term "annealing" are:

(a) **Full annealing.**—Heating iron base alloys above the critical temperature range, and holding above that range for a proper period of time followed by slow cooling through the range.

NOTE.—The annealing temperature is generally about 100° F. (55° C.) above the upper limit of the critical temperature range, and the time of holding is usually not less than one hour for each inch of section of the heaviest objects being treated. The objects being treated are ordinarily allowed to cool slowly in the furnace. They may, however, be removed from the furnace, and cooled in some medium which will prolong the time of cooling as compared to unrestricted cooling in the air.

⁴² These definitions are those prepared by the Joint Committee on Definitions of Terms Relating to Heat Treatment and submitted by the joint committee to the society in 1927. The following organizations are represented on the joint committee: American Society for Steel Treating, Society of Automotive Engineers, and the American Society for Testing Materials.

(b) **Process annealing.**—Heating iron base alloys to a temperature below or close to the lower limit of the critical temperature range followed by cooling as desired.

NOTE.—This heat treatment is commonly applied in the sheet and wire industries and the temperatures generally used are from 1,020° to 1,200° F. (550° to 650° C.).

(c) **Normalizing.**—Heating iron-base alloys above the critical temperature range followed by cooling to below that range in still air at ordinary temperature.

NOTE.—In the case of hypereutectoid steel, it is often desirable to heat above the $A_{c,m}$ line, as shown in Figure 49.

(d) **Patenting.**—Heating iron-base alloys above the critical temperature range followed by cooling to below that range in molten lead maintained at a temperature of about 700° F. (365° C.).

NOTE.—This treatment is usually applied in the wire industry either as a finishing treatment or especially in the case of eutectoid steel as a treatment previous to further wire drawing. Its purpose is to produce a sorbitic structure.

(e) **Spheroidizing.**—Prolonged heating of iron-base alloys at a temperature in the neighborhood of, but generally slightly below, the critical temperature range, usually followed by relatively slow cooling.

NOTE 1.—In the case of small objects of high-carbon steels, the spheroidizing result is achieved more rapidly by prolonged heating to temperatures alternately within and slightly below the critical temperature range.

NOTE 2.—The object of this heat treatment is to produce a globular condition of the carbide.

(f) **Tempering (also termed drawing).**—Reheating after hardening, to some temperature below the critical temperature range followed by any rate of cooling.

NOTE 1.—Although the terms "tempering" and "drawing" are practically synonymous as used in commercial practice, the term "tempering" is preferred.

NOTE 2.—Tempering meaning the operation of hardening followed by reheating is a usage which is illogical and confusing in the present state of the art of heat treating and should be discouraged.

(g) **Malleablizing.**—Malleablizing is a type of annealing operation with slow cooling whereby combined carbon in white cast iron is transformed

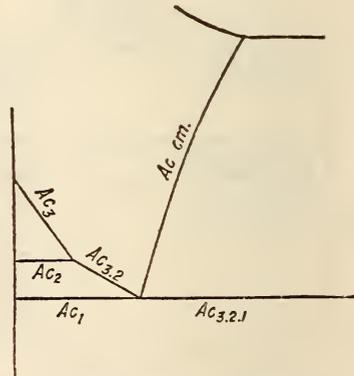

FIGURE 49

to temper carbon and in some cases the carbon is entirely removed from the iron.

NOTE.—Temper carbon is free carbon in the form of rounded nodules made up of an aggregate of minute crystals.

(h) **Graphitizing.**—Graphitizing is a type of annealing of cast iron whereby some or all of the combined carbon is transformed to free or uncombined carbon.

Carburizing (cementation).—Adding carbon to iron-base alloys by heating the metal below its

melting point in contact with carbonaceous material.

NOTE.—The term "carbonizing" used in this sense is incorrect so its use should be discouraged.

Case hardening.—Carburizing and subsequently hardening by suitable heat treatment, all or part of the surface portions of a piece of iron-base alloy.

Case.—That portion of a carburized iron-base alloy article in which the carbon content has been substantially increased.

Core.—That portion of a carburized iron-base alloy article in which the carbon content has not been substantially increased.

NOTE.—The terms "case" and "core" apply both to carburizing and case hardening.

Cyaniding.—Surface hardening of an iron-base alloy article or portion of it by heating at a suitable temperature in contact with a cyanide salt, followed by quenching.

600.6 PLUMBING.

AMERICAN RAILWAY ENGINEERING ASSOCIATION, PLUMBING FOR RAILWAY BUILDINGS, 1929

CAST-IRON PIPE AND FITTINGS

(See 607.11, p. 371.)

NATIONAL ASSOCIATION OF MASTER PLUMBERS, PLUMBING SYMBOLS, 1927

PLUMBING SYMBOLS

The standard symbols shown in the accompanying illustrations have been prepared by the standardization committee of the National Association of Master Plumbers for use by architects and engineers in designing plumbing and drainage systems.

Proper location of fixtures eliminates unnecessary cutting and notching of timbers and simplifies piping

installation. Adequate pipe space must be provided in walls or partitions or beneath floors to eliminate the use of unnecessary fittings which add to the cost of labor and material without increasing the efficiency of the system.

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, NATIONAL BUREAU OF STANDARDS, RECOMMENDED MINIMUM REQUIREMENTS FOR PLUMBING, BH13, 1929

PLUMBING REQUIREMENTS

(This is an illustrated publication of 280 pages. It is divided into four parts: Part 1 covers general considerations; part 2 covers plumbing materials and their installation; experimental investigations and the physics of plumbing are included in part 3; and in part 4 will be found appendixes covering corrosion of metals in plumbing systems, air currents in a horizontal waste pipe, and the specifications of the American Society for Testing Materials that concern themselves with plumbing materials. In the article on quality and weights of materials, this publication provides as follows:)

Vitrified-clay pipe.—All vitrified clay pipe shall conform to the A. S. T. M. standard specifications for clay sewer pipe, C13-24. (See Standards and Specifications for Nonmetallic Minerals and their Products, p. 517.)

Cast-iron pipe.—(a) *Quality.*—All cast-iron pipe and fittings shall conform to the A. S. T. M. standard specifications for cast-iron soil pipe and fittings, A74-29. (See 607.11, p. 371.)

(b) *Coating.*—All cast-iron pipe and fittings for underground use shall be coated with asphaltum or coal-tar pitch.

Wrought-iron pipe.—All wrought-iron pipe shall conform to the A. S. T. M. standard specifications for welded wrought-iron pipe, A72-31. (See 607.3, p. 431.)

Mild-steel pipe.—All steel pipe shall conform to the A. S. T. M. standard specifications for welded and seamless steel pipe, A53-30. (See 607.4, p. 476.)

Brass and copper pipe.—Brass and copper pipe shall conform, respectively, to the standard specifications of the A. S. T. M. for brass pipe, standard sizes, and for copper pipe, standard sizes, B43-24 (see 645.23, p. 1216) and B42-24 (see 642.23, p. 1182).

Lead pipe, diameter, weights.—All lead pipe shall be of best quality drawn pipe, of weight per linear foot not less than shown below.

(a) Lead soil, waste, vent, or flush pipes, including bends and traps (extra light):

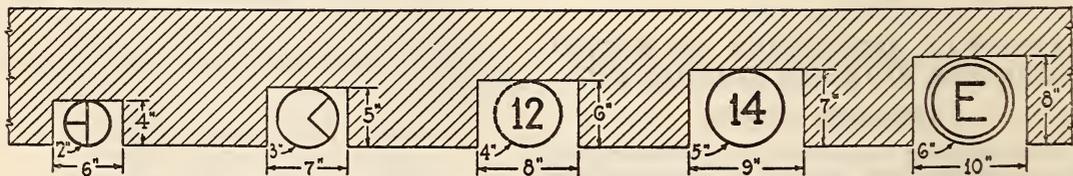

Internal diameter (inches)	Weight per foot (pounds and ounces)	Internal diameter (inches)	Weight per foot (pounds and ounces)
1	2 0	2	4 0
1¼	2 8	3	4 12
1½	3 8	4	6 0

(b) Lead water-supply pipe above ground (strong):

Internal diameter (inches)	Weight per foot (pounds and ounces)	Internal diameter (inches)	Weight per foot (pounds and ounces)
1½	2 0	1¾	4 12
2	2 8	1½	6 0
2½	3 0	1¾	6 8
3	4 0	2	7 0

(c) Lead water-supply pipe under ground (extra strong):

Internal diameter (inches)	Weight per foot (pounds and ounces)	Internal diameter (inches)	Weight per foot (pounds and ounces)
1/2	2 8	1 1/4	6 0
5/8	3 0	1 1/2	7 8
3/4	3 8	1 3/4	8 0
1	4 12	2	9 0

Sheet lead.—Sheet lead shall weigh not less than 4 pounds per square foot.

Sheet copper or brass.—Sheet copper or brass shall be not lighter than No. 18 B. and S. gage, except that for local and interior ventilating pipe it shall be not lighter than No. 26 B. and S. gage.

Galvanizing sheet iron.—Galvanized sheet iron shall be not lighter than the following B. and S. gages:

- No. 26 for 2 to 12 inch pipe.
- No. 24 for 13 to 20 inch pipe.
- No. 22 for 21 to 26 inch pipe.

Threaded fittings.—(a) Plain screwed fittings shall be of cast iron, malleable iron, or brass of standard weight and dimensions. (b) Drainage fittings shall be of cast iron, malleable iron, or brass, with smooth interior waterway, with threads tapped out of solid metal. (c) All cast-iron fittings used for water-supply distribution shall be galvanized. (d) All malleable iron fittings shall be galvanized.

Calking ferrules.—Brass calking ferrules shall be of the best quality red cast brass, with weights and dimensions in accordance with the following table:

Pipe size (inches)	Actual inside diameter	Length	Weight (pounds and ounces)
	Inches	Inches	
2.....	2 1/4	4 1/2	
3.....	3 1/4	4 1/2	
4.....	4 1/4	4 1/2	

Soldering nipples and bushings.—(a) Soldering nipples shall be of brass pipe, iron-pipe size, or of heavy, cast red brass not less than the following weights:

Diameter (inches)	Weight (ounces)	Diameter (inches)	Weight (pounds and ounces)
1 1/4	6	2 1/2	1 6
1 1/2	8	3	2 0
2	14	4	3 8

(b) Soldering bushings shall be of brass pipe, iron-pipe size, or of heavy, cast red brass.

Floor flanges for water-closets.—Floor flanges for water-closets shall be not less than three-sixteenths of an inch thick, and of brass or cast iron.

600.7. WEIGHTS AND TOLERANCES OF IRON AND STEEL.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD DEFINITIONS OF TERMS RELATING TO SPECIFIC GRAVITY, DESIGNATION E12-27, 1927

SPECIFIC-GRAVITY DEFINITIONS

(See 600.1, p. 43.)

ASSOCIATION OF AMERICAN STEEL MANUFACTURERS, STANDARD PRACTICE GOVERNING THE ALLOWABLE VARIATIONS IN SIZE AND WEIGHT OF HOT-ROLLED BARS, 1910

HOT-ROLLED BARS

STANDARD ALLOWABLE VARIATIONS IN WEIGHT OF BAR SIZES OF ANGLES, TEES, ZEES, AND CHANNELS

For bar sizes of angles, tees, zeos, and channels the following average variations in weight will be permitted for sections of the various dimensions and thicknesses stated, viz:

Dimensions	Thickness	Variation in weight
Any dimension over 1 1/2 inches.	Over 3/16 inch.	4 per cent over and under.
All dimensions 1 1/2 inches and less.do.....	5 per cent over and under.
Any dimension over 1 1/2 inches.	3/16 inch and less.	6 per cent over and under.
All dimensions 1 1/2 inches and less.do.....	7 per cent over and under.

NOTE.—A channel is in "bar" size when its greatest dimension is less than 3 inches. An angle, T or Z is in "bar" size when its greatest dimension is less than 3 inches; or when it is 3 inches or more and at the same time the thickness is less than one-fourth inch.

STANDARD ALLOWABLE VARIATIONS IN THE SIZE OF HOT-ROLLED BARS

Rounds, squares, hexagons

	Variation in size	
	Under	Over
Up to and including 1/2 inch.....	Inch 0.007	Inch 0.007
Over 1/2 inch up to and including 1 inch.....	.010	.010
Over 1 inch up to and including 2 inches.....	1/64	1/32
Over 2 inches up to and including 3 inches.....	1/32	3/64
Over 3 inches up to and including 5 inches.....	1/32	3/32
Over 5 inches up to and including 8 inches.....	1/16	1/8

Flats

Width of flats	Variation in width		Variation in thickness, under and over				
	Under	Over	Thickness of flats				
			$\frac{3}{16}$ inch and under	Over $\frac{3}{16}$ inch up to $\frac{1}{2}$ inch	Over $\frac{1}{2}$ inch up to 1 inch	Over 1 inch up to 2 inches	
Up to and including 1 inch	Inch $\frac{3}{64}$	Inch $\frac{1}{32}$	Inch 0.006	Inch 0.008	Inch 0.010	Inch -----	
Over 1 inch up to and including 2 inches		$\frac{1}{32}$	$\frac{3}{64}$.008	.012	.015	$\frac{1}{32}$
Over 2 inches up to and including 4 inches		$\frac{3}{64}$	$\frac{1}{16}$.010	.015	.020	$\frac{1}{32}$
Over 4 inches up to and including 6 inches		$\frac{1}{16}$	$\frac{3}{32}$.010	.015	.020	$\frac{1}{32}$

ASSOCIATION OF AMERICAN STEEL MANUFACTURERS, STANDARD PERMISSIBLE VARIATIONS IN GAGE WEIGHT, GAGE THICKNESS, AND SIZE AND FLATNESS OF SHEETS AND LIGHT PLATES BLUE ANNEALED, 1929

PERMISSIBLE VARIATIONS IN SHEETS AND PLATES

GAGE WEIGHT

When ordered by weight per unit area, sheets shall conform to Table 1. If ordered by gage number, the gage weights shall be those of the United States standard gage table for uncoated sheets and for long ternes, and of the galvanized sheet gage table for zinc-coated (galvanized) sheets.

TABLE 1

Ordered gage weight				Permissible variation from ordered gage weight, in percentage of estimated weight		
Less than—		Not less than—		All of 1 gage, and size in shipment	Single package	Single sheet
Ounce per square foot	Pound per square foot	Ounce per square foot	Pound per square foot			
-----	-----	1 40	2.5	5.0	7.0	10.0
1 40	2.5	2 20	1.25	3.5	5.5	10.0
2 20	1.25	-----	-----	2.5	4.0	10.0

1 No. 16.

2 No. 22.

"All of one gage and size in shipment" shall apply to lots of not less than 6,000 pounds.

References are to gross weights of bundled material and to net weights of crated and boxed material.

If minimum or maximum weight per unit area be ordered, the tolerance used shall be the one for the mean gage weight determined by that tolerance, and double that tolerance shall be allowed on the permissible side. Ordering by minimum or maximum weight per unit area is objectionable, as it is liable to cause error in manufacture and gage classification.

Sheets are not weighed singly at the mill and the 10 per cent limit can not be assured, but any sheets

found by purchaser that are outside this limit may be rejected.

Sheets ordered by weight per unit area shall be subject to weight gage tolerances only, and not to thickness gage tolerances.

Should weight variations be considered more important, yet sheets be so used that uniform thickness is desirable, they should be ordered by weight gage, and order should stipulate "Make of as nearly uniform thickness as practicable." Sheets so ordered will be of less average thickness than those ordered by the equivalent thickness.

Both resquared and nonresquared sheets, by custom of long standing, are subject to these weight gage tolerances, based upon the ordered area; though, logically, nonresquared sheets should have smaller under and greater over tolerances.

GAGE THICKNESS

When ordered by thickness, sheets shall conform to Table 2.

TABLE 2

Ordered thickness	Permissible variation from ordered thickness	Ordered thickness	Permissible variation from ordered thickness
Inch Over 0.249	Inch 0.016	Inch 0.099-0.080	Inch 0.009
0.249-.220	.015	.079-.070	.008
.219-.190	.014	.069-.060	.007
.189-.160	.013		
.159-.140	.012	.059-.050	.006
		.049-.040	.005
.139-.120	.011	.039-.030	.004
.119-.100	.010	.029	.003

The thickness variation range in any one sheet shall not exceed (to the nearest thousandth) one and one-fifth times the tabular limit for the ordered thickness.

If minimum or maximum thickness be ordered, the tolerance used shall be the one for the mean thickness determined by that tolerance, and double that tolerance shall be allowed on the permissible side. Ordering by minimum or maximum thickness is objectionable, as it is liable to cause error in manufacture and gage classification.

Sheets are not all gaged at the mill and the limits shown can not be assured, but any sheets found by purchaser that are outside the limits may be rejected except in extreme widths.

Sheets ordered by thickness shall be subject to thickness gage tolerances only, and not to weight gage tolerances.

Should weight variations be more important than thickness variations, but sheets be ordered by thickness by preference or custom, order should stipulate "Make of equivalent weight per unit area." In such case, sheets shall be subject to weight gage tolerances only, based on 40.80 pounds per square foot per inch thick.

Gage Thickness—Expected Average and Limiting Weights

While sheets ordered by thickness are not subject to weight gage tolerances, weights of such sheets are affected by the following considerations:

Weight of sheets ordered by thickness should be computed on the basis of the ordered size and ordered thickness at 40.80 pounds per square foot per inch thick, to which should be added 2 per cent

for greater cross section of the sheet than is represented by the mean of the thickest and thinnest points.

When resquared, no adjustment should be made to the weight so computed (41.62 pounds per square foot per inch thick).

When neither resquared nor cold-rolled after annealing (blue-annealed, black, one pass, hot-rolled pickled), 1.5 per cent should be added to account for excess width and length within the standard tolerance limits (42.24 pounds per square foot per inch thick).

When not resquared but cold-rolled after annealing (full cold-rolled, pickled, and cold-rolled), 3 per

cent should be added to account for excess width and length within the standard tolerance limits (42.86 pounds per square foot per inch thick).

Estimated weights on orders and in records and correspondence should be computed as shown above.

The weight computed on the proper basis with proper adjustments as explained, is, of course, affected by the usual permissible variation of 5 per cent for not lighter than No. 16 gage, of 3.5 per cent for lighter than No. 16 but not lighter than No. 22 gage, and of 2.5 per cent for lighter than No. 22 gage, as applied to all of one gage and size in a shipment.

These considerations are expressed in tabular form in Table 3.

TABLE 3.—Gage thickness—Expected average and limiting weights

If ordered thickness times 40.80 (pounds per square foot) be taken as base, this gage weight, or sheet weight, or total weight derived therefrom, should be multiplied by—		Base of estimated weight (pounds per square foot per inch thick)	Considerations affecting gage and sheet weights	Base of estimated weight (pounds per square foot per inch thick)	If sheets be ordered by approximate thickness (to full number of decimal places) of U. S. S. G. table, and corresponding U. S. S. G. unit weight erroneously taken as base, gage weight or sheet weight or total weight should be multiplied by—

SIZE

Sheets shall be not less than widths and lengths ordered.

Width of sheets not cold rolled (blue-annealed, hot-rolled pickled) shall not exceed that ordered by more than—

One-fourth inch if ordered 48 inches wide and less and 144 inches long and less.

Five-sixteenth inch if ordered 48 inches wide and less and more than 144 inches long.

Three-eighths inch if ordered more than 48 inches wide and 144 inches long and less.

Seven-sixteenths inch if ordered more than 48 inches wide and more than 144 inches long.

Width of sheets cold rolled shall not exceed that ordered by more than—

One-fourth inch if ordered 36 inches wide and less and 120 inches long and less.

Five-sixteenth inch if ordered 36 inches wide and less and more than 120 inches long.

Three-eighths inch if ordered more than 36 inches wide and 120 inches long and less.

Seven-sixteenth inch if ordered more than 36 inches wide and more than 120 inches long.

Length of sheets not cold rolled (blue annealed, hot-rolled pickled) shall not exceed that ordered by more than—

One-half inch if ordered 120 inches long and less.

Three-fourths inch if ordered more than 120 inches long to 180 inches, inclusive.

One inch if ordered more than 180 inches long to 240 inches, inclusive.

One and one-fourth inches if ordered more than 240 inches long to 300 inches, inclusive.

One and one-half inches if ordered more than 300 inches long.

Length of sheets cold rolled before annealing (black, one pass, light gage pickled) shall not exceed that ordered by more than—

Three-fourths inch if ordered 96 inches long and less.

One inch if ordered more than 96 inches long to 120 inches, inclusive.

One and one-fourth inches if ordered more than 120 inches long to 144 inches, inclusive.

One and one-half inches if ordered more than 144 inches long to 168 inches, inclusive.

One and three-fourths inches if ordered more than 168 inches long.

Length of sheets cold rolled after annealing (full cold rolled, pickled and cold rolled) shall not exceed that ordered by more than 2 per cent of ordered length.

Out-of-square of sheets not cold rolled shall not be more than one-sixteenth inch per 6 inches, or fraction thereof, of sheet width, along end edge.

Out-of-square of sheets cold rolled shall not be more than one-sixteenth inch per 4 inches, or fraction thereof, of sheet width, along end edge.

Total out-of-square is the greatest deviation of an end edge from a straight line at right angle to a side and touching one corner.

Camber shall not exceed the tolerances given in Table 4.

TABLE 4

Sheets not cold rolled, ordered length		Camber	Sheets cold rolled, ordered length		Camber
More than—	Not more than—	Not more than—	More than—	Not more than—	Not more than—

264	288	7/8	156	168	7/8
288	-----	1	-----	-----	1

Camber is the greatest deviation of a side edge from a straight line touching both ends of the side.

Sheets required of accurate size shall be ordered "resquared." Such sheets shall not be in excess of ordered width and length by more than one-sixteenth inch and shall not be out of square or cambered by more than one-sixteenth inch, if not more than 48 inches wide and 120 inches long. For wider and longer sheets, the tolerance shall be one-eighth inch in each respect. For widths 12 inches and less and for all circle diameters, excess tolerance shall be one-eighth inch.

Resquaring excess allowance for sheets not stretcher-leveled (patent-leveled) shall be one-eighth for each intended cut, in addition to the foregoing tolerances.

Resquaring excess allowance for sheets stretcher-leveled (patent-leveled) shall be in accordance with Table 5.

TABLE 5

Ordered length		Width excess not more than—	Length
More than—	Not more than—		
Inches	Inches	Inches	
-----	120	3/4	(Not less than ordered between grip marks, and not more than 6 inches in excess. If "No allowance for grip marks" be ordered, excess shall be not more than 3 inches for lengths not over 120 inches, and 4 inches for longer sheets.)

Height of buckles is the maximum rise from a flat surface on which the sheet lies.

Sheets ordered stretcher-leveled (patent-leveled) shall not have buckles exceeding one-fourth inch in height. This standard of flatness can not be assured in sheets of less than 20 ounces per square foot (1.25 pounds per square foot, No. 22 U. S. S. G., 0.030 inch).

These height limits are for not more than two buckles in a side or in the middle. If more, the tolerance shall be proportionately less, but an approach to corrugation shall not be permitted.

601. ORES, PIG IRON, AND SCRAP.

601.1 IRON ORE.

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, STANDARD SAMPLES, CIRCULAR NO. 25 AND SUPPLEMENT, 1927

IRON ORE SAMPLES

(The Bureau of Standards prepares and sells standard samples of iron ores and other materials, for use by industrial organizations and others, as comparison standards for checking the accuracy of analysis of iron ores, etc. Each sample is accompanied by a certificate giving the composition of that particular sample as regards certain important constituents. Sample No. 25b is manganese ore, sample No. 26 is crescent iron ore, sample No. 27a is Sibley iron ore, sample No. 28 is Norrie iron ore, and sample No. 29 is magnetite iron ore (titaniferous).)

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, ANALYZED IRON AND MANGANESE ORES—METHODS OF ANALYSIS, CIRCULAR NO. 26, APRIL 5, 1921

METHODS OF ANALYSIS OF IRON AND MANGANESE ORES

(The methods of analysis described in Circular No. 26 are methods which have been found satisfactory at the Bureau of Standards and which may be used in the analysis of standard iron-ore samples described in Circular No. 25 above.)

601.2 PIG IRON.

601.20 GENERAL ITEMS.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD METHODS OF SAMPLING AND CHEMICAL ANALYSIS OF PIG AND CAST IRON, SERIAL DESIGNATION A64-27, 1927

SAMPLING AND CHEMICAL ANALYSIS OF PIG AND CAST IRON

SAMPLING

Pig iron.—One pig shall be selected at random from each 4 tons of iron and 10 such pigs (representing 40 tons of iron) shall constitute a unit for sampling. The surface of each pig shall be cleansed with a stiff wire brush or in any manner that will remove all loose sand without introducing deleterious matter.

The skin, down to clean metal, shall then be removed with an emery wheel at the center of the

upper face of each pig and the surface carefully brushed off.

Drillings shall be taken with a 1/4-in. twist drill, from top to bottom of each pig, starting from the center of the cleared space and stopping when the point of the drill appears below. One hole only shall be bored in each pig.

Suitable precautions shall be taken to prevent the escape of fine particles during the drilling. To this end a disk of clean sheet metal shall be clamped upon the pig after the skin has been removed. This disk shall have a hole in its center just large enough to receive the drill. Most of the drillings should then accumulate on top of the disk and can be brushed off after the drill is withdrawn. The pig shall then be turned bottom side up over any suitable receptacle for collecting what may have remained in the drill hole.

Castings.—In accordance with the standard specifications for gray-iron castings, A48 (see 611.11, p. 636), three test bars, 1.2 in. in diameter, shall be cast in sand from each heat at the beginning and again at the end of the pouring.

One bar from each set having been broken, one end of each next to the fracture shall be thoroughly cleaned and the outer skin removed for a sufficient distance from the fracture and down to clean metal. Chips shall then be taken by means of a lathe or milling machine across the whole face of the bar and until not less than 100 g has been collected. The same amount shall be taken from each bar. The bar shall be so clamped as to permit the attachment or use of any suitable device for collecting every part of the sample and the machine shall be run slowly enough to reduce to a minimum the danger of loss of fine particles.

Subsequent treatment of sample from both pig and castings.—In the determination of total and graphitic carbon, and in the case of check analyses on the other constituents, the following precautions shall be taken: The entire unit shall be weighed and then sifted on No. 80 (177 micron) (and if need be No. 120 (125 micron)) tight-fitting sieves (with cover).⁴³ The finer sieve need be used only in case the particles passing the coarse sieve are not sufficiently uniform in size and shape to meet the requirements of the treatment that follows.

The two (or three) portions so obtained shall be separately weighed. Each one shall then be thoroughly mixed without any loss of material and divided by weight into two (or three) exactly equal portions, each of which shall be placed in a clean, glass-stoppered bottle or other suitable receptacle and appropriately labeled. Of the three sets of the subdivided samples, one shall be retained by the works, one sent to the purchaser's chemist, and the third reserved.

Before weighing out for analysis, the contents of each bottle shall be thoroughly mixed, and each portion used for analysis shall be made up of the two (or three) partial samples in the same proportion which they bear to the gross sample. Thus, if the gross sample, weighing, say, 500 g, has been separated into portions weighing 400, 80, and 20 g, the amounts of each that must be weighed to yield a 2 g portion for analysis are 1.6 g, 0.32 g, and 0.08 g, respectively.

As a general rule the very fine material is richest in carbon, the coarse material next, while the intermediate sizes are the poorest. For routine analyses, the aim should be to obtain the iron in as small particles as possible, as for example, by milling. In such case, the samples for graphite and carbon may be taken by forming a cone, flattening it out, and taking small dabs with a spatula from at least ten

representative positions for each weighed portion. Less care is needed in taking portions for the determinations of the other constituents, grab samples from the container after gentle tumbling is satisfactory.

METHODS OF CHEMICAL ANALYSIS

In all of the following methods it is suggested that the analyst check the methods and his technique against Bureau of Standards standard samples of cast iron, or irons that have been standardized in comparison with these, except that in the case of analyses on the iron of chilled car wheels, the method and technique shall be checked against standard analyzed samples of wheel iron prepared by the Association of Manufacturers of Chilled Car Wheels.

Permissible variations in analyses of cast iron.—The following tabulation shows the variations that may occur between the results obtained by two good laboratories in the analysis of a proper sample of cast iron by the umpire method:

	Per cent
Total carbon.....	0.05+(0.01×per cent carbon found) ⁴⁴
Graphitic carbon.....	0.10
Combined carbon.....	0.10
Manganese.....	0.03
Phosphorus, alkalimetric or gravimetric.....	0.003+(0.02×per cent phosphorus found)
Sulphur, gravimetric.....	0.005
Sulphur, evolution.....	0.010
Silicon.....	0.05

Determination of Total Carbon by the Direct-Combustion Method

The method of direct combustion of the metal in oxygen is recommended, the carbon dioxide obtained being absorbed in soda-asbestos with suitable purifying and protecting trains following the furnace. Owing to the diversity of apparatus by which correct results may be obtained in the determination of carbon, the recommendations are intended more to indicate what is acceptable than to prescribe definitely what shall be used.

Apparatus and Reagents

Material for lining boats.—Alundum, "RR alundum, alkali free, specially prepared for carbon determination," as supplied by dealers, is suitable and is recommended. The 90-mesh or finer grades are used. Low-silica chrome ore, properly sized and freed from materials causing a blank, may also be employed. Freedom from alkali or alkaline earth metals, or carbon as carbonates or in other form, must be established before the above compounds are used as a lining material. Quartz sand owing to its liability to fuse or to slag with the oxides of iron, causing bubbles of gas to be inclosed, is objectionable. Aluminum oxide, made by calcining alum or otherwise, often contains sulphate not easily destroyed, or may contain objectionable substances of an alkaline nature.

Catalyzers.—Suitable catalyzers are asbestos, copper oxide, platinized quartz or asbestos, or platinum gauze. One of these should be used in the forward part of the combustion apparatus, as well as in the preheater preceding the combustion tube. (See below.) Platinized materials sometimes give off volatile substances on heating, and whatever material is used should not be subject to this defect.

Accelerators.—Millings of ingot iron or other iron with 0.01 to 0.02 per cent of carbon are the most satisfactory aids in the combustion of large drillings.

⁴⁴ For example, with iron containing 3 per cent carbon, this represents 0.08 per cent.

⁴⁵ This will vary, depending on whether or not the sample is annealed before test, or the manner in which the titer of the solution is obtained.

⁴³ For detailed specifications for these sieves see E11 (645.31, p. 1226).

Combustion apparatus.—Any apparatus heated by electricity or gas which will bring the sample to a temperature of 950° to 1,100° C. may be used. Combustion tubes may be porcelain, glazed on one or both sides, quartz, or platinum. Quartz is liable to devitrification when used continuously at temperatures above 1,000° C., and may then become porous. Tubes 30 inches long and 1¼ inches inside diameter drawn out at one end are convenient. This length permits at least 12 inches of the exit end to project from the furnace, the drawn-out end allows direct connection with the absorber and the large inner diameter accommodates larger boats and small Gooch crucibles as in the determination of graphite.

Boats or other containers of samples being burned.—These may be porcelain, quartz, alundum, clay, platinum, or nickel, and should always receive a lining of granular alundum or any other material found to be suitable for the purpose. Nickel boats should not be made of sheet nickel containing more than 0.15 per cent of carbon. Before use, new boats should always be preheated in oxygen until no more carbon dioxide is given off. In order to prevent spattering and attack of the tube, a platinum or nickel cover, open at both ends and allowing free access of oxygen, is desirable.

Purifying train before combustion apparatus.—This consists of a tower filled with soda asbestos, soda lime, or granular sodium hydroxide preceded by a preheater when necessary.

Oxygen.—Oxygen of not less than 97 per cent purity is recommended. Endeavor should be made to obtain oxygen which gives no blank, since the correction for or elimination of this is troublesome and uncertain. For the most accurate work, particularly with low-carbon products, such as ingot iron, etc., the blank should be completely eliminated by the use of a preheater before the furnace, with a carbon dioxide absorbent interposed between furnace and preheater.

Factors Influencing Rapid Combustion

Size of particles of sample.—The finer the chips (short of dust, which causes low values on a hot boat) the better, except with samples which burn too vigorously. (See Rate of Admitting Oxygen.) Particles too coarse to pass a No. 20 (840 micron) sieve are not recommended. Oil, dust, and other foreign matter should be carefully excluded.

Manner of distributing sample in boat.—This is of considerable importance. With all samples, close packing in a small space is conducive to rapid combustion. In the case of samples which burn too vigorously, a satisfactory regulation may sometimes be attained by spreading the sample loosely over the lining in the boat.

Rate of admitting oxygen.—The rate at which oxygen is admitted is also a factor in the velocity of combustion. Assuming the combustion apparatus to be heated to the temperature range above recommended (950° to 1,100° C.), it is possible, if the material is closely packed and if oxygen is admitted at too rapid a rate, that the combustion may be so violent as to cause excessive spattering of fused oxides, and such fluidity of the molten slag that the boat or other container may be injured or destroyed; therefore, a moderate rate of burning is to be sought. Sufficient oxygen, however, must be run in to insure a current of gas through the absorber at all stages of the combustion. The factors, temperature of combustion apparatus, manner of distribution of sample, and rate of admission of oxygen, can be governed so as to burn successfully irons of a very wide range of compositions in either fine or coarse particles.

Determination of Total Carbon (Carbon Dioxide Absorbed in Soda-Asbestos)

Special Apparatus

Purifying and protecting trains.—This method requires a purifying train before and after the combustion furnace.

The purifying train before the furnace, or between the furnace and preheater, if the latter is necessary for the purpose of oxidizing organic matter in the oxygen, may be a calcium chloride tower filled with soda asbestos, soda lime, or granular sodium hydroxide.

The purifying train after the furnace should be so designed that it will accomplish the following: (1) Remove impalpable oxide of iron which readily passes through loosely packed plugs of glass wool or asbestos or even solutions through which the oxygen is rapidly bubbled; (2) remove oxides of sulphur which are always formed; (3) dry the gases before entering the weighed carbon dioxide absorber; (4) dry the gases issuing from this absorber to the same extent as when they entered; in other words, the desiccant in the weighed absorber must be of the same kind as that which precedes it; and (5) protect the weighed absorber from outside effects.

Absorbing bulbs.—No special types are recommended, although the Fleming, Miller, and Midvale (sometimes called Stetzer and Norton) bulbs have proved satisfactory. When filled, the tubes should not weigh over 200 g and they should always be weighed filled with oxygen and against a like counterpoise. Open bulbs such as the Midvale lose oxygen by diffusion. They should be filled with oxygen before weighing when not in continuous use, and the same time interval shall be held between weighings.

Absorbents.—The most desirable absorbent is soda asbestos. The use of soda lime is not recommended unless the reagent has been carefully tested and found to be satisfactory. Pulverized sodium hydroxide may be used.

General arrangement of apparatus.—Figure 50 presents a typical arrangement in works' laboratories. Combustion tubes as large as 30 inches in length with an internal diameter of 1¼ inches may be substituted if desired. For work of the highest accuracy the issuing gases in this train would be bubbled through concentrated sulphuric acid saturated with chromic acid before passing through the phosphorus pentoxide tube, and the upper chamber of the Fleming bulb would be filled with phosphorus pentoxide. "Dehydrite" (magnesium perchlorate trihydrate) may be substituted for phosphorus pentoxide and is more convenient to use.

Method

After having properly set up and tested the apparatus, moderately pack the desired weight of iron (in the form recommended above) on the bed material in the boat and introduce the boat into the combustion apparatus, which has already been heated to the proper temperature. Allow the sample to heat up for one to three minutes, depending upon the size of particles, and then admit the gas at such a rate that the gases leave the absorbents at the rate of 200 to 400 c c per minute. The sample burns completely in one or two minutes, and all that is now necessary is to sweep all of the carbon dioxide into the absorption bulb. Regulate the rate of flow of the oxygen between 200 and 400 c c per minute and continue the flow for 10 minutes. Withdraw the absorption tube while filled with oxygen, place in the balance case for 10 minutes, open momentarily, and weigh against a like tube used as a counterpoise. The increase in weight represents

carbon dioxide which when multiplied by 27.27 and divided by the weight of the sample represents the percentage of total carbon in the iron. Remove the boat from the tube and examine the fusion for evidences of incomplete combustion. If the drillings are not thoroughly fused in a solid pig the determination must be rejected.

NOTES.—1. Oxides of sulphur cause positive errors when no provision is made for their removal. Sulphur trioxide can be almost entirely removed by interposing some baffle which condenses it, such as asbestos, phosphorus pentoxide, or sulphuric acid. Sulphur dioxide is not so easily removed; the most satisfactory medium is concentrated H_2SO_4 saturated with chromic acid.

2. The oxides of sulphur which are fixed and accumulate in the end of the combustion tube should be periodically removed by heating the end of the tube in the hot zone of the furnace.

3. In accurate work it is desirable to include in the weighed system a dehydrating agent which will dry the escaping gas to the same degree as when it entered the system. The loss of water from a good grade of soda asbestos may cause losses higher than 0.01 per

Ignited asbestos.—Gently ignite prepared asbestos under oxidizing conditions until all carbonaceous matter has been consumed. Prepared asbestos is asbestos that has been digested with HCl and then thoroughly washed with water.

Potassium hydroxide solution (specific gravity approximately 1.10).—Dissolve 120 g of stick KOH in 1,000 c c of water.

Dilute hydrochloric acid (1:20).—Mix 50 c c of HCl (specific gravity 1.19) and 1,000 c c of water.

Method

Dissolve 1 to 3 g of the sample in 50 c c of HNO_3 (specific gravity 1.20) and heat gently on the steam bath until action ceases. If silicic acid separates, add 5 c c of HF to facilitate filtration. Collect the residue conveniently on ignited asbestos by the use

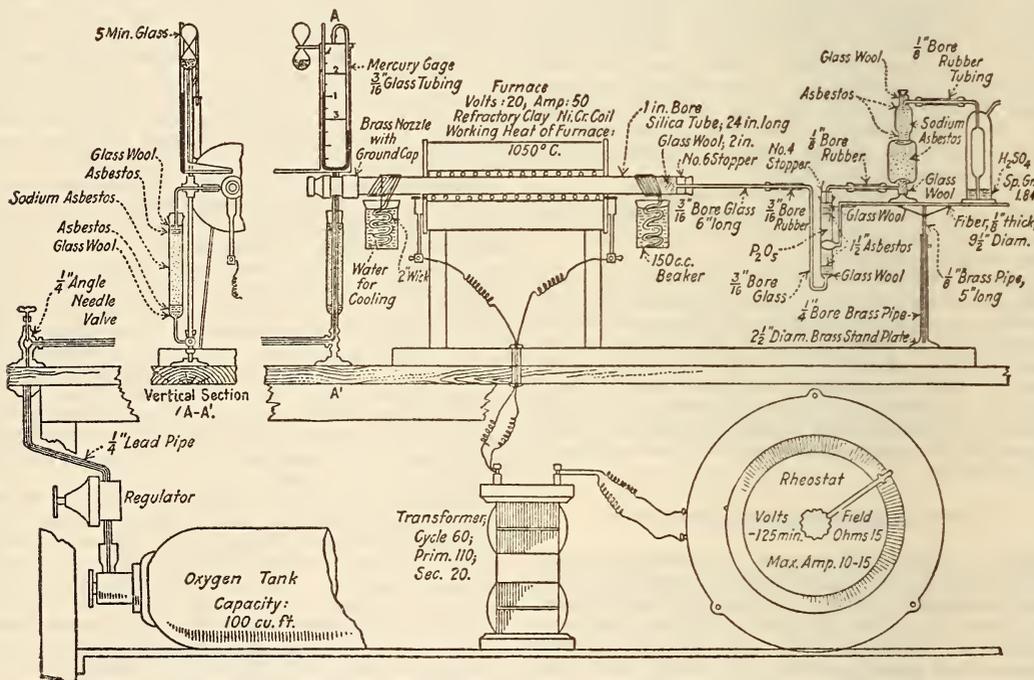

FIGURE 50.—Apparatus for determination of carbon by the direct-combustion method

cent carbon in ordinary combustions. In careful work it is also desirable to protect the weighed system from moisture and carbon dioxide by means of suitable end tubes.

4. Soda asbestos is commercially known as "Ascarite," and directions for its preparation are to be found in *J. Ind. Eng. Chem.*, vol. 8, pp. 1038-9, 1916. For the use of granular sodium hydroxide see *J. Ind. Eng. Chem.*, vol. 13, p. 1052, 1921.

5. In some laboratories the absorbing bulbs are always kept in the balance case. In this case the balances are placed on the same table with the furnaces and each balance usually contains two absorbing bulbs which are connected by short lengths of rubber tubing to glass tubes extending out of the balance and connecting with a pair of furnaces.

6. The operator should occasionally test the apparatus and his technique by means of the irons noted in the introductory paragraph or irons which have been standardized in comparison with these.

(For the alternative method of absorbing carbon dioxide—carbon dioxide absorbed in barium hydroxide solution—see A33 (600.1, p. 10).)

Determination of Graphite

Solutions Required

Dilute nitric acid (specific gravity approximately 1.20).—Mix 380 c c of HNO_3 (specific gravity 1.42) and 620 c c of distilled water.

of suction and fused-silica Gooch crucibles of such diameter as will go in the combustion tube. Wash the residue thoroughly with hot water, then with a hot solution of KOH (specific gravity 1.10), then with dilute HCl (1:20) and finally with hot water. Dry at a temperature not to exceed $150^\circ C.$ and determine the graphite by direct combustion in the apparatus used for the determination of total carbon, taking care to close the combustion tube immediately after inserting the sample.

It is preferable to run the combustion at approximately $700^\circ C.$ An oxidant, such as oxidized copper gauze, should be provided in the hot exit end of the tube to insure complete combustion to carbon dioxide.

Determination of Combined Carbon

Direct determinations of combined carbon in cast iron are not satisfactory and, therefore, for the present it is recommended that the percentage of combined carbon be obtained by subtracting the percentage of graphite from the percentage of total carbon.

Determination of Manganese by the Bismuthate Method

(REFEREE METHOD IN THE ABSENCE OF COBALT)

Solutions and Reagents Required

Dilute nitric acid (1:3).—Mix 500 c c of HNO_3 (specific gravity 1.42) and 1,500 c c of distilled water.

Dilute nitric acid (3:97).—Mix 30 c c of HNO_3 (specific gravity 1.42) (free from oxides of nitrogen) and 970 c c of distilled water.

Asbestos.—The asbestos for this work should be shredded, digested with HCl , thoroughly washed with water, then digested on the steam bath with dilute HNO_3 (1:3), and finally thoroughly washed with water to remove chlorides and to oxidize any ferrous iron contained in the asbestos. In making the asbestos filter-pad it is advisable to have a thin bed and as much surface as possible. This insures rapid filtration, and the filter can be used until it becomes clogged with bismuthate.

Bismuthate.—The sodium bismuthate should contain at least 70 per cent of NaBiO_3 or 4 per cent of active oxygen and not more than 0.005 per cent of manganese. Each bottle of bismuthate should be tested for strength and manganese contents. Its strength can be determined as follows: Weigh accurately about 3 g of the bismuthate, mix in a 100 c c graduated flask with a solution of 20 g of KI in 30 c c of water and shake well. Add 20 c c of HCl (specific gravity 1.19), stopper the flask, allow to stand for one hour in the dark, and dilute to the mark. Mix and titrate 10 c c of the solution with 0.1 *N* sodium thiosulphate, using starch as an indicator. One cubic centimeter of 0.1 *N* thiosulphate equals 0.0008 g of active oxygen. Determine the manganese content by boiling 3 g of bismuthate with 30 c c of dilute HNO_3 (1:3) and matching the color by adding standard permanganate solution to a like amount of acid.

Ferrous ammonium sulphate solution.—Dissolve 12 g of ferrous ammonium sulphate in a cold mixture of 950 c c of distilled water and 50 c c of H_2SO_4 (specific gravity 1.84).

Standard potassium permanganate solution.—Dissolve 1 g of KMnO_4 in 1,000 c c of distilled water. Allow it to stand for at least one week and then filter through purified asbestos. Standardize against the Bureau of Standards standard sodium oxalate as follows: In a 200 c c beaker, dissolve 0.1 g of sodium oxalate in 75 to 100 c c of hot water (80° to 90° C.) and add 5 c c of H_2SO_4 (1:1). Titrate at once with the permanganate solution, stirring the liquid vigorously and continuously. The permanganate must not be added more quickly than 10 to 15 c c per minute, and the last 0.5 to 1 c c must be added dropwise, with particular care to allow each drop to be fully decolorized before the next is introduced. The excess of permanganate used to cause an end-point color must be estimated by matching the color in another beaker containing the same bulk of acid and hot water. The temperature of the solution should not be below 60° C. by the time the end point is reached.

Standard sodium arsenite solution.—Dissolve 2 g of sodium arsenite in distilled water, filter if necessary, and dilute to 1 liter. Standardize against the standard permanganate solution by titrating 10 c c portions under the acidity and dilution conditions that obtain in the method. A clear green color free from brownish or purplish tints will be found a satisfactory and reproducible end point. The solution can also be standardized against a standard cast iron or steel.

— *Method*

Dissolve 1.000 g of the sample in 25 c c of dilute HNO_3 (1:3) and boil to expel oxides of nitrogen.

Cool, filter, and wash with 25 to 50 c c of dilute HNO_3 (1:3). Add 0.5 g of sodium bismuthate to the filtrate, heat to boiling, and boil for at least three minutes. Clear the solution if permanganic acid or manganese dioxide is present by adding a few drops of a saturated solution of sulphur dioxide or other suitable reducing agent free from manganese and chlorides, and boil to expel oxides of nitrogen and sulphur. Cool to 15° C., add an excess of sodium bismuthate, agitate, and let stand for a few minutes. Add 50 c c of 3 per cent HNO_3 (free from nitrous acid) and filter through asbestos. Wash with HNO_3 (3 per cent) until the washings run through colorless. The filtrate must be clear and absolutely free from particles of bismuthate. Titrate by either method (a) or (b) as follows:

(a) *Ferrous sulphate—permanganate titration.*—Add from a burette or pipette 10 to 50 c c (depending on the amount of permanganic acid) of ferrous ammonium sulphate solution and then titrate with the standard KMnO_4 solution. In exactly the same manner carry through a blank determination using the same amounts of acid and bismuthate as was done with the regular sample. Finally add the exact volume of ferrous ammonium sulphate solution which was employed and titrate with the standard KMnO_4 solution. The difference between the volumes required in the two titrations represents the manganese in the sample.

(b) *Arsenite titration.*—Titrate immediately with the standard sodium arsenite solution to the clear green color used as an end point in the standardization of the solution. In this titration, permanganic acid does not react in accordance with the ratio $\text{Mn}_2\text{O}_7:2\text{MnO}$. Consequently the theoretical titre of the arsenite solution can not be employed.

Determination of Manganese by the Persulphate Method

(ROUTINE AND IN THE PRESENCE OF COBALT)

Solutions required

Dilute nitric acid (specific gravity approximately 1.20).—Mix 380 c c of HNO_3 (specific gravity 1.42) and 620 c c of distilled water.

Silver nitrate (0.133 per cent).—Dissolve 1.33 g of AgNO_3 in 1,000 c c of distilled water.

Ammonium persulphate solution (10 per cent).—Prepare as needed by dissolving 10 g of the salt in 100 c c of distilled water. The salt should show at least 80 per cent of persulphate by test. The pure salt ordinarily contains 95 per cent of persulphate. For method of test see solutions required in determination of small amounts of chromium, given below.

Sodium chloride (0.2 per cent).—Dissolve 2 g of NaCl in 1,000 c c of distilled water.

Standard sodium arsenite.—Dissolve 0.8 g of sodium arsenite in distilled water, filter if necessary; dilute to 1 liter and standardize against measured portions of a standard permanganate solution which have been reduced by hydrogen peroxide or ferrous sulphate, that is free from manganese and then treated as in the method to be described, or against standard samples of iron.

Method

In a small Erlenmeyer flask or large test tube (8 by 1 inches) dissolve 0.1 to 0.3 g of iron, depending on the manganese content of the sample, in 15 c c of dilute HNO_3 (specific gravity 1.20) and boil to expel oxides of nitrogen. Add 5 c c of $(\text{NH}_4)_2\text{S}_2\text{O}_8$ solution (10 per cent) and heat several minutes to oxidize the combined carbon. Remove graphite by filtration through a small rapid paper, and wash the paper with 15 c c of AgNO_3 solution (0.133 per cent) and a small amount of water. If a tube

is used, add 10 c c of the $(\text{NH}_4)_2\text{S}_2\text{O}_8$ solution (10 per cent) and heat in the water bath until the color develops. If a flask is employed, bring the solution to boiling, add 10 c c of the persulphate solution and then set aside in a warm place until the color develops. When the full color has developed, cool the solution in running water, transfer to a 250 c c beaker and dilute to a volume of 75 c c. Add 10 c c of NaCl solution (0.2 per cent) and titrate with standard arsenite solution.

NOTES.—In the arsenite titration, permanganic acid does not react in accordance with the ratio $\text{Mn}_2\text{O}_3:2\text{MnO}$, but more nearly as indicated by the ratio $\text{Mn}_2\text{O}_7:\text{Mn}_2\text{O}_3$. Consequently, the theoretical titre of the arsenite can not be used and the manganese titre must be obtained by titration of material of known manganese content and under the conditions that obtain in the method.

The persulphate oxidation requires careful attention; the solution must not be too acid and sufficient AgNO_3 must be present (about fifteen times as much AgNO_3 as Mn). Consequently, in irons of high manganese content the amount of AgNO_3 and NaCl should be increased.

No MnO_2 must be separate on heating after the first addition of persulphate, for this would be lost when the solution is filtered.

Determination of Phosphorus by Weighing as Magnesium Pyrophosphate

(REFEREE METHOD)

Solutions required

Dilute nitric acid (1:1).—Mix equal parts of HNO_3 (specific gravity 1.42) and water.

Dilute hydrochloric acid (1:1).—Mix equal parts of HCl (specific gravity 1.19) and water.

Dilute hydrochloric acid (1:20).—Mix 50 c c of HCl (specific gravity 1.19) and 1,000 c c of water.

Dilute ammonium hydroxide (1:2).—Mix 300 c c of NH_4OH (specific gravity 0.90) and 600 c c of distilled water.

Dilute ammonium hydroxide (1:20).—Mix 100 c c of NH_4OH (specific gravity 0.90) and 2,000 c c of distilled water.

Dilute nitric acid (2:100).—Mix 20 c c HNO_3 (specific gravity 1.42) and 1,000 c c of distilled water.

(Ammonium molybdate solutions No. 1 and No. 2 and directions for handling are identical with the determination of phosphorus by the alkalimetric method in B28. See 646.0, p. 1243.)

Magnesia mixture.—Dissolve 50 g of $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ and 100 g of NH_4Cl in 200 c c of distilled water, and then add 5 c c of NH_4OH (specific gravity 0.90). Let stand overnight, filter if a precipitate appears, make just acid with HCl, and dilute to 1,000 c c with water.

Method

Dissolve 1 to 3 g of the sample in a covered casserole in 30 c c of dilute HNO_3 (1:1). When solution is complete add 10 c c of dilute HCl (1:1), evaporate to dryness, and bake for 15 to 20 minutes on the hot plate. Cool, drench the residue with concentrated HCl, dilute to 50 c c with hot water, and warm until the salts are in solution. Filter without delay, wash with dilute HCl (1:20), and evaporate the filtrate to sirupy consistency. In the meantime, place the paper containing graphite and silica in a platinum crucible, burn off the carbon, cool, and add 5 to 10 drops of concentrated HCl and 1 to 2 c c of HF. Evaporate just to dryness, take up any residue in 5 c c of concentrated HCl and add the solution to the main solution which is being evaporated. When the solution is of sirupy consistency, transfer it to a 300 c c Erlenmeyer flask by alternate washing with dilute HNO_3 (1:1) and hot water, using not more than 30 c c of the former and 70 c c of the latter. Heat to boiling, add NH_4OH until a permanent precipitate has formed, dissolve in dilute HNO_3 (1:1) and then add 100 c c of molybdate reagent. Shake for 10 minutes and allow to stand not less than six hours.

Filter on a paper of close texture, and wash the flask and the precipitate with not more than 50 c c

of cold dilute HNO_3 (1:99). Set the filtrate and washings aside after thorough mixing. If further separation of phosphomolybdate occurs in four hours recover the precipitate and determine its phosphorus content. Dissolve the precipitate on the filter and in the flask in 20 c c of dilute NH_4OH (1:1) to which has been added 2 g of citric acid, catch the solution in a 250 c c beaker, wash the filter several times with dilute NH_4OH (1:20), then with hot water, and finally several times with dilute HCl (1:20). If the ammoniacal solution of the phosphomolybdate is not clear at this point, heat it to boiling, filter through the same paper, wash the paper with hot water, ignite in a small platinum crucible, fuse any residue with as little carbonate as possible (not over 0.5 g), extract the cooled melt with hot water, filter, and add the water solution to the ammoniacal solution.

Render the ammoniacal solution acid with HCl, add 20 c c of magnesia mixture, then add NH_4OH (specific gravity 0.90) cautiously until a crystalline precipitate appears. From this point proceed very slowly until the solution is alkaline and then add 5 cc of NH_4OH in excess. The volume of the solution at this point should not exceed 100 c c. Allow the solution to stand in a cool place for not less than six hours. Filter, and wash the precipitate moderately with dilute NH_4OH (1:19). Dissolve the precipitate on the filter in 25 c c of dilute HCl (1:1), catching the solution in the original beaker. Wash the filter thoroughly with dilute HCl (1:20.) Add 0.5 to 1 g of ammonium bromide and boil the HCl solution to a volume of 5 to 10 c c (but not to dryness) to eliminate small amounts of arsenic. Precipitation with hydrogen sulphide can be substituted for the evaporation with hydrobromic acid and is desirable in case much arsenic is present. Dilute to a volume of 50 to 75 c c, add 0.1 to 0.2 g of citric acid, 2 to 3 c c of magnesia mixture, make ammoniacal as above, and allow to stand in a cool place for not less than four hours.

Filter, wash with dilute NH_4OH (1:20) until chlorides have been removed; ignite the precipitate carefully and at as low a temperature as possible, until the carbon has been destroyed and the residue is white. Finally, ignite at approximately $1,000^\circ\text{C}$. to constant weight. Dissolve the ignited precipitate in 10 c c of dilute H_2SO_4 (1:4). Evaporate to fumes of sulphuric acid, dilute, filter, and wash with hot water. Ignite, weigh, treat with a few drops of HF, evaporate to dryness, ignite, and reweigh. Subtract any loss of weight from the original weight of the pyrophosphate, and calculate on the basis of this purified magnesium pyrophosphate.

Determination of phosphorus by the alkalimetric method

(ROUTINE)

Solutions required

Dilute nitric acid (specific gravity approximately 1.135).—Mix 280 c c of HNO_3 (specific gravity 1.42) and 720 c c of water.

Potassium permanganate (1.5 per cent).—Dissolve 15 g of KMnO_4 in 1,000 c c of water.

Ammonium bisulphite (3 per cent).—Dissolve 30 g of ammonium bisulphite in 1,000 c c of distilled water. This salt must be free from phosphorus.

Ammonium hydroxide (specific gravity 0.96).—Mix 400 c c of NH_4OH (Specific gravity 0.90) and 600 c c of water. The strength of this solution should be verified by hydrometer or titration.

(Ammonium molybdate solution, potassium nitrate (1 per cent), phenolphthalein indicator, standard sodium hydroxide, and standard nitric acid—all are the same as in B28. (See 646.0, p. 1243.)

Method

Dissolve 0.5 to 2 g of the sample in 50 c c of HNO_3 (specific gravity 1.135) and destroy organic matter by boiling with 10 c c of a 1.5 per cent solution of KMnO_4 until oxide of manganese is precipitated. Dissolve the oxide by addition of ammonium bisulphite, boil to expel the oxides of nitrogen, filter, and wash with 50 c c of HNO_3 (specific gravity 1.135). Add to the cool solution 40 c c of NH_4OH (specific gravity 0.96), 40 c c of ammonium molybdate solution, and shake for 5 minutes. Let settle and filter on a 9 cm No. 42 Whatman or equivalent paper which had been fitted tightly in the funnel. With irons high in vanadium or titanium the solution should be allowed to settle for two hours. Wash the flask, the precipitate, and the filter paper with 25 c c portions of a 1 per cent solution of KNO_3 until 10 c c of washings will not decolorize one drop of the standard alkali plus one drop of phenolphthalein. Return the paper and precipitate to the precipitating vessel, add a 2 to 5 c c excess of standard NaOH solution and 25 c c of water, both free from carbon dioxide, and shake or stir until the precipitate is dissolved. Dilute to from 100 to 200 c c with water free from carbon dioxide, add three drops of 0.2 per cent phenolphthalein solution, and discharge the pink color with standard acid. Finish the titration by adding standard alkali until the reappearance of the pink color. In the analysis of low phosphorus iron this titration should be corrected by a blank carried through all steps of the method.

NOTE.—With irons containing vanadium in excess of 0.05 per cent, cool the solution to 10° to 15° C. and add 1 g of ferrous sulphate just before the addition of molybdate reagent.

Determination of Sulphur by the Gravimetric Method

(REFEREE METHOD)

Solutions required

Dilute hydrochloric acid (1:99).—Mix 10 c c of HCl (specific gravity 1.19) and xxx c c of water.

Barium chloride solution (10 per cent).—Dissolve 100 g of $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$ in 1,000 c c of distilled water.

Dilute sulphuric acid (1:1).—Carefully add while stirring 100 c c of H_2SO_4 (specific gravity 1.84) to 100 c c of water.

Method

Dissolve the sample (4.57 g) in 50 c c of HNO_3 , (specific gravity 1.42) in a covered beaker or flask. Add 0.5 g of Na_2CO_3 , evaporate to dryness and bake for one hour on the hot plate. Add 30 c c of HCl (specific gravity 1.19) and repeat the evaporation and baking. Add another 30 c c of HCl (specific gravity 1.19) and evaporate to dryness. Add 25 c c of HCl (specific gravity 1.19), 25 c c of water, 5 g of 20 to 30 mesh zinc free from sulphur, and warm on the steam bath until the iron is reduced to ferrous chloride and the evolution of hydrogen has nearly ceased. Filter from the silica and undissolved zinc, wash with approximately 75 c c of HCl (1 per cent by volume), warm to 60° to 80° C., and add 10 c c of 10 per cent barium chloride. Let stand 18 to 24 hours, filter on a paper of close texture and discard the filtrate. Wash once or twice with cold 1 per cent HCl and then with hot water until free from chlorides. Reserve the precipitate and evaporate the washings to dryness. Dissolve the slight residue in 1 c c of dilute HCl (1:1), dilute to 25 c c with hot water, add 1 c c of 10 per cent BaCl_2 solution, and digest at the side of the steam bath for one hour. Filter on a small paper of close texture, and wash with hot water until free from chlorides. Ignite both papers in platinum and treat with one drop of H_2SO_4 (1:1) and 1 c c of HF . Evaporate

to dryness, ignite, and weigh. A blank should be carried through all steps of the determination. The corrected weight of the ignited barium sulphate multiplied by 3 is equal to the percentage of sulphur.

NOTE.—The solution should preferably contain not more than 2 per cent by volume of HCl at the time of the precipitation with BaCl_2 . Ordinarily, there will be no hydrolysis of iron during the filtration and washing of the undissolved zinc or the precipitation with BaCl_2 . Should this occur, the solution must be cleared by the addition of HCl , having due regard to the final permissible acidity.

Determination of Sulphur by the Gravimetric Method

(OPTIONAL REFEREE METHOD)

Solutions required

Double chloride solution.—Dissolve 756 g of copper potassium chloride ($\text{CuCl}_2 \cdot 2\text{KCl} \cdot 2\text{H}_2\text{O}$) in 2,000 c c of water, and add 200 c c of HCl (specific gravity 1.19).

Method

Transfer 4.57 g of the sample to an Erlenmeyer flask, treat with 250 c c of the double chloride solution, and stir gently by mechanical means until all of the iron is in solution. For more rapid solution of the iron, first place the double chloride solution in a flask provided with a stopper containing inlet and outlet tubes for carbon dioxide, warm to approximately 40° C. as a stream of CO_2 is bubbled through the solution, introduce the sample, replace the stopper, and continue the passage of the gas with occasional shaking of the flask to prevent clogging of the inlet tube.

When solution is complete, let settle for a moment, decant through a rapid filter, and wash quickly, by decantation as much as possible, with a little hot water. Place filter paper and contents in the original flask, add 25 c c of water, then 5 c c of bromine and finally 5 c c of concentrated HCl . Heat gently till free of bromine, dilute to 100 c c, filter, and wash the residue thoroughly with hot water. Precipitate with BaCl_2 and finish the determination as described in the determination of sulphur by the gravimetric method (referee method).

The results must be corrected by blanks run under the same conditions as the determination.

Determination of Sulphur by the Evolution Method

(ROUTINE)

Apparatus

Figure 51 shows a typical apparatus for this determination. A spray trap may be put in the outlet tube to prevent iron from passing over into the ammoniacal solution.

Solutions required

Dilute hydrochloric acid (1:1).—Mix 500 c c of HCl (specific gravity 1.19) and 500 c c of distilled water.

Ammoniacal cadmium chloride.—Dissolve 10 g of cadmium chloride in 400 c c of distilled water and add 600 c c of NH_4OH (specific gravity 0.90).

Ammoniacal zinc sulphate (optional solution).—Dissolve 200 g of zinc sulphate in 1,080 c c of water, and add 920 c c of NH_4OH (specific gravity 0.90).

Starch solution.—To 500 c c of boiling distilled water, add a cold suspension of 5 g of soluble starch in 25 c c of distilled water, cool, add a cool solution of 5 g of NaOH in 50 c c of distilled water, then add 15 g of KI and mix thoroughly.

Potassium iodate.—Dissolve 1.12 g of KIO_3 and 12 g of KI in 1,000 c c of distilled water. For general work the theoretical sulphur titre of this solution should be used; for specialized work on one kind of

material, the solution may be standardized against like material. The theoretical titre is based on standard sodium oxalate and is obtained as follows: To 300 c c of water in a 600 c c flask, preferably glass stoppered, add 10 c c of HCl (specific gravity 1.19) and 1 g of KI. Cool and add 25 c c of 0.03 NKMnO_4 solution which has been standardized against sodium oxalate. Swirl gently, stopper, and let stand for five minutes. Titrate the liberated iodine with thiosulphate solution until the color nearly fades. Then add 10 c c of starch solution and continue the titration until the blue color is destroyed. In a new flask, repeat the experiment with the sole difference that 25 c c of the iodate solution is substituted for the standard permanganate solution. Calculate the normality of the iodate solution, and dilute if desired so that its normality is 0.0312, or 1 c c is equivalent to 0.01 per cent of sulphur on a 5 g sample. For standardization against like material, 5 g portions of the proper standard cast iron is carried through all steps of the method. The

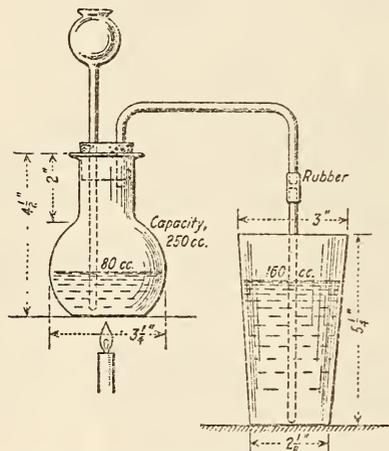

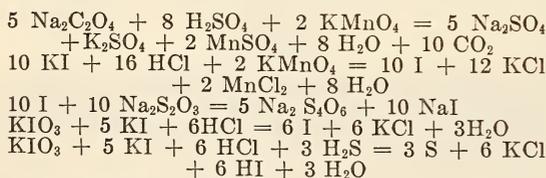

FIGURE 51.—Apparatus for determining sulphur by the evolution method

following equations represent the reactions that are involved:

The ratios are, therefore:

Method

Place 5 g of the cast-iron sample in the flask (fig. 51) and connect the latter as shown in the sketch. Place 10 c c of the ammoniacal solution of cadmium chloride or zinc sulphate solution and 150 c c of distilled water in the tumbler. Add 80 c c of the dilute HCl (1:1) to the flask through the thistle tube, heat the flask and its contents gently until the solution of the iron is complete, then boil the solution for one-half minute. The heat must be so adjusted that there is a rapid, steady, evolution of gas. Disconnect the delivery tube leaving it in the solution and remove the tumbler. Add 5 c c of starch solution, then 40 c c of dilute HCl (1:1) and titrate immediately with the iodate solution to a permanent blue color.

NOTES—If cast-iron samples are not annealed and the theoretical titre is used, the results obtained by the evolution method will be

low by as much as 0.015 per cent. Annealed samples behave more nearly normal, but there is enough uncertainty so that the evolution method should never be used when high accuracy or settlement of disputes are in question.

Samples are annealed as follows: Transfer 5 g of the drillings to a 12.5 cm filter paper, and wrap the sample securely in the paper so that at least three thicknesses of paper cover the iron. Place the packages in a 25 c c porcelain crucible, cover the crucible tightly so that air can not enter freely, and heat for 20 minutes at a bright red heat over a Meker burner or preferably in a muffle. The filter paper should be charred but not burned.

Direct sunlight should be avoided if cadmium solutions are used, otherwise low results are obtained. Cast irons of high titanium content do not yield all of their sulphur even after annealing.

Determination of Silicon by the Nitro-Sulphuric Acid Method

Solutions required

Nitro sulphuric acid.—Mix 160 c c of H_2SO_4 (specific gravity 1.84), 180 c c of HNO_3 (specific gravity 1.42), and 660 c c of water.

Dilute hydrochloric acid (5:95).—Mix 50 c c of HCl (specific gravity 1.19) and 950 c c of distilled water.

Method

Cautiously add 100 c c of the nitro-sulphuric acid to 2.336 g of iron in a platinum or porcelain dish of 300 c c capacity, cover with a watch glass, heat until the iron is dissolved, and evaporate until copious fumes of sulphuric acid are evolved. Cool, add 125 c c of distilled water and 5 c c of HCl (specific gravity 1.19), heat with frequent stirring until all salts are dissolved, and immediately filter on a 9 cm paper. Wash the precipitate with cold dilute HCl (5:95) and hot water alternately to complete the removal of iron salts, and finally with hot water, until free from acid. Transfer the filter to a platinum crucible, burn the paper without inflaming, and finally ignite with the crucible covered over a blast lamp or in a muffle furnace at $1,000^\circ \text{C}$., for at least 10 minutes, cool in a desiccator, and weigh. Add sufficient dilute H_2SO_4 (1:1) to moisten the silica, and then a small amount of HF. Evaporate to dryness, ignite, and weigh. The difference in weights in milligrams divided by 50 equals the percentage of silicon.

A blank determination on all reagents used should be made and the results corrected accordingly.

Determination of Silicon by the Hydrochloric-Sulphuric Acid Method

To 2.336 g of iron in a covered 600 c c beaker or a 250 c c casserole add 40 c c of dilute HCl (1:1), heat gently until the solution is complete, and then wash and remove the cover glass. Evaporate to dryness, but do not bake. If basic salts are formed by accidental baking, moisten the hot mass with 1 to 3 c c of HCl (specific gravity 1.19). Cool slightly, add 15 c c of H_2SO_4 (specific gravity 1.84), and scrape down any salts on the sides of the vessel. Evaporate to fumes of sulphuric acid, cool, add 150 c c of water, and heat with frequent stirring until salts are in solution. Immediately filter on a 9 cm paper, and proceed as in the determination of silicon by the nitro-sulphuric acid method.

NOTE.—This determination can be carried out in the HCl solution of the iron obtained in the determination of sulphur by the evolution method (routine).

Determination of Silicon by the Sulphuric Acid Method

(Optional)

Solutions required

Dilute hydrochloric acid (5:95).—(Same as in determination of silicon by the nitro-sulphuric acid methods given above.)

Method

To 2.336 g of iron in a 500 c c beaker of low form add 60 c c of distilled water, and then cautiously 15

c c of H_2SO_4 (specific gravity 1.84). Cover with a watch glass, heat until the iron is dissolved, remove the cover, and evaporate until copious fumes of sulphuric acid are evolved. Cool, add 100 c c of distilled water, and heat with frequent stirring until the salts are in solution. Immediately filter on a 9 cm paper and proceed as in the determination of silicon by the nitro-sulphuric acid method.

Determination of Small Amounts of Chromium

Solutions required

Dilute sulphuric acid (1:9).—Slowly stir 100 c c of H_2SO_4 (specific gravity 1.84) into cool water, cool, and then dilute to 1,000 c c. It is important that this acid be of the indicated strength.

Sodium bicarbonate solution.—Dissolve 80 g of NaHCO_3 in water and dilute to 1,000 c c.

Dilute sulphuric acid (1:1).—Slowly stir 500 c c of H_2SO_4 (specific gravity 1.84) into 500 c c of water.

Dilute nitric acid (specific gravity approximately 1.20).—Mix 380 c c of HNO_3 (specific gravity 1.42) and 620 c c of distilled water.

Silver nitrate solution (0.133 per cent).—Dissolve 1.33 g of AgNO_3 in 1,000 c c of water.

Ammonium persulphate solution (10 per cent).—Make up as needed by dissolving 10 g of the salt in 100 c c of water. The salt should be at least 95 per cent pure and can be tested as follows: Dissolve 0.3 g of the salt, accurately weighed, in 25 c c of a 10 per cent solution of potassium iodide and add 10 c c of dilute sulphuric acid (1:9). Let it stand for one-half hour and titrate the liberated iodine with a 0.1 N solution of sodium thiosulphate. One cubic centimeter 0.1 N $\text{Na}_2\text{S}_2\text{O}_3$ equals 0.01141 g of $(\text{NH}_4)_2\text{S}_2\text{O}_8$. Or, the salt can be tested by treating 0.3 g of the salt with 30 c c of 0.1 N FeSO_4 solution and then with 200 c c of hot water in a nonoxidizing atmosphere. After the salt has dissolved, cool, and determine the excess of FeSO_4 by titration with 0.1 N KMnO_4 solution.

Sodium chloride solution (5 per cent).—Dissolve 5 g of NaCl in 100 c c of water.

Standard ferrous sulphate solution (0.03 N).—See the determination of manganese by the bismuthate method.

Standard potassium permanganate solution.—See the determination of manganese by the bismuthate method.

Sodium hydroxide solution (5 per cent).—Dissolve 50 g of stick NaOH in 1,000 c c of water.

Standard potassium chromate.—Dissolve 0.2828 g of C. P. $\text{K}_2\text{Cr}_2\text{O}_7$ in 1,000 c c of water. One cubic centimeter of this solution contains 0.1 mg of chromium. In the colorimetric comparison the solution is added to a NaOH solution of the same strength as the solution which is to be tested.

Method

(a) *Titration method (referee method).*—Treat 10 g of the sample, contained in a 500 c c Erlenmeyer flask, with 110 c c of dilute H_2SO_4 (exactly 1:9). Cover, heat to boiling, and as soon as the action is complete dilute to 200 c c with boiling water. (See note.) Immediately add 50 c c of sodium bicarbonate solution slowly and with stirring from a pipette, and then continue the addition from a burette until a permanent precipitate appears (10 to 30 c c depending on the composition of the iron) and then add 4 c c more. Boil for one minute, let settle, filter on a rapid filter and quickly wash the flask and precipitate two or three times with hot water. If the proper portions of iron and H_2SO_4 were taken in the beginning and the precipitation is properly performed, there will be no more precipitate than can be conveniently handled on an 11 cm paper. The filtrate will become cloudy in the funnel

stem and in the receiving vessel on account of oxidation and hydrolysis. Ignite the paper and precipitate in an iron or nickel crucible (free from chromium), mix the ash with 10 or 12 times its volume of sodium peroxide (free from chromium) and heat gently until the contents are fused. Dissolve the cooled melt by immersing it in 100 c c of cold water, remove the crucible, and destroy any remaining peroxide by heating for at least one-half hour on the steam bath. Filter through paper or an asbestos pad, wash with hot water, and discard the residue.

If some iron passes into the filtrate, it will not interfere with the subsequent titration of chromium. Neutralize the filtrate with H_2SO_4 (1:1), using litmus paper as indicator, and add 20 c c in excess. Add 5 c c of HNO_3 (specific gravity 1.20), 10 c c of AgNO_3 solution and 20 c c of freshly prepared ammonium persulphate solution (10 per cent). Boil for 10 minutes. If small amounts of permanganic acid are now indicated, add 5 c c of NaCl solution (5 per cent) and continue the boiling for five minutes after the pink color has been destroyed. If no permanganate acid is indicated, as is usually the case, the boiling with NaCl can be omitted. Cool the solution, dilute to 300 c c and titrate for chromium by adding a small measured excess of the standard ferrous sulphate solution and then titrating back with an approximately 0.03 N standard potassium permanganate solution. The titration should be corrected by a "blank" run carried through the various steps of the method, not omitting the fusion which tests the crucible.

(b) *Colorimetric method (routine).*—A reasonably correct determination of small amounts of chromium requires such care that a rapid routine method is not possible. The titration method (referee method), above, can be shortened somewhat for less accurate work as follows:

When the hydrogen peroxide has been destroyed, filter the NaOH solution through an asbestos pad, preferably on a Büchner funnel, and wash with a cold 5 per cent solution of NaOH . Dilute to a measured volume (preferably 100 c c) and compare the color with a standard solution of $\text{K}_2\text{Cr}_2\text{O}_7$. In this method peroxide need not be destroyed, but the solution is heated to give better separation of iron which occasionally goes through the filter and gives a false color.

In the colorimetric work asbestos should be used as the filtering medium as coloring matter may be extracted from filter paper by strongly alkaline solutions.

Vanadium is quantitatively precipitated by sodium bicarbonate in this method, but it does not interfere in the determination of chromium in either volumetric or colorimetric methods.

NOTE.—As soon as attack is complete, the solution can be rapidly filtered by suction, the paper and contents washed with hot water and burned with the bicarbonate precipitate. This aids a beginner to determine the bicarbonate end point.

Determination of Nickel by the Dimethylglyoxime Method

Solutions required

Dilute hydrochloric acid (1:1).—Mix 500 c c of HCl (specific gravity 1.19) and 500 c c of water.

Dilute hydrochloric acid (1:20).—Mix 50 c c of HCl (specific gravity 1.19) and 1,000 c c of water.

Dimethylglyoxime solution (1 per cent).—Dissolve 20 g of dimethylglyoxime in 1,800 c c of NH_4OH (specific gravity 0.90) and dilute to 2,000 c c. Ten cubic centimeters of this solution allow sufficient excess completely to precipitate 0.015 g of nickel.

Method

Dissolve 5 g of the iron in 40 c c of dilute HCl (1:1), add about 10 c c of HNO_3 (specific gravity

1.42) to oxidize the iron, and evaporate to dryness on the steam bath. Drench the dried mass with 10 c c of HCl (specific gravity 1.19) and then dilute with 100 c c of hot water. Filter, wash with dilute HCl (1:20) and evaporate the filtrate to a sirupy consistency. Take up in 15 c c of HCl (1:1) and transfer to a 150 or 250 c c separatory funnel, rinsing the beaker several times with small portions of dilute HCl (1:1). Cool, add 50 c c of ether, shake for one to two minutes in a stream of cold water, let settle for one minute, and then draw off the lower clear solution. Add 10 c c of cold dilute HCl (1:1) to the solution in the separatory funnel, shake thoroughly, allow to settle for one minute, and again draw off the clear solution into the same beaker as was used for the first. Gently heat the solution in the beaker to expel the ether, add 0.2 g of potassium chlorate, boil until the chlorate is decomposed, dilute to 100 c c and add 3 g of tartaric acid. Make the solution alkaline with ammonia and filter. If a precipitate of iron is present insufficient tartaric acid was added. In this case the precipitate must be dissolved in HCl, the whole solution acidified, and treated with more tartaric acid. If no precipitate appear, render the solution slightly acid with HCl, dilute to 200 c c and add 20 c c of dimethylglyoxime solution. Heat to boiling, make slightly ammoniacal, and let stand on the steam bath for one hour. Filter on a weighed Gooch Pyrex-Alundum, or fritted-glass crucible, wash with hot water and dry for one hour at 110° to 120° C. Weigh as nickel-dimethylglyoxime and multiply the weight by 0.2031 to obtain the weight of nickel.

NOTE.—In routine analyses, the dimethylglyoxime precipitate can be caught on paper and ignited to NiO or decomposed and titrated with cyanide. In the former case, care must be taken to prevent sublimation of the undecomposed salt. This can be accomplished by enclosing the wet paper and precipitate in one or two wet ashless papers and slowly igniting so that the papers char before taking fire. In his way the compound is decomposed and ignition can then proceed at full red heat. In the latter case proceed as follows: Dissolve the nickel-dimethylglyoxime in HNO₃, oxidize with ammonium persulphate or potassium chlorate and boil for five minutes. Cool, neutralize with NaOH and add 5 c c in excess. Rosolic acid is a convenient indicator. Dilute to 200 c c, cool thoroughly, add 2 c c of a 10 per cent solution of KI and then from a burette 1 c c of standard AgNO₃ solution (5.7903 g per liter). Titrate with a standard solution of potassium cyanide (4.5 g KCN per liter) until the AgI is dissolved. Finish the titration by adding AgNO₃ to a reappearance of the opalescence. With exactly agreeing AgNO₃ and KCN solutions, each cubic centimeter excess of standard cyanide solution over the AgNO₃ solution will equal 0.1 per cent nickel on a 1 g sample.

Determination of Copper

Solutions required

Dilute sulphuric acid (1:5).—Slowly stir 200 c c of H₂SO₄ (specific gravity 1.84) into 1,000 c c of distilled water.

Dilute sulphuric acid (2:98).—Mix 20 c c of H₂SO₄ (specific gravity 1.84) and 980 c c of distilled water.

Acidulated hydrogen sulphide water.—Saturate 500 c c of dilute sulphuric acid (2:98) with hydrogen sulphide.

Sodium hydroxide (5 per cent).—Dissolve 50 g of stick NaOH in 1,000 c c of distilled water and filter through asbestos if necessary.

Sodium thiosulphate (50 per cent).—Dissolve 100 g of Na₂S₂O₃·5H₂O in 100 c c of distilled water and filter if necessary.

Dilute nitric acid (1:1).—Mix 500 c c of HNO₃ (specific gravity 1.42) and 500 c c of distilled water

Method

(a) *Precipitation by hydrogen sulphide (reference method).*—Dissolve 10 g of iron in 100 c c of dilute H₂SO₄ (1:5), and when solution is complete evapo-

rate to fumes of sulphuric acid, cool, dilute to 100 c c and filter. Wash the residue with hot water and dilute the filtrate to 500 c c with water. Heat to boiling and saturate with H₂S. Digest for one to two hours, filter on paper or paper pulp and wash with acidulated hydrogen sulphide water. Ignite the precipitate and paper in a porcelain crucible and fuse with a small amount of alkali pyrosulphate. Dissolve the cooled melt in 50 c c of dilute H₂SO₄ (2:98), transfer to a 200 c c beaker, dilute to 100 c c and add NaOH (5 per cent) solution in slight excess. Boil, digest, and filter, in order to separate such elements as vanadium, tungsten, and molybdenum. Dissolve the precipitate in hot dilute HNO₃ (1:1), add 5 c c of H₂SO₄ (specific gravity 1.84), evaporate to the appearance of fumes of sulphuric acid, cool, dilute to 40 c c, filter, and add sufficient NH₄OH (specific gravity 0.90) to reduce the acidity to approximately 2 c c of H₂SO₄ (specific gravity 1.84) per 100 c c of solution. Heat the acid solution to boiling and saturate with H₂S. Digest a while, filter, wash thoroughly with acidulated H₂S water, and proceed according to method (1) or (2) under (b) *Precipitation by thiosulphate.*

(b) *Precipitation by thiosulphate.*—Transfer 5 g of the sample to a 600 c c beaker, add 100 c c of H₂SO₄ (1:5) and heat until the sample is dissolved. Dilute to 300 c c heat to boiling, add 15 c c of thiosulphate solution (50 per cent), and continue the boiling for five minutes or until the precipitate of copper sulphide has coagulated. Collect the precipitate upon an 11 cm paper and wash slightly with dilute H₂SO₄ (2:98). Ignite the residue and paper in a porcelain crucible and fuse with alkali pyrosulphate. Dissolve the cooled melt in the crucible in 1 to 2 c c of HCl (specific gravity 1.19) and a few cubic centimeters of water, transfer to a 200 c c beaker, dilute to 100 c c, and add NaOH (5 per cent) solution in slight excess. Boil, digest, and filter in order to separate such elements as vanadium, tungsten, and molybdenum. Dissolve the precipitate in hot dilute HNO₃ (1:1), carefully add 20 c c of H₂SO₄ (specific gravity 1.84), evaporate to the appearance of fumes of H₂SO₄, cool, dilute, and filter. Dilute the solution to a volume of 300 c c and precipitate the copper with thiosulphate as above. Filter, wash with dilute H₂SO₄ (2:98) until sodium salts have been removed, and proceed according to method 1 or 2 below.

(1) *Electrolytic method.*—Dissolve the sulphides obtained as above in hot dilute HNO₃ (1:1), and electrolyze after the addition of H₂SO₄ according to usual procedures.

(2) *Gravimetric method.*—Ignite the sulphides obtained as above and weigh as copper oxide. As this compound is somewhat hygroscopic, care must be observed to prevent the absorption of moisture. It is difficult to convert large amounts of CuS to CuO by ignition and if the percentage of copper is in excess of 0.2, the electrolytic method should be used or the size of sample reduced.

Determination of Copper

(Routine method)

Solutions required

Potassium ferrocyanide.—Dissolve 10 g of potassium ferrocyanide in 100 c c of distilled water.

Standard copper nitrate.—Dissolve 2 g of purest electrolytic copper in 20 c c of HNO₃ (1:1), and dilute to 1,000 c c with distilled water. Each cubic centimeter is equivalent to 0.02 per cent of copper on the basis of a 10 g sample.

Method

Proceed as in (a) precipitation by hydrogen sulphide or (b) precipitation by thiosulphate, under determination of copper; until the alkali pyrosulphate fusion has been made. Extract the cooled melt with hot water, filter, and complete the determination colorimetrically as follows:

Evaporate the filtrate to about 25 c c, filter into a 100 c c Nessler tube, wash with hot water, add 5 c c of NH_4OH (specific gravity 0.90) and dilute to 50 c c.

(a) *If the solution is a strong blue.*—To another 100 c c Nessler tube add 50 c c of distilled water, 5 c c of NH_4OH (specific gravity 0.90) and from a burette the standard copper nitrate solution until the blue colors match.

(b) *If the solution is a faint blue.*—To the filtrate in a Nessler tube add dilute H_2SO_4 (1:5) to faint acidity and then a few drops of the potassium ferrocyanide solution. To another 100 c c Nessler tube add 50 c c of distilled water, a few drops of the potassium ferrocyanide solution, and from a burette the standard copper nitrate solution until the reddish brown colors match.

Determination of Titanium by the Colorimetric Method*Solutions required*

Dilute hydrochloric acid (1:2).—Mix 500 c c of HCl (specific gravity 1.19) with 1,000 c c of water.

Dilute sulphuric acid (1:9).—Carefully stir 100 c c of H_2SO_4 (specific gravity 1.84) into 900 c c of water.

Standard titanium solution.—Transfer 3 g of potassium titanium fluoride (K_2TiF_6), which has been twice recrystallized from hot water, to a platinum dish, add 100 c c of H_2SO_4 (specific gravity 1.84) and evaporate three times to fumes of the acid, with intervening washing down of the sides of the vessel. Cool and pour the solution rapidly and with stirring into 900 c c of water. Cool to room temperature, and standardize the solution by taking 100 c c portions, precipitating with ammonia in boiling solution, filtering, igniting and weighing as TiO_2 .

Ferric sulphate solution.—Dissolve 10 g of ingot iron or plain carbon steel which is free from titanium in HNO_3 , add 20 c c of H_2SO_4 (specific gravity 1.84), evaporate to fumes of sulphuric acid, cool and dilute to 100 c c.

Method

Dissolve 5 g of the sample in 100 c c of HCl (1:2). When all action has ceased, filter, wash the insoluble matter with water, dry, and ignite in a platinum crucible under good oxidizing conditions. Treat with 1 to 2 c c of HF and 1 c c of dilute H_2SO_4 (1:1) to eliminate silica, and evaporate to dryness. Fuse the residue with sodium carbonate, dissolve the fusion in water, digest for 15 minutes, filter and wash with water. Ignite the residue in platinum, fuse with a small quantity of alkali pyrosulphate, cool, and take up in dilute H_2SO_4 (1:9). Compare the amount of titanium in this solution with a standard titanium solution as follows: Treat the proper amount of a standard titanium solution with the same quantity of alkali pyrosulphate as was used in the above fusion and add sufficient ferric sulphate solution to give the same tint as the sample when both are at the same dilution. Add 2 c c of 3 per cent hydrogen peroxide to the solution and standard respectively and compare in a colorimeter.

Determination of Arsenic

(Umpire method)

(As As_2S_3 or by titration with KSCN)

Dissolve the sample (10 g) in 200 c c of dilute HNO_3 (1:3). Retard action by cooling if it grows

violent. After solution is complete, cool, add 50 c c of concentrated H_2SO_4 and evaporate until fumes of sulphuric acid begin to appear. Remove from the hot plate, cool, wash down the sides of the beaker, and fume again. (It is better to fume twice moderately than to fume once very strongly on account of the possibility of volatilizing arsenic at the higher temperature.) Cool, carefully add 50 c c of water and again cool to room temperature.

Transfer the solution by means of 150 to 175 c c of concentrated HCl to a distillation flask fitted with a two-holed stopper, preferably of glass, carrying a separatory funnel and an outlet tube. The latter should be provided with a hole on the side about 1 cm from the end within the distillation flask. This allows for circulation in the outlet tube and prevents small particles of the material in the flask from passing over into the distillate. Add 20 g of cuprous chloride, stopper, and connect the outlet tube with a vertical condenser having its lower end dipping into a beaker containing 150 c c of distilled water and immersed in ice water. Distill until 100 c c of distillate have passed over.

After the distillation is done, add 15 c c of strong NH_4OH (specific gravity 0.90), to the distillate in order to neutralize some of the acid and pass a rapid stream of H_2S through the solution until saturated. Allow to stand at least one hour, preferably overnight.

(a) *To weigh as As_2S_3 .*—Filter on a weighed Gooch crucible, wash with alcohol, then with carbon disulphide, then with alcohol, and dry at 100° to 105°C . Weigh as As_2S_3 and multiply by the factor 0.6092 to obtain the weight of arsenic.

(b) *To Titrate with KSCN .*—Titration with KSCN does away with uncertainty concerning the purity of the arsenic sulphide and is done as follows:

Filter through asbestos or paper and wash the precipitate moderately with dilute H_2SO_4 (1:99) that has been saturated with H_2S . Dissolve the washed sulphide in 2 to 3 c c of strong NH_4OH or the same volume of a 10 per cent solution of NaOH . Wash the pad or paper with water, evaporate nearly to dryness, add 10 c c of concentrated HNO_3 and again evaporate nearly to dryness. Take up with 50 c c of water, add a few drops of phenolphthalein and then a 10 per cent solution of NaOH drop by drop until the solution is decidedly alkaline. Now add dilute acetic acid (1:1) drop by drop until the solution just turns colorless, and precipitate the arsenic as silver arsenate by the addition of 10 c c of AgNO_3 solution (34 g per liter). Heat just to boiling to coagulate the precipitate, cool, filter on an asbestos pad, and wash with cold water.

Dissolve the silver arsenate in dilute HNO_3 (1:1) and titrate the silver in the solution with 0.01 *N* potassium or ammonium sulphocyanate, using ferric alum (free from chlorides) as the indicator. The sulphocyanate solution may be standardized against either pure silver or pure silver nitrate and its arsenic titre calculated from the ratio 3 Ag :1 As .

NOTES.—A blank determination should be carried through all steps of the determination.

Distillation should be carried out so that no copper from the cuprous chloride is carried over into the distillate.

In routine analyses, the HCl distillate may be nearly neutralized with NaOH , the still acid solution treated with an excess of sodium bicarbonate and the arsenic determined by titration with a standard 0.01 *N* solution of iodine in the presence of starch as indicator. The iodine solution is preferably standardized against a standard iron carried through the method.

601.21 CHARCOAL PIG IRON.

(See foundry pig iron.)

601.22 COKE PIG IRON.

(See foundry pig iron.)

601.23 FOUNDRY PIG IRON.

AMERICAN RAILWAY ASSOCIATION, MECHANICAL DIVISION, IRON, FOUNDRY PIG, RECOMMENDED PRACTICE, 1916

FOUNDRY PIG IRON

1. *Scope.*—These specifications apply to all foundry pig iron which should be bought according to the grades shown by section 3.

MANUFACTURE

2. *Process.*—The pig iron shall be made in accordance with the best modern practice and may be either sand or machine cast.

CHEMICAL PROPERTIES AND TESTS

3. *Chemical composition.*—The pig iron shall conform to the following requirements as to chemical composition:

	No. 1	No. 2	No. 3
	Foundry coke iron	Low silicon coke foundry iron	High manganese coke foundry iron
	Per cent	Per cent	Per cent
Silicon.....	2.50-3.25	1.00-1.50	1.00-1.50
Manganese.....	.50-1.00	.50-1.00	1.75-3.00
Phosphorus.....	.50-.90	.20-.70	.20-.70
Sulphur.....	.05	.05	.05

Foundry charcoal pig iron will be bought in grades according to the following limits:

	Per cent
Silicon, maximum variation, any grade.....	0.25
Manganese, maximum variation, any grade.....	.40
Phosphorus (not over).....	.50
Sulphur (not over).....	.05

4. *Ladle analyses.*—An analysis to determine the percentages of silicon, manganese, phosphorus, and sulphur shall be made by the manufacturer from a test ingot taken during the pouring of each melt, a copy of which shall be given to the purchaser or his representative. This analysis shall conform to the requirements specified in section 3.

5. *Check analyses.*—Analyses may be made by the purchaser from the pigs in accordance with section 6. This analysis shall conform to the requirements specified in section 3.

6. *Sampling.*—Ten pigs shall be taken at random from the various parts of each carload or less. These pigs shall be broken in half, and from one-half of each pig the same amount of drillings shall be taken at or near the center by boring parallel to the axis of the pigs. These drillings shall be well mixed and a sample for chemical analysis shall be taken from this mixture.

INSPECTION AND REHEARING

(Inspection and rehearing are identical with the requirements for A. R. A. galvanized sheets. See 604.32, p. 243.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR FOUNDRY PIG IRON, SERIAL DESIGNATION A43-24, 1924

FOUNDRY PIG IRON

MANUFACTURE

1. The pig iron shall be clean foundry pig iron, as free as possible from an excessive amount of dross and sand, and may be either sand or machine cast,

CHEMICAL PROPERTIES

2. (a) The pig iron shall conform to the chemical requirements specified by the purchaser at the time of purchase, with the following permissible variations from the specified percentages in the case of pig iron intended for the manufacture of gray-iron castings:

Element	Variation from specified percentage
Silicon.....	0.25 per cent above or below.
Manganese.....	0.20 per cent above or below.
Phosphorus.....	0.15 per cent above or below.
Sulphur.....	Not over specified percentage.
Total carbon.....	Not less than specified percentage.

(b) In the case of pig iron for making steel and malleable-iron castings, a maximum percentage of phosphorus, and either a maximum or minimum percentage of manganese, may be specified.

SAMPLING AND ANALYSIS

3. (a) In sampling, each carload or its equivalent shall be considered as a unit.

(b) One pig shall be taken to every 4 tons in the car, and they shall be so chosen from different parts of the car as to secure, as nearly as possible, a sample representing the average quality of the iron.

(c) The pigs thus taken shall be sampled by drilling so as fairly to represent the composition of the pigs as cast.

(d) An equal weight of the drillings from each pig shall be thoroughly mixed to make up the sample for analysis.

4. It is recommended that analysis be made in accordance with the standard methods of sampling and chemical analysis of pig and cast iron. (See A. S. T. M. A64-27, 601.20, p. 119.)

INSPECTION AND REJECTION

5. In case of dispute, the sampling and chemical analysis shall be made in accordance with the standard methods of sampling and chemical analysis of pig and cast iron (see preceding paragraph) by an independent chemist, mutually agreed upon—if practicable at the time the contract is made—whose decision shall be final. The cost of such resampling and reanalysis shall be borne by the party in error.

6. All pig iron which fails to conform to these specifications shall be subject to rejection.

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR IRON; PIG, FOUNDRY, QQ-I-676, FEBRUARY 2, 1932

FOUNDRY PIG IRON

(This specification is substantially the same as A. S. T. M. A43-24, given above, except that reference is made herein to four regular grades of foundry pig iron, and to special grades as required. In the matter of general and detail requirements this specification states that in addition to conforming to F. S. B. No. 339a (current designation QQ-M-151) (see 600.0, p. 3) it shall meet the following:)

GENERAL REQUIREMENTS

1. The pigs shall be free from excessive sand or slag.

2. Not more than 12 per cent of sow iron shall be of a size easily handled.

DETAIL REQUIREMENTS

3. Grades A, B, C, and D pig iron shall conform to the respective requirements given in the accompanying table:

Grade	Silicon (maximum)	Sulphur	Manganese	Phosphorus
	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>
A-----	2.75-3.25	0.04	0.50-1.00	0.50-0.80
B-----	2.25-2.75	.05	.50-1.00	.50-.80
C-----	1.75-2.25	.05	.50-1.00	.50-.80
D-----	1.25-1.75	.05	.50-1.00	.50-.80

4. Contracts and purchase orders for special grades of foundry pig iron should state the maximum or minimum total carbon desired, as well as the limits for the other elements.

5. Bidders should state whether the iron they propose to furnish is machine made or sand cast. Preference will be given to machine-cast foundry pig iron, other things being equal.

601.24 MALLEABLE PIG IRON.

(No nationally recognized specifications available.)

601.3 IRON AND STEEL SCRAP.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, CLASSIFICATION OF SCRAP MATERIALS, PS100-29, 1929

SCRAP MATERIALS

(See 600.2, p. 51.)

602. FINISHED AND SEMIFINISHED IRON AND STEEL

602.1 IRON BILLETS.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR WROUGHT-IRON ROLLED OR FORGED BLOOMS AND FORGINGS FOR LOCOMOTIVES AND CARS, DESIGNATION A73-30, 1930

WROUGHT-IRON FORGINGS

(See 611.3, p. 705.)

602.2 STEEL BARS AND BILLETS.

AMERICAN RAILWAY ASSOCIATION, MECHANICAL DIVISION, SPECIFICATIONS FOR CARBON-STEEL BLOOMS, BILLETS, AND SLABS FOR FORGINGS, 1925

CARBON STEEL BILLETS

SCOPE

These specifications cover five classes of billets, determined by their carbon ranges. (The carbon ranges are identical with those specified below in A. S. T. M., A17-29 as Grades Nos. 1, 2, 4, 7, and 8.)

The purposes for which these classes of billets are frequently used are as follows:

- Class A (grade 1 in A. S. T. M., A17)—for welding and casehardening.
- Class B (grade 2 in A. S. T. M., A17)—for casehardening when subsequently heat treated.
- Class C (grade 4 in A. S. T. M., A17)—for special purposes.
- Class D (grade 7 in A. S. T. M., A17)—for axles, shafts, connecting rods, and similar forgings.
- Class E (grade 8 in A. S. T. M., A17)—for class D forgings when they are to be heat treated.

CHEMICAL COMPOSITION

The steel shall conform to the following requirements as to chemical composition:

Elements considered	Class				
	A	B	C	D	E
Carbon-----	<i>Per cent</i> 0.05-0.15	<i>Per cent</i> 0.15-0.25	<i>Per cent</i> 0.25-0.40	<i>Per cent</i> 0.40-0.55	<i>Per cent</i> 0.45-0.60
Manganese-----	.30-.60	.30-.60	.40-.70	.40-.70	.40-.70
Phosphorus (maximum)-----	.045	.045	.045	.045	.045
Sulphur (maximum)-----	.05	.05	.05	.05	.05

BASIS OF PURCHASE

Billets shall be purchased as semifinished rolled or forged material. In ordering, all dimensions shall be expressed in feet and inches.

MANUFACTURE

The steel shall be made by the open-hearth process.

(In respect to definition of terms, discard, ladle analyses, check analyses, workmanship and finish, marking, and inspection and rejection, this specification conforms with A. S. T. M., A17, given below, including reference therein to A. S. T. M. standard specifications for steel in 605.0, p. 247.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR CARBON-STEEL AND ALLOY-STEEL BLOOMS, BILLETS, AND SLABS FOR FORGINGS, DESIGNATION A17-29, 1929

STEEL BILLETS

1. The term "billet" is used in these specifications to include blooms, billets, and slabs.

SCOPE

2. (a) These specifications cover billets of carbon and alloy steel. Eight types of steel are covered, one type of carbon and seven types of alloy steel, classification by type being made according to the chemical composition other than carbon.

(b) Each type of steel is subdivided into grades according to the carbon content. There are eight grades of carbon steel and seven grades of each type of alloy steel.

(c) The billets are further divided into two classes, designated Classes I and II. Class I is the standard for all types and grades, and Class II is a special class applicable to grades Nos. 4 to 8, inclusive, in type A, and to grades Nos. 14 to 17, inclusive, in all other types. Class II differs from Class I in the method of sampling for chemical analysis and in chemical requirements.

3. Billets shall be purchased as semifinished rolled or forged material.

MANUFACTURE

4. The steel shall be made by either or both of the following processes: Open-hearth or electric furnace.

5. A sufficient discard shall be made from each ingot to secure freedom from injurious piping and undue segregation.

6. Unless otherwise specified, the billets shall be made from ingots of at least three times the cross-sectional area of the billet.

CHEMICAL PROPERTIES AND TESTS

7. The steel shall conform to the following requirements as to chemical composition for type and grade:

(a) *Type*.—The types of steel shall be as indicated in Table 1.

(b) *Grade*.—The carbon ranges for the various grades shall be as follows for carbon and alloy steel:

Carbon steel—Type A		Alloy steels—Types B to H, inclusive	
Grade	Carbon	Grade	Carbon
	<i>Per cent</i>		<i>Per cent</i>
1.....	0.05-0.15	11.....	0.10-0.20
2.....	.15-.25	12.....	.15-.25
3.....	.20-.30	13.....	.20-.30
4.....	.25-.40	14.....	.25-.38
5.....	.30-.45	15.....	.30-.43
6.....	.35-.50	16.....	.35-.50
7.....	.40-.55	17.....	.45-.60
8.....	.45-.60		

NOTE 1.—When the steel is to be used for casehardening purposes, the manganese should be specified not to exceed 0.50 per cent. When the minimum carbon specified is 0.35 per cent or over, the manganese range may be specified 0.30-0.60 per cent.

NOTE 2.—In selecting billets for making forgings of classes K, L, and M, as defined in the standard specifications for carbon-steel and alloy-steel forgings, A. S. T. M., A18 (see 611.51, p. 754), it is suggested that the use of steel with a relatively high carbon content will permit the use of a high draw-back temperature and thus put the steel in its best physical condition for service, shock, and similar conditions.

8. An analysis of each melt of steel shall be made by the manufacturer to determine the percentages of the elements specified in section 7. This analysis shall be made from a test ingot taken during the pouring of the melt. The chemical composition thus determined shall be reported to the purchaser or his representative, and shall conform to the requirements specified in section 7.

9. (a) *Class I*.—For billets of Class I, an analysis may be made by the purchaser from one billet representing each melt. The chemical composition thus determined shall conform to the requirements specified in section 7. Drillings for analysis shall be taken with a $\frac{1}{8}$ -inch drill, parallel to the axis of the ingot as cast, at any point midway between the center and surface of the billet.

(b) *Class II*.—For billets of Class II, the purchaser or his representative may select one top-cut billet from which to make check analyses to represent each melt. Two sets of drillings shall be taken from the top face of this billet at points on the same diagonal of the billet. The drillings shall be taken with a $\frac{1}{8}$ -inch drill parallel to the axis of the ingot as cast. The distance from the center of the billet to the drilling points shall be respectively 15 and 80 per cent of the length of the half diagonal of the billet.

(c) From the drillings taken at the 80 per cent point a complete analysis may be made. The chemical composition thus determined shall conform to the requirements specified in section 7.

TABLE 1.—Types of steel

Elements considered	Type			
	A	B	C	D
	Carbon steel	Nickel steel	Chrome-nickel steel	
			1-1.50 per cent Ni	1.50-2 per cent Ni

Vanadium (minimum).....				.15

¹ Minimum.

(d) From the drillings taken at the 15 per cent point a carbon determination may be made. The difference between the carbon content of the drillings from the 15 per cent point and that of the drillings from the 80 per cent point, expressed as a percentage of the latter, shall not exceed the following values: (1) For billets 15 inches or under in thickness, 15 per cent; and (2) for billets over 15 inches in thickness, 20 per cent.

(e) If in any melt the drillings taken in accordance with paragraph (b) do not conform to the requirements of paragraph (d), additional drillings may be taken in a similar manner after making a further top discard from the material from each ingot of at least 10 per cent of the original ingot weight. The results of this analysis shall conform to the requirements of paragraph (d); otherwise, the melt represented shall be rejected.

WORKMANSHIP AND FINISH

10. (a) Billets may be chipped to remove surface defects, provided that the depth of chipping does not exceed one-sixteenth inch for each inch of dimension concerned, up to a maximum depth of three-fourths inch, and provided that the width of the chipping is at least four times its greatest depth; except that in the case of slabs where the width is at least twice the thickness, the depth of chipping on the wide surfaces may exceed this allowance by 50 per cent, up to a maximum depth of three-fourths inch.

(b) In special cases—particularly, large alloy-steel billets—where it is necessary and is not injurious, greater depth of chipping may be permitted by special agreement between the manufacturer and the purchaser.

11. The billets shall be free from injurious defects and shall have a workmanlike finish.

MARKING

12. (a) The melt number shall be legibly stamped on each billet 6 inches or over in thickness, and on billets of smaller section when so specified.

(b) For billets of Class I, the top end of all top-cut billets 6 inches or over in thickness shall be legibly hot stamped with the letter "T" and marked with paint.

(c) For billets of Class II, the top ends of the top, second, third, and following cut billets from each ingot shall be legibly hot stamped with the letters "A," "B," "C," etc., to show the position of the billet in the ingot, and marked with paint.

INSPECTION AND REJECTION

(Requirements covering inspection, rejection, and reheating conform with those specified in A. S. T. M. standard specifications for steel, paragraphs 7, 8, and 9 (see 605.0, p. 247), with the addition of the following:)

The purchaser may make the tests to govern the acceptance or rejection of billets in his own laboratory or elsewhere. Such tests, however, shall be made at the expense of the purchaser.

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR STEEL BLOOMS, BILLETS, SLABS, AND BARS FOR REFORGING, CARBON AND ALLOY, NO. 316, AUGUST 8, 1925. (CURRENT DESIGNATION: QQ-S-675.)

STEEL BLOOMS FOR REFORGING

GENERAL SPECIFICATIONS

(General specifications for metals, Federal Specifications Board specification No. 339a (current designation: QQ-M-151), in effect on date of invitation for bids, shall form part of this specification. See 600.0, p. 3.)

Types and Grades

I. Steel blooms, billets, slabs, and bars for reforcing, carbon and alloy (hereinafter referred to as billets), in a semifinished condition, shall be furnished in the several types and grades listed in Table 1.

Material

II. Billets shall be reasonably straight and of uniform quality and condition, free from twists, pipes, seams, laps, cracks, sand, hard spots, porosity, excessive nonmetallic inclusions, segregations, or other defects that affect their suitability for the service intended.

General Requirements

III. 1. Billets for reforcing purposes shall be reduced from ingots by hot rolling, pressing, or hammering.

2. The ingots from which the billets are made shall be poured from dead-melted steel manufactured by the open-hearth, crucible, or electric-furnace process and shall be cast in metal molds, unless a particular process and method of casting is specified in the contract or purchase order.

3. Sufficient discard shall be taken from each ingot to insure freedom from injurious piping and undue segregation. Such discard, in terms of the total ingot weight, shall be not less than 4 per cent from the bottom and 30 per cent from the top in the case of top-poured ingots, and not less than 4 per cent from the bottom and 20 per cent from the top in the case of bottom-poured ingots or fluid-compressed ingots not be to bored. When the billets are to be made from bored, fluid-compressed ingots, the discard shall be not less than 3 per cent from the bottom and 10 per cent from the top.

4. The percentage of top discard may be reduced by the inspector in specific instances where the contractor can submit evidence, based on fracture and metallographic examination of the crop ends of representative billets from the ingots under consideration, which indicates entirely sound and normal metal.

5. Unless otherwise specified in the contract or purchase order, material 18 inches or less in diameter, or 250 square inches or less in cross-sectional

area, shall be rolled or forged from ingots with a cross-sectional area of at least four times that of the billet. Material over 18 inches in diameter or over 250 square inches in cross-sectional area shall be rolled or forged from ingots with a cross-sectional area of at least twice that of the billet.

6. Billets shall contain no welds.

(Paragraphs 7 and 8 are identical with paragraphs 10 (a) and 10 (b) of A. S. T. M., A17-29, given above.)

Detail Requirements

IV. 1. *Chemical composition.*—(a) Material shall conform to the requirements as to chemical composition specified in Table 1.

(b) An analysis of each heat of steel shall be furnished by the contractor showing the percentages of the elements designated.

2. *Metallographic requirements.*—Billets may be subjected to macroscopic or microscopic examination to determine compliance with Section II. In the case of material intended for important forgings, definite metallographic requirements may be incorporated in the contract, requisition, or purchase order.

3. *Dimensions and permissible variations.*—Billets shall conform to the shapes and dimensions specified in the contract or purchase order with a permissible variation of plus or minus 3 per cent on transverse dimensions.

4. *Physical condition.*—Unless otherwise specified in the contract or purchase order, material shall be furnished mill or hotbed annealed.

Methods of Inspection and Tests

V. 1. *Check analyses.*—(a) Check analyses may be made by the inspector, or through him by any Government laboratory or other designated representative, and without cost to the contractor.

(b) Three sets of drillings for check analyses shall be taken from each heat or part of heat submitted for inspection, each from a different billet. The drillings for determination of the elements other than carbon shall be taken from the end of the material which was uppermost in the ingot mold, at a position halfway between the center or the inner surface and the outer surface of a solid or bored object, in a line parallel to the axis lying in the direction in which the material is most drawn out. Drillings for the determination of carbon shall be taken as specified above, except that they should be made to represent, by the location from which they are taken and by mixing, the average content for top and bottom of the ingot. The samples shall be fine, clean, and free from oil, dirt, grit, or other foreign matter, and shall consist of not less than 2 ounces.

2. *Definition of lot.*—For purposes of physical inspection, a lot shall consist of all material from the same heat or melt differing not more than 1 inch in any cross-sectional dimension.

3. *Fracture test.*—A cold-fracture test shall be made of the top portion of each ingot to insure that all piping, porosity, and other injurious defects have been removed. The fracture shall show a fresh surface not less than one-sixth of the sectional area of the ingot and shall be centrally located. In case the fracture test reveals piping or other defects, further discard may be made until the inspector is satisfied as to the soundness of the material.

4. *Metallographic tests.*—(a) When microscopic examinations are made, the specimens therefor shall be selected in the following manner, unless otherwise provided in the purchase order or drawing pertaining thereto:

For material, the cross-sectional area of which is 50 square inches or more, at least 3 metallographic specimens shall be taken—1 from the center, 1 from the outer edge, and 1 from a point halfway between the center and outer edge. If the end section is other than round, the specimen from the outer edge shall be taken from the middle of one of the sides.

For material, the cross-sectional area of which is less than 50 square inches, and which is made from the same heat, 2 billets shall be selected; if possible, 1 from the first ingot poured in the heat and 1 from the last ingot poured in the heat. From each end of each billet so selected, 2 metallographic specimens shall be taken, 1 from the center and 1 from the outer edge. If the end section is other than round, the second specimen shall be taken from the middle of one of the sides.

(b) Specimens for microscopic examinations shall be at least one-fourth square inch in area and at least one-half inch in length.

Packing and Marking

VI. All material over 16 square inches in cross-sectional area ordered under this specification shall be legibly hot stamped with the melt or heat number, and the words "For reforcing" on each end of each billet, and the ends of the billet corresponding respectively to the top and bottom of the ingot from which it was rolled or forged shall be plainly marked "M" to indicate the top, or "B" to indicate the bottom. Material 16 square inches or less in cross-sectional area shall be stamped with the heat number only, unless otherwise required by the contract or purchase order.

Additional Information

VII. Table 2 is for the information of purchasing agencies and designers. It gives the minimum physical properties that may be expected of the material of the corresponding grade designation in Table 1 after normal working and heat treatment.

TABLE 1.—Chemical composition

Type	Grade	Carbon	Manga- nese	Phos- phorus, maximum ¹	Sulphur, maximum	Silicon ²	Nickel	Chromium	Vanadium	Molyb- denum

¹ Maximum of 0.050 per cent permitted when acid steel is specified.

² Waived except when acid steel is specified.

NOTE.—The silicon requirements of Table 1 shall apply only when the contract or purchase order specifies an "acid steel"; that is, a steel made by either the acid open-hearth or acid electric process.

The grade letters assigned are not mandatory on the several departments. It is anticipated that these designations will be changed as soon as an authoritative numbering system for steel comes into general use.

The limits prescribed for phosphorus and sulphur are advisory only. Each department may insert such limits for phosphorus and sulphur in its specifications as are considered necessary for its particular use.

TABLE 2.—Physical properties

603. IRON AND STEEL BARS, RODS, AND WIRE

603.0 GENERAL ITEMS.

AMERICAN RAILWAY ASSOCIATION, PURCHASES AND STORES DIVISION, STANDARDIZATION AND SIMPLIFICATION OF STORES STOCKS, PROCEEDINGS 1928, AND NO. D-V1-238, 1930

SIMPLIFICATION OF STORES STOCKS

(Recommendations contained in these publications relating to the standardization and simplification of stores stocks have been placed in this compilation under their proper commodity headings, as follows:)

Commodity designation	Material	Page
603. 0	Iron and steel bars.....	135
603. 32	Carbon tool steel.....	150
604. 10	Annealed steel sheets.....	226
604. 20	Sheet steel and iron.....	236
607. 4	Steel tubing.....	463
603. 12	Wire brads.....	572
603. 2	Screws.....	574
603. 31	Bolts.....	588
603. 4	Rivets.....	612
603. 51	Cotter keys.....	616
615. 61	Files.....	834
621. 35	High-speed tool steel.....	1128
645. 9	Brass wood screws.....	1240

AMERICAN RAILWAY ASSOCIATION, PURCHASES AND STORES DIVISION, STANDARDIZATION AND SIMPLIFICATION OF STORES STOCK, NO. D-V1-135, 1926

STANDARD METHOD OF DESIGNATING CLASS, KIND, OR GRADE OF STEEL AND IRON BARS BY PAINTING THE ENDS

1. The committee recommends the following color designations:

Engine bolt iron.....	White.
Staybolt iron.....	Green.
Mild, soft, or open-hearth steel.....	Red.
Bar iron.....	Brown.

2. Since there are so many different grades and brands of tool steel and welding rod being used, it has seemed impracticable to standardize color designation for this class of material.

AMERICAN RAILWAY ASSOCIATION, PURCHASES AND STORES DIVISION, STANDARDIZATION AND SIMPLIFICATION OF STORES STOCKS, PROCEEDINGS, 1929

MILD STEEL OR OPEN HEARTH BARS

1. One feature essential to the simplification of bar iron or steel is to bring about the adoption of one grade of steel to cover all (or at least 90 per cent) of the roads' general requirements. This has been done and is proving successful on many roads, and does away with carrying the same size bar in possibly three or four grades, such as merchant bar, mild steel, double refined, etc.

2. The committee recommends standard stocks of 24 rounds ranging in diameter from one-fourth inch to 4 inches; 11 squares ranging from one-half inch to 2½ inches; 4 half-rounds ranging from three-fourths inch to 1½ inches; and 89 flat bars, bands, and plates ranging in size from ½ by ½ inch to 2 by 12 inches.

603.1 WROUGHT IRON BARS AND RODS.

AMERICAN BUREAU OF SHIPPING, RULES FOR BUILDING AND CLASSING STEEL VESSELS; QUALITY AND TESTING OF MATERIALS—SHIP CONSTRUCTION, 1930

ROUND AND FLAT IRON BARS

(For general information and requirements, see 600.0, p. 2.)

1. Round and flat iron bars are to have a tensile strength of not less than 45,000 pounds per square inch of prepared section, with an elongation of 20 per cent in 8 inches. For round bars under one-

half inch in diameter and for flat bars under three-eighths inch thick, which are tested as rolled, and for round and flat bars, the test specimens for which are reduced by machining, an elongation of 16 per cent in 8 inches will be approved. On bars having a nominal area of 4 square inches or under, a test specimen must stand being bent cold through 180° without fracture on the outside of the bent portion, the radius of the bend being twice the diameter or thickness of the specimen.

2. A test specimen when heated to a temperature between 1,700° and 1,800° F. must bend through 180° without fracture on the outside of the bent portion as follows: For round bars under 2 square inches in section, flat on itself; for round bars 2 square inches or over in section; and for all flat bars, around a pin the diameter of which is equal to the diameter or thickness of the specimen.

3. Tension and bend test specimens are to be of the full section of the material as rolled, if possible; otherwise, the specimens are to be machined from the material as rolled. One bar of each size ordered shall be selected for testing from each 100 bars or fraction thereof. In the event of the above tests failing, one additional bar shall be selected and the tests repeated; and if these are satisfactory, the batch of bars represented shall be accepted. If the bars are not satisfactory, the batch of bars represented shall be rejected.

AMERICAN BUREAU OF SHIPPING, RULES FOR BUILDING AND CLASSING STEEL VESSELS; MATERIALS FOR MACHINERY, BOILERS, AND PIPING, 1930

IRON STAYS FOR BOILERS

(For general information and requirements, see 600.0, p. 1. For test requirements, see 600.1, p. 7.)

1. At least 4 per cent of the bars are to be selected by the surveyor from each diameter for tension and cold bend tests.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, STANDARD SPECIFICATION FOR REINED WROUGHT-IRON BARS, E16-30, 1930

WROUGHT-IRON BARS

(Identical with A. S. T. M. A41-30, given below.)

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, SPECIFICATION FOR MATERIALS FOR USE IN THE MANUFACTURE OF SPECIAL TRACKWORK, W104-28, 1928

(Approved as tentative American standard by the American Standards Association, January 23, 1929)

SPECIAL TRACKWORK MATERIALS

(See 606.3, p. 342.)

AMERICAN RAILWAY ASSOCIATION, MECHANICAL DIVISION, IRON, ENGINE BOLT, RECOMMENDED PRACTICE, 1926

IRON, ENGINE BOLT

I. MANUFACTURE

1. *Process.*—The iron shall be made wholly from all-pig puddled iron and shall be free from any admixture of iron scrap or steel.

2. *Definition of terms.*—The term "iron scrap" applies only to foreign or bought scrap and does not include local mill products free from foreign or bought scrap.

II. PHYSICAL PROPERTIES AND TESTS

3. *Tension tests.*—(a) The iron shall conform to the following requirements as to tensile properties:

Tensile strength, pounds per square inch:	
1¼ square inches and under in sectional area.....	49,000-53,000
Over 1¼ square inches in sectional area.....	47,000-53,000
Yield point, pounds per square inch:	
1¼ square inch under in sectional area.....	0.6 tensile strength
Over 1¼ square inches to 4 square inches, inclusive, in sectional area.....	0.55 tensile strength
Over 4 square inches in sectional area.....	0.5 tensile strength
Elongation in 8 inches, minimum.....	per cent. 25
Reduction in area, minimum.....	do. 40

(b) The yield point shall be determined by the drop of the beam of the testing machine. The speed of the crosshead of the machine shall not exceed three-fourths inch per minute. After passing the yield point the testing speed shall not exceed a maximum of 3 inches per minute.

4. *Bend tests.*—(a) *Cold bend test.*—The test specimen shall bend cold through 180° around a pin the diameter of which is equal to the diameter of the specimen without fracture on the outside of the bent portion.

(b) *Hot-bend test.*—The test specimen, when heated to a temperature between 1,700° and 1,800° F., shall bend through 180° flat on itself without fracture on the outside of the bent portion.

(c) *Nick-bend test.*—At the option of the purchaser, the following test shall be made: The specimen, when nicked 25 per cent around with a tool having a 60° cutting edge, to a depth of not less than 8 nor more than 16 per cent of the diameter of the specimen, and broken, shall show a clean fiber, free from crystallization.

(d) Bend tests may be made by pressure or by blows.

5. *Step test.*—The test specimen, when reduced to 50 per cent of its original diameter by smooth-turned steps, each 2 inches long and one-eighth inch less in diameter than the preceding, shall indicate freedom from injurious seams, laminations, and other internal defects.

6. *Etch test.*—The cross section of the test specimen shall be ground or polished and etched for a sufficient period to develop the structure. This test shall show the material to be free from steel.

7. *Test specimens.*—(a) Tension test specimens shall be the full section of material as rolled, if possible. Otherwise, the specimens shall be taken from the material as rolled; for bars 2½ inches or less in diameter, the axis of the specimen shall coincide with the axis of the bar; for bars over 2½ inches in diameter, the axis of the specimen shall be located at any point one-half the distance from the center to the surface and shall be parallel to the axis of the bar; and the specimens shall be turned to a diameter of 1 inch for a length of at least 9 inches, with enlarged ends.

(b) Bend and etch test specimens shall be of the full section of material as rolled, except that for bars over 1½ inches in diameter the cold-bend test specimen may be machined to not less than 1 square inch in section.

8. *Number of tests.*—(a) Bars of one size shall be sorted into lots of 100 each. Two bars shall be selected at random from each lot or fraction thereof, and tested as specified in sections 3 and 4, but only one of these bars shall be tested as specified in section 6.

(b) If any test specimen from either of the bars originally selected to represent a lot of material contains surface defects not visible before testing but visible after testing, or if a tension test specimen

breaks outside the middle third of the gage length, one retest from a different bar will be allowed.

III. PERMISSIBLE VARIATIONS IN GAGE

9. *Permissible variations.*—(a) Round, square, and hexagon bars shall not vary more than the limits given in the following table:

	Variations in size	
	Under	Over
Up to and including ½ inch.....	Inch 0.007	Inch 0.007
Over one-half inch and including 1 inch.....	.010	.010
Over 1 inch and including 2 inches.....	¼₆₄	¼₆₄
Over 2 inches and including 3 inches.....	¼₃₂	¼₆₄
Over 3 inches and including 5 inches.....	¼₃₂	¼₃₂
Over 5 inches and including 8 inches.....	¼₁₆	¼₁₆

(b) The widths or thickness of flat bars shall not vary more than 2 per cent from that specified.

IV. FINISH

10. *Finish.*—The bars shall be smoothly finished and free from slivers, depressions, seams, crop ends, and evidences of being burned.

V. MARKING

11. *Marking.*—The bars shall be stamped or marked as designated by the purchaser.

INSPECTION AND REJECTION

(Requirements covering inspection, rejection, and reheating conform to those specified in A. S. T. M. standard specifications for steel. See 605.0, p. 247.)

AMERICAN RAILWAY ASSOCIATION, MECHANICAL DIVISION, STAY-BOLT IRON, HOLLOW, LOCOMOTIVE; RECOMMENDED PRACTICE, 1926

STAY-BOLT IRON, HOLLOW

I. MANUFACTURE

1. *Process.*—The iron shall be rolled from a bloom, slab pile, or box pile, made wholly from reworked all-pig puddled iron or reworked knobbed charcoal iron. The puddle mixture and the component parts of the bloom, slab pile, or box pile shall be free from any admixture of iron scrap or steel.

2. *Definition of terms.*—(a) A bloom is a solid mass of iron that has been hammered into a convenient size for rolling.

(b) *Slab pile.*—A slab pile is built up wholly of flat bars of iron of the full length of the pile.

(c) *Box pile.*—A box pile is a pile the sides, top, and bottom of which are formed by four flat bars and the interior of which consists of a number of small bars the full length of the pile.

(d) *Iron scrap.*—This term applies only to foreign or bought scrap and does not include local mill products free from foreign or bought scrap.

II. CHEMICAL PROPERTIES AND TESTS

3. *Chemical composition.*—The iron shall conform to the following requirement as to chemical composition:

Manganese.....not over 0.05 per cent

4. *Check analyses.*—(a) An analysis may be made by the purchaser from a broken tension test specimen representing each lot as specified in section 10 (a). The chemical composition thus determined shall conform to the requirements specified in section 3.

(b) Drillings for analysis shall be so taken as to represent the entire cross section of the specimen.

III. PHYSICAL PROPERTIES AND TESTS

5. *Tension tests.*—(a) The iron shall conform to the following requirements as to tensile properties:

Tensile strength.....	lbs./in. ² .	47,000-52,000
Yield point, minimum.....	lbs./in. ² .	0.60 tensile strength
Elongation when measured in 8 inches, minimum.....	per cent.	28
Elongation when measured in 4 inches, minimum.....	per cent.	35
Reduction of area, minimum.....	do.	42

(b) The yield point shall be determined by the drop of the beam of the testing machine. The speed of the crosshead of the machine shall not exceed three-fourths inch per minute. For the tensile strength the speed shall not exceed 3 inches per minute.

6. *Cold-bend tests.*—(a) The test specimen shall bend cold through 180° flat on itself in both directions without fracture on the outside of the bent portion.

(b) Bend tests may be made by pressure or by blows.

7. *Splitting test.*—For bars rolled or drawn hollow, a piece not less than 2 inches long shall be split open from end to end by driving a drift through the hole. The structure thus exhibited shall be free from signs of imperfect welding and the presence of slag or scale in the welds.

8. *Etch tests.*⁴⁶—The cross section of the test specimen shall be ground or polished, and etched for a sufficient period to develop the structure. This test shall show the material to have been rolled from a bloom, slab pile, or box pile, and to be free from steel.

9. *Test specimens.*—All test specimens shall be of the full section of material as rolled.

10. *Number of tests.*—(a) Bars of each size shall be sorted into lots of 1,600 lineal feet. Two bars shall be selected at random from each lot or fraction thereof and tested as specified in sections 5, 6, and 7, but only one of these bars shall be tested as specified in sections 3 and 8.

(b) If any test specimen from either of the bars originally selected to represent a lot of material contains surface defects not visible before testing but visible after testing, or if a tension test specimen breaks outside the middle third of the gage length, the individual bar shall be rejected, and one retest from a different bar will be allowed.

IV. PERMISSIBLE VARIATIONS IN GAGE

11. *Permissible variations.*—The bars shall be truly round within 0.01 inch. The diameter shall not be less than 0.005 inch under nor more than 0.020 inch over the specified diameter.

V. FINISH

12. *Finish.*—The bars shall be smoothly finished and free from slivers, depressions, seams, crop ends, and evidences of being burnt. The hole shall be as nearly axial and as nearly round as the best manufacturing practice permits, and shall have an area equivalent to that of a round hole three-sixteenths inch in diameter. The hole shall be free from slag and other obstructions.

INSPECTION AND REJECTION

(Requirements covering inspection and rejection, marking, and reheating conform to those specified in A. S. T. M. standard specifications for steel (see 605.0, p. 247), with the addition of the following item:)

⁴⁶ A solution of two parts water, one part concentrated hydrochloric acid, and one part concentrated sulphuric acid is recommended or the etch test.

Bars which will not take a clean, sharp thread, with dies in fair condition, or which develop defects in forging or machining, will be rejected, and the manufacturer shall be notified.

AMERICAN RAILWAY ASSOCIATION, MECHANICAL DIVISION, STAY-BOLT IRON, SOLID, LOCOMOTIVE, RECOMMENDED PRACTICE, 1926

STAY-BOLT IRON, SOLID

(Identical with specification for stay-bolt iron, hollow, given above, except no splitting test is required, and that in tension tests the elongation in 8 inches, minimum is 30 per cent; and the reduction of area, minimum is 48 per cent; and the addition of the following items:)

In no case shall the variation in tensile strength between the maximum and minimum figures, for one offering of iron under these specifications, be more than 3,000 pounds.

Nick-bend test.—At the option of the purchaser, the following test shall be made: The specimen, when nicked 25 per cent around with a tool having a 60° cutting edge, to a depth not less than 8 nor more than 16 per cent of the diameter of the specimen; and broken, shall show a clean fiber, free from crystallization.

INSPECTION AND REJECTION

(Requirements covering inspection and rejection, marking, and reheating, conform to those specified in A. S. T. M. standard specifications for steel. See 605.0, p. 247.)

AMERICAN RAILWAY ASSOCIATION, MECHANICAL DIVISION, WROUGHT-IRON BARS, REFINED, RECOMMENDED PRACTICE, 1914

WROUGHT-IRON BARS

I. MANUFACTURE

1. *Process.*—The finished product shall consist either of new muck-bar iron or a mixture of muck-bar iron and scrap, but shall be free from any admixture of steel. Muck bars shall be made wholly from puddled iron.

II. PHYSICAL PROPERTIES AND TESTS

2. *Tension tests.*—Unless otherwise specified, the iron shall conform to the following requirements as to tensile properties:

Tensile strength.....	lbs./in. ² .	47,000-53,000
Elongation in 8 inches, minimum.....	per cent.	22

3. *Permissible variations in physical properties.*—(a) *Tensile strength.*—Large sections reduced or flats and rounds of one-half inch or under may show a tensile strength of 45,000-52,000 pounds per square inch.

(b) *Elongation.*—Twenty per cent of the test specimens representing one size may show the following percentage of elongation in 8 inches:

	Per cent
Round bars:	
½ inch or over, tested as rolled.....	20
Under ½ inch, tested as rolled.....	16
Reduced by machining.....	18
Flat bars:	
¾ inch or over, tested as rolled.....	18
Under ¾ inch, tested as rolled.....	16
Reduced by machining.....	16

4. *Bend tests.*—(a) *Cold-bend test.*—Round, square, and hexagon bars under 2 square inches in section and flats less than three-fourths inch thick shall bend

cold around a pin the diameter of which is equal to the diameter or thickness of the specimen, without fracture on the outside of the bent portion. Rounds, flats, and hexagon bars 2 square inches or over in section and all flat bars over three-fourths inch in thickness shall bend cold around a pin the diameter of which is equal to twice the diameter or thickness of the specimen.

(b) *Hot-bend test.*—The test specimen, when heated to a temperature between 1,700° and 1,800° F. (light cherry red), shall bend through 180° without fracture on the outside of the bent portion, as follows: Round, flat, and hexagon bars under 2 square inches in section, flat on itself; round, flat, and hexagon bars 2 square inches and over in section, around a pin the diameter of which is equal to the diameter or thickness of the specimen.

(c) *Nick-bend test.*—The test specimen, when nicked 25 per cent around the round bar, and along one side for flat bars, with a tool having a 60° cutting edge, to a depth of not less than 8 or more than 16 per cent of the diameter or thickness of the specimen, and broken, shall not show more than 10 per cent of the fractured surface to be crystalline.

5. *Test specimen.*—Tension and bend test specimens shall be of the full section of material as rolled, if possible, otherwise the specimens shall be machined from the material as rolled; the axis of the machined specimen shall be located at any point one-half the distance from the center to the surface of round bars, or from the center to the edge of flat bars, and shall be parallel to the axis of the bar.

6. *Number of tests.*—(a) All bars of one size shall be piled separately. One bar from each 200 or less shall be selected at random and tested as specified.

(b) If any test specimen from the bar originally selected to represent a lot of material contains surface defects not visible before testing, but visible after testing, or if a tension test specimen breaks outside the middle third of the gage length, one retest from a different bar will be allowed.

III. PERMISSIBLE VARIATIONS IN GAGE

7. *Permissible variations.*—(a) Round bars shall conform to the standard A. R. A. limit gages (see 615.82, p. 900).

(b) *Flat bars.*—The width and thickness of flat bars shall not vary more than 2 per cent from that specified.

(1) Sizes under 3 inches wide shall not be more than one thirty-second inch under or over size in width.

(2) Sizes 3 inches and over shall not be under size or more than one-sixteenth inch wider than ordered.

INSPECTION AND REJECTION

(Requirements covering inspection, rejection, and reheating conform to those specified in A. S. T. M. standard specifications for steel. See 605.0, p. 247.)

AMERICAN RAILWAY ASSOCIATION, SIGNAL SECTION, SPECIFICATION FOR WROUGHT-IRON BARS, JULY, 1930

WROUGHT-IRON BARS

(In respect to physical properties, determination of yield point, tensile tests, cold-bend tests, and etch tests, this specification is identical with A. S. T. M. A41-30, given below. In respect to permissible variations in elongation, hot-bend tests, nick-bend tests, tension and bend test specimens, number of tests, and permissible variations in gage (omitting references to sizes over and under 3 inches), it is identical with the specification of the American Railway Association for hollow stay-bolt iron, given above. In other respects it provides that:)

PURPOSE

The purpose of this specification is to provide for wrought-iron bars.

DRAWINGS

Contractor shall furnish with his tender, drawings forming an essential part thereof.

TENDER

The tender shall be for apparatus meeting the requirements of this specification. If the contractor wishes to vary from the specification, a tender may be submitted covering the apparatus he desires to furnish. This tender shall be accompanied by full information showing wherein variations from the requirements of the specification exists.

MATERIAL AND WORKMANSHIP

Material and workmanship shall be first class in every respect.

All sections must be true to size and shape ordered. Round iron must conform to the Master Car Builders' standard limit gages. (See 615.82, p. 900.)

Iron must be free from cracks, flaws, unwelded seams, and mechanical defects of all kinds, and must be free from steel scrap.

INSPECTION

Purchaser may inspect the material at all stages of manufacture.

Purchaser may inspect the completed product to determine that the requirements of this specification have been met.

If the material has not been accepted at point of production and if, upon arrival at destination, it does not meet the requirements of this specification, it may be rejected, and the contractor, upon request, shall advise the purchaser what disposition is to be made of the defective material. The contractor shall pay all freight charges.

If the purchaser is to make inspection at point of production it shall be so stated.

TESTS

Tests may be made at point of production, or on samples submitted, and may also be made at destination.

Contractor shall give the purchaser sufficient notice of time when material will be ready for testing.

Contractor shall provide, at point of production, apparatus and labor for making the required tests under supervision of the purchaser.

PACKING

Material shall be so prepared as to permit convenient handling and to protect against loss or damage during shipment.

MARKING

Purchaser's order, requisition, and package number; name of consignor; and name and address of consignee shall be plainly marked on outside of package.

Detail list of loose pieces, containers, and their contents shall be furnished for each shipment. Where carload shipments are made, routing and car identification shall be shown. Where carload shipments are made, name and address of consignee may be omitted.

WARRANTY

Contractor shall warrant the material covered by this specification to be free from defects in material

and workmanship under ordinary use and service, his obligation under this warranty being limited to making, at point of production, any part or parts to replace those which shall be found defective after shipment to the purchaser. This warranty shall not apply to any apparatus which has been subjected to misuse, negligence, or accident.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS, SPECIFICATIONS FOR BOILER-RIVET, STAY-BOLT, AND EXTRA-REFINED BAR IRON, S-16, 1930

WROUGHT-IRON BARS

(In substantial agreement with A. S. T. M. A84-30, given below.)

AMERICAN SOCIETY OF MUNICIPAL ENGINEERS, STANDARD SPECIFICATIONS FOR SEWERS, A-27, 1927

WROUGHT IRON

Quality.—All wrought iron to be used on the work shall be of the class known as merchant iron, grade A, and must be free from cinder spots, injurious flaws, buckles, blisters, or cracks. Wrought iron shall be made by the puddling process, or rolled from fagots or piles made from wrought-iron scrap, alone or with muck bar added. All iron shall have a minimum tensile strength of 50,000 pounds per square inch and an elastic limit of at least 25,000 pounds per square inch. A specimen cut from the iron, when nicked on one side and bent back through an angle of 180°, shall show a long, clean, silky fiber; free from slag, dirt, or coarse crystalline spots.

Finishing painting.—Wrought iron before leaving the factory shall be thoroughly cleaned and dipped in a preparation of asphalt or coal tar and oil.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR REFINED WROUGHT-IRON BARS, DESIGNATION A41-30, 1930

REFINED WROUGHT-IRON BARS

(In respect to permissible variations in elongation, hot-bend tests, nick-bend tests, test specimens, number of tests, permissible variations in gage (omitting references to sizes under and over 3 inches), this specification conforms to the specification of the American Railway Association for wrought-iron bars, refined, given above. In respect to finish, inspection and rejection, and reheating, it conforms to A. S. T. M. standard specifications for steel. See 605.0, p. 247. In other respects it provides that:)

MANUFACTURE

1. The bars shall be made from wrought iron, and may consist either of all new iron or a mixture of new iron and scrap, but shall be free from any admixture of steel.

PHYSICAL PROPERTIES AND TESTS

2. (a) The iron shall conform to the following minimum requirements as to tensile properties:

Tensile strength.....	lbs./in. ² ..	48,000
(See sections 3 and 4.)		
Yield point.....	do.....	25,000
Elongation in 8 inches.....	per cent..	22

(b) The yield point shall be determined by the drop of the beam of the testing machine. The speed of the crosshead of the machine shall not exceed three-fourths inch per minute.

3. For material over 4 square inches in sectional area, a reduction of 500 pounds per square inch from the tensile strength specified in section 2 will be permitted for each additional 2 square inches and a proportionate amount of reduction for fractional parts thereof; provided that the tensile strength shall not be less than 45,000 pounds per square inch.

4. Twenty per cent of the test specimens representing one size, may show tensile strengths 1,000 pounds per square inch under, or 5,000 pounds per square inch over that specified in sections 2 and 3; but no specimen shall show a tensile strength less than 45,000 pounds per square inch.

5. (a) *Cold-bend tests.*—Cold-bend tests will be made only on bars having a nominal sectional area of 4 square inches or under, in which case the test specimen shall stand being bent cold through 180° without fracture on the outside of the bent portion, around a pin the diameter of which is equal to twice the diameter or thickness of the specimen.

(b) Bend tests may be made by pressure or by blows.

6. (a) The cross section of the test specimen shall be ground or polished, and etched for a sufficient period to develop the structure. This test shall show the material to be free from steel.

(b) Etch test specimens shall be of the full section of material as rolled.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR STAY BOLT, ENGINE-BOLT, AND EXTRA REFINED WROUGHT IRON BARS, DESIGNATION A84-30, 1930

WROUGHT-IRON BARS

(In respect to definitions of terms, check analysis, determination of yield point, number of tests, and permissible variations in gage of grade A, this specification conforms to the specification of the American Railway Association for stay-bolt iron, hollow, locomotive, given above. In respect to workmanship and finish, marking, inspection and rejection, and reheating, it conforms to A. S. T. M. standard specifications for steel. See 605.0, p. 247. In other respects it provides that:)

1. These specifications cover three grades of bar iron: Grade A, stay-bolt iron; grade B, engine-bolt iron; and grade C, extra refined wrought iron bars.

MANUFACTURE

2. *Grade A.*—The bars shall be rolled from a bloom, slab pile, or box pile made from reworked wrought iron or reworked knobbed charcoal iron. The original muck or knobbed bar shall be twice piled and rerolled. All bars shall be the full length of the piles. The wrought iron and the component parts of the bloom, slab pile, or box pile shall be free from any admixture of iron scrap or steel.

Grades B and C.—The bars shall be made from wrought iron and shall be free from any admixture of iron scrap or steel.

CHEMICAL PROPERTIES AND TESTS

4. *Grade A.*—At the option of the purchaser and when so specified, the iron shall conform to the following requirement as to chemical composition:

Manganese.....	Not over 0.10 per cent
----------------	------------------------

PHYSICAL PROPERTIES AND TESTS

6. (a) The iron shall conform to the following requirements as to tensile properties:

	Grade A	Grade B	Grade C
Tensile strength, pounds per square inch:			
1/4 square inches or under in sectional area	48,000-52,000	49,000-53,000	48,000-54,000
Over 1/4 square inches in sectional area	(1)	47,000-53,000	48,000-54,000
Yield point, minimum, pounds per square inch:			
1/4 square inches or under in sectional area	0.6	0.6	0.6
Over 1/4 square inches to 1/2 square inches, inclusive, in sectional area	(Ten. Str.)	(Ten. Str.)	(Ten. Str.)
Over 1/2 square inches in sectional area		0.55	0.55
		(Ten. Str.)	(Ten. Str.)
		0.5	0.5
		(Ten. Str.)	(Ten. Str.)
Elongation in 8 in., minimum	30	25	25
Reduction of area, minimum	48	40	37

¹ See section 7 (b).

² See section 7 (a).

³ See section 7 (d).

⁴ See section 7 (b) and (c).

7. (a) *Grade A.*—For bars seven-eighths inch in diameter, a reduction in the minimum elongation in 8 inches specified in section 6 (a) shall be permitted, but in no case shall the elongation be less than 28 per cent. For bars three-fourths inch or under in diameter, the elongation shall be not less than 25 per cent.

(b) *Grade A.*—For bars over 1/4 square inches in sectional area, the following deductions from the minimum requirements specified in section 6 (a) shall be made for each square inch of nominal section above 1/4 square inches:

Tensile strength... 250 pounds, but not under 46,000 pounds per square inch.

Reduction of area... 3 per cent, but not under 40 per cent.

(c) *Grade A.*—For flats of all sizes the minimum reduction of area shall be 40 per cent.

(d) *Grade C.*—For material over 4 square inches in sectional area, the following deductions from the minimum requirements specified in section 6 (a) shall be made for each square inch of nominal section above 4 square inches:

Tensile strength... 250 pounds, but not under 46,000 pounds per square inch.

Elongation... 0.5 per cent, but not under 22 per cent.

Reduction of area... 1.0 per cent, but not under 32 per cent.

8. (a) *Cold-bend tests—Grade A.*—The test specimen shall withstand being bent cold through 180° flat on itself in both directions, without fracture on the outside of the bent portions.

Grade B.—The test specimen shall withstand being bent cold through 180° around a pin, the diameter of which is equal to the diameter of the specimen, without fracture on the outside of the bent portion.

Grade C.—Cold-bend tests will be made only on bars having a nominal sectional area of 4 square inches or under, in which case the test specimen shall withstand being bent cold through 180° without fracture on the outside of the bent portion, around a pin the diameter of which is equal to the thickness of the specimen.

(b) *Hot-bend tests.*—

Grades B and C.—The test specimen when heated to a temperature between 1,700° and 1,800° F. shall stand being bent through 180° flat on itself without fracture on the outside of the bent portion.

(c) *Nick-bend tests—All grades.*—The test specimen when nicked 25 per cent around with a tool having a 60° cutting edge, to a depth of not less than

8 nor more than 16 per cent of the diameter of the specimen, and broken, shall show a wholly fibrous fracture.

(d) Bend tests may be made by pressure or by blows.

9. The cross section of the test specimen shall be ground or polished, and etched⁴⁷ for a sufficient period to develop the structure. This test shall show the material as follows:

Grade A.—The material to have been rolled from a bloom, slab pile, or box pile and to be uniform and free from steel.

Grades B and C.—The material to be uniform and free from steel.

10. (a) Tension and bend test specimens shall be of the full section of material as rolled, if possible. Otherwise the specimens shall be machined from the material as rolled; the axis of the specimen shall be located at any point midway between the center and surface of round bars, or midway between the center and edge of flat bars, and shall be parallel to the axis of the bar.

(The table of standard limit gages for engine-bolt iron is the same as that in the specification of the American Railway Association for limit gages for round iron. See 615.82, p. 900. Grade B bars shall conform to this table. Grade C bars shall not vary, in width or thickness, more than 2 per cent from that specified.)

(b) Etch test specimens shall be of the full section of material as rolled.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR COMMON IRON BARS, DESIGNATION A85-27, 1927

COMMON IRON BARS

(In respect to physical properties, determination of yield point, permissible variations in tensile strength, cold-bend tests, etch tests, and etch-test specimens, this specification is identical with A. S. T. M., A41-30, given above. In respect to permissible variations in elongation, hot-bend tests, nick-bend tests, test specimens, number of tests, and permissible variations in gage (omitting references to sizes under and over 3 inches), it is identical with the specification of the American Railway Association for wrought-iron bars, refined, given above. In respect to finish, inspection and rejection, and reheating, it conforms to A. S. T. M. standard specifications for steel. See 605.0, p. 247. In other respects it provides that:)

MANUFACTURE

1. Common iron bars may be made from reworked iron scrap or a reworked mixture of iron and steel scrap, but shall be free from large areas of steel.

CHEMICAL PROPERTIES AND TESTS

2. The iron shall conform to the following requirement as to chemical composition:

Manganese..... Not over 0.30 per cent

3. (a) An analysis may be made by the purchaser from a broken tension-test specimen representing each lot as specified. The chemical composition thus determined shall conform to the requirement specified in section 2.

⁴⁷ A solution of 10 per cent hydrochloric acid (specific gravity 1.19), 30 per cent sulphuric acid (specific gravity 1.84), and 60 per cent water; or 25 per cent nitric acid (specific gravity 1.42), and 75 per cent water, is recommended for the etch test.

(b) Drillings for analysis shall be so taken as to represent the entire cross section of the specimen.

4. *Appearance of fracture.*—The broken ends of the tension-test specimen shall show a uniform fibrous structure similar to that of wrought iron.

5. For material over 4 square inches in sectional area, a reduction of 250 pounds per square inch from the tensile strength specified will be permitted for each additional square inch, and a proportionate amount of reduction for fractional parts thereof; provided that the tensile strength shall not be less than 45,000 pounds per square inch.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR HOLLOW ROLLED STAY-BOLT IRON, DESIGNATION A86-30, 1930

HOLLOW ROLLED STAY-BOLT IRON

(Identical with specification of American Railway Association for hollow stay-bolt iron, given above, except that manganese shall not be over 0.10 per cent, the tensile strength ranges from 48,000 to 52,000 pounds per square inch, and the reduction of area, minimum, is 48 per cent.)

INSPECTION AND REJECTION

(Requirements covering inspection and rejection, marking, and reheating conform to those specified in A. S. T. M. standard specifications for steel. See 605.0, p. 247.)

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR IRON BAR, WROUGHT, REFINED, NO. 391, MARCH 1, 1926. (CURRENT DESIGNATION: QQ-I-686)

IRON BARS

(This specification is substantially the same as A. S. T. M., A41, given above, except that No. 391 includes F. S. B., No. 339 (current designation: QQ-M-151) general specifications for metals, for which see 600.0, p. 3.)

603.2 CARBON-STEEL BARS AND RODS.

603.21 STEEL STOCK FOR BOLTS, NUTS, RIVETS, AND SCREWS.

AMERICAN BUREAU OF SHIPPING, RULES FOR BUILDING AND CLASSING STEEL VESSELS; QUALITY AND TESTING OF MATERIALS, SHIP CONSTRUCTION, 1930

STEEL RIVET BARS

(For general information and requirements, see 600.0, p. 2.)

For steel rivet bars at least one tension test shall be taken from each heat. Where the heat weight exceeds 22,000 pounds, a second tension test will be required. For rivet bars no bend tests will be required. The tensile breaking strength of the bars shall be between the limits of 55,000 and 65,000 pounds per square inch, with an elongation of not less than 25 per cent on a gage length of eight times the diameter, or 31 per cent on three and one-half times the diameter of the test specimen. Intermediate proportions of length to diameter are to have intermediate percentages.

AMERICAN BUREAU OF SHIPPING, RULES FOR BUILDING AND CLASSING STEEL VESSELS; MATERIALS FOR MACHINERY, BOILERS, AND PIPING, 1930

STEEL BARS AND STAYS FOR BOILERS

(For general information and requirements, see 600.0, p. 1. For test requirements, see 600.1, p. 7.)

At least one tension, one cold-bend, and one quench-bend test shall be made for each 2,000 pounds or less of bars rolled from each heat.

AMERICAN RAILWAY ASSOCIATION, MECHANICAL DIVISION, RIVET STEEL AND RIVETS FOR LOCOMOTIVE TENDERS AND PASSENGER AND FREIGHT EQUIPMENT CARS, 1925

RIVET STEEL AND CAR RIVETS

SCOPE

1. These specifications cover steel bars for the manufacture of rivets, and finished steel rivets for locomotive tanks and underframes and passenger and freight equipment cars.

MANUFACTURE

2. The steel shall be made by the open-hearth process.

CHEMICAL PROPERTIES AND TESTS

3. The steel shall conform to the following requirements as to chemical composition:

Carbon.....	Percentage optional.
Manganese.....	Do.
Phosphorus.....	Not over 0.04 per cent.
Sulphur.....	Not over 0.05 per cent.

LADLE AND CHECK ANALYSES

(Same as in American Railway Association specification for steel tank plates. See 621.32, p. 1124.)

PHYSICAL PROPERTIES AND TESTS

A. Requirements for Bars

4. *Tension tests.*—The bars shall conform to the following requirements as to tensile properties:

Tensile strength.....	lbs./in. ² ..	45,000-60,000
Elongation in 8 inches (minimum).....	per cent.....	1,500,000
		Tensile strength
		(But need not exceed 30 per cent.)

5. *Bend test.*—The test specimen shall bend cold through 180° flat on itself without cracking on the outside of the bent portion.

B. Requirements for Rivets

6. *Bend tests.*—The rivet shank shall bend cold through 180° flat on itself, as shown in Figure 52 without cracking on the outside of the bent portion.

7. *Flattening test.*—Rivet heads shall be flattened sideways, when cold, to a thickness of one-third, and when at a driving heat to a thickness of one-fourth the original diameter of the shank, without splitting.

8. *Test specimens*—(a) *Bars.*—Tension and bend test specimens shall be of the full section of bars as rolled.

(b) *Rivets.*—Bend and flattening test specimens shall be of the full section of rivets as manufactured.

(c) When accurate account of the material has been kept and the melts can be identified, only one

set of specimens for each diameter in each melt shall be taken from either bars or the finished rivets.

9. *Number of tests*—(a) *Bars*.—One tension and one bend test shall be made from each lot of 200 bars, or from each diameter in any one melt, each of which shall conform to the requirements specified.

(b) *Rivets*.—One bend and one flattening test shall be made from each lot of 50 kegs of each diameter or

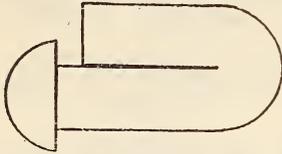

FIGURE 52.—Rivet shank bent cold flat on itself

from each diameter in any one melt, each of which shall conform to the requirements specified.

(c) If any test specimen from the bar or rivets originally selected to represent a lot of bars or rivets contain surface defects not visible before testing,

but visible after testing, or if a tension-test specimen breaks outside the middle third of the gage length, one retest shall be allowed.

PERMISSIBLE VARIATIONS IN GAGE

(Identical with A. S. T. M., A31, given below.)

10. *Dimensions of rivet heads*.—Rivet heads shall conform to the dimensions shown on the purchaser's standard drawings when so specified, otherwise the heads shall conform, within 5 per cent above or below, to the dimensions shown in the accompanying table.

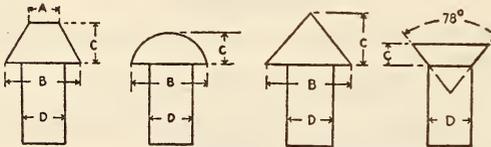

FIGURE 53

Cone head	Button head	Steeple head	Countersunk head
$A = 1\frac{1}{16}$ by D . $B = 1\frac{3}{4}$ by D . $C = \frac{7}{8}$ by D .	$B = 1\frac{3}{4}$ by D . $C = \frac{3}{4}$ by D .	$B = 2$ by D . $C = D$.	$C = \frac{1}{2}$ by D . Taper = 75° .

Dimensions for rivets (in inches)

Diameter of rivet	Cone head			Button head		Steeple head		Countersunk head

WORKMANSHIP AND FINISH

11. *Workmanship*.—The rivets shall be concentric, true to form, and shall be made in a workmanlike manner.

12. *Finish*.—The finished bars and rivets shall be free from injurious defects and shall have a workmanlike finish.

MARKING

13. *Marking*—(a) *Bars*.—Rivet bars shall, when ready for shipment, be properly separated and marked with the name or brand of the manufacturer and the melt or lot number for identification.

(b) *Rivets*.—Kegs of finished rivets shall, when ready for shipment, be properly marked with the name or brand of the manufacturer, diameter of rivets, and the melt or lot numbers for identification.

(c) *Samples*.—The melt or lot number shall be legibly stamped on each test specimen representing a lot of bars. Samples representing a lot of rivets shall be marked in a manner that will not impair their value for test purposes.

INSPECTION AND REJECTION

(Requirements covering inspection, rejection, and reheating conform to A. S. T. M. standard specifications for steel, paragraphs 7, 8, and 9. See 605.0. p. 247.)

AMERICAN RAILWAY ASSOCIATION, MECHANICAL DIVISION, RIVET STEEL AND RIVETS FOR STEAM BOILERS AND OTHER PRESSURE VESSELS, 1923

RIVET STEEL FOR BOILERS

SCOPE

1. These specifications cover steel bars for the manufacture of rivets and finished steel rivets.

MANUFACTURE

2. The steel shall be made by the open-hearth process.

CHEMICAL COMPOSITION

The steel shall conform to the following requirements as to chemical composition:

	Bars	Rivets
Carbon	0.30 to 0.50 per cent	Not over 0.18 per cent.
Manganese	0.30 to 0.50 per cent	0.30 to 0.50 per cent.
Phosphorus	Not over 0.04 per cent	Not over 0.04 per cent.
Sulphur	Not over 0.045 per cent	Not over 0.045 per cent.

LADLE AND CHECK ANALYSES

(Same as in American Railway Association specification for steel tank plates. See 621.32, p. 1124.)

PHYSICAL PROPERTIES AND TESTS

(Requirements covering tension tests for bars, determination of yield point, bend tests for bars and rivets, and quench-bend test all are the same as in A. S. T. M. A31, given below. Requirements covering flattening test for rivet heads, and test specimens for bars and rivets, are the same as in the A. R. A. specification for rivet steel and rivets for locomotive tenders and equipment cars, given below, with the following additional provision as to cold-worked test specimens:)

(d) If rivet bars or rivets have been cold worked the test specimens shall be heated to a drawing heat and allowed to cool in air before testing.

3. *Number of tests*—(a) *Bars*.—Two tension, two cold-bend and two quench-bend tests shall be made from each lot of 200 bars, or from each diameter in any one melt, each of which shall conform to the requirements specified.

(b) *Rivets*.—One cold-bend, one quench-bend, and one flattening test shall be made from each lot of 50 kegs of each diameter or from each diameter in any one melt, each of which shall conform to the requirements specified.

(c) If any test specimen from the bar or rivets originally selected to represent a lot of bars or rivets contain surface defects not visible before testing, but visible after testing, or if the percentage of elongation of any tension test specimen be less than that specified, and any part of the fracture is outside the middle third of the gage length, as indicated by scribe scratches marked on the specimen before testing, a retest shall be allowed.

PERMISSIBLE VARIATIONS

(Same as A. S. T. M. A31, given below.)

MARKING

(Same as A. R. A. specification for rivet steel and rivets for locomotive tenders and equipment cars, given above.)

INSPECTION AND REJECTION

(Requirements covering workmanship and finish, inspection and rejection, and reheating conform to A. S. T. M. standard specifications for steel, paragraphs 5, 7, 8, and 9. See 605.0, p. 247.)

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR STEEL RAILWAY BRIDGES, 1924

STRUCTURAL AND RIVET STEEL

(See 605.11, p. 249. See also 611.11, p. 636; 611.41, p. 707; and 611.51, p. 753.)

AMERICAN SOCIETY OF MECHANICAL ENGINEERS, BOILER-CONSTRUCTION CODE SPECIFICATIONS FOR BOILER RIVET STEEL, S-5, 1930

BOILER RIVET STEEL

(Identical with A. S. T. M. A31-24, given below.)

AMERICAN SOCIETY OF MECHANICAL ENGINEERS, BOILER-CONSTRUCTION CODE SPECIFICATIONS FOR STEEL BARS FOR STAY BOLTS, S-6, 1930

STEEL BARS FOR STAY BOLTS

A. BARS

1. *Solid or hollow stay bolts*.—Steel for solid or hollow bars for stay bolts shall conform to the requirements for boiler rivet steel, except as follows:

(a) *Tension tests*.—The bars shall conform to the following requirements as to tensile properties:

Tensile strength, maximum.....lbs./in. ² ..	60,000
Yield point, minimum.....lbs./in. ² ..	26,000
Elongation in 8 inches, minimum	1,500,000
-----per cent.-----	Tensile strength

(b) *Permissible variation in gage*.—Solid or hollow bars for stay bolts, not exceeding 1¼ inches in diameter, which are to be threaded as rolled, shall be truly round within 0.01 inch and shall not vary more

than 0.005 inch under or more than 0.01 inch over. All other bars for stay bolts shall conform to the specified tolerances for steel bars.

B. SEAMLESS STEEL TUBING FOR STAY BOLTS

2. *Scope*.—These specifications cover seamless steel tubing for threaded stay bolts. They do not apply to stay tubes for locomotive boilers.

3. *Process*.—The steel shall be made by the open-hearth process.

4. *Chemical composition*.—The steel shall conform to the following requirements as to chemical composition:

Manganese.....	Per cent
Phosphorus, not over.....	0.30-0.60
Sulphur, not over.....	0.04
	0.045

5. *Check analyses*.—(a) Analyses of two tubes in each lot of 250 tubes or less, may be made by the purchaser. The chemical composition thus determined shall conform to the requirements specified. Drillings for analyses shall be taken from several points around each tube selected for analysis.

(b) If the analysis of one tube does not conform to the requirements specified, analyses of two additional tubes from the same lot shall be made, each of which shall conform to the requirements specified.

6. *Tension tests*.—The tubes shall conform to the following requirements as to tensile properties:

Tensile strength, maximum.....lbs./in. ² ..	60,000
Yield point, minimum.....lbs./in. ² ..	25,000
Elongation in 8 inches, minimum	1,500,000
-----per cent.-----	Tensile strength

7. *Test specimens*.—Test specimens shall consist of either full-section specimens or of sections cut longitudinally from a tube.

8. *Number of tests*.—(a) Two tension tests from each 2,500 feet of tubing shall be made, or in case the tubing from separate melts can be identified, two tension tests shall be made from each melt.

(b) If the results of the physical tests of one specimen from any lot do not conform to the requirements specified, two additional specimens from the same lot may be tested, each of which shall conform to the requirements specified.

(c) If any test specimen develops flaws, it may be discarded and another specimen substituted.

(d) If the percentage of elongation of any tension-test specimen is less than that specified, and any part of the fracture is outside the middle third of the gage length, as indicated by scribe scratches marked on the specimen before testing, a retest shall be allowed.

9. *Fracture test*.—A special fracture test shall be made from each 2,500 feet of tubing by cutting partly through the wall of the tube and breaking it off when removing the crop end. The fracture thus produced shall be fine grained.

10. *Permissible variation in gage*.—The finished tubing shall be circular within 0.015 inch, and the outside diameter shall not vary more than 0.01 inch over or under the size specified.

(Requirements covering finish, inspection and rejection, and reheating conform to A. S. T. M. standard specifications for steel, paragraphs 5, 7, 8, and 9. See 605.0, p. 247.)

AMERICAN SOCIETY OF MECHANICAL ENGINEERS, SMALL RIVETS, SEVEN-SIXTEENTHS INCH NOMINAL DIAMETER AND UNDER, B-18a, 1927

RIVET STEEL FOR SHIPS

(See 605.15, p. 269.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR BOILER RIVET STEEL, DESIGNATION A31-24, 1924

BOILER RIVET STEEL

(In respect to manufacture, determination of yield point, cold-bend tests, test specimens, flaws in test specimens, physical properties and tests of rivets, and workmanship and finish, this specification is identical with A. S. T. M. A13. See 605.15, p. 269. In respect to ladle and check analyses it is identical with A. S. T. M. A70. See 604.11, p. 227. In respect to marking, inspection and rejection, and reheating it conforms to A. S. T. M. standard specifications for steel. See 605.0, p. 247. Its original provisions are as follows:)

REQUIREMENTS FOR ROLLED BARS

Chemical Composition

1. The steel shall conform to the following requirements as to chemical composition:

	Per cent
Manganese.....	0.30-0.50
Phosphorus, not over.....	.04
Sulphur, not over.....	.045

Physical Properties and Tests

2. The bars shall conform to the following requirements as to tensile properties:

Tensile strength.....	lbs./in. ²	45,000-55,000
Yield point, minimum.....	lbs./in. ²	0.5 tensile strength.
Elongation in 8 inches, minimum.....	per cent.	1,500,000
		Tensile strength

But need not exceed 30 per cent

3. *Quench-bend tests.*—The test specimen, when heated to a light cherry red as seen in the dark (not less than 1,200° F.), and quenched at once in water the temperature of which is between 80° and 90° F., shall stand being bent through 180° flat on itself without cracking on the outside of the bent portion.

4. *Number of tests.*—Two tension, two cold-bend, and two quench-bend tests shall be made from each melt, each of which shall conform to the requirements specified.

Permissible Variations in Diameter

5. The diameter of hot-finished rivet bars shall not vary from that specified by more than the amount given in the following table:

Diameter (in inches)	Variations in diameter		Out of round
	Under	Over	
Up to 1/2, inclusive.....	0.007	0.007	0.010
Over 1/2 to 1, inclusive.....	.010	.010	.013
Over 1 to 1 1/4, inclusive.....	.012	.012	.016
Over 1 1/4 to 1 1/2, inclusive.....	.015	.015	.021
Over 1 1/2 to 2, inclusive.....	.022	.022	.023

REQUIREMENTS FOR RIVETS

Permissible Variations in Diameter

6. *Finished rivets.*—The diameter of finished rivets, measured cold, shall not vary from that specified more than the amounts given in the following table:

Diameter (in inches)	Variations in diameter	
	Snap gage measurement (under)	Ring gage measurement (over)
Up to 1/2, inclusive.....	0.022	0.020
Over 1/2 to 1, inclusive.....	.025	.030
Over 1 to 1 1/4, inclusive.....	.027	.035
Over 1 1/4 to 1 1/2, inclusive.....	.030	.040
Over 1 1/2 to 2, inclusive.....	.037	.040

Snap gage measurement shall be made at the point of minimum diameter, but it is not required that the rivet shall turn completely in the gage. Measurements of the maximum tolerance shall be made with a ring gage, all rivets to slip full to the head in the gage of the required size for the various diameters.

7. *Rivet heads.*—The dimensions of the rivet heads shall not vary from that specified more than the amounts given in the following table:

Ordered diameter of rivets	Head tolerances	
	Width	Height
<i>Inch</i>	<i>Inch</i>	<i>Inch</i>
1/2	+1/16 -1/32	+1/32
3/16	+1/16 -1/32	+1/32
5/16	+1/16 -1/32	+1/32
1 1/16	+1/16 -1/32	+1/32
3/4	+5/64 -1/32	+1/32
7/8	+5/64 -1/32	+1/32
1	+5/64 -1/32	+1/32

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR STEEL, STAY BOLT, BOILER, QQ-S-701, MARCH 1, 1932

STAY-BOLT STEEL, BOILER

I. GENERAL SPECIFICATIONS

United States Government general specification for metals, Federal Specifications Board specification No. 339 (current designation: QQ-M-151), in effect on date of invitation for bids, shall form a part of this specification. (See 600.0, p. 3.)

II. GRADES

This specification covers a single grade of material for either solid or hollow stay bolts.

III. MATERIAL AND WORKMANSHIP

1. The steel shall be made by the open-hearth or electric-furnace process.
2. The workmanship shall be first class in every respect.

IV. GENERAL REQUIREMENTS

1. *Surface defects.*—The solid or hollow bars shall be straight, true to form, concentric, free from bends, blisters, or other injurious defects which might affect their strength or serviceability.
2. *Permissible variation.*—The diameter of each bar shall not vary from that specified more than the amount given in the following table:

Diameter (in inches)	Variation in diameter		Out of round
	Under	Over	
Up to 1 inclusive.....	<i>Inch</i> 0.01	<i>Inch</i> 0.01	<i>Inch</i> 0.013
Over 1 to 1¼, inclusive.....	.012	.012	.016
Over 1¼ to 1½, inclusive.....	.015	.015	.021
Over 1½ to 2, inclusive.....	.022	.022	.023

3. Ends of stay-bolt material upset for threading or flanged for riveting shall be thoroughly annealed.

V. DETAIL REQUIREMENTS

1. The stay-bolt steel shall conform to the chemical and physical requirements contained in the following table:
- | | |
|---|------------------|
| Tensile strength, maximum.....lbs./in. ² | 60,000 |
| Minimum yield point.....do..... | 26,000 |
| Minimum elongation in 8 inches, per cent..... | 1,500,000 |
| | Tensile strength |
| Phosphorus (not more than).....do..... | 0.04 |
| Sulphur (not more than).....do..... | .045 |
2. The yield point shall be determined by the use of dividers or by the drop of the beam of the testing machine, as required by the inspector.

VI. METHODS OF INSPECTION AND TESTS

1. All stay-bolt material shall be surface inspected.
2. Drillings or millings for chemical analysis shall be taken from several points from each bar selected for test and the chips combined and mixed. The resultant sample shall be free from dirt, grit, or other foreign matter and consist of at least one ounce.
3. Two tension, one bend and one fracture, test specimen shall be taken from each lot of 2,500 feet of material, or fraction thereof, or in case separate melts can be identified, the above-mentioned specimens shall be taken from each melt. Where upset or flanged stay bolts are required, the physical and chemical tests shall be made before upsetting or flanging.
4. Tension test specimens shall consist of full section specimens, or, if over 1½ inches diameter, of specimens machined to a diameter of at least three-fourths inch for a length of at least 9 inches, or for hollow bars of over 1½ inches diameter specimens may be cut longitudinally and machined to shape. Flattening of hollow bar specimens shall not be permitted.
5. Bend test specimens cut from hollow bars or of full section if solid bars, shall withstand being bent cold through 180° flat on itself without fracture on the outside of the bent portion for material 1 inch or under in diameter; for material over 1 inch to and including 1½ inches diameter around a pin the diameter of which is equal to the diameter of the specimen; and for material over 1½ inches in diameter around a pin the diameter of which is equal to twice the diameter of the specimen.
6. A fracture test shall be made by cutting partly through the bar or the wall of the hollow bar, and

breaking it off when removing the crop end. The fracture thus produced shall be fine grained.

7. If the results of the physical tests of one specimen from any lot do not conform to the requirements specified, two additional specimens, each from a different bar, of the same lot may be tested, each of which shall conform to the requirements specified.
8. If the percentage of elongation of any test specimen is less than that specified and any part of the fracture is outside the middle third of the gage length as indicated by scribe scratches marked on the specimen before testing, a retest shall be permitted.

VII. PACKING AND MARKING OF SHIPMENTS

Shipments shall be packed and marked as required by the contract or order.

VIII. NOTES

1. Stay bolt material should be ordered by giving the type of material required, whether hollow or solid, outside and inside diameters, and length.
2. Material furnished in accordance with this specification is intended for staying surfaces or pressure boilers and may be applied by threading and riveting or by flanging the solid bar and connecting to the boiler plate with rivets.
3. The following specification was considered in the preparation of this specification.
A. S. M. E. Boiler Construction Code, 1930.

603.22. STEEL FOR CASE HARDENING.

SOCIETY OF AUTOMOTIVE ENGINEERS, IRON AND STEEL SPECIFICATIONS; SPECIFICATIONS FOR AUTOMOTIVE STEELS, S. A. E. STANDARD, FEBRUARY, 1929

CARBON STEELS

(See 603.27, p. 150, including certain references to 600.0, p. 2, and 600.1, p. 49).

603.23. COMMERCIAL GRADE STEEL BARS AND RODS.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS, BOILER CONSTRUCTION CODE, SPECIFICATIONS FOR STEEL BARS, S-7, 1930

STEEL BARS

(This specification is based on and conforms to A. S. T. M. A7-29 (see 605.11, p. 249), except that in tension tests the elongation in 2 inches, minimum, per cent is 26 instead of 22 as in A7-29, and the addition of the following data on gage variation:)

Permissible variation in gage.—The diameter of each bar shall not vary from that specified more than the amount given in the following table:

Diameter (in inches)	Variation in diameter		Out of round
	Under	Over	
Up to ½, inclusive.....	<i>Inch</i> 0.007	<i>Inch</i> 0.007	<i>Inch</i> 0.010
Over ½ to 1, inclusive.....	.010	.010	.013
Over 1 to 1¼, inclusive.....	.012	.012	.016
Over 1¼ to 1½, inclusive.....	.015	.015	.021
Over 1½ to 2, inclusive.....	.022	.022	.023
Over 2 to 2½, inclusive.....	¼/32	¾/64	.023
Over 2½ to 3, inclusive.....	½/32	¾/64	.035

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR COMMERCIAL QUALITY HOT-ROLLED BAR STEELS, DESIGNATION A107-30, 1930

COMMERCIAL QUALITY BAR STEELS

(In respect to scope, process, chemical composition, ladle analyses, check analyses, and finish this specification conforms with that of the Association of American Steel Manufacturers for commercial quality bar steel (see below), except for the addition in A107-30 of the following chemical compositions of screw steel grades:)

Grades	Carbon	Manganese	Phosphorus	Sulphur
Bessemer screw.....	<i>Per cent</i> 0.08-0.16	<i>Per cent</i> 0.60-0.90	<i>Per cent</i> 0.09-0.13	<i>Per cent</i> 0.10-0.18
Open-hearth screw....	.15- .25	.60- .90	.06 max.	.075-. 15

(In respect to permissible variations in sizes of bars, this specification is identical with that of the Association of American Steel Manufacturers for hot-rolled bars. (See 600.7, p. 116.)

(In respect to samples for analysis it is identical with the specification of the Association of American Steel Manufacturers for sampling rolled and forged steel products. See 600.1, p. 47.)

(In respect to inspection, rejection, and reheating it conforms with the A. S. T. M. standard specifications for steel in 605.0, p. 247.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR COMMERCIAL COLD-FINISHED BAR STEELS AND COLD-FINISHED SHAFTING, DESIGNATION A108-30, 1930

COMMERCIAL COLD-FINISHED BAR STEELS AND COLD-FINISHED SHAFTING

SCOPE

1. (a) These specifications cover commercial cold-finished bar steels of grades considered to be in common use, including cold-finished Bessemer screw stock and cold-finished open-hearth screw stock, also cold-finished shafting and commercial key stock.

(b) The sections of bar steel covered are rounds, squares, and hexagons of all sizes, and flats not over 6 inches wide. The sections of shafting covered are rounds up to 6 inches, inclusive.

BASIS OF PURCHASE

2. (a) Bars and shafting may be cold-rolled, cold-drawn, turned and polished, or turned and ground.

(b) The purchaser shall specify each grade of bar steel desired, by its grade designation or by its complete chemical limits.

(c) The steel in Bessemer and open-hearth screw stock shall be free-cutting and suitable for high-speed screw machine work, leaving a smooth finish after machining under proper conditions.

(d) Cold-finished shafting, when not specified by the purchaser in any particular grade, shall be in

such grades as are in accordance with the manufacturer's practice for the respective sizes.

MANUFACTURE

3. (a) Bar steel shall be made by the open-hearth or Bessemer process, as specified.

(b) Shafting shall be made by either or both the following processes: Bessemer or open-hearth.

CHEMICAL PROPERTIES AND TESTS

4. Bar steel shall conform to the requirements as to chemical composition specified in Tables 1 and 2 for the respective grades.

TABLE 1.—Grades and chemical compositions for commercial cold-finished bar steels

BESSEMER GRADES			
Grades	Carbon	Manganese	Phosphorus
Bessemer soft, maximum.....	<i>Per cent</i> 0.15	<i>Per cent</i> 0.60	<i>Per cent</i> 0.11

(Bessemer screw and open-hearth screw grades are identical with like grades in A. S. T. M. A107-30, given above. Open-hearth grades ranging from 0.05-0.15 to 0.40-0.50 carbon per cent are the same as in A. A. S. M. commercial quality bar steel, given below, except for 0.005 per cent more phosphorus in A. S. T. M. A108, and 0.005 per cent more sulphur in the A. A. S. M. specification.)

5. An analysis of each melt of open-hearth steel shall be furnished by the manufacturer when requested, showing the percentage of the elements specified, which shall conform to the requirements for the grade specified in Table 1 (including reference to the A. A. S. M. specification).

CHECK ANALYSES

6. (a) Analyses may be made by the purchaser from finished bars representing each melt of open-hearth steel and each melt, or lot of 10 tons, of Bessemer steel. The chemical composition thus determined shall conform to the requirements in Table 1, with the permissible variations in ranges and in maximum limits specified in Table 2.

(b) Samples for analysis shall be taken by machining off the entire cross section of the bar, or by drilling parallel to the axis of the bar at any point midway between the center and surface.

PERMISSIBLE VARIATIONS IN DIMENSIONS

7. The variations from the specified diameters, or distances between parallel faces, of cold-finished bars specified in carbon up to and including 0.30 per cent shall not exceed the limits specified in Table 3. For bars specified in carbon over 0.30 per cent, the variations shall be a matter of agreement between the purchaser and the manufacturer.

(b) The variations from the specified diameters of cold-finished shafting shall not exceed the limits specified in Table 4.

(In respect to finish, inspection, rejection, and reheating, this specification conforms to the requirements specified in A. S. T. M. standard specifications for steel. See 605.0, p. 247.)

TABLE 2.—Variations in ranges and in maximum limits specified in Table 1 permitted on check analysis

(Open-hearth and Bessemer screw stock not included)

OPEN-HEARTH GRADES

Grades	Permissible variations from limits specified in Table 1					
	Carbon		Manganese		Phosphorus, over maximum	Sulphur, over maximum
	Under lower limit	Over upper limit	Under lower limit	Over upper limit		
Open-hearth 05-15 carbon		0.03	0.05	0.05	0.01	0.01
Open-hearth 10-20 and 15-25 carbon	0.02	.04	.05	.05	.01	.01
Open-hearth 20-30 and 15-35 carbon	.03	.06	.05	.10	.01	.01
Open-hearth 30-40 and 35-45 carbon	.03	.06	.05	.10	.01	.01
Open-hearth 40-50 carbon	.03	.07	.05	.10	.01	.01

ASSOCIATION OF AMERICAN STEEL MANUFACTURERS, STANDARD SPECIFICATIONS FOR COMMERCIAL-QUALITY BAR STEEL, 1924

COMMERCIAL-QUALITY BAR STEEL

1. *Scope.*—These specifications cover hot-rolled carbon-steel bars, produced in accordance with good mill practice for general commercial purposes. Bars for drop-forging and heat-treatment purposes should be purchased to the Association of American Steel Manufacturers' standard specifications for special forging-quality bar steel. (See 603.24, p. 149.)

2. *Process.*—The steel shall be made by the open-hearth process or the Bessemer process, as specified.

3. *Chemical composition.*—The steel shall conform to the requirements as to chemical composition specified in the following table:

Chemical compositions

	Carbon	Manganese	Phosphorus (maximum)	Sulphur (maximum)
	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>
Open-hearth steel	0.05-0.15	0.30-0.60	0.04	0.055
	.10-.20	.30-.60	.04	.055
	.15-.25	.30-.60	.04	.055
	.20-.30	.50-.80	.04	.055
	.25-.35	.50-.80	.04	.055
	.30-.40	.50-.80	.04	.055
	.35-.45	.50-.80	.04	.055
	.40-.50	.50-.80	.04	.055
	.45-.55	.50-.80	.04	.055
	.50-.65	.50-.80	.04	.055
Bessemer steel	.55-.70	.50-.80	.04	.055
	.60-.75	.50-.80	.04	.055
	.65-.80	.50-.80	.04	.055
	.05-.10	.30-.60	.11	.08
	.08-.15	.40-.70	.11	-----
	.15-.25	.50-.90	.11	-----
	.25-.35	.50-.90	.11	-----
	.30-.40	.50-.90	.11	-----
	.40-.50	.50-.90	.11	-----
	.50-.60	.60-1.00	.11	-----

4. *Ladle analysis.*—(a) For Bessemer steel a carbon determination shall be made of each melt, and determinations for manganese, phosphorus, and sulphur, representing the average of the melts made in each 12-hour period.

(b) For open-hearth steel an analysis of each melt shall be made for carbon, manganese, phosphorus, and sulphur.

(c) These analyses shall be made by the manufacturer from test ingots taken during the pouring of each melt. The chemical composition thus determined shall conform to the requirements specified, and shall be reported to the purchaser or his representative, if requested.

5. *Check analyses.*—Check analyses of the finished material may be made by the purchaser, using samples obtained in accordance with the manufacturers' standard methods of sampling for check analysis. (See 600.1, p. 47.) The average chemical composition thus determined shall not vary from the limits specified more than 0.03 over or 0.02 under in carbon, 0.03 over or 0.02 under in manganese, 0.005 over in phosphorus, and 0.005 over in sulphur.

6. *Permissible variations in dimensions.*—The dimensions of bars shall conform to the manufacturers'

standard practice governing the allowable variations in size of hot-rolled bars. (See 600.7, p. 116.)

7. *Finish*.—The bars shall have as good surface finish as is consistent with good hot-mill practice. They shall be free from injurious piping and undue segregation, and free from surface defects which would be injurious for general or ordinary purposes.

8. *Rejection*.—(a) Any rejection for chemical composition must be based on the manufacturers' standard methods of sampling for check analysis. (See 600.1, p. 47.)

(b) The manufacturer shall be notified, within six months from date of shipment, of any rejection at destination.

9. *Rehearing*.—Samples analyzed in accordance with sections 5 and 8, which represent material rejected by the purchaser, shall be preserved for one month from the date of notice to the manufacturer. In case of dissatisfaction with the results of the tests, the manufacturer may make claim for a rehearing within that time.

603.24 STEEL FOR SHAFTS, AXLES, AND FORGINGS.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR COMMERCIAL COLD-FINISHED BAR STEELS AND COLD-FINISHED SHAFTING, DESIGNATION A108-30, 1930

BAR STEELS AND SHAFTING

(See 603.23, p. 147.)

ASSOCIATION OF AMERICAN STEEL MANUFACTURERS, STANDARD SPECIFICATIONS FOR SPECIAL FORGING-QUALITY BAR STEEL, 1924

FORGING-QUALITY BAR STEEL

1. *Scope*.—These specifications cover hot-rolled carbon-steel bars, in the manufacture of which special precautions are taken with a view of securing material suitable for forging, heat treating, or similar purposes.

2. *Process*.—The steel shall be made by the open-hearth process.

3. *Discard*.—A sufficient discard shall be made from each ingot to secure freedom from injurious piping and undue segregation.

CHEMICAL COMPOSITION

(Chemical composition is identical with that for commercial-quality bar steel for carbon percentages ranging from 0.05-0.15 to 0.65-0.80 except for the addition in commercial-quality bar steel of 0.005 per cent of sulphur in each grade of open-hearth steel. See 603.23, p. 148.)

5. *Ladle analysis*.—(Conforms with commercial-quality bar steel. See 603.23, p. 148.)

6. *Check analyses*.—(a) Check analyses of the finished material may be made by the purchaser, using samples obtained in accordance with the manufacturers' standard methods of sampling for check analysis. (See 600.1, p. 47.) The average chemical composition thus determined shall not vary from the limits specified more than 0.02 over or under in carbon, 0.02 over or under in manganese, 0.005 over in phosphorus, and 0.005 over in sulphur.

(b) The chemical compositions of individual samples shall not exceed the permissible variations

specified below, and no single melt shall vary both above and below the range specified.

Variations from limits of chemical compositions permitted in individual samples

Elements	Permissible variations	
	Under lower limit	Over upper limit
Carbon—maximum limits up to 0.25, inclusive.....	0.02	0.03
Carbon—maximum limits over 0.25 to 0.30, inclusive.....	.03	.04
Carbon—maximum limits over 0.30 to 0.80, inclusive.....	.03	.05
Manganese—all ranges.....	.05	.05
Phosphorus.....01
Sulphur.....01

(Permissible variations in dimensions, and finish, rejection, and rehearing, conform with specifications for commercial-quality bar steel, including references therein to A. A. S. M. under 600.1 and 600.7. (See 603.23, p. 148.)

AMERICAN SOCIETY OF AUTOMOTIVE ENGINEERS, IRON AND STEEL SPECIFICATIONS; SPECIFICATIONS FOR AUTOMOTIVE STEELS, S. A. E. STANDARD, FEBRUARY, 1929

CARBON STEELS

(See 603.27, p. 150 including certain references to 600.0, p. 2, and 600.1, p. 49.)

603.25 STEEL REINFORCING BARS AND RODS.

(See 605.25.)

603.26 STEEL BARS AND RODS FOR WELDING.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, STANDARD SPECIFICATION FOR WELDING RODS, W46-30, 1930

WELDING RODS

SCOPE

The specification is intended to cover the manufacture and general characteristics of plain uncoated steel arc-welding rods for purchase and use by the electric-railway industry. Coated, covered, flux-bearing welding rods, or those produced by patented processes, are not intended to be covered by this specification.

I. MANUFACTURE

Process

101. (a) The steel for the welding rod shall be either hot-rolled or cold-drawn from crucible, electric-furnace, or open-hearth steel, as specified by the purchaser.

(b) The welding rod shall be commercially straight, of uniform longitudinal structure, and free from irregularities in surface and hardness, segregation, pipes, and seams.

(c) The welding rod shall be unannealed, unless otherwise specified by the purchaser.

Chemical Composition

102. (a) *High-carbon welding rod (for metallic-arc welding)*—

	Per cent
Carbon.....	0.95-1.10
Manganese.....	.45-.65
Phosphorus, not more than.....	.03
Sulphur, not more than.....	.03
Silicon, not more than.....	.20

(b) *Medium low-carbon welding rod (for metallic and carbon arc welding)*—

	Per cent
Carbon.....	0.13-0.18
Manganese.....	.40-.60
Phosphorus, not more than.....	.03
Sulphur, not more than.....	.035
Silicon, not more than.....	.06

(c) *Extra low carbon welding rod (for metallic and carbon arc welding)*—

	Per cent
Carbon, not more than.....	0.05
Manganese, not more than.....	.30
Phosphorus, not more than.....	.025
Sulphur, not more than.....	.025
Silicon.....	Trace.

Tolerances

103. (a) The diameter of the welding rod shall not vary more than 0.003 inch over or under that specified.

(b) The length of the welding rod shall not vary more than one-fourth inch under or over that specified.

II. SIZES

201. The following sizes shall be considered standard, as covered by this specification:

(a) *High-carbon welding rod.*— $\frac{3}{16}$ by 36 inches; $\frac{1}{4}$ by 36 inches.

(b) *Medium low-carbon welding rod.*— $\frac{5}{32}$ by 24 inches; $\frac{1}{4}$ by 24 inches; $\frac{3}{16}$ by 24 inches; $\frac{3}{32}$ by 24 inches.

(c) *Extra low carbon welding rod.*— $\frac{5}{32}$ by 24 inches; $\frac{3}{16}$ by 24 inches; $\frac{3}{32}$ by 24 inches.

III. PHYSICAL PROPERTIES AND TESTS

301. The purchaser or his representatives shall select two welding rods from three separate bundles selected at random from each 1,000-pound lot, or less, and these welding rods in the hands of an experienced welder shall demonstrate good welding properties such as smooth even flowing, without excessive sputtering at the arc or other unusual characteristics when tested in positions encountered in actual welding practice. The deposited metal must be free from blow holes or gas pockets. If the test welding rods do not pass this test the shipment from which the welding rods were selected shall be rejected.

IV. WORKMANSHIP AND FINISH

401. The surface of the welding rod shall be smooth and free from rust, oil, grease, or any other injurious substance.

V. MARKING AND SHIPPING

501. (a) The welding rods shall be securely tied in bundles weighing 50 pounds each, net weight, and fully wrapped in burlap or other suitable covering to protect them from moisture, etc.

(b) To each bundle shall be securely attached a tag bearing the size, specification number, and the name of the manufacturer.

VI. INSPECTION AND REJECTION

601. (a) Unless otherwise agreed upon, the purchaser will make the tests to govern the acceptance

or rejection of the welding rod. Such tests shall be made at the expense of the purchaser.

(b) Any rejection based on tests made in accordance with this specification shall be reported within 10 working days after the receipt of the welding rod.

603.27 STEEL BARS AND RODS FOR AUTOMOTIVE AND RAILWAY USE.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, SPECIFICATION FOR MATERIALS FOR USE IN THE MANUFACTURE OF SPECIAL TRACKWORK, W104-28, 1928

[Approved as tentative American Standard by the American Standards Association, January 23, 1929]

SPECIAL TRACKWORK MATERIALS

(See 606.3, p. 342.)

SOCIETY OF AUTOMOTIVE ENGINEERS, IRON AND STEEL SPECIFICATIONS, CHEMICAL COMPOSITIONS, JUNE, 1929

CARBON STEELS

(For prefatory remarks, see 600.0, p. 2; for specification details, see 600.1, p. 49.)

Chemical composition

1360 ¹55-.70	.90-1.20	.040	.050

¹ The silicon content for steels Nos. 1350 and 1360 shall not exceed 0.30 per cent.

603.3 SPRING AND TOOL STEEL BARS AND RODS.

603.31 DRILL TOOL STEEL BARS AND RODS.

(No nationally recognized specifications available.)

603.32 HAND, HIGH-SPEED, AND MACHINE TOOL STEELS.

AMERICAN RAILWAY ASSOCIATION, PURCHASES AND STORES DIVISION, STANDARDIZATION AND SIMPLIFICATION OF STORES STOCKS, D-V1-238, 1930

CARBON TOOL STEEL

(Recommended practice in stocking certain specified sizes of octagon, square, and round carbon tool steel.)

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR MOVABLE RAILWAY BRIDGES, TOOL STEEL, 1929

(See also 611.41, p. 707; 611.51, p. 753; 647.31, p. 1268; 692.1, p. 1320.)

TOOL STEEL

Tool steel shall be made by the open-hearth or the crucible process. It shall conform to the following chemical requirements:

	Per cent
Carbon, minimum.....	1.00
Phosphorus, maximum.....	.04
Sulphur, maximum.....	.04
Manganese, maximum.....	.50

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR CARBON TOOL STEEL, DESIGNATION A71-26, 1926

CARBON TOOL STEEL

SCOPE

- (a) These specifications cover carbon tool steels, the composition of which shall be as agreed upon by the purchaser and the vendor, with the permissible variations specified in section 4.
- (b) These steels are suitable for lathe and planer tools, drills and milling cutters, dies and other miscellaneous purposes, etc.

MANUFACTURE

- The steel shall be made either by the crucible or electric-furnace process.
- The steel shall be furnished unannealed unless otherwise specified.

CHEMICAL PROPERTIES AND TESTS

- The composition of the tool steels shall be as agreed upon by the purchaser and the vendor, with the following permissible variations in composition:

	Permissible variation	
	Over	Under
Carbon.....	Per cent 0.05	Per cent 0.05
Manganese:		
When under 1.00.....	.10	.10
When over 1.00.....	.20	.20
Phosphorus.....	.005	-----
Sulphur.....	.005	-----
Silicon.....	.15	.15
Other elements as agreed.		

- (a) Milled samples for analysis shall be taken from the sample bar to represent the full cross section, or drillings shall be taken by drilling a bar midway between the center and the surface, parallel to the axis of the bar. In either case, the decarburized material shall be rejected.
- (b) In general, the minimum depth to which the surface shall be removed before a sample is taken shall be in accordance with the following requirements:

Thickness or diameter (in inches)	Material removed
1 or under.....	Inch 1/32
Over 1 to 2 1/2, inclusive.....	1/16
Over 2 1/2 to 4, inclusive.....	1/8
Larger sizes.....	As agreed.

- (c) In the case of drill rod and other material of similar finish where freedom from decarburization is specified, samples shall be taken from the surface in addition to the methods described in paragraph (a).
- In case of dispute, the chemical analysis shall be made in accordance with the standard methods of chemical analysis of plain carbon steel. See A. S. T. M. A33 (600.1, p. 10).

MANUFACTURING TOLERANCES IN DIMENSIONS

- Variations in the cross-sectional dimensions of the material shall not exceed the following amounts:

FORGED AND ROLLED MATERIAL

	Permissible variation	
	Over	Under
1/2 inch or under.....	Inch 0.010 (1/100)	Inch 0.010 (1/100)
Over 1/2 inch to 1 inch, inclusive.....	.015 (3/164)	.015 (3/164)
Over 1 inch to 1 1/2 inches, inclusive.....	.031 (3/82)	.031 (3/82)
Over 1 1/2 inches to 2 inches, inclusive.....	.046 (3/64)	.031 (3/82)
Over 2 inches to 4 inches, inclusive.....	.125 (1/8)	.031 (3/82)
Over 4 inches to 6 inches, inclusive.....	.156 (3/32)	.031 (3/82)
Over 6 inches to 8 inches, inclusive.....	.188 (3/16)	.063 (1/16)
Over 8 inches.....	.250 (1/4)	.063 (1/16)

FINISHED MATERIAL (DRILL ROD)

3/16 inch and under.....	0.0005	0.0005
Over 3/16 inch.....	.001	.001

FINISH

- (a) The material shall be free from injurious defects and shall have a workmanlike finish.
- All drill rods shall be coated with a rust preventive.

MARKING

- (a) Identification marks shall be stamped on the material as agreed by the purchaser and the vendor. All identification marks shall be about one-fourth inch in height when the size permits.
- (b) In lieu of marking as specified in paragraph (a), the ends of bars and rods may be painted as agreed by the purchaser and the vendor.
- All rods and bars of which the largest cross-sectional dimension is three-eighths inch or less shall be boxed or bundled, each box or bundle to contain bars or rods of the same size, shape, and class of material. A metal tag shall be securely attached to the wrapping wire or box. Rods and bars of cross-sectional dimensions exceeding three-eighths inch and not exceeding 1 1/2 in., where convenient to purchaser and vendor, may be bundled and marked as specified above. Bundles shall be of suitable size to permit easy handling and shall be securely fastened.

INSPECTION AND REJECTION

- The vendor shall afford the inspector, without charge, all reasonable facilities to satisfy him

that the material is being furnished in accordance with these specifications.

12. The steel shall correspond in quality and characteristics to the samples submitted under the specifications and approved by the purchaser.

13. Material which does not conform to the chemical composition and specified dimensions, or which at any time shows injurious defects inherent in the steel, will be rejected and the vendor shall be notified.

603.33 SPRING STEEL BARS AND RODS.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, SPECIFICATION FOR MATERIALS FOR USE IN THE MANUFACTURE OF SPECIAL TRACK WORK, W104-28, 1928

[Approved as tentative American Standard by the American Standards Association, January 23, 1929]

SPECIAL TRACK-WORK MATERIALS

(See 606.3, p. 342.)

AMERICAN RAILWAY ASSOCIATION, MECHANICAL DIVISION, STEEL BARS, CARBON, FOR RAILWAY SPRINGS, 1917

BARS FOR RAILWAY SPRINGS

(Identical with A. S. T. M. A14, given below, including references in A14 to A. R. A. and A. S. T. M. specifications, except for permissible variations in gage, which are as follows:)

PERMISSIBLE VARIATIONS IN GAGE

Permissible variations.—The dimensions of the bars shall not vary from those ordered more than the amount shown in the following table:

Flats

Size	Width		Thickness			
			Up to 3/8 inch, inclusive		Over 3/8 to 1/2 inch, inclusive	
	Over	Under	Over	Under	Over	Under
1 to 2 inches, inclusive.....	Inch 0.015	Inch 0.015	Inch 0.015	Inch 0.005	Inch 0.015	Inch 0.010
Over 2 to 4 inches, inclusive.....	.047	.015	.015	.005	.015	.010
Over 4 to 5 inches, inclusive.....	.047	.032	.015	.005	.015	.010
Over 5 to 6 inches, inclusive.....	.062	.032	.015	.005	.015	.010

Rounds and squares

Size	Diameter or thickness	
	Over	Under
Up to 1/16 inch, inclusive.....	Inch 0.005	Inch 0.005
Over 1/16 to 1/8 inch, inclusive.....	.007	.005
Over 1/8 to 3/16 inch, inclusive.....	.009	.005
Over 3/16 to 1/4 inch, inclusive.....	.010	.006
Over 1/4 to 5/16 inch, inclusive.....	.011	.007
Over 5/16 to 3/8 inch, inclusive.....	.012	.008
Over 3/8 to 1/2 inch, inclusive.....	.013	.009
Over 1/2 to 5/8 inches, inclusive.....	.014	.010
Over 5/8 to 3/4 inches, inclusive.....	.014	.010
Over 3/4 to 7/8 inches, inclusive.....	.016	.011
Over 7/8 to 1 inches, inclusive.....	.019	.012

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR CARBON-STEEL BARS FOR RAILWAY SPRINGS, DESIGNATION A14-27, 1927

BARS FOR RAILWAY SPRINGS

SCOPE

1. These specifications cover two grades of carbon-steel bars to be used for the manufacture of railway springs, determined by the carbon ranges specified in section 3. The choice of the grade of bar to be used for the manufacture of any spring will depend on the design of the spring and the stresses and service for which it is intended. The purposes for which these grades are frequently used are as follows: Grade A, for elliptical and helical springs; and grade B, for helical springs.

MANUFACTURE

2. The steel shall be made by one or more of the following processes: Open-hearth, crucible, or electric furnace.

CHEMICAL PROPERTIES AND TESTS

3. The steel shall conform to the following requirements as to chemical composition:

Elements considered	Grade A	Grade B
	Per cent	Per cent
Carbon.....	0.90-1.10	0.95-1.15
Manganese, maximum.....	.50	.50
Phosphorus, maximum.....	.05	.05
Sulphur, maximum.....	.05	.05

LADLE AND CHECK ANALYSES

(Same as in American Railway Association specification for steel tank plates. See 621.32, p. 1142.)

PERMISSIBLE VARIATIONS IN DIMENSIONS

6. The permissible variations in the width and thickness of the bars shall be:

Flats

	Variations in width		Variations in thickness			
			Up to 3/8 inch, inclusive		Over 3/8 to 1/2 inch, inclusive	
	Over	Under	Over	Under	Over	Under
1 to 2 inches, inclusive.....	Inch 0.030	Inch 0.015	Inch 0.015	Inch 0.005	Inch 0.015	Inch 0.010
Over 2 to 4 inches, inclusive.....	.047	.015	.015	.005	.015	.010
Over 4 to 6 inches, inclusive.....	.062	.032	.015	.005	.015	.010

Rounds and squares

	Variations in diameter or thickness	
	Over	Under
Up to 1/4 inch, inclusive.....	Inch 0.007	Inch 0.007
Over 1/4 to 1/2 inch, inclusive.....	.010	.010
Over 1/2 to 1 inches, inclusive.....	.016	.016

(Workmanship and finish, marking, inspection, and rejection, and reheating conform to paragraphs 5, 6, 7, 8, and 9 in A. S. T. M. standard specifications for steel. See 605.0, p. 247.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR CARBON-STEEL BARS FOR VEHICLE AND GENERAL PURPOSE SPRINGS, DESIGNATION A58-27, 1927

BARS FOR VEHICLE SPRINGS

SCOPE

1. These specifications cover two grades of carbon-steel bars to be used for the manufacture of vehicle and general purpose springs, determined by the carbon ranges specified in section 3. The choice of the grade of bar to be used for the manufacture of any spring will depend on the design of the spring and the stresses and service for which it is intended.

MANUFACTURE

2. The steel shall be made by one or more of the following processes: Open-hearth, crucible, or electric-furnace.

CHEMICAL PROPERTIES AND TESTS

3. The steel shall conform to the following requirements as to chemical composition:

Elements considered	Grade A	Grade B
	<i>Per cent</i>	<i>Per cent</i>
Carbon.....	0.85-1.05	0.90-1.05
Manganese.....	.25-.50	.25-.50
Phosphorus, maximum:		
Acid.....	.05	.05
Basic.....	.05	.04
Sulphur, maximum.....	.05	.05

LADLE AND CHECK ANALYSES

(Same as in American Railway Association specification for steel tank plates. See 621.32, p. 1124.)

PERMISSIBLE VARIATIONS IN DIMENSIONS

4. The permissible variations in the width and thickness of the bars shall be agreed upon by the manufacturer and the purchaser.

(Workmanship and finish, marking, inspection and rejection, and reheating conform to paragraphs 5, 6, 7, 8, and 9 in A. S. T. M. standard specifications for steel. See 605.0, p. 247.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR CARBON-STEEL BARS FOR RAILWAY SPRINGS WITH SPECIAL SILICON REQUIREMENTS, DESIGNATION A68-27, 1927

BARS FOR RAILWAY SPRINGS

(Identical with A. S. T. M. A14, given above, including references in A14 to A. R. A. under 621.32, and A. S. T. M. standard specifications for steel under 605.0, with the exception that the two grades of carbon steel in A68 have special silicon requirements. These requirements are specified under chemical composition as a silicon percentage in grades A and B of 0.25 to 0.50, respectively.)

		2-0			.380
			3-0		.372
2 0					.365
	3-0				.3625
			2-0	90	.354
		0			.348
					.340
0	2-0				.3310
			0		.325
					.324
				80	.315

¹ In this table the values printed in boldfaced type are exact as given; values which are not exact have been rounded off to four significant figures, except that the diameters in inches of the American (B. & S.) wire gage and of the metric wire gage in the column headed "Diameter, inches," have been given to 0.001 inch for the larger sizes and to 0.0001 inch for the smaller. This represents the usual degree of accuracy in the measurement of wires.

² The steel wire gage is the same gage which has been known by the various names: "Washburn and Moen," "Roebbling," "American Steel and Wire Co.'s." Its abbreviation should be written "Stl. W. G.," to distinguish it from "S. W. G.," the usual abbreviation for the (British standard) wire gage.

Combined table of sizes in the principal wire gages¹—Continued

The use of each particular type of electrode is specified below.

SCOPE

2. The electrodes herein specified are recommended as covering the usual railroad, shipyard, and industrial requirements as are allowed by authoritative regulating bodies, such as the American Bureau of Shipping, the Interstate Commerce Commission, etc.

MATERIAL

3. Material made by the puddling process is not permitted.

PHYSICAL PROPERTIES

4. Electrodes shall be made of commercially straight wire of uniform homogeneous structure, free from irregularities in surface hardness, segregation, oxides, pipe, seams, etc. Diameter shall not vary more than plus or minus 3 per cent from diameter specified.

NOMENCLATURE

5. The prefix letter E is to indicate that the material is intended for electric-arc welding.

CHEMICAL COMPOSITION

6. The chemical composition of electrodes shall be within the following limits for uses specified:

LOW CARBON IRON OR STEEL

E-No. 1A

Carbon.....	Not over 0.06 of 1 per cent.
Manganese.....	Not over 0.15 of 1 per cent.
Phosphorus.....	Not over 0.04 of 1 per cent.
Sulphur.....	Not over 0.04 of 1 per cent.
Silicon.....	Not over 0.08 of 1 per cent.

E-No. 1B

Carbon.....	0.13-0.18 of 1 per cent.
Manganese.....	0.40-0.60 of 1 per cent.
Phosphorus.....	Not over 0.04 of 1 per cent.
Sulphur.....	Not over 0.04 of 1 per cent.
Silicon.....	Not over 0.06 of 1 per cent.

The difference between E-No. 1A and E-No. 1B electrodes is one of chemical composition incident to manufacture only. In order to assure uniformity of product, close limits are demanded. Either E-No. 1A or E-No. 1B may be supplied unless the purchaser, in ordering, specifically excludes either.

MEDIUM CARBON STEEL

The data at hand show that bare steel electrodes having a carbon content of 0.18 to 0.85 are of no particular value.

HIGH CARBON STEEL

E-No. 1C

Carbon.....	0.85-1.10 per cent.
Manganese.....	0.30-0.60 of 1 per cent.
Phosphorus.....	Not over 0.04 of 1 per cent.
Sulphur.....	Not over 0.04 of 1 per cent.

RECOMMENDED SIZE

7.

Diameter (in inches)

E-No. 1A and E-No. 1B.....	1/16, 3/32, 1/8, 5/32, 3/16, 1/4.
E-No. 1C.....	1/8, 3/32, 1/16, 1/32, 1/4, 5/32, 3/16.

USES

8. E-No. 1A and E-No. 1B for welding mild steel, structural shapes, plates, bars, or low-carbon steel forgings and castings. E-No. 1C for welding high-carbon steel and worn surfaces where great resistance to abrasive wear is desired, and where machin-

603.41 BARE AND COATED IRON AND STEEL WIRE.

AMERICAN BUREAU OF WELDING, WELDING WIRE SPECIFICATIONS AND FOLIOS, BULLETIN NO. 2, 1921

BARE IRON AND STEEL ELECTRODES

GENERAL

1. The following specifications prefixed by the letter E are recommended for the purchase of all bare iron and steel electrodes for use in arc welding.

ing is not necessary, such as rails, frogs, switch points, bearing surfaces, etc.

SURFACE FINISH

9. The surface shall be smooth and free from rust, oil, or grease.

TESTS

10. In the hands of an experienced welder electrodes shall demonstrate good weldability in flat and overhead positions, and shall pass through the arc smoothly and evenly without any unusual characteristics.

PACKING

11. Electrodes shall be delivered in coils or in straight 14-inch lengths, packed and wrapped as follows:

- (a) Bundles of 50 pounds net weight, securely wired and wrapped in heavy weatherproof paper.
- (b) Bundles of 50 pounds net weight, securely wrapped in heavy burlap.
- (c) Boxes or kegs of 100, 200, or 300 pounds net weight, and wrapped as per paragraph (a).
- (d) Boxes or kegs of 100, 200, or 300 pounds net weight, and wrapped as in paragraph (b).
- (e) Coils of approximately 50 or 100 pound net weight, and wrapped as per paragraph (a) or (b).

MARKING

12. All bundles, coils, boxes, or kegs shall be provided with a metal, linen, or strong fiber tag securely wired to, or in the case of boxes or kegs, nailed on the outside, bearing the following information:

Make.....
 Specif. No.....
 Dia.....
 Nom. Weight.....

ORDERING

13. Material ordered under these specifications shall be known as:

"Electrodes, iron and steel, bare," American Welding Society Specifications Number 1, Revised May 1, 1921.

All orders should be specified in pounds. In addition, requisitions shall show the following:

Specif. No.
Size
Packing

As a guide in ordering, the following information is of use:

Size, inches.....	1/16	3/32	1/8	5/32	3/16	7/32	1/4	5/16	3/8
Pounds per 100 feet.....	1.04	2.3	4.1	6.5	9.3	12.76	16.7	21.0	26.0
Feet per 100 pounds.....	9,615	4,273	2,403	1,537	1,067	700	600	473	383
Mils.....	63	94	125	156	188	218	250	281	312

GAS WELDING RODS

(In respect to scope, material, chemical composition of No. 1A rods, uses, tests, packing, marking, the specifications for gas welding rods are identical with those for electrodes, given above, with the following exceptions:)

PHYSICAL PROPERTIES

4. Welding rods shall be made of annealed wire.

NOMENCLATURE

5. The use of the prefix letter G is to indicate that the material is intended for gas welding.

RECOMMENDED SIZES

7.

Diameter (in inches)..... 1/16, 3/32, 1/8, 5/32, 3/16, 1/4, 5/16, 3/8

SURFACE FINISH

9. The surface shall be smooth and free from scale, rust, oil or grease, and may be plain or copper coated.

PACKING

11. Welding rods shall be delivered in coils or in straight 36-inch lengths (packed and wrapped as specified for electrodes above). (Information for ordering is the same as above for electrodes except that there is no 7/32-inch gas welding rod. Chemical analyses of coated or covered electrodes and of gas welding rods for welding high-carbon steels, non-ferrous metals, and mild steel are appended to these specifications as a guide in selecting welding material. They do not form part of the specifications.)

AMERICAN RAILWAY ASSOCIATION, MECHANICAL DIVISION, SPECIFICATIONS FOR WELDING WIRE AND RODS, 1924

WELDING WIRE AND RODS

SCOPE

1. This specification covers six classes of material, as follows:

- A or B. Wire for gas or electric welding of wrought iron, and cast or wrought steel.
- C. Cast-iron welding rods for gas welding of gray cast iron.
- D. Brass welding rods for gas welding of miscellaneous brass and gray cast-iron parts. (For chemical composition see 645.11, p. 1203.)
- E or F. Aluminum welding rods for gas welding all parts made of aluminum. (For chemical composition see 631.31, p. 1157.)

PHYSICAL PROPERTIES

2. All wire and rods shall be commercially straight, of uniform homogeneous structure, and shall be free from oxides, slivers, seams, and all other injurious physical defects. Class A shall be furnished annealed or unannealed as specified on the order.

CHEMICAL COMPOSITION

3. Welding wire and rods shall conform to the following chemical composition:

	Class A (maximum)	Class B (maximum)	Class C
Carbon.....	Per cent 0.06	Per cent 0.13-0.18	Per cent 1.3-0.0
Manganese.....	.15	.40-.60	0.50-0.75
Phosphorus.....	.04	.04	.50-0.70
Sulphur.....	.04	.04	2.10
Silicon.....	.08	.06	12.90

¹ Minimum.

² Maximum.

WELDING TEST

4. Welding wire and rods shall render satisfactory welding properties and shall flow smoothly and evenly without unusual characteristics when used by a competent operator upon the class of work for which intended.

SAMPLES FOR CHEMICAL ANALYSIS

5. From each class of material ordered upon every shipment, one sample for chemical analysis shall be taken, representative of each lot of 1,000 pieces or less, when cut to length, or of each five coils of uncut wire. This analysis shall in each case conform to the requirements of section 3.

DIMENSIONS AND TOLERANCES

6. Welding wire and rods shall conform closely to the dimensions specified upon orders. Drawn wires shall not vary more than 3 per cent from the diameter specified. Cast rods shall not vary more than 10 per cent from the diameter specified. All electrodes shall be furnished in 14-inch lengths and drawn wire for gas welding in 36-inch lengths, unless otherwise specified. Cast rods shall be furnished in lengths of not less than 12 inches.

WORKMANSHIP AND FINISH

7. Welding wire and rods shall have a smooth clean surface, free from rust and scale, and shall not carry more than a slight trace of oil or grease.

PACKING AND MARKING

8. Rods, and welding wire cut to length, shall be securely tied at both ends with wire and wrapped in heavy weatherproof paper or burlap for shipment in bundles of 50 pounds net weight. If the manufacturer desires, the wire and rods may be packed in suitable boxes or kegs of 100 or 200 pounds net weight. Wire ordered in coils shall be furnished in coils of approximately 50 pounds net weight, unless otherwise specified. Each bundle of rods or wire cut to length, and each coil of wire, shall be provided with a linen or metal tag, securely wired on, showing the manufacturer, the letters A. R. A. and the class of wire, and the diameter and nominal weight. (Inspection, rejection, and rehearing are substantially the same as in A. S. T. M. standard specifications for steel. (See 605.0, p. 247.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR COLD-DRAWN STEEL WIRE FOR CONCRETE REINFORCEMENT, DESIGNATION A82-27, 1927

STEEL WIRE FOR CONCRETE REINFORCEMENT

(See 605.25, p. 305.)

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR WELDING WIRE, IRON AND STEEL, NO. 174, JUNE 30, 1924. (CURRENT DESIGNATION: QQ-W-351)

WELDING WIRE, IRON AND STEEL

GRADES AND TYPES

1. (a) This specification covers three types of welding wire, viz:
 - I. Electrodes, iron and steel, bare.
 - II. Gas welding, wire, iron, and steel, plain.
 - III. Cast-iron welding rod.
- (b) The welding wire shall be of grades as given in Tables 1, 2, 3, paragraph 5 (a).

MATERIAL

2. (a) Welding wire made by the puddling process will not be accepted.

GENERAL REQUIREMENTS

3. (a) Electrodes shall be made of straight wire of uniform homogeneous structure free from irregularities in surface hardness, segregation, oxides, other nonmetallic inclusions, pipes, seams, etc. The surface shall be free from scale and rust, and shall be free from oil or grease except that resulting from the last drawing operation.

(b) Gas welding rods shall be made of annealed, straight wire of uniform homogeneous structure free from irregularities in surface hardness, segregation, oxides, other nonmetallic inclusions, pipes, seams, etc. The surface shall be free from scale, rust, oil, or grease.

(c) Cast-iron welding rods shall be of uniform homogeneous structure, straight, cleaned, and free from rust, sand, dirt, scale, oil, or grease.

(d) The diameter of all wire except cast iron shall not vary more than plus or minus 3 per cent from the diameter specified.

DETAIL REQUIREMENTS

4. (a) The welding wire shall conform to the requirements shown in Tables 1, 2, and 3 below.

TABLE 1.—Chemical composition electrodes, iron and steel, bare

Grades	C	Mn	P (maximum)	S (maximum)	Si (maximum)
	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>
A.....	¹ 0.06	¹ 0.15	0.04	0.04	0.08
B.....	0.10- .18	0.40- .60	.04	.04	.06
C.....	.35- .45	.40- .60	.04	.04	.15
D.....	.85- 1.10	.30- .60	.04	.04	.25

¹ Maximum.

TABLE 2.—Chemical composition gas-welding wire, iron and steel, plain

Grade	C	Mn	P (maximum)	S (maximum)	Si
	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>
E.....	¹ 0.06	¹ 0.15	0.04	0.04	¹ 0.08
F.....	0.10- .18	0.45- .60	.04	.04	¹ .06
G.....	.20- .30	.40- .60	.04	.04	(²)

¹ Maximum.

² Ni, 2.00 to 3.50 per cent; Cr (maximum), 0.20.

TABLE 3.—Chemical composition cast-iron welding rod

Grade	Total C	Mn	P	S (maximum)	Si
	<i>Per cent</i>				
H.....	3.00-3.50	0.50-0.75	0.50-0.70	0.10	3.00-3.50

METHODS OF INSPECTION AND TESTS

5. (a) Electrodes shall demonstrate good weldability in flat and overhead positions and shall pass through the arc smoothly and evenly without any unusual characteristics. Gas welding and cast-iron

welding rods shall demonstrate good weldability and shall flow smoothly and evenly without any unusual characteristics.

(b) Check chemical analyses may be made by the inspector or through him by any Government laboratory or other designated representative and without cost to the contractor. The chemical composition thus determined shall conform to the requirements specified in the tables for the grade ordered.

(c) If a check analysis be made, a composite sample of not less than 4 ounces shall be taken for analysis from each 1,000 pounds or less. At least one wire from every size in each 1,000 pounds or less shall be selected. Where the 1,000 pounds or less consists of but one size, one wire from each of five bundles shall be selected. Samples shall consist of fine particles obtained by clipping, sawing, or drilling, depending on the size of the wire.

(d) *Umpire method of analysis.*—Suitable methods for umpire chemical analysis are being developed and will be added at later revision.

6. (a) Electrodes shall be delivered straight in 14-inch lengths, gas-welding wire straight in 36-inch lengths, and cast-iron rods in 12 to 20 inch lengths, in bundles of 50 pounds net weight securely wired and wrapped in heavy waterproof paper and burlap. Each bundle shall be provided with a metal tag and indelibly marked with the manufacturer's name, grade, quantity, diameter of wire, and the contract or order number.

(b) Electrodes and gas-welding wire may be delivered in coils of 50 pounds net weight when so ordered. The coils to be securely wired, wrapped, and marked as specified above.

ADDITIONAL INFORMATION

7. (a) Coated or covered welding wire is not to be furnished under these specifications unless specifically required in the purchase order.

(b) Grades A, B, and E are used for welding mild steel structural shapes, plates, and bars, or low-carbon steel forgings and castings.

(c) Grade C is used for building up worn surfaces that require a machine finish.

(d) Grade D is used on high-carbon steels and worn surfaces subject to resistance to abrasive wear and where machining is not necessary.

(e) Grade F is used for welding mild steel and in general for same purpose as Grade E.

(f) Grade G is used for welding mild or nickel steels, producing a weld of greater strength than with Grades A, B, or C.

(g) Grade H is used for general welding of cast-iron parts.

(h) Grades covered in Tables 1 and 2 are furnished commercially in the following sizes: $\frac{1}{16}$, $\frac{3}{32}$, $\frac{1}{8}$, $\frac{5}{32}$, $\frac{3}{16}$, $\frac{1}{4}$, $\frac{5}{16}$, and $\frac{3}{8}$ inch. The grade covered in the Table 3 is furnished commercially in the following sizes: $\frac{3}{16}$, $\frac{1}{4}$, $\frac{3}{8}$, and $\frac{1}{2}$ inch.

603.42 BARE AND COATED WIRE ROPE.

AMERICAN ASSOCIATION OF STATE HIGHWAY OFFICIALS, TENTATIVE STANDARD SPECIFICATION FOR WIRE ROPE AND FITTINGS FOR HIGHWAY GUARD RAIL, M-30, 1927

WIRE ROPE AND FITTINGS

A. Material Covered

1. This specification covers $\frac{3}{4}$ -inch and 1-inch wire rope and fittings for use in the construction of wire-rope railing supported by wood or other suitable posts erected as indicated.

I. WIRE ROPE

B. General Requirements

2. All rope shall be manufactured of double-galvanized annealed steel having the properties hereinafter required. The wire shall be cylindrical in form and shall be free from scales, inequalities, flaws, and splits.

C. Physical Properties

3. *Galvanizing.*—Each wire from the rope shall be galvanized by the hot-dip method and shall have a continuous coating of zinc, of a uniform thickness, so applied that it will adhere firmly to the surface of the wire. The weight of zinc coating for each wire shall be 0.8 ounce minimum of zinc per square foot of surface after fabrication, and it shall be capable of withstanding four immersions in a standard testing solution of copper sulphate without showing any trace of metallic copper on the steel. The first three immersions shall be for a period of one minute each and the fourth immersion for a period of one-half minute.

4. *Three-fourths inch rope.*—The rope shall be composed of three strands, each strand having seven wires. The diameter of the finished rope shall not be less than three-fourths inch. The wire composing the rope shall be of such quality that the finished rope shall satisfy all the requirements hereinafter set forth. All the wires in the rope shall be of the same grade of steel and shall have approximately the same breaking strain.

5. The lay of the finished rope shall be not more than $7\frac{1}{2}$ inches. The lay of wires in the strand shall be not more than $4\frac{1}{2}$ inches.

6. The diameter of the finished wires entering into the rope shall be not less than 0.117 inch and not more than 0.124 inch.

7. The minimum tensile strength of the rope shall be 13,000 pounds.

8. *One-inch rope.*—The rope shall be composed of six strands with wire-strand center, each strand having seven wires. The diameter of the finished rope shall be not less than 1 inch. The wires composing the rope shall be of such quality that the finished rope shall satisfy the requirements hereinafter set forth. All the wires in the rope shall be of the same grade of steel and shall have approximately the same breaking strain.

9. The lay of the finished rope shall be not more than 10 inches. The lay of the wires in the strand shall be not more than $4\frac{1}{2}$ inches.

10. The diameter of the finished wires entering into the rope shall be not less than 0.105 inch and not more than 0.112 inch.

11. The minimum tensile strength of the rope shall be 30,000 pounds.

D. Marking and Shipping

12. All wire rope must be shipped upon substantial wooden reels. Each reel shall have the length and weight of the rope plainly and indelibly marked on a strong tag, firmly attached. The wooden reel shall be mounted so that it will revolve and the rope run off by pulling straight ahead.

II. EYEBOLTS

13. All eyebolts shall be drop-forged, 1 inch in diameter, with an eye having a minimum diameter of $1\frac{3}{8}$ inches. They shall be double galvanized by the hot-dip method. Each eyebolt of 12-inch and 24-inch lengths shall have double-galvanized wrought-iron washers and nuts attached, and these washers shall be at least one-eighth of an inch thick and 4 inches in diameter. The eyebolts of 48-inch lengths shall have attached washers consisting of steel plates, three-quarters of an inch thick and 6 inches in

diameter, or 5 inches by 5 inches, having a center hole 1¼ inches in diameter.

14. The eyebolts shall have a minimum tensile strength of 30,000 pounds.

15. The eyebolts shall be of the following lengths, the length specified being for the straight shaft only:

Length	Length, threaded
Inches 48	Inches 12
24	18
12	6

III. CLIPS

16. All clips shall be double galvanized and of approved design. Galvanizing shall be by the hot-dip process.

E. Sampling and Testing

17. Sampling and testing of wire rope and fittings for highway guard rail shall be in accordance with A. A. S. H. O. T-39, given below.

AMERICAN ASSOCIATION OF STATE HIGHWAY OFFICIALS, METHODS OF TEST FOR WIRE ROPE (GUARD RAIL), TENTATIVE METHOD T-39, 1931

TESTING WIRE ROPE

1. The report of the physical test of wire rope shall include the following information: Diameter of the rope, diameter of the wire, number of strands and wires, length of lay of strands and wires, cross-sectional area in square inches, breaking load in pounds, and a note as to whether the failure was in the body of the rope or at the socket.

DEFINITIONS

2. (a) The lay of the rope is the length expressed in inches for each complete turn of a strand around the axis of the rope measured along the axis.

(b) The lay of the strand is the length expressed in inches for each complete turn of a wire around the axis of the strand measured along the axis.

(c) The diameter of a wire rope is the diameter of a circle inclosing it.

3. The cross-sectional area of the rope shall be determined as follows: Measure the diameter of the component wires of a strand and obtain the mean diameter. The area calculated from the mean diameter of the wire multiplied by the number of wires in each strand and by the number of strands gives the aggregate area of the wires in the rope.

4. The test specimen for the tension test shall be free from bends and not less than 4 feet in length. Before cutting the test pieces from the coil of rope,

the ends must be "served" or wound about with wire for a length of about 1 inch to prevent the strands from unlaying.

PREPARATION OF SPECIMEN FOR TEST

5. A socket shall be attached to each end of the rope for the tension test. In preparing the rope for socketing the ends are first served or wound around with fine soft wire for a length of about one-half inch at the ends and also at a distance from the ends equal to the lengths of the basket of the socket. The ends of the rope are then slipped through the socket and the serving wire removed from the end only. Unlay the strands, separate the individual wires, and straighten them. Cut out the hemp center, if any. Cleanse the wire thoroughly with kerosene or gasoline and wipe dry. Tin the wires by dipping first in a mild zinc-chloride solution and then in molten zinc. When removed from the latter, they should be knocked with a stick or hammer to remove the excess zinc. Repeat the tinning until all the wires are thoroughly coated. Pull the frayed ends back into the basket of the socket and spread the wires evenly in the socket and even with the top of the basket. Put fire clay or asbestos fiber around the rope at the bottom of the socket, heat the socket for a short time with a blow torch, and pour in molten pure zinc (not babbitt or lead).

6. Put the sockets through the heads of the testing machine and place pins through the eyes of the sockets, using steel blocks on each side of the socket, if necessary, to secure a firm bearing (pins should be as large as possible). Apply the load slowly to give the strands and wires opportunity properly to bed upon one another during the application of the load. Continue loading until fracture of one or more strands of the rope occurs.

7. The uniformity of the galvanizing or spelter coating, if any, shall be determined in accordance with the method for uniformity of spelter coating.

AMERICAN BUREAU OF SHIPPING, RULES FOR BUILDING AND CLASSING STEEL VESSELS, 1930

STEEL WIRE ROPES

(For general information and requirements see 600.0, p. 2.)

1. When these are adopted for stream cables, tow-lines, hawsers, and warps, they are to be subjected to the following breaking tests in the presence of the surveyors of the American Bureau of Shipping. (Those marked with an asterisk (*) comprise standard equipment adopted by the American Bureau of Shipping for steam vessels, sailing vessels and barges, and for seagoing tugs.) Substitution of steel wire ropes of equivalent strength to those prescribed as standard equipment will also be approved as indicated in the table following.

[Diameter in inches]

Break test (in pounds)	Stranding

77,300	* 1 1/4	1 1/8	1 1/8	1	1 1/4	1 1/8	1 1/8	1	1 1/4	1 1/4	1 1/8	1 1/8
86,700	* 1 1/4	1 1/8	1 1/8	1 1/8	1 1/4	1 1/4	1 1/8	1 1/8	1 3/8	1 1/4	1 1/4	1 1/8
96,500	* 1 3/8	1 1/4	1 1/4	1 1/8	1 3/8	1 1/4	1 1/4	1 1/8	1 3/8	1 3/8	1 1/4	1 1/4
117,800	* 1 1/2	1 3/8	1 3/8	1 1/4	1 1/2	1 3/8	1 3/8	1 1/4		1 1/2	1 1/2	1 1/2

Manufacturers must furnish a certificate guaranteeing that the ropes will stand the above tests before breaking and that in addition the individual wires have been twisted around themselves at least eight times, then untwisted and straightened, without breaking.

This testing is to be open at any time to the inspection of the surveyors of the American Bureau of Shipping, who are also empowered to retest any wire rope, irrespective of any previous certificate in regard to same that may have been issued by a manufacturer.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, OVERHEAD LINE MATERIAL FOR DIRECT AND CATENARY SUSPENSION, RECOMMENDED SPECIFICATION, D102-30, 1930

OVERHEAD LINE MATERIAL

(D102-30, par. 313, includes requirements for galvanized steel strand cable. For specification see 611.29, p. 682.)

AMERICAN MARINE STANDARDS COMMITTEE, SHIP FITTINGS FOR DECKS AND RIGGING, H NO. 9-1926

WIRE ROPE SOCKETS

1. *Material.*—Wrought steel, 55,000 to 65,000 pounds per square inch tensile strength.

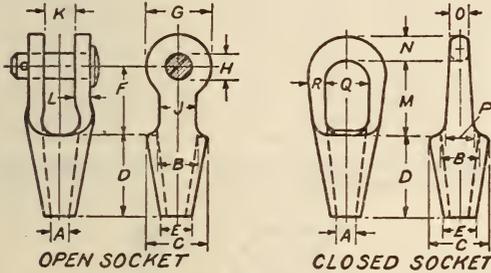

FIGURE 54.—Wire rope sockets

2. These sockets are commercially manufactured.
3. The sizes shown for pin H are commercial standards. Sockets with pins of different sizes, to

suit strength of rope used, can be procured if so specified in the purchase order.

4. Instructions for attaching sockets to rope is a subject for a separate standard.

AMERICAN MARINE STANDARDS COMMITTEE, SHIP FITTINGS FOR DECKS AND RIGGING, H NO. 10-1926

SOLID THIMBLES FOR WIRE ROPE

1. *Material.*—Cast iron, galvanized.
2. Thimbles for ropes to be wormed, parceled, or canvased and served, are to be of sizes to suit

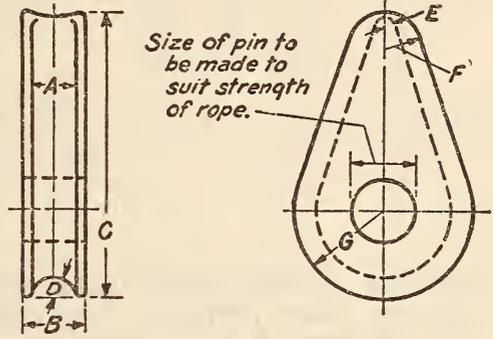

FIGURE 55.—Solid thimble

(For dimensions of solid thimbles for wire rope, see table top of p. 162.)

columns X and Y. (See general notes accompanying standard of rigging sockets with spliced ropes, H No. 6-1926 (608.7, p. 626).)

AMERICAN MARINE STANDARDS COMMITTEE, SHIP FITTINGS FOR DECKS AND RIGGING, H NO. 11-1926

OPEN THIMBLES FOR WIRE ROPE

1. Material.—Wrought steel, galvanized.
2. Wire rope thimbles as listed are commercial standards, excepting those with 2 3/4 and 3 inch scores, which are special sizes.
3. Thimbles for ropes to be wormed, parceled, or canvased and served, are to be of sizes to suit columns X and Y. (See general notes accompanying

standard of rigging screws with spliced ropes H No. 6-1926 (608.7, p. 626.)

AMERICAN MARINE STANDARDS COMMITTEE, STANDARD WIRE ROPES FOR MARINE USES, 0 NO. 25-1930

WIRE ROPES FOR MARINE USES

Section I. BASIC INFORMATION

1. Scope of Specifications

These specifications describe those types of wire ropes deemed most suitable for marine service. Uses are stated for the respective types to cover prevailing practices in different services, but only for general information and guidance of the users and not as part of the specifications.

2. Standard Defined

(a) *Steel rope grades.*—Steel ropes are made in a variety of grades and construction, some of which are marketed under various trade names. For the purpose of these specifications, uncoated cast-steel rope is made the basic standard, and this rope shall be supplied when another grade, or coated rope, is not specifically called for. This, however, shall not apply to the 6 by 24 and 6 by 12 ropes, types E and F, hereinafter described in subdivision 4, which are generally manufactured and marketed in galvanized form, and which shall be so furnished unless otherwise ordered. Four grades, which are deemed sufficient to cover all likely requirements of marine service, are classified as follows:

Grade classifications	Relative strengths of rope of equal size and construction	
	Uncoated	Galvanized
1. Cast steel.....	1.00	0.90
2. Extra strong cast steel.....	1.10	.99
3. Plow steel.....	1.20	1.08
4. Improved plow steel.....	1.37	1.23

The size of rope, choice of grade, and whether or not the rope should be galvanized are matters which depend upon the requirements and judgment of the user. If any one of the grades other than cast steel is required, or the rope is to be different in any particular from its standard herein defined, such special requirements must be specifically stated in ship contract specifications, in asking for quotations and in ordering. (See tables in Sec. II for the relative physical properties of ropes of various types and sizes.)

(b) *Diameter or size.*—The nominal diameter of a wire strand or of wire rope is its greatest diameter, which coincides with that of a circumscribing circle inclosing all wires and strands.

(c) *Lay and stranding.*—The lay of a strand or rope is the distance parallel to their respective axes in which a wire of the strand or a strand of the rope makes one complete turn about the axis. This is generally more for galvanized ropes than for uncoated ropes. (See Sec. III, par. 3.) The ropes comprised in these specifications are of right regular lay. In this type of construction, the wires form a left-hand helix about the axis of the strand, and the strands form a right-hand helix about the axis of the rope. The outer wires in the finished rope are approximately parallel to the axis of the rope.

(d) *Strand fabrication.*—All of the wires in a strand shall, so far as practicable in the process of

manufacture, be laid in a common helix, so that each wire is in continuous contact with the same adjacent wires. This may be accomplished in one or more operations of stranding, at the option of the manufacturer. This type of stranding is deemed best for marine work, especially for galvanized ropes; first, because the load is evenly distributed on, or carried by, all the wires; and, second, because the wires have the greatest possible surfaces in contact, and spot-wear or nicking across wires is avoided.

(e) *Cores.*—Hard fiber shall be the standard for all cores except the small sizes, which shall be cotton. Jute shall not be used. Cotton is used in the small sizes only because it can be spun into small diameters more satisfactorily than other fibers. Jute is unsatisfactory because, as compared with the harder fibers, it has less cellulose for its volume and is therefore weaker; it is also more hygroscopic and, therefore, subject to more rapid deterioration.

3. Kinds and Uses in General

(a) *Uncoated rope.*—This rope should be used for all purposes wherever it is protected from the elements, especially for hoisting. When used where it is exposed to the elements, a protective coating should be applied to it at regular intervals.

(b) *Galvanized rope.*—This rope is advisable only for standing rigging. It should not, in general, be used for hoisting or other services involving chafing or abrasion, because zinc coating is rapidly worn off by friction. Furthermore, galvanizing decreases the strength of the wires by about 10 per cent and, therefore, galvanized ropes must be correspondingly larger.

(c) *Marline-clad rope.*—(The covering of this rope has no relation to the marline covering or serving of wire ropes as applied on various parts of ships' standing rigging.) This type of rope is easily lubricated and coated for preservation. The marline covering protects the wires from wear and supplies them with lubricant. Compared with uncovered wire rope, it is appreciably larger for equivalent strength; it has a greater coefficient of friction on smooth drums, and the covering protects the wires against gases, grit, and moisture. It is not, however, advocated for heavy duty or services in which failure would endanger human life or cause material damage, because the wires are not visible for inspection.

(d) *Phosphor-bronze rope.*—Compared to steel rope, phosphor-bronze rope has less strength and, therefore, larger sizes are required for equivalent safe working loads, and the sheaves or drums over which it is run must be comparatively larger. It is superior to steel rope from the standpoint of its non-corrodible and nonmagnetic properties.

4. Standard Ropes and Their Uses

The following are hereby designated as standard types of ropes for marine services. The statements made regarding their uses are to be understood only as indicating prevailing practice. They are intended for general information and guidance of users. The proper type of rope to order for any particular purpose depends upon the service requirements and the judgment of the user.

Type A. 6 by 7 rope.—Six strands of 7 wires each, total 42 wires, single core of hard fiber. Lay not greater than 7½ times the nominal diameter of the rope if the wires are uncoated, or eight times the nominal diameter of the rope if the wires are galvanized.

Uses.—This is the stiffest of the ropes herein described, and its stretch under tension is less than any other type. Steel rope of this type for marine uses is generally galvanized, but may be used

uncoated if properly protected. It is suitable for standing rigging, such as stays, shrouds, and guys; also for other purposes in which it is not subject to bending stresses, such as straight transmission leads, life lines, awning ridges, vang and topping lift pendants, davit slings, and guys, and, in general, where flexibility is not a requisite and comparatively large wires and a minimum of stretch are desirable. Phosphor-bronze rope of this type is not as strong as steel rope and is advocated only for uses where noncorrodible or nonmagnetic properties are specified requisites.

For physical properties, see Section II, Tables 1 and 2 for steel ropes, and Table 8 for phosphor-bronze ropes.

Type B. 6 by 19 rope.—Six strands which may be of one or more diameters of wires. The numerical designation for this rope is only typical as the number of wires in ropes made by different manufacturers may vary if filler wires are used. Each strand shall contain 19 main wires, but when filler wires are used, the number of wires per strand may be up to 25. The total wires in the rope may, therefore, be from 114 to 150. The single core shall be of hard fiber.

Uses.—Uncoated steel rope of this type in sizes up to 1¾ inches in diameter is suitable for general hoisting. When rope of diameter exceeding 1¾ inches would be required for hoisting, it is advisable to use one of the more flexible ropes, such as 8 by 19 or 6 by 37. Among uses for which this uncoated rope is suitable are cargo falls, topping lifts, slings, relieving tackles, and radio halyards; also standing rigging and guys if the rope can be properly protected. Galvanized rope of this type is suitable for standing rigging, guys, boat slings, topping lifts, boom vangs, anchor buoys, fire lines, shrouds, preventors, towlines, stream cables, warps, and hawsers. Phosphor-bronze rope of this type is not as strong as steel rope, and is advocated only for uses where noncorrodible or nonmagnetic properties are specified requisites.

For physical properties, see Section II, Tables 1 and 2 for steel ropes, and Table 8 for phosphor-bronze ropes.

Type C. 8 by 19 rope.—Eight strands of one or more diameters of wire. The numerical designation for this rope is only typical as the number of wires in rope made by different manufacturers may vary if filler wires are used. Each strand shall have 19 main wires, but if filler wires are used, the number of wires per strand may be up to 25 and the total wires in the rope may, therefore, be from 152 to 200. The single core shall be of hard fiber.

Uses.—This rope is more flexible, but not as strong for any given size as the 6 by 19 construction. It is suitable for similar uses, but is advisable in lieu thereof only in cases where rope of greater flexibility is required.

For physical properties, see Section II, Tables 1 and 2.

Type D. 6 by 37 rope.—Six strands made up of main and filler wires of various diameters. The numerical designation of this rope is only typical as the number of wires in ropes made by different manufacturers may vary according to position and size of main and filler wires. Each strand shall have not less than 34 nor more than 46 wires. The total wires in the rope may, accordingly, be from 204 to 276. The number of outside wires of each strand shall be not less than 15 or more than 20. The single core shall be of hard fiber.

Uses.—This rope is flexible by reason of its comparatively small wires. It is efficient because at least 50 per cent of the wires and, consequently, over 50 per cent of the strength are in the inner layers of the strand and thus protected from abrasion. Uncoated rope of this type is suitable for hoisting

gears, steering gear transmission, boat-crane falls, relieving tackle, and running rigging where sheaves or drums are of necessity smaller than desirable for 6 by 19 rope; also for bridles, dip ropes, slings for general hoisting; and for hawsers, mooring lines, stream cables, towlines, and warps requiring great strength; provided that the rope can be properly protected. Galvanized rope is suitable for any of the purposes stated for the uncoated rope where the rope could not be adequately protected against corrosion, except hoisting and running rigging.

For physical properties, see Section II, Tables 1 and 2.

Type E. 6 by 24 rope.—This rope is generally made and marketed in galvanized form. It shall be so furnished on the basis of these specifications unless specifically ordered to be uncoated. It has 6 strands, each consisting of 24 wires laid in 2 layers over a soft core. Total wires in the rope 144. This rope has 7 soft cores, 1 in each strand and 1 main core, all of which shall be of hard fiber, except the strand cores for ropes of diameters under 1 inch which shall be of cotton.

Uses.—This type of rope is more flexible than any of the types hereinbefore described. It is suitable for hawsers, mooring lines, stream cables, towlines, warps, topping lift pendants, and similar uses where greater flexibility than that of previously described ropes is required.

For physical properties, see Section II, Table 3.

Type F. 6 by 12 rope.—This rope is generally made and marketed in galvanized form. It shall be so furnished on the basis of these specifications unless specifically ordered to be uncoated. It has 6 strands, each of 12 wires laid over a soft core; total wires in the rope 72. This rope has 7 soft cores, 1 in each strand and 1 main core, all of which shall be of hard fiber, except the strand cores for ropes of diameters under five-eighths inch, which shall be of cotton.

Uses.—This rope is more flexible than, but not as strong as, any of the types hereinbefore described. It is deemed suitable in preference to previously described ropes only for aerial hoists, life lines, awning ridge ropes, boat ladders, pilot ladders, and boom pendants; also for mooring lines, hawsers, stream cables, towlines, and warps of comparatively low strength, and for running rigging requiring great flexibility rather than strength.

For physical properties, see Section II, Table 3.

Type G. 6 by 6 by 7 (6 by 42) tiller rope.—Six main strands of 42 wires, each of which is composed of 6 strands of 7 wires, being in effect 6 separate ropes twisted together. There are 7 cores, 1 in each strand and 1 main core, all of which shall be of hard fiber except the strand cores which may be of either hard fiber or cotton.

Uses.—This is the most flexible of all ropes herein specified and is capable of being used around small sheaves or drums. It is, however, unsuitable for hoisting or for heavy or continuous duty owing to the comparatively fine wires of which it is composed and its inability to withstand abrasion. Steel rope of this type is used for steering ropes and signal pulls which are required to wind over small diameters. Phosphor-bronze rope of this type is not as strong as steel rope, and its use is advocated only where noncorrodible and nonmagnetic properties are specified requisites.

For physical properties, see Section II, Tables 1 and 2 for steel ropes, and Table 8 for phosphor-bronze ropes.

Type H. 5 by 19 marline-clad steel rope.—This type of rope has each of its strands completely inclosed in a continuous marline or hemp covering. It is composed of 5 strands which may be of one or more diameters of wires. The numerical designa-

tion for this type of rope is only typical as the number of wires in ropes made by different manufacturers may vary if filler wires are used. Each strand shall have 19 main wires. If filler wires are used each strand may have from 19 to 25 wires. The total wires in the rope may, therefore, be from 95 to 125. Each strand has a hemp covering tightly wound or laid on, uniformly smooth, and free of knots or imperfections. The single soft core shall be of hard fiber. The wires may be either uncoated or galvanized, but the uncoated type of rope is most generally marketed as the wires are deemed to be adequately protected from corrosion by the covering if the latter is kept saturated with suitable lubricating compound.

Uses.—This type of rope is stronger than manila rope and suitable for similar uses, especially all kinds of running rigging, topping lifts, boat-handling gear, and comparatively light hoisting; also mooring lines.

For physical properties, see Section II, Table 4.

Type I. Strands.—(1) *1 by 7 stiff strand.*—Six wires twisted around a central wire. Lay not more than twelve times the nominal diameter of the strand.

Uses.—This is the stiffest wire-strand construction. This strand is generally made of galvanized wire and shall be so furnished on the basis of these specifications unless specifically ordered to be uncoated. It is used on ships only in comparatively small sizes for guys and other purposes where stiffness is desired and comparatively great strength for size is required.

For physical properties and various grades obtainable, see Section II, Table 5.

(2) *Seizing strands.*—Sizes under three-sixteenths-inch diameter shall be of 7-wire construction. Sizes three-sixteenths inch and more in diameter shall be of 19-wire construction, each of these numerical constructions comprising a single wire core. The wires may be of iron or low-carbon steel, annealed and galvanized. The lay shall be not greater than 12 times the nominal diameter of the strand. These strands are used mostly for seizing the ends of wire ropes.

For physical properties see Section II, Table 6.

Type J. 6 by 7 sash and bell cord.—Six strands of 7 wires each. Single soft core of cotton. Lay to be not greater than eight times the nominal diameter of the rope. This may be required of annealed iron, tinned or galvanized, or of copper or phosphor-bronze wire, according to the requirements of the work in which the cord is to be used.

Uses.—The principal uses for this cord are on sash weights, window shades, curtains, and for bell and whistle cords.

For physical properties, see Section II, Table 7.

Type K. Lead line with wire-cord center.—This is a cotton cord braided over a center of phosphor-bronze wire cord composed of 6 strands, each containing 7 wires and a single cotton core. It is marketed in several sizes, the following of which are deemed adequate for all likely requirements on shipboard:

The cotton yarn used in the braided covering shall be of good quality 3-ply warp twist, free from husks and other defects. It shall be dyed mahogany color while in the skein in order to insure a solid color in the finished article, and thoroughly waterproofed. The number of cotton strands and yarn ends per strand shall be such as to give a firmly braided covering over the wire cord to the over-all diameter specified and finished with a hard and smooth surface free from imperfections of braid or finish. The phosphor-bronze wires shall possess the characteristics of the phosphor-bronze wire herein specified for phosphor-bronze ropes.

This type of cord does not stretch, and its use is advocated for lead lines in the interest of accurate soundings. It is serviceable as tiller rope on motor boats, also as bell cord, and is suitable for other purposes of similar character in ship operation.

Section II. PHYSICAL PROPERTIES

The approximate weights and minimum breaking strengths of the ropes, etc., hereinbefore specified are set forth in the annexed tables numbered 1 to 8 inclusive. The breaking strengths given in Table 2 are for uncoated cast-steel ropes. Factors are given in footnotes on this table from which the relative breaking strengths for other grades of steel ropes can be approximately determined. The properties of galvanized ropes, marline-clad ropes, galvanized-wire strands, sash and bell cords, and phosphor-bronze ropes are separately compiled in Tables 3 to 8, inclusive. (See Appendix II, notes on wire-rope strengths and working loads.)

TABLE 1.—Approximate weights, in pounds per foot; uncoated steel wire ropes

Rope diameters	Types				
	A 6 by 7	B 6 by 19	C 8 by 19	D 6 by 37	G 6 by 6 by 7 tiller

$2\frac{3}{4}$	-----	12.10	-----	11.72	-----
3	-----	-----	-----	13.95	-----
$3\frac{1}{4}$	-----	-----	-----	16.37	-----
$3\frac{1}{2}$	-----	-----	-----	19.00	-----

For weights per fathom, multiply the above by 6.

Trade No.	Approximate over-all diameter	Approximate diameter of wire-cord center	Approximate breaking strength
	<i>Inch</i>	<i>Inch</i>	<i>Pounds</i>
8	$\frac{1}{4}$	$\frac{1}{16}$	300
10	$\frac{5}{16}$	$\frac{3}{32}$	500

TABLE 2.—Minimum breaking strengths, in pounds; uncoated cast-steel wire ropes

Rope diameters	Types				
	A	B	C	D	G
	6 by 7	6 by 19	8 by 19	6 by 37	6 by 6 by 7 tiller
<i>Inches</i>					
¼	4,000	4,200	3,580	-----	2,280
⅜	5,040	-----	-----	-----	-----
½	6,200	6,400	5,580	-----	3,540
⅝	8,600	9,000	7,880	8,800	5,080
¾	11,600	12,000	10,600	12,000	6,880
1	15,000	15,400	13,600	15,400	8,920
1 ⅛	18,800	19,200	17,000	19,000	11,200
1 ¼	23,000	23,600	20,800	23,200	13,800
1 ½	27,800	-----	-----	-----	-----
1 ⅝	33,000	33,600	29,600	32,800	19,400
1 ¾	-----	-----	-----	-----	-----
2	44,800	45,600	40,000	44,000	26,000
2 ⅛	58,000	59,000	52,000	57,200	33,400
2 ¼	72,800	74,000	65,600	72,000	-----
2 ½	89,000	92,000	80,800	88,600	-----
2 ¾	106,000	110,000	97,200	107,000	-----
3	-----	-----	-----	-----	-----
3 ⅛	125,000	130,000	115,000	127,000	-----
3 ¼	-----	152,000	-----	148,600	-----
3 ½	-----	176,000	-----	172,000	-----
3 ¾	-----	200,000	-----	196,000	-----
4	-----	228,000	-----	222,000	-----
4 ⅛	-----	258,000	-----	278,000	-----
4 ¼	-----	352,000	-----	340,000	-----
4 ½	-----	-----	424,000	408,000	-----

The above breaking strengths are for ropes of uncoated cast-steel wires. The minimum breaking strengths of ropes made of other grades of uncoated steel wires may be ascertained with sufficient accuracy for the purpose of these specifications by multiplying the strengths above tabulated by factors as follows: Extra strong cast steel, 1.10; plow steel, 1.20; improved plow steel, 1.37. If the wires are galvanized, the minimum breaking strengths are 10 per cent less than those tabulated or ascertained as above.

TABLE 3.—Properties of 6 by 24 and 6 by 12 galvanized cast-steel wire ropes, types E and F

Rope diameters	Approximate weights per foot		Minimum breaking strengths	
	E	F	E	F
	6 by 24	6 by 12	6 by 24	6 by 12
<i>Inches</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>
¼	-----	0.07	-----	2,300
⅜	-----	.10	-----	3,520
½	0.194	.15	7,340	4,940
⅝	-----	.20	-----	6,580
¾	.35	.26	12,740	8,460
1	-----	.33	-----	10,520
1 ⅛	.54	.41	19,180	12,920
1 ¼	.78	.59	27,200	18,520
1 ½	.91	.69	31,600	21,600
1 ⅝	1.06	.80	36,600	25,000
1 ¾	1.38	1.05	47,400	32,600
2	1.56	1.19	53,400	36,600
2 ⅛	1.75	1.33	59,800	41,000
2 ¼	1.95	1.48	66,400	45,600
2 ½	2.16	1.64	73,400	50,200
2 ¾	2.61	1.99	88,800	60,400
3	2.85	2.17	96,800	65,000
3 ⅛	3.11	2.36	105,200	71,600
3 ¼	3.64	2.77	123,200	83,600
3 ½	3.93	2.99	132,600	90,000
3 ¾	4.23	3.22	142,400	96,600
4	4.53	3.45	152,400	103,400
4 ⅛	5.18	3.94	173,200	118,000
4 ¼	5.52	4.20	184,000	125,400
4 ½	5.87	4.47	196,000	133,200

For weights per fathom, multiply tabulated weights by 6. The tabulated breaking strengths are for ropes of galvanized cast-steel wires. The minimum breaking strengths of ropes made of other grades of galvanized steel wires may be ascertained with sufficient accuracy for the purpose of these specifications by multiplying the tabulated strengths by factors as follows: Extra strong cast steel, 1.10; plow steel, 1.20; improved plow steel, 1.37. (Should ropes of these types be made of uncoated steel wires, their minimum breaking strengths would be about 11 per cent more than those tabulated or ascertained as above.)

TABLE 4.—Properties of 5 by 19 marine-clad uncoated cast-steel wire ropes, type H

Nominal diameters		Approximate weights per foot	Minimum breaking strengths
Equivalent bare-wire rope	After serving		
<i>Inches</i>	<i>Inches</i>	<i>Pounds</i>	<i>Pounds</i>
¼	⅜	0.21	3,500
⅜	½	.28	5,800
½	⅝	.36	8,200
⅝	¾	.42	11,600
¾	1	.51	14,200
1	1 ⅛	.62	17,600
1 ⅛	1 ¼	.81	21,600
1 ¼	1 ½	1.10	30,800
1 ½	1 ¾	1.32	42,000
1 ¾	2	1.70	54,000
2	2 ⅛	2.12	68,000
2 ⅛	2 ¼	2.58	84,000
2 ¼	2 ½	3.14	101,000
2 ½	2 ¾	3.69	120,000
2 ¾	3	4.29	140,000
3	3 ⅛	5.00	162,000
3 ⅛	3 ¼	5.69	184,000
3 ¼	3 ½	6.38	210,000
3 ½	3 ¾	8.00	264,000

For weights per fathom, multiply tabulated weights by 6. The tabulated breaking strengths are for ropes of uncoated cast-steel wires. The minimum breaking strengths of ropes made of other grades of uncoated steel wires may be ascertained with sufficient accuracy for the purpose of these specifications by multiplying the tabulated strengths by factors as follows: Extra strong cast steel, 1.10; plow steel, 1.20; improved plow steel, 1.37. If the wires are galvanized, the minimum breaking strengths are 10 per cent less than those tabulated or ascertained as above.

TABLE 5.—Properties of galvanized stiff strands, type I (1)

Approximate diameters		Number of wires	Approximate weights per foot	Approximate breaking strengths
Strand	Wire			
<i>Inch</i>	<i>Inch</i>		<i>Pounds</i>	<i>Pounds</i>
¼	0.083	7	0.121	1,900
⅜	.095	7	.164	2,570
½	.109	7	.205	3,200
⅝	.120	7	.296	4,250
¾	.148	7	.399	5,700
1	.165	7	.517	7,400
1 ⅛	.203	7	.671	9,600
1 ¼	.220	7	.813	11,600
1 ½	.259	7	1.200	16,700

The tabulated breaking strengths are for strands of galvanized cast-steel wires, the grade in which they are generally marketed. These strands are obtainable in extragalvanized wires, the latter being protected by heavier coating of spelter to meet requirements for additional protection and wearing value. Strands made of higher grades of wires may also be obtained, the relatively greater strengths of which may be ascertained with sufficient accuracy for the purpose of these specifications by multiplying the tabulated strengths by factors as follows: Siemens Martin steel, 1.60; high strength steel, 2.50; extra high strength steel, 3.50.

TABLE 6.—Properties of galvanized seizing strands, type I (2)

Approximate diameters		Number of wires	Approximate weights per foot	Approximate breaking strengths	Quantities on reels	
Strand	Wire				Weights	Lengths
<i>Inch</i>	<i>Inch</i>		<i>Pounds</i>	<i>Pounds</i>	<i>Feet</i>	
¼	0.022	7	0.010	130	50	5,000
⅜	.022	7	.020	250	50	2,500
½	.042	7	.0318	490	50	1,570
⅝	.058	7	.0513	750	50	970
¾	.042	19	.0729	1,100	100	1,370
1	.052	19	.121	1,900	100	820

The tabulated breaking strengths are for iron or low-carbon-steel wires, annealed and galvanized, which is the grade in which these strands are generally marketed.

TABLE 7.—Properties of 6 by 7 wire sash and bell cords, type J

Nominal diameters	Approximate weights per foot		Approximate breaking strengths	
	Iron	Copper or phosphor-bronze	Annealed iron tinned or galvanized or bright copper	Phosphor-bronze
Inch	Pound	Pound	Pounds	Pounds
1/16	0.006	0.007	77	242
3/32	.014	.016	172	383
1/8	.025	.029	306	715
3/16	.056	.064	688	1,470
7/32	.076	.087	940	2,100
1/4	.100	.115	1,225	2,550

TABLE 8.—Properties of phosphor-bronze wire ropes, types A, B, and G

Rope diameters	Approximate weights per foot			Minimum breaking strengths		
	A 6 by 7	B 6 by 19	G 6 by 6 by 7 tiller	A 6 by 7	B 6 by 19	G 6 by 6 by 7 tiller
Inch	Pounds	Pounds	Pounds	Pounds	Pounds	Pounds
1/4	0.113	0.110	0.076	2,675	1,900	1,680
3/16	.178	.160	.120	3,645	3,000	2,600
3/8	.256	.230	.174	5,500	4,400	3,800
7/16	.333	.320	.229	6,500	5,900	4,750
1/2	.439	.410	.305	9,500	7,700	6,900
5/16	.55	.520	.382	11,500	9,800	8,000
3/8	.69	.640	.469	14,850	12,100	10,360
7/16	1.01	.920	.676	20,900	17,100	16,100
1/2	1.35	1.260	30,000	23,400

For weights per fathom, multiply tabulated weights by 6.

Section III. MATERIALS AND WORKMANSHIP

1. *In general.*—The rope shall be made from the best quality of the specified materials, shall be of good workmanship, and shall be free from defects which might affect its appearance or serviceability.

2. *Diameter and tolerances.*—No strand or rope, other than marine-clad rope, shall be accepted, the diameter of which is under the diameter ordered. The amount which the actual diameter of rope may be oversize from the diameter ordered shall not exceed the following:

Rope diameters:	Oversize tolerances
0 to 3/4 inches.....	inches..... 1/32
3/4 to 1 1/8 inches.....	do..... 3/64
1 1/8 to 1 1/2 inches.....	do..... 1/16
1 1/2 to 2 1/4 inches.....	do..... 3/32
2 1/4 inches and larger.....	do..... 1/8
Stiff strands all sizes.....	do..... 1/16
Seizing strands all sizes.....	do..... 1/64

The actual diameter of marine-clad rope, after serving, shall be not more than one-sixteenth inch larger or smaller than its specified nominal diameter.

3. *Lay.*—The ropes covered by these specifications shall be of right regular lay. Except as otherwise hereinbefore specified for ropes of types A, 6 by 7 and I, strands, the lay of the ropes included in these specifications shall be not greater than six and three-fourths times the nominal diameter of the rope if the wires are uncoated, or seven and one-quarter times the diameter of the rope if the wires are galvanized. In the case of the marine-clad rope, type H, 5 by 19, the nominal diameter of the rope from which the lay is determined is the diameter after serving.

4. *Tensile strength of steel wires.*—The minimum tensile strength of the steel wires of grades hereinbefore specified shall be as follows:

Grade	Uncoated	Galvanized
	Pounds per square inch	Pounds per square inch
Cast steel.....	170,000	155,000
Extra strong cast steel.....	190,000	170,000
Plow steel.....	210,000	190,000
Improved plow steel.....	230,000	210,000

5. *Phosphor-bronze wire.*—The tensile strength of phosphor-bronze wire shall be not less than 100,000 pounds per square inch. The chemical composition shall be as follows: Copper (minimum), 94 per cent; tin (minimum), 3.5 per cent; phosphorus, 0.05 to 0.5 per cent; lead (maximum), 0.2 per cent; iron (maximum), 0.1 per cent; and zinc (maximum), trace.

6. *Galvanizing wire.*—Wires for galvanized rope shall be uniformly and continuously coated with zinc adhering firmly to the wire. The zinc shall be applied in a molten condition by what is known in the trade as "hot-process galvanizing."

7. *Fiber cores.*—These shall be of either hard fiber or cotton as specified in Section I. Jute fiber shall not be used. Hard fiber may be abaca (manila), sisal, or other suitable and generally recognized trade variety. A mixture of two or more kinds of the hard fibers mentioned may be used. All fiber shall be of the best quality, thoroughly cleaned, and free from waste. The cotton for the cores of the small ropes shall be of the best suitable quality. The cores shall be of uniform ply, evenly twisted, and of good workmanship.

8. *Lubrication.*—The fiber cores shall be thoroughly impregnated with suitable lubricant.

9. *Marline covering.*—The covering for wire rope of type H, Section I, 4, shall be of good quality hard American or Russian hemp saturated with pine tar.

Section IV. INSPECTION AND TESTS

1. *General.*—Unless otherwise agreed upon, inspection of ropes purchased on the basis of these specifications shall be made after delivery. The physical tests hereinafter specified serve further to define the character of the ropes. The tests shall not be made, however, unless agreed upon in the conditions of purchase, as for small orders especially the cost of making such tests would be prohibitive. When tests are to be made, they shall, unless otherwise agreed upon, be made by the manufacturer, who shall furnish certified reports of the results thereof to the purchaser. The omission of test requirements in connection with any purchase shall not be construed to deprive the purchaser of the right to make tests as herein specified, at his own expense, to verify the grade and quality of the rope, or of the right to require replacement of any inferior rope supplied, provided that claim for replacement shall be presented within 30 days following delivery of the rope.

2. *Guaranty in lieu of tests.*—When rope purchased on the basis of these specifications is to be delivered without tests, the manufacturer or dealer shall, upon request, furnish to the purchaser a written guaranty that the rope delivered meets the requirements of these specifications.

3. *Diameter.*—The diameter of the rope (overall diameter), shall be measured at three places at least 5 feet apart and at least 5 feet from the end. The average of the three measurements shall be taken as the diameter of the rope. (Measuring the diameter of a rope over the flats between strands is incorrect.

See Sec. III, (2), for requirements as to diameter and tolerances.)

4. *Lay*.—The lay of wire rope shall be ascertained by measuring, parallel to the axis of the rope, the distance in which a strand makes five or more complete turns around the rope. This distance divided by the number of turns is the lay of the rope. When measuring the lay, there shall be no axial load on the rope, and the measured distance shall not be within 10 feet of the end of the rope. (See preceding sections for construction requirements.)

5. *Strand fabrication*.—To determine whether a strand consisting of two or more layers has been fabricated in accordance with these specifications, remove one of the strands from the rope and unlay one outside wire, holding the remaining wires in their proper positions. The outside wire, which is unlayed, should be found in contact continuously with the same underlying wires. If it was in contact with different underlying wires, the stranding does not comply with the requirements. Strands having more than two layers are tested by applying this test to the adjacent layers successively.

6. *Tensile test of wires*.—For tensile tests of the wires, a section shall be cut from each length of rope. From each section at least six tensile tests shall be made, one or more wires being selected from each strand. Specimens for obtaining the tensile strength of the wires shall be not less than 15 inches long, and the distance between the grips of the testing machine shall be not less than 10 inches. The speed of the movable head of the testing machine, under no load, shall not exceed 1 inch per minute.

7. *Torsional tests of wires*.—(a) This test shall apply only to wires for uncoated steel ropes. Specimens for torsional tests of the wires, taken either before or after the rope is fabricated, shall be straight and at least 12 inches long. Not less than one specimen of each size of wire from each strand of the rope shall be selected, but the total number of specimens shall not exceed 25 per cent of the total number of wires in the rope. The distance between the clamps in which the wire is held before the test shall be 8 inches. One clamp shall be movable, parallel to the axis of the wire, and of adequate weight to cause sufficient tension on the specimen to keep it straight during the test. The wire shall be twisted by rotating one of the clamps at a uniform rate graded according to size of wire, but not exceeding 60 revolutions per minute for the smallest wire. If the temperature of the wire increases perceptibly during the test, the speed shall be decreased. Under this test the wires shall not break at less than the number of complete revolutions (of 360°) given in the following table:

Material	Number of revolutions (in 8 inches)
Cast steel.....	2.6
Extra strong cast steel.....	2.4
Plow steel.....	2.2
Improved plow steel.....	2.0

Divided by the diameter of the wire in inches.

(b) If the first torsional specimen fails, two more specimens shall be tested from the same wire. If both of these comply with the requirements, the test shall be deemed satisfactory.

8. *Wrapping test for wires*.—(a) When wrapped in a close helix, for six complete turns about a mandrel, and then unwrapped, the wire for galvanized steel wire rope shall not break. The diameter of the mandrel shall be twice the diameter of the wire.

(b) The specimens for the wrapping test, taken either before or after the rope is fabricated, shall be

straight and of any convenient length. At least one specimen of each size of wire from each strand of the rope shall be selected, but the total number of specimens shall not exceed 25 per cent of the total number of wires in the rope.

(c) One end of the specimen shall be secured in any convenient way and the wire held by the free end shall be tightly wrapped around the mandrel, with the six coils of the helix practically in contact and then unwrapped.

9. *Tensile test of rope*.—(a) The breaking strength shall be determined as far as possible from the full section of the completed rope. The breaking strength thus ascertained shall conform to the requirements given for each size and type in the tables and notes comprised in Section II of these specifications. One tensile test specimen shall be cut from each type and size of rope.

(b) The distance between the sockets or grips may be from twenty-five to sixty times the nominal diameter of the rope. The ends of the specimen may be secured in tapered sockets by using molten zinc or held in any other suitable device. (See par. 7 on socketing in Appendix I.)

(c) Whenever the size to be tested is such that the tensile test can not be made on the completed rope, the strength shall be determined by obtaining the breaking strength of each individual wire. The breaking strength of ropes of 6 by 7 and 6 by 19 construction shall be assumed as 85 per cent, and that of the more flexible ropes as 80 per cent of the sum of the breaking strength of all of the wires in the rope section.

10. *Galvanizing*.—(a) Tests to determine the quality of the galvanizing will not be made unless specifically required in asking for quotations and in the purchase order, or unless the inspector has reason to believe that the galvanizing does not meet the requirements of these specifications.

(b) When this test is required, it shall be made by the Preece method, in which wire specimens are subjected to specified immersions in a standard solution of copper sulphate, washed thoroughly in water, and wiped dry. This produces a bright metallic copper deposit on the specimens wherever zinc coating is lacking. The procedure is as follows:

(1) *Specimens*.—Specimens at least 6 inches long shall be cut from the galvanized wire to be tested, before stranding. Not less than three specimens shall be cut from each size of wire to be used in the rope. The specimens shall be cleaned before testing, using cotton waste saturated with carbon tetrachloride, benzine, or turpentine. A brush shall not be used. The specimens shall then be rinsed thoroughly in clear water and wiped dry with clean cotton waste.

(2) *Copper solution*.—The standard solution of copper sulphate consists of 36 parts by weight of commercial copper-sulphate crystals dissolved in 100 parts by weight of cold water. To neutralize any free acid, chemically pure cupric oxide (CuO) shall be added until excess thereof is indicated by the oxide appearing on the bottom of the container. The neutralized solution shall be filtered through filter paper before using. It shall have a specific gravity of 1.186 at 65° F. at the beginning of each test. If the specific gravity is too high, clean water should be added; if too low, a filtered solution of a higher specific gravity should be added. The solution shall be contained in a glass vessel at least 2 inches inside diameter and filled to a depth of at least 4 inches before immersing the specimens. Its temperature shall be between 60° and 65° F.

(3) *Test*.—One immersion shall consist of dipping the wire into the solution for one minute, after which it shall be removed, washed thoroughly in water, and wiped dry. Not more than seven specimens shall be immersed simultaneously, and they shall be

separated to allow the solution to act on all of their immersed surfaces. The specimens shall not show the appearance of bright adherent copper, indicating exposed iron, as a result of the number of immersions shown in the following table:

Diameter of wire (in inches)	Number of immersions
0.028 to 0.047-----	1
0.048 to 0.054-----	2
0.055 to 0.063-----	2½
0.064 to 0.079-----	3
0.080 to 0.092-----	3½
0.093 to 0.114-----	4
0.115 and larger-----	5

¹ The duration of one half immersion in one-half minute.

If, after the last immersion, any specimen shows a bright metallic copper deposit, the galvanizing shall be regarded as defective, and the wire represented by that specimen shall be rejected: *Provided, however*, That no wire shall be rejected because a copper deposit appeared within 1 inch of the ends of its test specimen.

(4) *Color samples*.—Each day that tests of the galvanizing are made, standard color samples of the bright metallic copper deposit shall be made, with which the test specimens shall be compared. These color samples, cut from the wire to be tested, shall be immersed in concentrated hydrochloric acid until all zinc is removed. They shall be immediately washed and wiped dry and then immersed in the standard copper solution for one minute, removed, washed, and wiped dry.

Section V. PACKING AND MARKING OF SHIPMENTS

(a) Rope furnished under these specifications shall be properly protected for shipment by the shipper. The ends of all ropes shall be suitably seized to prevent untwisting. The manner of preparing the rope for shipment, whether in coils or on reels, shall be determined by the shipper unless specific instructions are given in the purchase order.

(b) The cost of preparing ropes for shipment shall be borne by the shipper, provided that if so agreed at the time of purchase, reels may be billed as extra cost and the purchaser may return them to the shipper in good condition, normal wear and tear excepted, within 12 months from date of shipment and receive a refund of the amount paid therefor.

(c) Each package of a shipment shall be marked with the name of the material, the size and length of rope, the name of the manufacturer or shipper, and the purchaser's order number or date.

(d) In all cases where the purchase order calls for inspection and tests before shipment, a metal seal or tag stamped by the inspector for identification shall be securely fastened to each length of rope inspected or tested, and accepted.

APPENDIX I

Recommended Practice for the Storage, Handling, Use, Inspection, and Maintenance of Wire Ropes

1. *Storage*.—Rope should be stored in a dry and cool place. Heat would impair or destroy the core.

2. *Handling*.—Great care should be used in handling wire rope to avoid either twisting or untwisting and "kinks." The latter are caused by loops in the rope which are "pulled through" by tension on the rope until the diameter of the loop is only a few inches. The wires at a kink are permanently bent and injured. Wire rope that has been kinked will not give satisfactory service.

3. *Unreeling*.—(a) The best way to unreel a rope is to place an axle through the hole in the center of

the reel and support it horizontally so that the reel can turn freely. The rope should then be pulled off in a straight line. The reel should be prevented from turning more rapidly than the rope is pulled away in order to prevent loops of the rope falling over the flange as this would probably result in kinks or other damage. This is easily accomplished by using a board or other form of brake against the flange of the reel.

(b) An alternative method which, however, is deemed to be inferior, is to mount the reel on a turntable with the axis vertical. The rope is pulled off in a straight line as by the other method, but it is likely to drop over the bottom flange of the reel and liable to be pulled around the axle with resultant damage. This can be avoided by keeping the loops on the reel. Under no circumstances should a loop be thrown over the upper flange of the reel and pulled out, as the rope would, when pulled straight, either be twisted or untwisted or even kinked, and the length of its service would be shortened.

4. *Uncoiling*.—If wire rope is in a coil, the outer end of the rope should be released and the coil rolled along the ground in a straight line, unwinding the rope as it proceeds. Under no circumstances should the coil be laid flat on the ground and the loops thrown off and pulled out, as the rope would thereby be twisted or untwisted and kinked as in the case of improper unreeling.

5. *Seizing and seizing wire*.—(a) The end of a wire rope should have at least three seizings to prevent unlaying. Unlaid rope would be useless. The length of each seizing should be at least equal to the diameter of the rope. Fittings which prevent unlaying of the rope may be substituted.

(b) Satisfactory seizing may be accomplished in either of two ways, viz:

Method A, in which both ends of the seizing wire are brought out at the same end of the seizing. This is done by laying the wire in the groove between two strands and wrapping the other end of the wire in a close helix around the rope back over this portion. A seizing iron (round bar, one-half to five-eighths inch in diameter by 18 inches long) should be used, especially if the rope is over 1 inch in diameter. To keep the necessary tension in the wire, the free end should be given one complete turn about the rope. The ends of the wire should be twisted tightly together.

Method B.—(1) Wind the seizing wire on the rope by hand, keeping the coils together and considerable tension on the wire. (2) Twist the ends of the wire together by hand, so that the twisted portion of the wires is near the middle of the seizing. (3) Using a proper tool, tighten the twist just enough to take up the slack, but do not try to tighten the seizing itself by twisting. (4) Tighten the seizing by prying the twist away from the rope and tighten the twist again as in (3). Repeat this operation as far as necessary to make the seizing tight. (5) Cut off the ends of the wires and pound the twist flat against the rope.

(c) Any annealed low-carbon steel wire may be used for temporary seizings. Proper sizes are as follows:

Wire rope diameters (in inches)	Seizing wire diameters
	<i>Inch</i>
¼ to 1¼-----	0.054
1 to 1½-----	.105
1½ and over-----	.135

(d) Permanent seizings should be made with seizing strands described in the preceding specifications.

6. *Cutting*.—Before cutting a wire rope, three seizings of the character described in the preceding paragraphs should be placed on each side of the place to be cut, the first on each side to be close to the

cut, and the others at short distances apart. These seizings are very important as they prevent unlaying or untwisting and ensure equal tension in the strands when load will be applied to the rope.

7. *Socketing*.—Standard forged steel sockets may be attached to a rope as follows:

(a) The rope should be securely seized before cutting as per preceding paragraph, but with at least an extra seizing placed at a distance from the end equal to the length of the basket of the socket. For large ropes these seizings should be several inches long and securely wrapped with a seizing iron.

(b) After cutting, the end seizing should be taken off, leaving the next or extra seizing at a distance from the end of the rope equal to the length of the socket basket. The fiber core should be cut back to this seizing, and the wires should all be untwisted and broomed out, but not necessarily straightened.

(c) The wires for the distance that they are to be inserted in the socket, should be washed with benzine, naphtha, or gasoline, and then dipped, for a distance not greater than three-fourths of the cleaned length, in commercial muriatic acid for from 30 seconds to one minute, or until the acid has thoroughly cleaned each wire. Care should be taken that the acid does not come in contact with any other portion of the rope, as if it does the wires will become brittle. The wires should then be dipped in boiling water containing a small amount of soda to neutralize the acid and be thoroughly dried. Do not handle the cleansed wires with greasy hands or tools.

(d) Insert the wires into the basket of the socket taking care that the socket is in line with the axis of the rope. The socket and wires must be dry, and the socket slightly heated before pouring the zinc. The base of the socket should be sealed with putty, clay, or any similar substance. Molten zinc should then be poured slowly and evenly into the socket until it is full, tapping its side with a light hammer to jar the zinc into the crevices between the wires. Do not use babbitt metal or lead for socketing wire ropes, as these metals would produce a fastening of much less strength than that of the rope. A safety mask should be worn by the man while he pours the molten zinc in order to guard against possible injury.

(e) The zinc must not be too hot or it will anneal the wires, particularly for small ropes. The temperature should not be above 830° F. When the zinc has solidified sufficiently the socket may be plunged into cold water. If socketing is properly done, the strength of the connection will at least equal that of the rope. (A simple and practical method to determine the proper temperature of molten zinc is as follows: A dry soft pine stick dipped into the zinc and quickly withdrawn must have no zinc adhering to it, and should be only slightly discolored by scorching. If the zinc adheres to the stick, it is too cold for pouring. If the stick is charred, the zinc is too hot.)

(f) Socketed connections used for services where failure would endanger human life should be tested to twice the maximum working load to which they are to be subjected.

(See American Marine Standards H No. 7-1928, Rigging Screws with Sockets, see 608.7, p. 626, and H No. 9-1926; Wire Rope Sockets, above.)

8. *Clips and clamps*.—(a) A wire rope may be attached to its load by looping its end around a thimble which is to sustain the load, with sufficient length in the short end of the rope above the thimble to be fastened to the long end by means of properly designed clips. The thimbles may be of pressed steel or cast, galvanized, and of adequate size. (See American Marine Standards H No. 10-1926, Solid Thimbles, and H No. 11-1926, Open Thimbles, above.)

(b) A wire rope clip consists of a forged steel "roddle," or base, having diagonal grooves which fit

the strands of the rope and a steel U-bolt. A forged steel saddle for the U-bolt is advisable. The U-bolt is placed over its saddle and its ends pass through the roddle. The ropes are fastened by tightening the nuts on each end of the U-bolt. It is good practice to place the roddle in contact with the main rope and the U-bolt in contact with the loop end.

(c) Although fastening with clips requires little skill and can be readily inspected, rope so fastened is apt to slip, the clips frequently crush and bruise the rope, and the strength of the fastening is usually less than 80 per cent of that of the rope. Clip fastenings should, therefore, be limited to uses where failure would not endanger human life.

(d) Wire rope clamps consist of two similar pieces, each having two straight parallel grooves which fit the rope, one of which may have diagonal depressions which fit the strands of the rope. They have a comparatively low holding power and, therefore, they should not be used except where the stress in the rope is low in comparison to its strength.

(e) The distance between clips should not be less than six times the diameter of the rope. The minimum number of clips per fastening should be as follows:

Rope diameters (inches):	Clips
¾ and smaller.....	2
Over ¾ to 1, inclusive.....	3
Over 1 to 1¼, inclusive.....	4
Over 1¼ to 1½, inclusive.....	5
Over 1½ to 1¾, inclusive.....	6

For ropes larger than 1¼ inches, it is advisable to use sockets instead of clips.

9. *Splicing*.—(a) There are two types of splices, viz, long splices, which secure ends of rope together so as to form a longer or an endless rope; and short splices, which secure the loop end of a rope over an eye or thimble. Splicing should be done only by men experienced in such work.

(b) Generally speaking, the longer a splice is made, the greater is its strength. The minimum lengths recommended are as follows:

Long splices.—Four feet for every one-eighth inch of rope diameter. (Example: Minimum length of long splice for 1 inch diameter rope, 8×4=32 feet.)

Short splices.—Four inches for every one-eighth inch of rope diameter; provided that no such splice should be less than 12 inches long. This is additional to the length of rope passing around the eye or thimble. (Example: Minimum length of short splice for 1 inch diameter rope, 8×4=32 inches.)

(c) Splices, failure of which would endanger human life, should be tested to at least twice their minimum working load before being placed in service.

10. *Sheaves and drums*.—(a) The length of service of wire rope is greatly affected by the diameters of the sheaves or drums over which it is run. The length of service decreases as the diameter of sheaves or drums is made smaller. It is seldom possible on ships to have the sheaves or drums as large as they should be for utmost life of rope, but it is in the interest of safety and economy to make them as large as practicable.

(b) In the following data, given for general guidance, the tread diameters of sheaves or drums are expressed in times the diameters of the ropes.

Typical rope constructions.....	6 by 19; 5 by 19	8 by 19	6 by 37
Tread diameters recommended for economical results.....	45	27	31.5
Allowable minimum tread diameters for reasonable service and safety.....	30	18	21

¹ For 5 by 19 marline-clad rope compute tread diameter on the basis of the equivalent bare rope size. (See Table 4, Sec. II of specifications.)

(c) If lesser tread diameters than the minimum specified in the preceding paragraph are unavoidable, comparatively rapid deterioration of the rope may be expected and it should be closely watched in operation for signs of failure. It is inadvisable in any case to use tread diameters less than 75 per cent of the allowable minimum. When sheaves or drums of lesser diameters must unavoidably be used, proportionately stronger rope should be provided for any given maximum load. This means higher grade rather than larger size rope as the bending stress of rope over a given sheave or drum increases rapidly as the rope diameter is increased and a condition is soon reached where increased strength due to increased size would be overbalanced by the increased bending stress. (See Appendix II re safe loads.)

(d) Whenever possible the drums or sheaves for wire rope of any construction should be so arranged that the rope is not bent in service first in one direction then in the reverse direction. If reverse bending is unavoidable, the life of the rope will be prolonged by making the sheave about which the reverse bending occurs larger than the preceding one.

11. *Lubrication.*—(a) The wear upon a running rope is both external and internal and, it being impossible in manufacturing rope to provide lubricant for its entire life, it is necessary to lubricate it at frequent intervals in order to protect the wires from friction and corrosion. This applies especially to ropes in running rigging.

(b) The lubricant should be chemically neutral and should not dry out rapidly under service conditions. A heavy-bodied oil with graphite is satisfactory and comparatively inexpensive. A heavy viscous preparation may be desirable to cover the outside of the rope, but it does not give the requisite internal lubrication.

12. *Deterioration and replacement.*—(a) The principal causes of deterioration of wire rope are abrasion, overstrain, bending, and corrosion. Evidence of abrasion is shown by wear on the outside wires. If the wires are slightly worn, and break off squarely, sticking out all over the rope, there is evidence of an overload or severe working.

(b) No definite rules can be given which will enable an inexperienced person to determine when a worn rope should be discarded and replaced. The service for which the rope is used, and the possible consequences if it broke, are important factors in such determination. If breaking of the rope would cause little or no damage, it might theoretically be used until it fails, but this is not to be contemplated under any circumstances. The following suggestions are made for general guidance only:

(1) If material only is hoisted and no serious damage would result from failure of the rope, it may be used, if there are no broken wires, until the thickness of the outside wires is worn to about 35 per cent of their original diameter. It should, in any event, be renewed if it shows 10 per cent of broken wires per lay, or when adjacent broken wires in one of the strands exceed 20 to 25 per cent of the wires in that strand, even if it does not show appreciable wear.

(2) If persons are hoisted, or if material damage would result from failure of the rope, it should be renewed when, in the judgment of the inspector, its strength is appreciably impaired by broken wires, or in any event when the outside wires are worn to a thickness of one-half of their original diameter, even if there are no broken wires.

13. *Refastening.*—When there is reason to believe that a socket or clip fastening is impaired, it is advisable to renew it. It is recommended that in renewing fastenings, a section of 4 to 10 feet of the rope above the socket or the upper clip be cut off. This removes a portion of the rope which is likely to fail. The effective life of fastenings depends upon

the service to which the rope is subjected. Under ordinary conditions it may be assumed to be but one-sixth or even less of the expected life of the rope.

14. *Service inspection.*—(a) All ropes should be inspected at intervals sufficiently frequent to detect indications of wear or corrosion. The interval between inspections depends upon the character and importance of the service and the prevailing conditions.

(b) Fastenings should be inspected at regular frequent intervals. Clips and clamps should be inspected daily and their bolts tested for tightness, and tightened when necessary to the proper degree.

(c) Hoisting rope should be carefully examined at least once a day by a competent and responsible inspector, a signed record of whose inspection should be kept in a suitable record book.

(d) It is advisable to keep general records of the life of hoisting ropes with the name of their manufacturer or dealer and their characteristics, the date when they were put in service, what was done in way of their maintenance, and the date and cause of their removal from service.

(e) It has been found that wires nearly always break on the outside or crown of the strand. Therefore, visual inspection along this line is likely to disclose the condition of the rope as regards broken wires. This, however, might not apply to ropes which are not sufficiently lubricated, and in which undetectable corrosion of internal wires might set in. Therefore, condition of lubrication should be regularly inspected; and upon discovering lack of it, the internal condition of the rope should be ascertained.

15. *Available additional information.*—(a) Trade publications issued by manufacturers of wire ropes and of elevators contain valuable data relative to the characteristics of wire ropes, and illustrated descriptions of the right and wrong way to perform various operations in handling and working them.

(b) Technical Paper No. 237, of the Bureau of Mines of the United States Department of Commerce, entitled "Safe Practice in Using Wire Ropes in Mines," by Kudlich and Hood, and Technologic Paper No. 229, of the Bureau of Standards, entitled "Some Tests of Steel-Wire Rope Sheaves" also contain much valuable information.

(c) Users of wire ropes are advised to study such publications for their full information and guidance, especially as to seizing, socketing, proper application of clips, and splicing.

(d) Wire rope for elevator installations should comply with the requirements of the Safety Code for Elevators and Escalators, published by the American Society of Mechanical Engineers, New York.

APPENDIX II

Notes on Wire Rope Strengths and Working Loads

1. *Certificates of strength of wire ropes, required in foreign countries.*—Some foreign authorities, including the British Board of Trade, require certificates, drawn up on their own forms, of the strength of rope rigging used in handling cargoes at ports of their respective countries. Operators of ships engaged in foreign trade should ascertain the requirements of those authorities, assure themselves that the rope rigging on ships intended to handle cargo in those countries is of adequate strength to comply with the requirements, instruct the officers of such ships accordingly, and provide them with the requisite certificates in proper form or with authenticated data for use abroad.

2. *Working loads.*—Determination of the proper working load for any rope is a matter best left open for decision by the user. It is deemed advisable to limit the working load of a wire rope for ordinary services, particularly running ropes, to one-fifth of

the breaking strength. This means that the factor of safety should be not less than 5. To determine the proper working load, divide the breaking strength of the rope by the proper factor of safety; for example, a 1-inch diameter 6 by 19 uncoated cast-steel rope has a breaking strength of 59,000 pounds and with a factor of safety of 5 the proper working load would be $\frac{59,000}{5} = 11,800$ pounds. (For breaking strengths, see tables in Sec. II of specifications.)

3. *Factor of safety.*—Factors of safety in excess of 5, varying up to 8 and even more, are often required for safe and economical operation. The proper factor of safety for a wire rope should be determined by careful and thorough consideration of all pertinent data. Such data should include the probable maximum and average loads, acceleration, deceleration, rope speed, and character of rope attachments, with special consideration to the number, size, and arrangement of all sheaves and drums, existing conditions which may cause corrosion and abrasion, length of rope in service, economical rope life, and the degree of danger to life and property. No fixed arbitrary factor of safety can properly be set for any classification of service; but such factor can safely vary, within reasonable limits, with the conditions present on individual installations. Should any doubt arise as to the proper factor for any rope or service, it is suggested that rope manufacturers or other authorities be consulted.

4. *Ship classification requirements.*—The ship classification societies prescribe rules governing the sizes of wire ropes for stream cables, towlines, hawsers, and warps, also for rigging. The wire ropes for any ship or service subject to such rules should conform thereto. The breaking tests for wire ropes specified by the American Bureau of Shipping and the diameters of standard steel ropes to meet such tests are set forth in the American Bureau of Shipping, Rules for Building and Classing Steel Vessels, given above.

AMERICAN MINING CONGRESS, WIRE ROPES FOR MINES, 1927

[Approved as American Standard M11-1927, by the American Standards Association, February 24, 1927]

Part 1. TYPES

Section 100.—*Rule 1,000.*—The wire ropes covered by this specification are of the following types:

- 1 by 7 seizing strand.
- 1 by 7 steel strand.
- 6 by 7 cast steel.
- 6 by 7 extra strong cast steel (mild plow).
- 6 by 7 plow steel.
- 6 by 19 cast steel.
- 6 by 19 extra strong cast steel (mild plow).
- 6 by 19 plow steel.
- 6 by 37 cast steel.
- 6 by 37 extra strong cast steel (mild plow).
- 6 by 37 plow steel.
- 8 by 19 cast steel.
- 8 by 19 extra strong cast steel (mild plow).
- 8 by 19 plow steel.

Any other manufacturer's trade name of equivalent material which passes the tests complies with this specification.

(In respect to material and workmanship, general requirements, inspection and tests, and recommended practice in the use of wire rope, this specification conforms to the specification of the American Marine Standards Committee Specification O No. 25, wire rope for marine uses, given above. Detail requirements, including both text and illustrations, are identical for 1 by 7 seizing strand and 6 by 7 extra strong cast steel with those in Federal Specifi-

cations Board Specification No. 297 (current designation: RR-R-571, given below.)

(Wire rope specified in Federal Specifications Board Specification No. 297 (current designation: RR-R-571), given below, but not included in this specification are as follows:)

- 1 by 19 seizing strand.
- 5 by 19 marine covered extra strong cast steel.
- 5 by 19 marine covered high-grade plow steel.
- 6 by 12 cast steel.
- 6 by 12 high-grade plow steel.
- 6 by 12 phosphor bronze.
- 6 by 19 high-grade plow steel.
- 6 by 19 phosphor bronze.
- 6 by 24 cast steel.
- 6 by 24 high-grade plow steel.

(Detail requirements in this specification covering original wire rope specifications are as follows:)

Section 401.—1 by 7, steel strand.

Rule 4010.—1 by 7 steel strand shall be made as described here and have the properties given in Table 1. (Illustration same as in F. S. B. 297, for 1 by 7 seizing strand.)

TABLE 1.—Properties of 1 by 7 steel strand

Nominal diameter	Approximate weight per foot	Minimum breaking strength	Maximum safe working load
<i>Inch</i>	<i>Pound</i>	<i>Pounds</i>	<i>Pounds</i>
$\frac{3}{8}$	0.295	4,500	1,000
$\frac{1}{2}$.510	7,900	1,760
$\frac{5}{8}$.800	12,400	2,750

(Requirements covering construction, material, diameter, and lay are identical with those for 1 by 7 seizing strand in F. S. B. 297, given below, except that the diameter tolerance shall be one-sixteenth inch instead of one-sixty-fourth-inch.)

Section 402.—6 by 7, cast steel.

Rule 4020.—Wire rope 6 by 7, cast steel, shall be made as described here and shall have the properties shown in Table 8 in F. S. B. 297, given below, except for working and breaking strengths of both uncoated and galvanized rope, which are as follows:

TABLE 2.—Properties of 6 by 7 cast steel wire rope

Nominal diameter	Uncoated		Galvanized	
	Minimum breaking strength	Maximum safe working load	Minimum breaking strength	Maximum safe working load
<i>Inches</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>
$\frac{3}{8}$	7,500	1,670	6,750	1,500
$\frac{1}{2}$	11,700	2,600	10,500	2,330
$\frac{5}{8}$	21,200	4,720	19,100	4,240
$\frac{3}{4}$	30,600	6,800	27,600	6,130
$\frac{7}{8}$	41,800	9,280	37,600	8,360
1	54,500	12,100	49,100	10,900
$1\frac{1}{8}$	69,400	15,400	62,400	13,900
$1\frac{1}{4}$	85,000	18,900	76,500	17,000
$1\frac{3}{8}$	102,000	22,700	91,800	20,400
$1\frac{1}{2}$	122,000	27,100	110,000	24,400

NOTE.—The maximum safe working loads are the highest allowable under any conditions. Safety requires that most installations have a higher factor of safety, and therefore a lower working load.

Rule 4021—Construction.—One diameter of wire. One operation. Six strands of seven wires each. One main core. (Illustration same as for F. S. B. 6 by 7 extra strong cast steel)

Rule 4022—Material.—Wires: Cast steel, either uncoated or galvanized. Main core, hard fiber.

Rule 4023—Diameter.—The difference between the nominal diameter and the actual diameter shall not be greater than the tolerances given in American Marine Standards Committee Specification O-25, given above.

Rule 4024—Lay.—The rope shall be regular lay, and the lay shall not be greater than seven and one-half times the nominal diameter if the wires are uncoated steel, nor more than eight times the diameter if the wires are galvanized steel.

(The 6 by 7 extra strong cast steel rope in this specification requires that the lay shall not be greater than seven and one-half times the nominal diameter, instead of eight times as in the F. S. B. specification. Also this specification carries the breaking strengths and safe working loads of uncoated wire rope, instead of the galvanized rope requirements in F. S. B. Specification No. 297. These properties of the uncoated wire rope are as follows:)

TABLE 3.—Properties of 6 by 7 extra strong cast steel wire rope

Nominal diameter	Uncoated	
	Minimum breaking strength	Maximum safe working load
<i>Inches</i>	<i>Pounds</i>	<i>Pounds</i>
1/2	16,000	3,580
5/8	25,000	5,560
3/4	35,600	7,890
7/8	47,800	10,600
1	62,800	14,000
1 1/8	78,900	17,600
1 1/4	97,800	21,700
1 3/8	119,000	26,400
1 1/2	140,000	31,100

NOTE.—The maximum safe working loads are the highest allowable under any conditions. Safety requires that most installations have a higher factor of safety, and therefore a lower working load.

Section 404.—6 by 7, plow-steel wire rope.

Rule 4040.—Wire rope, 6 by 7, plow steel, shall be made as described here, and shall have the properties given in Table 4. (Illustration same as for F. S. B. No. 297, 6 by 7 extra strong cast steel.)

TABLE 4.—Properties of 6 by 7 plow-steel wire rope

Nominal diameter	Approximate circumference	Approximate weight per foot	Uncoated		Recommended minimum diameter of sheave or drum
			Minimum breaking strength	Maximum safe working load	
<i>Inches</i>	<i>Inches</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Feet</i>
1/2	1 1/2	0.39	17,000	3,780	3.8
3/8	2	.62	27,200	6,020	4.5
3/4	2 1/4	.89	38,400	8,540	5.5
7/8	2 3/4	1.20	51,800	11,600	6.5
1	3	1.58	68,000	15,100	7.2
1 1/8	3 1/2	2.03	86,500	19,300	8.2
1 1/4	4	2.52	106,000	23,500	9.0
1 3/8	4 1/4	3.05	128,000	28,400	10.0
1 1/2	4 3/4	3.65	153,000	34,000	11.0

NOTE.—The maximum safe working loads are the highest allowable under any conditions. Safety requires that most installations have a higher factor of safety, and therefore a lower working load.

Rule 4041—Construction.—One diameter of wire, one operation. Six strands of seven wires each. One main core.

Rule 4042—Material.—Wires: Plow steel, uncoated. Main core, hard fiber.

Rule 4043—Diameter.—(Same as in rule 4023, above.)

Rule 4044—Lay.—The rope shall be regular lay, and the lay shall not be greater than seven and one-half times the nominal diameter.

Section 405.—6 by 19, cast steel.

Rule 4050.—Wire rope, 6 by 19, cast steel, shall be made as described here, and shall have the properties shown in Table 12 of F. S. B. No. 297, given below, with the following additional properties for galvanized rope:

TABLE 5.—Properties of 6 by 19 cast-steel wire rope

Nominal diameter	Galvanized	
	Minimum breaking strength	Maximum safe working load
<i>Inches</i>	<i>Pounds</i>	<i>Pounds</i>
3/8	7,560	1,680
1/2	13,500	3,000
5/8	20,700	4,600
3/4	28,400	6,310
7/8	37,500	8,330
1	48,600	10,800

NOTE.—The maximum safe working loads are the highest allowable under any conditions. Safety requires that most installations have a higher factor of safety, and therefore a lower working load.

Rule 4051—Construction.—Each strand shall be fabricated in one operation of stranding. Six strands. Each strand shall have not less than 16 and not more than 31 wires. One main core.

Rule 4052—Material.—Wires: Cast steel, either uncoated or galvanized. Main core, hard fiber.

Rule 4053—Diameter.—(Same as in rule 4023, above.)

Rule 4054—Lay.—The rope shall be regular lay, and the lay shall not be greater than seven and one-fourth times the nominal diameter, if the wires are uncoated steel, nor more than nine times the diameter if the wires are galvanized steel.

Section 406.—6 by 19 extra strong cast steel.

Rule 4060.—Wire rope, 6 by 19, extra strong cast steel shall be made as described here, and shall have the properties shown in Table 13 of F. S. B. No. 297, given below, in respect to uncoated rope only.

Rule 4061—Construction.—Each strand shall be fabricated in one operation of stranding. Six strands. Each strand shall have not less than 16 and not more than 31 wires. One main core.

Rule 4062—Material.—Wires, extra strong cast steel, uncoated. Main core, hard fiber.

Rule 4063—Diameter.—(Same as rule 4023, above.)

Rule 4064—Lay.—The rope shall be regular lay, and the lay shall not be greater than seven and one-fourth times the nominal diameter.

Section 407.—6 by 19, plow steel.

(Properties are the same as for uncoated wire rope in Table 14 of F. S. B. No. 297, given below. Material, diameter, and lay are the same as for 6 by 19 extra strong cast steel, given above, except that plow steel takes the place of extra strong cast steel.)

Section 408.—6 by 37, cast steel.

Rule 4080.—Wire rope, 6 by 37, cast steel, shall be made as described here, and shall have the properties given in Table 6. (Illustration same as F. S. B. No. 297, 6 by 37 extra strong cast steel, given below.)

TABLE 6.—Properties of 6 by 37 cast-steel wire rope

Nominal diameter	Approximate circumference	Approximate weight per foot	Uncoated		Recommended minimum diameter of sheave or drum
			Minimum breaking strength	Maximum safe working load	
<i>Inches</i>	<i>Inches</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Feet</i>
1/2	1 1/2	0.39	12, 400	2, 750	1.2
5/8	2	.62	19, 300	4, 290	1.5
3/4	2 1/4	.89	28, 000	6, 220	1.9
7/8	2 3/4	1.20	38, 000	8, 440	2.1
1	3	1.58	49, 500	11, 000	2.5
1 1/8	3 1/2	2.00	62, 800	14, 000	2.7
1 1/4	4	2.45	77, 600	17, 200	3.1
1 3/8	4 1/4	2.95	94, 000	20, 900	3.3
1 1/2	4 3/4	3.55	112, 000	26, 600	3.7
1 5/8	5	4.15	132, 000	29, 300	3.9

NOTE.—The maximum safe working loads are the highest allowable under any conditions. Safety requires that most installations have a higher factor of safety, and therefore a lower working load.

Rule 4081—Construction.—Each strand shall be fabricated in either one or two operations of stranding. Six strands. Each strand shall have not less than 29 and not more than 46 wires. One main core.

Rule 4082—Material.—Wires: Cast steel, uncoated. Main core, hard fiber.

Rule 4083—Diameter.—(Same as rule 4023, above.)

Rule 4084—Lay.—(Same as rule 4064, above.)

Section 409.—6 by 37, extra strong, cast steel.

(Properties are the same as for uncoated wire rope in Table 19 of F. S. B. No. 297, given below. Illustration same as for F. S. B. 6 by 37 extra strong cast steel, given below. Diameter and lay are the same as in rule 4023 and rule 4064, respectively, given above. Construction same as rule 4081, above. Material of extra strong cast steel, uncoated. Main core, hard fiber.)

Section 410.—6 by 37, plow steel.

Rule 4100.—Wire rope, 6 by 37, plow steel, shall be made as described here, and shall have the properties given in Table 7. (Illustration same as for F. S. B. 6 by 37 high-grade plow steel, given below.)

TABLE 7.—Properties of 6 by 37 plow-steel wire rope

Nominal diameter	Approximate circumference	Approximate weight per foot	Uncoated		Recommended minimum diameter of sheave or drum
			Minimum breaking strength	Maximum safe working load	
<i>Inches</i>	<i>Inches</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Feet</i>
1/2	1 1/2	0.39	15, 600	3, 470	1.2
5/8	2	.62	24, 400	5, 420	1.5
3/4	2 1/4	.89	35, 400	7, 860	1.9
7/8	2 3/4	1.20	47, 800	10, 600	2.1
1	3	1.58	63, 000	14, 000	2.5
1 1/8	3 1/2	2.00	79, 200	17, 600	2.7
1 1/4	4	2.45	98, 300	21, 900	3.1
1 3/8	4 1/4	2.95	119, 000	26, 400	3.3
1 1/2	4 3/4	3.55	142, 000	31, 500	3.7
1 5/8	5	4.15	157, 000	37, 100	3.9
1 3/4	5 1/2	4.85	194, 000	43, 200	4.3
1 7/8	5 3/4	5.50	222, 000	49, 400	4.5
2	6 1/4	6.30	252, 000	56, 000	4.8

NOTE.—The maximum safe working loads are the highest allowable under any conditions. Safety requires that most installations have a higher factor of safety, and therefore a lower working load.

(Construction same as rule 4081, above. Diameter same as rule 4023 above. Lay same as rule 4064

above. Material of plow steel, uncoated. Main core, hard fiber.)

Section 411.—8 by 19, cast steel.

Rule 4110.—Wire rope, 8 by 19, cast steel.

(Properties and material are the same as for 8 by 19 cast-steel rope in F. S. B. No. 297, given below. Diameter and lay are the same as in rule 4023 and rule 4064, respectively, given above. Construction is as follows:)

Rule 4111—Construction.—Each strand shall be fabricated in one operation of stranding. Eight strands. Each strand shall have not less than 16 and not more than 31 wires. One main core.

Section 412.—8 by 19 extra strong cast steel.

(Properties and material are the same as for 8 by 19 extra strong cast steel rope in F. S. B. No. 297, given below. Construction is the same as in rule 4111, above. Diameter and lay are the same as in rule 4023 and rule 4064, respectively, given above.)

Section 413.—8 by 19, plow steel.

Rule 4130.—Wire rope, 8 by 19, plow steel, shall be made as described here and shall have the properties given in Table 8.

TABLE 8.—Properties of 8 by 19 plow-steel wire rope

Nominal diameter	Approximate circumference	Approximate weight per foot	Uncoated		Recommended minimum diameter of sheave or drum
			Minimum breaking strength	Maximum safe working load	
<i>Inches</i>	<i>Inches</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Feet</i>
1/2	1 1/2	0.35	14, 800	3, 290	1.3
5/8	2	.55	23, 200	5, 160	1.6
3/4	2 1/4	.80	33, 800	7, 520	1.9
7/8	2 3/4	1.08	45, 700	10, 200	2.2
1	3	1.42	60, 000	13, 400	2.5
1 1/8	3 1/2	1.80	75, 700	16, 800	2.8
1 1/4	4	2.20	93, 700	20, 800	3.1
1 3/8	4 1/4	2.67	114, 000	25, 300	3.5
1 1/2	4 3/4	3.19	135, 000	30, 000	3.7

NOTE.—The maximum safe working loads are the highest allowable under any conditions. Safety requires that most installations have a higher factor of safety, and therefore a lower working load.

Rule 4132—Material.—Wires: Plow steel, uncoated. Main core, hard fiber.

(Construction is the same as rule 4111 above. Diameter and lay are the same as in rule 4023 and rule 4064, respectively, given above. Illustrations showing the correct and incorrect way of measuring the diameter of wire rope are the same as in the specification of the American Petroleum Institute, given below.)

AMERICAN PETROLEUM INSTITUTE, SPECIFICATIONS FOR WIRE ROPE, STANDARD NO. 9-A (8TH ED.), JULY, 1931

WIRE ROPE

SECTION I

Material Covered

1. (a) These specifications apply to wire rope for oil country use, and include the following: Cable tool drilling lines, cable tool casing lines, sucker rod and tubing lines, sand lines, rotary drilling or casing lines, and rotary bailing lines.

(b) Specifications for the following lines are covered in Section VI.

Galvanized wire guy strands.—1. (c) Specifications to be added later for torpedo lines and well-measuring tapes.

SECTION II

Grades of Material

2. (a) Grade J shall refer to a good grade acid or basic open-hearth steel of the physical properties hereinafter specified. (Otherwise called "plow steel.")

(b) Grade L shall refer to a good grade of acid or basic open-hearth steel of the physical properties hereinafter specified. (Otherwise called "extra strong cast steel.")

(c) Grade N shall refer to an acid or basic open-hearth steel of the physical properties hereinafter specified. (Otherwise called "cast steel.")

(d) Lines composed of combination of two grades shall be permitted: The first letter referring to grade of outside wires, the second letter to grade of inside wires, each of which must pass the physical characteristics of the respective grades. For example: Grade NJ would mean that all outside wires are to be made of grade N and all inside wires to be of grade J.

SECTION III

Properties and Tests for Wire

3. Selection of wires to be tested.—(a) For tests of the wire in a rope a section shall be cut from a finished piece of unused and undamaged wire rope, samples to be taken within 30 days of actual delivery of the rope.

(b) From each strand there shall be selected and tested certain wires as follows: The total number to be tested shall be equal to the number of wires in any one strand. They shall be selected from all strands of the rope. The specimens shall be selected from all locations or positions so that they would constitute a complete composite strand exactly similar to a regular strand in the rope. The specimen for all like positioned wires to be selected so as to use as nearly as possible an equal number from each strand.

NOTE.—Whenever "like positioned" wires are mentioned it will be understood to mean wires symmetrically placed in a strand. For instance, in Warrington all the outside wires are not necessarily "like positioned," since in the outside layer are placed alternately large and small wires. All large wires are "like positioned" with respect to each other and all small wires are "like positioned" with respect to each other.

(c) Any unsymmetrically placed wires or marker wires are to be disregarded entirely. Annealed heart wires not to be considered in averages, but must have a minimum tensile strength of 50,000 pounds per square inch; must stand a test of at least 60 twists as described under "Torsion test" and a Bending test as described under paragraph 7, "Bend test of wires."

(d) Each specimen except those for tension tests shall be carefully hand straightened.

(e) The tests shall be so run and records kept in such a manner that the results of each of the various tests on any one specimen are associated and may be studied separately from other specimens.

(f) In case of controversy the purchaser may at his expense test all of the wires.

(g) If the first specimen fails to pass the minimum requirement for individual wires, two more specimens shall be tested from the same wire, both of which must comply with the requirements for the wire. The average of the two tests showing either failure or acceptance of the three made shall be used as the value to represent the wire.

(h) In torsion tests the additional tests may be made at a reduced rate of speed, not exceeding 30 twists per minute.

(i) In bending tests the additional tests may be made at a reduced rate of speed, not exceeding 15 bends per minute.

4. Tensile strength of wire.—(a) Specimens shall not be less than 18 inches long, and the distance between the grips of the testing machine shall not be less than 12 inches. The speed of the movable head of the testing machine, under no load, shall not exceed one inch per minute. Any specimen breaking within one-fourth inch from the jaws shall be disregarded and a retest made.

NOTE.—It has been found that the diameter of wire can more easily and accurately be determined by placing the wire specimen in the test machine and applying a load not over 25 per cent of the breaking strength of the wire.)

(b) The tensile strength of the various grades shall be within the value shown in Table 1.

TABLE 1.—Tensile strength

[Pounds per square inch]

A. P. I. grade	Individual wire minimum	Minimum average sum of all breaking stresses divided by sum of areas of all wires tested	Individual wire maximum
J.....	210,000	220,000	260,000
L.....	190,000	200,000	250,000
N.....	170,000	180,000	230,000

5. Elongation.—(a) The ultimate elongation shall be measured when making the tensile tests of wire. The ultimate elongation, measured on a 10-inch length of specimen, at instant of rupture, which must occur within the 10-inch length, shall not be less than the values given in Table 2 for grades J, L, and N. When determining elongation a stress shall be imposed upon the wire equal for grades L and N, to 75,000 pounds per square inch, at which point the extensometer is applied. Direct to the reading of the extensometer shall be added 0.3 per cent to allow for the initial elongation occurring before application of the extensometer. For grade J and stronger 100,000 pounds per square inch shall be applied; the additive elongation to be 0.4 per cent.

TABLE 2.—Elongation

Size of wire	Minimum elongation
Wire 0.07 inch diameter and larger.....	Per cent 2
Wire less than 0.070 to 0.040 inch diameter.....	1¾
Wire less than 0.040 to 0.020 inch diameter.....	1½
Wire less than 0.020 inch diameter.....	1

6. Torsion tests of wire.—(a) The distance between the jaws of the testing machine shall be 8 inches, plus or minus one-sixteenth inch when the wire is straight. One end of the wire is to be rotated with respect to the other end of the wire at a continuous, uniform speed until breakage occurs. During the test the applied tension shall not exceed 5 per cent of its breaking strength as measured in the tensile test. The speed of rotation shall not exceed 60 twists per minute. A distance on the untwisted wire equal to one hundred times the diameter is to be taken as the unit of test length and the wire under test must withstand the number of twists given in Table 3 computed on this unit of length. One clamp of the torsion machine shall

be movable in a direction parallel to the axis of the wire. The wire shall be twisted by rotating one or both clamps at a uniform rate not exceeding a sum of 60 twists per minute. Tests in which breakage occurs within one-eighth inch of jaw shall be discarded.

TABLE 3.—*Torsion test*

[Minimum number of twists of 360° for individual wires in a length equal to one hundred times the wire diameter]

A. P. I. grade	Number of twists for individual wires
J-----	27½
L-----	30
N-----	32½

(b) If when making the specified test of wires any wires fail to meet the torsion-test requirement, all the wires in the rope must then be tested and 95 per cent of all such wires must meet the requirement for torsion herein specified, none of the remaining 5 per cent to be less than 60 per cent of the torsion values herein given. (See par. 3 (h).)

(c) The torsion-testing machine for rope wire testing shall have following characteristics:

(d) One jaw fixed axially, and the other jaw movable axially and arranged to permit tension weights to be applied to wire under test.

(e) The jaws to be capable of holding wire firmly without slippage. Machine must be equipped with automatic counter to record the number of twists. Control of speed so that it can be uniform can best be had with a power-operated machine, and this is recommended as standard.

(f) Weights to be applied shall be as shown in Table 4.

TABLE 4.—*Tension weights for torsion tests*

Size wire	Applied weights
<i>Inch</i>	<i>Pounds</i>
0.011-0.016	1
.017- .020	2
.021- .030	4
.031- .040	6
.041- .050	8
.051- .060	9
.061- .070	11
.071- .080	13
.081- .090	16
.091- .100	19
.101- .110	21

7. *Bend test of wires.*⁴⁷—(a) The machine shall be so designed that the mandrels touch the wire and maintain it in a symmetrical position with respect to the axis for all sizes of wire under test. The center of rotation for bend test shall fall on the center line of the axis of the wire and directly in line with the point of tangency of the mandrel with the wire. Bends shown in Table 5 shall be at a speed of between 30 and 40 bends per minute. At

⁴⁷ Because of the difficulties experienced by operators in bending hand-straightened wire, the committee recommends that no rope be condemned by the bend test, pending further investigations.

a greater speed values will be reduced. (See par. 3 (i).) Each bend will be understood to mean bending the wire at right angles and returning to the central position. The machine should be arranged so that it can be driven with power to secure uniformity of speed.

(b) The distance between top of jaw or mandrel and lower edge of guide not to exceed 2 inches.

(c) The wire must stand the bend test shown in Table 5 before fracture.

TABLE 5.—*Bend test on rope wire*

Size of wire	Number of bends over radius equal to six times diameter of wire	
	Grades L and N	Grade J
<i>Inch</i>		
0.031-0.050	50	45
.051- .070	47	43
.071- .090	43	39
.091- .110	40	36

(d) Mandrels for bend test shall be accurate to correspond to the values given in Table 6.

TABLE 6.—*Mandrel sizes for bend test*

Wire size	Mandrel radius
<i>Inch</i>	<i>Inch</i>
0.031-0.040	0.210
.041- .050	.270
.051- .060	.330
.061- .070	.390
.071- .080	.450
.081- .090	.510
.091- .100	.570
.101- .110	.630

(e) The bend test not to apply to wire 0.030 inch diameter and smaller.

8. *Strength of ropes: Testing full-rope size specimens.*—(a) Minimum ultimate strength of ropes shall be as specified in Tables 7 and 8. When testing finished ropes to their ultimate strength, suitable sockets shall be attached by the method described under the heading "Directions for attaching sockets to wire rope," as contained in Appendix D.

(b) The length of test specimen shall not be less than 3 feet between sockets for ropes up to 1-inch diameter, inclusive, and for ropes 1½ inches diameter and larger the minimum length between testing sockets shall be 5 feet.

(c) If the first specimen fails at a value below the specified ultimate strength, a second test shall be made, and if the second test meets the strength requirements the wire rope shall be accepted.

(d) The machine used for the finished rope test shall not have a capacity of more than twenty times the strength of the rope being tested. When testing, it is recommended that oversize wire rope sockets be used; that is a socket for a rope ¼-inch larger in diameter than the rope under test. The counterpoise used on such a machine shall not be in excess of five times the strength of the rope being tested.

TABLE 7.—Ultimate strength of 6 by 19 ropes

Nominal diameter of rope	Approximate weight	Grade N	Grade L	Grade J
<i>Inches</i>	<i>Pounds per foot</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>
3/8	0.23	9,000	10,000	11,000
7/16	.31	12,000	13,200	14,600
1/2	.40	15,400	17,000	18,500
9/16	.51	19,200	21,200	23,400
5/8	.63	23,600	26,200	28,500
3/4	.90	33,600	37,400	41,200
7/8	1.23	45,600	50,800	56,000
1	1.60	59,000	66,000	73,000
1 1/8	2.03	74,000	83,000	92,000
1 1/4	2.50	92,000	102,000	113,000
1 3/8	3.03	110,000	123,000	136,000
1 1/2	3.60	130,000	145,000	161,000

TABLE 8.—Ultimate strength of 6 by 7 ropes

Nominal diameter of rope	Approximate weight	Grade N	Grade L	Grade J
<i>Inch</i>	<i>Pounds per foot</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>
3/8	0.21	8,600	9,400	10,300
7/16	.29	11,600	12,600	13,800
1/2	.38	15,000	16,400	18,000
9/16	.48	18,800	20,600	22,600
5/8	.59	23,000	25,200	27,600
3/4	.84	33,000	36,200	39,600
7/8	1.15	44,800	49,200	53,600
1	1.50	58,000	63,800	69,600

SECTION IV

Manufacture and Tolerances

9. *Strand construction.*—(a) Strands for 6 by 19 construction ropes shall have not less than 16 wires and not more than 25 wires per strand. Individual strands shall be fabricated in one operation of stranding, as stipulated in Federal Specifications Board specification for wire rope No. 297 (current designation: RR-R-571) given below.

(b) Strands for 6 by 7 and 6 by 8 construction ropes shall contain the number of wires as specified by the trade name; namely, 7 wires per strand for the 6 by 7 construction, and 8 wires per strand for the 6 by 8 construction.

10. *Joints in wire.*—(a) In the manufacture of wire ropes, wire shall be made continuous by brazing or electric welding, and no two joints in any one strand shall be closer than 25 feet to each other. Joints shall be made so they will withstand a strength of at least 50 per cent of the original strength of the wire.

11. *Direction of lay.*—(a) Standard right-lay rope will be furnished unless specified to the contrary by the purchaser.

12. *Length of lay.*—(a) For 6 by 7 and 6 by 8 drilling lines, also for 6 by 7 ropes used for sand lines, the lay of the finished rope shall not exceed eight times the diameter of the rope.

(b) For 6-strand ropes made of strands containing 16 to 25 wires, the lay shall not be more than seven and one-fourth times the nominal diameter.

13. *Diameter of ropes—Tolerance limits.*—(a) The diameter of a wire rope shall be measured as least 5 feet from end with a suitable measuring device, with at least 3 inches length of jaw. Figure 57 illustrates the correct and incorrect methods of measuring the diameter of wire rope when using a machinist's caliper.

MEASUREMENT OF DIAMETER

(b) Figure 58 illustrates an approved type of caliper for measuring the diameter of wire rope.

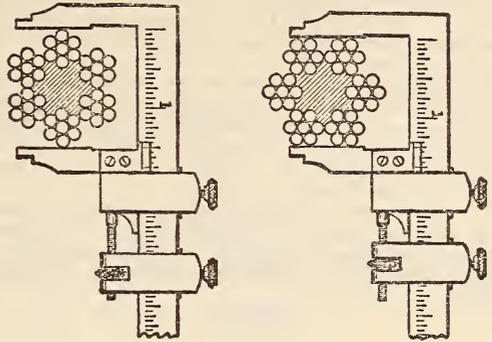

FIGURE 57.—Correct and incorrect way to measure diameter of wire rope

Use a machinist's caliper square.

(c) The diameter of a wire rope is the diameter of the circumscribed circle. The amount which the actual diameter of a rope differs from the nominal diameter shall not be greater than the values in Table 9.

TABLE 9.—Tolerance on rope diameters

Nominal diameter of rope	Under-size	Over-size
<i>Inches</i>	<i>Inch</i>	<i>Inch</i>
0-3/4	0	3/64
1 1/4-1 1/2	0	1/16
1 3/4-1 1/2	0	5/64

14. *Diameter of wire—Tolerance limits.*—(a) In separating the wire rope for gaging of wire, care must be taken to separate the various sizes of wire

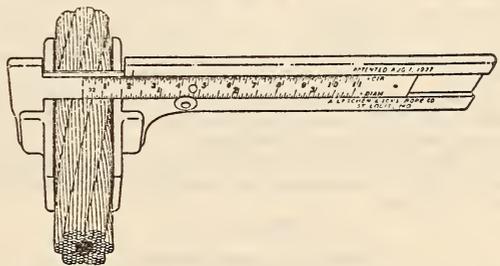

FIGURE 58.—Wide faced wire line calipers

composing the different layers of wires in strand. In like-positioned wires total variations of wire diameters shall not exceed:

Wire size	Total variation
0.064 and larger	<i>Inch</i> 0.004
Smaller than 0.064	.003

15. *Fiber cores.*—(a) For all wire ropes manufactured under this specification, all fiber cores will be of hard-twisted, best-quality Manila or Java hemp, or its equivalent. They shall be of uniform diameter and hardness, and effectively support the strands. They shall be thoroughly impregnated with a suitable lubricating compound, free from acid. No jute cores shall be used.

16. *Lubrication.*—(a) All wire ropes, unless otherwise specified, shall be lubricated and impregnated in the manufacturing process with suitable compound thoroughly to protect the ropes both internally and externally, to minimize rust or corrosion, until the rope is put into service.

17. *Workmanship.*—(a) The rope shall be made from the best quality of specified grade of material, shall be of good workmanship, and shall be free from defects which might affect its appearance or serviceability.

SECTION V

Type of Lines

18. (a) Cable-tool drilling lines shall be $\frac{3}{4}$, $\frac{7}{8}$, 1, and $1\frac{1}{8}$ inches in diameter, lengths to vary in multiples of 500 feet.

(b) Strand fabrication may be 6 by 7, 6 by 8, or 6 by 19 of either Seale, Warrington, or filler-wire construction. However, the arrangement of the different-size wires must be uniform and according to a regular symmetrical plan throughout.

(c) Warrington construction is to be made in one operation, consisting of 6 strands of 19 wires to the strand; the outside of each strand shall be of large and small diameter wires, laid alternately. There are three diameters of wire in the strand.

(d) Seale construction is to be made in one operation, consisting of 6 strands of 19 wires to the strand; the outside wires are to be 9 in number of one diameter around 9 smaller wires; the center wire to be of a larger diameter. There are three diameters of wire in the strand.

(e) Filler-wire construction is to be made in one operation consisting of 6 strands of 19 wires to the strand. All the wires except the center wire to be of approximately the same size; the center wire to be slightly larger. The filler wires are used to support the structure and are therefore not considered as component wires in the rope so far as strength is concerned.

(f) Rotary drilling lines or casing lines shall be $\frac{3}{4}$, $\frac{7}{8}$, 1, and $1\frac{1}{8}$ inches, length to vary in multiples of 250 feet.

(g) Sand lines shall be 6 by 7 construction and shall be $\frac{3}{8}$, $\frac{1}{2}$, $\frac{5}{16}$, and $\frac{3}{8}$ inch in diameter. Lengths to vary in multiples of 500 feet.

(h) Rotary bailing lines shall be $\frac{1}{16}$, $\frac{5}{8}$, and $\frac{3}{4}$ inch, shall be 6 by 19 construction, lengths to vary in 500-foot multiples.

SECTION VI

Galvanized-Wire Guy Strands

19. *Single galvanized-wire guy strand.*—(a) This shall consist of a strand made up of seven twisted galvanized wires of the following minimum breaking stresses per strand:

TABLE 10

Size	Minimum breaking stresses
<i>Inch</i>	<i>Lbs./in.²</i>
$\frac{1}{4}$	1,900
$\frac{5}{16}$	3,200
$\frac{3}{8}$	4,250
$\frac{7}{16}$	5,700
$\frac{1}{2}$	7,400

(b) No test of galvanizing shall be applied to single guy wire strand.

20. *Double or extra galvanized wire guy strand.*—

(a) This shall consist of a strand made up of seven twisted galvanized wires of the following minimum breaking stresses per strand:

TABLE 11

Size	Minimum breaking stresses
<i>Inch</i>	<i>Lbs./in.²</i>
$\frac{1}{4}$	1,900
$\frac{5}{16}$	3,200
$\frac{3}{8}$	4,250
$\frac{7}{16}$	5,700
$\frac{1}{2}$	7,400

(b) Galvanized wire composing the above strand shall be uniformly and continuously coated with zinc which adheres firmly to the wire. The zinc shall be applied in a molten condition by what is designated commercially as "hot-process galvanizing." Using the Preece test, the wire shall not show the appearance of bright, adherent copper, indicating exposed iron, for the number of immersions shown in the following table:

	Immersion
Wires taken from $\frac{1}{4}$ inch strand.....	3
Wires taken from strands $\frac{5}{16}$ to $\frac{1}{2}$ inch diameter, inclusive.	4

21. *Test of galvanizing.*—(Conforms to specification of American Marine Standards Committee, given above.)

SECTION VII

Packing and Marking

22. *Reels.*—(a) Finished wire rope, when so required, shall be shipped in round head, substantial, wooden reels; reels shall preferably have a round arbor hole of 5 inches in diameter for drilling lines, casing lines and sand lines. When reel is full of rope, there shall be a clearance of not less than 2 inches between the full reel and the outside diameter of the flange.

(b) The manufacturer shall properly serve the outer end of rope so that the required 10-foot sample can be cut out for preservation by the purchaser for test purposes, as described in paragraph 24 (c).

23. *Marking of reels.*—(a) The following data shall be plainly marked on the face of the reel on which is wound wire rope meeting the A. P. I. specifications:

- (1) Name of manufacturer.
- (2) Reel number.
- (3) A. P. I. monogram.

(Size of monogram to be in proportion to size of reel, with a minimum height of 2 inches and a maximum height of 4 inches.)

- (4) Grade (J, L, N, or NJ, etc.)
- (5) Diameter of line.
- (6) Length of line.
- (7) Type of construction (Warrington, Seale, or filler wire.)
- (8) Type of core (fiber, wire).

(b) Wire rope which does not comply with these specifications shall not be wound on reels carrying the A. P. I. monogram.

(c) Authority to use the A. P. I. monogram will be granted in accordance with the rules and regulations contained in an appendix.

SECTION VIII

Inspection and Rejection

24. *Inspection.*—(a) Manufacturer will, on request of purchaser, conduct tests as called for in this specification on reasonable notice from the purchaser;

during which tests the manufacturer will afford opportunity to the purchaser's representative to be present.

(b) A manufacturer delivering wire rope bearing the A. P. I. monogram and grade designation warrants that such material complies with these specifications. No rejections under these or any other specifications are to be wound on reels bearing the A. P. I. monogram, or sold as A. P. I. wire rope. When wire rope wound on reels bearing the A. P. I. monogram is rejected, it shall be removed from said reel; or the A. P. I. monogram on said reel shall be canceled by the painting or stenciling of two horizontal and two vertical lines through the body of the monogram.

(c) It is recommended that whenever possible the purchaser upon receipt shall test all new rope purchased in accordance with these specifications. It is realized after a rope is put in use and it fails to render satisfactory service that it is impracticable to retest such used rope. It is therefore required that the purchaser shall preserve at least one test specimen of all new rope purchased; length of specimen to be at least 10 feet, properly identified by reel number, etc. Care must be taken that no damage will result by storage of specimen.

(d) If a purchaser receiving rope purchased on these specifications does not make physical test before putting rope into use, or does not preserve in proper manner the sample as outlined, recourse on the manufacturer shall be considered waived.

(Appendix attached to this specification cover recommended practice for the use and preservation of wire rope, suggested improvements in design of oil-field equipment to lengthen life of wire rope, field troubles and their causes, and directions for attaching sockets to wire ropes.)

AMERICAN RAILWAY ASSOCIATION, SIGNAL SECTION, GALVANIZED MESSENGER WIRE, SPECIFICATION 4714, 1914

GALVANIZED MESSENGER WIRE

1. GENERAL

(a) The intent of this specification is to provide for the furnishing of galvanized messenger wire in strand form.

(b) The strand shall be composed of seven galvanized wires twisted together to the specified lay.

(c) The wires composing the strand shall be cylindrical in form, free from scales, flaws, inequalities, splits, and all imperfections. Each length shall contain no weld joint or splice. All the wires of a strand shall be of the same grade of steel and shall have the same breaking strength.

(d) The galvanizing shall consist of a continuous coating of pure zinc of uniform thickness so applied that it adheres firmly to the wire and presents a smooth surface.

2. PROPERTIES

(a) The mechanical properties of the finished wire shall be in accordance with the following requirements:

Wire

Diameter of strand	Diameter	Area
<i>Inch</i>	<i>Inch</i>	<i>Square inch</i>
½	0.162	0.0206
⅞	.144	.0163
⅝	.120	.0113

Strand

Diameter of strand	Area	Breaking strength	Elongation 24 inches	Lay	Weight
<i>Inch</i>	<i>Square inch</i>	<i>Pounds</i>	<i>Per cent</i>	<i>Inches</i>	<i>Pound per foot</i>
½	0.144	11,000	10	5.5	0.510
⅞	.114	9,000	10	5.0	.415
⅞	.114	15,000	6	5.0	.415
⅝	.079	6,800	10	4.5	.295
⅝	.079	11,500	6	4.5	.295

3. BENDING TEST

(a) The wires shall withstand, without fracture, being wrapped five times around mandrels of certain sizes. This shall not be construed as a test of the galvanizing. Sizes as follows:

Diameter of strand	Diameter of wire	Strand breaking strength	Diameter of mandrel
<i>Inch</i>	<i>Inch</i>	<i>Pounds</i>	<i>Inch</i>
½	0.162	11,000	½
⅞	.144	9,000	½
⅞	.144	15,000	¾
⅝	.120	6,800	½
⅝	.120	11,500	¾

(b) If the wire breaks, three additional tests shall be made from the same wire and if any fail the strand shall be rejected.

4. GALVANIZING TEST

(a) Galvanizing shall comply with Railway Signal Association specification for galvanizing for iron or steel.

5. INSPECTION AND TESTS

(a) The purchaser is to have the right to make such inspection and tests as he may desire of the materials and of the wire at any stage of manufacture.

(b) The manufacturer must provide, at the mill, all apparatus and labor for making the required tests under the supervision of the purchaser.

(c) Tests shall be made at the mill or on samples submitted by the manufacturer and may also be made on the wire upon its arrival at destination.

(d) If, upon arrival at destination, the wire does not meet the requirements of this specification, it will be rejected and returned to the manufacturer, who shall pay all freight charges.

6. PACKING FOR SHIPMENT

(a) The wire shall be furnished in {coils} of the following minimum lengths: Feet.

½-inch strand	1,500
⅞-inch strand	2,000
⅝-inch strand	2,500

(b) When furnished in reels, each reel shall have the weight, length of strand, the name of the manufacturer and purchaser's order or inspection number plainly and indelibly marked on a strong tag securely fastened to the strand and also stenciled on the outside of the reel.

(c) When furnished in coils, each coil shall have the weight, length and size of strand, the name of the maker, the purchaser's order and inspection number and the proper shipping address plainly and indelibly marked on a strong tag securely fastened to the coil.

AMERICAN RAILWAY ASSOCIATION, TELEGRAPH AND TELEPHONE SECTION, SPECIFICATION FOR GALVANIZED STEEL GUY AND MESSENGER STRAND, 1-A-17, 1927

GALVANIZED STEEL GUY AND MESSENGER STRAND

PURPOSE

A-1. The purpose of this specification is to guide the seller or contractor in the manufacture of galvanized steel guy and messenger strand for use in pole line construction and aerial cable installations in the telegraph and telephone plant.

GENERAL

C-1. The quality of the material used and the methods of manufacture shall be such as to insure for the completed wire the properties called for in this specification.

C-2. The seller or contractor must make sure that all material and work are in accordance with the specification before the wire is offered.

(Composition of strand, character, and quality of wires, and galvanizing conform to requirements for A. R. A. Signal Section specification for galvanized messenger wire, given above.)

D-4. All joints in wire composing a strand shall be well made, thoroughly brazed or welded and galvanized. No two joints in the wire of the strand shall be less than 150 feet apart. The outside of the completed strand shall be marked with paint or by other suitable means at each spliced wire.

PHYSICAL AND MECHANICAL REQUIREMENTS

E-1. Any section of the galvanized strand, free from factory joints, shall conform to the requirements of Table 1.

TABLE 1.—Galvanized steel guy and messenger strand

Size of strand	Number in strand	Wires			Strand				
		Gage each wire	Diameter			Minimum breaking strain	Elongation in 2 feet		Lay
			Minimum	Nominal	Maximum		Maximum	Minimum	
Inch 1/4	7	13 B. W. G.	Inch 0.093	Inch 0.095	Inch 0.097	Pounds 4,000	P. ct. 11	P. ct. 3.5	
5/16	7	12 B. W. G.	.107	.109	.111	6,000	22	11	3.5
3/8	7	11 B. W. G.	.116	.120	.124	11,500	17	4 1/2	4.5
7/16	7	7 A. W. G.	.138	.144	.150	218,000	15	4	5.0

¹ Minimum breaking strain, with 1 wire cut, 10,000 pounds.
² Minimum breaking strain, with 1 wire cut, 16,000 pounds.

INSPECTION

G-1. *Place and facilities.*—All testing and inspection shall be made at the place of manufacture. The seller or contractor shall afford the inspector representing the purchaser all reasonable facilities to enable him to satisfy himself that the material conforms to the requirements of this specification.

G-2. *Time.*—The seller or contractor shall notify the purchaser when the strand is ready for inspection, unless otherwise arranged by the purchaser, and shall agree upon a time convenient to the purchaser for inspection.

G-3. *Rejection.*—Strand failing to meet the requirements of this specification in any respect shall be rejected.

G-4. *Factory inspection waived.*—If factory inspection be waived by the purchaser, it shall be so stated on the order and detailed factory test sheets for the wire for which inspection is so waived shall be forwarded to the purchaser.

TESTS

H-1. *Samples.*—Samples for tests shall be selected by the inspector from each 2,500 feet of strand in the shipment or from each reel if more than 2,500 feet is contained thereon. If, upon testing a sample from any lot of strand, the results are found to not agree with the requirements of this specification, tests upon two additional samples shall be made and the average of the three tests shall determine acceptance or rejection of the lot represented by the samples.

H-2. *Tensile strength and elongation.*—Tensile tests shall be made upon the samples and the elongation shall be determined as the permanent increase in length, due to the breaking of the strand in tension, measured between the jaws of the testing machine. The zero length shall be the distance between the jaws when a load equal to 5 per cent of the required ultimate breaking strength shall have been applied, and the final length shall be the distance between the jaws at the time of rupture. The zero length shall be as near 2 feet as possible. The fracture shall be between the jaws and not closer than 1 inch to either jaw.

PREPARATION FOR SHIPMENT

J-1. Strand for shipment in lots of less than 500 feet shall be wound in coils with a diameter of eye of from 20 to 30 inches. Each coil shall be securely bound in not less than four separate places with strong twine or soft galvanized iron wire.

J-2. Lots of 500 feet or more shall be wound on reels in the lengths specified on the order.

J-3. Strand ends shall be securely wrapped to prevent untwisting.

MARKING

K-1. Each coil or reel shall have the size, weight, and length of strand plainly and indelibly marked on a strong tag securely attached.

In less than carload lots, tags shall show in addition the purchaser's order and requisition numbers, name of consignor and name and address of consignee.

K-2. For carload shipments, routing and car identification shall be furnished the purchaser.

(Warranty conforms to that in A. R. A. Signal Section No. 1630. See 611.11, p. 635.)

L-2. The seller or contractor shall covenant and agree to save harmless and indemnify the purchaser against all claims, suits, actions or proceedings, damages, costs, fees, and expenses by reason of alleged infringement of patents, or for patent royalties involved, in consequence of the purchase or the use of the material covered hereby.

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR MOVABLE RAILWAY BRIDGES, WIRE ROPES AND ATTACHMENTS, 1922

WIRE ROPES AND ATTACHMENTS

MANUFACTURER

501. Wire rope shall be made by a manufacturer whose facilities and reputation are approved by the engineer.

LAYING

502. Ropes shall be laid in accordance with the best practice, in an approved lubricant.

SPLICES

503. Ropes shall not be spliced.

WIRES—SIZE AND NUMBER

504. The diameter of counterweight ropes shall be not less than 1 inch, not more than 2½ inches; of operating ropes not less than three-fourths of an inch.

The ropes shall be made of improved plow steel and shall consist of six strands of 19 wires each laid around a hemp center.

SOCKETS

505. Sockets shall be forged without welds from solid steel. The dimensions of sockets shall be such that no part under tension will be stressed higher than 65,000 pounds per square inch when the rope is stressed to its specified ultimate strength. The sockets shall be attached to the rope by a method which is reliable and which will not permit the rope to slip in its attachment to the socket.

WIRE—PHYSICAL PROPERTIES

506. The wire from which counterweight ropes are made shall be tested in the presence of an inspector designated by the engineer. It shall show the following physical properties:

(a) A tensile strength of not less than 225,000 pounds a square inch.

(b) A total elongation (measured on a piece 12 inches long) of not less than 2.4 per cent.

(c) The number of times a piece 6 inches long can be twisted around its longitudinal axis without rupture shall be not less than 1.4 divided by the diameter in inches.

(d) The number of times the wire can be bent 90° alternately in opposite directions over a jaw the radius of which is equal to twice the diameter of the wire, without fracture, shall be not less than six. This test shall be made in a mechanical bender so constructed that the wire actually conforms to the radius of the jaws and is subjected to little tensile stress.

ULTIMATE STRENGTH

507. In order to test the strength of the rope and fastenings, a number of test pieces not more than 12 feet long, with sockets (selected at random from those which are to be used in filling the order) attached to each end, shall be stressed to destruction in a suitable testing machine. The number of test pieces shall be not more than 10 per cent of the total number of finished lengths of rope to be made, nor less than two from each original length. Under this test, the rope shall develop the ultimate strength given in the table below:

Ultimate strength of 6 by 19 improved plow-steel rope

Diameter of rope	Area of section 0.4D ²	Ultimate strength	
		Persquare inch	Entire rope
<i>Inches</i>	<i>Sq. In.</i>	<i>Pounds</i>	<i>Pounds</i>
½	0.100	210,000	21,000
⅝	.156	208,000	32,000
¾	.225	206,000	46,000
⅞	.306	204,000	63,000
1	.400	202,000	81,000
1⅛	.506	200,000	101,000
1¼	.625	198,000	124,000
1⅝	.756	196,000	148,000
1⅞	.900	194,000	175,000
2	1.056	192,000	202,000
2¼	1.225	190,000	233,000
2½	1.406	188,000	264,000
2¾	1.600	186,000	298,000
3	2.025	184,000	373,000
3½	2.500	182,000	455,000

REJECTION

508. If the physical qualities of the rope or of its individual wires fall below those specified, the entire length from which the test pieces were taken shall be replaced by the manufacturer with a new length, the physical qualities of which conform to those specified.

TESTING SOCKETS

509. If slipping in the sockets should occur during the test, the method of fastening the sockets shall be changed until slipping does not occur. The sockets shall be stronger than the rope to which they are attached. If a socket should break during the test, two others shall be selected and attached to another piece of rope and the test repeated. This process shall be continued until the inspector is satisfied as to the reliability of the sockets. If the inspector is satisfied, the lot shall be accepted. If, however, 10 per cent or more of the sockets tested break at a load less than the specified minimum ultimate strength of the rope, the lot shall be rejected.

FACILITIES FOR TESTING

510. The manufacturer shall provide proper facilities for making the tests, and shall make, at his own expense, the tests required. Tests shall be made in the presence of an inspector representing the engineer.

LENGTH

511. The length of each rope shall be measured while the rope is supported throughout its length in a straight line and under a tension of 2 per cent of its ultimate strength. A variation from the required length of not more than one-quarter of an inch in 100 feet, will be allowed.

COILS

512. Ropes shall be shipped on reels of a diameter not less than thirty times that of the rope.

EQUALIZING LEVERS

513. The equalizing levers, and their pins more than 7 inches in diameter, shall be of forged steel. Pins 7 inches or less in diameter shall be of either rolled steel or forged steel.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR ZINC-COATED (GALVANIZED) STEEL WIRE STRAND, DESIGNATION A122-30, 1930

GALVANIZED STEEL WIRE STRAND

SCOPE

1. These specifications cover zinc-coated steel wire strand composed of a multiplicity of wires and suitable for use as guy wires, messenger wires, span wires, etc. The weight classification and all test procedure shall be in accordance with the standard methods of testing zinc-coated (galvanized) iron and steel wire and wire products A. S. T. M., A110. (See 600.3, p. 66.)

MANUFACTURE

2. (Requirements covering zinc used for coating are identical with A. S. T. M., A116. See 603.43, p. 192.)

3. The base metal shall be iron or steel of such quality and purity that, when drawn and galvanized to the size of wire specified, the finished strand will have the properties and characteristics herein specified.

WEIGHT AND UNIFORMITY OF COATING

4. The zinc coating shall be tested for quantity by a stripping test only and for uniformity by the Preece test. The weight and uniformity of the coating shall be defined and tested in accordance with the requirements of the standard methods of testing zinc-coated (galvanized) iron and steel wire products, A. S. T. M., A110. (See 600.3, p. 66.)

TABLE 1.—Commercially available zinc-coated steel wire strand

Nominal diameter of wire in the strand	"Galvanized" common			"Extra or double galvanized" common, Siemens-Martin, high strength, and extra-high strength

.052	-----	-----	✓	-----	-----	-----	-----	✓
.041	-----	-----	✓	-----	-----	-----	-----	✓

NOTE.—Sizes in which any given weight of coating may be regularly obtained in the open market are indicated by a ✓ opposite the nominal diameter in the above table.

For intermediate sizes of wire in the strand the weight and dip designations are the same as for the next finer size shown in above table.

TABLE 2.—Physical properties of zinc-coated steel wire strand

Approximate diameter of the strand	Number of wires in strand	Diameter of wires in strand	Weight of strand per 1,000 feet	Minimum breaking strength			
				Common	Siemens-Martin	High strength	Extra-high strength
Inches		Inch	Pounds	Pounds	Pounds	Pounds	Pounds
3/8	7	0.041	31.8	540	910	1,330	1,830
5/32	7	.052	51.3	870	1,470	2,140	2,940

9/16	7	.188	671	9,600	15,700	24,500	35,000
5/8	7	.207	813	11,600	19,100	29,600	42,400
3/4	19	.125	796	11,000	18,100	28,100	40,200
3/4	19	.150	1,155	16,000	26,200	40,800	58,300
7/8	19	.177	1,581	21,900	35,900	55,800	79,700
1	19	.200	2,073	28,700	47,000	73,200	104,500
1	37	.143	2,057	28,300	46,200	71,900	102,700
1 1/8	37	.161	2,691	36,000	58,900	91,600	130,800
1 1/4	37	.179	3,248	44,600	73,000	113,600	162,200

5. The weight and uniformity of the coating of the various sizes of wire composing the strand shall be as specified by the purchaser and in accordance with the weights and dips designated in Table 1. Commercial strand designated as common strand is available in two weights of coating known as "gal-

vanized" and "extra or double galvanized." Strand designated as Siemens-Martin, high strength, and extra-high strength is furnished and used in one weight of coating only, namely, that which is ordinarily known as "extra galvanized" or "double galvanized."

6. All strand shall have a length of lay not to exceed sixteen times the nominal or approximate diameter of the strand, in inches.

PHYSICAL PROPERTIES AND TESTS

7. The number of wires in a strand, the size of the component wires, the weight per 1,000 feet of strand, and the minimum breaking strength shall conform to the values specified in Table 2.

8. The elongation of the strand in 24 inches shall not be less than the following:

	Per cent
Common strand.....	10
Siemens-Martin.....	8
High strength.....	5
Extra-high strength.....	4

SIZE AND PERMISSIBLE VARIATIONS

9. (a) The size of the finished strand shall be expressed as the diameter of the wire in fractions of an inch.

(b) The diameter of the wire forming the strand shall be within the limits shown in Table 3.

WORKMANSHIP AND FINISH

10. (a) The wire shall be free from splinters, scales, inequalities, flaws, and other imperfections not consistent with good commercial practice.

(b) The zinc coating shall be smooth and continuous.

PACKING AND MARKING

11. Strand wire shall be furnished in lengths as specified and in compact coils or on reels, and shall be well protected against mechanical injury in shipping as agreed upon at the time of placing the order.

INSPECTION, SAMPLING, AND REJECTION

12. (Inspection conforms to A. S. T. M. standard specifications for steel, par. 7. See 605.0, p. 247.)

TABLE 3.—Permissible variations in diameter of zinc-coated steel wire strand

Nominal or approximate diameter of strand	Number of wires in strand	Diameter of wire		
		Nominal	Maximum	Minimum
Inches		Inch	Inch	Inch
3/8	7	0.041	0.043	0.039
5/32	7	.052	.054	.049

1	19	.200	.206	.194
1 1/8	37	.143	.149	.137
1 1/4	37	.161	.167	.155
1 1/2	37	.179	.185	.173

13. In quantities of three or less coils, a sample for all tests shall be taken from each reel or coil.

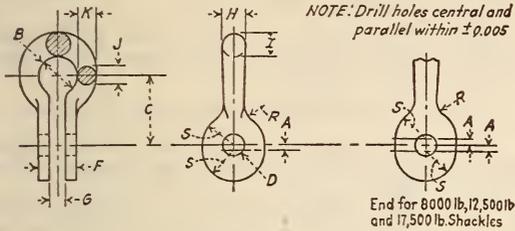

FIGURE 59.—Shackles

On larger quantities, samples shall be taken from 10 per cent of the lot. If over 3 per cent of the samples fail in any one test, the entire lot may be

rejected. In case there is a reasonable doubt as to the failure of the wire or strand in the first trial, two additional tests shall be made, and if no failure occurs in either of these tests, the wire or strand shall be considered acceptable.

**SOCIETY OF AUTOMOTIVE ENGINEERS,
AERONAUTIC; SHACKLES, S. A. E.
STANDARD, AUGUST, 1928**

SHACKLES

PHYSICAL PROPERTIES

Shackles shall show the ultimate strength required when subjected to a tensile test. Shackles, when subjected to a bend test made by opening the shackle and bending flat, shall show no signs of cracking.

UNITED STATES GOVERNMENT, DEPARTMENT OF AGRICULTURE, BUREAU OF PUBLIC ROADS, SPECIFICATIONS FOR FOREST ROAD CONSTRUCTION, 1929

WIRE-CABLE GUARD RAIL

(This specification conforms to tentative specification M-30 of the American Association of State Highway Officials, given above, except that here only 3/4-inch cables are provided for, no mention is made of eyebolts, and requirements covering weight of zinc coating for each wire are omitted.)

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR ROPE, WIRE, NO. 297, 1925. (CURRENT DESIGNATION: RR-R-571)

WIRE ROPE

(In respect to material and workmanship, general requirements, inspection and tests, packing and marking, and additional information, this specification conforms to American Marine Standards Committee O No. 25-1930, given above. In respect to detail requirements, covering types and their physical properties, this specification makes the following provisions:)

IV. DETAIL REQUIREMENTS

1. Type A, 1 by 7 Seizing Strand

Seizing strand of type A shall be made as described and shown in Figure 60 and have the properties given in Table 4.

Construction.—One diameter of wire, one operation. One strand of seven wires, total seven wires. No core.

Material.—Wires: Iron or low carbon steel, annealed and galvanized.

Diameter.—The actual diameter of seizing strand, type A, shall not be smaller than the nominal

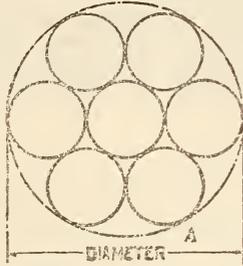

FIGURE 60.—Type A, 1 by 7 seizing strand

diameter nor larger than the nominal diameter plus one-sixty-fourth-inch.

Lay.—Seizing strand, type A, shall be standard lay, and the lay shall not be more than twelve times the nominal diameter.

TABLE 3.—Diameter tolerances for wire rope

Nominal diameter of rope (in inches)	Under size	Over size
	Inch	Inch
0 to 3/4	0	1/32
13/16 to 1 1/8	0	3/64
1 1/8 to 1 1/2	0	1/16
1 1/2 to 2 1/4	0	3/32
2 1/4 and larger	0	1/8

TABLE 4.—Properties of seizing strand, type A

Nominal diameter	Approximate diameter of wire	Approximate weight per foot	Approximate weight per fathom (6 feet)	Weight of reel	Length of strand on reel		Minimum breaking strength
					Feet	Fathoms	
1/16	0.022	0.010	0.06	50	5,000	834	130
3/32	.032	.020	.12	50	2,500	416	280

3/16	.052	.050	.30	50	1,000	166	750

2. Type B, 1 by 19 Seizing Strand

Seizing strand of type B shall be made as described and shown in Figure 61 and have the properties given in Table 5.

Construction.—One diameter of wire, one operation. One strand of 19 wires, total 19 wires. No core.

Material.—Wires: Iron or low carbon steel, annealed and galvanized.

Diameter.—The actual diameter of seizing strand, type B, shall not be smaller than the nominal diameter nor larger than the nominal diameter plus one-sixty-fourth inch.

Lay.—Seizing strand, type B, shall be standard lay, and the lay shall not be more than twelve times the nominal diameter.

3. Type C, 5 by 19 Marline Covered Extra Strong Cast Steel

Wire rope of type C shall be made as described and shown in Figure 62 and shall have the properties given in Table 6.

Construction.—Either (a), (b), (c), or (d) of IV, 9. Five strands of 19 wires each, total 95 wires.

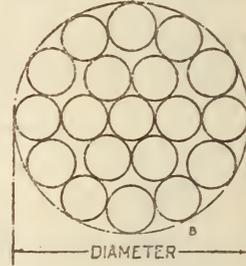

FIGURE 61.—Type B, 1 by 19 seizing strand

Each strand shall be served with marline wound tightly on the strand, so that it is firm, durable, uniformly smooth, and free from knots and imperfections. One main core.

Material.—Wires: Extra strong cast steel, uncoated. Main core, hard fiber.

Diameter.—The actual diameter of wire rope, type C, shall not be more than one-sixteenth inch larger or smaller than the nominal diameter.

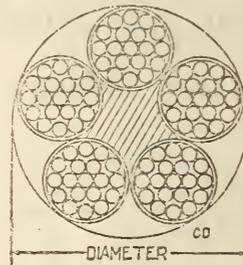

FIGURE 62.—Type C, 5 by 19 marline covered extra strong cast steel

Lay.—Wire rope, type C, shall be regular lay, and the lay shall not be greater than six and three-fourths times the nominal diameter.

TABLE 5.—Properties of seizing strand, type B

1 3/4	2 1/8	4.90	29.4	174,000	38,700	7.0

¹ If the diameter of the drum or sheave is less than the recommended diameter, lower safe working loads should be used.

4. Type D, 5 by 19 Marline Covered High-Grade Plow Steel

Wire rope of type D shall be made as described and shown in Figure 63 and shall have the properties given in Table 7.

Construction.—Either (a), (b), (c), or (d) of IV, 9. Five strands of 19 wires each, total, 95 wires. Each strand shall be served with marline wound tightly on the strand, so that it is firm, durable, uniformly smooth, and free from knots and imperfections. One main core.

Material.—Wires: High-grade plow steel, uncoated. Main core, hard fiber.

Diameter.—The actual diameter of wire rope, type D, shall not be more than one-sixteenth inch larger or smaller than the nominal diameter.

Lay.—Wire rope, type D, shall be regular lay, and the lay shall not be greater than six and three-fourths times the nominal diameter.

TABLE 7.—Properties of wire rope, type D

Diameter before serving	Approximate diameter after serving	Approximate weight per foot	Approximate weight per fathom (6 feet)	Uncoated		Recommended minimum diameter of sheave or drum
				Minimum breaking strength	Maximum safe working load ¹

1 3/4	2 1/8	4.90	29.4	218,000	48,400	7.0

¹ If the diameter of the drum or sheave is less than the recommended diameter, lower safe working loads should be used.

5. Type E, 6 by 7 Extra Strong Cast Steel

Wire rope of type E shall be made as described and shown in Figure 64 and shall have the properties given in Table 8.

Construction.—One diameter of wire, one operation. Six strands of 7 wires each, total 42 wires. One main core.

Material.—Wires: Extra strong cast steel, galvanized. Main core, hard fiber.

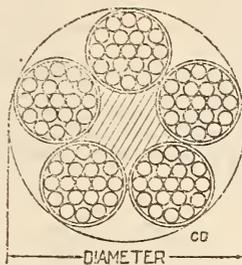

FIGURE 63.—Type D, 5 by 19, marline covered high grade plow steel

Diameter.—The difference between the nominal diameter of wire rope, type E, and the actual diameter shall not be greater than the tolerances given in American Marine Standards Committee Specification O-25, given above.

Lay.—Wire rope, type E, shall be regular lay, and the lay shall not be greater than eight times the nominal diameter.

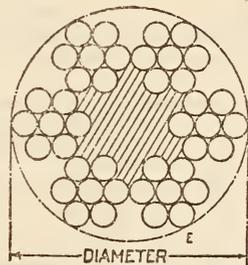

FIGURE 64.—Type E, 6 by 7, extra strong cast steel

6. Type F, 6 by 12 Cast Steel

Wire rope of type F shall be made as described and shown in Figure 65 and shall have the properties given in Table 9.

Construction.—One diameter of wire, one operation. Six strands of 12 wires each, total 72 wires. Six strand cores and one main core, total seven cores.

Material.—Wires: Cast steel, galvanized. Cores. (See Table 9.)

Diameter.—The difference between the nominal diameter of wire rope, type F, and the actual diameter shall not be greater than the tolerances given in Table 3.

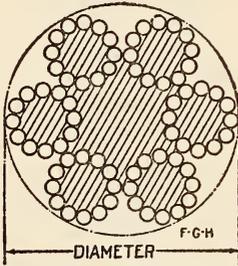

FIGURE 65.—Type F, 6 by 12, cast steel

Lay.—Wire rope, type F, shall be regular lay and the lay shall not be greater than seven and one-fourth times the nominal diameter.

7. Type G, 6 by 12 High-Grade Plow Steel

Wire rope of type G shall be made as described and shown in Figure 66 and shall have the properties given in Table 10.

Construction.—One diameter of wire, one operation. Six strands of 12 wires each, total 72 wires. Six strand cores and one main core, total seven cores.

Material.—Wires: High-grade plow steel, galvanized. Cores. (See Table 10.)

Diameter.—The difference between the nominal diameter of wire rope, type G, and the actual di-

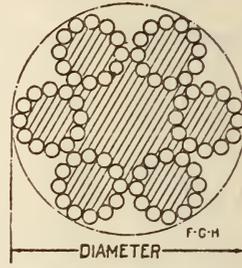

FIGURE 66.—Type G, 6 by 12, high-grade plow steel

ameter shall not be greater than the tolerances given in Table 3.

Lay.—Wire rope, type G, shall be regular lay, and the lay shall not be greater than seven and one-fourth times the nominal diameter.

8. Type H, 6 by 12 Phosphor Bronze

Wire rope of type H shall be made as described and shown in Figure 67, and shall have the properties given in Table 11.

Construction.—One diameter of wire, one operation. Six strands of 12 wires each, total 72 wires. Six strand cores and 1 main core, total 7 cores.

Material.—Wires: Phosphor bronze. Cores. (See Table 11.)

Diameter.—The difference between the nominal diameter of wire rope, type H, and the actual

diameter shall not be greater than the tolerances given in Table 3.

Lay.—Wire rope, type H, shall be regular lay, and the lay shall not be greater than six and three-fourths times the nominal diameter.

9. Types J, K, L, M, and N, 6 by 19 General

The four constructions described and shown in Figure 68, (a), (b), (c), and (d), may be used at the option of the seller or manufacturer for wire rope of

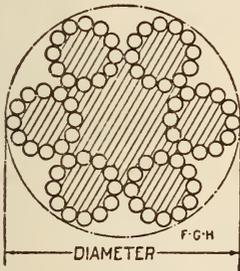

FIGURE 67.—Type H, 6 by 12, phosphor bronze

types J, K, L, M, and N. If Seale construction is desired by the purchaser, this requirement shall be so stated in the order.

Construction.—(a) One diameter of wire, two operations. Six strands of 19 wires each, total 114 wires. All the wires in each strand shall be laid left hand. All the outside wires of each strand shall be of the same diameter. One main core.

(b) Three diameters of wire (Warrington), one operation. Six strands of 19 wires each, total 114 wires. The outside wires of each strand shall be of large and small diameter wires, laid alternately. One main core.

(c) Three diameters of wire (Seale) one operation. Six strands of 19 wires each total 114 wires. All the outside wires of each strand shall be of the same diameter. All the inside wires in each strand, except the central wire, shall be of the same diameter. One main core.

(d) Three diameters of wire and filler wires, one operation. Six strands of 25 wires each, total 150 wires. All the outside wires of each strand shall be of the same diameter. All the inside wires of each strand except the small filler wires and the central wire, shall be of the same diameter. All the small filler wires shall be the same diameter. One main core.

(e) Diameter.—The difference between the nominal diameter of wire rope, types J, K, L, M, and N, and the actual diameter shall not be greater than the tolerances given in Table 3.

(f) Lay.—Wire rope, types J, K, L, M, and N, shall be regular lay, and the lay shall not be greater than six and three-fourths times the nominal diameter, if the wires are uncoated steel or phosphor

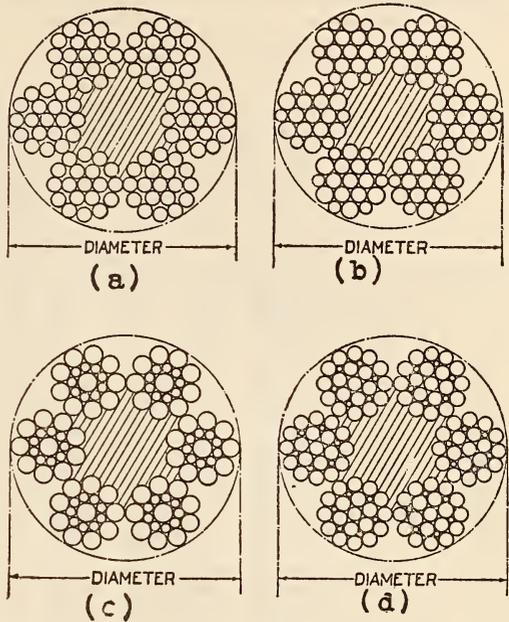

FIGURE 68.—Types J, K, L, M, and N; 6 by 19 cast steel; 6 by 19 extra strong cast steel; 6 by 19 plow steel; 6 by 19 high-made plow steel; 6 by 19 phosphor bronze.

bronze, nor more than seven and one-fourth times the diameter, if the wires are galvanized steel.

10. Type J, 6 by 19 Cast Steel

Wire rope of type J shall be made as described here and in IV, 9, and shall have the properties given in Table 12.

Material.—Wires: Cast steel, uncoated. Main core, hard fiber.

¹ If the diameter of the drum or sheave is less than the recommended diameter, lower safe working loads should be used.

11. Type K, 6 by 19, Extra Strong Cast Steel

Wire rope of type K shall be made as described here and in IV, 9, and shall have the properties given in Table 13.

Material.—Wires: Extra strong cast steel, either uncoated or galvanized. Main core, hard fiber.

15. Type P, 6 by 24 Cast Steel

Wire rope of type P shall be made as described and shown in Figure 69 and shall have the properties given in Table 17.

Construction.—Either 1 diameter of wire, 2 operations (9 inside, 15 outside wires), or 3 diameters of wire, 1 operation (8 inside, 16 outside wires). Six strands of 24 wires each, either 9 inside and 15 outside wires as shown, or 8 inside and 16 outside

wires, total 144 wires. Six strand cores and 1 main core, total 7 cores.

Material.—Wires: Cast steel, galvanized. Cores (see Table 17).

Diameter.—The difference between the nominal diameter of wire rope, type P, and the actual diameter shall not be greater than the tolerances given in Table 3.

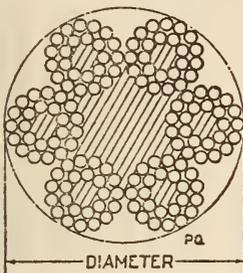

FIGURE 69.—Type P, 6 by 24, cast steel

Lay.—Wire rope, type P, shall be regular lay, and the lay shall not be greater than seven and one-fourth times the nominal diameter.

TABLE 17.—Properties of wire rope, type P

16. Type Q, 6 by 24 High-Grade Plow Steel

Wire rope of type Q shall be made as described and shown in Figure 70 and shall have the properties given in Table 18.

Construction.—Either 1 diameter of wire, 2 operations (9 inside, 15 outside wires) or 3 diameters of wire, 1 operation (8 inside, 16 outside wires). Six strands of 24 wires each, either 9 inside wires and 15 outside wires, as shown, or 8 inside and 16 outside wires, total 144 wires. Six strand cores and 1 main core, total 7 cores.

Material.—Wires: High-grade plow steel, galvanized. Cores (see Table 18).

Diameter.—The difference between the nominal diameter of wire rope, type Q, and the actual diameter shall not be greater than the tolerances given in Table 3.

Lay.—Wire rope, type Q, shall be regular lay, and the lay shall not be greater than seven and one-fourth times the nominal diameter.

TABLE 18.—Properties of wire rope, type Q

17. Type R, 6 by 37 Extra Strong Cast Steel

Wire rope of type R shall be made as described and shown in Figure 71 and shall have the properties given in Table 19.

Construction.—Either 1 diameter of wire, 3 operations, or 4 or 5 diameters of wire, 2 operations.

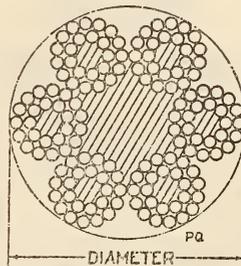

FIGURE 70.—Type Q, 6 by 24, high-grade plow steel

Six strands. Each strand shall have not less than 37 nor more than 43 wires. The number of outside wires of each strand shall be not less than 18 nor more than 20. Total 222 to 258 wires. One main core.

Material.—Wires: Extra strong cast steel, either uncoated or galvanized. Main core. Hard fiber.

Diameter.—The difference between the nominal diameter of wire rope, type R, and the actual diameter shall not be greater than the tolerances given in Table 3.

Lay.—Wire rope, type R, shall be regular lay, and the lay shall not be greater than six and three-fourths times the nominal diameter, if the wire is uncoated, nor greater than seven and one-fourth times the nominal diameter, if the wire is galvanized.

¹ If the diameter of the drum or sheave is less than the recommended diameter, lower safe working loads should be used.

18. Type S, 6 by 37 High-Grade Plow Steel

Wire rope of type S shall be made as described and shown in Figure 72 and shall have the properties given in Table 20.

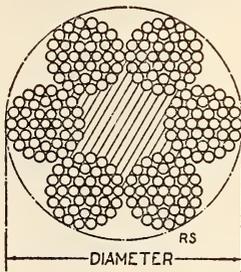

FIGURE 71.—Type R, 6 by 37, extra strong cast steel

Construction.—Either 1 diameter of wire, 3 operations, or 4 or 5 diameters of wire, 2 operations. Six strands. Each strand shall have not less than 37 nor more than 43 wires. The number of outside wires of each strand shall be not less than 18 nor more than 20. Total, 222 to 258 wires. One main core.

Material.—Wires: High-grade plow steel, either uncoated or galvanized. Main core, hard fiber.

Diameter.—The difference between the nominal diameter of wire rope, type S, and the actual diameter shall not be greater than the tolerances given in Table 3.

Lay.—Wire rope, type S, shall be regular lay, and the lay shall not be greater than six and three-fourths times the nominal diameter, if the wire is

uncoated, nor greater than seven and one-fourth times the diameter, if the wire is galvanized.

¹ If the diameter of the drum or sheave is less than the recommended diameter, lower safe working loads should be used.

19. Type T, 8 by 19 Cast Steel

Wire rope of type T shall be made as described and shown in Figure 73 and shall have the properties given in Table 21.

Construction.—One diameter of wire, two operations. Eight strands of 19 wires each, total 152 wires. Strands for wire rope of type T may be of the Warrington, Seale, or of three diameters of wire and filler wire construction as shown for types J, K, L, M, and N. One main core.

Material.—Wires: Cast steel, uncoated. Main core, hard fiber.

Diameter.—The difference between the nominal diameter of wire rope, type T, and the actual diameter shall not be greater than the tolerances given in Table 3.

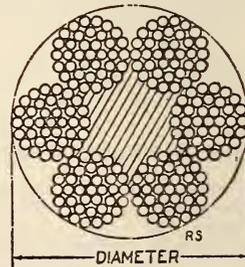

FIGURE 72.—Type S, 6 by 37, high-grade plow steel

eter shall not be greater than the tolerances given in Table 3.

Lay.—Wire rope, type T, shall be regular lay, and the lay shall not be greater than six and three-fourths times the nominal diameter.

TABLE 21.—Properties of wire rope, type T

Nominal diameter	Approximate circumference	Approximate weight per foot	Approximate weight per fathom (6 feet)	Uncoated		Recommended minimum diameter of sheave or drum

603.43. MANUFACTURES OF IRON AND STEEL WIRE.

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR STANDARD RIGHT-OF-WAY FENCES, 1926

RIGHT-OF-WAY FENCES

CLASSES

1. Standard right-of-way fences shall be divided into four classes, the height to conform to statutory requirements, generally about 4 feet 6 inches above the ground.

Class A Fence

2. Class A fence shall consist of nine longitudinal smooth galvanized steel wires; the top and bottom wires shall be No. 7 gage; the intermediate and stay wires shall be No. 9 gage.

The spacing of the longitudinal wires (commencing at the bottom) shall be 4, 4 1/2, 5, 5 1/2, 6, 7, 8, and 9 inches. The bottom wires shall be 5 inches above the ground and the stay wires shall be spaced 12 inches apart.

When used as a hog-tight fence, a strand of barbed wire shall be added 2 1/2 inches below the woven wire.

Class B Fence

3. Class B fence shall consist of seven longitudinal smooth galvanized steel wires; the longitudinal and stay wires shall be No. 9 gage.

The spacing of the longitudinal wires, commencing at the bottom, shall be 6 1/2, 7, 7 1/2, 8, 8 1/2, and 9 inches. The bottom wire shall be 7 inches above the ground and stay wires shall be spaced 12 inches apart.

Class C Fence

4. Class C fence shall consist of woven wire fencing 25 1/2 inches high with three strands of barbed wire above. The woven wire fencing shall consist of seven longitudinal, smooth galvanized steel wires. The longitudinal and stay wires shall be No. 9 gage and the stay wires shall be 12 inches apart. The spacing of the longitudinal wires, commencing at the bottom, shall be 3, 3 1/2, 4, 4 1/2, 5, and 5 1/2 inches, and the bottom wire shall be 2 inches above the ground. The spacing of the barbed wires above the woven wire shall be 4 1/2, 10, and 12 inches.

Class D Fence

5. Class D fence shall consist of five strands of galvanized steel ribbon, smooth, round, or barbed wire fencing.

The spacing of the wires, commencing at the bottom, shall be 10, 10, 12, and 12 inches. The bottom wire shall be 10 inches above the ground.

The longitudinal wires of all woven wire fencing under classes A, B, and C shall be provided with tension curves to take up expansion and contraction.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR ZINC-COATED (GALVANIZED) FARM-FIELD AND RAILROAD RIGHT-OF-WAY WIRE FENCING, DESIGNATION A116-30, 1930

GALVANIZED WIRE FENCING

SCOPE

1. These specifications cover zinc-coated wire fencing of the following commercial types: Farm-field fencing and railroad right-of-way fencing. The weight classification and all test procedure shall be in accordance with the standard methods of testing zinc-coated (galvanized) iron and steel wire and wire products, A. S. T. M., A110. (See 600.3, p. 66.)

MANUFACTURE

2. It is recommended that styles and sizes of fence fabrics covered by these specifications be in accordance with those recommended by the United States Department of Commerce in its Simplified Practice Recommendation No. 9 or its subsequent recommendations. (See below.)

3. The zinc used for the coating shall be any grade of zinc conforming to the requirements of the standard specifications for slab zinc (spelter), A. S. T. M., B6. (See 683.1, p. 1310.)

4. The base metal of the fabric shall be of a good commercial quality of steel or iron wire. If copper is desired, the copper content shall conform to the following requirements:

Copper (minimum):	Per cent
Ladle analysis.....	0.20
Check analysis.....	.15

WEIGHT AND UNIFORMITY OF COATING

5. The weight and uniformity of the coating shall be defined and tested in accordance with the requirements of the standard methods of testing zinc-coated (galvanized) iron and steel wire and wire products, A. S. T. M., A110. (See 600.3, p. 66.)

6. The weight and uniformity of the coating for the various gages of wire composing the fencing shall be as specified by the purchaser and in accordance with the weights and dips designated in Tables 1 and 2.

TABLE 1.—Zinc-coated farm-field fence wire

Nominal diameter of wire	Size, steel wire gage	Class designation	
		Weight 5, dip 3	Weight 3½, dip 2
<i>Inch</i>			
0.192	6	✓	-----
.177	7	✓	-----
.162	8	✓	-----
.148	9	✓	-----
.135	10	-----	✓
.120	11	-----	✓
.105	12	-----	✓
.098	12½	-----	✓

TABLE 2.—Zinc-coated railroad right-of-way fence wire

Nominal diameter	Size, steel wire gage	Class designation—weight 6, dip 4
<i>Inch</i>		
0.192	6	✓
.177	7	✓
.162	8	✓
.148	9	✓

NOTE.—Sizes in which any given weight of coating may be regularly obtained in the open market are indicated by ✓ opposite the gage in the above tables.

In special cases wire may be obtained carrying weights 6 and 5 on smaller gages than indicated in the above table.

SIZE AND PERMISSIBLE VARIATIONS

7. (a) The size of the finished wire shall be expressed as the diameter of the wire in decimal fractions of an inch.

(b) The permissible variations from the nominal diameter shall be:

For wire, 0.109 inch or over in diameter.....	±0.004
For wire, under 0.109 inch in diameter.....	±.003

PACKING AND MARKING

8. Each length of fencing shall be tightly rolled and firmly tied. For ease of handling, consideration should be given to the weight of the roll, depending upon the length of fencing. Each roll shall carry a tag showing the class of coating, the gage of the wire, the length of fencing in the roll, type of fencing, and the manufacturer's name or mark.

INSPECTION, SAMPLING, AND REJECTION

9. (Inspection conforms to A. S. T. M. standard specifications for steel, paragraph 7. See 605.0, p. 247.)

10. All rolls of fencing accepted by the purchaser shall be billed to him on the basis of the original weight or footage of the rolls before sampling.

11. For purpose of tests, 1 roll from each 20 rolls of fencing, but not less than 3 rolls of each lot, shall be taken for a sample. Sufficient length of the fencing shall be cut from the end of the roll to include three stay wires. The test specimens for the line wire shall be cut between these three stays. The test specimens for the stays shall be cut from two of these three stays. All wire knots, wraps, or welds shall be excluded from the test. The resultant specimens of line and stay wire from each sample roll shall be put into separate groups. Three specimens from each of these groups shall be subjected to the test for the weight of coating in accordance with sections 5 and 6, and three specimens from each of these groups shall be subjected to the test for uniformity of coating, in accordance with sections 5 and 6. If 20 per cent of the specimens tested by the weight-of-coating test, or the uniformity test, fail to meet the requirements of these specifications, additional specimens shall be selected as described above, and a retest for the nonconforming properties shall be made; and if 20 per cent of these specimens fail, the entire lot thus inspected may be rejected.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR ZINC-COATED CHAIN-LINK FENCE FABRIC, GALVANIZED AFTER WEAVING, DESIGNATION A117-30, 1930

GALVANIZED CHAIN-LINK FENCE FABRIC

SCOPE

1. These specifications cover zinc-coated chain-link fence fabric in which the individual pickets are helically wound and interwoven in the form of a continuous link fabric without knots or ties. The weight classification and all test procedure shall be in accordance with the standard methods of testing zinc-coated (galvanized) iron and steel wire and wire products, A. S. T. M. A110. (See 600.3, p. 66.)
 2. These specifications cover the usual sizes of wire and mesh as follows:

Nominal diameter of wire	Size, steel wire gage	Size of mesh	Height of fence fabric	
			Inches	
<i>Inch</i> 0.192	6	2	36, 42, 48, 60, 72, 84, 96, 108, 120, 144	
.148	9	2	36, 42, 48, 60, 72, 84, 96, 108, 120, 144	
.120	11	2	36, 42, 48, 60, 72, 84, -----	
.120	11	1½	-----	96, 108, 120, 144

MANUFACTURE

3. The wire shall be woven in the form of approximately uniform square mesh throughout, having parallel sides and horizontal and vertical diagonals of approximately uniform dimensions. The top and bottom of the fabric shall be knuckled or barbed as specified. The fencing shall be galvanized after weaving.
 4. (Requirements covering zinc used for coating are identical with A. S. T. M. A116, given above.)
 5. The base metal of the fabric shall be of good commercial quality of steel or iron wire. If copper is desired, the copper content shall not be less than 0.2 per cent.

WEIGHT AND UNIFORMITY OF COATING

6. (Requirements covering definition and testing are identical with A. S. T. M. A116, given above.)
 7. The weight and uniformity of the coating for the various gages of wire composing the fencing shall be as specified by the purchaser and in accordance with the weights and dips designated in Table 1.

TABLE 1.—Zinc-coated chain-link fence fabric galvanized after weaving

Nominal diameter of wire	Size, steel wire gage	Class designation minimum weight 12, dip 4
<i>Inch</i> 0.192	6	✓
.148	9	✓
.120	11	✓

NOTE.—Sizes in which any given weight of coating may be regularly obtained in the open market are indicated by a ✓ opposite the gage in the above table.

PACKING AND MARKING

8. The continuous lengths of fence fabric shall be 25, 50, or 100 feet, or as specified. Each length of fabric shall be tightly rolled and firmly tied. For ease of handling, consideration should be given to the weight of the roll, depending upon the length of fabric. Each roll shall carry a tag showing the class of coating, the gage of the wire, the length of fencing in the roll, and the manufacturer's name or mark.

INSPECTION, SAMPLING, AND REJECTION

9. (Inspection conforms to A. S. T. M. standard specifications for steel, paragraph 7. See 605.0, p. 247.)
 10. All rolls of fencing accepted by the purchaser shall be billed to him on the basis of the original weight or footage of the rolls before sampling.
 11. For purpose of tests, one roll for each 10 per cent of the rolls of fabric in shipments of less than 50 rolls shall be taken as a sample. One roll representing each 5 per cent of the rolls in shipments of over 50 rolls shall be taken as a sample. In no case shall there be less than three samples taken. The specimens for testing shall consist of 1 square foot of woven fencing selected at any point in the width of the fence fabric, exclusive of the twisted or knuckled portions, and taken from the end of the roll. A specimen from each sample shall be subjected to the test for the weight of coating in accordance with sections 6 and 7, and a specimen from each sample shall be subjected to the test for uniformity of coating in accordance with sections 6 and 7, including reference to A. S. T. M. A116.

By means of the following formulas, the wire surface area in square feet contained in 1 square foot of fabric can be calculated to facilitate the computation of the surface area of the specimens:

$$\text{Square feet of wire surface of size 6 (steel wire gage) wire} = 0.516 W$$

$$\text{Square feet of wire surface of size 9 (steel wire gage) wire} = 0.674 W$$

$$\text{Square feet of wire surface of size 11 (steel wire gage) wire} = 0.830 W$$

where *W* is the weight in pounds of wire in 1 square foot of fabric after being stripped of galvanizing.

If any specimen tested fails to meet the requirements of these specifications, two additional specimens shall be cut from the remainder of the sample and tested, both of which shall meet the requirements in every respect or the lot represented by the sample may be rejected.

AMERICAN SOCIETY FOR TESTING MATERIALS, TENTATIVE SPECIFICATIONS FOR ZINC-COATED CHAIN-LINK FENCE FABRIC, GALVANIZED BEFORE WEAVING, DESIGNATION A118-30T, 1930

GALVANIZED CHAIN-LINK FENCE FABRIC

(This specification is identical with A. S. T. M. A117, given above (including the references in A117 to A. S. T. M. A110, A116, and A. S. T. M. standard specifications for steel under 605.0) except for the weight and uniformity of the coating for the various gages of wire composing the fencing, and permissible variations. In A118-30T the weights and dips and permissible variations are as follows:)

TABLE 1.—Commercially available zinc-coated chain-link fence fabric galvanized before weaving

Nominal diameter of wire	Size, steel wire gage	Class designation, weight 5, dip 3
<i>Inch</i> 0.192	6	✓
.148	9	✓
.120	11	✓

NOTE.—Sizes in which any given weight of coating may be regularly obtained in the open market are indicated by a ✓ opposite the gage in the above table.

SIZE AND PERMISSIBLE VARIATIONS

8. (a) The size of the finished wire shall be expressed as the diameter of the wire in decimal fractions of an inch.
 (b) The permissible variations from the nominal diameter shall be plus or minus 0.004 inch.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR ZINC-COATED (GALVANIZED) BARB WIRE, DESIGNATION A121-30, 1930

GALVANIZED BARB WIRE
SCOPE

1. These specifications cover zinc-coated barb wire in which the wire is coated before or after fabrication, as herein noted. The weight classification and all test procedure shall be in accordance with the standard methods of testing zinc-coated (galvanized) iron and steel wire and wire products A. S. T. M. A110. (See 600.3, p. 66.)

2. These specifications cover the usual sizes and standard constructions of barb wire as follows:

Nominal diameter of wire in the strand	Size, steel wire gage	Commercial designation	Number of barbs	Barb spacing
<i>Inch</i>				<i>Inches</i>
0.105	12	Hog.....	4	4
.105	12	Cattle.....	4	6
.098	12½	Hog.....	4	4
.098	12½	Cattle.....	4	4
.098	12½	Hog.....	2	3
.098	12½	Cattle.....	2	5
.080	14	Hog.....	2	3
.080	14	Cattle.....	2	5

MANUFACTURE

3. (Requirements covering zinc used for coating are identical with A. S. T. M. A116, given above.)

4. The base metal of the barb wire shall be of a good commercial quality of steel or iron wire. If copper is desired, the copper content shall not be less than 0.2 per cent.

WEIGHT AND UNIFORMITY OF COATING

5. (Requirements covering definition and testing are identical with A. S. T. M., A116, given above.)

6. The weight and uniformity of the coating for the various gages of wire composing the barb wire shall be as specified by the purchaser and in accordance with the weights and dips designated in Table 1.

TABLE 1.—Zinc-coated barb wire

Size, steel wire gage	Nominal diameter of strand wire	Class designation, weight 3½, dip 2
	<i>Inch</i>	
12	0.105	✓
12½	.098	✓
14	.080	✓

NOTE.—Sizes in which any given weight of coating may be regularly obtained in the open market are indicated by a ✓ opposite the gage in the above table.

For special purposes, barb wire galvanized before weaving may be obtained in 12½ and larger gages, carrying heavier coatings than indicated in the above table.

For special purposes, barb wire galvanized after weaving is available in the above and larger sizes with a coating of weight 10, dip 4.

SIZE AND PERMISSIBLE VARIATIONS

7. (a) The size of the finished wire shall be expressed as the nominal diameter of the wire in decimal fractions of an inch.

(b) The permissible variations from the nominal diameter in barb wire galvanized before weaving shall be ±0.005 inch.

PACKING AND MARKING

8. Each spool of barb wire shall be compactly wound and fastened and shall be legibly marked in accordance with the specifications of the purchaser.

INSPECTION, SAMPLING, AND REJECTION

9. (Inspection conforms to A. S. T. M. standard specifications for steel, paragraph 7. See 605.0, p. 247.)

10. All spools of barb wire accepted by the purchaser shall be billed to him on the basis of the original weight or footage of the spools before sampling.

11. (a) For purpose of tests, one spool shall be selected at random from every 10 spools or fraction thereof in a shipment. Sufficient length of barb wire shall be cut from the end of the reel to include three barbs.

(b) In the case of barb wire galvanized before weaving, the barbs shall be cut from the strand and discarded. The strand wires shall be tested separately.

(c) Barb wire galvanized after weaving shall be tested as woven with barbs and strand in place.

12. If 20 per cent of the samples tested fail to conform to the requirements of these specifications, then a check test of these same sample spools shall be made, and if in the check test 20 per cent of the samples fail to conform to the requirements, then the entire lot represented by the samples may be rejected.

(See 646.52, p. 1256.)

SOCIETY OF AUTOMOTIVE ENGINEERS, AERONAUTIC; WIRE LOOPS AND FERRULES, S. A. E. RECOMMENDED PRACTICE, AUGUST, 1917

WIRE LOOPS AND FERRULES

AERONAUTIC

The loops for round tinned steel wire are made by threading the tension wire through a ferrule, forming a loop of the specified size, slipping the ferrule

up against the loop and bending the free end of the tension wire over the ferrule as shown in Figure 75. The ferrule is then thoroughly soldered in place without drawing the temper of the tension wire.

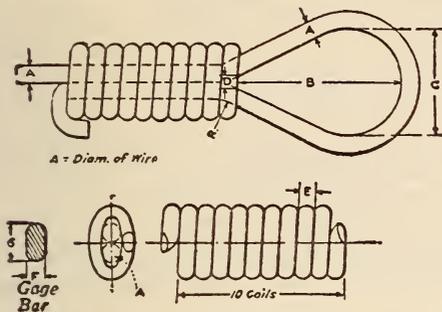

FIGURE 75

Round wire loops					Ferrule E		Gage bar			
Size of wire (A)	B. & S. gage	Inch	B	C	D	R	B. & S. gage	Inch	F	G
8	.128	7/16	17/64	1/16	9/64	9	.114	.130	.260	
10	.102	13/32	9/32	3/32	9/64	11	.091	.104	.208	
12	.081	13/32	17/64	3/32	9/64	13	.072	.083	.166	
14	.064	13/32	17/64	3/32	9/64	15	.057	.066	.132	

Dimensions given in inches. Dimensions "A" and "E" are minima—tolerance, plus 0.002 inch. The gage bar has semicircular edges and shall pass through the ferrule with a clearance of approximately 0.003 inch.

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, WOVEN-WIRE FENCING, SIMPLIFIED PRACTICE RECOMMENDATION R9-28, 1928

WOVEN-WIRE FENCING

In accordance with the unanimous action of the joint conference of representative manufacturers, distributors, and users of woven-wire fencing, the industry has adopted, and approved for promulgation by the United States Department of Commerce, a simplified practice recommendation establishing the following schedule of sizes and varieties of woven-wire fencing:

NOTE.—The changes made by the revision meeting of May, 1928, are indicated in the following tables by *:

TABLE 1.—Field fence

Style ¹	Top ²	Bot- tom ²	Filler ²	Spacing ³			
					No.	No.	No.
11-55, 10-47, 9-39, 8-32, 7-26	9	9	9	} Either 12 or 6 inches.			
					9	9	11
					10	10	12½
					9	9	9
9-49, 8-45, 6-35	9	9	11	} 12 inches only.			
					10	10	12½
9-39*, 8-32, 7-26	11	11	*14½	6 inches only.			

TABLE 2.—Close-mesh hog and cattle field fence

Style ¹	Top ²	Bot- tom ²	Filler ²	Spacing ³
13-46, 12-40, 11-34	No. 10	No. 10	No. 12½	Either 12 or 6 inches.

Gage No.	Wire diameter	Gage No.	Wire diameter
9	Inch 0.1483	13	Inch 0.0915
10	.1350	14	.0800
11	.1205	14½	.0760
12	.1055	15	.0720
12½	.0985	15½	.0672

TABLE 3.—Wolf-proof fence

Style ¹	Top ²	Bot- tom ²	Filler ²	Spacing ³
15-48, 14-43, 10-35, 9-30, 8-25	No. 11	No. 11	*14½	Either 12 or 6 inches.

TABLE 4.—Poultry fence

Heights	Type	Top ²	Bot- tom ²	Filler ²	Spacing ³
36, 48, or 58 inches, with permissible variation of 2 inches higher or lower.	Heavy	No. 10	No. 10	No. 12½	} Either 12 or 6 inches.
	Medium	11	11	13	
	As above and also 72 inches, with 2 inches variation.	Light	11	11	*14½

¹ Style expressed in accordance with regular trade practice, the first number indicating the number of bars and the second the overall height in inches. Thus, 11-55, an 11-bar fence, 55 inches high.

² Steel wire gage (formerly Washburn & Moen gage). The gage numbers referred to in this recommendation are given under Table 2, with their equivalent in decimal parts of an inch. These gage numbers should not be confused with those of the American Wire Gage (formerly Brown & Sharpe).

³ 32 and 16 stays per rod considered equivalent, respectively, to 6 and 12 inch spacing.

This recommendation eliminates all fencing known as farm or field fence made out of Nos. 13, 14, 14½, and lighter gage wire, except the types specifically noted above, and provides that no fencing known as poultry fence shall be made of lighter gage than No. 14½. Fencing made as equivalent to poultry netting is to be so named and of gage not heavier than 15½.

It is further recommended that rolls of field fence be restricted to 10, 20, and 40 rod lengths and rolls of poultry fence to 10 and 20 rod lengths.

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, WIRE INSECT-SCREEN CLOTH, SIMPLIFIED PRACTICE RECOMMENDATION NO. 122, 1931

WIRE INSECT-SCREEN CLOTH

(For copper and commercial bronze-wire insect-screen cloth, see 646.52, p. 1256.)

In accordance with the unanimous action of a general conference of the industry held on June 18, 1931, the United States Department of Commerce submitted for the acceptance of the industry the following recommendation for the stock varieties of wire insect-screen cloth. The industry has since accepted this recommendation.

TABLE 1.—Steel wire insect screen cloth

[Black painted and electrogalvanized, selvaged both edges]

Description	Mesh openings per linear inch ¹	Wire size before weaving ²		Width of roll ³	Length of roll (approximate) ⁴	Packing
		Warp	Filling			
Painted with flexible black paint.....	12	0.0110	0.0110	Inches 18, 20, 22, 24, 26, 28, 30, 32, 34, 36, 38, 40, 42, 48.	Feet 100	Heavy wrapping paper.
Zinc coated by electrolytic method.....	12	.0110	.0110	18, 20, 22, 24, 26, 28, 30, 32, 34, 36, 38, 40, 42, 48.	100	
	14					
	16					
	18					

¹ Commercially exact for warp wires; one-half mesh variation plus or minus in filler wires in any one inch.² Two different sizes of warp and filler wire, approximately the same, having an average diameter of 0.0110 inch permissible.³ Permissible variation in width plus or minus one-eighth inch.⁴ The process of manufacture requires the inclusion of an occasional 2-piece roll; all 2-piece rolls have an extra footage of 2 to 4 linear feet

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR BUILDERS' HARDWARE (NONTEMPLATE), FF-H-101, AUGUST 19, 1930

BUILDERS' HARDWARE (NONTEMPLATE)

(See 617.0, p. 978.)

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR CHAIN AND ATTACHMENTS; STANDARD, MISCELLANEOUS, RR-C-271, DECEMBER 8, 1931.

WELDLESS CHAIN

(See 603.56, p. 212.)

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR FENCING; WIRE (BARBED, NETTING, AND WOVEN), BLACK AND GALVANIZED, RR-F-221, JUNE 24, 1930

WIRE FENCING

A. APPLICABLE FEDERAL SPECIFICATIONS

The following Federal specifications, or parts thereof that are below indicated, of the issue in effect on date of invitation for bids, shall form a part of this specification:

Federal specification	Former number	Title	See
QQ-M-151....	339a	General specifications for metals.	600.0, p. 3.
QQ-Z-351....	91a	Slab zinc (spelter).....	683.1, p. 1311.

B. TYPES

B-1. This specification covers three types of fence wire, as follows: Type A, wire, barbed, zinc coated; type B, wire, woven, farm or field fences, black or zinc coated; and type C, wire, netting, zinc coated.

C. MATERIAL AND WORKMANSHIP, ETC.

C-1. *Material*.—Unless otherwise specified, the base metal of any type of fence wire shall be a good

commercial quality of steel. The zinc used for coating shall be grade E conforming to the requirements of Federal specification QQ-Z-351 for slab zinc (spelter), in effect on date of invitation for bids. (See 683.1, p. 1311.)

C-2. *Workmanship*.—The manufacture of the types and sizes of fence covered by this specification and the zinc coating shall conform to the detail requirements under section E. Welding in the manufacture of the woven fence will not be permitted. This does not prevent the welding of one coil of line wire to another during manufacture. On all type C hexagon wire netting the zinc coating shall be done after weaving.

D. GENERAL REQUIREMENTS

D-1. See section E.

E. DETAIL REQUIREMENTS

E-1. The type and sizes of wire fencing covered by this specification, and the weight and dip of the zinc coating, shall be as follows:

E-2. Type A.

E-2a. In all type A fencing, the twist shall be uniform throughout and so twisted that the strain shall come equally on all main strands. The minimum zinc coating for type A wire shall be weight 3½, dip 2.

E-2b. *Four-point, 0.1055 wire, barbed, zinc coated*.—This shall be zinc-coated barbed wire made of two twisted wires, each 0.1055 inch in diameter, complete with 4-point thick-set barbs sharp pointed and spaced not more than 4 inches apart. The diameter of wire for the barb shall be 0.098 inch, and the length of the barb shall be approximately one-half inch.

E-2c. *Two-point, 0.098 wire, barbed, zinc coated*.—This shall be zinc coated, barbed wire made of two twisted wires, each 0.098 inch in diameter complete with 2-point thick-set barbs, sharp pointed and spaced approximately 5 inches apart. The diameter of wire for the barbs shall be 0.080 inch, and the length of the barb shall be approximately one-half inch or approximately seven-eighths inch as specified.

E-3. Type B.

E-3a. *Wire, woven, farm or field fences, zinc coated*.—This shall be fencing made of steel wire, and of the gage as specified in the invitation for bids. It is intended for fencing in corrals or yards. Unless otherwise specified, it shall be 55 inches wide, with meshes not over 6 inches square, and shall conform to style and sizes recommended by the United States Department of Commerce in simplified practice recommendation No. R9-28 (woven-wire fencing) or their subsequent recommendations. (See above.) For zinc-coated fences, the zinc coat-

ing for the various gages of wire composing the fence shall be as specified by the purchaser and in accordance with the weights and dips designated in Table 1.

E-3b. Sizes in which any given weight of coating may be regularly obtained in the open market are indicated by an X.

E-3c. In special cases wire may be obtained carrying heavier weight of coating on smaller sizes than indicated in Table 1.

E-4. Type C

E-4a. *Wire, netting, zinc coated.*—This shall be poultry netting of widths and meshes indicated below, or any commercial width of mesh that may be specified in the invitation for bids.

TABLE 1.—Commercially available zinc-coated fence wire

Diameter	Weight 5, dip 3	Weight 3½, dip 2	Weight 2, dip 1
<i>Inch</i>			
0.192	X		
.177	X		
.162	X		
.148	X		
.135		X	
.120		X	
.105		X	
.098		X	
.091			
.080			
.076			
.072			
.062			
.054			

Mesh in inches	Width of netting
	<i>Inches</i>
¾	30
1½	72
2	36
2	72

(The first eight items in the upper table are the same as for farm field fence given in A. S. T. M. specification A116-30 above.)

E-4b. Unless otherwise specified, the netting shall be made of steel wire 0.041 inch in diameter. The weight and uniformity of the zinc coating shall be not less than weight 2, dip 1.

F. METHODS OF SAMPLING, INSPECTION, AND TESTS

F-1. The tests for weight and uniformity of the zinc coating are optional with the purchaser.

F-2. *Inspection.*—The inspection, sampling, and rejection shall be as follows:

F-2a. The manufacturer shall afford the inspector representing the purchaser, without charge, all reasonable facilities to satisfy himself that the material is being furnished in accordance with this specification. All tests and inspection shall be made at the place of manufacture, prior to shipment, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

F-3. *For test purposes.*—

F-3a. *Wire, barbed, zinc coated; and wire, netting, zinc coated.*—One roll for each 100 rolls or fraction thereof of each kind of wire shall be taken at random for a sample for test. Sufficient length of both kinds of wire shall be cut from the ends of the roll and the specimen subjected to the tests for the weight of coating as described above.

F-3b. *Wire, woven, farm or field fences, zinc coated.*—(Method of sampling is the same as given in A. S. T. M. specification A116-30 for zinc-coated farm field fence given above.)

F-4. *Tests.*—The weight and uniformity of the zinc coating shall be as follows:

F-4a. *Uniformity of coating.*—The Preece, or copper sulphate, dip tests. (This method is the same as given in A. S. T. M. standard methods of determining weight of coating on zinc-coated articles, designation A90-30. See 600.3, p. 62.)

The requirements of zinc-coated wire withstanding the Preece test shall be designated as 1 dip, 2 dips, 3 dips, 4 dips, etc., depending on the number of 1-minute immersions in the standard Preece test solution the coated wire is required to withstand. Fractional dip classes may be used as 3½ dips, meaning three 1-minute dips plus one ½-minute dip. There is a general relation between the weight of zinc coating and the number of dips in copper sulphate which the coating will withstand.

F-4d. *Weight of coating.*—The weight of coating shall be determined by the hydrochloric acid-antimony chloride method as follows: (This method is the same as given under the hydrochloric acid-antimony chloride method of the standard methods of the A. S. T. M. for determining the weight of coating on zinc-coated articles, designation A90-30. See 600.3, p. 62.)

The sample of galvanized wire may be of any length over 12 inches but preferably about 24 inches.

F-4e. The classes of weights of coating per unit area on zinc-coated products shall be designated in accordance with the following illustrative scheme:

Class designation	Weight of coating
Weight 15.....	Minimum of 1.5 ounces per square foot.
Weight 10.....	Minimum of 1.0 ounce per square foot.
Weight 6.....	Minimum of 0.6 ounce per square foot.
Weight 1.....	Minimum of 0.1 ounce per square foot.
Etc.....	Etc.

(This classification is the same as given in A. S. T. M. standard methods of testing zinc-coated wire products, designation A110-30. See 600.3, p. 66.)

F-4f. This classification shall be extended or interpolated to provide a selection of classes as needed in writing specifications for zinc-coated wire and wire products.

F-4g. The weight of coating of any class of wire being found on inspection to be heavier than that defined for the class shall not constitute cause for rejection unless so specified on the purchase order.

F-5. See paragraph A-1.

G. PACKAGING, PACKING, AND MARKING

G-2. *Packaging.*—

G-2a. *Wire, barbed, zinc coated.*—This shall be furnished in approximately 75-pound or approximately 100-pound coils, as ordered, wound on reels or spools and firmly secured thereto.

G-2b. *Wire, woven, farm or field fences, black or zinc coated.*—Each roll of fabric shall be compactly rolled and tied. Commercial lengths will be acceptable under this specification.

G-2c. *Wire, netting, zinc coated.*—This shall be furnished in rolls of 150 feet each, unless otherwise specified. Each roll shall be compactly tied.

G-3. *Packing.*—Unless otherwise specified, the subject commodity shall be delivered so packed as to insure acceptance by common or other carriers, for safe transportation, at the lowest rate, to the point of delivery.

G-4. *Marking.*—Unless otherwise specified, shipping containers shall be marked with the name of

the material, the size, type, and the quantity contained therein, as defined by the contract or order under which the shipment is made, the name of the contractor, and the number of the contract or order.

G-4a. *Wire, barbed, zinc coated.*—Each coil shall carry a tag showing the net weight, manufacturer's name, and any other marking designated by the purchaser.

G-4b. *Wire, woven, farm or field fences, black or zinc coated.*—Each roll for identification shall carry a tag showing the nominal weight of coating, as ordered, corresponding to Table 1, the gage of the wire, the length of fencing in the roll, type of fence, and the manufacturer's name or mark.

G-4c. *Wire, netting, zinc coated.*—Each roll shall carry a tag showing the length, net weight, manufacturer's name, and any other marking designated by the purchaser.

I. NOTES

I-1. All rolls of fencing accepted by the purchaser shall be billed to him on the basis of the original weight or footage of the rolls before sampling.

I-2. It is believed that this specification adequately describes the characteristics necessary to secure the desired material, and that normally no samples will be necessary prior to award to determine compliance with this specification. If, for any particular purpose, samples with bids are necessary, they should be specifically asked for in the invitation for bids.

I-3. This specification governs all United States Government purchases of this commodity.

603.5 CHAINS AND ATTACHMENTS.

603.50 GENERAL ITEMS.

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, SIMPLIFIED PRACTICE RECOMMENDATION FOR WELDED CHAIN, R100-29, FEBRUARY 1, 1929

WELDED CHAIN

On November 15, 1928, a general conference of representative manufacturers, distributors, and users of welded chain drafted a simplified practice recommendation. The industry has since adopted, and approved for promulgation by the Department of Commerce, this recommendation, which eliminates from the list of stock items the following sizes and varieties:

NOTE.—Unless otherwise indicated, the dimensions shown below represent nominal sizes.

Straight link proof coil chain.—Eliminate sizes $\frac{1}{16}$, $\frac{3}{16}$, $\frac{5}{16}$, $\frac{1}{2}$, $\frac{3}{4}$, $\frac{7}{8}$, $1\frac{1}{8}$, and $1\frac{1}{4}$ inches.

Straight link BB chain.—Eliminate sizes $\frac{1}{16}$, $\frac{3}{16}$, $\frac{5}{16}$, $\frac{1}{2}$, $\frac{3}{4}$, $\frac{7}{8}$, $1\frac{1}{8}$, and $1\frac{1}{4}$ inches.

Straight link BBB chain.—Eliminate sizes $\frac{1}{16}$, $\frac{3}{16}$, $\frac{5}{16}$, $\frac{1}{2}$, $\frac{3}{4}$, $\frac{7}{8}$, $1\frac{1}{8}$, and $1\frac{1}{4}$ inches.

Dredge chain.—Eliminate sizes $\frac{1}{16}$, $\frac{3}{16}$, $\frac{5}{16}$, $\frac{1}{2}$, $\frac{3}{4}$, $\frac{7}{8}$, $1\frac{1}{8}$, and $1\frac{1}{4}$ inches.

Proof, BB, and BBB coil chain (exact sizes).—Eliminate sizes $\frac{3}{16}$, $\frac{1}{4}$, $\frac{5}{16}$, $\frac{3}{8}$, and $\frac{1}{2}$ inch.

Single breast chains.—Eliminate all sizes except 26-8-2, 28-10-2, and 30-10-1.

Double slack breast chains.—Eliminate all items except 26, 28, and 30 inch regular pattern.

Single tapered breast chains.—Eliminate all items except 27-inch, tapered $\frac{5}{16}$ to $\frac{1}{4}$ inch, and 32-inch, tapered $\frac{3}{8}$ to $\frac{5}{16}$ inch.

Bow breast chains.—Eliminate all items.

Slide breast chains.—Eliminate all items.

Single cart back chains.—Eliminate all sizes except $\frac{3}{32}$ -inch diameter.

Double cart back chains.—Eliminate.

Cart breeching chains.—Eliminate all sizes except $\frac{1}{2}$ -inch diameter.

Cold shuts.—Eliminate all sizes of No. 2 pattern with shoulder.

Double chin chains.—Eliminate.

Butt chains.—Eliminate all items except 8 links to the foot, made from No. 2, No. 1, and No. 0 gages.

Hip strap chains.—Eliminate.

Jockey chains.—Eliminate.

Lazy chains.—Eliminate.

Lap rings.—Eliminate.

C links.—Eliminate all items except $\frac{1}{2}$ by $2\frac{1}{2}$ inches.

Trace chains.—Eliminate all items except 8 links per foot and 10 links per foot, made from No. 2 No. 1, and No. 0 gages, and all to be made with 6 links measuring $\frac{5}{8}$ by 2 inches inside between ring and swivel.

Stage traces.—Eliminate all items except $3\frac{1}{2}$ -10-1 buckeye pattern, $3\frac{1}{2}$ -8-2 regular pattern, $3\frac{1}{2}$ -10-2 Pennsylvania pattern, and $3\frac{1}{2}$ -10-2 South Jersey pattern.

Stake chains.—Eliminate all items except $6\frac{1}{2}$ -8-2 and $6\frac{1}{2}$ -8-1.

Tug chains.—Eliminate.

Fifth chains.—Eliminate.

Wagon chains.—Eliminate $\frac{1}{4}$ -inch diameter.

Cow ties.—Eliminate all open-ring type; all closed-ring type; all sizes of Ohio pattern except 2/0-4 $\frac{1}{2}$, 3/0-4 $\frac{1}{2}$, 4/0-5, 5/0-5, 6/0-5 $\frac{1}{2}$, and 7/0-6 foot.

Chain dogs, ring dogs.—Eliminate all items except the following:

Style A chain dogs, plain point.—Blades, $\frac{3}{8}$ by $1\frac{1}{2}$ by $6\frac{1}{2}$ inches; center links, $1\frac{1}{2}$ inch; and end links, $1\frac{3}{4}$ inch.

Style B chain dogs, diamond point.—Blades, $\frac{1}{2}$ by $1\frac{1}{2}$ by $6\frac{1}{2}$ inches; center links, $1\frac{3}{4}$ inch; and end links, $1\frac{3}{4}$ inch.

Style C plain ring dog.—Blades, $\frac{3}{8}$ by $1\frac{1}{2}$ by $6\frac{1}{2}$ inches; and ring, $\frac{1}{2}$ by 3 inches internal diameter.

Style D diamond point ring dog.—Blades, $\frac{1}{2}$ by $1\frac{1}{2}$ by $6\frac{1}{2}$ inches; and ring, $\frac{1}{2}$ by 3 inches internal diameter.

Style E Norfolk pattern ring dog.—Blades, $\frac{1}{2}$ by 2 by $6\frac{1}{2}$ inches; and loop, $\frac{5}{16}$ by 3 by 4 inches internal diameter.

Heel chains.—

Nos. 5 and 8 eliminate.

Nos. 9, 10, and 11 eliminate No. 2 wire; make in No. 1 only.

Nos. 25, 35, 40, and 41 eliminate.

No. 45 eliminate No. 2 and No. 00, making only in No. 1 and No. 0 gages.

Nos. 46, 50, and 51 eliminate.

No. 52 eliminate No. 2 and No. 00 gages, making in No. 1 and No. 0 gages only.

Nos. 55 and 56 eliminate.

No. 57 eliminate No. 1 gage, making in No. 0 gage only.

No. 60 eliminate.

No. 61 eliminate No. 2 and No. 0 gages, making in No. 1 gage only.

Nos. 63, 64, and 65 eliminate.

No. 66 eliminate No. 1 and No. 2 gages, making in No. 0 gage only.

Nos. 80 and 81 eliminate.

Nos. 85 and 86 eliminate No. 2 gage, making in No. 0 and No. 1 gages only.

Nos. 88, 90, and 95 eliminate.

No. 99 eliminate No. 1 and No. 2 gages, making in No. 0 gage only.

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION RR-C-271, FOR STANDARD MISCELLANEOUS CHAIN AND ATTACHMENTS, DECEMBER 8, 1931

CHAIN AND CHAIN ATTACHMENTS

(Specifications contained in this publication relating to chain and chain attachments have been placed in this compilation under their proper commodity designations, as follows:)

Commodity designation	Material	Page
603. 50	General specifications	199
603. 51	Long straight link chain	201
603. 52	Close link coil chain	204
603. 54	Twist link coil chain	211
603. 56	Weldless chain	212
603. 57	Chain attachments	217
617. 5	Sash attachments	1049
631. 9	Aluminum safety chain	1164
642. 9	Plumbers, copper chain	1191
645. 9	Brass chain	1242
646. 59	Bronze sash chain	1258

GENERAL SPECIFICATIONS

General specification for metals, Federal Specifications Board No. 339a (current designation: QQ-M-151), in effect on date of issuance of proposals, shall form part of this specification. (See 600.0, p. 3.)

MATERIAL AND WORKMANSHIP

1. *Class 1.*—Wrought-iron chain. The wrought iron shall be any wrought iron which has been rolled first into muck bars and these bars twice piled and rerolled. It shall be free from any admixture of iron scrap or steel.

NOTE.—The term "iron scrap" applies only to foreign or bought scrap and does not include local mill products free from foreign or bought scrap.

2. *Class 2.*—Wrought-iron or open-hearth steel chain. The wrought iron may be made from a mixture of all pig-puddled iron and reworked scrap or from all reworked scrap. Unless otherwise specified, chain one-half inch and smaller may be made from open-hearth steel.

NOTE.—The term "reworked scrap" applies to steel and iron scrap, or a mixture of both.

4. Weldless chain shall be made from steel, copper, brass, or bronze wire; or stamped from sheets of steel, copper, brass, or bronze.

5. Chain attachments shall be of material as hereinafter specified. When a drop-forged steel piece is specified, the steel shall be of class 2. If the chain is of class 1 wrought iron, the attachments shall be of class 2 steel.

6. The chain and attachments shall be free from injurious defects and shall have a workmanlike finish.

GENERAL REQUIREMENTS

7. The nominal weights of 100 feet, nominal lengths of 100 links, and nominal dimensions of links for chain of various sizes shall be as given in Table 1 below.

8. The weights of 100 feet and lengths of 100 links of chain shall not vary more than 4 per cent over or under the nominal weights and lengths specified in Table 1 below. Excess weight over the permissible variations of 4 per cent may be cause for rejection.

9. *Nominal weights and dimensions.*—

TABLE 1

Nominal size of chain bar	Actual size of material	Nominal length of 100 links		Nominal weight per 100 feet

-----	-----	-----	5 3/4	2 3/4	-----	-----	-----	-----

NOTE.—Class 2. For ordinary chain, various lengths of links, dimensions, and weights are approximate only.

10. The diameter of the bar in all chain shall not be less than nominal size in the body and welds, and unless otherwise specified, the weld shall not exceed the diameter of the bar more than 25 per cent.

11. Class 1 chain shall be hot formed, hot scarfed and lap-fire-welded, unless otherwise specified. When handmade chain is specified, it shall be branded with the word "Handmade" every 6 feet. Class 2 may be made by either fire or electric welding processes.

12. Chain and attachments shall be self-colored, rough tumbled bright finish, black, hot or cold galvanized, electrocopperplated, brass, bronze, or nickel-plated finish, as specified.

DETAIL REQUIREMENTS

13. The wrought iron and steel of the respective classes of chain shall conform to the following requirements as to chemical composition.

	Iron, class 1	Steel, class 2
	Per cent 0.10	Per cent 0.05 .05
Manganese, not over.....		
Phosphorus, not over.....		0.05
Sulphur, not over.....		.05

PROOF AND BREAKING LOADS

14. *Class 1.*—The proof and breaking loads shall be in accordance with the requirements of class 1 chain. (See comparative table facing p. 200.) The percentage of elongation shall be as specified for class 1 chain.

15. *Class 2.*—The proof and breaking loads shall be in accordance with the requirements for class 2 chain. (See comparative table facing p. 200.) The dimensions and weights shall be in accordance with Table 1. The percentage of elongation shall be as specified for this class of chain.

METHOD OF INSPECTION AND TESTS

17. All chain having breaking and proof requirements, shall first be subjected to the breaking tests and after satisfactorily passing that, to the proof test. These requirements are covered in the comparative table facing page 200, except in those cases where individual tables are given or where tests are not required.

18. Samples from finished chain shall conform to the minimum requirements as to tensile strength specified in the comparative table facing page 200.

19. The inspector representing the purchaser shall have free entry at all times while the work on the contract of the purchaser is being performed, to all parts of the manufacturer's works which are concerned with the manufacture of the chain ordered. The manufacturer shall afford the inspector, free of charge, all reasonable facilities to satisfy him that the chain is being manufactured under this specification. Tests and inspection shall be conducted so as not to interfere unnecessarily with the operation of the works.

20. All handling of material necessary for purposes of inspection shall be performed, and all test specimens necessary for determining the qualities of the materials used, shall be prepared by and at the expense of the contractor.

21. All material when practicable shall be inspected and tested at the place of manufacture. Acceptance by the inspector shall be provisional only, subject to final acceptance upon delivery, except where delivery at the manufacturer's plant is specified.

22. Prior to testing and inspection the chain shall be free from paint or other coating which would tend to conceal defects. If chains are to be galvanized, surface inspection shall be made before and after galvanizing and proof tests and breaking tests shall be made before galvanizing.

23. When requested the manufacturer shall furnish a certificate of proof test. Unless break tests are made in the presence of the purchaser or his representative, the manufacturer shall furnish a certificate of break tests.

24. Proof tests of finished chain: After breaking tests, each lot which has satisfactorily passed that test shall be proof tested where required by subjecting it to the loads specified under each group. After proof test, the chain shall be thoroughly inspected and any links showing cold welding, surface rupture, deformation, inferior workmanship,

or other defects shall be taken out and replaced and the chain again subjected to proof stress. If the total number of defective links exceeds 5 per cent, the lot shall be rejected.

25. Tension-test specimens shall consist of a length not less than 2 feet cut from the finished chain. One tension test shall be made to represent each lot of 200 feet of chain or fraction thereof ordered. If the tension test fails to conform to the requirements specified, two additional tension tests may be made from the same lot, each of which shall meet the requirements.

26. The elongation, determined in a gage length of from 12 to 18 inches to the nearest link, shall conform to the following minimum requirements for the respective classes:

	Per cent
Class 1.....	15
Class 2.....	15

27. Standard chain attachments shall be subjected to the same proof-test load as the chain with which they are to be used. At least 1 out of every 50 or less to be furnished under a contract or order shall be selected for test on quantities of 100 or less and 1 for each additional 200 or less. If any of these pieces fails or shows defective welds the total number of test samples shall be doubled and a second failure will result in rejection of the lot.

28. Analysis of material for class 1 or class 2 may be made from bars or from finished chain. One sample of not less than 2 ounces of drillings or cuttings shall be taken from each class of chain delivered or from each ton or fraction thereof of wrought iron or each melt of steel. The cuttings or drillings shall be clean, fine, dry, free from all foreign substances and representative of the material and shall conform to the requirements specified.

29. Drillings for analysis shall be taken with a drill the diameter of which is approximately one-half the diameter of the bar from which drillings are taken, and the cutting shall be taken through the bar from surface to surface.

30. The length shall be measured after the chain has been proof tested and shall be measured to the inside of the end links.

31. In determining the length of the chain, a load not exceeding 10 per cent of the proof load shall be applied to take up the slack.

PACKING AND MARKING

32. Chain and chain attachments purchased under this specification shall be packed and marked as required by the purchaser.

NOTES

33. Bidders shall in all cases state the kind of material they proposed to furnish under class 2 and may submit separate prices for wrought iron or steel or both.

34. Coil chain will be paid for on a basis of actual weight delivered up to and including 4 per cent excess. Excess weight above 4 per cent if accepted will not be paid for.

35. Class 1 is for slings, cranes, hoists, steam shovels, and marine uses, and where an all-iron chain is desired and is sold under the trade designation "crane chain."

36. Class 2 is for ordinary slings and hoists and general service where safety is not a factor and is sold under the trade designation "proof coil."

37. Brass chain for mechanical communication is required for use in pulleys having a $\frac{1}{16}$ -inch groove used on a line of signal transmission of mechanical telegraphs.

38. Weldless close-link chain made from rolled steel or iron bar will be acceptable under this specification.

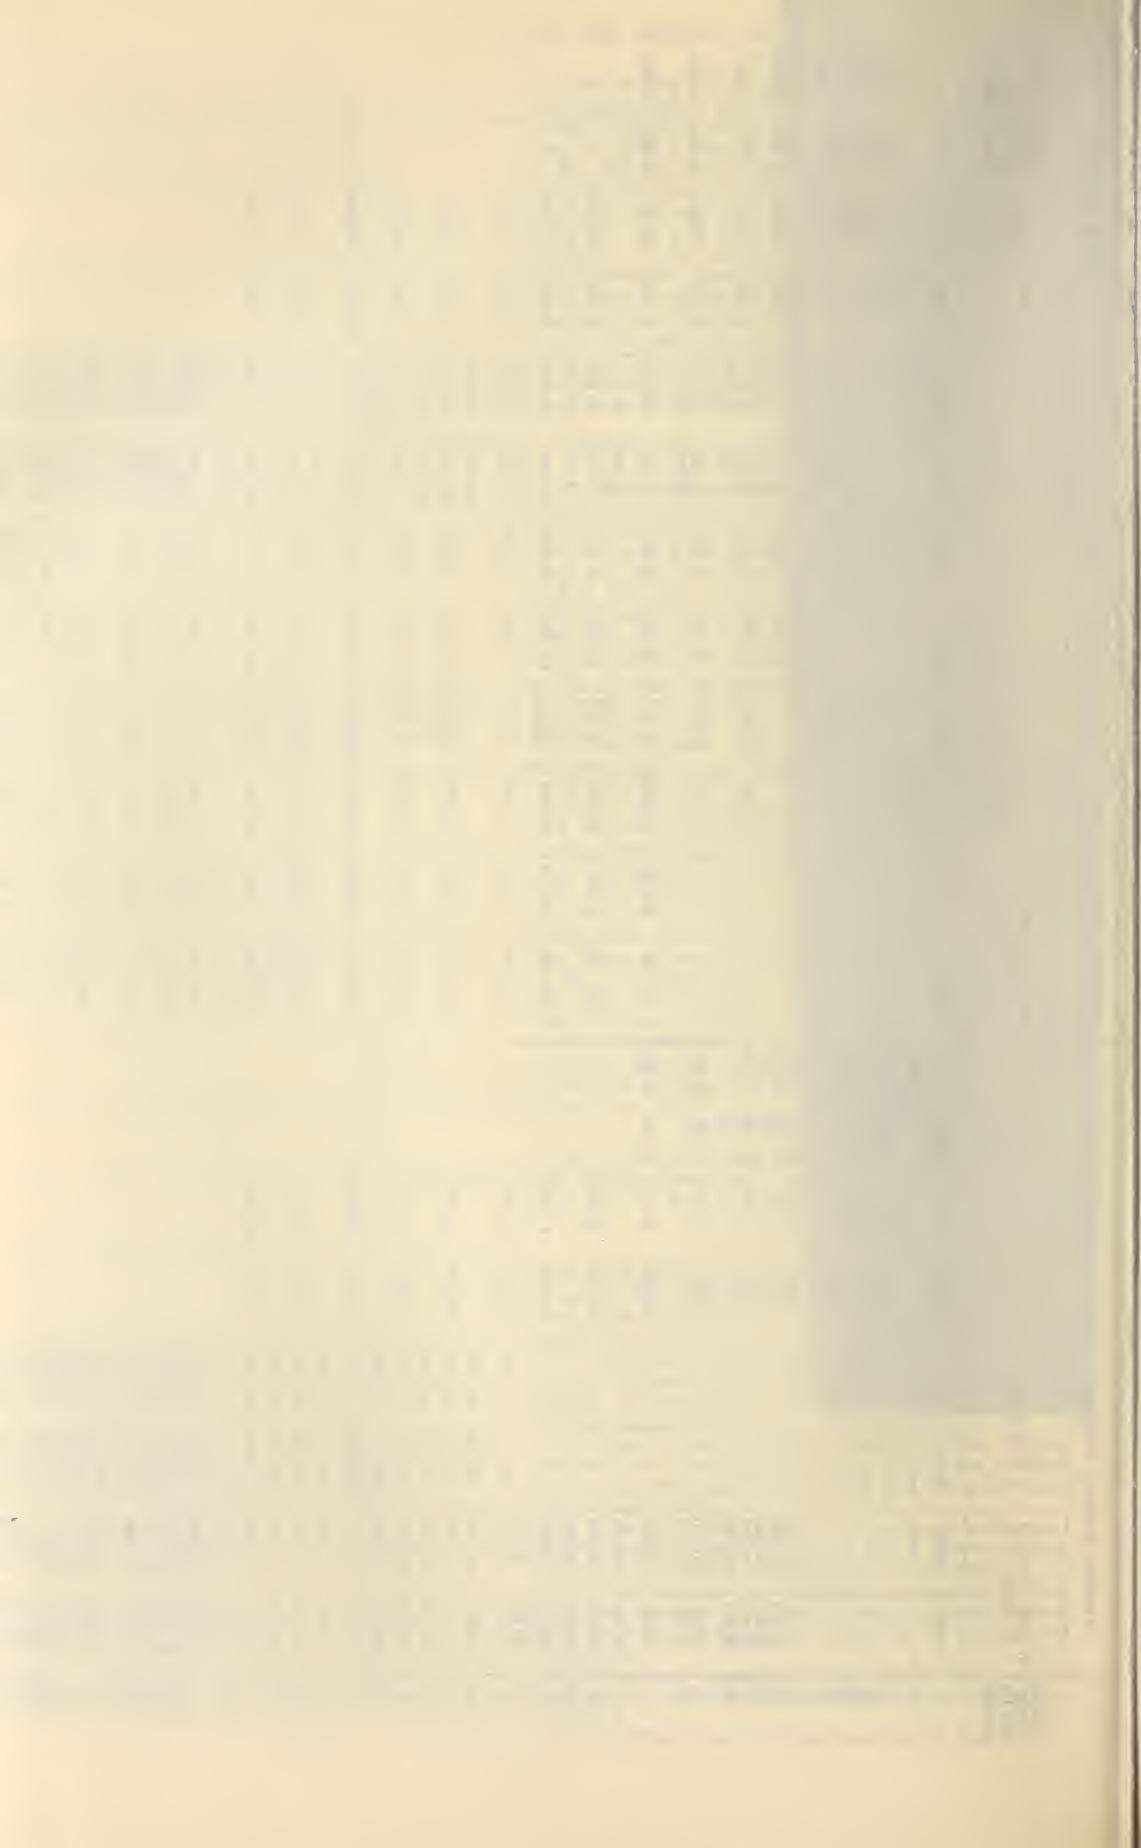

39. Weldless chain will be paid for by the foot.

4 1/8									1,243,200	888,000										

1 In cases where 2 proof loads are given annealing will only be required for chain which will be subjected to the higher proof test. For these sizes the purchaser shall specify which requirements are desired.

NOTE.—A. S. T. M. A56-30 break and proof test loads identical with F. S. B. RR-C-21.

603.51. LONG-LINK CHAINS.

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION RR-C-271, FOR STANDARD MISCELLANEOUS CHAIN AND ATTACHMENTS, DECEMBER 8, 1931.

MISCELLANEOUS CHAINS AND ATTACHMENTS
LONG LINK COIL CHAIN

1. Long link coil chain shall be of the following classes: (1) Wrought iron, (2) wrought iron or open-hearth steel.

(For general specifications, material and workmanship, detail requirements, and methods of inspection and tests, see 603.50, p. 199. For proof and breaking loads see comparative table facing p. 200. For other kinds of chain and chain attachments specified in F. S. B. No. 348 (RR-C-271) see 603.52, 603.54, 603.56, 603.57, and 617.5. See also 631.9, 642.9, 645.9, and 646.59.)

BUOY OR SUBMARINE NET CHAIN

2. Buoy or submarine net chain shall be made of class 2 material wrought iron only, and in accordance with Table 1. The proof and breaking loads shall be in accordance with the requirements for

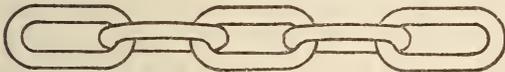

FIGURE 76.—Long link coil chain

this class as shown in comparative table facing p. 200. The percentage of elongation shall be as specified for this class of chain.

TABLE 1.—Buoy or submarine net chain (dimensions)

CONVEYOR OR SPROCKET-WHEEL CHAIN

3. Conveyor or sprocket-wheel chain shall be made of class 2 material. Chain from 1/2 inch to 1 1/4 inches, inclusive, shall be made of steel, chain from 1 1/2 inches and larger to be made of iron unless otherwise specified. The proof and the breaking loads shall be in accordance with the requirements for this class as shown in the comparative table facing page 200. The percentage of elongation shall be as specified for this class of chain. Otherwise the chain shall be in accordance with Table 2.

TABLE 2.—Conveyor or sprocket-wheel chain (dimensions)

Size	Inside width of link	Inside length of link	Weight per 100 feet

603.52 SHORT LINK, STRAIGHT-LINK CHAINS.

AMERICAN BUREAU OF SHIPPING, RULES FOR BUILDING AND CLASSING STEEL VESSELS; WROUGHT-IRON AND STEEL CHAINS, 1930

WROUGHT-IRON AND STEEL CHAINS

(For general information and requirements see 600.0, p. 2.)

1. No vessel can be classed with the letter E unless the chain cables have been tested, and the weights and dimensions are in accordance with the requirements of the American Bureau of Shipping. (The dimensions and weights for like diameter of chain bar are the same for outside length and outside width as those for stud-link chain cable shown in American Bureau of Shipping, Table 1. (See 603.53, p. 206).)

2. All chain cables, stream chains, and steering chains are to be tested under the inspection of a surveyor to the American Bureau of Shipping, and in a machine recognized for such purposes by the committee of the A. B. S.

MATERIAL AND WORKMANSHIP

3. Chains are to be manufactured from a good quality of wrought iron, or from steel made by the open-hearth process, which shall be ductile and of satisfactory welding quality. They may be hand forged, machine or die made, or electrically welded. The finished chain is to be of good workmanship and free from injurious defects, and is to be carefully gaged to ascertain if the material is full to size and in accordance with the table.

4. There is to be an odd number of links to each shot to insure shackles leading over the windlass in the same direction. The size for descriptive and test purposes is to be the diameter of the common link of the chain with a plus tolerance which is not to exceed one-thirty-second-inch in the case of chains up to and including 1½ inches in diameter. In the case of chains above 1½ inches in diameter the tolerance is not to exceed one-sixteenth inch.

5. The sectional area of the material at the weld of the common link is not to be reduced below that of the prescribed minimum diameter of the common links of the chain. The links may be either end or side welded. Prior to testing and inspection, the chain shall be free from paint or any other coating which would tend to conceal defects.

6. All chain studs must be well centered and firmly held in place, and may be of cast iron, wrought iron, or steel. Each shot should be stamped with a distinctive mark in order to identify it through the several processes of gaging, testing, measuring, examining, repairing, and weighing. In the event of the surveyor being in attendance at the works while chains are being fabricated which are ultimately proposed to be submitted for testing, he will arrange to select the break-test specimens as far as possible during the process of fabrication.

BREAKING AND PROOF TESTS

7. Where the rods from which the chain is made have been tested by the bureau's surveyor in accordance with the requirements for bars (see 603.1, p. 135) a specimen of 2 links or more, as may be found necessary, is to be cut from 1 shot of 15 fathoms or less of each lot of 5 shots presented and subjected to the breaking test. If this test is satisfactory the shot from which the specimen has been taken shall be joined with a joining link and the shot subjected to the proof test, along with the four remaining shots presented. If the first test is not satisfactory, one more specimen is to be cut out and subjected to the breaking test; and if this fails the shots shall be rejected, and, in addition, a specimen of 2 links or more as may be found necessary is to be cut from each of the 4 remaining shots of 15 fathoms or less and subjected to the breaking test. If this test is satisfactory then each shot from which the specimen has been taken shall be joined with a joining link and the shots subjected to a proof test.

8. Where the rods from which the chain is made have not been tested by the bureau's surveyor, a specimen of two links or more from each shot of 15 fathoms or less is to be subjected to the breaking test described above. If the break-test specimen satisfactorily withstands the breaking test as prescribed by the rules, the specimen need not be tested to

destruction, but must be discarded. Each 15 fathoms or less is to be subjected to the proof test.

9. After the proof test the length of the chain is to be ascertained. The chain shall then be carefully examined and any link showing surface rupture or deformation is to be taken out, the chain repaired, the proof test again applied, and the chain reexamined. If one link breaks under the proof test, a joining link shall be inserted and the proof test again applied. If a second link breaks under the second proof test, or if 5 per cent of the links are found defective, the shot shall be rejected.

10. The end shackles, joining shackles, spare shackles, and swivels required for a length of chain are to be tested to the same proof test as the chain, and at least 1 out of every 25 of the shackles is to be subjected to the breaking test, and must be discarded.

11. Where a chain which has already been in use is submitted for testing or retesting, the size for descriptive and testing purposes is to be the mean diameter of the part most worn. The certificate issued in regard to same will be marked in red: "This chain is not new but has been previously used."

12. When chains are supplied in continuous lengths without joining shackles it will be so noted on the certificate. In such cases a specimen of two links or more, as may be found necessary, is to be cut from each 30 fathoms or less and subjected to the breaking test. If this test is satisfactory the several shots are to be joined up and each 15 fathoms or less is to be subjected to the proof test.

13. Care must be taken that arrangements are made for each link to be tested once and only once during the test, and the gripping arrangements must be such that they do not put any stress on the end links of the portion under test, except such stress as is equally put on every link tested. Otherwise the requirements are to be as prescribed in this paragraph.

14. Where chains are not to be used for ships, and are not required to be in accordance with the rules of the American Bureau of Shipping, the committee will approve of their surveyors testing such chains to suitable specifications other than those stated in the rules, provided these are mutually agreed upon by the manufacturers and purchasers. A special form of certificate will be issued in such cases.

15. The breaking and proof tests, and minimum weights per 15 fathoms, of unstudded short-link chains are as shown in the table below.

WEIGHING AND MARKING

16. When chains have satisfactorily passed the above requirements they are to be weighed, together with the shackles forming the outfit, and this actual weight will be given on the certificate of test. The weight of the chain must not be more than 2½ per cent under the weight specified in the table, and it should not be more than 5 per cent over the weight specified in the table. After being weighed, the shackles and the end links of each shot, and every 15 fathoms in the case of chain which is in one continuous length without joining shackles, are to be clearly stamped by the manufacturer. (The stampings include identifying number, initials of surveyor, date of test, breaking test, proof test, and AB, the bureau's mark of approval.)

Unstudded short link chain (dimensions, weights, tests)

Diameter of common links	Breaking test	Proof test	Weight per 15 fathoms
Inches	Pounds	Pounds	Pounds

AMERICAN MARINE STANDARDS COMMITTEE, CARGO-HANDLING GEAR FOR SHIPS, AMERICAN MARINE STANDARDS H NO. 14-1926, AND H NO. 15-1926, JANUARY 25, 1926

(The specifications for this gear conform to the requirements of the American Bureau of Shipping

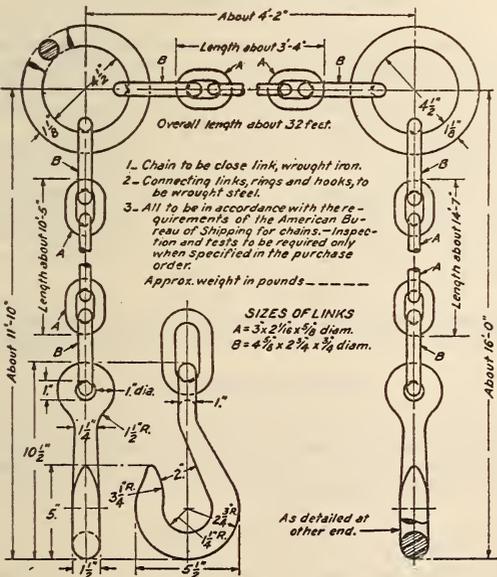

FIGURE 77.—Railroad iron sling; working load 2 tons

for wrought-iron and steel chains, given above. Inspection and tests are required only when specified in the purchase order.)

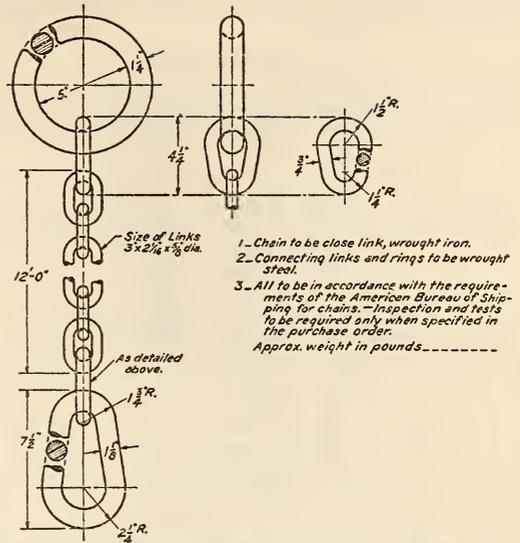

FIGURE 78.—Chain sling; working load 2 tons

AMERICAN RAILWAY ASSOCIATION, MECHANICAL DIVISION, SPECIFICATION FOR CHAIN, 1930

MATERIAL AND MANUFACTURE

1. SCOPE

These specifications cover two classes of chain generally used for the following purposes: Crane chain, for slings, hoists, steam shovels, and marine uses, and where an all-iron chain is desired. Proof coil, for railroad cars and construction and forestry work.

2. MATERIAL

The material shall be as follows: Crane chain.—Wrought iron, which shall be made from all-pig puddled iron, free from any admixture of iron scrap or steel.

NOTE.—The term "iron scrap" applies only to foreign or bought scrap, and does not include local mill products of crane chain iron quality.

Proof coil.—Wrought-iron or open-hearth steel. The wrought iron may be made from all reworked scrap.

NOTE.—The term "reworked scrap" applies to steel and iron scrap or to a mixture of both.

3. WELDING

Crane chain shall be lap fire welded. Unless otherwise specified, proof-coil chain may be made by either fire or electric welding process.

(In chemical composition and tests, standard weights and dimensions, workmanship and finish, inspection and rejection, this specification is in substantial agreement with F. S. B., RR-C-271. See 603.50, p. 199.)

(The standard weights and dimensions of crane chain in this specification are, for like sizes, the same as in F. S. B. RR-C-271. Weights and dimensions of corresponding proof coils are not specified. The A. R. A. specification also contains a table which

shows safe working loads in pounds. This is reproduced as Table 1.)

TABLE 1.—Safe working load

Nominal size of chain bar	Crane chain, wrought iron	Proof coil, iron or steel
Inches	Pounds	Pounds
¼	1,060	850
⅜	1,655	1,325
½	2,385	1,925
⅝	3,250	2,625
¾	4,240	3,425
⅞	5,370	4,325
1	6,630	5,350
1¼	9,540	7,675
1½	12,960	10,450
1¾	16,950	13,675
2	20,040	-----
2¼	24,750	-----
2½	29,910	-----
2¾	35,600	-----
3	41,800	-----
3¼	48,450	-----
3½	55,300	-----
4	63,300	-----

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR IRON AND STEEL CHAIN, A56-30, 1930

IRON AND STEEL CHAIN

(Identical with A. R. A. M., given above, in respect to scope, material, welding, and safe working loads. In respect to physical properties and tests, standard weights and dimensions, workmanship and finish, inspection and rejection, this specification conforms to F. S. B. RR-C-271. See 603.50, p. 199.) It provides as follows for—

CHEMICAL PROPERTIES AND TESTS

1. The wrought iron and steel of the respective classes of chain shall conform to the following requirements as to chemical composition:

	Wrought-iron crane chain	Steel proof coil
	Per cent	Per cent
Manganese, maximum	0.10	-----
Phosphorus, maximum	-----	0.05
Sulphur, maximum	-----	.05

CHECK ANALYSIS

2. (a) Analyses may be made by the purchaser from the bars or from the finished chain. The chemical composition thus determined shall conform to the requirements specified above.

(b) Drillings for analysis shall be taken from the entire cross section of the bar.

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION RR-C-271 FOR STANDARD MISCELLANEOUS CHAIN AND ATTACHMENTS, DECEMBER 8, 1931.

CLOSE-LINK COIL CHAIN

1. Close-link coil chain shall be of the following classes: (1) Wrought iron, (2) wrought iron or open-hearth steel.

(For general specifications, material and workmanship, weights and dimensions, detail requirements, and method of inspection and tests, see F. S. B. RR-C-271, (603.50, p. 199). For proof and breaking loads see comparative table facing page 200. For other kinds of chain and for chain attachments specified in F. S. B. RR-C-271 see 603.51, 603.54,

FIGURE 79.—Close link coil chain

603.56, 603.57, and 617.5. See also 631.9, 642.9, 645.9, and 646.59.)

603.53. STUD-LINK CHAINS.

AMERICAN BUREAU OF SHIPPING, RULES FOR BUILDING AND CLASSING STEEL VESSELS; QUALITY AND TESTING OF MATERIALS—SHIP CONSTRUCTION, 1930

WROUGHT-IRON AND STEEL STUD-LINK CHAIN; CAST-STEEL STUD-LINK CHAIN

(Specifications for wrought-iron and steel stud-link chain are the same as those for wrought-iron and steel unstudded short-link chain. See 603.52, p. 201.)

CAST-STEEL STUD-LINK CHAIN

(For general information and requirements see 600.0, p. 2.)

MATERIAL AND WORKMANSHIP

1. Cast steel made in accordance with the following specifications will be approved for use in all parts of stud-link chain, including stud links, enlarged links, end links, shackles, and shackle pins for chains 1½ inches and over in diameter.

2. The steel shall be made by the electric furnace process.

3. All castings shall be true to form and free from shrinkage, porosity, projections, or other defects in such location or of such nature as to impair the strength of the chain; and all castings shall be produced in dry sand molds or cores.

4. Each complete shot of chain shall be heat treated in such manner that the treatment will be complete and uniform throughout its entire length.

WEIGHTS AND DIMENSIONS

5. The weight of each shot of chain shall not be less than the minimum amount specified in Table 1. The dimensions and tolerances shall be in accordance with tabular requirements. (See Tables 1 and 2.)

PHYSICAL PROPERTIES

6. From each heat of steel entering into the production of any shot of chain, shackles, shackle pins, etc., there shall be cast not less than one link in each of two test chains, said test chains to be poured from heats in such manner as to insure that not more than two 15-fathom shots of chains are represented by any one break test. The links entering into these test chains shall be of the same wire diameter and general dimensions as the common "A" links that form a part of the shot or shots of chain they represent. Each of these test chains shall contain not

less than three links. These test chains shall be heat treated along with any shot or shots of chain containing links poured from the same heat or heats.

BREAKING AND PROOF TESTS

7. After heat treatment one of the test chains shall be subjected to the breaking stress, which shall consist of anchoring the ends of the test chain in an approved static testing machine, and pulling it to a breaking load in accordance with the comparative table facing page 200. If the test chain satisfactorily withstands this breaking load, the heats of steel represented by the links in the test chains shall be accepted so far as this test is concerned.

8. If the first test chain fails to withstand the breaking load, then the second test chain representing the same heats of steel shall be subjected to the required breaking test; and if it satisfactorily withstands the pull, the heats of steel represented by the links in this second test chain shall be accepted so far as this test is concerned. If any link or links in this second test chain fail during the test, then all the links in any shots of chain cast from the corresponding heat or heats represented by the links that fail in both the first and second test chains shall be rejected. Such rejected links may be cut out and replaced by new links cast in the shot.

9. Retreatment will be permitted between first and second tests, but such treatment shall be applied simultaneously to shots and corresponding test links.

10. If the second test chain is not required to be used for this test, it may be subsequently incorporated in any shot of chain.

11. After satisfactorily withstanding the required breaking tests, the complete lot of chain shall then

pass through the heat-treating process more than three times.

WEIGHING AND MARKING

13. Each shot of chain accepted shall be legibly marked in accordance with requirements. (The markings include identifying number, initials of

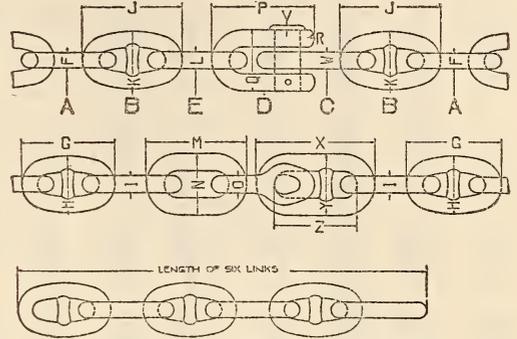

FIGURE 80.—Stud link chain cable

surveyor, date of test, breaking test, proof test, and AB, the bureau's mark of approval.)

All chain studs must be well centered and firmly held in place, and may be of cast iron, wrought iron, or steel. Each shot should be stamped with a distinctive mark in order to identify it through the several processes of gaging, testing, measuring, examining, repairing, and weighing. In the event of the surveyor being in attendance at the works while

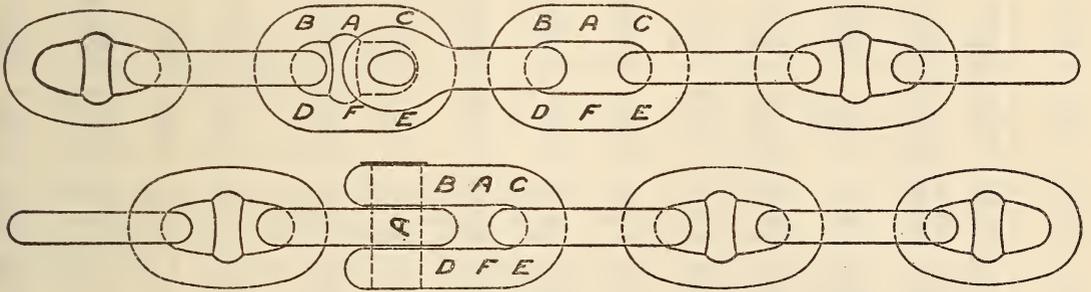

FIGURE 81

be subjected to the proof test given in table facing page 200, and if such shot of chain passes this test it shall be accepted.

12. If any link or links fail during the proof test they may be replaced by casting in new links from a heat which has satisfactorily passed the break test, and the shot may then be retreated and again subjected to the required proof test. If any link or links fail during the retest then all the links cast from the same heat or heats shall be rejected. Any links not so rejected may be used in making a new shot of chain, provided that in no case shall links

chains are being fabricated which are ultimately proposed to be submitted for testing, he will arrange to select the break test specimens as far as possible during the process of fabrication.

INSPECTION

14. Each complete shot of chain shall be carefully examined to insure that there are no fractured links or other defects, that the chain has been properly cleaned to remove all sand and scale, that all fins and partings have been removed, and that it is finished in a workmanlike manner.

TABLE 1.—Stud-link chain cable (dimensions)

Size of chain	Length of 6 links		Weight of 15 fathoms	Common links A			Enlarged links B			End links E			End links C

AMERICAN SOCIETY FOR TESTING MATERIALS, TENTATIVE SPECIFICATIONS FOR ELECTRIC CAST-STEEL STUD-LINK ANCHOR CHAIN, SERIAL DESIGNATION A77-28T, 1928

CAST-STEEL STUD-LINK ANCHOR CHAIN

The specifications for manufacture, physical properties, and tests are substantially the same as those shown in the American Bureau of Shipping specifications, given above. For like sizes of chain the corresponding dimensions of common links A, enlarged links B, end links C, and end links E are identical with those shown in A. B. S. Table 1. In that table the size of chain ranges from five-eighths of an inch to 3 3/4 inches, with one-sixteenth inch gradations; while the A. S. T. M. range in A77-28T is from 1 inch to 4 1/8 inches, with 1/8-inch gradations. Dimensions of cast-steel stud-link anchor chain in A77-28T which have no corresponding dimensions in the A. B. S. specification are as shown below in

Table 2 and Figures S2, S3, and S4. For like sizes of chain the weight in pounds per 15 fathoms is identical in both A. S. T. M. A77-28T and A. B. S.

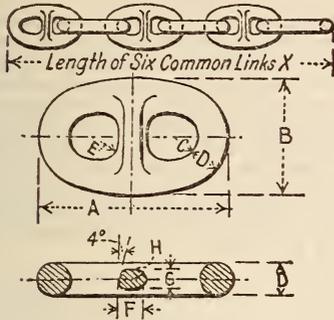

FIGURE 82.—Common links "A"

specifications. For break and proof test loads see comparative table facing page 200. (See also 603.57.)

PERMISSIBLE VARIATIONS

1. Permissible variations in dimensions for common A links shall conform to the tolerances specified

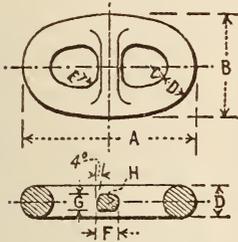

FIGURE 83.—Enlarged links "B"

in Table 1. Permissible variations for enlarged links and links, swivels, shackles, and shackle pins shall be permitted in accordance with the tolerances specified in Table 1 for common A links having the same size wire. In determining the permissible

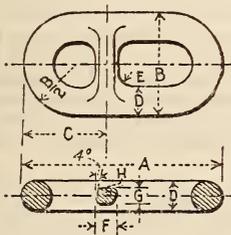

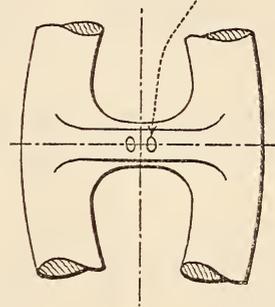

FIGURE 84.—End links "C"

variations for wire diameters, the diameter shall be measured at right angles, and one-half the sum of the two measurements shall be considered as representing the wire diameter.

TABLE 1.—Permissible variations of common A links, plus or minus

Size of chain cable (in inches)	Wire diameter	Width	Length
1 and 1 1/8	1/32	1/16	3/32
1 1/4-1 3/8	1/32	5/64	7/64
1 1/2-1 5/8	1/32	3/32	1/8
1 3/4-1 7/8	1/32	7/64	9/64

Manufacturer's Trademark or Initials and Size of Cable,

Obverse Side.

Same Marking on Reverse Side when not otherwise Specified.

Customer's Markings,

Reverse Side.

This Marking only when Specified. Otherwise Same as Obverse Side.

FIGURE 85.—Location of markings on chain cable

MARKING

2. The manufacturer's trade-mark or initials and the size of cable, if used, shall be marked on the cable as shown in Figure 85. These markings shall

be required only on alternate common A links unless otherwise agreed upon with the manufacturer. Other markings, including shot numbers, etc., shall be in accordance with the customer's or inspector's requirements. All markings shall appear on the studs of precast links only and shall be raised letters or figures of the maximum height permissible by the size of the stud but not to exceed three-fourths inch in height by one-eighth inch in relief. A standard practice of marking shall be followed in so far as possible and shall be the same for all sizes of chain cable.

INSPECTION AND REJECTION

3. Following the proof tests, all shots of chain swivels, shackles, shackle pins, and other appendages, shall be laid out for surface inspection. Any

part showing defects that will be injurious to the strength and service of the chain shall be rejected and replaced subject to the above provisions of the specifications covering the part rejected.

4. The inspector representing the purchaser shall have free entry, at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturer's works which concern the manufacture of the material ordered. The manufacturer shall afford the inspector, without charge, all reasonable facilities to satisfy him that the material is being furnished in accordance with these specifications. All tests and inspections shall be made at the place of manufacture prior to shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

FEDERAL SPECIFICATIONS BOARD, SPECIFICATION NO. 171a, FOR SHIP CHAIN, JUNE 30, 1924. (CURRENT DESIGNATION: RR-C-251)

(For general specifications, material and workmanship, and methods of inspection, see F. S. B. RR-C-271 603.50, p. 199) (See also 603.57.)

CLASSES AND TYPE

- The classes of chain shall be as follows: A. This class shall be used where an all-iron forged chain is desired. B. This class shall be used where a forged-steel chain is desired. C. This class corresponds to the commercial chain acceptable to the classification bureaus and shall be used where that grade will satisfactorily meet service requirements.
- The chain shall be of the stud-link type for use as anchor, mooring, buoy, and towing chain.
- Finished chain may have the welds in either the sides or ends of the links.
- Studs.—The studs shall be well centered and firmly held in place and shall be in accordance with

the design and dimensions submitted or approved by the purchaser. For class A chain the studs shall be made of cast iron or drop-forged from common steel, as may be ordered. If drop-forged, the steel used shall conform to the following requirements:

- Material.—Open-hearth or Bessemer steel.
- Tensile strength, minimum.—55,000 pounds per square inch.
- Elongation, minimum.—27 per cent in 2 inches, 22 per cent in 8 inches.
- Cold-bend test.—180° around a diameter of one thickness.
- For class B the studs shall be of forged steel or cast steel.
- For class C the studs shall be of forged iron, steel, or cast iron.

GENERAL REQUIREMENTS

- Link dimensions.—Stud link chain shall be in accordance with the dimensions listed in A. B. S. Table 1, above.
- Tolerances in dimensions and weights.—After proof test, and while the length of chain is still subjected to a load not in excess of 60 per cent of the

proof load, each link shall be inspected for outside length and width. Also, the over-all length of six links, measuring from every third link, shall be tested. The manufacturing tolerances allowed are as follows:

(a) *Tolerance in wire diameter of finished link.*—The size for descriptive and test purposes (nominal wire diameter) shall be the diameter of the common link of the chain with a plus tolerance which is not to exceed one thirty-second inch in the case of chains up to and including 1½ inches diameter. In the case of chains above 1½ inches diameter the tolerance shall not exceed one-sixteenth inch. The sectional area of the material at the weld of the common link shall not be reduced below that of the prescribed minimum diameter of the common links of chain.

(b) *Tolerances in lengths and widths of links.*—Maximum plus and minus tolerances in the designed widths of links, as listed in A. B. S. Table 1, above, will be permitted. Maximum plus and minus tolerances in the designed length of individual links as listed in A. B. S. Table 1 will be permitted provided the outside lengths of six consecutive links above or below that specified for chain of corresponding size do not exceed 60 per cent of the wire diameter.

(c) *Tolerance in weight.*—When chains have satisfactorily passed the above requirements, they shall be weighed, together with the shackles forming the outfit (if ordered), and this actual weight shall be given on the certificate of test. The weight of the chain shall be not more than 2½ per cent under nor more than 5 per cent above the weight specified in A. B. S. Table 1, above.

7. *Arrangement of links and shackles.*—Unless otherwise specified, chain shall be in 15-fathom lengths. There shall be an odd number of links in a shot or length of chain. The end links, also the swivels and shackles when ordered, and the shots of chain in complete cables shall be arranged in accordance with A. B. S. Figure 81, above. The enlarged end links may be omitted from the shots of chain at the option of the purchaser. (For end links, swivels, and shackles, see 603.57.)

8. *Finish.*—After inspection and before shipment, unless other finish is specified, the contractor shall coat the chain by hauling it through a bath of asphaltum diluted with turpentine substitute, in accordance with Federal specifications, in proportion of 25 gallons of turpentine substitute to 100 pounds of asphaltum, the bath to be maintained as near the boiling point as practicable.

DETAIL REQUIREMENTS

9. *Chemical requirements.*—The wrought iron and steel from which the respective classes of chain are to be manufactured shall conform to the following requirements as to chemical composition:

Classes of chain	Manganese	Phosphorus	Sulphur
A.....	Per cent 1 0.10	Per cent 1 0.10	Per cent 1 0.015
B.....	.30- .40	1.04	1.040

¹ Maximum.

NOTE.—No chemical analysis of material for class C chain is required. At the purchaser's option it may also be waived for class A chain.

10. *Physical requirements.*—The wrought iron and steel from which the respective classes of chain are to be manufactured shall conform to the following requirements as to physical properties:

Classes of chain	Tensile strength	Yield point (minimum)	Elongation (minimum)	Reduction of area (minimum)
A.....	Lbs./in. ² (Min.)48,000	Per cent 0.5 tensile strength.	Per cent 26 in 8 inches..	Per cent 40
B.....	45,000-55,000	0.5 tensile strength obtained.	30 in 8 inches; 35 in 2 inches.	60

NOTE.—No physical tests are required of material for class C chain. The elongation shall be measured and the physical requirements modified for certain sizes of bar as hereinafter specified.

11. *Modification for physical requirements.*—For wrought iron for class A chain over 4 square inches in sectional area, the following deductions from the minimum requirements specified above shall be allowed for each square inch of sectional area above 4 square inches:

Tensile strength.....lbs./in.².. 250, but not under 45,000.
Elongation.....per cent.. 0.5, but not under 23.
Reduction of area.....do.... 0.5, but not under 35.

MARKING

12. All test specimens before being cut from the bars, forgings, etc., shall be stamped for identification by the inspector unless otherwise specified.

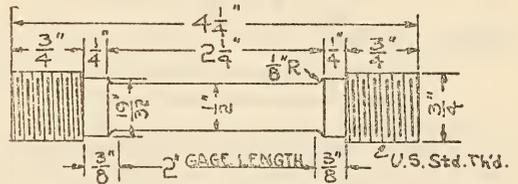

FIGURE 86.—Type I test specimen

NOTE.—The gage length, parallel portions, and fillets shall be as shown; the ends shall be threaded unless other forms of ends are approved by the chief inspector.

Each shot or length of chain shall be stamped with a distinctive identification number, the number to be supplied by the purchaser at his option and located as specified. The studs shall be marked at purchaser's option in accordance with plan or sketch submitted by the purchaser. Such other distinctive marks as are necessary for identification by the manufacturer may be placed on the links, shackles, swivels, shots, etc., provided they do not interfere with markings specified.

TESTING

13. Wrought iron for class A chain shall be tested in the sizes rolled, where practicable, and for each ton or less of each size the following tests shall be made; one tensile, one cold-bend, one hot-bend, one nick, one drift, and one etch test. Each test specimen shall be taken from a different bar. When material can not be tested in the sizes rolled, test bars shall be prepared of a sectional area as large as possible within the capacity of the testing machine.

14. Class B material shall be tested in the sizes rolled where practicable; otherwise test specimens as shown herein, shall be used. For each melt entering into each size, four tensile tests and one bend test shall be made. Each test specimen shall be taken from a different bar. When the material can not be tested in the sizes rolled, test bars of Type II or III as shown in Figures 87 and 88 shall be prepared if practicable; if not, a Type I test bar, as shown in Figure 86, shall be accepted.

15. *Measurement of elongation.*—The elongation of test specimens of wrought iron for class A chain shall be measured in 8 inches except for material of less than three-fourths inch diameter, in which case the elongation shall be measured on a length equal to ten times the diameter of the material to be tested.

16. The elongation of test specimens of soft steel for class B chain shall be measured as follows:

Nominal diameter	Length in which measured
	Inches
Over $\frac{1}{4}$ to $\frac{1}{2}$ inch, inclusive.....	4
Over $\frac{1}{2}$ to $\frac{3}{4}$ inch, inclusive.....	6
Over $\frac{3}{4}$ to $1\frac{1}{2}$ inches, inclusive.....	8
Over $1\frac{1}{2}$ inches (Type I test specimen) Figure 86.....	2

17. *Tensile tests.*—Tensile tests of specimens shall be made on a type of testing machine approved

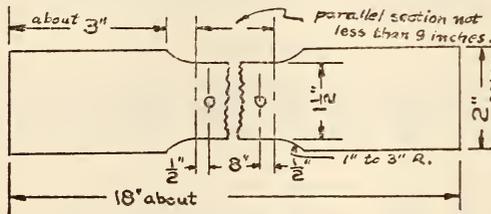

FIGURE 87.—Type II test specimen
[Parallel section not less than 9 inches]

by the purchaser. The pulling speeds shall be such as to permit of determination of the yield point by drop of the beam of the testing machine or by use of the dividers, but in no case should exceed $1\frac{1}{2}$ inches per minute at the yield point nor 6 inches per minute after the yield point is passed.

18. *Cold-bend tests.*—Test specimens for class A material shall be bent cold through 180° around a diameter of one thickness, without a fracture on the outside of the bent portion.

19. Test specimens for class B material shall be bent cold through 180° flat on themselves without sign of fracture on the outside of the bent portion. If one of these specimens fails, each bar from that melt entering into the chain of that size shall pass the cold-bend test before being cut to lengths.

20. *Quench tests.*—Test specimens for class A material, when heated to a temperature between

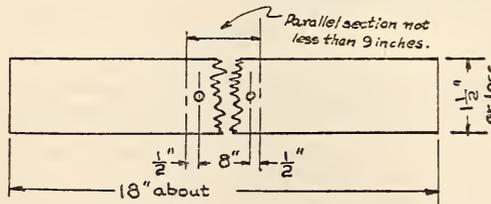

FIGURE 88.—Type III test specimen
[Parallel section not less than 9 inches]

1,700° and 1,800° F. and quenched in water at 80° F., shall bend back on themselves through 180° , without fracture.

21. *Nick tests.*—Those test specimens, when nicked to a depth of approximately 20 per cent of their thickness with a tool having a 60° cutting edge and bent back at this point through an angle of 180° , shall show a long, clean, silky fiber, free from slag or dirt. A few crystalline spots may be tolerated, provided they do not, in the aggregate,

exceed 10 per cent of the fractured area, and provided the etch test shows that such crystalline spots are not indicative of the presence of steel.

22. *Drift tests.*—Test specimens for class A material shall be punched and expanded hot by pointed drifts until a round hole is formed, the diameter of which shall not be less than nine-tenths the diameter of the bar. Any indication of fracture, cracks, or flaws, developed by this test shall be sufficient cause for rejection of the lot represented by the bar.

23. *Etch tests.*—The cross-section area of a test specimen for class A material shall be ground, polished, and etched in a solution of 2 parts water by weight, 1 part concentrated hydrochloric acid, and 1 part concentrated sulphuric acid by weight for a sufficient period to develop the structure. Under a magnification of 90 to 100 diameters, the material shall show no trace of steel.

24. *Tests of finished chain.*—The proof and breaking tests of finished chain shall be made on a chain-testing machine approved by the purchaser. The gripping arrangements shall be such that the stress applied to the end links of the portion under test shall be the same as equally put on every link tested; and the arrangement shall be such that each link is tested once and only once during the test.

25. *Breaking tests of finished chain.*—For class A or B, material, the tensile test specimen shall consist of two or, if the inspector considers it necessary, three links of finished chain taken at random from each length or shot. This specimen shall be tested for breaking strength as given in comparative table facing, page 200, for that class of material. If the test specimen fails, two additional test specimens located adjacent to it in the shot shall be taken and the same stresses applied; and if either of these specimens fails the shot shall be rejected, and a defective weld, even though the link satisfactorily withstood the prescribed stress, shall be sufficient cause to require additional break tests. At the purchaser's option one test specimen selected at random shall be tested to destruction to determine the ultimate strength.

26. For class C chain the tensile-test specimen shall consist of two or, if considered necessary by the inspector, three links from one shot of 15 fathoms or less of each shot presented. This specimen shall then be subjected to the breaking test specified herein for this class of chain. If the test is satisfactory the shots represented shall be considered satisfactory as far as this test is concerned. If the first test is not satisfactory, one more specimen shall be selected and subjected to the breaking test, and if this fails the shot shall be rejected. If the break-test specimen satisfactorily withstands the prescribed stress, it need not be tested to destruction but shall be discarded.

27. *Proof test of finished chain.*—After breaking test, each shot or length of chain which has satisfactorily passed that test, shall have the links which were cut out of it for breaking test replaced by new links and the complete shot or length subjected to proof test as given in comparative table facing page 200 for that class of material. Two proof loads are listed in comparative table facing page 200 for certain sizes of chain. When ordering chain of such sizes the purchaser shall stipulate the load to be applied. After proof test the chain shall be thoroughly inspected and any links showing cold welding, surface rupture, unusual deformation, inferior workmanship, or other defects shall be taken out and replaced and the chain again subjected to proof stress, provided the defective links do not exceed five per cent. If the defective links exceed five per cent, the shot shall be rejected. Shots of chain of class A or B material in which a link breaks under

proof load shall be rejected. If under proof load, a joining link shall be inserted and the proof test again applied, and if a second link breaks under the second proof test, the shot shall be finally rejected.

603.54 TWISTED-LINK CHAINS.

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION RR-C-271, FOR STANDARD MISCELLANEOUS CHAIN AND ATTACHMENTS, DECEMBER 8, 1931.

TWIST LINK COIL CHAIN

(For general specifications, material and workmanship, detail requirements, and methods of inspection and tests, see F. S. B. RR-C-271, 603.50, p. 199. For proof and breaking loads see comparative table facing p. 200. For other kinds of chain and chain attachments specified in F. S. B. RR-C-271, see 603.51, 603.52, 603.56, 603.57, and 617.5. See also 631.9, 642.9, 645.9, and 646.59.)

1. Twist link coil chain shall be of the following classes: (1) Wrought iron, (2) wrought iron or open-hearth steel.

2. Twist link coil chain shall be made of class 2 material and in accordance with the following table. No proof test shall be required. The breaking load shall be in accordance with the requirements for this class as shown in comparative table facing page 200. The percentage of elongation shall be as specified for this class of chain.

FIGURE 89.—Twist link coil chain

Twist link chain, plain pattern (weights and dimensions)

Size	Actual diameter	Length of 100 links	Weight per 100 feet
<i>Inch</i>	<i>Inch</i>	<i>Inches</i>	<i>Pounds</i>
1/4	9/32	103	75
5/16	11/32	120	124
3/8	13/32	128	180

.177 or 11/64	9.25	1,240	23.00
.192 or 3/16	8.75	1,430	28.00
.207 or 13/64	8.75	1,670	33.00
.244 or 1/4	7.75	2,530	49.00
.263 or 11/64	7.75	3,000	48.50
.283 or 9/32	7.75	3,250	64.00
.307 or 5/16	8.00	4,050	84.00

FIGURE 90 1/2.—Twist-link chain, short length pattern

4. Twist link chain (short-link pattern) shall be made of class 2 material. No proof test is required. Strength, dimensions, and weights as follows:

Diameter	Number links	Minimum tensile strength	Weight per 100 feet
<i>Inch</i>	<i>Per foot</i>	<i>Pounds</i>	<i>Pounds</i>
0.105 or 7/64	25.00	620	10
.120 or 1/8	23.50	750	13
.135 or 9/64	21.50	875	16
.148 or 5/32	21.00	1,000	21
.162 or 5/32	20.50	1,140	25
.177 or 11/64	17.50	1,310	29
.192 or 3/16	16.50	1,510	34
.207 or 13/64	15.00	1,760	40
.275 or 7/32	14.75	1,990	50
.244 or 1/4	14.00	2,660	64
.283 or 9/32	13.00	3,420	78
.307 or 5/16	10.25	4,260	94

603.55 STRAIGHT AND TWISTED LINK VEHICLE CHAINS.

(See 603.50, p. 198.)

603.56 WELDLESS CHAINS, VARIOUS LINK PATTERNS.

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, COMMERCIAL STANDARDS FOR BUILDERS' HARDWARE (NONTEMPERATURE), CS22-30, 1930

TRANSOM CHAINS

(See F. S. B. FF-H-101, 617.5, p. 1050.)

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION RR-C-271 FOR STANDARD MISCELLANEOUS CHAIN AND ATTACHMENTS, DECEMBER 8, 1931.

WELDLESS CHAIN

(For general specifications, material and workmanship, detail requirements, and methods of inspection and tests, see F. S. B. RR-C-271 (603.50, p. 199). For other kinds of chain and chain attachments specified in F. S. B. RR-C-271 see 603.51, 603.52, 603.54, 603.57, 617.5, 631.9, 642.9, 645.9, and 646.59.)

1. Weldless chain shall be automatic machine-made chain of the following classes: (a) Single-loop pattern; (b) double-loop pattern; (c) sash and flat link, long pitch chain; (d) plumber's, and flat link short pitch chain; (e) single jack chain; (f) double jack chain; (g) ladder chain; (h) register chain; and (i) brass chain for mechanical communication. (See 645.9.)

2. Weldless chain shall be made from steel, copper, brass, or bronze wire, or stamped from sheets of steel, copper, brass, or bronze.

3. Weldless close link chain made from rolled steel or iron bar will be acceptable under this specification.

4. Weldless chain will be paid for by the foot.

603.57 CHAIN ATTACHMENTS.

AMERICAN BUREAU OF SHIPPING, RULES FOR BUILDING AND CLASSING STEEL VESSELS; SHACKLES AND SHACKLE PINS, 1930

(Specifications for wrought iron and steel shackles and pins, and cast-steel shackles and pins, are the same as for wrought iron and steel stud-link chains and cast-steel stud-link chains. (See 603.52, p. 201, and 603.53, p. 204.) This is also true in respect to tolerances. Maximum tolerances in shackles D above and below the dimensions given in Table 1 below, will be found in Table 2. (See 603.53, p. 206.) The dimensions of shackles D and their respective pins are as shown in Table 1 and Figure 101. The dimensions of shackles F and their respective pins are as shown in Table 2 and Figure 102.)

SHACKLES AND SHACKLE PINS

(For general information and requirements see 600.0, p. 2.)

1. The end shackles, joining shackles, spare shackles, and swivels required for a length of chain are to be tested to the same proof test as the chain, and at least 1 out of every 25 of the shackles is to

be subjected to the breaking test, and must be discarded. (For the respective breaking and proof tests see comparative table facing p. 200.)

2. When shackles have satisfactorily passed the test requirements they are to be weighed, and this actual weight will be given on the certificate of test. After being weighed, the shackles and end links of each shot are to be clearly stamped by the manufacturer with identifying number, initials of surveyor, date of test, breaking test, proof test, and the bureau's mark of approval, A. B.

AMERICAN SOCIETY FOR TESTING MATERIALS, TENTATIVE SPECIFICATIONS FOR ELECTRIC CAST-STEEL STUD-LINK ANCHOR CHAIN, DESIGNATION A77-28T, 1928

SHACKLES AND SHACKLE PINS

(The specifications for materials for cast-steel shackles and shackle pins are the same as those for electric cast-steel stud-link anchor chain. (See A. S. T. M. A77-28T. 603.53, p. 206.)

BREAKING AND PROOF TESTS

1. *Break tests.*—In the event that shackles and shackle pins only are poured from any heat or heats of steel, one shackle and shackle pin shall be selected from each such heat of steel. If shackle and shackle pins of more than one size are poured from one heat of steel, the shackle and shackle pin selected for the break test shall be the average wire size. Shackles and shackle pins so selected shall be anchored in an approved static testing machine by connecting with one E and one C end link of the respective size chain and subjected to the break test load for the respective size chain. (Break-test loads for corresponding sizes of chain are as shown in comparative table facing p. 200.)

2. If the test shackle or shackle pin fails in the break test as described in the preceding paragraph, then two additional shackles and shackle pins shall be selected and tested individually in accordance with the preceding paragraph. If either of these shackles or shackle pins fail during this retest, then the shackles and shackle pins represented shall be rejected.

3. *Proof tests.*—All shackles and shackle pins that have met the requirements of the break tests described in the previous paragraphs shall be subjected to the proof test loads for the respective size of chain. (Proof test loads are as shown in comparative table facing p. 200.)

4. Shackles and shackle pins shall be proof tested individually, and for anchoring in the static testing machine shall be connected on either end with one E and one C end link or chain cable of respective size or shackles and shackle pins of the same size in the form of a chain. If the test shackle or shackle pin fails during the test, then the shackles and shackle pins represented shall be rejected.

DIMENSIONS OF SHACKLES, SHACKLE PINS, AND SWIVELS

(The dimensions of shackles D and F, and their pins, in the manual of the American Bureau of Shipping and in A. S. T. M. A77-28T are identical in some respects. In other respects the dimensions differ. Table 1, Figure 103, and Table 2, Figure 104, given below, show in what respect the A. S. T. M. dimensions differ from the dimensions in Table 1, Figure 101, and Table 2, Figure 102, given above.)

SWIVELS

(The specifications for cast-steel swivels are the same as those for electric cast-steel stud-link anchor chain. (See A. S. T. M. A77-28T, (603.53, p. 206.)

The dimensions of swivels are as shown in Table 3, Figure 105.)

PERMISSIBLE VARIATIONS OF SHACKLES, SHACKLE PINS, AND SWIVELS

5. Permissible variations for swivels, shackles, and shackle pins shall be permitted in accordance with the tolerances specified in Table 1 for common A links. (See A. S. T. M. A77-28T (603.53, p. 206.) In determining the permissible variations for wire diameters, the diameter shall be measured at right angles, and one-half the sum of the two measurements shall be considered as representing the wire diameter.

(The specifications for cast-steel shackles and shackle pins are the same as those for electric cast-steel stud-link anchor chain. (See A. S. T. M. A77-28T. 603.53, p. 206.)

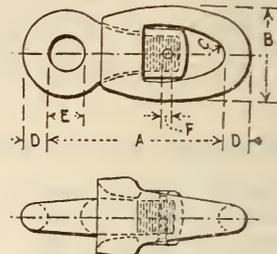

FIGURE 105.—Swivels

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION NO. 171A, FOR SHIP CHAIN, MAY 22, 1926. (CURRENT DESIGNATION: RR-C-251)

SHACKLES AND SWIVELS

(For general specifications, general requirements, material and workmanship, and methods of inspection see F. S. B. RR-C-271, (603.50, p. 199). For detail requirements and methods of test see F. S. B. No. 171a (RR-C-251), (603.53, p. 208).)

(The dimensions of shackles D and pins are the same as those of the American Bureau of Shipping, shown above in Table 1 and Figure 101. The breaking and proof tests of class C shackles D and pins are the same as those of the American Bureau of Shipping wrought iron and steel chain, as shown in comparative table facing p. 200. The breaking and proof tests of class A and class B shackles D and pins do not agree with the A. B. S. tests, but are as shown in comparative table facing p. 200.) (See also 603.53.)

1. No connection shackles, bending shackles, or swivels shall be furnished with chain ordered under this specification unless they are specifically called for. Shackles when ordered shall be in accordance with A. B. S. Table 1, above. When ordered, swivels shall be in accordance with design and dimensions to be submitted or approved by the purchaser.

2. *Material.*—When ordered, the shackles and swivels shall be drop-forged from the same grade of steel as is specified for use in the manufacture of class B chain, unless iron is specified, in which case the iron shall be of the same grade as the chain with which they are intended to be used.

3. *Manufacture.*—The wrought iron in all swivels and shackles shall be so worked that the strain, when they are in use, shall be across the fibers in shear and with the fibers in tension. All eyes and loops shall be formed by wrapping and welding the iron. The use of punched eyes will not be permitted except in forged-steel shackles. Shackles or swivels which are cold bent shall be annealed after fabrication or forging.

4. *Heat treatment.*—All class A chain shall be annealed except as stated in footnote in comparative table facing page 200. Annealing shall be done by a method approved by the purchaser. It shall consist of heating the chain to 950° C., holding at that temperature for 10 minutes, and air cooling.

5. *Arrangement of links and shackles.*—Unless otherwise specified, chain shall be in 15-fathom lengths. There shall be an odd number of links in a shot or length of chain. The end links, also the swivels and shackles when ordered, and the shots of chain in complete cables, shall be arranged in accordance with A. B. S. 603.53, (fig. 80). The enlarged

end links may be omitted from the shots of chain at the option of the purchaser.

6. *Test of shackles, swivels, etc.*—Shackles, swivels, etc., shall be proof tested to the same proof test as the chain with which they are intended to be used, and not less than 1 out of every 25 or less shall be subjected to a tensile breaking test equal at least to specified breaking strength of the chain with which they are intended to be used. The shackles so tested for breaking strength shall, after test, be discarded.

7. *Tolerances.*—(The tolerances are identical with those shown in A. B. S. Table 2. See 603.53, p. 206.)

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION RR-C-271, FOR STANDARD MISCELLANEOUS CHAIN AND ATTACHMENTS, DECEMBER 8, 1931.

ATTACHMENTS

(For general specifications, general requirements, material and workmanship, detail requirements, and methods of inspection and tests, see F. S. B., RR-C-271, (603.50, p. 199.) (See also 603.51, 603.52, 603.53, 603.54, 603.56, 617.5, 631.9, 642.9, 645.9, 646.59.)

1. The attachments shall be of the following types:

- A. Chain dogs.
- B. Ring dogs.
- C. Hooks.
- D. Connecting links.
- E. Repair or end lap links.
- F. Oval side lap links.
- G. Shackles.
- H. Rings.
- I. Toggles.
- J. Swivels.
- K. Sash.

- (a) Chain dogs shall be of the following classes—
 - (1) Plain point.
 - (2) Diamond point.
- (b) Ring dogs shall be of the following classes—
 - (1) Diamond point.
 - (2) Norfolk pattern.
 - (3) Plain.
- (c) Hooks shall be of the following classes—
 - (1) Vehicle and harness hooks.
 - (2) Slip hooks.
 - (3) Grab hooks.
 - (4) Hoist or sling hooks.
 - (5) Bale hooks.
 - (6) Box hooks.
 - (7) Barrel hooks.
 - (8) Stone-hoist hooks.
 - (9) Hogthead hooks.
 - (10) Can hooks.
- (d) Connecting links shall be of but one class.
- (e) Repair or end lap links shall be of but one class.
- (f) Oval-side lap links shall be as covered by table, page 220.
- (g) Shackles shall be of the following classes:
 - (1) Screw-pin anchor shackle.
 - (2) Screw-pin chain shackle.
 - (3) Oval-pin anchor shackle.
 - (4) Oval-pin chain shackle.
 - (5) Round-pin anchor shackle.
 - (6) Round-pin chain shackle.

K. Sash—Continued.

- (h) Rings shall be of but one class.
- (i) Toggles shall be of the following classes:
 - (1) Sheared toggles.
 - (2) Forged toggles.
- (j) Swivels shall be of but one class.
- (k) Sash attachments shall be as covered by sketches. (See F. S. B., RR-C-271, (figs. 981-983) (617.5, p. 1049).)

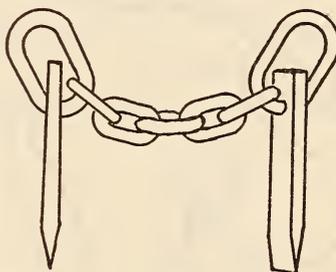

2. Chain attachments shall be of material as hereinafter specified. When a drop-forged steel piece is specified, the steel shall be of class 2, as ordered, depending on the chain with which the attachments are to be used. If the chain is class 1 wrought iron, the attachments shall be of class 2 steel.

3. The chain and attachments shall be free from injurious defects and shall have a workmanlike finish.

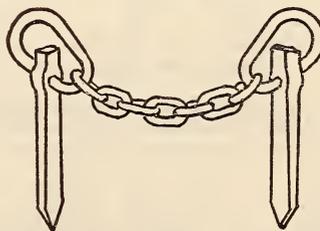

4. Standard chain attachments shall be subjected to the same proof-test load as the chain with which they are to be used. One attachment out of every 50 or less to be furnished under a contract or order shall be selected for test on quantities of 100 or less and 1 for each additional 200 or less. If any of these fails or shows defective welds the total number of test samples shall be doubled and a second failure will result in rejection of the lot. (For breaking and proof-test loads see comparative table facing p. 200.)

CHAIN DOGS

5. Chain dogs shall be of steel, grade 2, as specified. The types shall be in accordance with the following table. Forms of rings shall be in accordance with the sketches. When ordering chain dogs, the number of links between dogs shall be as specified.

Class 1

Class 2

FIGURE 106.—Chain dogs

TABLE 1.—Chain dogs (dimensions)

Class	Style	Dimensions	Diameter of chain	
			Center links	End links
1	Plain point.....	<i>Inches</i> 3/8 by 1 1/8 by 6 1/2	<i>Inch</i> 1 1/32	<i>Inch</i> 1 3/42
2	Diamond point....	1/2 by 1 1/2 by 6 1/2	1 3/32	1 1/42

RING DOGS

6. Ring dogs shall be of steel, grade 2, as specified. The types shall be in accordance with the following table. Forms of rings shall be in accordance with the sketches.

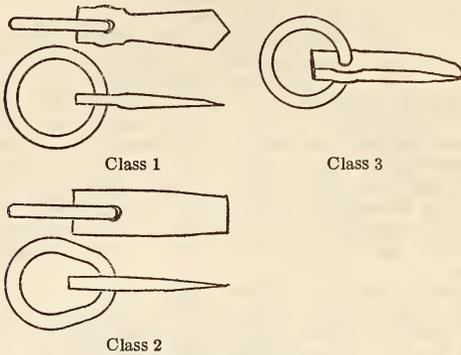

FIGURE 107.—Ring dogs

TABLE 2.—Ring dogs (dimensions)

Class	Pattern	Dimensions of dog	Ring, diameter of metal	Ring, inside diameter
1	Diamond point.....	<i>Inches</i> ½ by 1½ by 6½	<i>Inch</i> ½	<i>Inches</i> 3
2	Norfolk pattern.....	½ by 2 by 6½	9/16	3 by 4
3	Plain.....	¾ by 1½ by 6½	½	3

HOOKS

7. Vehicle and harness hooks.

Long-Slip Pattern

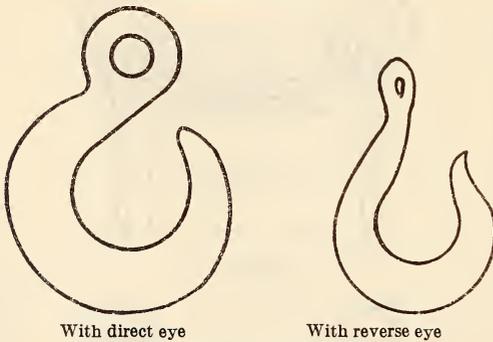

FIGURE 108.—Slip hooks

TABLE 3.—Drop-forged steel, long-slip pattern, for stay chains (dimensions and weights)

603.59 MISCELLANEOUS CHAINS.

SOCIETY OF AUTOMOTIVE ENGINEERS, SILENT CHAINS, S. A. E. STANDARD, 1917

SILENT CHAINS

(This recommendation contains an illustrated tabulation which shows, for different widths and pitches of silent chain, the maximum width in inches. This maximum width is always equal to the chain width plus 0.6 times the pitch in inches. The width of chain tabulated ranges from 1/2 to 6 inches, while the range in pitch is from 3/8 to 2 inches.)

604 IRON AND STEEL PLATES AND SHEETS

604.0 GENERAL ITEMS.

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, STANDARD THICKNESSES, WEIGHTS, AND TOLERANCES OF SHEET METAL (CUSTOMARY PRACTICE), CIRCULAR NO. 391, MARCH 24, 1931

IRON AND STEEL SHEET AND PLATE

The United States standard gage for sheet and plate iron and steel is the legal standard formerly used in determining duties and taxes levied by the

United States, and is the recognized commercial standard for all uncoated sheet and plate iron and steel. It is a weight gage, having been based upon weights in ounces per square foot. The provisions of the act of Congress, approved March 3, 1893 (27 Stat. L. 746), establishing this gage are as follows:

(a) AN ACT ESTABLISHING A STANDARD GAGE FOR SHEET AND PLATE IRON AND STEEL

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That for the purpose of securing uniformity, the following is established as the only standard gage for sheet and plate iron and steel in the United States of America, namely:

Gage No.	Approximate thickness in fractions of an inch	Approximate thickness in decimal parts of an inch	Approximate thickness in millimeters	Weight per square foot in ounces avoirdupois	Weight per square foot in pounds avoirdupois	Weight per square foot in kilograms	Weight per square meter in kilograms	Weight per square meter in pounds avoirdupois

And on and after July 1, 1893, the same and no other shall be used in determining duties and taxes levied by the United States of America on sheet and plate iron and steel. But this act shall not be construed to increase duties upon any articles which may be imported.

SEC. 2. That the Secretary of the Treasury is authorized and required to prepare suitable standards in accordance herewith.

SEC. 3. That in the practical use and application of the standard gage hereby established a variation of 2½ per cent either way may be allowed.

Approved, March 3, 1893.

(b) APPROXIMATE THICKNESSES OF STEEL PLATES AND SHEETS

The thicknesses given in the law as approximate equivalents were based upon the density of wrought iron of 480 pounds per cubic foot, or 0.2778 pound per cubic inch. Since the United States standard gage was established, steel and commercially pure open-hearth iron have come into general use for plates and sheets. For most commercial purposes the density of steel is taken as 489.6 pounds per cubic foot, 0.2833 pound per cubic inch, or in terms more familiar to the sheet maker and user, steel weighs 40.80 pounds per square foot per inch thick,

2 per cent more than wrought iron, which weighs 40 pounds per square foot per inch thick.

The density of steel varies, depending upon a number of factors, such as carbon content, presence of alloying elements, heat treatment, tempering temperature, amount and manner of cold working, etc.⁴³ The total variation for carbon steel, due to these factors, may be of the order of 1 per cent. In the case of hot-rolled steel, it has been found that the mechanical working of the metal during hot-rolling tends to decrease the density of the material, and of two sheets of different thicknesses rolled from the same material, the thicker sheet is always the denser. Cold-rolled steel sheets have been said to have a greater density than 0.2833 pound per cubic inch; however, two samples of full pickled, full cold-rolled sheets showed an average density of 0.2833 pound per cubic inch. Tests also have shown this value to be representative of commercially pure open-hearth iron.

In Table 1 the weights, and approximate thicknesses based upon 40 pounds per square foot per inch thick for wrought iron, and 40.80 for steel and open-hearth iron, are given for practical use.⁴⁹ Also, the gage numbers above No. 38 are included, which have become standardized by custom, but were not included in the congressional enactment. The numbers of decimal places given for weights in pounds and for equivalent thicknesses have been limited, but the values have been carried out further than they should be used practically.

Attention is directed to United States Department of Commerce Simplified Practice Recommendations R28-29, sheet steel, which covers simplified sizes and weights of galvanized flat sheets, one pass cold-rolled box annealed sheets, and blue annealed sheets (see 604.20, p. 236); and R78-28, iron and steel roofing (see 604.32, p. 246).

⁴³ See Density of Hot-Rolled and Heat-Treated Carbon Steels, by H. C. Cross and E. E. Hill, B. S. Sci. Paper No. 562.

⁴⁹ According to an opinion rendered by the Attorney General of the United States, Apr. 22, 1929, the commercial use of the data presented in Table 1, or of tolerances as presented in Secs. II (c) and II (d) herein, does not violate the act of Mar. 3, 1893, establishing the United States standard gage. An excerpt of the opinion is as follows:

"Compliance with the standard gage established by the above act is not made mandatory either upon American manufacturers or upon the Government departments in preparing their specifications for sheet and plate iron and steel. The only mandatory provision in the act is that the standard gage therein established 'shall be used in determining duties and taxes levied by the United States of America on sheet and plate iron and steel.' There is no prohibition against the importation of sheet and plate iron or steel not complying with the standard gage, but it is provided merely that the standard shall be followed in determining the duties and taxes levied thereon."

TABLE 1.—United States standard gage for sheet and plate iron and steel, and extension—Continued

Gage No.	Weight per square foot		Weight per square meter	Approximate thickness			
				Wrought iron		Steel and open-hearth iron	
	Ounces	Pounds	kg	Inch	mm	Inch	mm

(c) PERMISSIBLE VARIATIONS IN WEIGHT AND THICKNESS OF PLATES

Manufacturers have had considerable difficulty in keeping within the tolerance of plus or minus 2½ per cent specified in the law establishing the United States standard gage for sheet and plate iron and steel. As the law does not make this tolerance mandatory for commercial purposes, the Association of American Steel Manufacturers has adopted specifications regarding permissible variations in weight and thickness, which have been applied to plate-mill products regularly, but not to sheet and tin mill products. (See A. A. S. M. standard specifications for structural and boiler steel in 605.0, p. 248.)

(d) PERMISSIBLE VARIATIONS IN WEIGHT AND THICKNESS OF SHEETS

(Conforms to Association of American Steel Manufacturers, standard permissible variations in gage weight, gage thickness, size, and flatness of sheets and light plates blue annealed in 600.7, p. 117.)

(e) GALVANIZED SHEET GAGE

The galvanized sheet gage given in Table 2 is based upon the United States standard gage for sheet and plate iron and steel; 2.5 ounces per square foot being added to the weight per square foot corresponding to a given gage number of the United States standard gage to determine the weight per square foot of the corresponding gage number of

the galvanized sheet gage. This gage is a weight gage for finished sheet regardless of the weight of coating and has been established by custom in the United States. It appears, accordingly, that the sheet prior to coating must be rolled to such weight, depending upon the weight of coating to be applied, as to produce a sheet of the proper weight when coated. This is contrary to the principles of simplified practice, as it multiplies the number of gages to be rolled, a commercial practice which does not appear to be economically justified.

Tolerances for the weights per square foot of galvanized sheets, adopted March 28, 1929, by the Association of American Steel Manufacturers will be found in 600.7, page 117. Those of the American Society for Testing Materials, as given in standard specifications A93-27, zinc-coated (galvanized) sheets, will be found in 604.32, page 244.

The resistance of galvanized sheet to corrosion depends upon the evenness and weight of coating. The weight of coating is also a factor in determining the degree of deformation which a sheet can undergo without breaking the coating.* For specifications covering this subject see A. S. T. M. A93-27. (604.32, p. 244.)

(f) TIN-PLATE GAGE

Tin plates, which consist of soft sheet steel coated with tin, and roofing terneplates in which the coating is approximately 25 per cent tin and 75 per cent lead, are measured in a unit of area known as the base box. This is an old British unit amounting to 31,360 square inches, or 217.78 square feet, is independent of weight, and corresponds to the area covered by 112 plates, each 14 by 20 inches.

The tin-plate gage is based on pounds per base box. In Table 10 are given the essential dimensions and trade symbols of the tin-plate gage as published in the Reference Book of the American Sheet & Tin Plate Co. This gage is established by long custom and the symbols noted in the table are inherited from the British industry. It should be borne in mind that the corrosion-resisting qualities of terneplate depend on the thickness of the coating rather than on the total thickness of the plate. The term "coke tin plates" is used to designate tin plates of the lighter coating weights. "Charcoal tin plates" designates higher grades of finish, the amount of coating and the degree of finish being distinguished by letters A to 5A, the greater number of A's in the symbol, the heavier the coating. "AAA" tin plate, for example, has approximately 4 pounds of tin coating per base box. The designation "taggers tin" is usually applied to either "coke" or "charcoal plates," 65 pounds per base box or lighter.

Terneplate, used extensively as roofing, is manufactured in standard weights of coating of 8, 15, 20, 25, 30, 32, and 40 pounds per double base box. For roofing it is accepted practice to manufacture terneplates not lighter than IC weight (107 pounds per base box). (See U. S. Department of Commerce Simplified Practice Recommendation No. 30-28, roofing ternes 604.31, p. 241.) The United States standard gage is also used for long ternes.

Long terne, roofing terne, and tin plate are regarded by the industry as subject to the weight-gage tolerances given in A. A. S. M. (see 600.7, p. 117). Weights and permissible variations in weights, of re-squared terneplates (roofing tin) are specified in Federal specification QQ-T-201 (see 604.31, p. 241).

and to both A. S. T. M. standard specifications for steel and A. A. S. M. standard specifications for structural and boiler steel under commodity designation 605.0.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR BOILER AND FIRE-BOX STEEL FOR LOCOMOTIVES, DESIGNATION A30-24, 1924

BOILER AND FIRE-BOX STEEL FOR LOCOMOTIVES

(Identical with A. S. T. M. A70-27, given below, including references in A70-27 to both A. S. T. M. and A. A. S. M. under commodity designation 605.0, except for the following:)

SCOPE

1. These specifications cover two classes of steel for boilers for locomotives, namely; flange and fire box.

PHYSICAL PROPERTIES AND TESTS

6. (a) The material shall conform to the following requirements as to tensile properties:

	Flange	Fire box
Tensile strength.....lbs./in. ² ..	55,000-65,000	52,000-62,000
Yield point, minimum.....lbs./in. ² ..	0.5 tensile strength.	0.5 tensile strength.
Elongation in 8 inches, minimum.....per cent..	1,500,000	1,550,000
(See sec. 7 in A70-27.)	Tensile strength	Tensile strength

(Omit paragraphs 6 (b) and (c) and 8 (b) in A. S. T. M. A70-27 from this specification.)

3. One tension and one bend test shall be made from each plate as rolled.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR BOILER AND FIRE-BOX STEEL FOR STATIONARY SERVICE, DESIGNATION A70-27, 1927

BOILER AND FIRE-BOX STEEL FOR STATIONARY SERVICE

SCOPE

1. These specifications cover two classes of steel for boilers for stationary service, namely: Flange and fire box.

MANUFACTURE

2. The steel shall be made by the open-hearth process.

CHEMICAL PROPERTIES AND TESTS

3. The steel shall conform to the following requirements as to chemical composition:

	Flange	Firebox
Carbon:	Per cent	Per cent
For plates 3/4 inch or under in thickness.....	0.25	0.25
For plates over 3/4 inch in thickness.....	0.30	0.30
Manganese:		
For plates 3/4 inch or under in thickness.....	0.30-0.60	0.30-.50
For plates over 3/4 inch in thickness.....	.30-.60	.30-.60
Phosphorus:		
Acid.....	1.05	1.04
Basic.....	1.04	1.035
Sulphur.....	1.05	1.04

1 Maximum.

4. An analysis of each melt of steel shall be made by the manufacturer to determine the percentages of the elements specified in section 3. This analysis shall be made from a test ingot taken during the pouring of the melt. The chemical composition thus determined shall be reported to the purchaser or his representative, and shall conform to the requirements specified in section 3.

5. An analysis may be made by the purchaser from a broken tension test specimen representing each plate as rolled. The chemical composition thus determined shall conform to the requirements specified in section 3.

PHYSICAL PROPERTIES AND TESTS

6. (a) The material shall conform to the following requirements as to tensile properties:

	Flange	Firebox
Tensile strength-----lbs./in. ²	55,000-65,000	55,000-65,000
Yield point, minimum-----lbs./in. ²	0.5 tensile strength.	0.5 tensile strength.
Elongation in 8 inches, minimum -----per cent.	1,500,000 Tensile strength	1,550,000 Tensile strength

(b) Tensile strength only need be determined on the test specimen taken longitudinally from the top of fire-box plates, and it shall not exceed 70,000 pounds per square inch.

(c) Should the above rule for minimum allowable elongation give a value of less than 25 per cent for fire-box steel, the minimum allowable elongation shall be 25 per cent, subject to the modifications of section 7.

(d) The yield point shall be determined by the drop of the beam of the testing machine.

7. (a) For material over three-fourths inch in thickness, a deduction from the percentage of elongation specified in section 6 (a) of 0.125 per cent shall be made for each increase of one-thirty-second inch of the specified thickness above three-fourths inch, to a minimum of 20 per cent.

(b) For material one-fourth inch or under in thickness, the elongation shall be measured on a gage length of twenty-four times the thickness of the specimen.

8. (a) The test specimen shall stand being bent cold through 180° without cracking on the outside of the bent portion, as follows: For material 1 inch or under in thickness, around a pin the diameter of which is equal to the thickness of the specimen; and for material over 1 inch in thickness, around a pin the diameter of which is equal to twice the thickness of the specimen.

(b) *Bend test for universal edge rolled plates when permitted for double-butt-strap construction.*—The bend test specimen shall stand being bent cold through 180° without cracking on the outside of the bent portion, as follows: For material 1 inch or under in thickness, around a pin the diameter of which is equal to one and one-half times the thickness of the specimen; and for material over 1 inch in thickness, around a pin the diameter of which is equal to three times the thickness of the specimen.

9. For fire-box steel, a sample taken from a broken tension-test specimen shall not show any single seam or cavity more than one-fourth inch in length, in either of the three fractures obtained in the test for homogeneity, which shall be made as follows:

The specimen shall be either nicked with a chisel or grooved on a machine, transversely, about one-sixteenth inch deep, in three places about 2 inches apart. The first groove shall be made 2 inches from

the square end; each succeeding groove shall be made on the opposite side from the preceding one. The specimen shall then be firmly held in a vise, with the first groove about one-fourth inch above the jaws, and the projecting end broken off by light blows of a hammer, the bending being away from the groove. The specimen shall be broken at the other two grooves in the same manner. The object of this test is to open and render visible to the eye any seams due to failure to weld up, or interposed foreign matter, or any cavities due to gas bubbles in the ingot. One side of each fracture shall be examined and the lengths of the seams and cavities determined, a pocket lens being used if necessary.

10. (a) Tension-test specimens shall be taken longitudinally from the top and bottom corners of the finished rolled fire-box material and from the bottom only of flange material. Bend-test specimens shall be taken transversely from the middle of the top of the finished rolled material. The longitudinal test specimen shall be taken in the direction of the longitudinal axis of the ingot, and the transverse test specimen at right angles to that axis.

(b) Tension and bend test specimens shall be of the full thickness of material as rolled, and shall be machined to the form and dimensions shown in Figure 128 in A. S. T. M. standard specifications for steel (see 605.0, p. 247); except that bend-test specimens may be machined with both edges parallel.

11. (a) Two tension and one bend test shall be made from each fire-box steel plate as rolled. One tension and one bend test shall be made from each flange steel plate as rolled.

(b) If any test specimen shows defective machining or develops flaws, it may be discarded and another specimen substituted.

(c) If the percentage of elongation of any tension test specimen is less than that specified in section 6 (a) and any part of the fracture is outside the middle third of the gage length, as indicated by scribe scratches marked on the specimen before testing, a retest shall be allowed.

PERMISSIBLE VARIATIONS IN WEIGHT AND THICKNESS

12. The thickness of each plate shall not vary more than 0.01 inch under that ordered.

(For permissible overweights of plates ordered to thickness see Table 2 in Association of American Steel Manufacturers standard specification for structural and boiler steel (605.0, p. 247).)

13. The overweight of each lot (for definition of "lot" also see A. S. M. specification under 605.0) in each shipment shall not exceed the amount specified in the A. S. M. Table 2 referred to above. One cubic inch of rolled steel is assumed to weigh 0.2833 pound.

MARKING

(a) The name or brand of the manufacturer, the manufacturer's test identification number, class, and lowest tensile strength specified shall be legibly stamped on each finished plate in two places not less than 12 inches from the edges and on each butt strap near the center line not less than 12 inches from each end. The manufacturer's test identification number shall be legibly stamped on each test specimen.

(b) When specified on the order, plates shall be match marked as defined in paragraph (c) so that the test specimens representing them may be identified. When the plate rolled from a slab or ingot is cut into two or more smaller plates, each shall be match marked so that they may all be identified with the test specimens representing them.

(c) Each match mark shall consist of two overlapping circles, each not less than 1½ inches in

diameter, placed upon the shear lines, and made by separate impressions of a single-circle steel die.

(d) Match-marked coupons shall match with the sheets represented and only those which match properly shall be accepted.

(Requirements covering finish, inspection and rejection, and reheating conform to those specified in A. S. T. M. standard specifications for steel. See 605.0, p. 247.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR STEEL PLATES OF FLANGE QUALITY FOR FORGE WELDING, DESIGNATION A89-30, 1930

STEEL PLATES OF FLANGE QUALITY FOR FORGE WELDING

1. These specifications cover steel plates of flange quality suitable for forge welding, without the use of fluxes, where the weld is not reinforced.

MANUFACTURE

2. The steel shall be made by the open-hearth process.

CHEMICAL PROPERTIES AND TESTS

3. (a) The steel shall conform to the following requirements as to chemical composition:

	Grade A	Grade B
Carbon:	<i>Per cent</i>	<i>Per cent</i>
For plates 3/4 inch or under in thickness.....	0.15	0.20
For plates over 3/4 inch in thickness.....	.17	.22
Manganese.....	.35-.60	.35-.60
Phosphorus:		
Acid.....	1.06	1.06
Basic.....	1.04	1.04
Sulphur.....	1.05	1.05

¹ Maximum.

(b) The steel should preferably be free from nickel and chromium. When these elements are present the maximum quantity of either one shall not exceed 0.05 per cent. Unless otherwise specified, the silicon shall not exceed 0.05 per cent.

4. An analysis of each melt of steel shall be made by the manufacturer to determine the percentages of carbon, manganese, phosphorus and sulphur. This analysis shall be made from a test ingot taken during the pouring of the melt. The mechanical composition thus determined shall be reported to the purchaser or his representative, and shall conform to the requirements specified in section 3.

5. An analysis may be made by the purchaser from a broken tension-test specimen representing each plate as rolled. The chemical composition thus determined shall conform to the requirements specified in section 3.

PHYSICAL PROPERTIES AND TESTS

6. (a) The material shall conform to the following minimum requirements as to tensile properties:

	Grade A	Grade B
Tensile strength.....lbs./in. ²	45,000	50,000
Yield point.....lbs./in. ²	0.5 tensile strength.	0.5 tensile strength.
But in no case less than.....	24,000	27,000
Elongation in 8 inches.....per cent.....	30	27

(b) The yield point shall be determined by the elongation of the beam of the testing machine.

7. (a) For material over three-fourths inch in thickness, a deduction from the percentages of elongation specified in section 6 (a) of 1.25 per cent shall be made for each increase of one-thirty-second inch of the specified thickness above three-fourths inch.

(b) For material under five-sixteenths inch in thickness, a deduction from the percentage of elongation in 8 inches specified in section 6 (a) of 1.25 per cent shall be made for each decrease of one-thirty-second inch of the specified thickness below five-sixteenths inch.

8. The test specimen shall stand being bent cold through 180° without cracking on the outside of the bent portion, as follows: For material 1 inch or under in thickness, around a pin the diameter of which is equal to the thickness of the specimen; and for material over 1 inch in thickness, around a pin the diameter of which is equal to twice the thickness of the specimen.

9. (a) Tension test specimen shall be taken longitudinally from the bottom of the finished rolled material, and bend test specimens shall be taken transversely from the middle of the top of the finished rolled material. The longitudinal test specimens shall be taken in the direction of the longitudinal axis of the ingot, and the transverse test specimens at right angles to that axis.

(b) Tension and bend test specimens shall be of the full thickness of material as rolled, and shall be machined to the form and dimensions shown in Figure 128 in A. S. T. M. standard specifications for steel (see 605.0, p. 247), except that bend test specimens may be machined with both edges parallel.

(c) Test specimens for plates over 1 1/2 inches in thickness may be machined to a thickness or diameter of at least three-fourths inch for a length of at least 9 inches.

(d) The machined sides of rectangular bend test specimens may have the corners rounded to a radius not over one-sixteenth inch.

10. (a) One tension and one bend test shall be made from each plate as rolled.

(b) If any test specimen shows defective machining or develops flaws, it may be discarded and another specimen substituted.

(c) If the percentage of elongation of any tension test specimen is less than that specified in section 6 (a) and any part of the fracture is outside the middle third of the gage length, as indicated by scribe scratches marked on the specimen before testing, a retest shall be allowed.

PERMISSIBLE VARIATIONS IN WEIGHT AND THICKNESS

11. The thickness of each plate shall not vary more than 0.01 inch under that ordered.

The overweight of each lot in each shipment shall not exceed the amount given in Table 2 in Association of American Steel Manufacturers under 605.0, p. 248. One cubic inch of rolled steel is assumed to weigh 0.2833 lb.

FINISH

12. The finished material shall be free from injurious defects and shall have a workmanlike finish.

MARKING

13. (a) The name or brand of the manufacturer, melt or slab number, class, and tensile strength for the grade specified in section 6 (a) shall be legibly stamped on each plate. The melt or slab number shall be legibly stamped on each test specimen.

(b) When specified on the order, plates shall be match marked as defined in paragraph (c) so that

the test specimens representing them may be identified. When the plate rolled from a slab or ingot is cut into two or more smaller plates, each shall be match marked so that they may all be identified with the test specimens representing them.

(c) Each match mark shall consist of two overlapping circles each not less than 1½ inches in diameter, placed upon the shear lines, and made by separate impressions of a single-circle steel die.

(d) Match-marked coupons shall match with the sheets represented and only those which match properly shall be accepted.

(In respect to inspection and rejection, and reheating, this specification conforms to A. S. T. M. standard specifications for steel. See 605.0, p. 247. For table of permissible overweights of plates ordered to thickness, see Association of American Steel Manufacturers, standard specifications for structural and boiler steel, also under 605.0, p. 248.)

AMERICAN SOCIETY FOR TESTING MATERIALS, TENTATIVE SPECIFICATIONS FOR STEEL PLATES OF FLANGE AND FIRE-BOX QUALITIES FOR FORGE WELDING, DESIGNATION A89-31T, 1931

STEEL PLATES FOR FORGE WELDING

(In respect to ladle and check analyses, determination of yield point, modifications in elongation, bend tests, homogeneity tests, test specimens, number of tests, permissible variations, and marking, these specifications are substantially the same as A. S. T. M., A70-27, given above, including the references in A70-27 to both A. S. T. M. standard specifications for steel and A. A. S. M. standard specifications for structural and boiler steel under commodity designation 605.0. In addition these specifications provide for the following requirements:)

SCOPE

1. These specifications cover two grades of steel plate of flange and fire-box qualities suitable for forge welding without the use of fluxes where the weld is not reinforced.

MANUFACTURE

2. The steel shall be made by either or both the following processes: Open-hearth or electric furnace.

CHEMICAL COMPOSITION AND TESTS

3. (a) The steel shall conform to the following requirements as to chemical composition:

	Flange		Fire box	
	Grade A	Grade B	Grade A	Grade B
Carbon, maximum:				
For plates ¾ inch or under in thickness	Per cent 0.15	Per cent 0.20	Per cent 0.15	Per cent 0.20
For plates over ¾ inch in thickness	.17	.22	.17	.22
Manganese	0.35-.60	0.35-.60	0.35-.60	0.35-.60
Phosphorus, maximum:				
Acid	.06	.06	.04	.04
Basic	.04	.04	.035	.035
Sulphur, maximum	.05	.05	.04	.04

(b) The steel should preferably be free from nickel⁵⁰ and chromium. When these elements are present the maximum quantity of either one shall not exceed 0.05 per cent. Unless otherwise specified, the silicon shall not exceed 0.05 per cent.

PHYSICAL PROPERTIES AND TESTS

4. (a) The material shall conform to the following minimum requirements as to tensile properties:

⁵⁰ When these specifications are used for material to be fusion welded, the maximum limit for nickel shall not apply.

	Flange		Fire box	
	Grade A	Grade B	Grade A	Grade B
Tensile strength.....lbs./in. ²	45,000	50,000	^a 45,000	^b 50,000
Yield point.....do	0.5 tensile strength.	0.5 tensile strength.	0.5 tensile strength.	0.5 tensile strength.
But in no case less than.....do	24,000	27,000	24,000	27,000
Elongation in 8 inches ^bper cent	<u>1,500,000</u>	<u>1,500,000</u>	<u>1,550,000</u>	<u>1,550,000</u>
	tensile strength	tensile strength	tensile strength	tensile strength
Elongation in 2 inches.....do	<u>1,600,000</u>	<u>1,600,000</u>	<u>1,650,000</u>	<u>1,650,000</u>
	tensile strength	tensile strength	tensile strength	tensile strength

^a See par. (b).

^b See modifications in elongation in A. S. T. M., A70-27, above.

(b) Tensile strength only need be determined on the test specimen taken longitudinally from the top of fire-box plates, and it shall not exceed 60,000 pounds per square inch for grade A and 65,000 pounds per square inch for grade B.

TEST SPECIMENS

5. Tension-test specimens for plates over 1½ inches in thickness may be machined to a thickness or diameter of at least three-fourth inch for a length of at least 9 inches, or they may conform to the dimensions shown in Figure 129 in A. S. T. M. standard specifications for steel. (See 605.0, p. 247.)

6. Bend test specimens for plates over 1½ inches in thickness may be machined to a thickness or

diameter of at least three-fourth inch, or to 1 by ½ inch in section.

7. The machined sides of rectangular bend test specimens may have the corners rounded to a radius not over one-sixteenth inch.

MARKING

8. The name or brand of the manufacturer, the manufacturer's test identification number, class, and lowest tensile strength for the grade specified above under physical properties and tests shall be legibly stamped on each plate. The manufacturer's test identification number shall be legibly stamped on each test specimen.

AMERICAN SOCIETY FOR TESTING MATERIALS, TENTATIVE SPECIFICATIONS FOR MARINE-BOILER STEEL PLATES, DESIGNATION A114-29T, 1929

MARINE-BOILER STEEL PLATES

SCOPE

1. These specifications cover two grades of steel for marine boilers; namely, grade A and grade B.

MANUFACTURE

2. The steel shall be made by the open-hearth process.

CHEMICAL PROPERTIES AND TESTS

3. The steel shall conform to the following requirements as to chemical composition:

Phosphorus:	Per cent
Acid, not over.....	0.04
Basic, not over.....	.035
Sulphur, not over.....	.04

LADLE AND CHECK ANALYSIS

(Conform to A. S. T. M., A70-27, given above.)

PHYSICAL PROPERTIES AND TESTS

4. (a) The material shall conform to the following requirements as to tensile properties:

	Grade A	Grade B
Tensile strength.....lbs./in. ² ..	60,000-70,000	55,000-65,000
Yield point, minimum.....lbs./in. ² ..	0.5 tensile strength.	0.5 tensile strength.
Elongation in 8 inches, minimum.....per cent..	1,500,000	1,550,000
	Tensile strength	Tensile strength

(b) The yield point shall be determined by the drop of the beam of the testing machine.

MODIFICATION IN ELONGATION

5. For material over three-fourth inch in thickness, a deduction from the percentages of elongation specified in section 6 (a) of 0.125 per cent shall be made for each increase of one-thirty-second inch of the specified thickness above three-fourth inch to a minimum of 20 per cent for grade A steel and 22 per cent for grade B steel.

BEND-TESTS

6. (a) The test specimen for grade A steel shall stand being bent cold through 180° without cracking on the outside of the bent portion, as follows: For material 1 inch or under in thickness, around a pin the diameter of which is equal to one and one-half times the thickness of the specimen; for material over 1 inch to and including 1½ inches in thickness, around a pin the diameter of which is equal to three times the thickness of the specimen; and for material over 1½ inches in thickness, around a pin the diameter of which is equal to four times the thickness of the specimen.

(b) The test specimen for grade B steel shall stand being bent cold through 180° without cracking on the outside of the bent portion, as follows: For material 1 inch or under in thickness, around a pin the diameter of which is equal to the thickness of the specimen; for material over 1 inch to and including

1½ inches in thickness, around a pin the diameter of which is equal to twice the thickness of the specimen; and for material over 1½ inches in thickness, around a pin the diameter of which is equal to three times the thickness of the specimen.

TEST SPECIMENS

7. (a) The tension-test specimens shall be taken longitudinally from the finished rolled material. In the case of plates rolled from ingots, these specimens shall be taken in the direction of the longitudinal axis of the ingot; one from the top and one from the bottom of the same side of the plates as rolled. In the case of plates rolled from slabs, the tension test specimens shall be taken from diagonal corners.

(b) In the case of plates rolled from ingots, the bend-test specimen shall be taken from the middle of the top of the finished rolled material at right angles to the longitudinal axis of the ingot. In the case of plates rolled from slabs, it shall be taken from the middle of one end at right angles to the longitudinal axis of the plate as rolled.

(c) Tension and bend test specimens shall be of the full thickness of the material as rolled, and shall be machined to the form and dimensions shown in Figure 128 in A. S. T. M. standard specifications for steel (see 605.0, p. 247.); except that bend-test specimens may be machined with both edges parallel.

(d) The machined sides of rectangular bend test specimens may have the corners rounded to a radius not over one-sixteenth inch.

8. (a) Two tension tests and one bend test shall be made from each plate as rolled.

(Requirements covering flaws in or defective machining of test specimens, also retests of tests specimens, are identical with paragraphs 11 (b) and (c) in A. S. T. M., A70-27, given above.)

PERMISSIBLE VARIATIONS IN WEIGHT AND THICKNESS

(Identical with those specified in A. S. T. M., A70-27, given above, including references in A70-27 to Table 2 in Association of American Steel Manufacturers standard specification for structural and boiler steel (see 605.0 p. 248), and definition of term "lot".)

MARKING

9. (a) The name of the manufacturer, the place where manufactured, marine A or B, the manufacturer's test identification number, and the tensile strength as specified in paragraphs (b) and (c) shall be legibly stamped in two places on each finished plate not less than 12 inches from the edges. Each butt strap shall be stamped near the middle of the plate. The manufacturer's identification number shall be legibly stamped on each test specimen.

(b) Plates not over one-half inch in thickness to be used in externally fired boilers for steamers navigated under the provisions of title L 11. United States Revised Statutes, shall be stamped with the least tensile strength, expressed in thousands, as determined by the tests.

(c) Plates other than those described in paragraph (b) shall be stamped with the minimum tensile strength specified.

(d) The manufacturer shall furnish facilities to the representative of the United States Steamboat Inspection Service and, when required, to the representative of the ship classification society, to place their official monogram stamp adjacent to the stamping specified in paragraph (a).

(Requirements covering finish, inspection and rejection, and reheating conform to those specified in A. S. T. M. standard specifications for steel (see 605.0, p. 247).)

AMERICAN SOCIETY FOR TESTING MATERIALS, TENTATIVE SPECIFICATIONS FOR OPEN-HEARTH IRON PLATES OF FLANGE QUALITY, DESIGNATION A129-30T, 1930

IRON PLATES

SCOPE

1. These specifications cover three types of open-hearth iron plates of flange quality.

MANUFACTURE

2. The iron shall be made by the basic open-hearth process.

CHEMICAL PROPERTIES AND TESTS

3. The iron shall conform to the following requirements as to chemical composition:

	Type A	Type B	Type C
Phosphorus, maximum.....per cent..	0.015	0.015	0.015
Sulphur, maximum.....do.....	.040	.040	.040
Total of the metalloids: Carbon, manganese, phosphorus, sulphur, and silicon, maximum.....per cent..	.10	.25	.25
Copper, minimum.....do.....40	.20
Molybdenum, minimum.....do.....05

LADLE AND CHECK ANALYSES

4. *Ladle analyses*.—(Conform to A. S. T. M., A70-27, given above.)

5. *Check analyses*.—An analysis may be made by the purchaser from a broken tension-test specimen representing each plate as rolled, in which a variation of plus 0.01 per cent in sulphur, minus 0.02 per cent in copper, and plus 0.04 per cent in the total of the five metalloids will be permitted.

PHYSICAL PROPERTIES AND TESTS

6. (a) The material shall conform to the following minimum requirements as to tensile properties:

Tensile strength.....lbs./in. ² ..	44,000
Yield point.....do.....	27,500
Elongation in 8 inches.....per cent..	25

(b) The yield point shall be determined by the drop of the beam of the testing machine.

7. (a) For material over three-fourths inch in thickness, a deduction from the percentages of elongation specified in section 6 (a) of 0.125 per cent shall be made for each increase of one-thirty-second inch of the specified thickness above three-fourth inch.

(b) For material under five-sixteenths inch in thickness, a deduction from the percentage of elongation in 8 inches specified in section 6 (a) of 1.25 per cent shall be made for each decrease of one thirty-second inch of the specified thickness below five-sixteenths inch.

8. The test specimen shall stand being bent cold through 180° without cracking on the outside of the bent portion, as follows: For material 1 inch or under in thickness, flat on itself; and for material over 1 inch in thickness, around a pin the diameter of which is equal to the thickness.

TEST SPECIMENS

9. (a) Tension test specimens shall be taken parallel to the longitudinal axis and from the bottom of the plate as rolled. Bend-test specimens

shall be taken from the middle of the top and at right angles to the longitudinal axis of the plate as rolled. The longitudinal test specimen shall be taken in the direction of rolling, and the transverse specimen at right angles to that direction.

(b) Tension and bend test specimens shall be of the full thickness of the material as rolled and shall be machined to the form and dimensions shown in Figure 128 in A. S. T. M. standard specifications for steel (see 605.0, p. 247); except that bend-test specimens may be machined with both edges parallel.

(c) Test specimens for plates over 1½ inches in thickness may be machined to a thickness or diameter of at least three-fourths inch for a length of at least 9 inches.

(d) The machined sides of rectangular bend-test specimens may have the corners rounded to a radius not over one-sixteenth inch.

NUMBER OF TESTS

10. (a) One tension and one bend test shall be made from each plate as rolled.

(b) If any test specimen shows defective machining or develops flaws, it may be discarded and another specimen substituted.

(c) If the percentage of elongation of any tension-test specimen is less than that specified in section 6 (a), and any part of the fracture is outside the middle third of the gage length, as indicated by scribe scratches marked on the specimen before testing, a retest shall be allowed.

PERMISSIBLE VARIATIONS IN WEIGHT AND THICKNESS

11. The thickness of each plate shall not vary more than 0.01 inch under that ordered.

(For permissible overweights of plates ordered to thickness, see Table 2 in Association of American Steel Manufacturers standard specification for structural and boiler steel (605.0, p. 248).)

The overweight of each lot (for definition of "lot" also see A. A. S. M. specification under 605.0) in each shipment shall not exceed the amount specified in the A. A. S. M. table referred to above. One cubic inch of rolled open-hearth iron is assumed to weigh 0.2833 pound.

(Requirements covering marking are substantially the same as in A. S. T. M., A70-27, given above. Requirements covering finish, inspection, and rejection, and reheating conform to those specified in A. S. T. M. standard specifications for steel (see 605.0, p. 247).)

ASSOCIATION OF AMERICAN STEEL MANUFACTURERS, STANDARD SPECIFICATIONS FOR STRUCTURAL AND BOILER STEEL, NOVEMBER 24, 1922

(See also 605.11, p. 250.)

BOILER STEEL

(This specification is, in certain particulars, substantially the same as specification A7 of the American Society for Testing Materials. For requirements relating to process, ladle analysis, and test specimens, see A7 (605.11, p. 249), paragraphs 2, 4, and 8 (a), (c), (d), (e), and (j), omitting reference to shapes and eyebar flats in paragraph 8 (e). For requirements relating to yield point, number of tests, finish, inspection, rejection, and test specimen figures, see A. S. T. M. specifications (605.0, p. 247), paragraphs 2, 3 (c), 5, 7, and 8 (b), and Figures 128 and 129, omitting, in paragraph 3 (c), reference to 2-inch test specimen.)

(For tables of permissible variations in weight and thickness of rectangular sheared plates when ordered

to unit weight and when ordered to thickness, permissible variations in weight of bar sizes of angles, tees, zees, and channels, and permissible variations in size of hot-rolled rounds, squares, hexagons, and flats, see A. A. S. M., Tables 1, 2, 3, 4, and 5 (605.0, p. 248).)

1. *Classes.*—There shall be three classes of steel for boilers, namely: Flange, fire box, and boiler rivet.

2. *Chemical composition.*—The steel shall conform to the following requirements as to chemical composition:

Elements considered	Flange steel	Fire-box steel	Boiler-rivet steel
	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>
Manganese			0.30-0.50
For plates $\frac{3}{4}$ inch or under in thickness	0.30-0.60	0.30-0.50	
For plates over $\frac{3}{4}$ inch in thickness	.30-.60	.30-.60	
Phosphorus, maximum:			
Basic	.04	.035	.04
Acid	.05	.04	.04
Sulphur, maximum	.05	.04	.045

3. *Check analyses.*—An analysis may be made by the purchaser from a broken tension test specimen representing each plate as rolled, or from finished material representing each melt of rivet steel. The chemical composition thus determined shall conform to the requirements specified in the section on chemical composition.

4. *Tension tests.*—The steel shall conform to the following requirements as to tensile properties:

Properties considered	Flange steel	Fire-box steel	Boiler-rivet steel
Tensile strength			
.....lbs./in. ² ..	55,000-65,000	52,000-62,000	45,000-55,000
Yield point, minimum			
.....lbs./in. ² ..	0.5 tensile strength.	0.5 tensile strength.	0.5 tensile strength.
Elongation in 8 inches, minimum, per cent	$\frac{1}{1,450,000}$ Tensile strength	$\frac{1}{1,500,000}$ Tensile strength	$\frac{1}{1,450,000}$ Tensile strength

¹ See section on modifications in elongation.

5. *Modifications in elongation.*—(a) For plates over three-fourths inch in thickness a deduction from the percentage of elongation specified in table of tensile properties shall be made in the proportion of 0.5 for each increase of one-eighth inch in thickness above three-fourths inch, to the minima of 20 per cent for flange steel and 22 per cent for fire-box steel.

(b) For plates under five-sixteenths inch in thickness a deduction from the percentage of elongation specified in table of tensile properties shall be made in the proportion of 2.5 for each decrease of one-sixteenth inch in thickness below five-sixteenths inch.

6. *Bend tests.*—(a) Cold-bend tests shall be made on the material as rolled.

(b) Quench-bend test specimens, before bending, shall be heated to a light cherry red as seen in the dark (about 1,200° F.), and quenched in water the temperature of which is about 80° F.

(c) Specimens for cold-bend and quench-bend tests of flange and fire-box steel shall bend through 180° without fracture on the outside of the bent portion, as follows: For plates 1 inch or under in thickness, flat on themselves; for plates over 1 inch to and including 1½ inches in thickness, around a pin the diameter of which is equal to the thickness of the specimen; and for plates over 1½ inches in thick-

ness, around a pin the diameter of which is equal to one and one-half times the thickness of the specimen.

(d) Specimens for coal-bend and quench-bend tests of boiler rivet steel shall bend through 180° flat on themselves without fracture on the outside of the bent portion.

7. *Test specimens.*—Test specimens for rivet bars shall be of the full section of the bars as rolled.

8. *Number of tests.*—(a) One tension, one cold-bend, and one quench-bend test shall be made from each plate as rolled.

(b) Two tension, two cold-bend and two quench-bend tests shall be made from each melt of rivet steel.

(c) If any test specimen shows defective machining or develops flaws, it may be discarded and another specimen substituted.

9. *Permissible variations.*—(a) The thickness or weight of sheared mill plates shall conform to the manufacturers' standard practice governing the permissible variations for sheared plates. (See A. A. S. M., 605.0, p. 248.)

(b) The dimensions of rivet bars shall conform to the manufacturers' standard practice governing the allowable variations in the size of hot-rolled bars. (See A. A. S. M., 605.0, p. 248.)

10. *Marking.*—(a) The name or brand of the manufacturer, the manufacturer's test identification number, class, and the minimum tensile strength for its class specified in table of tensile properties shall be legibly stamped on each plate. The test identification number shall be legibly stamped on each test specimen.

(b) Rivet steel shall be shipped in securely fastened bundles, with the manufacturer's name and melt number legibly stamped on attached metal tags.

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR STEEL PLATES, MARINE BOILER, QQ-S-691, MARCH 1, 1932

MARINE BOILER STEEL PLATES

(This specification conforms to A. S. T. M. A114-29T, given above, except that a third class of marine boiler steel is provided for here. This is known as class C, and may be made by the Bessemer process. It has no specified physical and chemical properties. Class C plates are intended for smokestacks, boiler casings, uptakes, etc. Included in F. S. B. No. 549 (QQ-S-691) as part of the specification is F. S. B. 339a (QQ-M-151), general specifications for metals, for which see 600.00, p. 3.)

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, STEAMBOAT INSPECTION SERVICE, GENERAL RULES AND REGULATIONS, MAY 4, 1929

BOILER PLATE

CHEMICAL PROPERTIES, STEEL PLATES

1. Steel plates shall be made by the open-hearth process, except that steel for plates to be used in the manufacture of boiler tubes may be made by the Bessemer process.

Open-hearth steel shall contain not more than 0.04 per cent of phosphorus nor more than 0.05 per cent of sulphur.

The manufacturer shall furnish the inspector, with each order tested, a certificate stating the process by which the steel was manufactured and a

copy of the analysis of each melt. The analysis may, if deemed expedient by the supervising inspector general, be verified at the expense of the manufacturer. (Secs. 4405, 4430, R. S.)

PHYSICAL PROPERTIES, STEEL PLATES

2. All steel plates tested shall show an elongation of at least 20 per cent measured in a gage length of 8 inches. (Sec. 4430, R. S.)

PHYSICAL PROPERTIES, IRON PLATES

3. The tensile strength shall be not less than 45,000 pounds per square inch. The elongation shall be not less than 15 per cent. The reduction of area shall be not less than 15 per cent for 45,000 pounds tensile strength, and for each increase of 1,000 pounds tensile strength up to 55,000 pounds, an addition of 1 shall be made to the required percentage of reduction of area. The bend test specimen shall bend cold through 90° around a curve the radius of which is not greater than one and one-half times the thickness of the specimen. (Sec. 4430, R. S.)

4. All tension test specimens shall be milled to the form as shown in Figure 127, with the following dimensions: Length at least 16 inches, ends from 1½ to 3½ inches wide by about 3 inches in length, and parallel section at center 1 to 1½ inches wide by 9 inches in length. The percentage of elongation shall be measured in a gage length of 8 inches.

5. Where specimens are to be tested on the testing machines of the steamboat inspection service, they

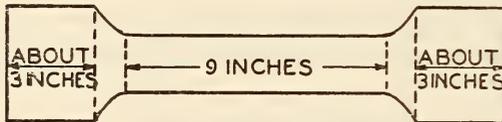

FIGURE 127

shall be 1 inch wide at parallel section in center, and shall not exceed 2 inches in width on the ends.

6. All bend test specimens shall be at least 12 inches in length and from 1 to 3½ inches in width, and the full thickness as rolled. The edges may be planed. The corners shall not be rounded, but the sharpness may be removed with a fine file. After bending, the specimens shall show no cracks or flaws on the outside of the bent portion.

TEST SPECIMENS FOR STEEL PLATES

7. Two tension tests and one cold-bend test shall be made from each plate as first rolled from a billet, slab, or ingot, the tensile test specimens to be taken from two diagonal corners of the plate, and a cold-bend specimen to be taken transversely from the middle of the top of the plate.

8. The bend test specimen shall bend cold 180° around a pin without showing any sign of cracking or other injurious defects on the outside of the bent portion, as follows: For plates under 1 inch in thickness the diameter of the pin shall be equal to one and one-half times the thickness of the plate; for plates 1 inch and over, up to and including 1½ inches in thickness, the diameter of the pin shall be equal to three times the thickness of the plate, and for all plates over 1½ inches in thickness the diameter of the pin shall be equal to four times the thickness of the plate.

9. The finished material shall be free from all injurious defects, and shall have a good and workmanlike finish.

10. All measurements of test specimens and material shall be made by any standard American gage, and record of tests shall be submitted on Form 934. (Secs. 4405, 4430, R. S.)

604.12 STEEL PLATES FOR NONPRESSURE TANKS AND STACKS.

AMERICAN BUREAU OF SHIPPING, RULES FOR BUILDING AND CLASSING STEEL VESSELS; QUALITY AND TESTING OF MATERIALS—SHIP CONSTRUCTION, 1930

IRON PLATES AND ANGLES

(For general information and requirements see 600.0. p. 2.)

1. Iron plates and angles are to be of the best quality and free from surface pitting and lamination,

and legibly stamped with the manufacturer's name or trade-mark. They are to have a tensile strength of 48,000 pounds per square inch of prepared section with the fiber and an elongation of 12 per cent in 8 inches. For plates under seven-sixteenths inch in thickness a deduction of one from the percentage of elongation shall be made for each decrease of one-sixteenth inch in thickness below seven-sixteenths inch.

2. Tension and bend test specimens shall be taken from the finished plates and must be of the full thickness of the plates as rolled. A test specimen must stand being bent cold through 90° without fracture on the outside of the bent portion, the radius of the bend being one and one-half times the thickness of the specimen. One tension and one cold-bend test shall be made for each variation of thickness of one-eighth inch and not less than one test for each 10 plates as rolled.

3. For angle bars pieces shall be heated red and so bent as to have their flanges shut until the outside edges touch and to have their flanges flattened out without fracture or cracks.

4. If any test specimen fails to conform to the above requirements through an apparent local defect, a retest shall be taken; and should the retest fail the plates or angle bars represented by such tests shall be rejected.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR WROUGHT-IRON PLATES, DESIGNATION A42-30, 1930⁵¹

WROUGHT-IRON PLATES

SCOPE

1. These specifications cover two classes of wrought-iron plates, as determined by the kind of material used in their manufacture, namely, class A, as defined in section 2 (b), and class B, as defined in section 2 (c).

MANUFACTURE

2. (a) All plates shall be rolled from piles entirely free from any admixture of steel.

(b) Piles for class A plates shall be made from wrought iron⁵² and such scrap as results from rolling the plates.

(c) Piles for class B plates shall be made from wrought iron⁵² together with wrought-iron scrap.

PHYSICAL PROPERTIES AND TESTS

3. (a) The plates shall conform to the following minimum requirements as to tensile properties:

Properties considered	Class A		Class B	
	6 to 24 inches inclusive, in width	Over 24 inches to 90 inches, inclusive, in width	6 to 24 inches inclusive, in width	Over 24 inches to 90 inches, inclusive, in width
Tensile strength.....lbs./in. ² ..	49,000	48,000	48,000	47,000
Yield point.....do.....	26,000	26,000	26,000	26,000
Elongation in 8 inches...per cent..	16	12	14	10

(See sec. 4.)

⁵¹ These specifications prior to their revision in 1930 had been approved as American Tentative Standard by the American Standards Association. The revised specifications have been resubmitted for approval.

⁵² Wrought iron is defined as follows in the Standard Definitions of Terms Relating to Wrought-Iron Specifications (A. S. T. M. Designation: A81) of the American Society for Testing Materials: *Wrought iron*.—A ferrous material, aggregated from a solidifying mass of pasty particles of highly refined metallic iron with which without subsequent fusion, is incorporated a minutely and uniformly distributed quantity of slag.

(b) The yield point shall be determined by the drop of the beam of the testing machine. The speed of the crosshead of the machine shall not exceed three-fourths inch per minute.

(Modifications in elongation, bend tests, test specimens, and number of tests are the same as in American Bureau of Shipping, iron plates and angles, given above, except that in A42, class B plates shall withstand bending around a pin the diameter of which is equal to three times the thickness of the specimen; and in addition to one tension, and one cold-bend test, there shall be one nick-bend test.)

4. *Nick-bend tests*.—The test specimen, when nicked on one side and broken, shall show for class A plates a wholly fibrous fracture, and for class B plates, not more than 10 per cent of the fractured surface to be crystalline.

FINISH

5. The plates shall be straight, smooth, and free from cinder spots and holes, injurious flaws, buckles, blisters, seams, and laminations.

MARKING

6. The plates shall be stamped or otherwise marked as designated by the purchaser.

INSPECTION AND REJECTION

(Conform with A. S. T. M. standard specifications for steel. See 605.0, p. 247.)

604.19 MISCELLANEOUS IRON AND STEEL PLATES.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS, BOILER CONSTRUCTION CODE, SPECIFICATIONS FOR STEEL PLATE FOR BRAZING, S-3, 1930

STEEL PLATE FOR BRAZING

1. The steel shall conform to the following requirements as to chemical composition:

	Per cent
Carbon, not over.....	0.28
Manganese, not over.....	.60
Phosphorus, not over.....	.04
Sulphur, not over.....	.05

2. *Ladle analyses*.—(a) The manufacturer shall make an analysis of each melt of steel, from a test ingot taken during the pouring of the melts, to determine the percentage of carbon, manganese, phosphorus, and sulphur. The results of analysis shall conform to requirements, and shall be reported to the purchaser or his representative.

Check analyses.—(b) The purchaser may make an analysis from finished material representing each melt. The chemical composition thus determined shall conform to the requirements.

3. *Tension tests*.—The material shall conform to the following requirements as to tensile properties:

Tensile strength, maximum.....lbs./in. ² ..	70,000
Yield point, minimum.....do.....	28,000
Elongation, minimum.....per cent..	1,500,000 Tensile strength

The elongation shall be measured on a gage length of twenty-four times the thickness of specimen, except that this may be reduced by 2½ per cent for each one-sixteenth inch under five-sixteenth inch.

4. *Bend test*.—The bend-test specimen shall bend cold through 180° without cracking on the outside of the bent portion, around a pin the diameter of which is equal to the thickness of the specimen.

5. *Number of tests*.—Two tension tests and two bend tests shall be taken from each heat, but not both tension or both bend tests from the same slab.

6. Sheets less than one-fourth inch in thickness shall not be required to be stamped at the mill on account of the small size and light weight of the sheets. The manufacturer must mark each vessel in some permanent manner which will enable him to identify the heat from which the sheet in each tank has been rolled.

The United States standard gage for sheet and plate iron and steel, as adopted by Congress, as applied to steel sheets, and the galvanized sheet gage as applied to galvanized steel sheets, will be found in Circular of the Bureau of Standards No. 391. (See 604.0, p. 224.)

604.21 IRON AND STEEL SHEETS FOR MAGNETO ELECTRIC APPARATUS.

(No nationally recognized specifications available.)

604.22 IRON AND STEEL STRIPS, BANDS, AND HOOPS.

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATION FOR TANK HOOPS, 1920

TANK HOOPS

MATERIAL

1. The tank hoops shall preferably be wrought iron. They may be open-hearth steel. Such wrought iron or steel shall fulfill all of the requirements of quality, strength, inspection, and test for wrought iron and open-hearth steel given in the specifications for steel railway bridges of the American Railway Engineering Association.

SHAPE

2. Hoops to be round in cross section, the same size throughout, and shall be bent to a true radius to fit the tank.

3. To be of such a size and so spaced that the stress shall not exceed 12,500 pounds per square inch, when computed from area at base of thread. No hoop less than three-fourths-inch diameter to be used.

SPACING

4. Spacing of hoops to be figured by the following formula:

$$\text{Spacing of hoops in inches} = \frac{\text{Safe load for given hoop in pounds}}{2.6 \text{ diameter (feet)} \times \text{depth,}^{53} \text{ (feet)}}$$

Top hoop to be placed within 2 inches of top of staves. No space between hoops to exceed 21 inches. Hoops to be so placed that lugs will not come in a vertical line.

On account of the swelling of the tank bottom, the hoops near the bottom may be subjected to a strain greater than that due to the water pressure alone, therefore additional hoops should be provided. Two hoops of the size used next above it should be placed around the bottom opposite the croze, one of which shall not be considered as withstanding any water pressure.

THREADS

5. The ends of each section of hoop shall be threaded with United States standard thread for length of 4½ inches.

NUTS

6. Each end of each section shall be provided with two hexagon nuts tapped to fit the thread on hoop.

LUGS

7. The lugs shall be of standard pattern, at least 8 inches long, and as strong as the hoop; they shall preferably be made of malleable iron, but cast iron may be used if approved by the engineer.

GENERAL

8. Each hoop shall be made in three sections for 16 by 24 foot tanks and in four sections for 20 by 30 foot tanks.

The several pieces constituting one hoop shall be tied together for shipment.

All pieces shall be furnished in full lengths, unwelded, and must not vary from the lengths given on order more than one-half inch.

NOTE.—The following table gives proper working strength for hoops of common sizes, based on the above allowable stress:

Diameter of round rod	Area of section of rod	Net area of root of thread	Safe working load
<i>Inches</i>	<i>Square inch</i>	<i>Square inch</i>	<i>Pounds</i>
¾	0.44	0.30	3,750
⅞	.60	.42	5,250
1	.79	.55	6,875
1½	.99	.69	8,625

AMERICAN SOCIETY FOR TESTING MATERIALS, TENTATIVE SPECIFICATIONS FOR COLD-ROLLED STRIP STEEL, DESIGNATION A109-27T, 1927

COLD-ROLLED STRIP STEEL

1. These specifications cover five grades of commercial cold-rolled strip steel as follows:

- Grade No. 1, or "Hard" temper;
- Grade No. 2, or "Half hard" temper;
- Grade No. 3, or "Quarter hard" temper;
- Grade No. 4, or "Planished" temper;
- Grade No. 5, or "Dead soft" temper.

2. (a) These five grades of cold-rolled strip steel are commonly used for blanking, bending, forming, spinning, and deep drawing.

(b) It should be understood, however, that the tempers and uses given are general. It is recom-

⁵³ Depth refers to distance from top of stave to point where hoop is to be located.

mended that the purchaser furnish the manufacturer with a sample or sketch of the article to be made.

MANUFACTURE

3. The steel shall be made by the open-hearth process for temper Nos. 3, 4, and 5.

CHEMICAL REQUIREMENTS

4. The steel shall conform to the following requirements as to chemical composition:

Temper Nos. 1 and 2

Carbon, not over.....	Per cent 0.25
-----------------------	------------------

Temper Nos. 3, 4, and 5

Carbon.....	Per cent 0.05 to 0.15
Manganese.....	.20 to .50
Phosphorus, not over.....	.04
Sulfur, not over.....	.055

5. Samples for analysis shall be taken by machining the entire cross-section of the strip.

PHYSICAL PROPERTIES AND TESTS

6. The material shall conform to the following requirements as to tensile properties:

	No. 1, hard	No. 2, half hard	No. 3, quarter hard	No. 4, planished	No. 5, dead soft		
Tensile strength, minimum.....lbs./in. ²	60,000	55,000	45,000	40,000	40,000		
		Mini- mum	Maxi- mum	Mini- mum	Maxi- mum	Mini- mum	Maxi- mum
Elongation in 2 inches, per cent:							
Below 0.062 inch.....		5 15.0	15.0	30.0	30.0	32.5	
Below 0.125 to 0.062 inch, inclusive.....		5 16.0	16.0	32.5	32.5	33.5	
Below 0.187 to 0.125 inch, inclusive.....		5 17.5	17.5	33.5	33.5	36.0	
Below 0.250 to 0.187 inch, inclusive.....		5 19.0	19.0	36.0	36.0	38.5	
0.250 inch or over in thickness.....		5 20.0	20.0	38.5	38.5	40.0	

7. The bend test specimens shall stand being bent cold as specified below without cracking on the outside of the bent portion:

No. 1, hard	No. 2, half hard	No. 3, quarter hard	No. 4, planished	No. 5, dead soft
Shall not be required to make bends in either direction of grain.	Shall bend to a sharp right angle across the grain.	Shall bend flat on itself across the grain and to a sharp right angle along the grain.	Shall bend flat upon itself both ways of the grain.	Shall bend flat upon itself both ways of the grain.

NOTE.—To bend across the grain means that the axis of the bend shall be at right angles to the direction of rolling. To bend with the grain means that the axis of the bend shall be parallel to the direction of rolling.

8. (a) The tension test specimens shall be cut in both a longitudinal and transverse direction from the strip except in the case of widths narrower than 10 inches, in which case only longitudinal specimens shall be taken. The specimen shall be machined to the form and dimensions shown in Figure 127-A.

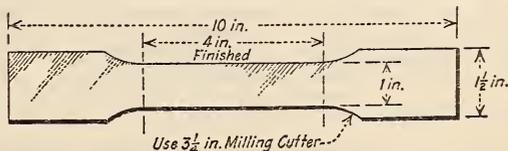

FIGURE 127-A.—Test specimen

(b) The test specimens shall be marked off for every 1-inch length within the 4-inch gage length. The percentage of elongation in 2 inches shall be

determined by averaging the increase in length of the two 2-inch lengths that include the break.

(c) Bend-test specimens may have the edges rounded.

PERMISSIBLE VARIATIONS IN DIMENSIONS

9. The thickness of the strip measured at a point one-half inch from the edge shall not vary from the thickness specified by more than the following plus or minus variations:

[All dimensions in inches]

Thickness	Width			
	Up to 2 inches, inclusive	Over 2 to 4 inches, inclusive	Over 4 to 6 inches, inclusive	Over 6 to 8 inches, inclusive
0.200 or over	0.003	0.004	0.005	0.005
Below 0.200 to 0.100	.002	.003	.004	.004
Below 0.100 to 0.050	.002	.002	.003	.003
Below 0.050 to 0.035	.002	.002	.002	.002
Below 0.035 to 0.015	.0015	.002	.002	.002
Below 0.015 to 0.010	.001	.0015	.0015	.0015
Below 0.010 to 0.006	.00075	.001	.001	-----
Below 0.006	.0005	.0005	.0005	-----

Thickness	Width			
	Over 8 to 12 inches, inclusive	Over 12 to 16 inches, inclusive	Over 16 to 24 inches, inclusive	Over 24 inches
0.200 or over	0.006	0.006	0.007	0.008
Below 0.200 to 0.100	.005	.005	.006	.007
Below 0.100 to 0.050	.004	.004	.005	.006
Below 0.050 to 0.035	.003	.003	.004	-----
Below 0.035 to 0.015	.002	-----	-----	-----
Below 0.015 to 0.010	.0015	-----	-----	-----

10. The width of the strip shall not vary from that specified by more than the following amounts:

Mill edge steel

	Plus		Minus	
	Inch	Inch	Inch	Inch
Up to 6 inches, inclusive	1/16	1/16	1/16	1/16
Over 6 to 10 inches	3/32	3/32	5/32	5/32
Over 10 to 16 inches	1/8	1/8	5/32	5/32
Over 16 inches	1/4	1/4	1/4	1/4

Slit, sheared, or file edge steel

	Plus		Minus	
	Inch	Inch	Inch	Inch
Up to 0.100 inch	0.015	0.015	0.015	0.015
0.100 to 0.200 inch	.025	.025	.020	.020
0.200 to 0.300 inch	.035	.035	.025	.025
0.300 to 0.400 inch	1/16	1/16	1/16	1/16
0.400 to 0.500 inch	1/8	1/8	1/8	1/8

Round or square-rolled edge steel

Width	Thickness	Tolerances in width, plus or minus
1/2 inch and narrower	3/16 inch and thinner	1/64
Over 1/2 to 1 inch, inclusive	3/16 to 0.025 inch, inclusive	1/32
Over 1 to 2 inches, inclusive	1/4 to 0.025 inch, inclusive	1/32
Over 2 to 4 inches, inclusive	1/4 to 0.035 inch, inclusive	3/64
Over 4 to 6 inches, inclusive	1/4 to 0.047 inch, inclusive	3/64

Strip wider than 6 inches is not furnished.

11. (a) Cold-rolled strip steel is usually furnished in coils, but may be furnished in cut lengths when ordered. Unless otherwise specified, the cut lengths will be 8 feet and ends. When so furnished the allowance shall be plus 3 inches with no minus allowance.

(b) When a definite length in inches is specified, the permissible variation shall be plus 1 inch with no minus allowance. Cutting to definite lengths over 36 inches does not relieve the buyer from scrap loss and short lengths will be included, cut to multiples, if so desired.

12. The standard for straightness shall be one-half inch bow in 8 feet.

13. When flatness is an essential to the purchaser, it should be so specified. Flatness shall be determined by placing the strips in 8-foot lengths on a flat surface, when no part of the strip shall rise more than one-fourth inch from the surface.

(Requirements covering finish, inspection, rejection, and reheating conform to those specified in A. S. T. M. standard specifications for steel (see 605.0, p. 247) except that rejections shall be reported within 10 working days from receipt of samples, and that rejected material shall be preserved for one month from the date of the test report.)

The Birmingham wire gage is used by the manufacturers of steel bands, hoops, and strips. The thickness desired, however, should be expressed in thousandths of an inch when writing specifications for bands, hoops, or strips.

UNITED STATES GOVERNMENT, INTER-STATE COMMERCE COMMISSION, REGULATIONS FOR TRANSPORTATION BY RAIL OF EXPLOSIVES AND OTHER DANGEROUS ARTICLES. SHIPPING CONTAINER SPECIFICATIONS, 1930

10A—WOODEN BARRELS AND KEGS (TIGHT)

8. (a) Hoops must be made from cooperage-grade hoop steel, and as follows:

Carbon content: At least 0.16 per cent.
Tensile strength: Maximum 90,000 pounds per square inch.
Elongation in 8 inches: At least 15 per cent.

(b) Hoops must be as follows with respect to number and size:

Maximum capacity of container (gallons)	Minimum number of hoops	Minimum size of hoops (inches in width, and Birmingham gage)							
		Head		First quarter		Second quarter		Bilge	
		Inches	Gage	Inches	Gage	Inches	Gage	Inches	Gage
50.....	8	1¾	16	1½	18	1½	18	1¾	17
30.....	6	1½	17	1¼	19	-----	-----	1½	18
15.....	6	1¼	18	1½	19	-----	-----	1¼	19
10.....	6	1½	19	1	19	-----	-----	1½	19
5.....	6	1½	19	1	19	-----	-----	1	19

10B—WOODEN BARRELS AND KEGS (TIGHT)

4. Head hoops with minimum width and thickness prescribed for bilge hoops in paragraph 8 (b) (see above) are authorized.

10C—WOODEN BARRELS AND KEGS (TIGHT)

4. Head hoops with minimum width and thickness prescribed for bilge hoops in paragraph 8 (b) (see above) are authorized. Second-quarter hoops not required.

35—WOODEN BARRELS WITH REMOVABLE HEADS

4. Hoops must be at least six in number with minimum size as follows:

Head hoops..... 11½/16 inches by 17 gage.
Quarter hoops..... 17/16 inches by 18 gage.
Bilge hoops..... 11½/16 inches by 17 gage.

11A—WOODEN BARRELS AND KEGS (SLACK)

5. (a) Hoops must be of cooperage-grade hoop steel—of beaded or rolled edge type—or of coiled elm, well finished and free from defects.

(b) Steel hoops must have one beaded or rolled edge, and with respect to number and size must be as follows:

Maximum:		150	300	600
Net weight of article shipped.....pounds..		150	300	600
Head diameter of barrel or keg.....inches..		16	17	20
Stave length of barrel or keg.....do.....		28	30	34
Minimum:				
Steel hoops required.....number.....		4	6	6
Head hoops, width.....inches.....		1¾	1¾	1¾
Quarter hoops, width.....do.....		-----	1¾	1¾
Bilge hoops, width.....do.....		1¾	1¾	1¾
Head hoops (Birmingham gage No.).....		23	22	21
Quarter hoops (Birmingham gage No.).....		-----	23	23
Bilge hoops (Birmingham gage No.).....		23	23	23

11B—WOODEN BARRELS AND KEGS (SLACK)

Steel hoops must conform to the following:

	150	300	600
Maximum:			
Net weight of article shipped.....pounds..	150	300	600
Head diameter of barrel or keg.....inches..	16	17	20
Stave length of barrel or keg.....do.....	28	30	34
Minimum:			
Steel hoops required.....number.....	4	4	6
Head hoops, width.....inches.....	1¾	1¾	1¾
Quarter hoops, width.....do.....	-----	1¾	1¾
Bilge hoops, width.....do.....	1¾	1¾	1¾
Head hoops (Birmingham gage No.).....	23	21	21
Quarter hoops (Birmingham gage No.).....	-----	23	23
Bilge hoops (Birmingham gage No.).....	23	23	23

604.23 IRON AND STEEL SHEETS FOR DRAWING AND FORMING.

AMERICAN SOCIETY FOR TESTING MATERIALS, TENTATIVE SPECIFICATIONS FOR COLD-ROLLED STRIP STEEL, DESIGNATION A109-27T, 1927

COLD-ROLLED STRIP STEEL

(See 604.22, p. 237.)

604.24 SPRING AND TOOL STEEL SHEETS.

(No nationally recognized specifications available.)

604.25 IRON AND STEEL SHEETS FOR AUTOMOTIVE AND RAILWAY USE.

AMERICAN RAILWAY ASSOCIATION, MECHANICAL DIVISION, STEEL SHEETS AND THIN PLATES, RECOMMENDED PRACTICE, 1926

STEEL SHEETS AND THIN PLATES

1. *Scope.*—These specifications apply to all uncoated steel sheets and plates under three-sixteenth inch in thickness for locomotives, freight and passenger equipment cars. Plates are rolled on a plate mill and are usually rolled to a minimum thickness of 0.109 inch (12 USSG). Sheets are rolled on a jobbing or sheet mill and are usually rolled to a maximum thickness of 0.187 inch (7 USSG), though occasionally to 0.250 inch (3 USSG).

I. MANUFACTURE

2. *Process.*—The steel shall be made by the open-hearth process.

II. CHEMICAL PROPERTIES AND TESTS

3. *Chemical composition.*—The steel shall conform to the following requirements as to chemical composition.

Phosphorus in material not less than 0.04 inch thick (1.6 pounds per square foot) not over 0.06 per cent.

Phosphorus in material less than 0.04 inch thick (1.6 pounds per square foot) not over 0.10 per cent.

Sulphur, not over 0.06 per cent.

Copper (when so ordered), not under 0.20 per cent.

4. *Ladle analysis.*—An analysis shall be made by the manufacturer from a test ingot taken during the pouring of each melt to determine the percentage of carbon, manganese, phosphorus, and sulphur, also copper, when copper steel is ordered. Drillings for

analysis shall be taken not less than one-fourth inch beneath the surface of the test ingot. Upon request, a copy of this analysis shall be given to the purchaser or his representative for all lots ordered not less than 20,000 pounds of one gage and size. This analysis shall conform to the requirements specified in section 3.

5. *Check analysis.*—Check analysis may be made by the purchaser from the bend-test specimens. The chemical composition thus determined shall conform to the requirements specified in section 3.

III. PHYSICAL PROPERTIES AND TESTS

6. *Bend tests.*—The test specimen shall bend cold through 180° flat upon itself without cracking on the outside of the bent portion.

7. *Test specimens.*—(a) Bend-test specimens shall be taken from the finished product.

(b) Bend-test specimens shall be taken longitudinally as rolled and shall be cut from the edge of the sheet or plate midway between middle and end. They may be machined with both edges parallel.

8. *Number of tests.*—(a) One bend test shall be made from the thickest and thinnest material rolled from each melt, if sheets or plates are ordered in lots of not less than 20,000 pounds of one gage and size; otherwise, from each lot of 60,000 pounds, or fraction thereof, of each thickness (or weight per square foot).

(b) If the bend-test specimen shows defective machining or develops flaws, it may be discarded and another specimen substituted.

(c) If the bend-test specimen fails to meet the physical requirements of these specifications, two retests shall be taken from two other sheets or plates from the same lot, both of which shall meet all the bend-test requirements.

IV. PERMISSIBLE VARIATIONS IN WEIGHT, THICKNESS, AND SIZE

9. When ordered to weight per square foot, the weight of sheets and plates shall be determined from draft lots. The theoretical weight of sheets and plates ordered by gage number shall be based upon the weights of the United States standard gage table. The maximum allowable variation from the theoretical weight shall not exceed the amounts given in Table 1.

TABLE 1.—Permissible variation in weight of sheets and plates

Ordered weight (lbs. per sq. ft.)	Permissible variation over or under
	Per cent
2.45 and over.....	5.0
Under 2.45 to and including 1.22.....	3.5
Under 1.22.....	2.5

10. When ordered to thickness, the thickness of each sheet or plate shall not vary more than 0.01 inch under that ordered. The overweight of each lot in each shipment shall not exceed the amount given in Table 2. The term "lot" means all of the sheets or plates of each group width and each group thickness. One cubic inch of rolled steel is assumed to weigh 0.2833 pound.

TABLE 2

Ordered thickness	Permissible excess in average weights per square foot of sheets or plates for widths given, expressed in percentages of nominal weights			
	Under 48 inches	48 to 60 inches, exclusive	60 to 72 inches, exclusive	72 to 84 inches, exclusive
Under ¼ inch.....	9	10	12	14
¼ to ¾ inch, exclusive.....	8	9	10	12

11. *Size.*—(a) All sheets shall be sheared not less than the widths and lengths ordered.

(b) Sheets ordered 48 inches and less in width shall not exceed the ordered width by more than one-fourth inch, and for sheets ordered over 48 inches wide, the overwidth shall not exceed three-eighths inch.

(c) The length ordered for sheets 96 inches and less shall not be exceeded by more than three-fourths inch. For each 24 inches over 96 inches in length, an additional one-fourth inch shall be permitted to a maximum of 1½ inches.

(d) On full cold-rolled sheets, there shall be permitted excess length of not more than 2 inches.

(e) Sheets required of accurate size shall be ordered "resquared," and such sheets shall not be in excess of ordered width and length by more than one-sixteenth inch, if not more than 48 inches wide and 120 inches long, and one-eighth inch for wider or longer sheets.

(f) All plates shall be sheared not more than one-fourth inch less than the widths and lengths ordered.

12. *Flatness.*—(a) Sheets not ordered "patent leveled" and plates shall have the following tolerances for height of buckles:

Gage range		Width range		Maximum height of buckle ¹
Less than—	Not less than—	More than—	Not more than—	
Inch	Inch	Inches	Inches	Inches
	0.123 (5 pounds.)	48 60	48 60	5/8 3/4 1
	0.123 (5 pounds.)	48 60	48 60	3/4 1 1 1/4
	0.061 (2½ pounds.)	36 48	36 48	3/4 1 1 1/4

¹ Height of buckle refers to maximum rise from a flat surface on which sheet or plate lies.

(b) Sheets ordered "patent leveled" shall not have buckles exceeding one-fourth inch in height. Sheets shall not be ordered patent leveled when under 0.03 inch thick (1.22 pounds per square foot).

V. FINISH

13. *Finish.*—The finished material shall be free from injurious defects and shall have a workmanlike finish.

VI. MARKING

14. *Marking.*—(a) Sheets shall be properly marked for identification and in accordance with instructions on the purchaser's order.

(b) The name or brand of the manufacturer and the melt number shall be legibly marked on all finished plates.

(c) The melt number shall be legibly stamped on each test specimen that is taken from material that is identified according to melts.

VII. INSPECTION AND REJECTION

(Inspection and rejection conform to the requirements for galvanized sheets in A. R. A.-M (see 604.32, p. 243) except for the addition in this case of the following requirement:)

All tests (except check analyses) and inspection shall be made at the place of manufacture, prior to shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

604.29 IRON AND STEEL SHEETS FOR MISCELLANEOUS PURPOSES.

TIN-PLATE GAGE

(See 604.0, p. 224.)

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, ROOFING TERNES, SIMPLIFIED PRACTICE RECOMMENDATION R30-28, 1928

ROOFING TERNES

In accordance with the unanimous action of a general conference of representative manufacturers, distributors, and users of roofing ternes held on

October 15, 1924, and reviewed by the meeting of the standing committee on October 18, 1927, the industry has adopted, and approved for promulgation by the United States Department of Commerce, a simplified practice recommendation limiting the weights and thicknesses of roofing ternes to the following:

Weights.—8, 15, 20, 25, 30, 32, and 40 pounds.

No roofing ternes to be manufactured lighter than IC thickness for roofing.

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR TERNEPLATE (ROOFING TIN), QQ-T-201, NOVEMBER 11, 1930

TERNEPLATE

A. APPLICABLE FEDERAL SPECIFICATIONS

A-1. Federal specification No. 339a (QQ-M-151), general specifications for metals, in effect on date of invitation for bids, shall form a part of this specification, as far as applicable. (See 600.0, p. 3.)

B. TYPE AND GRADE

B-1. *Type.*—Terneplate shall be one type, commercially called roofing tin.

B-2. *Grade.*—Terneplate shall be furnished in prime sheets only.

C. MATERIAL AND WORKMANSHIP

C-1. Base metal shall be either Bessemer or open hearth steel of soft grade, or iron, as ordered.

C-2. Black sheets shall be free from blisters, slivers, scale, laminations, open seams, dirt and grease spots, roll and opening marks, ragged edges, holes, pickling patches, stains, burnt edges, bent corners, black or white edges, brittleness, and internal or surface defects impairing their use for the purpose intended.

C-3. Coated sheets shall be free from defects referred to above, and in addition shall be free from bare or imperfectly coated spots, deep scratches or heavy list edges.

D. GENERAL REQUIREMENTS

D-1. See section E.

E. DETAIL REQUIREMENTS

E-1. *Base metal.*—

E-1a. *Iron.*—The carbon, manganese, phosphorus, sulphur, and silicon shall not exceed 0.25 per cent, and if copper is specified the minimum copper content shall be not less than 0.20 per cent.

E-1b. *Steel.*—The sum of carbon, manganese, phosphorus, sulphur, and silicon not exceeding 0.70 per cent, and copper shall be not less than 0.20 per cent.

E-1c. Sheets shall be cold rolled, double annealed and double pickled. All sheets shall be as nearly uniform in thickness as is practicable and shall be commercially flat.

E-2. Coating shall consist of not less than 25 per cent of tin, and not more than 75 per cent of lead, both by weight. Tin plus lead shall equal not less than 99 per cent of the total coating exclusive of iron. The process of applying coating shall thoroughly amalgamate it with the base sheets, and they shall be as thoroughly and evenly coated on both sides as good mill practice will permit. All sheets shall be clean, and excess oil shall be removed.

E-3. *Resquaring*.—All sheets shall be resquared after cold rolling and before coating. They shall have straight edges and shall be rectangular.

E-4. *Tolerances*.—

E-4a. *Tolerances in dimensions*.—Sheets shall have no minus tolerance. A plus tolerance of one-sixteenth inch in width or length, or out of square will be allowed.

E-4b. *Tolerances in net weights of finished product* will be allowed as follows:

Unit:

All of one base weight and size in a shipment, or individual package 2.5 per cent plus or minus.
Single sheets in accordance with the minimums and maximums shown in Table 1.

E-4c. *Tolerances in coating*.—The average weight of coating shall not fall below that specified. No spot on the sheet shall have a coating less than 75 per cent of the weight specified.

E-5. *Bending quality*.—Sheets shall be capable of withstanding bending, without fracture on the outside of the bent portion, under the method covered by paragraph F-6.

E-6. *Seaming quality*.—Sheets shall be capable of withstanding double-seaming, without fracture. (See par. F-6.)

E-7. *Weights of sheets* shall conform to the limits shown in Table 1.

TABLE 1.—Weights

Trade symbol	Weight of black sheets after pickling		Weight of coating, in pounds per box												
			8	15	20	25	30	40							
			Weight of coating, in ounces per square foot of sheet

	{Nominal..	10.00	272	10.29	280	10.55	287	10.73	292	10.92	297	11.10	302	11.47	312
	{Maximum..	11.00	299	11.29	307	11.55	314	11.73	319	11.92	324	12.10	329	12.47	339

F. METHODS OF SAMPLING, INSPECTION, AND TESTS

F-1. *Inspection*.—The inspector shall take at random one package in each 10 packages or fraction included in the lot and shall weigh and make check measurements on each sheet therein. He shall also inspect each sheet for surface defects and poor coating. If any of these sheets fail to meet the specified requirements, he shall take two additional packages and proceed as before. If any of these sheets fail to meet the specified requirements the entire lot may be rejected.

F-2. *Chemical analysis*.—When required, chemical analyses shall be made by the manufacturer for each melt or blow, and duplicate copies of analyses shall be given to the Government inspector.

F-3. *Chemical analyses may be made by the Government*.—The inspector shall obtain drillings from each melt or blow, which may be taken as a composite sample of drillings from three coating test pieces, or pieces adjacent thereto.

F-4a. *Test specimens*.—Specimens for tests shall be taken by the Government inspector, and, as far as practicable, may be cut at contractor's option from rejected sheets which are imperfect outside of the zones from which the specimens are to be taken, as follows: One sheet shall be taken from each five boxes or fraction thereof, and from each there shall be cut three pieces each 2 inches square, one from the center and the others from diagonally opposite corners and 1 inch from the edges.

F-4b. *Retests*.—If any test specimen fails to meet the requirements of the specification, a retest may be allowed from the same lot, using specimens from two additional sheets for each original sheet. If

the test specimens from either of those sheets fail to meet the specified requirements the entire lot may be rejected.

F-5. *Weight of coating, determination of iron, determination of tin, determination of lead*.—(Methods for determination of weight of coating and of chemical analysis are the same as given in A. S. T. M. standard methods of determining weight of coating on tin, terne, and lead coated sheets, designation A91-24, with corrections in calculation factors due to difference in number of test specimens. See 600.3, p. 64.)

F-6. *Bending and seaming tests*.—Sheets shall withstand bending through an angle of 180°, and flattening down with a wooden mallet on a wooden block, without fracture on the outside of the bent portion. Sheets shall also stand double seaming without fracture. Both tests shall be made both with and across the direction of rolling.

G. PACKAGING, PACKING, AND MARKING

G-1. *Packaging*.—Commercial custom designates a standard package of roofing ternes as 112 sheets, unless the limiting weight would thereby be exceeded, in which cases fractional units of 56, 28, or 14 sheets are used as standard. Packages containing special sheetages may be ordered if desired. The weight of any single package shall not exceed 302 pounds (nominal net weight), except by specific permission first obtained from the purchaser.

G-2. *Packing*.—Sheets shall be packed in standard commercial containers so constructed as to insure acceptance by common or other carrier for safe transportation at the lowest rate to point of deliv-

ery. A sheet of heavy paper shall be placed between outside sheets and the container.

G-3. *Marking.*—Each sheet shall be stamped with the trade symbol (1C or 1X) and the weight of coating, together with identification of manufacturer by name, brand, or trade-mark. Containers shall have the following information clearly stenciled or lettered, making use of a durable marking medium—trade symbol, weight of coating, size of sheets, identification of manufacturer, and requisition, contract, or order numbers as may be directed.

I. NOTES

I-1. Box, wherever used in this specification, refers to the double-base box, consisting of 112 sheets 20 by 28 inches, equal to 62,720 square inches or 435.56 square feet of sheet, or equivalent.

I-2. Invitations for bids should specify the base, if desired (open-hearth or Bessemer steel, or iron, and if copper bearing), trade symbol, weight of coating, number of packages, sheets per package, and width and length of sheets, also whether inspection will be made at place of manufacture or after delivery.

I-3. *Samples.*—It is believed that this specification adequately describes the characteristics necessary to secure the desired material, and that normally no samples will be necessary prior to award to determine compliance with this specification. If, for any particular purpose, samples with bids are necessary, they should be specifically asked for in the invitation for bids, and the particular purpose to be served by the bid sample should be definitely stated, the specification to apply in all other respects.

I-5. This specification governs all United States Government purchases of this commodity.

shall be at least 75 per cent of the minimum weight of coating specified in Table 1.

(b) The weight of the zinc coating shall be determined by the basic lead acetate, hydrochloric acid-antimony chloride or sulphuric-permanganate method.

(c) The minimum weight of coating specified in Table 1 is the total coating on both sides of a sheet 1 foot square, the numerical value of which in ounces is the same as that determined in grams from a sample 2¼ inches square.

604.32 ZINC-COATED (GALVANIZED) STEEL SHEETS.

AMERICAN RAILWAY ASSOCIATION, MECHANICAL DIVISION, GALVANIZED SHEETS, RECOMMENDED PRACTICE, 1923

GALVANIZED SHEETS

1. *Scope.*—These specifications cover galvanized steel and iron sheets for all purposes.

I. CHEMICAL PROPERTIES AND TESTS

2. *Chemical composition.*—When copper bearing sheets are specified the base metal in the sheet shall conform to the following requirements as to chemical composition:

Copper..... Not less than 0.18 per cent.

3. *Ladle analysis.*—An analysis of each melt or lot of copper-bearing sheets shall be made by the manufacturer to determine the percentage of copper. The chemical composition thus determined shall be reported to the purchaser or his representative, and shall conform to the requirements specified in section 2.

4. *Check analysis.*—An analysis of copper-bearing sheets may be made by the purchaser from the test specimen specified in section 7. The copper content thus determined shall conform to the requirements specified in section 2.

5. *Zinc coating.*—(a) The weight of the zinc coating shall conform to the requirements specified in Table 1, the average being taken of the chemical determinations from three specimens 2¼ inches square cut from the ends and middle of the test specimen specified in section 7; provided, however, that the coating on any one of the three specimens

II. PHYSICAL PROPERTIES AND TESTS

6. *Bend tests.*—(a) *Base metal tests.*—Any portion of the test specimen specified in section 7, shall bend cold 180° flat on itself without fracture of the base metal. For steel, the bend may be made in any direction; for iron the line of the bend shall be transverse to the direction of the rolling of the sheet.

(b) *Coating test.*—Any portion of the test specimen specified in section 7, of sheets lighter than No. 16 gage, shall stand bending in any direction without flaking of the coating on either side when bent flat on itself over four thicknesses of the material, and for sheets ordered to gages 26 to 30 inclusive, when made in the form of a double-lock seam.

(c) A vise with smooth jaws and operated by hand shall be used for making the bend tests. A brake shall be used for making the double-lock seam test.

7. *Test specimens.*—A rectangular test specimen 2½ inches wide shall be cut diagonally across the sheet, the ends terminating within 2 inches of the sides and 4 inches of the ends of the sheet.

8. *Number of tests.*—(a) One each of the tests specified shall be made from one sheet in each lot of 1,000 sheets or fraction thereof of each gage on each order.

(b) If any test specimen fails to meet the requirements of this specification a retest will be allowed from two other sheets in the same lot, both of which shall meet the requirements.

III. PERMISSIBLE VARIATIONS

9. *Dimensions.*—The sheets shall conform to the dimensions specified with following permissible variations.

(a) The width shall be not less than that specified, but may be up to one-fourth inch greater for sheets

48 inches wide and under, and up to three-eighths inch greater for sheets over 48 inches wide.

(b) The length shall not be less than that specified, but for sheets 96 inches long and under may be up to three-fourths inch greater, to which latter figure add one-fourth inch for each 24 inches or fraction thereof above 96 inches length.

(c) Where sheets are required accurate to size, they shall be specified "to be resquared."

(d) The thickness may vary from the specified gage, the average being controlled by the minimum and maximum weights specified in Table 1.

10. *Weight*.—The average weight per square foot of the galvanized sheets as determined by the weighing of lots not exceeding 6,000 pounds, shall conform to the requirements specified in Table 1 which are based on a maximum variation from the nominal weight of 5 per cent for gages 8 to 16 inclusive, and 2½ per cent for gages lighter than 16.

IV. FINISH

11. *Finish*.—The finished sheets shall be of first-class commercial quality, free from flaws or mechanical defects such as pin holes, cracks, blisters, and blackened sal-ammoniac or acid spots.

V. MARKING

12. *Marking*.—The top sheet in each bundle, the top sheet in each lot, or a number of sheets when shipped loose shall legibly show the name and brand of manufacturer, point of shipment, amount and size of sheets, lot number, and purchaser's order number.

VI. INSPECTION AND REJECTION

13. *Inspection*.—(a) The inspector representing the purchaser shall have free entry, at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturer's works which concern the manufacture of the material ordered. The manufacturer shall afford the inspector, free of charge, all reasonable facilities to satisfy him that the material is being furnished in accordance with these specifications.

(b) The purchaser may make the tests and inspection to govern the acceptance or rejection of the material in his own laboratory or elsewhere. Such tests and inspection shall be made at the expense of the purchaser.

14. *Rejection*.—(a) Sheets represented by samples which fail to conform to the requirements of these specifications will be rejected.

(b) Sheets which, subsequent to tests and inspection at the mills or elsewhere and their acceptance, show blackened sal-ammoniac or acid spots, improper galvanizing, improper trimming or other defects for which the manufacturer is responsible, will be rejected and shall be replaced by the manufacturer.

15. *Rehearing*.—Samples tested in accordance with section 8 (a), which represent rejected material, shall be preserved for two weeks from the date of the test report.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR ZINC-COATED (GALVANIZED) SHEETS, DESIGNATION A93-27, 1927

[Approved as American Tentative Standard by the American Standards Association, 1931]

ZINC-COATED (GALVANIZED) SHEETS

SCOPE

1. These specifications cover sheets of Bessemer steel, open-hearth steel, and open-hearth iron, with

five classes of zinc coatings, applied by the hot-dip process, as follows:

Class A.—Extra heavily coated sheets that are not intended to be formed other than by corrugating.

Class B.—Heavily coated sheets that are not intended to be formed other than by corrugating and curving to large radii.

Class C.—Moderately heavily coated sheets for moderate bending.

Class D.—Ordinary coated sheets for general utility. These coatings approximate those of class C except in medium gages in which coatings of class D are appreciably lighter. Class D represents material generally available in warehouse stocks, which is not intended for use where relatively long life, represented by classes A, B, and C, or severe forming, represented by class E, is required.

Class E.—Sheets having lighter, more tightly adherent coatings to reduce liability of flaking in severe forming. The sheet maker should be made acquainted with the requirements of fabrication.

CHEMICAL PROPERTIES AND TESTS

2. No detailed requirements for the chemical composition of the base metal are specified, except when base metal containing copper is ordered, in which case it shall conform to the following requirements:

Copper, minimum:	Per cent
Ladle analysis.....	0.20
Check analysis.....	.18

3. An analysis of copper-bearing sheets may be made by the purchaser from the test specimens specified in section 6. The copper content thus determined shall conform to the requirements specified in section 2.

PHYSICAL PROPERTIES AND TESTS

4. (a) The weight of the zinc coating shall conform to the requirements specified in Tables 1 and 2. The weight of coating is the total coating, expressed in ounces, on both sides of a sheet 1 foot square.

TABLE 1.—Desired or ordered weight of coatings (in ounces per square foot)

Galvanized sheet gage No.	Class A	Class B	Class C	Class D	Class E
8	2.75	2.50	2.00	No specified coatings. (See sec. 1.)	
9	2.75	2.50	2.00		
10	2.75	2.50	2.00		
11	2.75	2.50	2.00		
12	2.75	2.50	2.00		
13	2.75	2.50	2.00		
14	2.75	2.50	2.00		
16	2.75	2.50	2.00		
18	2.75	2.50	1.75		
20	2.75	2.50	1.75		
22	2.75	2.50	1.75		
24	-----	2.50	1.50		
26	-----	2.25	1.25		
27	-----	2.00	1.25		
28	-----	1.75	1.25		
29	-----	1.50	1.25		
30	-----	1.25	1.25		

(b) The weight test is to be preferred and shall consist of a 10-sheet lot of a light gage or a 5-sheet lot of No. 16 gage or heavier. The test lots shall be weighed after pickling, washing, and drying, and again after coating, and the weight of coating calculated from the difference on the basis of the ordered

size. The scale used shall be sensitive to one-half pound. The average of weight tests shall be determined from not less than 10 successive weight tests that have met the requirements of the specification as provided in section 7 (a).

(c) The triple spot test shall consist of the average of determinations from the three specimens cut from the test sheet as provided in sections 6 and 7 (b). The average of triple spot tests shall be determined from not less than 10 successive triple spot tests and shall include all such tests made.

The minimum spot test shall be that one of the three specimens of the triple spot test bearing the lightest coating, or the purchaser may select a single specimen taken from any part of the sheet, at least 2 inches from the side and 4 inches from the end. The average of minimum spot tests shall be determined from not less than 10 successive minimum spot tests and shall include all such tests made.

(d) The weight of the zinc coating by triple and minimum spot tests shall be determined by the hydrochloric acid-antimony chloride, or sulphuric-permanganate method as described in A. S. T. M. A90 (see 600.3, p. 62). The weight of coating, in ounces per square foot, is numerically equal to that determined in grams from a sample 2 1/4 inches square.

TABLE 2.—Minimum weight-of-coating test limits (ounces per square foot)

Class according to desired or ordered coating	Rejection limits by different tests ¹					
	Average of weight tests	Any one weight test	Average of triple spot tests	Any one triple spot test	Average of minimum spot tests	Any one minimum spot test
2.75	2.60	2.45	2.40	2.30	2.20	2.00
2.50	2.30	2.20	2.15	2.00	1.95	1.80
2.25	2.10	2.00	1.95	1.80	1.75	1.60
2.00	1.90	1.80	1.75	1.60	1.55	1.40
1.75	1.65	1.55	1.50	1.35	1.30	1.20
1.50	1.40	1.30	1.25	1.15	1.10	1.00
1.25	1.15	1.10	1.05	0.95	0.90	0.85

¹ Different methods of sampling and testing give different results as indicated in the above table. The purchaser shall specify which method he will use.

5. (a) *Base metal tests.*—Any part of the test specimen specified in section 6 shall stand being bent cold through 180° flat on itself without fracture of the base metal. The bend may be made in any direction.

(b) *Coating tests.*—Sheets of class A of No. 18 gage and lighter shall stand corrugating without flaking of the coating. Sheets of class B of No. 12 gage and lighter shall stand corrugating and also subsequent longitudinal curving, as given below, without flaking of the coating. The corrugations for these tests shall not be less than 2 1/4 inches in width and not more than one-half inch in depth.

Galvanized sheet gage No.	Diameter of circle
12	Inches 36
14	24
16	18

In the case of sheets of class C, any part of the test specimen specified in section 6, of sheets lighter than No. 16 gage, shall stand being bent in any direction without flaking of the coating on either

side when bent through 180° over four thicknesses of the material. A vise with smooth jaws and operated by hand shall be used for making the bend tests.

6. For the triple and minimum spot tests, three specimens exactly 2 1/4 inches square shall be cut from each test sheet, one being cut from the center and the others from diagonally opposite corners, but at least 4 inches from the end and 2 inches from the side. The bend test specimens shall be cut from the test sheet at least 4 inches from the end and 2 inches from the side. These specimens, so far as practicable, shall be cut from sheets that are imperfect outside the zone from which the specimens are to be taken.

7. (a) Weight tests shall be made of not less than 1 per cent of the sheets of each gage and ordered coating, or at approximately hourly intervals. If an inspector representing the purchaser witnesses and accepts weight tests, the triple and minimum spot tests shall not be made. If certificate of weight tests be accepted, the triple and minimum spot tests shall not be made unless doubt arises regarding uniformity of the material.

(b) The bend and spot tests, if required, shall be made from one sheet in each lot of 1,000 sheets or fraction thereof, of each gage and ordered coating.

(c) If any sheet fails to meet the requirements of these specifications, a retest shall be made from two other sheets in the same lot, both of which shall meet the requirements.

PERMISSIBLE VARIATIONS

8. The sheets shall conform to the dimensions specified with the following permissible variations:

(a) The width shall be not less than that ordered, but may be one-fourth inch over for sheets 48 inches or less in width, and three-eighths inch over for sheets over 48 inches in width.

(b) The length shall be not less than that ordered, but for sheets 96 inches or less in length it may be three-fourths inch greater. For each 24 inches or fraction thereof above 96 inches the permissible variation may be increased one-fourth inch over three-fourths inch.

(c) When sheets are required accurate to size, they shall be ordered "resquared." Resquared sheets shall be not less than the ordered width and length and shall be in excess by not more than one-sixteenth inch unless wider than 48 inches or longer than 120 inches, in either of which case the excess tolerance shall be one-eighth inch. Should the sheets be resquared before galvanizing, double the foregoing tolerances are permissible.

9. The gage of galvanized sheets shall be determined by weight only. The weight per square foot of galvanized sheets shall conform to the tolerances given in Table 3:

TABLE 3

Gage range		Permissible tolerances in weights of sheets, plus or minus, in percentage of theoretical weight ¹			Gage range	
Weight of sheets (in ounces per square foot)		All of 1 gage and size in shipment ²	Single packages	Single sheets	Galvanized sheet gage number	
Less than	Not less than				Lighter than	Not lighter than
-----	42.5	5.0	7.0	10.0	-----	16
42.5	22.5	3.5	5.5	10.0	16	22
22.5	-----	2.5	4.0	10.0	22	-----

See footnotes at end of table.

TABLE 3—Continued

WEIGHT OF GALVANIZED SHEETS, ALL CLASSES

Galvanized sheet gage No.	Ounces per square foot	Pounds per square foot	Galvanized sheet gage No.	Ounces per square foot	Pounds per square foot
8	112.5	7.031	20	26.5	1.656
9	102.5	6.406	22	22.5	1.406
10	92.5	5.781	24	18.5	1.156
11	82.5	5.156	26	14.5	.906
12	72.5	4.531	27	13.5	.844
13	62.5	3.906	28	12.5	.781
14	52.5	3.281	29	11.5	.719
16	42.5	2.656	30	10.5	.656
18	34.5	2.156			

¹ References are to gross weights of bundled material and to net weights of crated and boxed material. If the minimum or maximum only be ordered double tolerance is to be taken on permissible side.

² All of one gage and size in shipment shall apply to lots of not less than 6,000 pounds.

FINISH

10. The finished sheets shall be of first-class commercial quality, free from injurious defects, such as blisters, flux, and uncoated spots.

MARKING

11. The top sheet of each bundle or the top sheet of a number of sheets when shipped loose, shall show legibly the name and brand of the manufacturer, class, gage, and size, unless otherwise ordered.

INSPECTION AND REJECTION

(Requirements covering inspection, rejection, and rehearing conform to those specified in A. S. T. M. standard specifications for steel. See 605.0, p. 247.)

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, STANDARD THICKNESSES, WEIGHTS, AND TOLERANCES OF SHEET METAL (CUSTOMARY PRACTICE), CIRCULAR NO. 391, MARCH 24, 1931

GALVANIZED SHEET GAGE

(See 604.0, p. 224.)

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, SIMPLIFIED PRACTICE RECOMMENDATION FOR IRON AND STEEL ROOFING, R78-28, JUNE 1, 1928

IRON AND STEEL ROOFING

(Simplified practice recommended and accepted by industry establishing a limited list of standard varieties and sizes.)

GALVANIZED OR PAINTED ROOFING

All styles and forms.—Corrugated, roll, V crimp, and pressed standing steam.

Widths.—Corrugated, 26 and 27½ inches; roll, 26½ inches; and all other, 24 inches.

Lengths.—5, 6, 7, 8, 9, 10, 11, and 12 feet; roll roofing shall be 50 linear feet.

Gages.—Corrugated, 28, 26, and 24; roll, 29, 28, and 26; and all other, 28 and 26.

Weights.—Standard weight subject to the usual mill tolerances of 2½ per cent plus or minus.

TABLE 1.—Gages

Galvanized sheet gage ¹		Painted sheets, United States standard gage		
Gage No.	Weight per square foot	Gage No.	Thickness	Weight per square foot
	<i>Ounces</i>		<i>Inch</i>	<i>Ounces</i>
29	11.5	29	0.014	9
28	12.5	28	.016	10
26	14.5	26	.019	12
24	18.5	24	.025	16

¹ Weights given are identical with requirements of American Society for Testing Materials specification A93-27, zinc-coated (galvanized) sheets. (See above.)

605. STRUCTURAL IRON AND STEEL.

605.0 GENERAL ITEMS.

AMERICAN INSTITUTE OF ARCHITECTS, A FILING SYSTEM FOR ARCHITECTS' OFFICES, 1927

STANDARD CONSTRUCTION CLASSIFICATION FOR FILING

(A standard classification for the materials, methods, and test data useful in the construction industry by which information reaching the architect may be filed where it is readily available. Advertising matter supplied by manufacturers may then be marked with the proper file number by the manufacturer and be ready for immediate filing on reaching the architect. The classification is principally a use classification with particular reference to use in the construction industry.)

AMERICAN INSTITUTE OF STEEL CONSTRUCTION, STEEL CONSTRUCTION HANDBOOK, APRIL, 1929

CODE OF STANDARD PRACTICE

(This code covers standard practice in steel construction which is not included in the A. I. S. C. specification on the design, fabrication, and erection of structural steel) (For the latter specification, see 605.12, p. 252.) This code includes a classification of all the iron and steel furnished on a building into structural iron and steel, ornamental iron and steel, steel floor joists, and miscellaneous iron and steel. Regulations are given on invoicing of materials by weight and on the type and number of drawings to be furnished by the buyer and seller. Regulations under workmanship include requirements on straightening, punching, reaming, assembling, and riveting. Other regulations cover inspection and delivery, erection, delays in prosecution of work, extra work, standard terms of payment, and standard form of proposal.)

AMERICAN SOCIETY OF MECHANICAL ENGINEERS, BIBLIOGRAPHY ON RIVETED JOINTS, MAY, 1924

BIBLIOGRAPHY ON RIVETED JOINTS

Riveted joints are used so universally in mechanical and structural engineering work that a study of their strength and other physical properties is of importance to nearly all designers of metal structures.

The art or practice of riveting has reached such a high state of development that such structures as built-up riveted columns may be greatly deformed before any rivet fails, the tying power of the rivets being sufficient to make the built-up specimen act as if it were one piece.

It is believed that the bibliography contains a list of most of the results of tests on riveted joints that have been published up to the present time. A list of textbooks which contain chapters on design has been included, and there are several articles of a miscellaneous nature that deal either with riveting in general or with some particular phase not important enough to be listed as a subject by itself.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR STEEL.

Structural steel for bridges, serial designation A7-29, 1929. (See also 605.11, p. 249.)

Structural steel for buildings, serial designation A9-29, 1929. (See also 605.12, p. 252.)

Structural steel for ships, serial designation A12-21, 1921. (See also 605.15, p. 269.)

Rivet steel for ships, serial designation A13-24, 1924. (See also 605.15, p. 269.)

Structural steel for locomotives and cars, serial designation A113-29, 1929. (See also 605.13, p. 266.)

(The following general requirements are in substantial agreement in, and form an integral part of, the specifications listed above, except that in part A of specification A13, paragraphs 3 (a) and 4 and Figures 1 and 2 do not apply, and in part B of specification A13, only paragraphs 7 and 8 (b) apply; also, paragraph 4 (a) does not apply to specification A113.)

1. *Check analyses.*—Analyses may be made by the purchaser from finished material representing each melt. The phosphorus and sulphur content thus determined shall not exceed that specified under

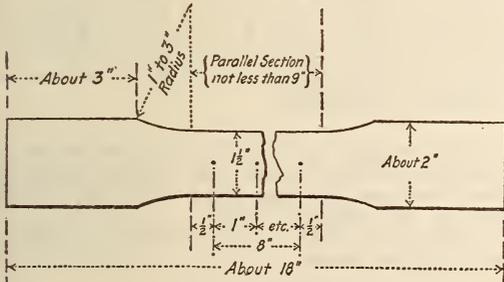

FIGURE 128.—Test specimen for plates, shapes, and flats

requirements as to chemical composition by more than 25 per cent.

2. *Yield point.*—The yield point shall be determined by the drop of the beam of the testing machine.

3. *Number of tests.*—(a) One tension and one bend test shall be made from each melt; except that if material from one melt differs three-eighths inch or more in thickness, one tension and one bend test shall be made from both the thickest and the thinnest material rolled.

(b) If any test specimen shows defective machining or develops flaws, it may be discarded and another specimen substituted.

(c) If the percentage of elongation of any tension test specimen is less than that specified in the table of tensile properties and any part of the fracture is more than three-fourths inch from the center of the gage length of a 2-inch specimen or is outside the middle third of the gage length of an 8-inch specimen, as indicated by scribe scratches marked on the specimen before testing, a retest shall be allowed.

4. *Permissible variations in weight and thickness of materials.*—(a) The cross section or weight of each piece of steel shall not vary more than 2.5 per cent from that specified; except in the case of sheared plates, which shall be covered by the permissible variations specified in paragraphs (b) and (c). (One

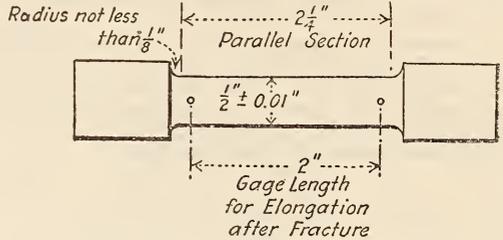

FIGURE 129.—Tension test specimen

NOTE.—As shown in the illustration, this tension test specimen has a diameter of one-half inch, with a tolerance of ± 0.01 inch. Tension test specimens specified by several other associations show a diameter of 0.505 inch, a difference of 0.005 inch. (See fig. 1, under 600.0, p. 5.) The diameter of 0.505 inch has been adopted for the purpose of permitting an exact expression for the cross-sectional area of the test specimen.

cubic inch of rolled steel is assumed to weigh 0.2833 pound.)

(b) *Sheared plates, when ordered to weight per square foot.*—The weight of each lot⁵⁴ in each shipment shall not vary from the weight ordered more than the amount given in Table 1. (See A. A. S. M. below.)

(c) *Sheared plates, when ordered to thickness.*—The thickness of each plate shall not vary more than 0.01 inch under that ordered.

The overweight of each lot in each shipment shall not exceed the amount given in Table 2. (See A. A. S. M. below.)

5. *Finish.*—The finished material shall be free from injurious defects and shall have a workmanlike finish.

6. *Marking.*—The name or brand of the manufacturer and the melt number shall be legibly stamped or rolled on all finished material, except that rivet and lattice bars and other small sections shall, when loaded for shipment, be properly separated and marked for identification. The identification marks shall be legibly stamped on the end of each pin and roller. The melt number shall be legibly marked, by stamping, if practicable, on each test specimen.

7. *Inspection.*—The inspector representing the purchaser shall have free entry, at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturer's works which concern the manufacture of the material ordered. The manufacturer shall afford the in-

⁵⁴ The term "lot" as applied to Table 1 means all of the plates of each group width and group weight; as applied to Table 2, it means all of the plates of each group width and group thickness. (For Tables 1 and 2, see A. A. S. M. below.)

spector, without charge, all reasonable facilities to satisfy him that the material is being furnished in accordance with these specifications. All tests (except check analyses) and inspection shall be made at the place of manufacture prior to shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

8. *Rejection.*—(a) Unless otherwise specified, any rejection based on tests made in accordance with paragraph 1 shall be reported within five working days from the receipt of samples.

(b) Material which shows injurious defects subsequent to its acceptance at the manufacturer's works will be rejected, and the manufacturer shall be notified.

9. *Rehearing.*—Samples tested in accordance with paragraph 1, which represent rejected material, shall be preserved for two weeks from the date of the test report. In case of dissatisfaction with the results of the tests, the manufacturer may make claim for a rehearing within that time.

ASSOCIATION OF AMERICAN STEEL MANUFACTURERS, STANDARD SPECIFICATIONS FOR STRUCTURAL AND BOILER STEEL, NOVEMBER 24, 1922

PERMISSIBLE VARIATIONS IN WEIGHT AND SIZE OF PLATES AND BARS

1. *When ordered to weight per square foot.*—Each lot in each shipment shall not vary from the weight ordered more than the amount given in the following table.

2. This table shall not be used when a minimum edge thickness is required. In such cases the table of permissible variations for plates ordered to thickness shall apply.

3. The weight per square foot of individual plates shall not vary from the ordered weight by more than one and one-third times the amount given in the table.

4. The term "lot" applied to these tables means all of the plates of each group width and each group thickness or weight.

TABLE 1.—Permissible variations of rectangular plates ordered to weight

Ordered weight (in pounds per square foot)	Permissible variations in average weights per square foot of plates for widths given, expressed in percentages of ordered weights

(See 605.22, p. 276.)

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, STANDARD THICKNESSES, WEIGHTS, AND TOLERANCES OF SHEET METAL (CUSTOMARY PRACTICE), CIRCULAR NO. 391, MARCH 24, 1931

IRON AND STEEL SHEET AND PLATE

(Standard gage for sheet and plate steel and iron. See above Bureau of Standards Circular 391 under 604.0, p. 224.)

(Permissible variations in weight and thickness of plates given in this circular are identical with those of the Association of American Steel Manufacturers. See 605.0, p. 248.)

605.1 STRUCTURAL SHAPES AND PLATES, NOT FABRICATED

605.11 STRUCTURAL STEEL FOR BRIDGES.

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR STEEL RAILWAY BRIDGES, 1924

(See also 611.11, p. 636; 611.41, p. 707; and 611.51, p. 753.)

STRUCTURAL AND RIVET STEEL

(This specification is nearly identical with specification A7 of the American Society for Testing Materials (see below) with the exceptions that all reference to copper steel is omitted, there is a slight difference in permissible variation of plate weights, and the following additional material is given:)

1. *Speed of testing machine.*—The crosshead speed of the testing machine shall be such that the beam of the machine can be kept balanced, but in no case shall the values given in the following table be exceeded:

Gage length of specimen	Maximum crosshead speed in determining—	
	Yield point	Tensile strength
Inches 2	Inches per minute 0.5	Inches per minute 2
8	2	6

2. The manufacturer shall furnish, without charge, the test specimens as specified herein, and the labor, testing machines, and tools necessary to make the specimen and full-size tests.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR STRUCTURAL STEEL FOR BRIDGES, SERIAL DESIGNATION A7-29, 1929

1. *Steel castings.*—The standard specifications for steel castings, A. S. T. M. A27-24 (see 611.41, p. 707), shall govern the purchase of steel castings for bridges. Unless otherwise specified, class B castings, medium grade, shall be used.

2. *Process.*—The steel shall be made by the open-hearth process.

3. *Chemical composition.*—The steel shall conform to the following requirements as to chemical composition:

	Structural steel	Rivet steel
Phosphorus:	Per cent	Per cent
Acid, not over.....	0.06	0.04
Basic, not over.....	.04	.04
Sulphur, not over.....	.05	.045
Copper, when copper steel is specified, not under.....	.20	.20

4. *Ladle analyses.*—An analysis of each melt of steel shall be made by the manufacturer to determine the percentages of carbon, manganese, phosphorus, and sulphur; also copper when copper steel is specified. This analysis shall be made from a test ingot taken during the pouring of the melt. The chemical composition thus determined shall be reported to the purchaser or his representative and the percentages of phosphorus and sulphur, and copper when copper steel is specified, shall conform to the requirements specified under chemical composition.

5. *Tension tests.*—(a) The material shall conform to the following requirements as to tensile properties:

Properties considered	Structural steel	Rivet steel
Tensile strength.....lbs./in. ²	^a 55,000-65,000	46,000-56,000
Yield point (minimum).....	0.5 tensile strength.	0.5 tensile strength.
But in no case less than.....	30,000	25,000
Elongation in 8 inches (minimum).....	^b 1,500,000	1,500,000
.....per cent.....	Tensile strength	Tensile strength
Elongation in 2 inches (minimum).....	22
.....per cent.....		

^a See par. (b).

^b See sec. 6.

(b) In order to meet the required minimum tensile strength of full-size annealed eye-bars, the purchaser may determine the tensile strength to be obtained in specimen tests; the range shall not exceed 14,000 lbs./in.², and the maximum shall not exceed 74,000 lbs./in.². The material shall conform to the requirements as to physical properties other than that of tensile strength.

6. *Modification in elongation.*—(a) For structural steel over three-fourths inch in thickness or diameter, a deduction from the percentage of elongation in 8 inches specified in table of tensile properties of 0.25 per cent shall be made for each increase of one-thirty-second inch of the specified thickness or diameter above three-fourths inch, to a minimum of 18 per cent.

(b) For structural steel under five-sixteenths inch in thickness or diameter, a deduction from the percentage of elongation in 8 inches specified in table of tensile properties of 1.25 per cent shall be made for each decrease of one-thirty-second inch in thickness or diameter below five-sixteenths inch.

7. *Bend tests.*—(a) Bend-test specimens, except as specified below, shall stand being bent cold through 180° without cracking on the outside of the bent portion, as follows: For material three-fourths inch or under in thickness, flat on itself; for material over three-fourths inch to and including 1¼ inches in thickness, around a pin the diameter of which is equal to the thickness of the specimen; and for material over 1¼ inches in thickness, around a pin the diameter of which is equal to twice the thickness of the specimen.

(b) Bend-test specimens for eye-bar flats shall stand being bent cold through 180° without cracking on the outside of the bent portion as follows: For material three-fourths inch or under in thickness, around a pin the diameter of which is equal to the thickness of the specimen; for material over three-fourths inch to and including 1¼ inches in thickness, around a pin, the diameter of which is equal to twice the thickness of the specimen; and for material over 1¼ inches in thickness, around a pin, the diameter of which is equal to three times the thickness of the specimen.

(c) Bend-test specimens for rivet steel shall stand being bent cold through 180° flat on themselves without cracking on the outside of the bent portion.

8. *Test specimens.*—(a) Test specimens shall be prepared for testing from the material in its rolled or forged condition, except as specified below.

(b) Test specimens for annealed material shall be prepared from the material as annealed for use, or from a short length of a full section similarly treated.

(c) Test specimens for rivet bars which have been cold-drawn shall be normalized before testing.

(d) Test specimens shall be taken longitudinally and, except as specified below, shall be of the full thickness or section of material as rolled.

(e) Test specimens for plates, shapes, and flats may be machined to the form and dimensions shown in Figure 128 standard specifications for metals (see 605.0, p. 247), or with both edges parallel. Bend-test specimens for eye-bar flats may have three rolled sides.

(f) Tension-test specimens for material over 1½ inches in thickness or diameter, except pins and rollers, may be machined to a thickness or diameter of at least three-fourths inch for a length of at least 9 inches, or they may conform to the dimensions shown in Figure 129 in A. S. T. M. standard specifications for metals (see 605.0, p. 247).

(g) Bend-test specimens for material over 1½ inches in thickness or diameter, except eye-bar flats, pins, and rollers, may be machined to a thickness or diameter of at least three-fourths inch or to 1 by ½ inch in section.

(h) Tension-test specimens for pins and rollers shall conform to the dimensions shown in Figure 129 and bend-test specimens shall be 1 by ½ inch in section.

(i) Test specimens for pins and rollers shall be taken so that the axis is 1 inch from the surface.

(j) The machined sides of rectangular bend-test specimens may have the corners rounded to a radius not over one-sixteenth inch.

9. (For tables of permissible variations of rectangular plates ordered to weight and permissible overweights of rectangular plates ordered to thickness, see A. A. S. M., Tables 1 and 2 (605.0, p. 248).)

10. (For general requirements relating to check analyses, yield point, number of tests, permissible variations in weight and thickness of plates, finish, marking, inspection, rejection, and reheating, also test specimen Figures 128 and 129, see A. S. T. M. specifications, 605.0, p. 247.)

ASSOCIATION OF AMERICAN STEEL MANUFACTURERS, STANDARD SPECIFICATIONS FOR STRUCTURAL AND BOILER STEEL, NOVEMBER 24, 1922

(See also 604.11, p. 223.)

STRUCTURAL STEEL

1. *Classes.*—These specifications cover three classes of structural steel, namely: Class A steel, to be used for railway bridges, ships, cars, and similar structures; class B steel, to be used for buildings, highway bridges, train sheds, and similar structures; and class C steel, to be used for structural rivets.

2. *Process.*—(a) Steel for classes A and C shall be made by the open-hearth process. Steel for class B may be made by either or by both the open-hearth or Bessemer processes, except as specified in (b).

(b) Steel for class B plates and angles over three-fourths inch in thickness which are to be punched, shall be made by the open-hearth process.

3. *Chemical composition.*—The steel shall conform to the following requirements as to chemical composition:

Elements considered	Class A steel	Class B steel	Class C steel
Phosphorus, maximum:	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>
Basic open-hearth.....	0.04	0.06	0.04
Acid open-hearth.....	.06	.08	.04
Bessemer.....11
Sulphur, maximum.....	.0605

4. *Ladle analysis.*—An analysis of each melt of steel shall be made by the manufacturer to determine the percentages of the elements specified in section 3. This analysis shall be made from a test ingot taken during the pouring of the melt. The chemical composition thus determined shall conform to the requirements specified in section 3, and shall be reported to the purchaser or his representative, if requested.

5. *Tension tests.*—The steel shall conform to the following requirements as to tensile properties:

Properties considered	Class A steel	Class B steel	Class C steel
Tensile strength.....	55,000-65,000	1 55,000-65,000	46,000-56,000
Yield point (minimum).....	0.5 tensile strength. 2 1,400,000	0.5 tensile strength. 2 1,400,000	0.5 tensile strength 1,400,000
Elongation in 8 inches (minimum).....	Tensile strength 22	Tensile strength 22	Tensile strength
Elongation in 2 inches (minimum).....

¹ See sec. 6.

² See sections on modifications in elongation.

6. *Modification in tensile strength.*—Class B steel may have tensile strength up to 70,000 pounds maximum, provided the elongation is not less than the percentage required for 65,000 pounds tensile strength.

7. *Bend tests.*—The 1 by ½ inch test specimen for pins, rollers, and other bars, shall bend cold through 180° around a pin 1 inch in diameter without cracking on the outside of the bent portion.

8. *Test specimens.*—(a) Tension-test specimens for plates and eyebar flats over 1½ inches in thickness, and bend-test specimens for plates over 1½ inches in thickness may be machined to a thickness or diameter of at least three-fourths inch for a length of at least 9 inches.

(b) Test specimens for bars over 1½ inches in thickness may be machined to a thickness or diameter of at least three-fourths inch for a length of at least 9 inches; or tension-test specimens may conform to the dimensions shown in Figure 129. Bend-test specimens may be 1 by ½ inch in section.

(c) The tension-test specimen shown in Figure 129 and the 1 by ½ inch bend-test specimen for pins and rollers shall be taken so that the axis is 1 inch from the surface; and for other bars over 1½ inches in thickness, midway between the center and surface.

9. *Number of tests.*—Plates three-sixteenths inch and under in thickness; shapes less than 1 square inch sectional area; rounds (except rivet rods) under one-half inch in diameter; and squares, hexagons, and flats less than one-half square inch sectional area, shall not be subject to tension tests.

10. *Permissible variations.*—(a) The sectional area or weight of each structural shape, and of each rolled edge plate up to and including 36 inches in width, shall not vary more than 2.5 per cent from the theoretical or specified amounts.

(b) The thickness or weight of sheared mill plates, and of universal mill plates over 36 inches in width, shall conform to the manufacturers' standard practice governing the permissible variations for sheared mill plates. (See A. A. S. M., 605.0, p. 248, Tables 1 and 2.)

(c) The weights of angles, tees, zees, and channels of bar sizes, and the dimensions of rounds, squares, hexagons, and flats, shall conform to the manufacturers' standard practice governing the allowable variations in size and weight of hot-rolled bars. (See A. A. S. M., 605.0, p. 248, Tables 3, 4, and 5.)

(For requirements relating to check analyses, yield point, modification in tensile strength, modifications in elongation, bend tests, test specimens, number of tests, finish, marking, inspection, rejection, and test specimen figures, see A. S. T. M. A7 (above), paragraphs 5 (b), 6, 7, and 8 (a), (b), (c),

(d), (e), (h), and (j), and A. S. T. M. specifications (605.0, p. 247,) paragraphs 1, 2, 3, 5, 6, 7, and 8, and Figures 128 and 129.)

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR STRUCTURAL STEEL FOR BRIDGES, NO. 351a, MARCH 25, 1929. (CURRENT DESIGNATION: QQ-S-711)

(This specification is, for certain requirements, substantially the same as specification A7 of the American Society for Testing Materials. For requirements relating to process, manufacturers' analyses, tension tests, modifications in elongation, bend tests, test specimens, and copper steel, see A. S. T. M. A7 (above), paragraphs 2, 4, 5, 6, 7, and 8 (a), (b), (c), (d), (e), (f), (g), (h), and (j), and that part of paragraph 3 which relates to copper steel. For requirements relating to yield point, permissible variations in sheared plates and structural shapes except of bar sizes, finish, and marking, see A. S. T. M. specifications (605.0, p. 247), paragraphs 2, 4, and 5, and the first two sentences in paragraph 6.)

(For tables of permissible variations in plates ordered to weight and thickness, and in angles, tees, zees, channels, rounds, squares, hexagons, and flats, see A. A. S. M. (605.0, p. 248), Tables 1, 2, 3, 4, and 5.)

(The following additional material is given:)

GENERAL SPECIFICATIONS

1. Federal specification No. 339a (QQ-M-151) for metals, in effect on date of invitation for bids, shall form part of this specification. (See 600.0, p. 3.)

CLASSES

2. Structural steel for bridges shall be of the following classes: (a) structural steel, noncopper; (b) structural steel, copper; (c) rivet steel, noncopper; and (d) rivet steel, copper.

GENERAL REQUIREMENTS

3. *Structural shapes of bar sizes.*—The weight of each piece shall not vary from the weight specified more than the amount given in Table 3.

4. *Rolled edge plates.*—Each plate up to and including 36 inches in width, shall not vary more than 2.5 per cent from the cross section (or sectional area) or weight specified; rolled edge plates more than 36 inches in width shall conform to limits specified for sheared plates.

5. *Rounds (including rivet bars), squares, and hexagons.*—No piece shall vary from the limits given in Table 4.

6. *Flats.*—No piece shall vary from the limits given in Table 5.

DETAIL REQUIREMENTS

7. *Chemical composition.*—The amounts of phosphorus and sulphur shall not exceed the following percentages:

	Structural steel, classes A and B	Rivet steel, classes C and D
Phosphorus:	<i>Per cent</i>	<i>Per cent</i>
Acid.....	0.070	0.050
Basic.....	.050	.050
Sulphur.....	.075	.070

METHODS OF TEST

8. *Number of tests.*—Two tension and two bend tests shall be made from each melt, unless the finished material from a melt is less than 26 short tons, when one tension and one bend shall be sufficient. If, however, material from one melt differs three-eighths inch or more in thickness, the thickest and thinnest material rolled shall each be represented by one tension and one bend test, regardless of the weight of the melt. Plates and flats three-sixteenths inch and less in thickness and shapes less than 1 square inch in section, shall not be subject to tension tests.

9. *Test specimens.*—For bars over 1½ inches in thickness or diameter, other than flats, when not tested in the full section as rolled, the tension test specimens shall be taken so that the axis shall be at a point one-half the distance between the center and the surface of the bar.

NOTES

10. Material covered by this specification is suitable for the following classes of work, among others: Reamed work, oil-tight and water-tight work, railroad and highway bridges, cranes of 40-ton capacity and over, radio towers 300 feet high or more, and any other structures in which there is a considerable and rapid variation of stress intensity.

11. When specifying materials in accordance with this specification, the class or classes (A, B, C, and D) should be stated definitely.

605.12 STRUCTURAL STEEL FOR BUILDINGS.

AMERICAN INSTITUTE OF STEEL CONSTRUCTION, STANDARD SPECIFICATION FOR STRUCTURAL STEEL FOR BUILDINGS, 1923

MATERIAL

(The institute indorses specification A9, of the American Society for Testing Materials, for structural steel for buildings. See below.)

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR BUILDINGS FOR RAILWAY PURPOSES, 1929

STRUCTURAL STEEL

(The association indorses American Society for Testing Materials specification A9, for structural

steel for buildings (below), with the following exceptions:)

1. Structural steel shall be made by the open-hearth process.

2. The reference to Bessemer steel in paragraph 2 of A. S. T. M. A9 shall be omitted.

CAST STEEL

(The association indorses American Society for Testing Materials specification A7, for structural steel for bridges. (See 605.11, p. 249.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR STRUCTURAL STEEL FOR BUILDINGS, DESIGNATION A9-29, 1929

1. *Process.*—(a) Structural steel, except as noted in paragraph (b), shall be made by either or both the following processes: Bessemer or open hearth.

(b) Rivet steel, and steel for plates or angles over three-fourths inch in thickness which are to be punched, shall be made by the open-hearth process.

2. *Chemical composition.*—The steel shall conform to the following requirements as to chemical composition:

	Structural steel	Rivet steel
Phosphorus, maximum:	<i>Per cent</i>	<i>Per cent</i>
Bessemer.....	0.10
Open hearth.....	.06	0.06
Sulphur, maximum.....045
Copper, when copper steel is specified, minimum.....	.20	.20

3. *Ladle analyses.*—(a) A carbon determination, and a copper determination when copper steel is specified, shall be made of each melt of Bessemer steel, and determinations for manganese, phosphorus, and sulphur representing the average of the melts applied for each 12-hour period.

(b) An analysis of each melt of open-hearth steel shall be made to determine carbon, manganese, phosphorus, and sulphur; also copper when copper steel is specified.

(c) These analyses shall be made by the manufacturer from test ingots taken during the pouring of each melt. The chemical composition thus determined shall be reported to the purchaser or his representative and the percentages of phosphorus and sulphur, and also copper when copper steel is specified, shall conform to the requirements specified in section 2.

4. *Tension tests.*—The material shall conform to the following requirements as to tensile properties:

Properties considered	Structural steel	Rivet steel
Tensile strength.....lbs./in. ²	55,000-65,000	46,000-56,000
Yield point, minimum.....do.....	0.5 tensile strength.	0.5 tensile strength.
but in no case less than.....	30,000	25,000
Elongation in 8 inches, minimum.....	1	1
.....per cent.....	1,400,000	1,400,000
.....Tensile strength.....	Tensile strength	Tensile strength
Elongation in 2 inches, minimum.....	22
.....per cent.....

¹ See section on modifications in elongation.

5. (For general requirements relating to check analyses, yield point, number of tests, permissible variations in weight and thickness of plates, finish, marking, inspection, rejection, and reheating, also test specimen Figures 128 and 129, see A. S. T. M. specifications (605.0, p. 247).)

6. (For requirements relating to modifications in elongation, bend tests, and test specimens. See A. S. T. M. A7 (605.11, p. 249), pars. 6, 7 (a) and (c), and 8.)

7. (For tables of permissible variations of rectangular plates ordered to weight and permissible overweights of rectangular plates ordered to thickness, see A. A. S. M., Tables 1 and 2 (605.0, p. 248).)

ASSOCIATION OF AMERICAN STEEL MANUFACTURERS, STANDARD SPECIFICATIONS FOR STRUCTURAL AND BOILER STEEL, NOVEMBER 24, 1922

STRUCTURAL STEEL

(See 605.11, p. 250.)

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, SIMPLIFIED PRACTICE RECOMMENDATION, OPEN-WEB STEEL JOISTS, R94-30, 1930

OPEN-WEB STEEL JOISTS

Prior to 1930 designers found it difficult to specify accurately when using steel joists in construction unless they designated the product of some particular producer. This condition resulted from the then existing variation in capacities of the joists produced by the different manufacturers.

In order to correct this condition and to make the use of steel joists as easy as possible, the manufacturers, through their association, the Steel Joist Institute, drafted a table of sizes and loads. They felt that its use by the architects and contractors throughout the country would do much to eliminate waste and make for more efficient designing of steel-joist construction. (The table thus prepared is given below.)

Open-web steel joists

Properties and allowable total loads (in pounds per linear foot); Steel Joist Institute designation															
	SJ81	SJ82	SJ102	SJ103	SJ104	SJ123	SJ124	SJ125	SJ126	SJ145	SJ146	SJ147	SJ166	SJ167

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR STRUCTURAL STEEL FOR BUILDINGS, NO. 352a, MARCH 15, 1929. (CURRENT DESIGNATION: QQ-S-721)

CHEMICAL COMPOSITION

1. The amount of phosphorus and sulphur shall not exceed the following percentages:

	Structural steel classes A and B	Rivet steel classes C and D
Phosphorus:	Per cent	Per cent
Bessemer.....	0.125
Open hearth.....	.07	0.07
Sulphur.....07

NOTES

2. Material covered by this specification is suitable for the following classes of work, among others: Building columns and girders, roof trusses, mill buildings, light structures, and all work of a similar character in which the live load is largely static or the construction is light or of a commercial character.

3. (For requirements relating to modification in elongation, bend tests, test specimens, and copper, see A. S. T. M. A7 (605.11, p. 249), paragraphs 6, 7 (a) and (c), 8 (a), (b), (c), (d), (e), (f), (g), (h), and (j), and that part of paragraph 3 dealing with copper.)

4. (For requirements relating to yield point, permissible variations in sheared plates and structural shapes except of bar sizes, finish, and marking, see A. S. T. M. specifications (605.0, p. 247), paragraphs 2, 4, 5, and 6.)

5. (For requirements relating to process, manufacturers' analyses, and table of tensile properties, see A. S. T. M. A9 (above), paragraphs 1, 3, and 4.)

6. (For general specifications, classes, permissible variations in structural shapes of bar sizes, rolled-edge plates, rounds, and flats, number of tests, test specimens, and notes, see F. S. B. 351a (QQ-S-711) (605.11, p. 251), paragraphs 1, 2, 3, 4, 5, 6, 8, 9, and 11. In paragraph 8, number of tests, change "26 short tons" to "25 short tons.")

7. (For tables of permissible variations in plates ordered to weight and thickness, and in angles, tees, zebs, channels, rounds, squares, hexagons, and flats, see A. A. S. M. (605.0, p. 248), Tables 1, 2, 3, 4, and 5.)

(For requirements relating to process, ladle analysis, modification in elongation, bend tests for structural steel and plates for cold pressing, and test specimens: See A. S. T. M. A7 (605.11, p. 249), paragraphs 2, 4, 6, 7 (a) and (c), and 8 (d), (e), (f), (g), and (j). Add to (4): Drillings for analysis shall be taken not less than one-fourth inch below surface of test ingot.)

(For tables of permissible variations of rectangular plates ordered to weight; permissible overweights of rectangular plates ordered to thickness; permissible variations in weight of bar sizes of angles, tees, zebs, and channels; and permissible variations in cross-sectional dimensions of rounds, squares, hexagons, and flats, see A. A. S. M., Tables 1, 2, 3, 4, and 5 (605.0, p. 248).)

(The following additional material is given:)

1. *Scope.*—(a) These specifications apply to all structural and bar size shapes and structural plates and bars for locomotives, freight and passenger equipment cars. Plates will be classed as structural plates when three-sixteenths inch or greater in thickness.

(b) A channel will be considered as in a "bar" size when its greatest dimension is less than 3 inches, and the angle, T or Z as in a "bar" size when its greatest dimension is less than 3 inches, or when it is 3 inches or more and at the same time the thickness is less than one-fourth inch. Shapes not falling within the above limits will be classed as "structural."

2. *Chemical composition.*—The steel shall conform to the following requirements as to chemical composition:

Phosphorus, maximum:	Per cent
Acid.....	0.06
Basic.....	.05
Sulphur, maximum.....	.06
Copper, when copper-bearing steel is specified, minimum.....	.20

3. *Check analysis.*—Check analysis may be made by the purchaser from the finished material representing each melt. Such analysis shall meet the requirements specified under chemical composition.

4. *Tension tests.*—The material shall conform to the following requirements as to tensile properties:

	Structural	Plates for cold flanging
Tensile strength...lbs./in. ² ..	50,000-65,000	48,000-58,000
Yield point, minimum.....
.....lbs./in. ² ..	0.5 tensile strength	0.5 tensile strength
Elongation in 8 inches, minimum.....per cent..	1,500,000	1,500,000
.....	Tensile strength	Tensile strength
Elongation in 2 inches, minimum.....per cent..	25	25

5. *Test specimens.*—(a) Tension and bend test specimens shall be taken from the finished rolled product.

(b) The tension test specimen conforms to that shown (fig. 129) in A. S. T. M. standard specifications for steel (see 605.0 p. 247), except as stated above that the diameter is 0.505 inch, and the 1 by 1/2 inch bend test specimen for sections over 1 1/2 inches in thickness or diameter shall be taken so that the axis is midway between the center and surface of the material as rolled.

6. *Number of tests.*—Tension tests will not be required for shapes less than 1 square inch in cross section or for sheets three-sixteenths inch or under in thickness.

7. *Permissible variations in weight and gage.*—(a) The cross-sectional area, or weight, of each structural

605.13 STRUCTURAL STEEL FOR CARS AND LOCOMOTIVES.

AMERICAN RAILWAY ASSOCIATION, MECHANICAL DIVISION, SPECIFICATIONS FOR STRUCTURAL STEEL SHAPES, PLATES AND BARS, 1923

(For general requirements relating to yield point, number of tests, finish, marking, inspection, rejection, and reheating, also test specimen figures: See A. S. T. M. specifications (605.0, p. 247), paragraphs 2, 3 (a) and (c), 5, 6, 7, 8 (b), and 9, and Figures 128 and 129. Omit last sentence in (9). The tension test specimen specified by the A. R. A. carries a diameter of 0.505 inch in order to aid in the computation of the cross-sectional area.)

shape and of each rolled-edge plate, up to and including 36 inches in width, shall not vary more than 2.5 per cent from that specified. One cubic inch of steel is assumed to weigh 0.2833 pound.

(b) The variations in weight of bar sizes of angles, tees, zees, and channels shall conform to Table 3.

(c) *When ordered to weight per square foot.*—The weight of each lot of universal plates over 36 inches in width, and of each lot of sheared plates, shall not vary from the weight ordered more than the amount shown in Table 1.

(d) *When ordered to thickness.*—The thickness of each universal plate over 36 inches in width and of each sheared plate shall not vary more than 0.01 inch under that specified. The overweight of each lot of plates in each shipment shall not exceed the amount given in Table 2.

(e) Unless covered by special agreement between the purchaser and the manufacturer that the material shall be furnished recut to exact dimensions ordered, the permissible variations under the dimensions ordered shall not be more than one-fourth inch under in length and width, in case of sheared mill plate, and in the case of universal mill plate, the length shall not be more than one-fourth inch under and the width more than one-eighth inch under. The variations over the dimensions ordered shall be the minimum obtainable under the mill conditions and consistent with the thickness and linear dimensions of the material. The same shall apply to structural and bar size shapes.

(f) All bars shall conform to the limits given in Tables 4 and 5.

8. *Inspection.*—The purchaser may make the tests and inspection to govern the acceptance or rejection of the material in his own laboratory or elsewhere. Such tests and inspection shall be made at the expense of the purchaser.

AMERICAN RAILWAY ASSOCIATION, MECHANICAL DIVISION, ARCH BARS, COLUMN AND JOURNAL-BOX BOLTS AND COLUMN CASTINGS TO BE USED FOR MAINTENANCE OF EXISTING ARCH-BAR TRUCKS OF 40 AND 50 TON CAPACITY, STANDARD, 1929

ARCH BARS

1. The dimensions of arch and tie bars to be used for maintenance of existing trucks shall be:

Arch bars.—Either 1¼ by 4½ inches or 1½ by 5 inches for 40-ton trucks; 1¼ by 5 inches or 1½ by 6 inches for 50-ton trucks.

Tie bars.—¾ by 4½ inches or ¾ by 5 inches for 40-ton trucks and ¾ by 5 inches or ¾ by 6 inches for 50-ton trucks.

2. When, for any cause, it is necessary to renew an arch bar or a tie bar, and the construction of truck and car body will permit, it shall conform to these requirements, the renewal to be confined to the defective bar or bars.

3. Column castings should be of malleable iron or cast steel and conform to the general design and dimensions as covered by Figure 134.

4. The shear value of arch-bar connections above the journal box should be increased by one of the optional methods shown in Figures 130, 131, 132, and 133.

5. The shear value of journal-box and tie-bar connections should be increased by turning up the end of the tie bars, as shown on Figures 130, 131, 132, and 133.

6. Arch bars and column and journal-box bolts should be manufactured of refined wrought iron or mild steel bars.

7. The use of the oxy-acetylene torch for burning out holes in old or new arch bars is prohibited.

8. Improperly matched bolt holes should be avoided. To assist in proper matching of bolt holes and to obtain the proper fit of arch bars against each other, it is recommended, when only one arch bar is being renewed, that the new bar be fitted to the bar that is retained and the old bar used as a template for drilling holes.

9. No bolts that have been welded should be used in conjunction with arch-bar trucks. Clean-cut full-size threads should be insisted upon in order to obtain proper holding power between the holding nut and the bolt and assurance that locking nuts will function properly when used.

AMERICAN RAILWAY ASSOCIATION, MECHANICAL DIVISION, TRUCK BOLSTERS, RECOMMENDED PRACTICE, 1929

TRUCK BOLSTERS

1. *Scope.*—These specifications cover truck bolsters for freight equipment with either integral or separable center plate.

2. *Material.*—May be of cast steel, structural steel, or forged iron or steel, in accordance with A. R. A. specifications.

3. *Design.*—All standard fundamental A. R. A. requirements, not specifically mentioned herein, shall also govern.

The basis for the calculation of maximum combined unit stress shall be the vertical load equal to "P" as given in Table 1, and the transverse load equal to 0.25 P.

TABLE 1

Size of journal	Type of truck	Vertical load = P
<i>Inches</i>		<i>Pounds</i>
5 by 9	2C	62,000
5½ by 10	2D	77,000
6 by 11	2E	96,000
6½ by 12	2F	115,000

The vertical load shall be taken as acting on the center line of the bolster anywhere within 8 inches each side of the center of the bolster; also anywhere from the center of spring support to a point 23 inches from the center of the bolster. The section moduli shall decrease uniformly from the section 8 inches from the center to the section 23 inches from the center of the bolster. The transverse load shall be taken as acting on the neutral axis (or, for test, on a line 5 inches below the center plate bearing face), and shall be applied only at the center of the bolster. On this basis of calculation for checking relative designs, the maximum combined unit stress in the design shall not exceed 16,000 pounds per square inch and the maximum unit stress for vertical or transverse loads considered separately shall not exceed 12,500 pounds per square inch for vertical load equal to "P" or horizontal load equal to 0.8 P.

4. *Test load requirements.*—(a) At least two specimens of each new design shall be tested on a suitable static-testing machine. The two specimens selected shall be good average product.

(b) Bolsters shall comply with the requirements in Table 2, the vertical and transverse tests to be made separately. The vertical loads shall be applied separately at center plate, and at one side bearing.

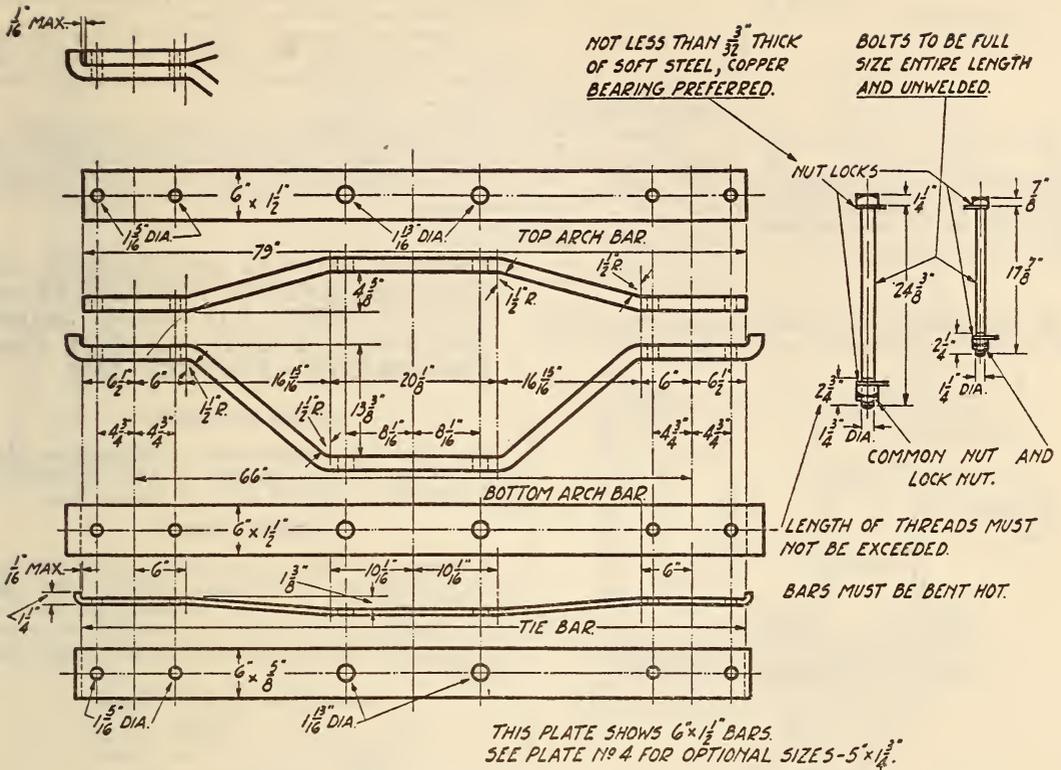

FIGURE 132

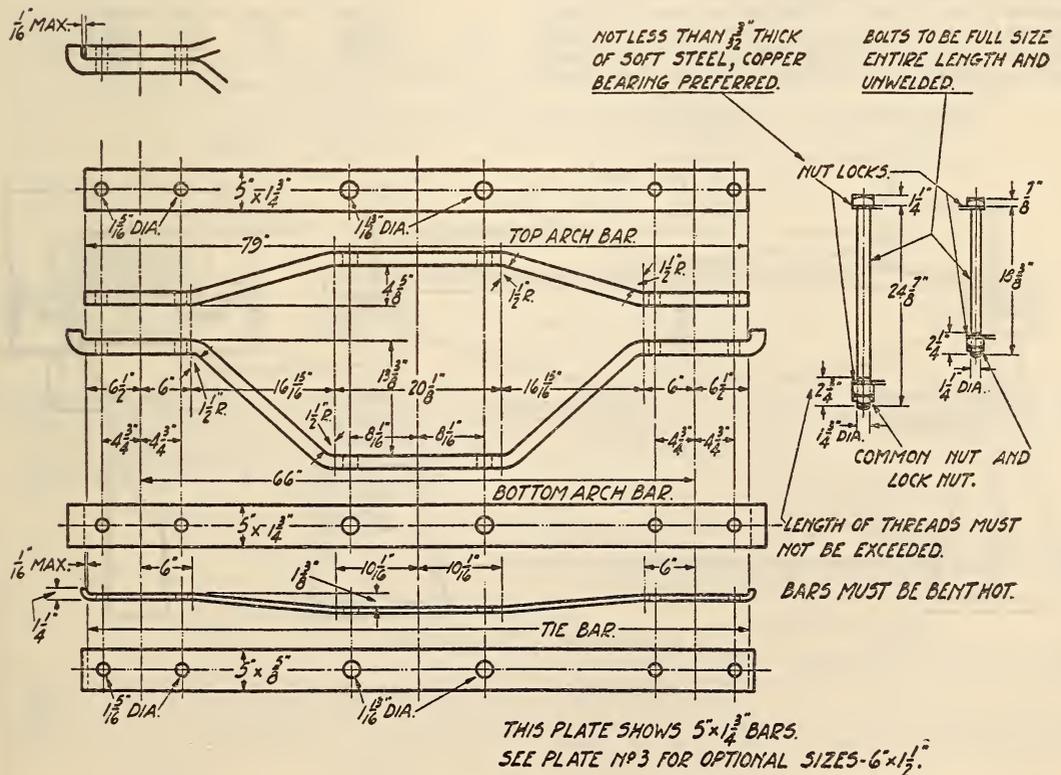

FIGURE 133

TABLE 2

	Vertical		
	Center plate	Side bearing	Transverse
Load for zero setting of instrument.....	Pounds 5,000	Pounds 5,000	Pounds 5,000
Load at 0.065 inch, maximum deflection.....	1.5P	1.5P	1.0P
Load at 0.075 inch maximum permanent set.....	3.0P	2.5P	2.0P
Maximum load not less than.....	5.5P		

(c) The deflection measuring instruments shall be located midway between supports of specimen, and

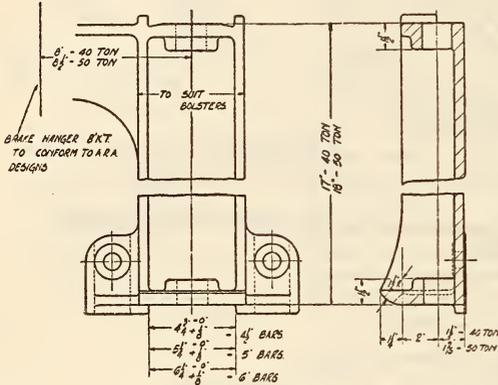

FIGURE 134

shall be set at zero under an initial load of 5,000 pounds after a load of 20,000 pounds has been applied for five minutes and then released to 5,000 pounds. The load for the deflection measurement shall be 5,000 pounds additional to the load shown

in Table 2, but the load for the permanent set and maximum load shall be as given in Table 2.

5. *Loading diagrams.*—Figure 135 shows the recommended method for vertical test loading and Figure 136 for transverse test loading of truck bolsters.

NOTE.—This specification covers all bolsters, except vertical truss bolster composed of a tension member, a compression member and a counterpost between; for such bolsters the specifications do not apply, until construction of such bolsters can be further investigated, to determine whether or not they should also comply with the same specifications.

AMERICAN RAILWAY ASSOCIATION, MECHANICAL DIVISION, BOLSTERS, TRUCK, PRESSED STEEL, FOR 80,000, 100,000, AND 140,000 POUND CAPACITY CARS, RECOMMENDED PRACTICE, 1915

TRUCK BOLSTERS

The steel for pressed-steel truck bolsters shall conform to the requirements of the specifications and tests for structural steel for freight cars.

LIMITING WEIGHTS

Bolsters, including center plate and side bearings, shall conform to the weights given in the table shown below. In case the bolsters have met all requirements except that of overweight, they may be accepted at the maximum allowable weight here specified.

Car capacity	Weight		
	Minimum	Normal	Maximum
Pounds 80,000	Pounds 775	Pounds 795	Pounds 815
Pounds 100,000	Pounds 840	Pounds 865	Pounds 890
Pounds 140,000	Pounds 1,110	Pounds 1,140	Pounds 1,170

CENTER PLATES

(See fig. 140, p. 261.)

AMERICAN RAILWAY ASSOCIATION, MECHANICAL DIVISION, COUPLER YOKES, RECOMMENDED PRACTICE, 1929

COUPLER YOKES

1. *Scope.*—These specifications cover coupler yokes of either horizontal or vertical plane types for freight equipment.

2. *Material.*—May be of cast steel, structural steel, or forged iron or steel, in accordance with A. R. A. specifications.

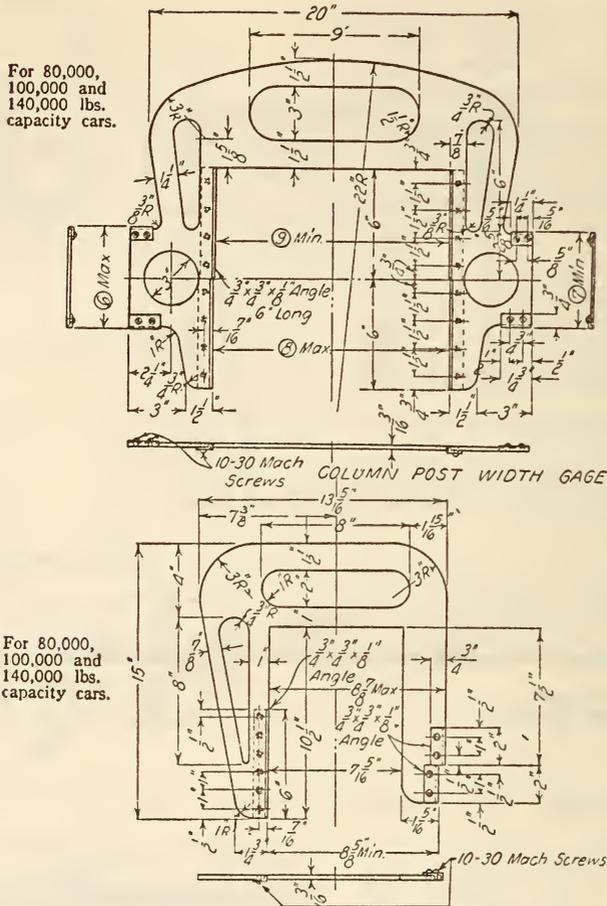

FIGURE 138.—Spring seat to side bearing gage
Dimensions as in Table 1, p. 259.

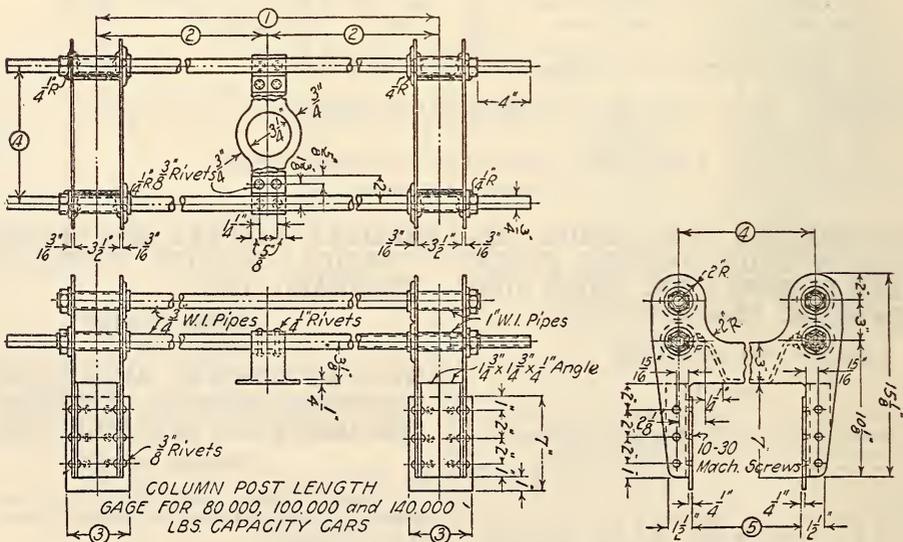

FIGURE 139.—Gages for truck bolsters
Dimensions as in Table 1, p. 259.

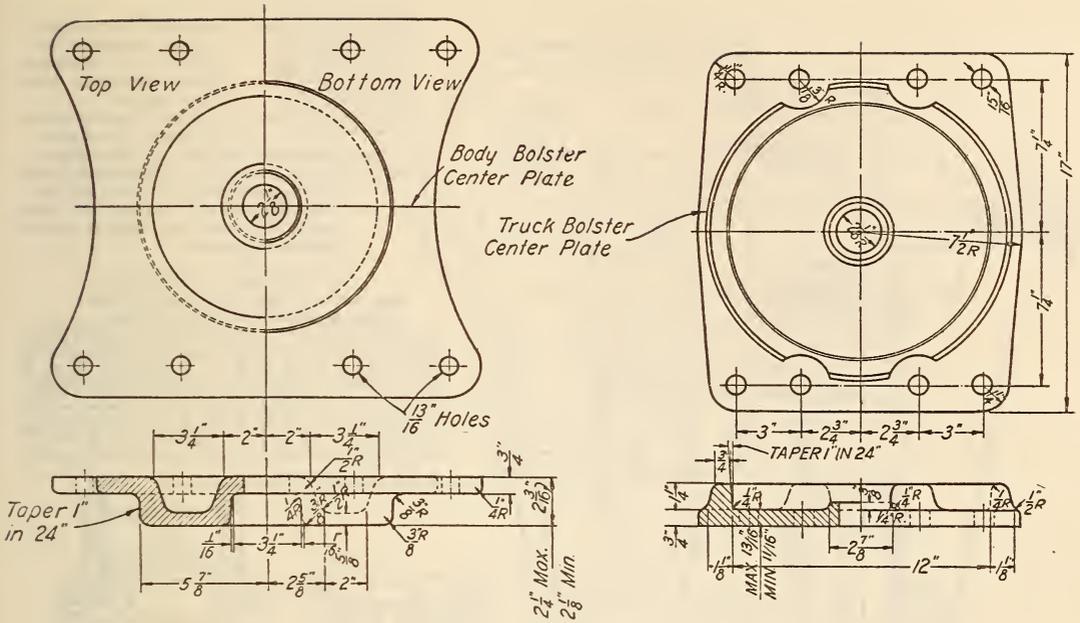

FIGURE 140.—Center plates

3. Design.—Each coupler yoke design intended for use with type “D” coupler and 6 by 1½ inch key, shall meet the following design requirements: If made from grade “A” cast steel, or its equivalent, the tension area shall not be less than 12 square

4. Test requirements.—(a) At least two specimens of each new design shall be tested on a suitable static testing machine.

(b) The method of support and loading shall be equivalent to service conditions on tangent track. The maximum set shall not exceed 0.031 inch under a load of 325,000 pounds. The breaking load shall not be less than 550,000 pounds. The set shall be taken in the length from the rear follower bearing face on the yoke to the front coupler-key bearing face.

(c) The deflection measuring instruments shall be set at zero under an initial load of 5,000 pounds after a load of 20,000 pounds has been applied for five minutes and then released to 5,000 pounds.

5. Loading diagrams.—Figure 141 indicates the recommended method for testing of yokes and taking the measurement determining the maximum set.

H	8	8½	9	+1/8 -1/8
J	10½	10½	11½	+1/4 -1/8
K	¾	¾	7/16	

NOTE 1.—Inside dimensions of journal box and contained parts must conform to A. R. A. standards.

NOTE 2.—The side frame must conform to the A. R. A. Specifications for strength.

NOTE 3.—Alternate designs involving nonstandard bolster, spring plank, or spring arrangement will be permissible, providing that they conform to A. R. A. specifications for strength, and the truck, as a whole, meets the A. R. A. requirements for interchangeability.

NOTE 4.—The distance from bottom of frame to top of rail should be 5 inches minimum when all parts are new for side frames intended to be used with multiple-wear wheels, and 3¾ inches minimum when all parts are new for side frames intended to be used with 1-wear wheels.

3. Tension tests.—(a) The material, except as specified in paragraph (b), shall conform to the following requirements as to tensile properties:

Properties considered	Structural steel for cars	Structural steel for locomotives	Plates for cold pressing	Rivet steel
Tensile strength.....lbs./in. ²	50,000-65,000	55,000-65,000	48,000-58,000	45,000-60,000
Yield point, minimum.....do.	0.5 tensile strength	0.5 tensile strength	0.5 tensile strength	0.5 tensile strength.
Elongation in 8-inch, ^a minimum.....per cent.	1,500,600	1,500,000	1,500,000	1,500,000
Elongation in 2-inch, minimum.....do.	Tensile strength 22	Tensile strength 22	Tensile strength	Tensile strength

^a See section on modifications in elongation.

(b) Plates three-sixteenths inch and under in thickness, shapes less than 1 square inch in cross section, flats three-sixteenths inch and under in thickness, and other bars, except rivet rods, less than one-half inch in thickness or diameter, need not be subjected to tension tests.

4. Permissible variations.—(a) One cubic inch of rolled steel is assumed to weigh 0.2833 pound. The cross-sectional area or weight of each structural-size shape shall not vary more than 2.5 per cent from the theoretical or specified amounts. The thickness or weight of rectangular sheared mill plates and of rectangular universal mill plates over 36 inches in width shall conform to the requirements of paragraphs 4 (b) and (c) of A. S. T. M. (605.0,

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR STRUCTURAL STEEL FOR LOCOMOTIVES AND CARS, SERIAL DESIGNATION A113-29, 1929

(For general requirements relating to check analyses, yield point, number of tests, variations in weight and thickness of sheared and universal mill plates, finish, marking, inspection, rejection, and re-heating, also test specimen Figures 128 and 129, see A. S. T. M. specifications (605.0, p. 247), omitting paragraph 4 (a).)

(For tables of permissible variations of rectangular plates ordered to weight; permissible overweights of rectangular plates ordered to thickness; permissible variations in weight of bar sizes of angles, tees, zeos, and channels; and permissible variations in cross-sectional dimensions of rounds, squares, hexagons, and flats, see A. A. S. M., Tables 1, 2, 3, 4, and 5 (605.0, p. 248).)

(For requirements relating to process, ladle analyses, modifications in elongation, bend tests, and test specimens, see A. S. T. M., A7 (605.11, p. 249), paragraphs 2, 4, 6, 7 (a) and (c), and 8 (a), (c), (d), (e), (f), (g), and (j). In paragraph 7 (c), after "rivet steel," insert: "and plates for cold pressing.")

(The following additional requirements are given:)

1. Scope.—These specifications apply to shapes, plates (except boiler and fire-box plates), rivet steel, and bars.

2. Chemical composition.—The steel shall conform to the following requirements as to chemical composition:

	Structural steel for cars	Structural steel for locomotives	Plates for cold pressing	Rivet steel
Phosphorus:	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>
Acid (maximum).....	0.06	0.06	0.06	0.04
Basic (maximum).....	.04	.04	.04	.04
Sulphur (maximum).....	.06	.05	.06	.045
Copper, when copper steel is specified (minimum).....	.20	.20	.20	.20

p. 247): the cross-sectional area or weight of bar size⁵⁵ angles, tees, zeos, and channels shall conform to the requirements of paragraph (b); and the cross-sectional dimensions of bars shall conform to the requirements of paragraph (c).

(b) The weight of each lot⁵⁶ of bar sizes of angles, tees, zeos, and channels in each shipment shall not vary from the weight ordered more than the amounts given in Table 3 under A. A. S. M. 605.0, p. 248.

⁵⁵ A channel is in "bar" size when its greatest dimension is less than 3 inches. An angle, T, or Z is in "bar" size when its greatest dimension is less than 3 inches, or when it is 3 inches or more and at the same time the thickness is less than one-fourth inch.

⁵⁶ The term "lot" here means all of the bars of each group dimension and group thickness shown in Table 3. (See A. A. S. M., 605.0, p. 248.)

(c) The cross-sectional dimension of bars shall not vary from the size ordered more than the amounts given in Tables 4 and 5 under A. A. S. M. 605.0. p. 248.

5. Except in cases of special agreement between the purchaser and manufacturer that the material shall be furnished recut to exact ordered dimensions, the length of all shapes, plates, and bars shall not vary under the dimensions ordered more than one-fourth inch. The width of plates shall not vary under the dimensions ordered more than one-fourth inch. The variation over the dimension ordered shall not be more than is consistent with thickness, length, and good mill practice.

ASSOCIATION OF AMERICAN STEEL MANUFACTURERS, STANDARD SPECIFICATIONS FOR STRUCTURAL AND BOILER STEEL, NOVEMBER 24, 1922

STRUCTURAL STEEL

(See 605.11, p. 250.)

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR STRUCTURAL STEEL FOR CARS, NO. 373a, MARCH 25, 1929. (CURRENT DESIGNATION: QQ-S-731)

(This specification is in some respects substantially the same as F. S. B. 351a (QQ-S-711) (605.11, p. 251). For general specifications, permissible variations in structural shapes of bar sizes, rolled-edge plates, rounds (including rivet bars), squares, hexagons, and flats, and number of tests, see F. S. B. 351a (QQ-S-711), paragraphs 1, 3, 4, 5, 6, and 8. Substitute in paragraph 8, "25 short tons" for "26 short tons," and add: "Bars, except rivet rods, less than one-half inch in section shall not be subjected to tension tests.")

(For requirements relating to process, manufacturers' analyses, modifications in elongation, bend tests, test specimens, and copper steel, see A. S. T. M., A7 (605.11, p. 249), paragraphs 2, 4, 6, 7 (a) and (c), 8 (a), (b), (c), (d), (e), (f), (g), and (j), and that part of paragraph 3 relating to copper steel. In paragraph 7 (c), after "rivet steel," insert: "and plates for cold pressing.")

(For requirements relating to yield point, permissible variations in sheared plates and structural shapes except of bar sizes, finish, and marking, see A. S. T. M. specifications (605.0, p. 247), paragraphs 2, 4, and 5, and the first sentence of paragraph 6.)

(For tables of permissible variations in plates ordered to weight and thickness, and in angles, tees, zees, channels, rounds, squares, hexagons, and flats, see A. A. S. M. (605.0, p. 248), Tables 1, 2, 3, 4, and 5.)

(The following additional material is given):
 1. *Classes.*—Structural steel for cars shall be of the following classes: A, structural steel, noncopper; B, structural steel, copper; C, steel for cold pressing, noncopper; D, steel for cold pressing, copper; E, rivet steel, noncopper; and F, rivet steel, copper.

2. *Chemical composition.*—The amounts of phosphorus and sulphur shall not exceed the following percentages:

	Classes A and B structural steel, classes C and D plates for cold pressing	Classes E and F rivet steel
Phosphorus:	<i>Per cent</i>	<i>Per cent</i>
Acid.....	0.070	0.050
Basic.....	.050	.050
Sulphur.....	.075	.070

3. *Tension tests.*—The material shall conform to the following requirements as to tensile properties:

Properties considered	Classes A and B structural steel	Classes C and D plates for cold pressing	Classes E and F rivet steel
Tensile strength.....lb./in. ² ..	50,000-65,000	48,000-58,000	45,000-60,000
Yield point, minimum.....lb./in. ² ..	0.5 tensile strength.	0.5 tensile strength.	0.5 tensile strength.
Elongation in 8 inches, minimum ^aper cent..	1,500,000 Tensile strength	1,500,000 Tensile strength	1,500,000 Tensile strength
Elongation in 2 inches, minimum.....per cent.	22	-----	-----

^a See section on modifications in elongation in A.S.T.M. A7, p. 249.

4. *Notes.*—(a) This specification applies to shapes, plates, and bars over one-eighth inch in thickness or diameter.
 (b) When specifying materials in accordance with this specification, the class or classes (A, B, C, D, E, and F) should be stated definitely.

605.14 STRUCTURAL STEEL FOR MACHINERY. AMERICAN BUREAU OF SHIPPING, RULES FOR BUILDING AND CLASSING STEEL VESSELS; QUALITY AND TESTING OF MATERIALS, SHIP CONSTRUCTION, 1930
STEEL PLATES, ANGLES, BULB ANGLES, CHANNELS, ETC.

(See 605.15, p. 268.)

AMERICAN RAILWAY ASSOCIATION, SIGNAL SECTION, SPECIFICATION FOR MACHINERY STEEL, NO. 2111, 1911

MACHINERY STEEL

1. MATERIAL

(a) All sections must be true to size, free from cracks, flaws, and defects of all kinds.

(b) When subjected to a tensile test the steel must show: Tensile strength per square inch 48,000 to 58,000, pounds. Elongation in 8 inches, not less than 25 per cent.

(c) Phosphorus not to exceed 0.1 per cent, sulphur not to exceed 0.065 per cent.

(d) When subjected to a bending test, either hot or cold, the steel must bend double over a diameter equal to its own thickness without showing any fracture.

(e) Results of the chemical analysis made at the steel works of each melt used to fill the order must be furnished to the purchaser's inspector when requested.

(f) Mild steel will be inspected and tested at the shops where it is to be used.

(g) If material fails to meet the requirements of this specification, it will be rejected and returned to the manufacturer, who must pay all freight charges.

605.15 STRUCTURAL IRON AND STEEL FOR SHIPS.

AMERICAN BUREAU OF SHIPPING, RULES FOR BUILDING AND CLASSING STEEL VESSELS; QUALITY AND TESTING OF MATERIALS, SHIP CONSTRUCTION, 1930

IRON PLATES AND ANGLES

(See 604.14, p. 234.)

AMERICAN BUREAU OF SHIPPING, RULES FOR BUILDING AND CLASSING STEEL VESSELS; QUALITY AND TESTING OF MATERIALS, SHIP CONSTRUCTION, 1930

STEEL PLATES, ANGLES, BULB ANGLES, CHANNELS, ETC.

(For general information and requirements see 600.0, p. 2.)

1. The tensile strength and ductility shall be determined from test specimens cut lengthwise or crosswise from the finished material; when material is annealed or otherwise treated before dispatch the test specimens shall be similarly and simultaneously treated before testing. Wherever practicable the rolled surfaces shall be retained on two opposite sides of the test specimens; any straightening of test specimens which may be required shall be done cold. The parallel part of the tension-test piece shall not be less than 9 inches in length; the width shall not exceed 1½ inches for material more than 0.875 inch in thickness; from 0.875 to 0.375 inch it shall not exceed 2 inches, and under 0.375 inch the width shall not be more than 2½ inches.

2. Should a tension-test specimen break outside the middle half of its gage length the specimen may, at the maker's option, be discarded and another test made of the same plate or bar. Test specimens for bends shall not be less than 1½ inches wide and for small bars the whole section may be used. For quench-bend tests the specimens are to be heated to a light cherry red and quenched at once in water, the temperature of which is between 80° and 90° F. The color shall be judged indoors in the shade. The rough edge caused by the shearing may be removed by filing or grinding from all test specimens for cold bends, and from test specimens for quench bends which are 0.50 inch and above in thickness; specimens 1 inch thick and above may be machined; the test specimens shall receive no other preparation. The specimens are not to be annealed unless the material from which they are cut is similarly and simultaneously treated.

At least one tension test shall be made from the finished material of each heat; where the heat weight exceeds 56,000 pounds, a second tension test will be required; an additional test shall be made for each variation of 0.15 inch thickness of the material rolled from each heat. A cold or quench bend test is to be made from each plate or bar as rolled; these tests shall be made in about equal numbers from each

heat; a cold-bend test shall be made from each plate rolled which is specially marked for cold flanging.

3. The tensile strength of plates not intended for cold flanging shall be between the limits of 62,000 and 72,000 pounds per square inch of section; sectional material shall be between the limits of 62,000 and 74,000 pounds per square inch; garboard strake plates and other plates intended for cold flanging are to be marked so as to be easily identified by the surveyor at the steel works and in the shipyard, and are to have a tensile strength between the limits of 55,000 and 65,000 pounds per square inch. Material for purposes where tensile strength is not important need not be subjected to tensile tests if specified by the builders and approved by the committee, but will be subjected to bend tests and should be marked so as to be easily identified by the surveyors.

4. (a) The material shall conform to the following requirements:

Yield point, minimum.....lbs./in.²	0.5 tensile strength.
Elongation in 8 inches, minimum	1,500,000
-----per cent--	Tensile strength

(b) For material over three-fourths inch in thickness, a deduction of 1 from the percentage of elongation specified in paragraph (a) shall be made for each increase of one-eighth inch in thickness above three-fourths inch, to a minimum of 20 per cent.

5. The cold-bend test specimen shall bend cold through 180° without cracking on the outside of the bent portion, as follows:

For material three-fourths inch or under in thickness, around a pin the diameter of which is equal to twice the thickness of the specimen; for material over three-fourths inch in thickness, around the pin the diameter of which is equal to three times the thickness of the specimen.

6. In the event of any test specimen failing to meet the requirements, unless two further specimens prove satisfactory, the plate or bar represented by such sample specimen shall be rejected. Further tests of specimens taken from the same heat shall then be made and if these fail the whole of the material produced from that heat is to be rejected.

7. All material, which has satisfactorily passed the requirements, must be clearly stamped by the manufacturer in at least two places on each finished plate or bar, thus: $\frac{AB}{F}$ signifying that the material has satisfactorily complied with the tests above described. Material having tensile strength which is between the limits of 55,000 and 65,000 pounds and complies with the corresponding requirements for elongation, should be marked thus $\frac{AB}{F}$ to signify

that it is of "cold flanging" quality; material which has been approved on bend tests only is to be marked thus $\frac{AB}{B}$ so that it may be readily identified. No

material bearing these brands is to be forwarded from the steel works until the prescribed tests have been made by the surveyors and the mill sheets signed by them.

8. Before the mill sheets are signed, the manufacturers must furnish the surveyor with a certificate guaranteeing that the material has been made by the open-hearth process and that it has withstood satisfactorily the tests above described. The following form of certificate will be accepted if printed on each mill sheet with the name of the firm and initialed by the manufacturer's chief inspector:

We hereby certify that the material described herein has been made by the open-hearth process and has been tested by us in accordance with the rules of the American Bureau of Shipping with satisfactory results.

9. The maker must adopt a system of marking the ingots, billets, slabs, test pieces, and finished

material which will enable all material to be traced to its tests and original heat. The surveyor must be given every facility for tracing the material to the respective heats from which it is made, and he should be furnished with two copies of advice notes of such material as may have been satisfactorily dealt with, for his signature—one to be forwarded by the manufacturer to the shipbuilder, the other to be retained for the use of the surveyor in attendance at the shipyard.

10. Where steel is not produced in the works at which it is rolled, a certificate shall be supplied to the surveyor, deputed to witness the testing of the material, stating the open-hearth process by which it was manufactured, the name of the steel maker who supplied it, and the number of the heats from which it was made for reference to the books of the steel maker. The number of the heat shall be marked on each plate or bar for the purpose of identification.

11. The foregoing tests shall be made at the place of manufacture prior to the dispatch of the material, but in the event of any of the material proving unsatisfactory in the process of being worked it shall be rejected; such further tests may be made of material from the same heat as the surveyor in attendance may consider desirable and material then found defective shall also be rejected, notwithstanding any previous certificate of satisfactory testing.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR STRUCTURAL STEEL FOR SHIPS, DESIGNATION A12-21, 1921

(For general requirements relating to check analyses, yield point, number of tests, permissible variations in weight and thickness of plates, finish, marking, inspection, rejection, and reheating, also test specimen Figures 128 and 129: See A. S. T. M. specifications (605.0, p. 247), omitting, in paragraph 3 (c), reference to 2-inch specimens, and in paragraph 6, references to rivet and lattice bars and other small sections, and to pins and rollers.)

(Requirements relating to process, ladle analyses, modifications in elongation, and test specimens are substantially the same as in A. S. T. M. A7 (605.11, p. 249), paragraphs 2, 4, 6 (a), and 8 (a), (b), (d), (e), and (j). In paragraph 4 omit reference to copper steel.)

(For tables of permissible variations of plates ordered to weight, and permissible overweights of plates ordered to thickness, see A. A. S. M., Tables 1 and 2 (605.0, p. 248).)

(The following additional material is given:)

1. *Chemical composition.*—The steel shall conform to the following requirements as to chemical composition:

Phosphorus, maximum:	Per cent
Acid.....	0.06
Basic.....	.04
Sulphur, maximum.....	.06

2. *Tension tests.*—The material shall conform to the following requirements as to tensile properties:

Tensile strength.....lbs./in. ² ..	53,000-68,000
Yield point, minimum.....do.....	0.5 tensile strength
Elongation in 8 inches, minimum....per cent....	1,500,000

(See paragraphs on modifications in elongation.)

3. *Modifications in elongation.*—For material one-fourth inch or under in thickness, the elongation times be measured on a gage length of twenty-four times the thickness of the specimen.

4. *Bend tests.*—The test specimen shall bend cold through 180° without cracking on the outside of the bent portion, as follows: For material three-fourths inch or under in thickness, around a pin, the diam-

eter of which is equal to the thickness of the specimen; for material over three-fourths inch to and including 1¼ inches in thickness, around a pin, the diameter of which is equal to one and one-half times the thickness of the specimen; and for material over 1½ inches in thickness, around a pin, the diameter of which is equal to twice the thickness of the specimen.

5. *Test specimens.*—(a) Test specimens for plates over 1½ inches in thickness may be machined to a thickness or diameter of at least three-fourths inch for a length of at least 9 inches.

(b) Test specimens for bars over 1½ inches in thickness or diameter may be machined to a thickness or diameter of at least three-fourths inch for a length of at least 9 inches; or tension test specimens may conform to the dimensions shown in Figure 129 (p. 247), in which case the ends shall be of a form to fit the holders of the testing machine in such a way that the load shall be axial. Bend test specimens may be one by one-half inch in section.

(c) The tension test specimen shown in Figure 129 (p. 247), and the 1 by ½ inch bend test specimen for bars over 1½ inches in thickness or diameter shall be taken so that the axis is midway between the center and surface.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR RIVET STEEL FOR SHIPS, DESIGNATION A13-24, 1924

A. REQUIREMENTS FOR ROLLED BARS

(For general requirements relating to check analyses, yield point, number of tests, finish, marking, inspection, rejection, and reheating: See A. S. T. M. specifications (605.0, p. 247), paragraphs 1, 2, 3 (b) and (c), 5, 6, 7, 8, and 9. In paragraph 3 (c), omit reference to 2-inch specimen.)

(Requirements relating to process, ladle analyses, and test specimens are substantially the same as in A. S. T. M. A7 (605.11, p. 249), paragraphs 2, 4, and 8 (c). In paragraph 4 omit reference to copper steel.)

(The following additional material is given:)

1. *Chemical composition.*—The steel shall conform to the following requirements as to chemical composition:

Phosphorus, maximum:	Per cent
Acid.....	0.06
Basic.....	.04
Sulphur, maximum.....	.045

2. *Tension tests.*—The bars shall conform to the following requirements as to tensile properties:

Tensile strength.....lbs./in. ² ..	55,000-65,000
Yield point, minimum.....do.....	0.5 tensile strength
Elongation in 8 inches, minimum....per cent....	1,500,000

Tensile strength

(See section on modifications in elongation.)

3. *Modifications in elongation.*—For bars over three-fourths inch in diameter, a deduction from the percentage of elongation specified in paragraph 2 of 0.25 per cent shall be made for each increase of one thirty-second inch of the specified diameter above three-fourths inch.

4. *Bend tests.*—The test specimen shall bend cold through 180° flat on itself without cracking on the outside of the bent portion.

5. *Test specimens.*—Test specimens shall be of the full diameter of bars as rolled.

6. *Number of tests.*—Two tension and two bend tests shall be made from each melt, each of which shall conform to the requirements specified; except that if bars from one melt differ three-eighths inch or more in diameter, one tension and one bend test shall be made from both the greatest and the least diameters rolled.

7. *Permissible variations.*—The diameter of bars 1 inch or under in diameter shall not vary more than 0.01 inch from that specified; the diameter of bars over 1 inch to and including 2 inches in diameter shall not vary more than one sixty-fourth inch under nor more than one thirty-second inch over that specified.

B. REQUIREMENTS FOR RIVETS

(For general requirements relating to inspection and rejection, See A. S. T. M. specifications (605.0, p. 247), paragraphs 7 and 8 (b).)

(The following additional material is given:)

1. *Bend tests.*—The rivet shank shall bend cold

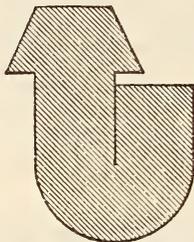

FIGURE 148

through 180° flat on itself, as shown in Figure 148, without cracking on the outside of the bent portion.

2. *Flattening tests.*—The rivet head shall flatten, while hot, to a diameter two and one-half times the diameter of the shank, as shown in Figure 149, without cracking at the edges.

3. *Number of tests.*—Three bend and three flattening tests shall be made from each size in each lot of rivets offered for inspection, each of which shall conform to the requirements specified.

4. *Workmanship and finish.*—The rivets shall be true to form and concentric, shall be made in a work-

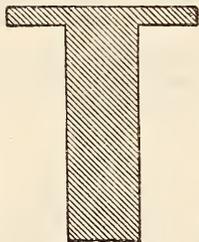

FIGURE 149

manlike manner and shall be free from injurious defects.

NOTE.—A tentative revision of A12 and A13, designated A131-31T, will, when adopted as standard, supersede these two specifications

ASSOCIATION OF AMERICAN STEEL MANUFACTURERS, STANDARD SPECIFICATIONS FOR STRUCTURAL AND BOILER STEEL, NOVEMBER 24, 1922

STRUCTURAL STEEL

(See 605.11, p. 250.)

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR STEEL; STRUCTURAL (INCLUDING STEEL FOR COLD FLANGING), AND STEEL, RIVET, FOR SHIPS OTHER THAN NAVAL VESSELS, QQ-S-751 JUNE 23, 1931.

STRUCTURAL STEEL FOR SHIPS

A. APPLICABLE FEDERAL SPECIFICATIONS

A-1. Federal specification No. 339a (current designation QQ-M-151), general specifications for metals, in effect on date of invitation for bids, shall form a part of this specification. (See 600.0, p. 3.)

B. GRADE

B-1. Structural steel, structural steel for cold flanging, and rivet steel for ships other than naval vessels shall be of but one grade each, as defined by paragraphs E-7 and E-8.

C. MATERIAL AND WORKMANSHIP, ETC.

C-1. Unless otherwise specified, steel shall be made by the open-hearth process or electric-furnace process.

C-2. The finished material shall be free from welds and injurious defects and shall have a workmanlike finish.

D. GENERAL REQUIREMENTS

D-1. See section E.

E. DETAIL REQUIREMENTS

E-1. *Structural shapes other than bar sizes.*—The cross section (or sectional area) or weight of each piece shall not vary from that specified more than 2.5 per cent.

E-2. *Structural shapes of bar sizes.*—The weight of each piece shall not vary from that specified more than the amount given in Table 2.

E-3. *Rolled edge plates.*—Each plate up to and including 36 inches in width shall not vary more than 2.5 per cent from the cross section (or sectional area) or weight specified; rolled edge plates more than 36 inches in width shall conform to limits specified in paragraph E-4 for sheared plates.

E-4. *Sheared plates.*—The weight of each lot in each shipment of rectangular plates shall not vary from the limits given in Table 1; the term "lot" meaning all of the plates of each group width and group weight. The weight per square foot of each individual plate shall not vary by more than one and one-third times the percentages allowed by Table 1.

E-5. *Rounds (including rivet bars), squares, and hexagons.*—No piece shall vary from the limits given in Table 3.

E-6. *Flats.*—No piece shall vary from the limits given in Table 4.

E-7. *Chemical properties.*—The amount of phosphorus and sulphur shall not exceed the following percentages:

	Structural steel and structural steel for cold flanging	Rivet steel
Phosphorus:	<i>Per cent (maximum)</i>	<i>Per cent (maximum)</i>
Acid.....	0.06	0.05
Basic.....	.04	.04
Sulphur.....	.06	.055

E-8. *Physical properties.*—The material shall have the following physical properties:

	Structural steel	Structural steel for cold flanging, and rivet steel
Tensile strength.....lbs./in. ² ..	60,000-72,000	55,000-65,000
Yield point, (minimum).....do....	0.5 tensile strength. 33,000	0.5 tensile strength. 30,000
Yield point, in no case less than. Elongation in 8 inches (minimum).....per cent..	1,500,000 Tensile strength	1,500,000 Tensile strength
Elongation in 2 inches (minimum).....do....	22	25

For material over 3/4 inch in thickness or diameter, a deduction from the percentage of elongation in 8 inches specified above of 0.25 per cent shall be made for each increase of 1/2 inch in the specified thickness or diameter above 3/4 inch, to a minimum of 16 per cent for structural steel and 18 per cent for structural steel for cold flanging and rivet steel.

For material under 3/16 inch in thickness or diameter, a deduction from the percentage of elongation in 8 inches specified above of 1.25 per cent shall be made for each decrease of 1/2 inch of the specified thickness or diameter below 3/16 inch.

F. METHODS OF SAMPLING, INSPECTION, AND TESTS

F-1. *Number of tests.*—

F-1a. Two tension and two bend tests shall be made from each melt of structural steel and steel for cold flanging unless the finished material from a melt is less than 25 short tons, when one tension and one bend test shall be sufficient. If, however, material from one melt varies 0.15 inch or more in thickness, the thickest and thinnest material rolled shall each be represented by one tension and one bend test, regardless of the weight of the melt. Two tension and two bend tests shall be made from each melt of rivet steel.

F-1b. When structural steel is ordered for cold flanging and also required to conform to ship classification societies' tests and inspection, one bend test specimen shall be taken from each plate as rolled.

F-1c. If any test specimen shows defective machining or develops flaws, it may be discarded and another specimen substituted.

F-2. *Test specimens.*—

F-2a. Unless specified otherwise, test specimens shall be taken longitudinally as approved by the inspector and, except as specified in paragraphs F-2f and F-2g, shall be of the full thickness or section of material as rolled.

F-2b. Test specimens shall be prepared for testing from the material in its rolled condition, except as specified in paragraphs F-2c and F-2d.

F-2c. Test specimens for annealed material shall be prepared from the material as annealed for use.

F-2d. Test specimens for rivet bars which have been cold-drawn shall be normalized before testing.

F-2e. Test specimens for plates, shapes, and flats may be machined to conform to type 2, Federal specification QQ-M-151, referred to in paragraph A-1, or with both edges parallel.

F-2f. Tension test specimens for material over 1 1/2 inches in thickness or diameter, may be machined to a thickness or diameter of at least three-fourths inch for a length of at least 9 inches, or they may conform to type 1, Federal specification QQ-M-151, referred to in paragraph A-1.

F-2g. Bend test specimens for material over 1 1/2 inches in thickness or diameter may be machined to a thickness or diameter of at least three-fourths inch or to 1 by 1/2 inch in section.

F-2h. For bars over 1 1/2 inches in thickness or diameter, other than flats, when not tested in the full section as rolled, the tension test specimens shall be taken so that the axis shall be at a point one-half the distance between the center and the surface of the bar.

F-2i. The machined sides of rectangular bend test specimens may have the corners rounded to a radius not over one-sixteenth inch.

F-3. *Bend tests.*—

F-3a. Bend test specimens for structural steel other than for cold flanging shall bend cold through 180° without cracking on the outside of the bent portion as follows: For material three-fourths inch or under in thickness, around a pin the diameter of which is equal to the thickness of the specimen; for material over three-fourths inch, to and including 1 1/4 inches in thickness, around a pin the diameter of which is equal to twice the thickness of the specimen; and for material over 1 1/4 inches in thickness around the pin, the diameter of which is equal to three times the thickness of the specimen.

F-3b. Bend-test specimens for structural steel for cold flanging and rivet steel shall bend cold through 180° without cracking on the outside of the bent portion as follows: For material three-fourths inch or under in thickness, flat on itself; for material over three-fourths inch, to and including 1 1/4 inches in thickness, around a pin the diameter of which is equal to the thickness of the specimen; and for material over 1 1/4 inches in thickness, around a pin the diameter of which is equal to twice the thickness of the specimen.

F-4. The yield point shall be determined by the drop of the beam of the testing machine.

G. PACKAGING, PACKING, AND MARKING

G-1. The name or brand of the manufacturer and the melt number, if practicable, shall be legibly stamped or rolled on all finished material, except that rivet and lattice bars and other small sections, when loaded for shipment, shall be properly separated and marked for identification. If it is not practicable to stamp or roll the melt number on finished material, other methods of marking may be used so long as the marking is legible.

G-2. Shipments shall be marked with the name of the material, the size, the shape, and the quantity contained therein as defined by the contract or order under which shipment is made, the name of the contractor, and the number of the contract or order.

NOTES

I-1. The contractor shall furnish for each melt a carbon determination and determinations for manganese, phosphorus, and sulphur representing the average of the melts applied for each 12-hour period.

I-2. When specifying material in accordance with this specification the grade should be definitely stated. When structural steel is for cold flanging, orders should so state.

I-3. It is believed that this specification adequately describes the characteristics necessary to secure the desired material, and that normally no samples will be necessary prior to award to deter-

mine compliance with this specification. If, for any particular purpose, samples with bids are necessary, they should be specifically asked for in the invitation for bids, and the particular purpose to be served by the bid sample should be definitely stated, the specification to apply in all other respects.

I-4. This specification governs all United States Government purchases of this commodity.

TABLE 1.—*Permissible variations in weights per square foot of rectangular sheared plates and universal plates over 36 inches, for widths given, expressed in percentage of ordered weights*
(Identical with Table 1 of A. A. S. M. standard specifications for structural and boiler steel. See 605.0, p. 248.)

TABLE 2.—*Permissible variations in weights of angles, tees, zees, and channels*
(Identical with Table 3 of A. A. S. M. standard specifications for structural and boiler steel. See 605.0, p. 249.)

TABLE 3.—*Permissible variations in dimensions of rounds, squares, and hexagons*
(Identical with Table 4 of A. A. S. M. standard specifications for structural and boiler steel. See 605.0, p. 249.)

TABLE 4.—*Permissible variations in dimensions of flats*
(Identical with Table 5 of A. A. S. M. standard specifications for structural and boiler steel. See 605.0, p. 249.)

605.19 MISCELLANEOUS STRUCTURAL STEEL.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, SPECIFICATION FOR MATERIALS FOR USE IN THE MANUFACTURE OF SPECIAL TRACKWORK, W104-28, 1928

[Approved as tentative American Standard by the American Standards Association, January 23, 1929]

SPECIAL TRACKWORK MATERIALS

(See 606.3, p. 342.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR STEEL PLATES OF STRUCTURAL QUALITY FOR FORGE WELDING, DESIGNATION A78-30, 1930

STEEL PLATES FOR FORGE WELDING

SCOPE

1. These specifications cover steel plates of structural quality suitable for forge welding without the use of fluxes where the weld is not reinforced.

MANUFACTURE

2. The steel shall be made by the open-hearth process.

CHEMICAL PROPERTIES AND TESTS

(The chemical composition of grade A is identical with that of flange quality, grade A, including phosphorus (acid) in A. S. T. M. A89-31T. See 604.11, p. 230. Grade B is identical with that of fire-box quality, grade B in A89-31T, except that phosphorus shall not be over 0.06 and sulphur not over 0.05 per cent. Requirements covering nickel, chro-

mium, and silicon, with footnote reference to nickel, are also identical with those in A89-31T.)

LADLE AND CHECK ANALYSES

(Conform to A. S. T. M. A70-27. See 604.11, p. 227.)

PHYSICAL PROPERTIES AND TESTS

3. The material shall conform to the following minimum requirements as to tensile properties:

	Grade A	Grade B
Tensile strength.....lbs./in. ² ..	45,000	50,000
Yield point.....do.....	0.5 tensile strength.	0.5 tensile strength.
But in no case less than.....	24,000	27,000
Elongation in 8 inches.....per cent..	28	25

(In respect to determination of yield point and modifications for material over three-fourths inch in thickness, this specification conforms to A. S. T. M. A70-27. In respect to modifications in elongation for material under five-sixteenths inch in thickness, machining of test specimens for plates over 1½ inches in thickness, rounding corners of rectangular bend test specimens, and retesting defective test specimens, this specification conforms to A. S. T. M. A129-30T. See 604.11, p. 232. Otherwise the test requirements are as follows:)

4. *Bend tests.*—The test specimen shall stand being bent cold through 180° flat on itself without cracking on the outside of the bent portion.

5. (a) *Test specimens.*—Test specimens shall be prepared for testing from the material in its rolled condition.

(b) Test specimens shall be taken longitudinally and, except in the case of test specimens for plates over 1½ inches in thickness, shall be of the full thickness of the material as rolled. They may be machined to the form and dimensions shown in Figure 128 in A. S. T. M. standard specifications for steel (see 605.0, p. 247), or with both edges parallel.

6. *Number of tests.*—One tension and one bend test shall be made from each melt; except that if material from one melt differs three-eighths inch or more in thickness, one tension and one bend test shall be made from both the thickest and the thinnest material rolled.

PERMISSIBLE VARIATIONS IN WEIGHT AND THICKNESS

7. The cross section or weight of plates shall be covered by the following permissible variations. One cubic inch of rolled steel is assumed to weight 0.2833 pound.

(a) *When ordered to weight per square foot.*—The weight of each lot⁵⁷ in each shipment shall not vary from the weight ordered more than the amount given in Table 1 in A. A. S. M. standard specifications for structural and boiler steel. (See 605.0, p. 248.)

(b) *When ordered to thickness.*—The thickness of each plate shall not vary more than 0.01 inch under that ordered. The overweight of each lot⁵⁷ in each shipment shall not exceed the amount given in Table 2 in A. A. S. M. standard specifications for structural and boiler steel. (See 605.0, p. 248.)

⁵⁷ The term "lot" as applied to Table 1 in A. A. S. M. standard specifications for structural and boiler steel (see 605.0, p. 248) means all of the plates of each group width and group weight. As applied to Table 2 it means all of the plates of each group width and group thickness.

MARKING

8. The name or brand of the manufacturer and the melt number shall be legibly rolled or stamped on all finished material. The melt number shall be legibly marked, by stamping if practicable, on each test specimen.

(In respect to finish, inspection and rejection, and reheating, this specification conforms to A. S. T. M. standard specifications for steel. (See 605.0, p. 247.)

605.2 STRUCTURAL SHAPES AND PLATES, FABRICATED.

605.20 GENERAL ITEMS.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, RULES FOR INSPECTION AND MAINTENANCE OF BRIDGES, MANUAL SECTION B207-20, 1920

BRIDGE INSPECTION

(These recommendations cover the frequency and scope of the inspections of bridges to be made by track force, by the bridge foreman, and by the engineering department in conjunction with the bridge foreman. Suggested forms for reporting inspections and repair work done are included.)

605.21 STEEL BRIDGES AND RAILWAY TURN-TABLES.

AMERICAN ASSOCIATION OF STATE HIGHWAY OFFICIALS, STANDARD SPECIFICATIONS FOR HIGHWAY BRIDGES AND INCIDENTAL STRUCTURES, 1931

HIGHWAY BRIDGES

Section 7. STRUCTURAL, RIVET, AND EYEBAR STEEL

2. 7. 1. *General.*—All structural, rivet, and eyebar steel shall conform to the requirements of the standard specifications for structural steel for bridges, designation A7, of the American Society for Testing Materials (see 605.11, p. 249), supplemented by the following paragraphs:

2. 7. 2. *Character of fracture.*—Test requirements of structural, rivet, or eyebar steel shall show a fracture having a silky or fine granular structure throughout, with a bluish gray or dove color, and shall be entirely free from granular, black, and brilliant specks.

2. 7. 3. *Defects in material.*—Finished rolled material shall be free from cracks, flaws, injurious seams, laps, blisters, ragged and imperfect edges, and other defects. It shall have a smooth, uniform finish, and shall be straightened in the mill before shipment.

Material shall be free from loose mill scale, rust pits, or other defects affecting its strength and durability.

2. 7. 4. *Full-size tests.*—When full-size tests of built-up structural members and eyebars are required by the contract, the contractor shall supply testing machines of the proper type and capacity and shall provide all facilities and labor incidental to the making of tests. In all tests involving the determination of tensile and compressive strengths, the ultimate strength, deformation, and other pertinent data shall be recorded.

2. 7. 5. *Payments for full-size tests.*—Any full-size member tested to destruction shall be paid for by the purchaser at the unit contract price, less its scrap value, if the test proves satisfactory. If the test proves the member to be unsatisfactory, the mem-

bers represented by it will be rejected. The expense of conducting tests shall be borne by the contractor unless otherwise provided.

Section 8. EYEBARS

2. 8. 1. *Full-size tests.*—When tests of full-size bars are required the following conditions and requirements shall supplement the general provisions of section 7.

2. 8. 2. *Number and size of test bars.*—The number and size of the bars to be tested shall be designated by the engineer before the mill order is placed. The number shall not exceed 5 per cent of the whole number of bars ordered, with a minimum of two bars on small orders.

2. 8. 3. *Selection of test bars.*—The test bars shall be of the same section as the bars to be used in the structure and of the same length if within the capacity of the testing machine. They shall be selected by the inspector from the finished bars, preferably after annealing. Test bars representing bars too long for the testing machine shall be selected from the full-length bar material after the heads on one end have been formed and shall have the second head formed upon them after being cut to the greatest length which can be tested.

2. 8. 4. *Physical requirements.*—Full-size tests of eyebars shall show a yield point of not less than 33,000 pounds per square inch, an ultimate strength of not less than 60,000 pounds per square inch, and an elongation, including fracture, of not less than 12 per cent in a length of 18 feet measured in the body of the bar. The fracture shall show a uniform silky or fine granular structure throughout.

2. 8. 5. *Failure to meet requirements.*—If a bar fails to fulfill the specified requirements, two additional bars of the same size and from the same melt shall be tested. The bars represented by the test may be reannealed before the additional bars are tested.

If two of the three test bars fail to give satisfactory results, the bars of that size and melt shall be rejected.

2. 8. 6. *Record of annealing.*—A record of the annealing charges shall be furnished the engineer showing the bars included in each charge and the treatment they received.

Section 9. STEEL FORGINGS

2. 9. 1. *General.*—Steel forgings from which pins, rollers, trunnions, or other forged parts are to be fabricated shall conform to the requirements of the standard specifications for carbon-steel forgings for locomotives, designation A20, of the American Society for Testing Materials. (See 611.51, p. 757.)

2. 9. 2. *Annealing.*—All forgings shall be thoroughly annealed prior to being machined to form finished parts.

Section 10. WROUGHT IRON

2. 10. 1. *Wrought iron.*—Wrought iron shall conform to the requirements of the standard specifications for refined wrought-iron bars, designation A41, of the American Society for Testing Materials. (See 603.1, p. 139.)

Section 11. STEEL CASTINGS

2. 11. 1. *General.*—Steel castings shall conform to the requirements of the standard specifications for steel castings, designation A27, of the American Society for Testing Materials. (See 611.41, p. 707). supplemented by the following: Unless otherwise specified, all castings shall be class B, medium grade.

2. 11. 2. *Annealing*.—All steel castings shall be thoroughly annealed unless otherwise provided.

2. 11.3. *Structural defects*.—Steel castings shall be true to pattern in form and dimensions, free from pouring faults, sponginess, cracks, blowholes and other defects in positions affecting their strength and value for the service intended.

Blowholes appearing upon finished castings shall be so located that a straight line laid in any direction will not cut a total length of cavity greater than 1 inch in any 1 foot, nor shall any single blowhole exceed 1 inch in any dimension or have an area greater than one-half square inch. Blowholes shall not have a depth injuriously affecting the strength of the casting. Minor defects which do not impair the strength may, with the approval of the engineer, be welded by an approved process. The defects shall be removed to solid metal by chipping, drilling, or other satisfactory methods and, after welding, the castings shall be annealed, if required by the engineer. Castings which have been welded without the engineer's permission shall be rejected.

Large castings, if required by the engineer, shall be suspended and hammered all over. No cracks, flaws, or other defects shall appear after such treatment.

No sharp unfiled angles or corners will be allowed.

Section 12. GRAY-IRON CASTINGS

2. 12. 1. *General*.—Iron castings shall conform to the requirements of the standard specifications for gray-iron castings, designation A48 of the American Society for Testing Materials. (See 611.11, p. 636.) Castings shall be boldly filleted at angles and the arrises shall be sharp and perfect.

2. 12. 2. *Structural defects*.—Iron castings shall be true to pattern in form and dimensions, free from pouring faults, sponginess, cracks, blowholes, and other defects in positions affecting their strength and value for the service intended.

Section 13. MALLEABLE CASTINGS

2. 13. 1. *General*.—Malleable castings shall conform to the requirements of the standard specifications for malleable castings, designation A47, of the American Society for Testing Materials. (See 611.21, p. 665.) The castings shall be boldly filleted at angles and the arrises shall be sharp and perfect.

The surfaces shall have a workmanlike finish.

2. 13. 2. *Structural defects*.—(Identical with gray-iron castings, given above.)

Section 14. PHOSPHOR-BRONZE

2. 14. 1. *General*.—Phosphor-bronze shall conform to the requirements of the standard specifications for bronze bearing metals for turntables and movable railroad bridges, designation B22, of the American Society for Testing Materials. (See 692.2, p. 1324.) Grade B metal shall be used.

2. 14. 2. *Structural defects*.—Bronze castings shall be free from inclusions of foreign material, casting faults, injurious blowholes, or other defects rendering them unsuitable for the service intended.

(Details of structural steel design and erection are included in these specifications.)

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR MOVABLE RAILWAY BRIDGES, 1929

MOVABLE RAILWAY BRIDGES

(Materials required for various parts, conditions specified for computation of stresses and machinery power requirements, proportioning of parts and machinery power, friction coefficients, allowable unit stresses, bearing stresses, permissible loads and

strength of wire rope, general design requirements for rail end connections, rim girders, counterweights, bearings, shafts, gears, and other bridge parts. Design and type requirements for steam-power equipment, gasoline-engine equipment, electrical power and controllers. Specifications for cast steel, forged steel, tool steel, bronzes, Babbitt metal, workmanship, and erection.)

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR STEEL RAILWAY BRIDGES, 1929

STEEL RAILWAY BRIDGES

(See 605.11, p. 249.)

AMERICAN RAILWAY ENGINEERING ASSOCIATION, STEEL RAILWAY TURN-TABLES, 1924

RAILWAY TURNABLES

(For balanced and 3-point support types; clearances, minimum live loads for design, allowable unit stresses and proportioning of parts, general features of design of center, end trucks, pit, and tracks.)

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR STEEL HIGHWAY BRIDGES, 1929

STEEL HIGHWAY BRIDGES

(Same as American Association of State Highway Officials specification, given above.) In scope these specifications are limited to the field of ordinary highway bridges and do not provide for unusual span lengths and types of construction, for which provision must be made by special supplemental specifications.

AMERICAN SOCIETY OF CIVIL ENGINEERS, SPECIFICATIONS FOR DESIGN AND CONSTRUCTION OF STEEL HIGHWAY BRIDGE SUPERSTRUCTURE, 1924

HIGHWAY BRIDGES

(Construction, loading and application of loads, allowable stresses, details of design, tension and bend test requirements for structural steel, permissible variations in weight and dimensions, test requirements for eyebars. Specifications for structural nickel steel to conform to those of the American Society for Testing Materials, A8-29. See 621.33, p. 1126.)

AMERICAN SOCIETY OF CIVIL ENGINEERS, SPECIFICATIONS FOR DESIGN AND CONSTRUCTION OF STEEL RAILWAY BRIDGE SUPERSTRUCTURE, 1923

RAILWAY BRIDGES

(Types of loading and other items requiring consideration in the design, allowable stresses in various materials and parts, design requirements, construction, eyebar tests, tension and bend test requirements for the steel, permissible variations in weight and dimensions, data and curves for use in bridge design. The specifications for structural nickel steel to conform to those of the American Society for Testing Materials, A8-29. See 621.33, p. 1126.)

605.22 STEEL BUILDINGS AND METAL PARTS OF BUILDINGS.**AMERICAN INSTITUTE OF STEEL CONSTRUCTION, STANDARD SPECIFICATION FOR FIREPROOFING STRUCTURAL STEEL BUILDINGS, OCTOBER 8, 1927****FIRE TESTS OF BUILDING CONSTRUCTION AND MATERIALS**

(The test procedure for determining the resistance of buildings and building materials to exposure to fire is the same in this specification as in the A. S. T. M. tentative specification C19-26T for fire tests of building construction and materials. The A. I. S. C. specification provides an alternate method of defining the end point of the tests which is based on the maximum temperatures at which the structural steel is permitted to carry the stresses used in the design. The A. S. T. M. procedure has been approved by the American Standards Association as A2-1926. It prescribes a standard exposing fire of controlled extent and severity. Performance is defined as the period of resistance to standard exposure elapsing before the first critical point in behavior is observed. The alternate method of the A. I. S. C. prescribes a certain placing of thermocouples on the test specimen (column, girder, or beam) and expressing the fire resistance in the number of hours it takes the standard fire to cause the average readings of these thermocouples to reach 1,000° F.)

SAFETY FACTOR IN FIREPROOFING BUILDINGS

Steel buildings whose conditions of exterior exposure and whose contents under fire hazards will not produce a temperature greater than 800° F. in the steel, shall be considered fire resistive without insulating protection for the steel.

If the steel work has an insulating protection, the safety factor shall be based on the fireproofing material providing protection for a greater period of time than the combustible contents of the building will burn as shown by tests of office occupancy and record storage. The safety factor for all skeleton frame and secondary members shall be one and one-half. For example: If a building contains 10 pounds of combustible material per square foot of floor, and has a fire hazard of 1-hour duration, the steel work shall be protected against the temperature defined in this specification for one and one-half hours.

AMERICAN INSTITUTE OF STEEL CONSTRUCTION, STANDARD SPECIFICATION FOR STRUCTURAL STEEL FOR BUILDINGS, 1923**STRUCTURAL STEEL FOR BUILDINGS**

(See 605.12. p. 252.)

AMERICAN RAILWAY ENGINEERING ASSOCIATION, 1930 SUPPLEMENT TO MANUAL OF 1929, SPECIFICATIONS FOR RAILWAY BUILDINGS, SECTION 12-B**ORNAMENTAL AND MISCELLANEOUS METAL WORK**

(Among other requirements covering permissible unit stresses in ornamental and miscellaneous metal work, standard A. S. T. M. specifications for steel,

wrought iron, and cast iron, requirements on castings, construction, and installation of pipe railings, fabric fences, wrought-iron fences, live loads to be used in design of stairs, balconies, ladders, and fire escapes, design and installation requirements for flagpoles, window guards, elevator inclosures, etc., are the following requirements for metal and metal-clad doors.)

METAL DOORS AND FIRE DOORS

Metal doors may be either swinging, rolling, or sliding, and of solid or hollow sections. Doors shall be so counter-weighted and balanced that they may easily be operated by one man. No metal shall be less than No. 22 U. S. standard gage, and if of steel shall be copper bearing. Doors shall be stiff enough to resist bending and warping and when of hollow section shall be absolutely water-tight to prevent internal corrosion. Fire doors shall meet all the requirements specified above for metal doors and shall meet the requirements of the National Board of Fire Underwriters for the particular use intended.

METAL-CLAD DOORS AND FIRE DOORS

Metal-clad doors shall consist of cores of not less than two ply of sound, kiln dried, nonresinous wood, covered with not less than 20-pound weight prime terneplate. The nonresinous wood may be either cedar, cypress, white pine, northern pine, redwood, eastern spruce, Sitka spruce, yellow poplar, or Douglas fir, but only one kind of wood may be used in any one door. Terneplate shall be I. C. base weight (107 pounds) or heavier, of an alloy of not less than 20 per cent tin and the balance lead, and the 20-pound weight shall be in accordance with the simplified practice recommendation of the U. S. Department of Commerce. R30-28. (See 604.31. p. 241.) All metal shall be made absolutely water-tight to protect the wood cores. Each wood core shall be covered separately before doors are assembled. Metal-clad doors shall meet all of the requirements of the National Board of Fire Underwriters.

METAL SASH

Metal sash may be either solid or hollow section as indicated on drawings. No metal shall be less than No. 22 U. S. standard gage, and, if steel, shall be copper bearing.

METAL-COVERED SASH

(The requirements for metal-covered sash are the same as for metal-clad doors and fire doors given above.)

AMERICAN RAILWAY ENGINEERING ASSOCIATION, MANUAL, 1929, SPECIFICATIONS FOR BUILDINGS FOR RAILWAY PURPOSES**SHEET-METAL WORK****MATERIALS**

Sheet-metal work shall be copper, galvanized iron, lead, or rolled zinc as shown on the drawings, or as specifically called for in the contract.

Copper.—Copper sheets shall be rolled from copper conforming to the specifications of the A. S. T. M. and marked with the weight and manufacturers' name. Copper flashings, valleys, eave strips, and roof pans shall be 16-ounce soft rolled copper.

Copper rain conductors, eave troughs, molded and hanging gutters, and conductor heads shall be 16-ounce cold-drawn or hard copper.

Copper cornices shall be 20-ounce cold-rolled or hard copper.

Galvanized iron.—Galvanized iron shall be 24 gage, of one of the following brands: —, —, —,

Lead.—Lead used for sheet-metal work shall be 6-pound rolled sheet lead.

Zinc.—Zinc used for sheet-metal work shall be 11-gage rolled zinc of one of the following brands: —, —, —,

Solder.—Solder shall be composed of one-half pig lead and one-half block tin (new metals) and shall conform to the specifications of the A. S. T. M., serial B32.

(The remainder of this specification dealing with sheet-metal work covers general requirements on installation, with limiting dimensions in some cases, for flashings, gutters, eave strips, and gravel stops, cornices, rain conductors, rain-conductor heads, ridge rolls and hip capping, ventilators, skylights.)

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR BUILDINGS FOR RAILWAY PURPOSES, 1929

STEEL FOR BUILDINGS

(See 605.12. p. 252.)

ASSOCIATED FACTORY MUTUAL FIRE INSURANCE COMPANIES, TIN-CLAD FIRE DOORS AND SHUTTERS, OCTOBER 1, 1925

TIN-CLAD FIRE DOORS

Cores must be constructed of white pine, cypress, or other soft wood. Stock must be dry and thoroughly seasoned, sound, and free from sap or loose knots. Boards must be tongued and grooved, dressed both sides to thirteen-sixteenths inch, not beaded, and not over 8 inches wide. The lengths of the boards must be such that not more than two pieces are used in any continuous strip on either exposed face, and at least alternate strips must be full length boards. Shorter lengths may be used in the middle section of 3-ply cores, but in no case shall there be more than three pieces in any of such middle layers.

Three-ply doors must have the outer layers vertical and the inner layer horizontal and 2-ply doors must have one layer vertical and one horizontal. The layers must be thoroughly fastened together by wrought-iron clinch nails not over 8 inches apart, extending clear through the door and clinched on the back side, leaving both surfaces of the door smooth. The edges and corners of the doors must be true and square.

The covering for doors and shutters, whether exposed to dampness or not, should be terneplate. Plates should be of basic open-hearth steel 14 inches by 20 inches and of I. C. thickness, weighing at least 103 pounds net per box of 112 sheets, exclusive of the coating. This should weigh 10 pounds per box additional, and should be an alloy of not less than 25 per cent tin and not more than 75 per cent lead.

The corners of the door should be covered first, using a whole sheet of tin without cutting and with a miter fold nailed under the fold. The edges should next be covered with either regular plates or long sheets. The faces should next be covered beginning at the lower right-hand corner. The top horizontal joint and all vertical ones must be double lock joints of a type illustrated. (Illustrations of the construction of doors and shutters are given in the

full text of these specifications.) The remaining joints should be single lock. The finished lap in all cases must be full one-half inch. The folds at the corners and all joints possible must be made to shed water. The plates should be fastened to the core with 2-inch wire nails barbed full length, five nails being used on the sides and four on the ends of each sheet, and driven close to the center of each joint. Finished seams must be well flattened, no nail heads must be exposed, and no solder must be used. When covering is complete cut a hole 3 inches in diameter through the middle plate on the exposed side of the door but not through the wood core. Secure the tin around this opening with small nails and thoroughly paint the wood thus exposed. (The hole will prevent bulging of the covering and rupture of the joints by permitting the escape of gases generated from the wood core when the door is exposed to fire.)

(The full text of this specification also includes requirements on types, sizes, and installation of hardware; fit and installation of doors; sizes of sills; etc.)

TIN-CLAD FIRE SHUTTERS

(Construction is the same as for 2-ply core fire doors given above.)

NATIONAL ASSOCIATION SHEET-METAL CONTRACTORS, STANDARD PRACTICE IN SHEET-METAL WORK, 1929

SHEET-METAL WORK

(This reference book of standards of practice in fabricating and erecting sheet-metal work for the building industry contains 768 pages, including 494 full-page illustrations. The contents are divided into 12 sections, as follows:

Roofing, gutters, conductors, flashing, and corrugated iron work.

Skylights and ventilators.

Metal cornices.

Metal ceilings.

Warm air furnaces.

Heating and ventilating.

Blowpipe and exhaust systems.

Fire doors, tin clad and kalamein.

Hollow metal doors and trim.

Hollow metal windows.

Restaurant, kitchen, and hotel equipment.

Protective coatings and paints.)

NATIONAL BOARD OF FIRE UNDERWRITERS, BUILDING CODE, 1931

BUILDING CODE

(Covers classification of buildings, tests, and quality of materials, working stresses, cast iron and steel construction, fire doors and windows, fireproof construction, fire tests. See also 611.19, p. 664.)

NATIONAL ELECTRICAL MANUFACTURERS ASSOCIATION, SWITCHGEAR STANDARDS, SG8-60. OUTDOOR SUBSTATIONS. PUBLICATION NO. 31-10, 1931

OUTDOOR SUBSTATIONS

(Structural steel according to specification A9 of the American Society for Testing Materials. (See 605.12, p. 252.) Requirements on strength of bolt and rivet steel, minimum thickness of metal in structure, minimum sizes of bolts and rivets, zinc

coating of steel work, allowances for ice and wind loads, permissible stresses, general design of foundations, spacing of rivets and bolts, fabrication, current ratings for bare conductors.)

NATIONAL FIRE PROTECTION ASSOCIATION, SPECIFICATIONS FOR STANDARD INDUSTRIAL BUILDINGS, 1929

INDUSTRIAL BUILDINGS

Standard industrial buildings shall include all structures more than one story in height used for industrial purposes, such as factories, lofts and manufacturing, mills, storage warehouses, workshops, etc.

Buildings of this class, in which the fire hazard is recognized to be from moderate to high, shall conform to the minimum specification requirements for reinforced concrete, slow-burning heavy timber, and protected steel construction.

(The requirements in this specification include permissible height and floor area, number of exits, materials and allowable stresses to be in accordance with the standard specifications quoted, requirements on construction and protection of roof and wall openings and shaft inclosures, on wall thicknesses, on fireproofing of structural members, floors and roofs, on electrical and fire equipment, etc.)

RAILWAY FIRE PROTECTION ASSOCIATION, HANDBOOK OF THE R. F. P. A., 1925

GARAGES AND REPAIR SHOPS FOR RAIL MOTOR CARS

Garage and repair shop construction should be in conformity with the National Building Code, of fire-resistant construction throughout, with no cellar, pit, or depression below the first floor level unless properly ventilated to remove all gas accumulations therefrom. Repair shops should be separated from garage proper by standard fire walls. See report of National Fire Prevention Association committee on bus garages, which regulations should be followed in so far as they apply. Floors shall be of concrete or earth construction. Garage floors of other than earth construction shall drain to an oil separator or trap and if area is extensive a series of drains shall be provided.

(Other recommendations given in the full text of this standard include recommendations on types of lighting and heating equipment, ventilation including recommended capacity of a mechanical ventilation system, removal of engine exhaust gases from repair shops, operation and maintenance of garages, storage and handling of gasoline and oil, recommended fire-fighting facilities.)

STEEL JOIST INSTITUTE, STEEL JOIST CONSTRUCTION, 1932

STEEL JOISTS

(This specification includes construction details for steel joists composed of rolled shapes, riveted or welded bars or rods, or expanded rolled shapes, as used between girders. Steel according to A. S. T. M. specification A9 (see 605.12, p. 252). Requirements on methods of design and stresses, span, spacing, bridging, etc. Table of open-web steel joists is identical with that in Simplified Practice Recommendation R94-30 of the United States Department of Commerce. See 605.12, p. 253.)

UNDERWRITERS' LABORATORIES, STANDARD FOR TIN-CLAD FIRE DOORS AND SHUTTERS, JUNE, 1930

TIN-CLAD FIRE DOORS AND SHUTTERS

GENERAL

These are requirements for tin-clad fire doors and shutters entitled to classification as "standard" for one or more of the situations defined in the Regulations of the National Board of Fire Underwriters for the protection of openings in walls and partitions against fire, as follows:

Class A.—Openings in division walls between separate buildings or sections of buildings (that is, fire walls).

Class B.—Openings in inclosures to vertical communications through buildings (that is, vertical shafts).

Class C.—Openings in corridor and room partitions.

Class D.—Openings in exterior walls subject to severe fire exposure.

Class E.—Openings in exterior walls subject to moderate fire exposure.

Fire doors and shutters conforming to these specifications have been shown by tests at the laboratories, and by records of service, to be capable of furnishing the degree of fire protection entitling them to classification as standard for the following situations when properly mounted with standard hardware:

Three-ply doors for classes A, B, C, D, and E situations.

Two-ply doors for classes B, C, D, and E situations.

Two and three ply shutters for classes D and E situations.

Two and three ply doors and shutters provided with glass panels for classes C and E situations.

LUMBER

The following soft woods listed in Appendix A of the American Lumber Standards given in Simplified Practice Recommendation R16-29 of the United States Department of Commerce may be used, provided only one kind is used in the assembly of a single core: Cedars, all classes; cypress, all classes; Douglas fir; white pine; northern white pine; redwood; eastern spruce; Sitka spruce; and yellow poplar (tupelo).

Lumber used shall be well seasoned so that it has reached its normal moisture content, as specified by the Forest Products Laboratory for its kind. In all cases stocks of lumber shall be stored under cover in the premises of the fire-door manufacturer for at least one month before being used in the manufacture of fire-door cores, and while in storage shall be piled in such manner that the air has free access to all surfaces of each board. Kiln drying will be accepted for the 30-day air-drying period.

The lumber shall be graded according to the American Lumber Standards as No. 1 Common, or better, matched yard lumber, 1-inch standard boards, surfaced on two sides. This specifies boards free from sap, dry-rot, knot or other holes, loose knots, unsound knots, or knots exceeding 2½ inches in any dimension. Sound boards 10 feet in length shall not exceed in extent or damage three 2½-inch knots.

The matched tongued-and-grooved boards shall be surfaced on two sides as specified for yard lumber, American Lumber Standards, and shall not be beaded or beveled in addition.

The tolerances in actual thickness for nominal 1-inch yard lumber surfaced on two sides shall be as specified in the American Lumber Standards, which provides a minimum thickness of board of twenty-five thirty-seconds of an inch.

Boards shall be at least 3 inches and not more than 8 inches in width, nominal width, according to American Lumber Standards.

NOTE.—The nominal width (or stock width) is usually slightly greater than the width over the tongue and groove.

METAL COVERING

Prime terneplate shall be used. (For the purpose of this specification "terne" shall be understood as indicating an alloy, for the coating, of tin and lead in the proportion of not less than about 20 per cent of tin.)

The plate shall be I. C., base weight 107 pounds or heavier, classified as being of a 20-pound weight as contemplated by Simplified Practice Recommendation No. 30 of the United States Department of Commerce, approved January 1, 1925.

Each "case" package of terneplate of 112 sheets 20 by 28 inches shall have a nominal net weight of not less than 226 pounds with a plus or minus tolerance of approximately 4 per cent.

Each "base box" package of terneplate of 112 sheets 14 by 20 inches shall have a nominal net weight of not less than 113 pounds with a plus or minus tolerance of approximately 4 per cent.

The plates shall have straight edges and square corners and shall be resquared by the plate manufacturer before shipment. (For the purpose of this specification "resquared" shall be understood as meaning that one long side is taken as a base edge without trimming and that the other three sides are trimmed true to it as a base. A deviation of one thirty-second of an inch per foot from square shall be accepted, provided the door manufacturer is able to obtain true, straight joints, and to avoid patching of the rows of sheets in the covering.)

Each plate shall be identified as to the actual manufacturer by means of name or registered trademark and the words "Fire Door Standard," "I. C. 20 lbs." In addition, private brand names or marks may be shown if desired.

NAILS

Core nails shall be cut nails of the clinch type. For 3-ply cores the nails shall be not less than 2½ inches or more than 3 inches long. For 2-ply cores the nails shall be not less than 1½ inches or more than 2 inches long. Nails for applying the metal covering shall be wire nails with flat heads, either full or quarter barbed. The shank of the nails shall be not less than 0.091 inch nor more than 0.109 inch in diameter. The nails for 3-ply cores shall be 2 inches long and for 2-ply cores shall be not less than 1¼ inches nor more than 1½ inches long.

CONSTRUCTION

Assembly of Boards

Only one stock width of board shall be used in any one core. Boards shall be not less than 1 foot in length with ends cut square. Not more than two pieces shall be used in any continuous strip in any outside layer of a 2-ply or 3-ply core, nor more than three pieces in any middle-layer strip of a 3-ply core. At least alternate strips in outside layers shall be full-length boards.

When glass panels are provided and the panel opening is of such a size that the distance between the opening and the edges of the door is less than 2 feet, all boards bordering the vertical edges of the opening may be laid vertically and all boards border-

ing the horizontal edges of the opening may be laid horizontally.

When glass panels are provided, the boards in the normally vertical layers bordering the sides of the panel opening shall be continuous from top to bottom of the door, and boards in the normally horizontal layer bordering the top or bottom of the panel opening shall be continuous from side to side of the door. The distance between the panel opening and the side of the door shall be not less than 7 inches.

Outside layers in a 3-ply core and one layer of a 2-ply core shall be vertical, and the other layer horizontal. The several boards in each layer and the ends of pieces of boards in strips shall make tight joints at edges and ends of boards. The top edge for sliding door or shutter designed to close by gravity shall conform to incline of three-fourths inch per foot. The maximum face width of the top horizontal board of a core having the top edge inclined shall be not less than 3 inches.

Nailing of Cores

The boards shall be nailed so that the several layers are fastened tightly together with the points of the nails turning back and clinching thoroughly in the face of the core and with no portion of the nails projecting beyond the surfaces of the core.

(The full text of this standard includes requirements on the location of rows of nails in the individual boards and the spacing of nails in the nailing of 2-ply and 3-ply cores for various widths of boards used. Illustrations are also given showing nailing details.)

Finished Core

The finished core shall be not less than 2½ inches nor more than 2¾ inches in thickness for a 3-ply core and not less than 1½ inches nor more than 1¾ inches in thickness for a 2-ply core. The cores shall have true corners. All edges shall be finished smooth and square excepting that meeting edges of doors when mounted in pairs may be beveled one quarter inch (not rabbeted).

Size of Plates

Face plates shall be not larger than the 14 by 20 inch size. Corner plates shall be not over 14 inches wide and of any length that will avoid joints with edge plates coming under miter fold. Edge plates (excepting cap plates) shall be of the same width as corner plates and of any convenient length. Cap plates shall be of any convenient length and equal in width to thickness of core plus ¾ inches.

Forming of Plates

Face plates, excepting the face plates used in the row forming the closure, shall have one vertical edge turned five-eighths inch and the other vertical edge doubled under 1½ inches and the doubled edge then turned up five-eighths inch from cut edge.

Face plates, excepting face plates forming top horizontal seams, shall have both horizontal edges turned five-eighths inch to lock with edge and other face plates.

Face plates forming top horizontal seams, excepting seams formed with a cap, shall have the lower horizontal edge turned five-eighths inch to lock with other face plates, and the other horizontal edge doubled under 1½ inches and the doubled edge then turned up five-eighths inch from cut edge.

Face plates forming top horizontal seams with a cap shall have both horizontal edges turned up five-eighths inch to lock with cap and other face plates. Corner plates shall have all edges turned five-eighths inch so as to lock with edge and face plates. Edge plates, excepting cap plates, shall have all edges

turned five-eighths inch so as to lock with corner, face, and other edge plates. Cap plates shall have edges forming seams with other cap plates turned five-eighths inch. Cap plates shall have edges forming top horizontal seams with face and edge plates doubled under $1\frac{3}{16}$ inches and the portion next to the cut edge then turned down five-eighths inch so

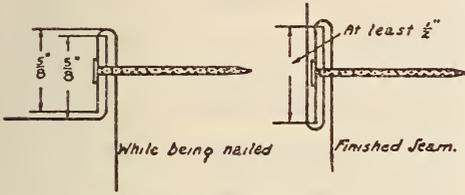

FIGURE 150.—Seams between corner and edge plates

as to lap the edge and face plates as shown in Figure 153.

Application of Plates

The plates shall fit the core as flatly and tightly as practicable. The plates shall be locked together not less than one-half inch. Both faces of the core shall be covered with plates laid with their longer sides vertical, except that the plates in one vertical row on each face of the core may be laid horizontally.

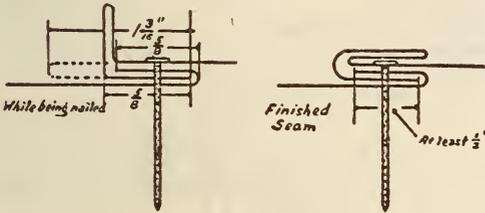

FIGURE 151.—Vertical seams of face plates (top view)

Vertical seams formed with face plates to be hook seams with the upper plate having a fold for covering the heads of the nails in the seam as shown in Figure 151. Horizontal seams formed with face plates, excepting top horizontal seams, shall be hook seams as shown in Figure 152. Top horizontal seams, excepting seams formed with a cap, shall have a fold for covering the heads of the nails in the seam as shown in Figure 151. Top horizontal seams formed with a cap shall be lock seams with the locking por-

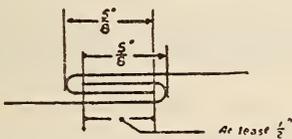

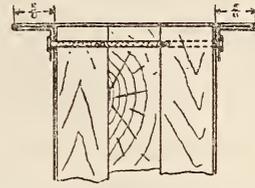

FIGURE 152.—Horizontal seams of face plates (side view)

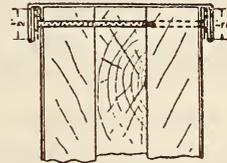

tion of the cap having a fold for covering the heads of the nails in the seam as shown in Figure 153. The upper ends of vertical seams shall be covered by the doubled edges of the top horizontal seams.

Each bottom corner of the core shall be covered with a plate bent over the edges of the core and lapped an equal distance on both faces of the core, making a miter fold (without cutting) on each face, the folds on a door or shutter for use at an opening in an exterior wall being arranged to shed water.

Each upper corner shall be covered the same as the bottom corners if a cap is not used for covering the top edge of the core. The bottom edge and the vertical edges of the core shall be covered with plates bent over the edges of the core and lapped an equal distance on both faces. The plates shall be

While being nailed

Finished Seam

FIGURE 153.—Application of cap plates at top edge of core

joined to each other and to the corners with hook seams, the seams being made so as to shed water when the door or shutter is for use at an opening in an exterior wall. The top edge of the core shall be covered with a cap when the door or shutter is for use at an exterior wall or when the door or shutter has a segmental head. The cap shall be formed of

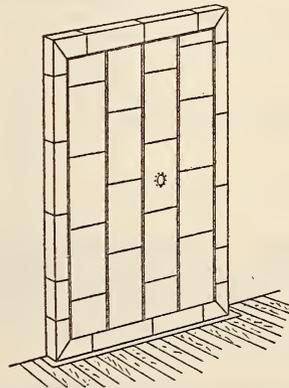

FIGURE 154.—Completed door or shutter showing vent hole

plates joined to each other with hook seams as shown in Figure 150.

When glass panels are provided and band or angle iron reinforcement for glass grooves is used, the vertical edges of the panel opening shall be covered with terne plate secured to the face plates by vertical seams. The covering at the horizontal edges of the opening shall be cap seams.

Nailing of Plates

(This standard includes requirements on the location of nails in the seams, the number of nails on each side of face plate, etc.)

Glass Sizes

Individual lights in doors bearing "Corridor and room partition" labels shall not exceed 1,296 square inches in exposed area or 54 inches in either dimension. Individual lights in doors bearing "Fire escape" labels shall not exceed 720 square inches in exposed area, 54 inches in height, or 48 inches in width.

Splicing of Doors Made in Sections

(The full text of this standard includes structural requirements on the splicing of doors made in sections, including thickness requirements for the splice sheets and sizes of angles or channels for 3-ply and 2-ply doors.)

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, SIMPLIFIED PRACTICE RECOMMENDATION FOR SOLID-SECTION STEEL WINDOWS, R72-32, 1932

STEEL WINDOWS

(This simplified practice recommendation as accepted by industry establishes a standard simplified nomenclature, standard symbol designations, and a limited list of stock, standard, and listed special sizes and types for pivoted windows, pro-

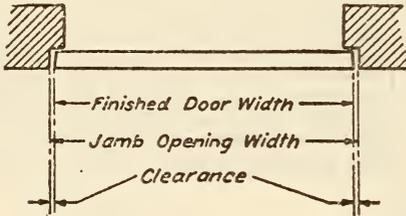

FIGURE 155

jected windows both commercial and architectural, industrial doors, underwriters' labeled windows, continuous windows, and counterbalanced windows. This recommendation as published by the Bureau of Standards includes about 22 plates illustrating these standard sizes and types.)

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, SIMPLIFIED PRACTICE RECOMMENDATION FOR HOLLOW-METAL SINGLE-ACTING SWING DOORS, FRAMES, AND TRIM, R82-28, AUGUST 1, 1928

HOLLOW-METAL DOORS, FRAMES, AND TRIM

(Simplified practice recommended and accepted by industry establishing a limited list of standard stock sizes and types.)

Section 1. SIZES OF DOORS

Designated as jamb-opening sizes. All sizes are measured between rabbets in side jambs and from rabbet in head jamb to finished floor line. (See fig. 155.)

All allowance for clearance and saddles shall be taken off the door.

Semistock

For single doors:

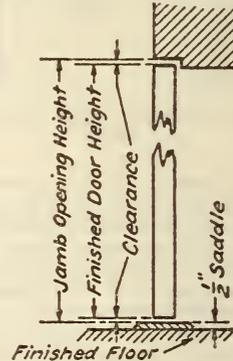

- 2 by 7 feet.
- 2 feet 3 inches by 7 feet.
- 2 feet 6 inches by 7 feet.
- 2 feet 9 inches by 7 feet.
- 3 by 7 feet.
- 3 feet 3 inches by 7 feet.
- 3 feet 6 inches by 7 feet.
- 3 feet 9 inches by 7 feet.
- 4 by 7 feet.

For resultant pairs:

- 4 by 7 feet.
- 4 feet 6 inches by 7 feet.
- 5 by 7 feet.
- 5 feet 6 inches by 7 feet.
- 6 by 7 feet.
- 6 feet 6 inches by 7 feet.
- 7 by 7 feet.
- 7 feet 6 inches by 7 feet.
- 8 by 7 feet.

Section 2. SEMISTOCK TYPES OF DOORS

- 1 panel, solid.
- 1 panel, open for glass.
- 2 panels, solid.
- 2 panels, upper open for 1 light.
- 2 panels, upper open for 4 lights.

jected windows both commercial and architectural, industrial doors, underwriters' labeled windows, continuous windows, and counterbalanced windows. This recommendation as published by the Bureau of Standards includes about 22 plates illustrating these standard sizes and types.)

Semistock sizes of doors, though not carried in stock, are made up from parts which are carried in stock.

Section 3. DOOR CLEARANCES

- $\frac{3}{32}$ inch between hinge stile and jamb.
- $\frac{3}{32}$ inch between lock stile and jamb.
- $\frac{1}{8}$ inch between meeting stiles of doors hung in pairs.
- $\frac{1}{16}$ inch between top rail and head jamb.
- $\frac{3}{16}$ inch between bottom rail and saddle, assuming use of $\frac{1}{2}$ -inch saddle.

NOTE.—All clearances are taken off the door, not from jamb-opening size. Thus the 3 by 7 foot door actually measures 2 feet $11\frac{3}{16}$ inches by 6 feet $11\frac{1}{4}$ inches.

Section 4. DOOR DIMENSIONS

No. 18 U. S. standard gage (0.05 inch) steel for stiles and rails.

No. 20 U. S. standard gage (0.0375 inch) steel minimum for panels.

- No. 18 U. S. standard gage (0.05 inch) steel minimum for panels over 60 inches in height if over 28 inches wide.
- 1 $\frac{3}{4}$ -inch finished door thickness.
- 5-inch face width of stiles and top rail.
- 7-inch face width of lock rail.
- 9 $\frac{3}{8}$ -inch face width of bottom rail.
- 10 inches height of top edge of bottom rail above finished floor line.
- 42 inches height of top edge of lock rail, if any, above finished floor line.
- $\frac{1}{8}$ -inch bevel in 2 inches on lock stile.
- $\frac{1}{8}$ -inch bevel in 2 inches on hinge stile and top rail, if bevel is used.
- $\frac{3}{8}$ -inch allowance for glass, where used (width of groove).

NOTE.—Width of stiles and rails is exclusive of panel molding and is measured on hinge side of door.

Section 5. BUTT MORTISE DETAILS

- 5 inches distance from jamb rabbet to top edge of top butt.
- 10 inches distance from finished floor line to bottom edge of bottom butt.
- X center butt, if any, to be evenly spaced between other two butts.
- $\frac{1}{4}$ inch distance from face edge of door to edge of butt mortise.
- $\frac{5}{16}$ inch distance from stop to edge of butt mortise on frame (thus providing $\frac{1}{16}$ -inch clearance between door and stop).
- X height and depth of individual hinge mortises and the number of mortises shall be governed by the following table:

Template butts

Width (inches)	Height (inches)	Number of butts	Size	Weight of butts	Template letter
To 32-----	(To 60-----)	2	4 $\frac{1}{2}$	Regular-----	A
	(Over 60 to 90-----)	3	4 $\frac{1}{2}$	-----do-----	A
	(Over 90 to 120-----)	4	4 $\frac{1}{2}$	-----do-----	A
Over 32 to 37----	(To 60-----)	2	5	-----do-----	A
	(Over 60 to 90-----)	3	5	-----do-----	A
	(Over 90 to 120-----)	4	5	-----do-----	A
Over 37 to 43----	(To 60-----)	2	5	Extra heavy.	B
	(Over 60 to 90-----)	3	5	-----do-----	B
Over 43 to 50-----	-----do-----	3	6	-----do-----	B
	(Over 90 to 120-----)	4	6	-----do-----	B

NOTE.—The above table is based on underwriters' requirements that 2 butts shall be used for doors measuring 5 feet or less in height and that doors of a greater height shall require 1 butt for each 2 $\frac{1}{2}$ feet or fraction thereof of height. Sizes given refer only to length of joint. Template letters refer to templates recommended as standard by the Advisory Committee on Standardization of Hardware for hollow-metal doors, December 1, 1923.

(For further details see United States Government, Department of Commerce, Bureau of Standards, Commercial Standard CS9-29. See 617.12, p. 982.)

Section 6. LOCK MORTISE DETAILS

- No. 16 U. S. standard gage (-0.0625 inch) steel, minimum for box placed within lock stile as reinforcement for lock and escutcheons.
- 39 $\frac{1}{2}$ inches height of center line of lock mortise above finished floor line, or 38 $\frac{1}{4}$ inches height of center line of lock mortise above bottom edge of door.
- 8 inches (+0.015-0.000) height of mortise for lock front.
- 1 $\frac{1}{4}$ inches (+0.015 -0.000) width of mortise for lock front.
- $\frac{3}{32}$ inch depth of mortise for lock front.

- 6 $\frac{1}{4}$ inches height of mortise for lock case (centered on height of mortise for lock front).
- 1 $\frac{1}{4}$ inches width of mortise for lock case (coincident with width of mortise for lock front).
- 4 $\frac{1}{4}$ inches minimum depth of mortise for lock case (clearance for lock inside stile).
- 3 $\frac{1}{2}$ inches distance from center of beveled door edge to beginning of contact between lock case and spring-leaf reinforcement for rear edge of case.
- 4 $\frac{3}{8}$ inches distance from center of beveled door edge to termination of contact between lock case and spring-leaf reinforcement for rear edge of case.
- $\frac{3}{4}$ inch normal distance between contact planes of the two spring-leaf reinforcements for rear edge of lock case.
- $\frac{1}{8}$ inch maximum distance which each spring reinforcement may be required to be sprung by insertion of lock case.
- 1 inch approximate width of bearing planes of spring reinforcements.
- 4 inches height of center line of spring reinforcements above bottom edge of lock front (or coincident with center line of lock.)
- $\frac{3}{8}$ inch (+0.005 -0.005) distance from center of lock front mounting screw holes to top or bottom edge of lock front.
- $\frac{5}{8}$ inch (+0.005 -0.005) distance from center of lock front mounting screw holes to vertical edge of lock front.
- No. 12-24 F. H. machine screw for mounting lock front (drill and tap accordingly).
- $\frac{1}{4}$ inch distance from either vertical edge of lock front mortise to face edge of door (thus centering lock front on beveled edge of lock stile).
- 2 $\frac{1}{4}$ inches backset for knobs, cylinders, thumb pieces, etc.

Section 7. STRIKE MORTISE DETAILS

- 39 $\frac{1}{2}$ inches height of center line of strike mortise above finished floor line (thus giving strike and lock front a common horizontal center line).
- 5 $\frac{3}{4}$ inches (+0.015 -0.000) height of mortise for body of strike.
- 1 $\frac{1}{4}$ inches (+0.015 -0.000) width of mortise for body of strike.
- 3 $\frac{1}{4}$ inches height of mortise for strike lip (centered on height of mortise for body of strike).
- X mortise for strike lip to provide for carrying lip beyond edge of jamb.
- $\frac{5}{32}$ inch depth of mortise for flat universal strike.
- $\frac{3}{8}$ inch (+0.005 -0.005) distance from center of strike mounting screw holes to top or bottom edge of strike.
- $\frac{5}{8}$ inch (+0.005 -0.005) distance from center of strike mounting screw holes to vertical edge of body of strike.
- No. 12-24 F. H. machine screw for mounting strike (drill and tap accordingly).
- $\frac{1}{4}$ inch distance from stop to edge of mortise for strike (thus making vertical center line of body of strike coincident with vertical center line of lock front).

NOTE.—Dimensions of strike box to be determined later.

NOTE.—Details for lock mortise and strike mortise will admit standard cylinder lock for hollow-metal doors and the universal strikes approved by the Manufacturers' Advisory Committee on Standardization of Builders' Hardware, CS1007b, April, 1928. (See United States Government, Department of Commerce, Bureau of Standards, Commercial Standard CS9-29, for builders' template hardware. See 617.21, p. 1020.)

Section 8. TRANSOM DIMENSIONS

- No. 18 U. S. standard gage (0.05 inch) steel, minimum for all stiles and rails.
- 2 inches face width of all stiles and rails, exclusive of panel molding.
- $\frac{3}{32}$ inch clearance all around.
- $\frac{3}{8}$ inch allowance for glass (width of groove).

2 inches face height of transom bars between rabbets.

1 3/4 inches thickness of transom.

3 inches from rabbet in side jamb to edge of butt, where butts are used.

NOTE.—Transom sizes are measured between rabbets with clearances taken off transom.

NOTE.—Where butts are used, both leaves are mortised into sash. Size and number of mortises are to be in accordance with the following table.

Width (inches)	Height (inches)	Number of butts	Size	Weight of butts	Tem-plate letter
To 48.....	To 20.....	2	3	Regular...	A
Over 48 to 72.....do.....	3	3do.....	A
To 48.....	Over 20 to 36.....	2	3 1/2do.....	A
Over 48 to 72.....do.....	3	3 1/2do.....	A

Section 9. ROUGH BUCK DIMENSIONS

No. 16 U. S. standard gage (0.0625 inch) steel, minimum for rough bucks.

1 inch height of clear opening in excess of jamb-opening height.

2 inches clear opening width in excess of jamb opening (1 inch on a side).

4 1/2 inches } Standard finished wall thicknesses
5 1/2 inches } (bucks cover full thickness of wall).
7 1/2 inches }

2 inches width of flanges.

24 inches O. C. approximate spacing for perforated, corrugated, or wire anchors.

Section 10. CABINET JAMB DIMENSIONS

No. 18 U. S. standard gage (0.05 inch) steel, minimum for cabinet jambs.

No. 16 U. S. standard gage (0.0625 inch) steel, minimum for cabinet jambs over 7 1/2 inches in width.

1 15/16 inch door rabbet in jamb.

3/8 inch height of stop.

2 inches width of flanges.

Section 11. CASING DIMENSIONS

4 inches maximum face width.

1 1/8 inches maximum projection.

3/8 inch setback for trim.

Section 12. COMBINATION FRAME DIMENSIONS

No. 16 U. S. standard gage (0.0625 inch) steel, minimum for combination frame.

1 15/16 inch door rabbet in jamb.

5/8 inch height of stop.

24 inches O. C. approximate spacing for perforated, corrugated, or wire anchors.

Section 13. COMBINATION FRAME TYPES

- (a) With 2 1/2-inch flange finishing flush with plaster and forming flush trim on both sides of wall.
- (b) With molded flanges, the molding being formed from the stock of the flange.
- (c) With molded flanges planted on, becoming an integral part of the flange.
- (d) With standard casings.

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, SIMPLIFIED PRACTICE RECOMMENDATION FOR KALAMEIN SINGLE-ACTING SWING DOORS, FRAMES, AND TRIM, R83-28, APRIL 1, 1928

KALAMEIN DOORS, FRAMES, AND TRIM

(Simplified practice recommended and accepted by industry establishing a limited list of standard stock sizes.)

Section 1. SIZES OF DOORS

Designated as jamb-opening sizes.

All sizes as given shall be considered the size between the jambs in the rabbet and from the jamb head in rabbet to the finished floor.

All allowance for clearance and saddles shall be taken off door.

Stock Door Sizes

2 feet 6 inches by 7 feet.

2 feet 9 inches by 7 feet.

3 by 7 feet.

3 feet 6 inches by 7 feet.

Semistock Door Sizes

For single doors:

2 by 7 feet.

2 feet 3 inches by 7 feet.

3 feet 3 inches by 7 feet.

3 feet 9 inches by 7 feet.

4 by 7 feet.

For resulting pairs:

4 by 7 feet.

4 feet 6 inches by 7 feet.

6 feet 6 inches by 7 feet.

7 feet 6 inches by 7 feet.

8 by 7 feet.

Semistock door sizes, though not carried in stock, are made up from parts which are carried in stock.

Section 2. STOCK TYPES OF DOORS

1 solid panel.

2 solid panels.

2 panels upper open for glass.

1 panel open for glass.

NOTE.—Two-panel doors, upper open for four lights of glass, are considered as semistock.

Section 3. DOOR CLEARANCES

3/32 inch between hinge stile and jamb.

3/32 inch between lock stile and jamb.

1/8 inch between meeting stiles of doors hung in pairs.

1/16 inch between top rail and head jamb.

3/16 inch between bottom rail and saddle.

1/2 inch saddle.

NOTE.—All clearances are taken off the door, not from jamb-opening sizes. Thus the stock 3 foot by 7 foot door actually measures 2 feet 11 1/4 inches by 6 feet 11 1/4 inches.

Section 4. DOOR DIMENSIONS

1 3/4-inch finished door thickness.

5-inch face width of stiles and top rail, exclusive of paneled molding.

7-inch face width of lock rail, exclusive of paneled molding.

9 5/16-inch face width of bottom rail, exclusive of paneled molding.

10-inch height of top edge of bottom rail from finished floor line.

42-inch height of top edge of lock rail, if any, from finished floor line.

1/8-inch bevel in 2 inches on both hinge and lock stile.

NOTE.—Top of top rail and bottom of bottom rail shall be square.

Section 5. STANDARD JAM DETAILS

Standard door rabbet, 1 1/16 inches.

Standard height to stop, 3/8 inch for steel bucks.

Standard height of stop, 1/2 inch for metal covered jambs.

NOTE.—Hinge stile of door when hung will have 1/16-inch clearance between door and jamb stop.

Section 6. GAGE OF METAL

26 Gage U. S. Standard (0.01875 inch) for commercial doors.

Section 7. BUTT MORTISE DETAILS

5 inches distance from jamb rabbet to top edge of top butt.
 10 inches distance from finished floor line to bottom edge of bottom butt.

X center butt, if any, to be evenly spaced between other two butts.

For butts 5 inches and larger used with 1⁵/₁₆-inch rabbet and 1³/₄-inch doors the distance between stop and rear edge of butt is ⁵/₁₆-inch on jamb, and from the rear edge of butt to edge of door ¹/₄ inch.

When 4-inch butts are used with 1³/₁₆-inch rabbet, these distances will be ¹/₂ inch on jamb and ⁷/₁₆ inch on door.

For spring hinges used with 1¹/₁₆-inch rabbet these sizes will be:

For 6-inch single-acting hinge, ⁹/₁₆ inch on jamb, ¹/₂ inch on door.

For 7-inch single-acting hinge, ⁷/₁₆ inch on jamb, ³/₈ inch on door.

For 8-inch single-acting hinge, ⁵/₁₆ inch on jamb, ¹/₄ inch on door.

For 10-inch single-acting hinge, ⁵/₁₆ inch on jamb, ¹/₄ inch on door.

605.23 STEEL TANKS, TOWERS, AND FLUMES.

AMERICAN PETROLEUM INSTITUTE, SPECIFICATIONS FOR STANDARD RIGS AND DERRICKS, STANDARD NO. 4 (FIFTH EDITION), JULY, 1931

STEEL DERRICKS

Section 1. MATERIAL COVERED

1. (a) These specifications cover the major dimensions of steel and wood derricks, including heights, bases, and water-table openings; also of standard rig parts, including Samson posts, walking beams, bull wheels, calf wheels, and band wheels. They cover also the safe working and wind load capacities of derricks and the working capacities of Samson posts and walking beams, together with the methods of computing these capacities.

(b) The standards contained herein are primarily dimensional, but they include also the minimum physical properties of material in so far as the strength computations require the use of unit stress figures, and apply to new material.

Section 2. WORKMANSHIP AND FINISH

2. (a) *Machined surfaces.*—All machined surfaces shall be finished in a good and workmanlike manner and shall be free from burrs, rough edges, etc.

(b) *Castings.*—All castings shall be thoroughly cleaned and all cored holes shall be drifted to insure free passage of proper size bolts.

(c) *Protective covering.*—All forged or rolled steel parts or sections, and all cast material shall be covered before shipment, with a good grade of commercial paint (or shall be galvanized), except such surfaces as are machined for bearing service, which latter shall be protected with a suitable lubricant or compound.

Section 3. STEEL DERRICK DIMENSIONS

Definitions of Measurements

3. (a) *Derrick heights.*—The height dimension "A" shall be measured along the neutral axis of the derrick leg from the top of the derrick floor joists to the bottom of the water-table beams or bumpers, with a tolerance of plus 6 inches, minus zero.

(b) *Derrick bases.*—Shall be square, and base square dimensions "B" shall be the measurement between the neutral axis of adjacent legs measured

at the top of the derrick floor joists, with a tolerance of 4¹/₂ inches plus or minus. Base dimension "B" is a fixed dimension which permits interchangeability of several-height derricks of this group on common-sized bases.

(c) *Water-table opening.*—Shall be square, and water-table opening dimension "D" shall be the inside or in-the-clear measurement of the opening in the water table, with a tolerance of 2 inches plus or minus.

Steel Derrick Sizes

(d) *Derrick heights, bases, and water-table openings.*—The standard sizes of A. P. I. steel derricks shall be as specified in Table 1. The eight sizes may be referred to by numbers, and each size shall have only the particular combination of height "A," base square "B" and water-table opening "D" as given.

TABLE 1.—A. P. I. steel-derrick standard sizes

Size No.	Heights		Base squares		Water-table opening	
	Nominal "A"	Tolerance	Nominal "B"	Tolerance	Nominal "D"	Tolerance
8	<i>Ft. in.</i> 66 0	<i>Inches</i> +6-0	<i>Ft. in.</i> 20 0	<i>Inches</i> ±4 ¹ / ₂	<i>Ft. in.</i> 4 4	<i>Inches</i> ±2
9	73 0	+6-0	20 0	±4 ¹ / ₂	4 4	±2
10	80 0	+6-0	20 0	±4 ¹ / ₂	5 6	±2
11A	87 0	+6-0	20 0	±4 ¹ / ₂	5 6	±2
11	87 0	+6-0	24 0	±4 ³ / ₈	5 6	±2
12	94 0	+6-0	24 0	±4 ³ / ₈	5 6	±2
16	122 0	+6-0	24 0	±4 ³ / ₈	5 6	±2
18	136 0	+6-0	26 0	±4 ³ / ₈	5 6	±2

Steel Derrick Parts Dimensions

(e) *Gin pole.*—The gin pole shall be constructed so as to extend across the center of the water-table opening. The clearance between the gin pole and the base of the crown block shall be 8 feet 0 inch minimum for derricks under 122 feet in height, and shall be 10 feet 0 inch minimum for derricks 122 feet and over in height.

(f) *Window opening of steel derricks for rotary drilling.*—On steel derricks for rotary drilling, the minimum window opening height shall be 23 feet 8 inches in the clear, measured parallel to the center line of the derrick side from the top of the derrick floor joists, and a calf wheel girt shall be provided for cable tool work.

(g) *Bull wheel girt clearance.*—The distance in the clear from the bull wheel girt to the top of the derrick floor joists shall be 9 feet 6 inches ±¹/₈ inch, measured parallel to the center line of the derrick side.

(h) *Calf wheel girt clearance.*—The distance in the clear from the calf wheel girt to the top of the derrick floor joists shall be 11 feet measured parallel to the center line of the derrick side, with a tolerance of plus or minus one-eighth inch.

(i) *Corner foundation bolt settings.*—At each A. P. I. steel derrick corner foundation there shall be set two 36-inch foundation bolts, 1 to 1¹/₄ inches in diameter, with upper ends threaded 6 inches with U. S. standard thread. These bolts shall be set on the sides of a square 12 inches larger than the nominal base square without tolerance, and located 10 inches plus or minus one-eighth inch from the corner of said larger square. Said bolts shall be set to protrude 6 inches above foundations. The foundation bolt holes in the derrick base shall be 1³/₈ inches in diameter.

(j) *Center of drill hole.*—The center of the drill hole shall be 6 inches from the center of the derrick base on the center line towards the Samson post, with a tolerance of plus or minus one-half inch.

Section 4. STEEL DERRICK STRENGTH OR CAPACITY REQUIREMENTS

4. (a) *Structural material.*—Structural steel used in the construction of A. P. I. steel derricks shall be new and shall conform to the requirements of the American Society for Testing Materials, "Standard Specifications for Structural Steel for Buildings," serial designation A-9-24 (see 605.12, p. 252), or A. S. T. M. "Standard Specifications for Structural Silicon Steel," serial designation "A94-29," as amended to date. (See 621.33, p. 1126.) Tubular steel used in construction of A. P. I. steel derricks shall be new and shall conform to A. P. I. pipe specifications as amended to date. (See A. P. I. Stds. No. 5-A.) (See 607.4, p. 444.) Structural lumber used for reinforcing legs in A. P. I. steel derricks shall be new and shall conform to the requirements of the American Lumber Standards for select or dense select grades as given in the revised Simplified Practice Recommendation No. 16 of the United States Department of Commerce.

(b) *Unreinforced safe-load capacity.*—The A. P. I. safe-load capacity of an A. P. I. derrick without leg reinforcing, expressed in pounds, shall be the gross capacity of the derrick, and shall be specified on the name plate. It shall be equal to the sum of the strengths of the four unreinforced legs at their weakest section.

(c) *Reinforced safe-load capacity.*—The A. P. I. safe-load capacity of an A. P. I. derrick, with leg reinforcing, expressed in pounds, shall be the gross capacity of the derrick when reinforced with properly applied reinforcing legs of a particular size. It shall be equal to the sum of the strengths of the four reinforced legs at their weakest section, the strength of each reinforced leg to be the sum of the strengths of the two or more leg elements. Both the safe-load capacity when reinforcing legs are used and the size, weight per foot, and type of section of the leg reinforcing shall be specified on the name plate.

Safe-Load Capacity Determinations

(d) (1). The leg members or reinforcing leg members of an A. P. I. derrick shall be classified as "Main compression member," and their *l/r* ratio shall not exceed 120. The A. P. I. safe-load capacities of A. P. I. derricks shall be determined by computing the sum of the strengths of the four leg members at their weakest section plus the sum of the strengths of the four reinforcing leg members at their weakest section, if the derrick is reinforced, considering same as columns unsupported between adjacent panel points, and determined in accordance with the column formula of the American Institute of Steel Construction, to wit:

For ratios of *l/r* up to and including 60

$$P/a = 15,000$$

and for ratios of *l/r* greater than 60,

$$P/a = \frac{18,000}{1 + \frac{l^2}{(18,000)(r^2)}}$$

where

- P* is the total compression load in pounds.
- a* is the gross cross-sectional area of the column or leg element in square inches.
- l* is the unsupported length of the column or leg element between adjacent panel points in inches.
- r* is the corresponding least radius of gyration of the column cross section in inches.

(2) The formula given in paragraph 4-d-1 shall apply to derricks fabricated of structural steel or steel pipe having a minimum yield point of 30,000 pounds per square inch; structural steel or pipe having a yield point of less than 30,000 pounds per square inch shall not be used in the construction of A. P. I. derricks.

(This specification contains a tentative formula for determining the safe-load capacity of leg members of derricks made of silicon structural steel of A. S. T. M. specification A94-29. Requirements for determining the safe-load capacity of wooden reinforcing legs are also given.)

(e) *Wind-load capacity.*—The A. P. I. wind-load capacity of an A. P. I. derrick, expressed in miles per hour, shall be the maximum wind velocity that the unboarded derrick can withstand without failure, assuming the four legs to be anchored solidly and the derrick to be unguyed, and shall be specified on the name plate. Every A. P. I. steel derrick shall have a minimum A. P. I. wind-load capacity of 70 miles per hour, as indicated by the United States Weather Bureau's standard Robinson 4-cup anemometer.

(This specification also contains requirements on methods of determining wind-load capacity, requirements on leg joints, determinations of strengths of joints, girts, and braces, design of water-table beams, computation details, standard headboard connections, standard bull wheel and calf wheel post connections, standard dimensions and locations of rig parts such as Samson post, walking beams, bull wheel, bull-wheel shaft, calf wheel, calf-wheel shaft, band wheel, bull-rope grooves, etc., standard rig strength and capacity requirements, marking, and inspection requirements.)

(The inspection requirements include the item given below.)

All tests and inspection shall be made at the place of manufacture prior to shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

AMERICAN PETROLEUM INSTITUTE, SPECIFICATIONS FOR STANDARD TANKS WITH RIVETED SHELLS, STANDARD NO. 12-A WITH SUPPLEMENT NO. 2, JULY, 1931

RIVETED TANKS FOR OIL STORAGE

(The American Petroleum Institute can supply detail drawings of seven standard tanks from 36 to 144 feet in diameter and also detail drawings for manholes, oil connections, drain connections, roof openings, and stairways. The use of appurtenances shown on these drawings, or designs of equivalent strength and tightness, will be required on tanks to which the A. P. I. monogram is attached.)

The following table shows the range of capacities that can be obtained using 11 different diameters and varying the height:

TABLE 1.—Tank sizes

Diameter (feet)	Nominal height (feet)						
	12	17½	23½	29½	35	40½	46
	Number of courses						
	2	3	4	5	6	7	8
	Capacity in 42-gallon barrels; approximately level full						
12	240	360	480	590	720	-----	-----
18	540	810	1,070	1,340	1,600	-----	-----
24	960	1,440	1,910	2,380	2,850	-----	-----
30	1,500	2,440	2,980	3,710	4,450	-----	-----
36	2,160	3,400	4,300	5,400	6,400	7,400	8,400
48	3,850	5,730	7,600	9,500	11,300	13,200	15,000
60	5,960	8,880	11,800	15,000	17,500	20,500	23,500
78	-----	-----	-----	25,000	30,000	35,000	39,500
102	-----	-----	-----	42,500	51,000	59,000	68,000
120	-----	-----	-----	59,000	70,000	82,000	93,000
144	-----	-----	-----	85,000	101,000	118,000	134,000

PART I. DESIGN SPECIFICATIONS

Section 1. Material

1. The various materials used shall conform in chemical and physical properties to the following specifications:

2. *Plates*.—Either class "A" Association of American Steel Manufacturers, current A. S. T. M. A-7 (see 605.11, p. 249) or current A. S. T. M. A-9 (open-hearth steel only) (see 605.12, p. 252).

3. Copper-bearing steel may be used for roof plates if so specified by the purchasers.

4. Plate specification by weight is recommended, and plates purchased on weight specifications shall individually comply with the normal tolerances as they appear in these specifications.

NOTE.—Where plates are referred to by thickness in the specification, or on the drawings, the thickness shall be considered as nominal only.

5. *Structural steel*.—Current A. S. T. M. A-9. (See 605.12, p. 252.)

6. *Rivets for hot driving*.—Either current A. S. T. M. A-7 (see 605.11, p. 249) current A. S. T. M. A-31, or A. S. M. E. Boiler Code (see 603.21, p. 144).

7. *Rivets for cold driving*.—Rivets conforming to either of the above specifications, annealed.

If copper bearing steel is specified for the roof plates, the rivets shall contain the same percentage of copper.

Section 2. Shell Design

Loads and working stresses.—

8. Stresses are to be computed on the assumption that the tank is filled level full of water at 60° F., and the tension in each ring is to be computed 12 inches above the bottom gage line of the ring in question.

9. In computing net section of plate, rivet holes when punched one-sixteenth inch over nominal diameter for hot driven rivets, are to be assumed one-eighth inch larger than nominal diameter of the rivet; when punched one-thirty-second inch over nominal diameter for cold driven rivets, holes are to be assumed three thirty-seconds inch larger than nominal diameter of rivet. When drilled, or when subpunched and reamed, holes are to be assumed one-sixteenth inch larger in diameter than nominal diameter of rivet. The net section of rivet to be used for computing shear values should be, in the case of hot driven rivets, nominal diameter plus one-sixteenth inch; in case of cold driven, nominal diameter plus one thirty-second inch.

10. All openings over 4 inches in diameter in the shell of the tank shall be reinforced. This reinforcement may be the flange of the fitting used, or an additional ring of metal, or both flange and ring.

11. The amount of reinforcement shall be determined in accordance with paragraph 1 of Appendix "A," attached to these specifications.

12. The following maximum allowable working stresses shall be used in design:

Maximum tensile stress in net section of plate.—21,000 pounds per square inch.

Maximum shear in net section of rivet.—16,000 pounds per square inch.

Maximum bearing stress on plates or rivets.—35,000 pounds per square inch when rivets are in double shear; 32,000 pounds per square inch when rivets are in single shear.

Sizes of plate and tank.—

13. Tanks shall be designed so that the diameter is a multiple of 6 feet, using shell plates having a net length (total length minus lap) of 6π feet (6 times 3.1416). The number of plates in each course will thus be equal to the diameter of the tank divided by 6. Shell plates shall have an over-all width of 72 inches.

14. The minimum thickness of shell plates shall be one-fourth inch in tanks over 48 feet in diameter, and shall be three-sixteenths inch in tanks 48 feet or less in diameter.

(This specification also contains requirements on the arrangement of parts, suggested rivet sizes, requirements on rivet spacing, and spacing of rivets from edge of plate.)

Section 3. Roof Design

22. Conical steel roof and supporting structure shall be designed to carry a live load of 25 pounds per square foot in addition to the dead load, and the supporting structure shall be designed in accordance with current American Institute of Steel Construction "Standard Specifications for the Design, Fabrication, and Erection of Structural Steel for Buildings," except that the value of l/r shall not exceed 180. Structural shapes shall be used for roof columns. The slope of the roof shall be one-half inch in 12 inches, except that the slope of the self-supporting roof of the 12-foot tank shall be 2 inches in 12 inches.

23. Roof plates shall be three-sixteenths inch thick, 72 inches wide, and shall have the same approximate length as three-sixteenths-inch shell plates. They may be either riveted or welded; if riveted, rivets shall be seven-sixteenths inch at $1\frac{1}{2}$ -inch pitch.

24. Rafters are to be spaced so that in the outer row there shall be not less than three rafters to each shell plate; spacing on inner rows is not to be greater than $5\frac{1}{2}$ feet.

Section 4. Bottom Design

Plate sizes.—

25. All rectangular bottom plates shall be one-fourth inch thick, 72 inches wide, and shall have the same approximate lengths as one-fourth-inch shell plates. These may be either riveted or welded.

26. Bottom sketch plates in tanks over 48 feet in diameter shall be five-sixteenths inch thick and 72 inches wide. Sketch plates in tanks 48 feet in diameter and less shall be one-fourth inch thick and 72 inches wide.

Rivets.—

27. For tanks with riveted bottoms the rivets shall be five-eighths inch in diameter.

Welded construction.—

28. Tanks with welded bottoms shall have all plates lapped a minimum of 1 inch and electric welded with a continuous fillet-weld.

29. Not less than 4 inches inside the bottom angle the welded lap joints on the bottom sketch plates shall be changed to welded butt-joints and continue thus underneath the angle to the end of the plate.

30. The bottom angle, for tanks with welded bottoms, shall be placed on the outside of the shell with the horizontal leg turned out. The vertical leg of the angle shall be riveted to the tank shell in accordance with the standard punching in the shell plate. The horizontal leg of the angle shall be welded to bottom plates with continuous fillet-welds at toe and heel of angle.

(Regulations concerning the identification of tanks by means of a special nameplate bearing the A. P. I. monogram are included in this specification.)

(Part II of this specification is made up of fabrication specifications for tanks and Part III covers erection specifications. The required tests for tanks are as given below.)

Testing and lowering of bottom.—The bottom and lower part of the first course of tank, when riveted bottoms are specified, shall be riveted and calked while supported above the grade. Where a welded bottom is specified the bottom shall be welded on the tank grade and one or more shell courses riveted up before the bottom is tested.

Where water is available, the tightness of a riveted bottom shall be tested with 6 inches of water before being lowered to foundation; bottom shall be entirely tight to the satisfaction of the purchaser's inspector before lowering.

For a tank with welded bottom and where water is not available for a tank with riveted bottom, tightness shall be tested by pumping oil underneath bottom and maintaining a head of 6 inches by holding that depth around the edge inside a temporary dam. The bottom shall be made entirely tight to the satisfaction of the purchaser's inspector. Oil for the above test shall be supplied by the purchaser.

Testing shell and roof.—Upon completion, the entire tank shell shall be tested by filling with oil or water to the level of the top angle. If it is not feasible to fill the tank as indicated, the test may be made by painting all seams on the inside with a highly penetrating oil, such as automobile spring oil, examining the outside of the seams for leakage. All leaks discovered by the above tests shall be stopped.

The roof shall be tested by applying an internal air pressure equivalent to not less than one-half inch of water, and applying strong soap solution to all seams. All leaks discovered shall be stopped.

Before acceptance, entire tank, when filled with oil, must be tight and free from leaks.

(The appendix to this specification contains details of design for small tanks and for large tanks, methods of computing reinforcement for openings in tank shell, method of computing working stresses in riveted butt-strap joints, tables on strength of butt joints and of lap joints.)

plier shall furnish gasket material of such texture and thickness that it will provide oil-tight connections in these joints.

(b) Gages of material as shown in Table 1 are minimum thicknesses acceptable under these standards; heavier material may be required at option of purchaser.

Fabrication

2. (a) Nominal spacing of all bolt holes is 2 inches. In bottoms and decks 3/4-inch minimum edge distance shall be provided for the vertical stave joints. Vertical seams having two or more rows of bolts shall be square pattern, with 2-inch gage between lines of holes. All bolt holes shall be laid out so that after bending and flanging they conform to the specified dimensions.

(b) Bolt holes shall be one thirty-second inch greater in diameter than the nominal diameter of the bolt.

(c) Bolts in chime of cone roof shall be three-eighths inch for 100 and 200 barrel tanks of which the upper course is 14-gage material, and one-half inch for all other tanks.

(d) Wherever 12-gage or heavier material is used, bolts shall be one-half inch.

Erection

3. (a) The stave design contemplates that they shall be assembled in a counterclockwise direction.

(b) The dimensions of Table 1 assume that most of the 1/32-inch slack, due to bolt clearances, will be taken up in all stave joints in erecting the tank. Bolts are expected to come nearer bearing in tension on vertical joints, and in compression against the roof and bottom, than being centered in their holes when the tank is fitted together, before filling. At vertical stave joints, some "pinning" will be required to squeeze gasket down to 1/16-inch thickness assumed in design.

Roof Pitch

4. (a) Pitch of cone roof shall be 1 inch in 12 inches.

AMERICAN PETROLEUM INSTITUTE, DIMENSIONAL SPECIFICATIONS FOR STANDARD BOLTED TANKS, STANDARD NO. 12-B, SECOND EDITION, JULY, 1931

BOLTED TANKS

Section 1. GENERAL DETAILS

Material

1. (a) Joints are designed on the assumption of 1/16-inch final net thickness of gasket in place. Sup-

TABLE 1.—A. P. I. dimensional specifications for bolted tanks

¹ Nominal inside diameter is considered as 2 inches less than bolt-circle diameter and actual capacity figured on that basis.

² Wherever 12-gage or heavier material is used, bolts shall be 1/2 inch. See pars. 2. (c) and (d).

(This specification also includes a detail drawing of a standard stove for bolted tanks showing bolt spacings and layouts, not shown herewith. Regulations are also included covering the identification of tanks manufactured in accordance with this specification by the use of the A. P. I. monogram.)

AMERICAN RAILWAY ENGINEERING ASSOCIATION, STEEL SUBSTRUCTURES FOR WATER TANK, 50,000 AND 100,000 GALLONS CAPACITY, 1921

STEEL SUBSTRUCTURES

GENERAL

1. The structure will consist of a 12-post steel tower, complete in all details for supporting a wooden water tank of the specified size and capacity at the required elevation. The intent of the plans and specifications is to include all material required between the top of foundation and the bottom of tank.

MATERIAL

2. Except as may be herein noted all metal in the structure will be made in accordance with specifications of the association as given in part second, Iron and Steel Structures, Manual of Recommended Practice.

WORKMANSHIP

3. Except as may herein be noted, workmanship on the structure will be performed in accordance with the requirements of the association as given in part second, Iron and Steel Structures, Manual of Recommended Practice.

PAINTING

4. Steel work before leaving the shop shall be thoroughly cleaned and given one good coat of red lead ground in linseed oil or such paint as may be specified by the engineer. Except as herein noted, cleaning and painting shall be done in accordance with specifications of the association as given in part second, Iron and Steel Structures, Manual of Recommended Practice.

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR STEEL WATER AND OIL TANKS, 1912

WATER AND OIL TANKS

SCOPE OF SPECIFICATIONS

1. These specifications are intended for steel tanks requiring plates not more than five-eighths inch thick.

QUALITY OF METAL

2. The metal in these tanks shall be open-hearth steel. The steel shall conform in physical and chemical properties to the specifications for steel railway bridges. (See 605.11, p. 249.)

LOADING

3. The weight of water shall be assumed to be 63 pounds, crude oil 56 pounds, and creosote oil 66 pounds per cubic foot. Wind pressure, acting in any direction, shall be assumed to be, in pounds, thirty times the product of the height by two-thirds of the diameter of the tank in feet.

UNIT STRESSES

4. Unit stresses shall not exceed the following:
(a) Tension in plates, 15,000 pounds per square inch

on net section; (b) shear plates, 12,000 pounds per square inch on net section; (c) shear on rivets, 12,000 pounds per square inch on net section; and (d) bearing pressure on field rivets, 20,000 pounds per square inch.

CYLINDRICAL RINGS

5. Plates forming the shell of the tank shall be cylindrical and of different diameters, in and out, from course to course.

WORKMANSHIP

6. Workmanship shall be first class. Plates shall be beveled on all edges for calking after being punched. The punching shall be from the surface to be in contact. The plates shall be formed cold to exact form after punching and beveling. Rivet holes shall be accurately spaced. Drift pins shall be used only for bringing the parts together. They shall not be driven with enough force to deform the metal about the holes. Power riveting and calking should be used. A heavy yoke or pneumatic buckler shall be used for power-driven rivets. Riveting shall draw the joints to full and tight bearing.

CALKING

7. The tank shall be made water or oil tight by calking only. No foreign substance shall be used in the joints. For water tanks, the calking shall preferably be done on the inside of tank and joint only; but for oil tanks the calking should be done on both sides. No form of calking tool or work that injures the abutting plate shall be used.

MINIMUM THICKNESS OF PLATES

8. The minimum thickness of plates in the cylindrical part of the tank shall be not less than one-fourth inch and in flat bottoms not less than five-sixteenths inch. In curved bottoms the thickness of plate shall be not less than that of the lower plate in the cylindrical part.

HORIZONTAL AND RADIAL JOINTS

9. Lap joints shall generally be used for horizontal seams and splices and for radial seams in curved bottoms.

VERTICAL JOINTS

10. For vertical seams and splices, lap joints shall be used with plates not more than three-eighths inch thick. With thicker plates, double butt joints with inside and outside straps shall generally be used. The edge of the plate in contact at the intersection of horizontal and vertical lap joints shall be drawn out to a uniform taper and thin edge.

RIVETS, RIVET HOLES, PUNCHING AND PITCH

11. For plates not more than three-eighths inch thick, $\frac{3}{8}$ -inch rivets shall be used. For thicker plates, $\frac{1}{2}$ -inch rivets shall be used. The diameter of rivet holes shall be one-sixteenth inch larger than the diameter of the rivets used. The punching shall conform to the specifications of this association for such work on steel bridges. A close pitch, with due regard for thickness of plate and balanced stress between tension on plates and shear on rivets, is desirable for calking.

TANK SUPPORT

12. If the tank is supported on a steel substructure, the latter shall conform to the specifications of this association for the manufacture and erection of steel bridges, except that allowance shall be made for wind pressure but not for impact.

PAINTING

13. In the shop the metal shall be cleaned of dirt, rust, and scale and, except the surfaces to be in contact in the joints of the tank, shall be given a shop coat of paint or metal preservative selected and applied as specified by the railway company.

After being completely erected, calked, and cleaned of dirt, rust, and scale, all exposed metal work shall be painted or treated with such coat or coats of paint or metal preservative as shall be selected by the railway company.

PLANS AND SPECIFICATIONS

14. Under these specifications and in conformity thereto the railway company shall cause to be prepared or shall approve detail plans and specifications for tanks, herein specified, as it shall construct. Such plans and specifications shall cover all necessary tank auxiliaries.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS, RULES FOR CONSTRUCTION OF UNFIRED PRESSURE VESSELS, A. S. M. E. BOILER CONSTRUCTION CODE, 1931

UNFIRED PRESSURE VESSELS

[These rules are not intended to apply (a) to pressure vessels which are subject to Federal inspection and control, (b) to locomotives of all types, (c) to vessels for containing only water under pressure for domestic supply, (d) to vessels for flammable liquids and/or gases at temperatures of over 300° F.]

U-1. The rules in this section apply to unfired pressure vessels over 6 inches in diameter, having a volume of more than 1.5 cubic feet and carrying a pressure of over 30 pounds per square inch, constructed of material herein specified.

SAFETY APPLIANCES

U-2. All pressure vessels shall be protected by such safety and relief valves and indicating and controlling devices as will insure their safe operation. These devices shall be so constructed, located, and installed that they can not readily be rendered inoperative. The relieving capacity of safety valves shall be such as to prevent a rise of pressure in the vessel of more than 10 per cent above the maximum allowable working pressure, and their discharges shall be carried to a safe place.

SAFETY VALVES FOR OTHER THAN NOXIOUS LIQUIDS OR NOXIOUS VAPORS

U-3. Safety valves shall be of the direct spring-loaded type, designed with substantial lifting device so that disk can be lifted from its seat by the spindle not less than one-eighth the diameter of the valve when the pressure on the vessel is 75 per cent of that at which the safety valve is set to blow. If the safety valve is to be used for relief of liquid pressure, no lifting device is required.

U-4. Safety valves having either the seat or disk of cast iron shall not be used.

U-5. If more than one safety valve is used, the discharge capacity shall be taken as the combined capacity of all valves.

U-6. For vessels in which pressure is not generated but is derived from an outside source, each safety valve shall be so connected to the vessel, vessels, or system which it protects, as to prevent a rise in pressure beyond the maximum allowable pressure (see par. U-2) in any vessel protected by the safety valve.

For vessels in which pressure may be generated, the safety valve or valves must be connected directly to the vessel which is to be protected or to a pipe line leading to the vessel; the internal cross-sectional area of the pipe line shall be not less than the nominal area of the safety valve or valves used,

and without any intervening valve between the vessel and the safety valve or valves protecting it. All vessels, the contents of which are likely to cause interference with the operation of a safety valve if attached directly to the vessel, shall have the safety valve or valves connected in such manner as to avoid such interference. When an escape pipe is used, it shall be full sized and fitted with an open drain, to prevent liquid from lodging in the upper part of the safety valve, and no valve of any description shall be placed on the escape pipe between the safety valve and the atmosphere. When an elbow is placed on an escape pipe, it shall be located close to the safety-valve outlet, or the escape pipe shall be securely anchored and supported. When two or more safety valves are placed on one connection, this connection shall have a cross-sectional area at least equal to the combined area of these safety valves.

U-7. Every safety valve which is exposed to a temperature of 32° F., or less, shall have a drain at least three-eighths inch in diameter at the lowest point where water can collect.

U-8. Safety-valve springs shall not be adjusted to carry more than 10 per cent greater pressure than that for which the springs were made.

U-9. Each safety valve shall be tested once every day, or oftener, by raising the disk from its seat.

U-10. Safety valves for compressed-air tanks shall not exceed 3 inches in diameter and shall be proportioned for the maximum number of cubic feet of free air that can be supplied per minute as shown in Table U-1.

CORROSIVE SUBSTANCES

U-11. All pressure vessels which are to contain substances having a corrosive action upon the metal of which the vessel is constructed, shall be designed for the pressure they are to carry, and the thickness of all parts subject to corrosion should be increased by a uniform amount to safeguard against early rejection.

MATERIAL

U-12. All materials used in the construction of the important parts of unfired pressure vessels, for which specifications are given in Section II of the code, shall conform to such requirements.

U-13. (a) Plates for any part of a riveted vessel required to resist stress produced by internal pressure shall be of flange or fire-box quality steel conforming with specifications S-1 for steel boiler plate and S-2 for steel plates of flange quality for forge welding of Section II of the code, except as provided in (b).

If desired, both flange and fire-box steel of lower tensile strength than specified may be used for an entire boiler or part thereof, the desired tensile limits to be specified with a range of 10,000 pounds per square inch. All such steel shall conform to the specifications for steel boiler plate.

(b) Steel plates for any part of a pressure vessel which is to be constructed with other than riveted joints shall be of the quality specified for the particular kind of joint used.

U-14. In determining the maximum allowable working pressure, the maximum allowable working stress as herein provided shall be used in the computations.

U-15. For resistance to crushing of steel plate, the maximum allowable working stress shall be 19,000 pounds per square inch of cross-sectional area.

U-16. In computing the maximum allowable stress on rivets in shear, the following values in pounds per square inch of the cross-sectional area of the rivet shank shall be used:

Iron rivets in single shear.....	7,600
Iron rivets in double shear.....	15,200
Steel rivets in single shear.....	8,800
Steel rivets in double shear.....	17,600

The cross-sectional area used in the computations shall be that of the rivet shank after driving.

TABLE U-1.—Maximum free air supplied in cubic feet per minute for different sizes of safety valves at stated pressures

Diameter of valve (in inches)	Gage pressure (in pounds)															
	50	100	150	200	250	300	350	400	500	600	800	1,000	1,200	1,600	2,000	2,400
1/4								53	61	70	84	97	109	128	147	160
1/2	20	32	42	51	59	67	74	111	129	147	177	205	230	270	304	330
3/4	27	39	48	56	64	72	79	116	134	152	182	210	235	275	309	336
1	33	44	54	62	70	78	85	122	140	158	188	216	241	281	315	342
1 1/4	41	52	62	70	78	86	93	130	148	166	196	224	249	289	323	350
1 1/2	49	60	70	78	86	94	101	138	156	174	204	232	257	297	331	358
2	57	68	78	86	94	102	109	146	164	182	212	240	265	305	339	366
2 1/2	65	76	86	94	102	110	117	154	172	190	220	248	273	313	347	374
3	73	84	94	102	110	118	125	162	180	198	228	256	281	321	355	382

The foregoing table is based on the following formulas:

$$Q=28 PDI \text{ for } 45^\circ \text{ bevel-seat valves}$$

$$Q=40 PDI \text{ for flat-seat valves}$$

and

where

Q=discharge in cubic feet of free air per minute.

P=absolute pressure at which the safety valve opens (gage pressure plus 14.7 pounds at sea level).

D=diameter, in inches, of the inside edge of the bearing surface between the disk and seat.

l=vertical lift of the safety-valve disk from its seat, in inches, representing the lift for minimum discharge capacity, for satisfactory operation of the valve.

CONSTRUCTION AND MAXIMUM ALLOWABLE WORKING PRESSURES

U-17. For all pressure vessels the minimum thicknesses of shell plates, heads and dome plates after flanging shall be as follows:

When the diameter of shell is—	Inch
16 inches diameter and under	3/8
Over 16 inches to 24 inches	3/16
Over 24 inches to 42 inches	1/4
Over 42 inches to 60 inches	5/16
Over 60 inches	3/8

U-18. The minimum thicknesses of butt straps for double-strap riveted joints shall be as given in Table U-2. Intermediate values shall be determined by interpolation. For plate thicknesses exceeding 1 1/4 inches the thickness of the butt straps shall be not less than two-thirds of the thickness of the plate.

TABLE U-2.—Minimum thicknesses of butt straps

Thickness of shell plates	Minimum thickness of butt straps	Thickness of shell plates	Minimum thickness of butt straps
1/4	1/8	1/2	3/16
3/8	1/4	5/8	1/4
1/2	1/4	3/4	1/4
5/8	1/4	7/8	1/4
3/4	1/4	1	1/4
7/8	1/4	1 1/8	1/4
1	1/4	1 1/4	1/4
1 1/4	3/8	1 3/4	3/8
1 1/2	1/2	2	1/2

U-19. The maximum allowable working pressure is the maximum pressure at which a pressure vessel may be operated.

Where the term "maximum allowable working pressure" is used it refers to gage pressure, or the pressure above the atmosphere, in pounds per square inch.

U-20. For internal pressure.—The maximum allowable working pressure on the shell of a pressure vessel shall be determined by the strength of the weakest course computed from the thickness of the plate, the efficiency of the longitudinal joint, the inside diameter of the course, and the maximum allowable unit working stress.

$$\frac{SXt \times E}{R} = \text{maximum allowable working pressure, pound per square inch.}$$

For riveted construction the minimum thickness shall be 3/16 inch.

where

S=maximum allowable unit working stress in pounds per square inch, taken from Table U-3.

t=minimum thickness of shell plates in weakest course, inches.

E=efficiency of longitudinal joint or of ligaments between openings.

for riveted joints=calculated riveted efficiency.

for fusion-welded joints=efficiency specified under rules for the fusion process of welding.

for seamless shells=100 per cent.

for ligaments between openings, the efficiency shall be calculated by the rules given in paragraphs P-192 and P-193 of Section I of the code.

R=inside radius of the weakest course of the shell, inches, provided the thickness of the shell does not exceed 10 per cent of the radius. If the thickness is over 10 per cent of the radius, the outer radius shall be used.

NOTE.—When the allowable efficiency of the joints is not given, the values for S X E for the maximum unit joint working stress at right angles to the direction of the joint given in paragraphs U-70, U-82, or U-94 shall be used.

TABLE U-3.—Values for S at various temperatures

Maximum temperature (° F.)	Minimum of specified range of the tensile strength of the material (in pounds per square inch)				
	45,000	50,000	55,000	60,000	75,000
700	9,000	10,000	11,000	12,000	15,000
750	8,220	9,110	10,000	11,200	13,000
800	6,550	7,330	8,000	9,000	10,200
850	5,440	6,050	6,750	7,400	8,300
900	4,330	4,830	5,500	5,600	6,000
950	3,200	3,600	4,000	4,000	4,000

This table applies to all plain carbon steels for which specifications are given in the code. Where the minimum tensile strength of the specified range or the temperature differs from those for which values are given in the table, the values for S for such materials may be determined by interpolation.

JOINTS

U-21. The joints of pressure vessels, if of riveted construction, shall conform to the requirements of paragraphs U-26 to U-35.

U-22. Pressure vessels may be fabricated by means of fusion or forge welding, or brazing, provided the rules governing the method adopted and as given in paragraphs U-67 to U-96 are followed.

U-23. Pressure vessels may be fabricated by means of fusion welding under the rules given for the fused process of welding, provided the construction is in accordance with the requirements for material and design as required by this code and the fusion welding process used conforms to the specifications for the welding indicated for each class of vessel.

U-24. Pressure vessels may be fabricated by means of forge welding when the rules given under forge welding are followed.

U-25. Pressure vessels for use at any temperature not exceeding 406° F., may be fabricated by means of the brazing process when the rules given under brazing are followed.

RIVETED JOINTS

U-26. The efficiency of a joint is the ratio which the strength of the joint bears to the strength of a solid plate. In the case of a riveted joint this is determined by calculating the breaking strength of a unit section of the joint, considering each possible mode of failure separately, and dividing the lowest result by the breaking strength of a length of a solid plate equal to that of the section considered.

U-27. The distance between the center lines of any two adjacent rows of rivets, or the "back pitch" measured at right angles to the direction of the joint, shall have the following minimum values:

(a) If $\frac{P}{d}$ is 4 or less, the minimum value shall be $1\frac{1}{4}d$

(b) If $\frac{P}{d}$ is over 4, the minimum value shall be:

$$1\frac{3}{4}d + 0.1(P - 4d)$$

where P = pitch of rivets in outer row when a rivet in the inner row comes midway between two rivets in the outer row, inches.

= pitch of rivets in the outer row less pitch of rivets in the inner row when two rivets in the inner row come between two rivets in the outer row, inches.

(It is here assumed that the joints are of the usual construction when the rivets are symmetrically spaced.)

d = diameter of the rivet holes, inches.

The back pitch of rivets in circumferential joints may be less than that called for by the above formulas provided the ligaments between rivets in a circumferential direction, as well as those in a diagonal direction as determined by the rules in paragraph P-193 of Section I of the code, are sufficient to withstand the stress due to pressure, together with any stress due to weight components in support of the vessel structure, with a factor of safety of five.

The back pitch of rivets shall be measured either on the flat plate before rolling, or on the median line after rolling, and the back pitch as there measured shall govern the locations of rivet holes in the butt straps.

U-28. On longitudinal joints, the distance from the centers of rivet holes to the edges of the plates, except rivet holes in the ends of butt straps, shall be not less than one and one-half and not more than one and three-fourths times the diameter of the rivet holes; this distance to be measured from the center of the rivet holes to the calking edge of the plate before calking. The corresponding distance for circumferential seams shall be not less than one and one-fourth times the diameter of the rivet holes.

U-29. (a) The strength of circumferential joints of pressure vessels, the heads of which are not

stayed by tubes or through braces, shall be at least 50 per cent of that required for the longitudinal joints of the same structure.

(b) When 50 per cent or more of the load which would act on an unstayed solid head of the same diameter as the shell, is, in consequence of the holding power of the tubes and stays, relieved by the effect of through tubes or stays the strength of the circumferential joints in the shell shall be at least 35 per cent of that required for the longitudinal joints.

U-30. The riveted longitudinal joints of a shell which exceeds one-half inch in thickness, shall be of butt-and-double-strap construction. This rule does not apply to the portion of a shell which is stay bolted to an inner sheet.

U-31. The longitudinal joints of a shell not more than one-half inch in thickness, with the exception given below, may be of lap-riveted construction; but the maximum allowable working pressure of such construction shall not exceed 200 pounds per square inch for vessels less than 24 inches in diameter nor 150 pounds per square inch for vessels 24 inches in diameter or over.

When a vessel is used for a purpose that makes it necessary to provide in its construction for extraordinary wear, corrosion, or other deterioration in service and plates of greater thickness are used than would otherwise be required, the longitudinal joints of shells exceeding 48 inches in diameter may be lap-riveted if the following conditions are met:

The operating pressure shall not exceed 50 pounds per square inch.

The plate thickness shall be at least 1.8 times the required plate thickness.

Telltale holes one-eighth inch to one-fourth inch in diameter shall be drilled to a depth of at least 60 per cent of the required plate thickness in those surfaces opposite the surfaces subjected to wear or other deterioration, with the spacing of the telltale holes not over 2 feet apart.

The spherical portion of vessels of any diameter which are wholly spherical or partly hemispherical, may be constructed with lap joints, provided that if the plate thickness exceeds three-eighths inch, the several spherical sections of plate shall be hot pressed to the proper radius of curvature. When the vessel can not be completed in the shop, the whole structure shall be carefully and completely fitted up ready for riveting before shipment.

U-32. Butt straps and the ends of shell plates forming the longitudinal joints shall be rolled or formed to the proper curvature by pressure and not by blows.

U-33. The longitudinal joint of a dome 24 inches or over in inside diameter shall be of butt-and-double-strap construction or made without a seam of one piece of steel pressed into shape, and its flange shall be double-riveted to the shell. In the case of a dome less than 24 inches in diameter, for which the product of the inside diameter and the maximum allowable working pressure does not exceed 4,000 inch-pounds, its flange may be single-riveted to the shell and the longitudinal joint may be of the lap type, provided it is computed with a factor of safety not less than 8.

When shells are cut to apply domes or manholes the net area of metal, after rivet holes are deducted, in flange and liner, if used, must not be less than the area required by these rules for a length of shell equal to the length removed. A height of vertical flange equal to three times the thickness of the flange may be included in the area of the flange.

U-34. Rivet and stay bolt holes.—All holes for rivets or stay bolts in plates, butt straps, heads, braces, and lugs shall be drilled; or they may be punched at least one-eighth inch less than full diameter for material not over five-sixteenths

inch in thickness and at least one-fourth inch less than full diameter for material over five-sixteenths inch.

Such holes shall not be punched in material more than five-eighths inch in thickness.

For final drilling or reaming the holes to full diameter, the parts shall be firmly bolted in position by tack bolts.

The finished holes must be true, clean, and concentric.

U-35. Rivets shall be of sufficient length to completely fill the rivet holes and form heads at least equal in strength to the bodies of the rivets. Forms of finished rivet heads that will be acceptable are shown in Figure 156.

(Other structural requirements include a formula for computing the thickness of blank unstayed dished heads, their dimensions, working pressures, manhole requirements; a formula for computing the thickness of unstayed flat heads; formula for determining the maximum allowable working pressure for various thicknesses of braced and stayed flat plates, design of stay bolts, structural reinforcements, maximum allowable pitch, in inches, of screwed stay bolts, ends riveted over, and maximum allowable stresses for stay bolts and stays or braces. The following requirements for calking form part of the rules:)

U-52. *Calking.*—(a) The calking edges of plates, butt straps, and heads shall be beveled to an angle not sharper than 70° to the plane of the plate, and as near thereto as practicable. Every portion of the unfinished surfaces of the calking edges of plates, butt straps, and heads shall be planed, milled, or chipped to a depth of not less than one-eighth inch. Calking shall be done with a tool of such form that there is no danger of scoring or damaging the plate underneath the calking edge, or splitting the calked sheet.

(b) Fusion welding may be used to seal the calking edges of riveted joints and rivet heads of unfired pressure vessels, provided the plates do not exceed 0.30 per cent carbon and that the thickness of the plate or head affected by the welding is at least one-eighth inch more than that required for a seamless shell of the same diameter, the same working pressure and the same grade of material. Such seal welding shall not be applied until after the vessel is made tight as evidenced by the regular hydrostatic pressure test prescribed. Seal welding may be used on nozzles and their reinforcing plates under the the same conditions. On unstayed dished heads, seal welding shall not be applied closer than one-half inch to the point of tangency of the knuckle of the flange. Seal welding may be applied only when the weld metal is deposited in a single layer having a throat thickness of not less than three-sixteenths inch nor more than five-sixteenths inch. The heat from welding shall not distort the plate or loosen the rivets in such a manner as to break the initial bond effected in the riveted joint. After seal welding, the vessel shall be resubjected to the prescribed hydrostatic test.

MANHOLES AND HANDHOLES

U-53. All vessels for use with compressed air, or subject to internal corrosion, 18 inches in diameter or over, and not exceeding 36 inches in diameter, shall have a handhole in the shell or head, or a manhole or at least two plugged threaded openings of not less than 2 inches pipe size. When two threaded openings are used, they should be located in the heads or in the shell near the heads.

All such vessels less than 18 inches in diameter shall be provided with at least two handholes, or two inspection holes, properly located for inspection, the inspection holes to be not less than 1½ inches

pipe size, unless the vessels have removable heads or cover plates.

In special cases where vessels 16 inches or less in diameter are located so that inspections can not be made without dismantling or removing same, special openings need not be provided if the tapping

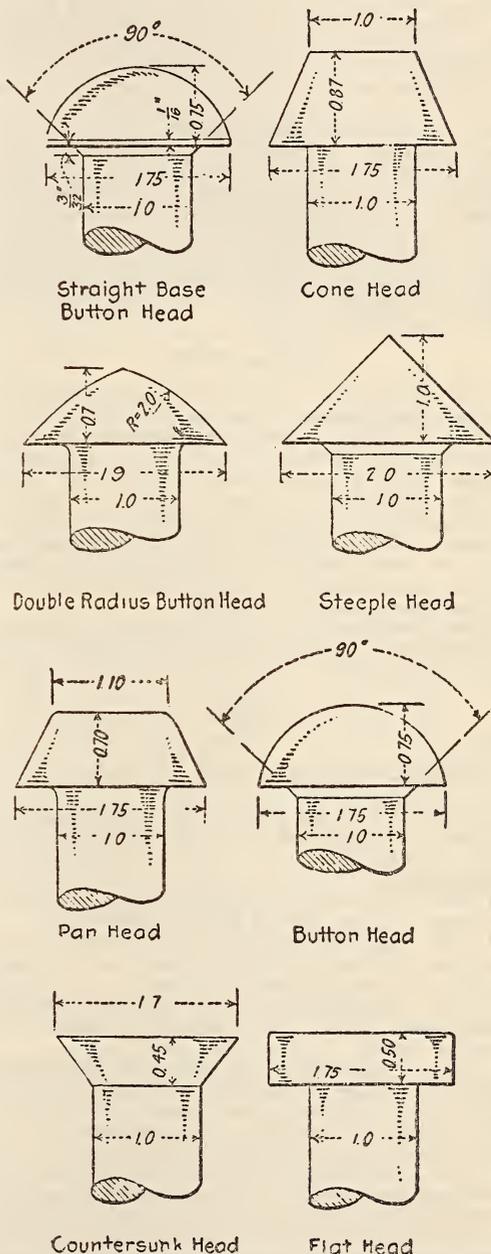

Figure 156.—Acceptable forms of finished rivet heads

for pipe connections properly located for inspection purposes is not less than 1½-inch pipe size.

U-54. Vessels for use with compressed air, or subject to internal corrosion, over 36 inches in diameter, shall have a manhole, excepting those whose shape or use make it impracticable, in which case they shall have a 4 by 6-inch handhole or its equivalent in area, located as near each head as

practicable. An elliptical manhole opening shall be not less than 11 by 15 inches or 10 by 16 inches in size. A circular manhole opening shall be not less than 15 inches in diameter.

U-55. A manhole reinforcing ring, when used, shall be of rolled, forged, or cast steel, shall be at least as thick as the shell plate, and shall have a net cross-sectional area, on a line parallel to the axis of the shell, not less than the cross-sectional area of shell plate removed on the same line.

(Additional requirements cover strength of rivets in shear and in tension, spacing of rivets attaching nozzles, material of manhole plates, pipe threads for nozzle openings, formulas for determining maximum diameter of unreinforced circular openings, types of nozzle fittings, supporting vessels so as properly to distribute the stresses due to weight of vessel and contents, hydrostatic tests, and inspection. Rules for the fusion process of welding, for forge welding, and for brazing are contained in three separate chapters. The following provisions are made for enameled vessels:)

ENAMELED VESSELS

U-97. *Material.*—All pressure vessels intended to be coated with glass or other enamel shall be made of steel or iron not under three-sixteenth inch nor more than five-eighth inch in thickness and may be welded by the oxyacetylene, electric, or forge-welding processes. If forge welding is used the requirements of paragraphs U-80 to U-90 shall be followed. All plates shall conform to the Specifications for Steel Plates of Flange Quality for Forge Welding, Specifications S-2, and any plate not conforming thereto may be rejected.

U-98. The maximum allowable working pressure for single-shell vessels shall be determined by the following formula:

$$P = \frac{5000t}{R}$$

where

t = thickness of plate, inches, and R = inside radius, inches

U-99. The formula given in paragraph U-36 shall be used in calculating the minimum thickness of heads necessary for the various pressures and diameters.

U-100. The ratio of diameter of the vessel to thickness of plate shall in no case exceed 320.

U-101. Any brand of welding wire which has been found by practice to give good results may be used, and may be bare, coated or covered.

U-102. Vessels of this class will be considered under two types, viz, single-shell vessels and jacketed vessels.

U-103. Longitudinal seams of single-shell vessels welded by either the oxyacetylene or electric processes or both shall be double V welded.

The weld on all surfaces to be enameled may be ground flush with the surface of the plate.

U-104. Jacketed or double-shell vessels may be of two types, one in which one of the heads of the inner vessel forms the sealer apron for the jacket, and one in which the sealer apron is joined to the shell of the inner vessel at some point between the heads, forming a partially jacketed vessel.

U-105. The inner shell of a jacketed vessel, when not stayed to the outer shell, should be of such construction as to safely withstand both the pressure in the jacket which tends to collapse it, and the pressure on the inside which tends to burst it, when either of these pressures acts singly.

U-106. The longitudinal seam of the jacket shall be double V welded. The circumferential seam in

the jacket joining the head to the shell may be single V welded.

U-107. In jacketed vessels where the sealer apron is welded to the shell of the inner vessel, and also where the sealer apron is welded to the shell of the jacket, the weld may be made from outside only, provided the thickness of the metal deposited is equal to or greater than the thickness of the apron or plate.

U-108. In jacketed vessels where the top head of the inner shell forms the sealer apron, the head may be welded to the shell of the inner vessel from the inside only, provided the thickness of the weld after grinding is equal to or greater than the thickness of the shell.

U-109. All cylinders shall be rerolled after welding.

ASSOCIATED FACTORY MUTUAL FIRE INSURANCE COMPANIES, GRAVITY WATER TANKS AND STEEL TOWERS, STRUCTURAL DETAILS, 1931

WATER TANKS AND STEEL TOWERS

(For steel tanks for fire protection, standard sizes; plates, shapes, and rivets according to A. S. T. M. specifications; thickness of plates and design details. Also covers steel towers for supporting water tanks, minimum number of columns; materials according to A. S. T. M. specifications; computation of dead, live, and wind load. Under piping, fittings, and heating systems this specification contains requirements for discharge pipe and fittings, expansion joint, overflow, clean out and drain, mill-use connections, telltale, valve pit or valve house, and frost-proof casings for pipes. General requirements for steam heaters and for coal-burning heaters.)

ASSOCIATED FACTORY MUTUAL FIRE INSURANCE COMPANIES, STORAGE AND HANDLING OF FLAMMABLE LIQUIDS, 1930

STORAGE TANKS

Horizontal, cylindrical steel tanks are most commonly and economically used for underground storage. They may be obtained readily in sizes up to 25,000 gallons capacity, this size usually being about 12 feet in diameter by 42 feet long.

(In respect to materials this specification is identical with that of the National Board of Fire Underwriters specification for containers for storing and handling flammable liquids, given below.)

NOTE.—For tanks of 1,100 gallons and more a variation of 10 per cent in capacity may be allowed from the tabulated sizes. (And, as stated in the N. B. F. U. specification referred to in the preceding paragraph, if adequate internal bracing is provided, tanks from 12,000 to 30,000 gallons capacity may be built of ¼-inch plate.)

NATIONAL BOARD OF FIRE UNDERWRITERS, OIL-BURNING EQUIPMENTS, 1928

OIL-BURNING EQUIPMENTS

(Requirements covering material, construction, and tests are identical with those for containers for storing and handling flammable liquids, given below, except that in this specification no provision is made for portable tanks.)

NATIONAL BOARD OF FIRE UNDERWRITERS, CONTAINERS FOR STORING AND HANDLING FLAMMABLE LIQUIDS, 1927

UNDERGROUND TANKS

Tanks shall be constructed of galvanized steel, open-hearth steel, or wrought iron of a minimum gage (U. S. standard), depending upon the capacity as given in Table 1. For liquids heavier than 35° Baumé, tanks may be of reinforced concrete.

TABLE 1

Capacity (in gallons)	Gage	Minimum weight of material
		<i>Lbs./in.²</i>
1 to 285.....	16.....	2.50
286 to 560.....	14.....	3.125
561 to 1,100.....	12.....	4.375
1,101 to 4,000.....	7.....	7.50
4,001 to 12,000.....	½ inch.....	10.00
12,001 to 20,000.....	¾ inch.....	12.50
20,001 to 30,000.....	¾ inch.....	15.00

Tanks of open-hearth steel or wrought iron thinner than No. 7 gage shall be galvanized.

For class 3 liquids, if adequate internal bracing is provided, tanks from 12,001 to 30,000 gallons capacity may be built of ¼-inch plate.

All joints of tanks shall be riveted and calked, brazed, welded, or made tight by some equally satisfactory process. Tanks shall be tight and sufficiently strong to bear without injury the most severe strains to which they may be subjected in practice. Shells of tanks shall be properly reinforced where connections are made, and all connections made through the top of tank above the liquid level.

NOTE.—Tanks for systems under pressure shall be designed for four times the working pressure and tested to twice the maximum working pressure.

(Provision is also made for venting of tanks, setting, location of filling pipe, manholes, gaging devices, withdrawal of liquids, care, and attendance.)

PORTABLE TANKS

Capacity of tank shall not exceed 65 gallons. Tank shall be made of iron or steel plate not less than three-sixteenths inch, with joints either riveted and calked, welded, brazed, or made tight by some equivalent method. Where necessary, tanks shall be substantially braced.

Tanks shall be made with as few openings as practicable and suitably reinforced where necessary. Openings for fittings shall be made in top above liquid level.

(Provision is also made for tank supports, withdrawal of liquid, stability, vents, wheels, fittings, and care and attendance.)

STATIONARY TANKS IN BUILDINGS

Rectangular tanks shall be made of sheet iron or steel not less than No. 14 U. S. standard gage in thickness. Cylindrical tanks not exceeding 120 gallons capacity shall be made of sheet iron or steel not less than No. 20 U. S. standard gage. Material lighter than No. 16 U. S. gage shall be galvanized.

All joints of tanks shall be riveted, brazed, welded, or made tight by some equally satisfactory process. Joints shall be tight and sufficiently strong to bear without injury the most severe strains

to which they are liable to be subjected in practice. The shells of tanks shall be properly reinforced where connections are made, and all connections made through upper side of tanks above the liquid level.

Tanks shall be thoroughly braced where necessary, and designed to withstand extreme service conditions.

All attachments shall be made at top of tank by means of suitable flanges.

(Fittings, care and attendance, and withdrawal of liquid are also provided for.)

ABOVEGROUND TANKS

Tanks, including top, shall be constructed of open-hearth steel or wrought iron of a thickness depending upon the capacity, and to be figured in accordance with the following table or formula. For liquids of 35° Baumé or heavier, tanks may be constructed of concrete in accordance with the regulations for the design and construction of concrete fuel-oil storage tanks.

1. *Horizontal or vertical tanks not over 1,100 gallons capacity.*—

Capacity (in gallons)	Minimum thickness of material
	<i>Gage</i>
1 to 60.....	18
61 to 350.....	16
351 to 560.....	14
561 to 1,100.....	12

2. *Horizontal tanks over 1,100 gallons capacity.*— Tanks having a diameter of not over 6 feet shall be made of at least three-sixteenth inch steel.

Tanks having a diameter of over 6 feet and less than 11½ feet shall be of at least ¼-inch steel.

3. *Vertical tanks over 1,100 gallons capacity.*— Tanks of this class shall be of such material and so constructed as to give a factor of safety of at least 2.5. The minimum thickness of shell or bottom shall be three-sixteenth inch.

The minimum thickness of roof shall be one-eighth inch.

The thickness of plates shall be figured in accordance with the following formula:

$$t = \frac{2.604 \times H \times D \times F \times S}{T \times E}$$

Where

- t* = thickness of plate in inches;
- H* = height of tank in feet above the bottom of the ring under consideration;
- D* = diameter of the tank in feet;
- F* = factor of safety (taken as 2.5);
- S* = specific gravity of liquid, taking water equal to 1;
- T* = tensile strength of plate in pounds per square inch;
- E* = efficiency of vertical joint in ring under consideration.

The tensile strength of the steel shall be taken as 55,000 pounds per square inch, while the shearing strength of rivets shall be taken as 40,000 pounds per square inch.

Tanks shall be riveted, welded, or brazed, and shall be calked or otherwise made tight in a mechanical and workmanlike manner. The top of tank shall be securely fastened to top ring with joints of practically equal tightness to those between the rings.

(Provision is also made for rusting, vents, setting of tanks, piping, embankments and dykes, withdrawal of liquid, care and attendance.)

NATIONAL BOARD OF FIRE UNDERWRITERS; TANKS, GRAVITY AND PRESSURE, TOWERS, ETC., 1926

STEEL GRAVITY WATER TANKS

Section 1. GENERAL

101. These specifications define the recommended practice for the design, fabrication, and erection of steel gravity water tanks, elevated or on concrete foundations.

102. *Capacity.*—The capacity of the tank is the number of U. S. gallons available above the outlet opening.

103. *Standard sizes.*—The standard sizes of steel tanks are: 5,000, 10,000, 15,000, 20,000, 25,000, 30,000, 40,000, 50,000, 60,000, 75,000, 100,000, 150,000, 200,000, 300,000, and 500,000 U. S. gallons net capacity. Tanks of other sizes are built occasionally.

104. *Form.*—The form of a steel tank shall be cylindrical with vertical axis. If supported by a steel tower without beams, a hemispherical or other acceptable form of suspended bottom shall be provided. The tank may have a flat bottom when placed on steel or concrete beams, or on a slab. Tanks of special shapes are sometimes permitted.

105. *Strength.*—The material as specified shall be without defects affecting its strength or service. The workmanship shall be good, so that defects or injuries are not produced during manufacture or erection. Unit stresses as specified shall not be exceeded. The structure and its details shall possess the requisite strength and rigidity.

Section 2. MATERIAL

201. *Plates and shapes.*—The steel for structural shapes and plates except in suspended bottoms, shall conform to current specification A-7 structural steel of the American Society for Testing Materials. (See 605.11, p. 249.) For suspended bottoms, steel not milder than A-7 rivet steel may be used provided that unit tension specified in article 402 is reduced in proportion to the reduction in the ultimate strength.

202. *Rivets.*—The steel for rivets shall conform to current specification A-7 rivet steel of the American Society for Testing Materials.

203. *Anchor bolts.*—Anchor bolts shall be of iron or steel conforming to current specification A-84, for engine bolt iron (see 603.1, p. 139), or current specification A-7 of the A. S. T. M. Welds are not permitted.

Section 3. LOADS

301. *Dead load.*—The dead load shall be the estimated weight of all permanent construction and fittings. The unit weight of steel shall be considered 490 pounds, and of concrete 144 pounds, per cubic foot.

302. *Live load.*—The live load shall be the weight of all the liquid when overflowing the top of the

tank. The unit weight of water shall be considered as 62.5 pounds per cubic foot. Proper provision must be made for temporary stresses during erection. When roofs have a slope of less than 30 degrees, they shall be designed to support a uniform weight of snow of 25 pounds per square foot on the horizontal projection.

303. *Wind load.*—The wind pressure shall be assumed to be 30 pounds per square foot on a vertical plane surface. In calculating the wind load on a cylindrical surface, six-tenths of the above pressure shall be applied to the total area of the vertical projection, and the point of application of the load shall be at the center of gravity of the projected area.

Section 4. UNIT STRESSES

401. *General.*—The maximum stresses in pounds per square inch produced by the above loads shall not exceed the following:

402. *Tension* on net section, rolled steel, 15,000; anchor bolts, 18,000.

403. *Shearing:* Rivets, 11,250.

404. *Bearing:* Rivets, 22,500.

405. *Bending:* Extreme fibers of rolled shapes and built-up sections, net sections, 16,000.

When the laterally unsupported length *l* exceeds ten times *b*, the width of the compression flange, the stress in the latter shall not exceed

$$16,000 - 150 \frac{l}{b}$$

The laterally unsupported length of beams and girders shall not exceed forty times *b*, the width of the compression flange.

406. *Wind allowance.*—When the wind load is considered in calculating stresses the permissible working unit stresses may be increased 25 per cent provided that the resulting section is not less than that required for dead and live loads alone.

Section 5. DETAILS OF DESIGN

501. *Minimum thickness.*—The minimum thickness of metal shall be one-quarter inch except in roofs, railings, and webs of channels and I beams.

502. *Thickness for corrosion.*—Interior bracing, if unavoidable, shall always have one-sixteenth inch additional thickness added to the calculated sections. The sections shall be open to facilitate cleaning and painting. The plates of tanks to contain salt or alkaline water shall be one-sixteenth inch thicker than calculated.

503. *Thickness of bottom cylindrical courses.*—The thickness of plates in the lowest cylindrical courses of tanks with suspended bottoms shall be not less than five-sixteenths inch for 100,000 and 150,000 gallons, three-eighths inch for 200,000-gallon tanks, and for larger tanks shall be at least one-sixteenth inch greater than that calculated.

504. *Thickness of flat bottoms.*—The thicknesses of plates in flat bottoms shall be not less than those given in Table 1.

TABLE 1.—Thickness, in inches, of bottom plates for flat-bottom tanks

Type of support	Depth of water (in feet)											
	10	12	14	16	18	20	22	24	26	28	30	40
Distance in clear between steel or concrete beams (in inches)	12	5/16	5/16	5/16	5/16	5/16	5/16	5/16	5/16	5/16	5/16	3/8
	14	5/16	5/16	5/16	5/16	5/16	5/16	5/16	5/16	5/16	5/16	3/8
	16	5/16	5/16	5/16	5/16	5/16	5/16	5/16	5/16	5/16	5/16	3/8
	18	5/16	5/16	5/16	5/16	5/16	5/16	5/16	5/16	5/16	5/16	3/8
	20	5/16	5/16	5/16	5/16	5/16	5/16	5/16	5/16	5/16	5/16	3/8
Concrete slab	24	3/8	3/8	7/16	7/16	7/16	7/16	7/16	7/16	7/16	7/16	7/16
		1/4	1/4	3/4	3/4	3/4	3/4	3/4	3/4	3/4	3/4	3/4

505. *Accessibility of bottoms.*—Grillages shall be designed so that the tank bottom and beams will be accessible for inspection and painting.

506. *Net sections.*—Net sections shall be used in calculating the tensile stress in plates and members. In deducting the rivet holes their diameter shall be taken one-eighth inch larger than the undriven rivets for punched holes and one-sixteenth inch larger for reamed or drilled holes.

507. *Rivet size considered.*—Nominal diameters shall be used in proportioning rivets in punched work. Diameters of the rivet holes may be used in drilled or reamed work.

508. *Edge distance.*—The minimum distance from the center of any rivet hole to a sheared edge shall be at least one and one-half times the nominal rivet diameter. This distance is to be measured from the center of the bevel of bevel-sheared plates greater than three-eighths inch in thickness.

509. *Spacing between rows.*—When the rivets of adjacent parallel rows are staggered, the distance between center lines of adjacent rows shall be at least twice the diameter of the rivets, and the section of the plate between two rivets in adjacent rows shall be at least six-tenths of the section between two rivets in the line of stress.

510. *Pitch of rivets.*—The minimum distance between center of rivet holes shall be at least two and one-half diameters of the rivet, but should preferably be not less than $1\frac{1}{8}$ inches for $\frac{3}{8}$ -inch rivets, $2\frac{1}{4}$ inches for $\frac{1}{2}$ -inch rivets, and $2\frac{3}{8}$ inches for $\frac{5}{8}$ -inch rivets.

511. *Rivet pitch for calking.*—The maximum distance between centers of rivet holes along calking edges of plates, except at the column connections, shall not exceed ten times the thickness of the thinnest plate for single-riveted joints or twelve times the thickness of the thinnest plate in joints having more than one row of rivets.

512. *Load location.*—Vertical joints shall be designed with the load applied at the center of plates for plates not exceeding 7 feet in width, except as specified in article 503.

513. *Opening reinforcement.*—Manholes, pipe openings, and connections for attachments shall be reinforced by additional steel plates of sufficient thickness and properly riveted to carry the total load that would be carried by the cut-out portion of the plate, without overstressing, when the average tensile stress in the net section of the cut plate exceeds 13,000 pounds per square inch.

514. *Curved-bottom plate location.*—Suspended bottom plates shall lap inside the plates of the lowest cylindrical course.

515. *Stiffening angle.*—Stiffening angles shall be provided around the tops of tanks without roofs.

516. *Bottom angle.*—The sides and bottoms of flat-bottom tanks over 20 feet in diameter shall be connected by spliced angles calked along both legs.

Section 6. WORKMANSHIP

601. *Shearing.*—All shearing shall be done neatly, and material exceeding three-fourths inch in thickness shall have one-eighth inch planed from the sheared edges. All calking edges shall be bevel sheared or planed to an angle of not less than 60° with the plane of the plate.

602. *Punching.*—Rivet holes in plates one-fourth inch up to five-eighths inch in thickness may be punched. The diameter of the punch shall be not more than one-sixteenth inch larger than that of the rivet, and the diameter of the die not more than three-thirty-seconds inch larger than that of the punch.

603. *Subpunching.*—Rivet holes in plates thicker than five-eighths inch but not exceeding seven-eighths inch shall be drilled or subpunched and

reamed. The diameter of the punch shall be at least three-sixteenths inch less than that of the undriven rivets. The diameter of the finished holes shall not be more than one-sixteenth inch greater than that of the rivets.

604. *Drilling.*—Rivet holes in plates over seven-eighths inch thick shall be drilled to a diameter not more than one-sixteenth inch greater than that of the rivets.

605. *Removing burrs.*—After drilling or reaming holes, the burrs shall be completely removed.

606. *Shaping.*—All plates shall be shaped to the proper curvature by cold working without reducing the elastic limit of the metal.

607. *Use of rivets.*—All joints between tank plates shall be riveted.

608. *Heads of rivets.*—Driven rivets over one-half inch in size shall have button, cone, or steeple heads central on the shank. The heads shall grip the assembled pieces firmly and be neat and of equal size. Heads shall be formed on the side of the plate which is calked.

609. *Assembling.*—Plates shall be bolted firmly together before riveting. Drift pins should preferably not be used for bringing the parts together and shall never be used to enlarge unfair holes.

610. *Driving of rivets.*—Rivets of greater diameter than one-half inch shall be uniformly heated to a light cherry red heat. Shop rivets shall be driven by pressure. Rivets in butt joints shall be driven with pneumatic hammers. Recupping and calking is not allowed. Loose, burned, or otherwise defective rivets shall be cut or drilled out and replaced without injuring the adjacent metal.

611. *Calking.*—The tank shall be made water-tight by calking the edges of the plates with a round-nosed tool before painting. Foreign materials such as lead, copper filings, cement, etc., shall not be used in the joints.

612. *Fitting roofs.*—The roof shall fit tightly to the top of the tank to prevent circulation of air over the surface of the water. To assist in obtaining a tight fit, a grid or spider consisting of steel rods spaced preferably not over 42 inches apart should be placed around the top of the tank running radially inward to a ring. The spider shall not obstruct the flow of water into the overflow inlet.

613. *Preventing ice damage.*—The contractor shall keep the tank, structure, and building roofs free of ice caused by leakage during the construction and until the tank equipment is made water-tight.

Section 7. ACCESSORIES

701. *Connections.*—Connections shall be provided on the tank for the necessary pipes, braces, frost-casing, and walkway supports.

702. *Roof (general).*—A conical steel roof shall be provided when the tank is out of doors. The roof plates shall be at least one-eighth inch thick, joined together with rivets spaced not more than 6 inches apart. Conical roofs with a minimum slope of 30° are self supporting when roof plates are one-eighth inch thick on tanks not over 30 feet in diameter and when plates are three sixteenths inch thick on tanks not over 40 feet in diameter. Flatter or larger roofs shall be supported by steel rafters. A cover may also be required when the tank is inside of a building.

703. *Roof anchorage.*—Each roof plate shall be securely fastened to the top of the tank by bolts or rivets at least one-half inch in diameter. At least two bolts or rivets shall be placed in each roof plate.

704. *Roof hatch.*—An easily accessible hatch not less than 20 by 22 inches shall be provided in the roof. The hatch cover shall be built of steel plate at least one-eighth inch thick and shall open to the

right on heavy hinges with noncorrodible pins. A substantial catch shall be provided to keep the cover closed. Other forms of hatch covers may be accepted but approval of the design shall first be obtained from the inspection department having jurisdiction.

705. *Ladders (general).*—Inside and outside steel ladders arranged for convenient passage from one to the other and through the roof hatch shall be provided. Ladders shall not interfere with opening the hatch cover and shall not incline outward from the vertical at any point. Ladders riveted to the tank side are preferred.

706. *Outside fixed ladder.*—The outside tank ladder should preferably be fixed at least 6 inches from the tank side and rigidly bolted to brackets riveted to the tank plates not over 12 feet apart. The top bracket shall not be more than 1 foot below the top of the shell and the bottom bracket not more than 6 feet above the base of the tank cylinder. The fixed ladder shall be in line with the roof hatch and there shall be at least 1 foot clearance at the sides and front of the ladder at the balcony.

707. *Outside revolving ladder.*—Outside revolving ladders, if provided, in lieu of outside fixed ladders, shall not exceed 30 feet in length and shall extend from tower ladder to painter's trolley. The ladder shall be rigidly bolted, at the top and bottom, in its normal position in line with the tower ladder and just to the left of the roof hatch.

708. *Inside ladder.*—The inside ladder shall be riveted to the cylindrical shell by brackets not over 12 feet apart, the upper bracket being located at the top of the tank. The portion of the ladder in the suspended bottom shall extend to the lowest point, and be provided with brackets not over 12 feet apart, which rest upon the tank without scraping off the paint. The brackets shall not be connected to the suspended bottom plates.

709. *Ladder bars and rungs.*—Ladder side bars shall be not less than 2 inches by one-fourth inch flat steel for fixed ladders and 2½ inches by three-eighths inch for movable ladders. Side bars shall be spaced 14 inches apart. Rungs shall be at least five-eighths inch round or square steel spaced 12 inches on centers. The rungs shall be firmly riveted to the side bars. Ladders and connections shall be designed to support a concentrated load of 350 pounds.

710. *Painter's trolley.*—Some form of trolley or other acceptable device shall be provided to facilitate repainting the outside of the tank. The connection of trolley at the top of the tank shall be substantial.

711. *Painting inaccessible parts.*—Parts inaccessible after fabrication shall be protected by paint before assembling.

712. *Shop painting.*—All steel, except where encased in concrete, shall be thoroughly cleaned and given a shop coat of red-lead paint, mixed with 100 pounds of red-lead paste (94 per cent Pb_3O_4) to 2½ gallons of linseed oil (if raw oil is used add one-half pint of dryer to every gallon of paint); or an approved ready-mixed red-lead paint.

713. *Field painting.*—After erection, a patch coat of the same kind of paint as the shop coat shall be applied to all surfaces from which the shop coat has become removed. An over-all field coat of a good grade of metallic paint of color specified by the purchaser shall be applied after the tank has been made water-tight.

714. *Painting conditions.*—All steel shall be thoroughly cleaned of mill scale, rust, and grease before painting by scraping, wire brushing and washing with carbon tetrachloride or other nonhazardous cleaning agent except soda compounds. Painting shall not be done out of doors during wet or freezing weather. The coats of paint shall completely cover the steelwork.

PRESSURE TANKS

Section 36. CONSTRUCTION AND GENERAL REQUIREMENTS

3601. *Service.*—Pressure tanks shall be used only as a supply to automatic sprinkler systems, unless otherwise approved by the inspection department having jurisdiction.

3602. *Capacity.*—The capacity shall be approved by the inspection department having jurisdiction. The capacity is the total contents, both air and water, in the cylinder, not including dished ends, and should generally be not less than 4,500 gallons nor more than 9,000 gallons in one tank.

3606. *Construction—(a) General.*—Except as herein specified to the contrary, pressure tanks shall be constructed in accordance with the current rules for the construction of unfired pressure vessels, Section VIII of the American Society of Mechanical Engineers, Boiler Construction Code. (See above.)

(b) *Allowance for corrosion.*—The computed or minimum required thickness of tank plates shall be increased one-sixteenth inch to allow for corrosion.

(c) *Rivet diameter.*—The rivet diameter used in computations shall be not more than one-sixteenth inch greater than the nominal diameter.

(d) *Tests.*—Each pressure tank shall be given the tests specified by the A. S. M. E. rules before painting, except that the hydrostatic test pressure shall in no case be less than 150 pounds per square inch.

In addition to the A. S. M. E. tests, each pressure tank shall be filled two-thirds full and tested at the normal working pressure with all valves closed, and shall not lose more than one-half pound pressure in 24 hours.

A certificate signed by the manufacturer shall be filed with the inspection department having jurisdiction, certifying that the foregoing tests have been made.

A repetition of the above tests may be required after the tank has been set in place and connected. In all cases where conditions do not permit shipping the tank assembled, the above tests shall be conducted after erection in the presence of a representative of the inspection department having jurisdiction.

(e) *Supports.*—The supports shall be steel or reinforced concrete located so as to prevent sagging or vibration, and properly to distribute the loads due to the weight of the vessel completely full of water. Stresses in steel supports shall not exceed those permitted by section 11 for steel towers. The stresses in rivets fastening lugs or brackets, if used, to the vessel shall not exceed 3,800 pounds per square inch for single shear, or, 7,600 pounds per square inch for double shear or bearing. For horizontal tanks there shall be at least one support for each course of the tank and the ends shall not overhang more than 4 feet. Lugs, brackets, or cradles shall be properly fitted and cradles or chucks braced to prevent movement. The supports shall be arranged to permit convenient inspection and maintenance of all parts of the equipment and shall not interfere with the piping or tank seams.

(Other requirements in this specification cover painting, care and maintenance, marking, name plate, water-level indicator, housing, and details connected with pipe connections and fittings.)

STEEL TOWERS

Section 8. GENERAL

801. These specifications define the recommended practice for the design, fabrication and erection of steel towers to support water tanks.

802. *Height.*—The height of tower is the vertical distance from the top of the foundations to the bottom capacity line of the tank.

803. *Number of columns.*—The minimum permissible number of columns for tanks with suspended bottoms is 4 for tanks of 50,000 to 200,000 gallons capacity, inclusive, 6 for tanks of over 200,000 gallons and including 300,000 gallons, and 8 for tanks of over 300,000 gallons capacity.

804. *Strength.*—The material as specified shall be without defects affecting the strength or service of the structure. The workmanship shall be good so that defects or injuries are not produced in the manufacture or erection. Unit stresses as specified shall not be exceeded. The structure and its details shall possess the requisite strength and rigidity.

Section 9. MATERIAL

901. *Shapes and plates.*—Structural steel for towers shall conform in its chemical and physical properties to current specification A-7, structural steel of the American Society for Testing Materials. (See 605.11, p. 249.)

902. *Rivets.*—Steel for rivets shall conform in its chemical and physical properties to current specification A-7, rivet steel of the American Society for Testing Materials.

903. *Rods and bolts.*—Adjustable tension members and anchor bolts shall be of wrought iron or steel. Wrought iron shall conform in its chemical and physical properties to current specification A-84, engine-bolt iron of the American Society for Testing Materials. (See 603.1, p. 139.) Steel shall conform in its chemical and physical properties to current specification A-7 of the American Society for Testing Materials. Welding by oxyacetylene or electric-arc processes is not permitted in members carrying calculated stress.

Section 10. LOADS

(Requirements covering dead load, live load, and wind load conform to those specified for steel gravity water tanks, given above. In the case of wind load, the load on the tower shall be assumed to be concentrated at the panel points. No provision is, of course, made for roof loads. Otherwise this section provides for the following:)

1003. *Live load (large risers).*—The water contained in a cylinder extending from the water surface to the base of the riser need not be included in the load supported by the tower. The diameter of the cylinder shall be taken as that at the contact between the riser and the foundation.

1005. *Walkway and balcony loads.*—The walkway under the tank and the balcony around the tank shall be designed to carry a 500-pound and a 1,000-pound concentrated load respectively, at any point without overstressing.

Section 11. UNIT STRESSES

(This section covers the maximum stresses in pounds per square inch produced by the above loads. The stresses include axial tension, axial compression, slenderness ratio of both main and secondary members, bending, shearing, bearing, combined stresses, wind allowance, and initial tension.)

Section 12. DETAILS OF DESIGN

1201. *Sections.*—Sections shall preferably be symmetrical. The metal shall be concentrated as much as possible in webs and flanges and the members shall be built of standard or Bethlehem structural shapes. Members shall be designed with open sections to permit painting all surfaces exposed to air or moisture and subject to corrosion.

1202. *Minimum thickness (general).*—The minimum thickness of metal shall be one-fourth inch except in the webs of channels and I-beams and in

minor parts which carry no load. The minimum size of sway rods shall be three-fourths inch.

1203. *Thickness of cover plates.*—The thickness of cover plates shall be at least one-fourth inch and not less than one-sixtieth of the distance between rivet lines. A cover plate may be used on but one side of a column.

1204. *Net sections.*—To calculate net sections of tension members the diameters of the rivet holes shall be taken one-eighth inch larger than the nominal diameters of the rivets. For compression members all bolt holes and openings other than rivet holes shall be deducted from the cross-sectional area. For a distance of twice the maximum width of the member from the end, the allowable unit compression on the net section may be taken as the unit compression on short lengths. Article 1103.

1205. *Rivet sizes.*—Nominal diameters shall be used in proportioning rivets. The diameters of rivets in the flanges of channels except in minor and unimportant parts shall be one-half inch or five-eighths inch for 6-inch and 5-inch channels, five-eighths inch for 7-inch and 8-inch channels, three-fourths inch for 9, 10, and 12 inch channels, and seven-eighths inch or three-fourths inch for larger channels. The diameters of rivets in the flanges of I-beams shall not be greater than five-eighths inch for flanges less than 4 inches in width, three-fourths inch from 4 to 6 inches, inclusive, and seven-eighths inch for widths greater than 6 inches.

1206. *Rivet edge distance.*—The distance from the center of any rivet hole to an edge, except rolled edges of structural shapes, shall be at least one and one-half times the nominal diameter of the rivet.

1207. *Minimum rivet pitch.*—The distance between centers of rivet holes shall be at least three diameters of the rivet.

1208. *Maximum rivet pitch.*—The distance between centers of rivet holes in the line of stress for members composed of plates and shapes shall not exceed sixteen times the thickness of the thinnest plate but shall be not more than 12 inches. When two rows of rivets are used and the rivets are staggered, the maximum distance between rivet holes in each line shall not exceed twice the above.

1209. *Riveting at ends of cover plates.*—The pitch of rivets at the ends of cover plates in built-up compression members shall not exceed four diameters of the rivet for a length equal to one and one-half times the maximum width of the member.

1210. *Lattice.*—The open sides of compression members shall be provided with lattice. The thickness of lattice bars shall be at least one-fortieth of their length between the centers of end rivets for single and one-sixtieth for double latticing. The minimum width of lattice bars shall be as follows:

For 15-inch channels or built sections with 3½-inch or 4-inch angles—2¼ inches (¾-inch rivets) or 2½ inches (⅝-inch rivets).

For 12-inch, 10-inch, and 9-inch channels or built sections with 3-inch angles—2¼ inches (¾-inch rivets).

For 8-inch and 7-inch channels or built sections with 2½-inch angles—2 inches (⅝-inch rivets).

For 6-inch and 5-inch channels or built sections with 2-inch angles—1½ inches (½-inch rivets) or 1¾ inches (⅝-inch rivets).

The inclination of lattice bars with the axis of the member shall not be less than 45°. Lattice bars shall be so spaced that the ratio l/r of one flange of the member included between two adjacent connections of lattice bars is not over three-fourths of that of the unsupported length of the member as a whole.

(Other details of design concern themselves with the dimensions and locations of batten plates, combined shapes, starred angles, pins, pin plate, clevises,

tank connections, tie plates, tension members, column bases and caps, circular girders, interior bracing, top struts, grillage, base braces, and web stiffeners.)

Section 13. WORKMANSHIP

(Covers requirements for shearing, punching, sub-punching and drilling, straightening and fitting, use of rivets and bolts, heads of rivets, driving of rivets, drifting, lattice bars, bearing surfaces, and threads and nuts.)

Section 14. ACCESSORIES

(Covers requirements for connections, ladders, walkways, painting inaccessible parts, shop painting, field painting, and painting conditions. All painting requirements are the same as for steel gravity water tanks, given above.)

NATIONAL FIRE PROTECTION ASSOCIATION, SUGGESTED ORDINANCE REGULATING THE USE, HANDLING, STORAGE, AND SALE OF FLAMMABLE LIQUIDS, 1926

STORAGE TANKS

(Contains specifications for storage tanks for flammable liquids, both vertical and horizontal types, material (galvanized steel, open-hearth steel, and wrought iron); capacity and location; thickness and weights of metal; tensile strength; piping; and valve requirements.)

UNDERWRITERS' LABORATORIES, STANDARD REQUIREMENTS FOR CONSTRUCTION OF INSIDE TANK EQUIPMENT FOR OIL BURNERS, 1927

TANKS FOR OIL BURNERS

SCOPE

1. These requirements apply to steel tanks of capacities of 275 U. S. gallons and less, used in basements of buildings for the storage and supply of oil fuels for oil burners.

2. *Group A.*—Individual storage tanks and gravity tanks up to 275 U. S. gallons capacity.

3. *Group B.*—Combination storage and gravity tank systems with pump for transferring oil from storage tank to gravity tank. The aggregate capacity of these systems shall not be over 275 U. S. gallons.

Group A. INDIVIDUAL TANKS

4. *Size.*—Tanks of this class shall not have capacities exceeding 275 U. S. gallons.

5. *Form.*—These tanks may be cylindrical or of special forms. Special designs will usually require special tests for strength and tightness to determine acceptability.

6. *Material.*—Open-hearth steel or wrought iron shall be used as material for these tanks.

7. *Thickness.*—The shell and heads of tanks up to and including 60 U. S. gallons shall be not less than No. 14 U. S. standard gage (0.078 inch) in thickness. Tanks of larger than 60 U. S. gallons capacity shall be made of metal not less than No. 12 U. S. standard gage (0.109 inch).

8. *Joints.*—The joints of these tanks shall be welded, brazed, or riveted and welded. (Acceptable designs are shown in sketches accompanying this specification.)

9. *Pipe connections.*—Pipe connections shall be made by welding or riveting standard taper threaded

pipe couplings, flanges, or spuds to the tanks. Riveted flanges shall be secured by not less than four rivets on a pitch not to exceed 2 inches. A pipe connection may be provided in or near the bottom of the tank for supply to burner, and at least two should be provided in or near the top for fill and vent pipes. The vent pipe should be of ample size to prevent abnormal pressure in case of fire or when filling, and in no case to be less than 1-inch pipe size. Means shall be provided for removing water and sediment from both gravity and storage tanks. The threaded portions of pipe connections shall not be less than shown in the following table:

Trade size of pipe	Minimum length of threaded part
<i>Inches</i>	<i>Inch</i>
3/8	0.348
1/2	.348
3/4	.348
1	.348
1 1/4	.435
1 1/2	.435
2	.435
2 1/2	.875

10. *Gages.*—Each tank shall be provided with a suitable listed liquid level gage or equivalent.

11. *Coating.*—Each tank shall be galvanized or coated outside with a suitable rust-resisting paint.

12. *Test.*—Each tank, after assembly and before being painted, shall be tested and proven tight against leakage under a test pressure of not less than 5 nor more than 10 pounds per square inch.

13. *Strength.*—These tanks shall be so designed and constructed that a strength test of 25 pounds per square inch will not rupture them, nor cause leakage.

14. *Marking.*—The inspection label shall be attached to one side of the tank near the top. In addition to the inspection label, each tank shall bear the name of the manufacturer.

15. *Shipping.*—Each tank, before shipping, shall have all pipe connection openings closed with suitable wood or metal plugs or caps to protect them and keep out foreign matter during shipping.

Group B. COMBINATION GRAVITY AND STORAGE TANKS WITH PUMP

(In respect to size, form, material, thickness, joints, pipe connections, gages, coating, test, strength, marking, and shipping, this part of the specification conforms to the requirements for group A tanks, given above. Other provisions are:)

16. *Two-compartment tanks.*—Single combination tanks having gravity and storage sections separated by a compartment head shall have the overflow opening in the head located as near the top as possible, and provided with a threaded fitting which can be tightly closed for testing.

17. *Attachment.*—The gravity tank shall be securely attached to the storage tank by substantial metal supports, special attention being given to the load required to be sustained and to the manner in which it is supported.

18. *Pump.*—A suitable listed hand-operated oil pump or its equivalent shall be provided for transferring oil from storage to gravity tank.

19. *Piping.*—An overflow pipe shall be provided connecting the gravity tank with the top of the storage tank for returning excess oil pumped. This pipe shall be one pipe-size larger than discharge pipe from hand pump. Standard wrought-iron pipe shall be used.

UNDERWRITERS' LABORATORIES, STANDARD FOR DESIGN AND CONSTRUCTION OF UNDERGROUND STORAGE TANKS, 1929

UNDERGROUND STORAGE TANKS

GENERAL

This standard covers the design and construction of underground storage tanks to be employed for the storage of flammable liquids, such as gasoline, kerosene, fuel oil, naphtha, etc., not under pressure, in accordance with the regulations of the National Board of Fire Underwriters for the installation of containers for storing and handling flammable liquids.

1. CAPACITY AND SIZE—HORIZONTAL TANKS

1. Horizontal tanks shall not exceed the maximum capacities, diameters, or lengths for the corresponding gages of metal outlined in the following table, except as noted below.

TABLE 1

U. S. standard metal gage	Approximate thickness	Maximum capacity	Equivalent capacity	Maximum diameter	Maximum length of shell
	<i>Inch</i>	<i>U. S. gallons</i>	<i>Imperial gallons</i>	<i>Inches</i>	<i>Feet</i>
16.....	1/16	285	238	38	8
14.....	5/64	560	467	46	11
12.....	7/64	1,100	917	56	14
7.....	3/16	4,000	3,333	84	22
3.....	1/4	12,000	10,000	126	32
0.....	5/16	20,000	16,667	132	42
000.....	3/8	30,000	25,000	132	50

NOTE.—To take care of miscalculations and mistakes in fabrication, for tanks made of No. 7 or heavier gage metal, a tolerance of 5 per cent in either the diameter or the length will be permitted.

(As stated above in N. B. F. U. specification for containers for storing and handling flammable liquids, if adequate internal bracing is provided, tanks up to 30,000 gallons capacity may be made of 1/4-inch material.)

CAPACITY AND SIZE, VERTICAL CONE-BOTTOM TANKS

2. Vertical cone-bottom tanks shall not exceed the maximum capacities, diameters, or lengths for the corresponding gages of metal outlined in the following table except as indicated in the note under Table 1.

(Table 2 is identical with Table 1 in respect to gage, thickness, and capacity in both U. S. and Imperial gallons. It differs from Table 1 in the following respects:)

TABLE 2

U. S. standard metal gage	Maximum diameter	Maximum length of cylinder	Maximum diameter unbraced flat tops (no tolerance)
	<i>Inches</i>	<i>Feet</i>	<i>Inches</i>
16.....	43	8	36
14.....	54	10	43
12.....	68	12	54
7.....	105	18	72
3.....	132	24	96
0.....	132	30	120
000.....	132	35	132

3. Flat tops, larger in diameter than shown by the last column of the above table shall be suitably braced. Bracing details are included in the Appendix.

STANDARD SIZES

4. The following are suggested as standard sizes, and wherever possible the manufacturer should make his tanks conform to these capacity denominations:

Size	Capacity in U. S. gallons	Equivalent capacity in imperial gallons	Size	Capacity in U. S. gallons	Equivalent capacity in imperial gallons
A.....	65	54	I.....	3,000	2,500
B.....	120	100	J.....	4,000	3,333
C.....	280	233	K.....	5,000	4,166
D.....	550	450	L.....	10,000	8,333
E.....	800	666	M.....	12,000	10,000
F.....	1,000	833	N.....	15,000	12,500
G.....	1,500	1,250	O.....	20,000	16,667
H.....	2,000	1,667	P.....	30,000	25,000

MATERIALS

5. Tanks shall be constructed of open-hearth steel or wrought iron. No seconds shall be used. All material lighter than No. 7 U. S. standard gage shall be galvanized.

(Construction details covering shell joints, heads and head joints, dished heads for horizontal tanks, cone heads for horizontal tanks and bottoms for cone-bottom tanks; flat, dished or cone tops of vertical cone-bottom tanks, joints of cone heads, tops or bottoms, pipe connections, and manholes—all are illustrated in sketches accompanying this specification.)

(An appendix contains tabular matter showing the number of both U. S. and imperial gallons in tanks 1 foot long with diameters ranging from 24 to 132 inches. Other tables show the maximum and minimum thickness limits for uncoated sheet and plate steel, also weights in pounds per square foot, for material ranging in size from 6/0 to 40 U. S. standard gage; and maximum and minimum thickness limits for galvanized sheet steel, with weights in pounds per square foot, for material ranging in size from 8 to 34 U. S. standard gage.)

UNDERWRITERS' LABORATORIES, STANDARD SPECIFICATIONS FOR HORIZONTAL AND VERTICAL ABOVEGROUND STORAGE TANKS FOR HAZARDOUS LIQUIDS, 1922

ABOVEGROUND STORAGE TANKS

GENERAL

These specifications cover only cylindrical tanks of a size that can be completely assembled and tested at the factory before shipment. These tanks are intended for the storage of hazardous liquids not normally under pressure and are not to be used in connection with pressure systems.

HORIZONTAL TANKS

CAPACITY

Capacity to be not less than 2,500 gallons nor greater than 35,000 gallons.

DIMENSIONS

These tanks may be of any diameter from 4 feet up to 11 feet inclusive, and any length that can be

shipped on a single railroad car, provided these dimensions give capacities within the limits specified above. In no case must the diameter be greater than the length, or the length be more than six times the diameter.

MATERIAL

Standard open-hearth steel tank plate is to be used in the construction of these tanks. The minimum thickness of metal required for shell and heads of tanks from 48 to 72 inches diameter is three-sixteenths inch, and from 73 to 132 inches diameter, one-fourth inch.

PIPE CONNECTIONS

Standard wrought-iron pipe couplings may be welded to the tank. Standard boiler flanges may be welded or riveted to the tanks.

(Various methods of attaching pipe connections are shown in blue prints accompanying this specification.)

All pipe connection openings in the tank must be protected with wooden plugs, metal covers, or their equivalent before the tank is shipped.

Each tank must have provision for the attachment of not less than a 2-inch vent. In case the largest inlet or outlet pipe has a cross-sectional area greater than four times that of a 2-inch vent, the area of the vent must be increased to at least one-fourth this area.

HEADS AND HEAD JOINTS

Heads may be in one or two pieces. If made of two pieces, the seam joining the two pieces together must be made in the same manner as the longitudinal shell seams are made. (Various types of heads and joints are shown in blue prints accompanying this specification.)

MANHOLES

All tanks over 5,000 gallons capacity must be provided with manholes. Standard malleable iron screw-cover manholes may be used. Face of collar and cover must be finished to a close fit. Gasket not required.

Bolted cover manholes may be used. Sheet packing gaskets not less than one-eighth inch thick must be used. These gaskets must be of a material listed by Underwriters' Laboratories for this purpose, or of some material authorized especially for this particular use.

Manholes located below the liquid level must be of the bolted-cover type. (Various types of manholes are shown in blue prints accompanying this specification.)

TESTING

Each tank must be tested and proven tight under a pressure of approximately one and one-half times the pressure exerted on the bottom when the tank is filled with water.

MARKING

Each tank must be plainly and durably marked with the name of the manufacturer in letters not less than 1½ inches high.

VERTICAL TANKS

CAPACITY

These tanks shall have a capacity of more than 2,500 gallons and less than 25,000 gallons.

DIMENSIONS

These tanks are cylindrical in shape, the height never being more than four times the diameter. A

maximum diameter of 11 feet and a maximum height of 35 feet are permissible.

MATERIAL

Standard sheets of open-hearth steel tank plate must be used in the construction of these tanks.

BOTTOM

The bottoms of these tanks shall be in one or two pieces and not less than three-sixteenths inch thick. They may be riveted or welded to the shell. (Various types of rivetings and weldings are shown in blue prints accompanying this specification.)

SHELL

The shell must be not less than three-sixteenths inch thick for tanks up to 25 feet in height. For tanks from 25 to 35 feet high the first ring must be not less than 1.4 inches thick and must be not less than 5 feet wide. The rings above the first must not be less than three-sixteenths inch thick. Tanks between 30 and 35 feet high must have first two rings not less than one-fourth inch thick. Each of these ¼-inch rings must be not less than 5 feet wide; the remaining rings must be not less than three-sixteenths inch thick. The seams of the shell may be riveted or welded. (Various types of rivetings and weldings are shown in blue prints accompanying this specification.)

TOP

The tops of these tanks must either be dished or cone shaped, and of No. 10 U. S. gage steel. (Various methods of fastening tops to shells are shown in blue prints accompanying this specification.)

PIPE CONNECTIONS

Pipe connections may be either standard steel flanges or standard wrought-iron pipe couplings. (Methods for securing couplings to shell are shown in blue prints accompanying this specification. In other respects this part of this specification conforms to the pipe connections for horizontal tanks, given above.)

(Manhole, test, and marking requirements are in conformity with those for horizontal tanks, given above.)

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, STEAMBOAT INSPECTION SERVICE, GENERAL RULES AND REGULATIONS, MAY 4, 1929

STEEL TANKS FOR STORAGE

(Requirements covering steel tanks for storage of fuel oil on passenger vessels are contained in the manuals for ocean, bay, lake, and river vessels published under the supervision of the Board of Supervising Inspectors. The requirements include riveting of joints, minimum thickness of plates, hydrostatic test, size of vent pipe, attachment of fittings, and installation of heaters.)

605.24. METAL LATH.

ASSOCIATED METAL LATH MANUFACTURERS, METAL LATH CONSTRUCTION, 1929

WOOD STUD AND JOIST CONSTRUCTION

(a) NAILED TO WOOD STUD PARTITIONS

The minimum weight of expanded metal lath for studs with a maximum spacing of 16 inches on centers shall be 2.5 pounds per square yard.

Flat rib lath for studs with a maximum spacing of 16 and 19 inches on centers shall weigh not less than 2.75 and 3 pounds per square yard, respectively.

Three-eighths inch rib lath for studs with a maximum spacing of 19, 24, and 31½ inches on centers shall weigh not less than 2.5, 2.75, and 3.4 pounds per square yard, respectively.

Sheet lath for studs with a maximum spacing of 24 inches on centers shall weigh not less than 4.5 pounds per square yard.

(b) FOR CEILINGS NAILED TO UNDERSIDE OF WOOD JOISTS

Expanded metal lath for joists with a maximum spacing of 13½ and 16 inches on centers shall weigh not less than 3 and 3.4 pounds per square yard, respectively.

Flat rib lath for joists with a maximum spacing of 16 and 19 inches on centers shall weigh not less than 2.75 and 3 pounds per square yard, respectively.

Sheet lath for joists with a maximum spacing of 24 inches on centers shall weigh not less than 4.5 pounds per square yard.

(Requirements covering nails, staples, and tie wires are also covered in this specification.)

SOLID METAL LATH AND PLASTER PARTITIONS

(a) Flat expanded metal lath shall weigh not less than 2.2 pounds per square yard for channels 12 inches on centers, 3 pounds per square yard for spacing of 13½ inches on centers, or 3.4 pounds for 16-inch centers.

(Requirements covering flat rib lath and three-eighths inch and sheet lath are the same as for wood stud and joist construction, given above. Provision is also made for size and spacing of channel studs, and for tie wire and spacing of ties.)

HOLLOW METAL LATH AND PLASTER PARTITIONS

(a) Flat expanded metal lath shall weigh not less than 2.5 pounds per square yard for channels 12 inches on centers, or 3 pounds per square yard for spacing not exceeding 13½ inches on centers.

(Requirements covering flat rib lath and three-eighths inch and sheet lath are the same as for wood stud and joist construction, given above. Provision is also made for size, spacing, and bracing of channel studs, and for tie wire and spacing of ties.)

SOUND-PROOF DOUBLE-METAL LATH AND PLASTER PARTITIONS

(Same as for solid metal lath and plaster partitions, given above.)

CONTRACTING PLASTERERS' INTERNATIONAL ASSOCIATION, OUTLINE SPECIFICATIONS FOR LATHING AND PLASTERING, 1930

WIRE LATH AND METAL LATH

WIRE OR METAL LATH

All wire lath to be No. 18 gage, (0.0475) ¾-inch mesh painted wire lath, weighing 3.3 pounds per square yard; or No. 24 gage metal lath painted, weighing no less than 3.4 pounds per square yard.

(Provision is also made in this specification for nails and staples, band iron furring, standard steel shapes for suspended ceilings, galvanized hangers and steel channels for furred or attached ceilings to concrete, metal corner beads, and metal lathing for exterior stucco work on frame construction.)

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, SIMPLIFIED PRACTICE RECOMMENDATION FOR METAL LATH, R3-28, JANUARY 1, 1928

METAL LATH

(Simplified practice recommended and accepted by industry establishing the following limited list of standard stock sizes and varieties.)

TABLE 1.—Flat expanded metal lath

Weight in pounds per square yard of—			Gages of sheets (U. S. standard) ¹	
Painted steel	Special metal	Sheets galvanized before fabrication	Minimum	Maximum
2.2	2.2	-----	28	26
2.5	2.5	2.5	28	26
3.0	3.0	-----	28	24
3.4	3.4	3.4	26	24

¹ United States Standard Gage for Sheet and Plate Iron and Steel.
² Included in the present schedule with the recommendation by the standing committee, that the industry work toward the eventual elimination of this weight.

TABLE 2.—¾-inch rib expanded metal lath

Weight in pounds per square yard of—			Gages of sheets (U. S. standard) ¹	
Painted steel	Special metal	Sheets galvanized before fabrication	Minimum	Maximum
2.5	2.5	-----	28	26
2.75	2.75	-----	28	26
3.0	3.0	-----	28	26
3.4	3.4	3.6	28	24
4.0	4.0	-----	26	24

¹ United States Standard Gage for Sheet and Plate Iron and Steel.
² Included in the present schedule with the recommendation by the standing committee, that the industry work toward the eventual elimination of this weight.

TABLE 3.—Flat rib expanded metal lath

Weight in pounds per square yard of—			Gages of sheets (U. S. standard) ¹	
Painted steel	Special metal	Sheets galvanized before fabrication	Minimum	Maximum
2.75	2.75	-----	30	28
3.0	3.0	-----	30	28
3.4	3.4	3.6	30	24
4.0	-----	-----	28	24

¹ United States Standard Gage for Sheet and Plate Iron and Steel.
² Included in the present schedule with the recommendation by the standing committee, that the industry work toward the eventual elimination of this weight.

All types of lath are to be specified and sold by weight per square yard. Manufacturers accepting this recommendation, and who so desire, may stamp or tag their product "Made in accordance with United States Department of Commerce Simplified Practice Recommendation R3."

All copper bearing, special analysis, and pure iron lath to be designated by an undetachable metallic seal, piercing all sheets of lath in each bundle. The above lath to be painted with the same material as open-hearth sheets.

Sheet lath.—Painted steel sheet lath is to weigh not less than 4.5 pounds per square yard, with corresponding minimum weights in this type of lath made from special metals or from sheets galvanized before fabrication.

Expanded and sheets.—Metal lath in all types and weights galvanized after fabrication is to be eliminated.

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR BASES, METAL; FOR PLASTER AND STUCCO CONSTRUCTION, QQ-B-101, AUGUST 19, 1930

METAL BASES

A. Applicable Federal Specifications

A-1. There are no other Federal specifications applicable to this specification.

B. Types

B-1. Metal bases sold under this specification may be of any one or more of the 14 following types, as stated in the invitation for bids.

B-2. *Type E—Expanded metal base.*—Expanded metal is formed by slitting and expanding sheets of metal.

B-2a. *Class EF—Flat expanded metal lath.*—Flat expanded metal lath has no further forming than that indicated in the preceding paragraph.

B-2b. *Class EFR—Flat rib lath.*—Flat rib lath is a combination of metal lath and ribs in which the rib has a total depth of less than three-sixteenths of an inch over all.

B-2c. *Class ESF—Self-furring lath.*—Self-furring lath is so formed that portions of it expand from the face of the lath to separate the face at least one-fourth inch from the background to which the lath is attached.

B-2d. *Class E3/8R—Three-eighths inch rib lath.*—Three-eighths inch rib lath is a combination of metal lath and ribs in which the rib has a total depth of approximately three-eighths of an inch over all. The rib is an unexpanded portion of the metal lath which leaves the plane of the lath at a certain angle and returns at the same angle.

B-2e. *Class E3/4R—Three-fourths inch rib lath.*—Three-fourths inch rib lath is a combination of metal lath and ribs, in which the rib has a total depth of approximately three-fourths of an inch over all. The rib is an unexpanded portion of the metal lath which leaves the plane of the lath at a certain angle and returns at the same angle.

B-2f. *Class EMR—Expanded metal reinforcement.*—Expanded metal reinforcement is formed by slitting and expanding sheets of metal, differing from expanded metal lath in that the opening is many times larger.

B-3. *Type S—Sheet-metal base.*—Metal sheet lath is formed by perforating sheets of metal.

B-3a. *Class SMF—Flat sheet-metal lath.*—Flat sheet-metal lath without ribs.

B-3b. *Class SMR—Ribbed sheet-metal lath.*—Flat sheet-metal lath further formed to provide ribs as described in B-2d.

B-4. *Type W—Wire base.*—Wire base is formed by weaving or welding wires.

B-4a. *Class WOL—Woven-wire lath.*—Woven-wire lath is woven from wires of light gage with square or triangular openings, usually less than 1 inch in greatest dimension. The lath has no ribs.

B-4b. *Class WOLR—Ribbed woven-wire lath.*—Woven-wire lath with small solid round rods acting as ribs.

B-4c. *Class WOLV—Ribbed woven-wire lath.*—Woven-wire lath with V-shaped metal strips acting as ribs.

B-4d. *Class WOF—Woven-wire fabric.*—Woven-wire fabric is usually made with longitudinal wires spaced by means of diagonal cross wires so arranged as to form a series of triangles between the longitudinal wires. The longitudinal wires are usually heavier in gage and spaced at greater distances than the cross wires.

B-4e. *Class WEF—Welded-wire fabric.*—Welded-wire fabric is formed by spot welding wires of the same or different gages at right angles to each other forming rectangular openings. Often one set of wires are crimped to provide furring and the fabric may be either without backing or have an integral paper or screen wire backing.

B-4f. *Class WFG.*—Galvanized hexagonal mesh wire fabric.

C. Material and Workmanship

C-1. The manufacturer is given a wide range in the selection of materials and processes of manufacture in order that metal bases of the prescribed quality may be produced.

D. General Requirements

D-1. All metal bases shall be specified by thickness of sheet or diameter of wire and weight per square yard and shall be furnished in the particular grade or grades listed below finished with the specified coating as ordered by the purchasing agent.

D-2. *Sizes.*—The thickness of sheet metal specified herein shall be United States standard gage for sheet and plate iron and steel (Bureau of Standards Circular No. 391, see 604.0, p. 224), and all diameters of wire shall be steel wire gages (Stl. W. G.) (Bureau of Standards Circular No. 67, see 603.40, p. 153).

Gage number, weight, and thickness of sheet metal

Gage No.	Minimum weight (pounds per square foot)	Approximate thickness (inches)
24	1.00	0.025
25	.87	.022
26	.75	.019
27	.68	.017
28	.62	.016
29	.56	.014
30	.50	.012

D-3. *Wires for lath or fabric.*—All wires used in the manufacture of woven-wire lath and fabric shall be cold-drawn mild steel having a minimum ultimate tensile strength of 60,000 pounds per square inch.

D-4. *Attached ribs.*—All attached V ribs for metal or wire lath shall be made of metal at least 0.025 inch in thickness and all round ribs shall be of mild steel. Metal ribs for all lath shall be spaced not more than 8 inches on centers. They shall be formed in the same sheet or be securely attached to the

lath in such a manner as will prevent their loss or displacement before the lath is in place.

D-5. *Paper*.—The paper used for backing any type of lath or fabric shall be of good quality, free from volatile oil and have a strength of not less than 80 pounds as determined by the bursting strength test. Where the fabric is to be used for stucco or other exterior work the paper shall be waterproof unless otherwise specified. Backing paper for any type of base shall be securely attached to the base in such a manner as to prevent tearing during handling and erection.

D-6. Galvanized wire mesh shall be galvanized after weaving.

D-7. *Lath*.—All metal lath shall be cut from galvanized sheets or shall be heavily coated after expansion by the use of a suitable paint.

D-8. Bases made of copper-bearing metals are within the scope of this specification.

E. Detail Requirements

E-1. Type E.—(Expanded metal base.)

E-1a. Class EF (flat expanded metal lath) and class ESF (self-furring lath).—

Subclass	Minimum weight pounds per square yard	Minimum thickness (inches)
1.....	2.20	0.016
2.....	2.50	.016
3.....	3.00	.016
4.....	3.40	.019

E-1b. Class E3/8R (3/8-inch rib).—

1.....	2.75	0.016
2.....	3.00	.016
3.....	3.40	.016
4.....	4.00	.019

E-1c.—Class E3/4R (3/4-inch rib).—

1.....	4.10	0.016
2.....	5.00	.019
3.....	6.60	.025

E-1d. Class EFR (flat ribbed).—

1.....	2.75	0.012
2.....	3.00	.012
.....	3.40	.012
.....	4.00	.016

E-1e. Class EMR (expanded metal reinforcement).—

1.....	1.80	0.025
--------	------	-------

E-2. Type S (sheet-metal lath).

E-2a. Class SMR (ribbed).—

1.....	7.00	0.016
2.....	8.70	.019
3.....	11.10	.025

E-2b. Class SMF (flat).—

1.....	4.50	0.012
2.....	5.00	.014
3.....	5.60	.016
4.....	6.10	.017
5.....	6.75	.019
6.....	9.00	.025

E-3. Type W (wire base).

E-3a. Class WOL (woven-wire lath, flat).—

Subclass	Meshes per inch	Minimum weight (pounds per square yard)		Minimum diameter of wire (inches)
		Galvanized	Painted	
1.....	2 1/2	2.48	1.80	0.035
2.....	2 1/2	3.15	2.48	.041
3.....	2 1/2	4.05	3.23	.047

E-3b. Class WOLR (woven-wire lath, three-sixteenths round ribbed).—

1.....	2 1/2	3.60	2.93	.035
--------	-------	------	------	------

E-3c. Class WOLV (woven-wire lath, three-eighths inch V ribbed).—

1.....	2 1/2	3.30	2.35	0.032
2.....	2 1/2	3.75	2.60	.035
3.....	2 1/2	4.35	3.30	.041
4.....	2 1/2	5.25	4.00	.047

E-3d. Class WOF (woven-wire fabric).—

Subclass	Mesh (triangular) (inches)	Minimum weight (pounds per square yard)	Minimum diameter of wire (inches)	
			Length	Transverse
1.....	4 by 4.....	1.94	0.105	0.080
2.....	2 by 4.....	2.10	.080	.080
3.....	2 by 4.....	2.84	.105	.080

E-3e. Class WEF (welded-wire fabric. Flat and self-furring).—

1.....	2 by 4.....	1.50	0.080	0.080
2.....	2 by 2.....	2.00	.080	.080
3.....	2 by 4.....	2.60	.105	.105

E-3f. Class WFG (galvanized hexagonal mesh wire fabric).—

Subclass	Mesh (hexagonal) (inches)	Minimum weight (pounds per square yard)	Minimum diameter of wire (inches)
1.....	1.....	1.50	0.047
2.....	2.....	1.50	.062

E-4. **NOTE**.—Backing paper will add from one-half to three-quarters of a pound per square yard to the weights given above. Screen wire will add approximately 1 pound to the above weights.

F. Method of Inspection and Test

F-1. *Inspection*.—One sheet shall be taken from every 10 bundles or every 10 rolls for inspection and test. The number of sheets taken shall not exceed five from every carload shipment.

F-2. *Rejection*.—Materials shall be rejected when 10 per cent or more of that examined fails to meet one or more of the requirements of the specification.

G. Packaging, Packing, and Marking

G-2. *Packaging.*—Unless otherwise specified commercial packages are acceptable under this specification.

G-2a. *Expanded and sheet-metal lath.*—All bundles of expanded and sheet-metal lath on any contract shall contain an equal number of sheets of definite area which may be crated or securely wired together.

G-2b. *Woven-wire lath and fabric.*—Woven-wire lath and fabric shall be furnished in rolls of definite area or in bundles of equal number of sheets of definite area, which may be crated or securely wired together.

G-3. *Packing.*—There are no special requirements.

G-4. *Marking.*—All bundles and rolls of material shall be marked with the name of the material, the size, type, class, and the quantity contained therein, as defined by the contract or order, the name of the contractor, and the number of the contract or order.

I. Notes

I-1. It is believed that this specification adequately describes the characteristics necessary to secure the desired material, and that normally no samples will be necessary prior to award to determine compliance with this specification. If, for any particular purpose, samples with bids are necessary, they should be specifically asked for in the invitation for bids, and the particular purpose to be served by the bid sample should be definitely stated, the specification to apply in all other respects.

I-2. This specification governs all United States Government purchases of this commodity.

605.25 STEEL FOR CONCRETE REINFORCEMENT.

AMERICAN ASSOCIATION OF STATE HIGHWAY OFFICIALS, TENTATIVE STANDARD SPECIFICATION FOR BILLET-STEEL CONCRETE REINFORCEMENT BARS, M-31, 1924

BILLET-STEEL CONCRETE REINFORCEMENT BARS

MATERIAL COVERED

1. (a) These specifications cover two classes of billet-steel concrete reinforcement bars, namely, plain and deformed.

(b) Plain and deformed bars are of two grades, namely, structural steel and intermediate. Structural grade shall be used unless otherwise specified.

2. The structural steel grade made by the open-hearth process shall be used unless otherwise specified.

MANUFACTURE

3. (a) These specifications include steel made by either the Bessemer or open-hearth process, but open-hearth steel shall be used unless otherwise specified.

(b) The bars shall be rolled from new billets. No high-carbon or rerolled material will be accepted.

(In all other respects this specification conforms to that of the Association of American Steel Manufacturers, given below, except that here the tensile strength in pounds per square inch for both plain and deformed bars of the intermediate grade ranges from 70,000 to 85,000 instead of from 70,000 to 90,000; that cold-twisted bars are omitted, and that test specimens shall not be less than 24 inches long.)

(Requirements covering finish, inspection, rejection, and reheating conform to those specified in A. S. T. M. standard specifications for steel. See 605.0, p. 247.)

AMERICAN ASSOCIATION OF STATE HIGHWAY OFFICIALS, TENTATIVE STANDARD SPECIFICATIONS FOR COLD-DRAWN STEEL WIRE FABRIC FOR CONCRETE FOR REINFORCEMENT, M-32, 1924

WIRE FABRIC FOR CONCRETE REINFORCEMENT

MATERIAL COVERED

1. These specifications cover cold-drawn steel wire to be used as such, or in fabricated form, for the reinforcement of concrete, in gages not less than 0.080 inch nor greater than 0.500 inch.

GENERAL REQUIREMENTS

2. When wire is ordered by gage number the following relation between number and diameter, in inches, shall apply unless otherwise specified.

Gage No.	Equivalent diameter	Gage No.	Equivalent diameter
	<i>Inch</i>		<i>Inch</i>
0000000	0.4900	5	0.2070
000000	.4615	6	.1920
000000	.4305	7	.1770
0000	.3938	8	.1620
000	.3625	9	.1483
00	.3310	10	.1350
0	.3065	11	.1205
1	.2830	12	.1055
2	.2625	13	.0915
3	.2437	14	.0800
4	.2253		

MANUFACTURE

3. (a) The steel shall be made by either or both the following processes: Bessemer or open-hearth.

(b) The wire shall be cold drawn from rods hot rolled from billets.

PHYSICAL PROPERTIES AND TESTS

4. (a) The wire, except as specified in paragraphs (b) and (c), shall conform to the following minimum requirements as to tensile properties:

Tensile strength.....	lbs./in. ² ..	80,000
Reduction of area.....	per cent..	30

(b) For wire to be used in the fabrication of mesh or fabric a minimum tensile strength of 70,000 pounds per square inch after fabrication shall be permitted.

(c) For wire with a tensile strength over 100,000 pounds per square inch the reduction of area shall be not less than 25 per cent.

5. The test specimen shall withstand being bent cold through 180° around a pin, the diameter of which is equal to the diameter of the specimen, without cracking on the outside of the bent portion.

6. Tension and bend test specimens shall be of the full size section of the wire, cut from fabricated material, with a minimum length of 24 inches.

7. (a) One tension and one bend test shall be made for each 10 tons or less of each size of wire.

(b) If any test specimen shows defects or develops flaws, it may be discarded and another specimen substituted.

8. If the fabricated material is specified to be of galvanized material, each wire shall be galvanized by the hot-dip method and shall have a continuous coating of zinc of uniform thickness.

PERMISSIBLE VARIATIONS IN GAGE

9. The diameter of the wire shall not vary more than 0.003 inch from the size ordered.
 (Requirements covering workmanship and finish, inspection, rejection, and reheating conform to those specified in A. S. T. M. standard specifications for steel. See 605.0, p. 247.)

SAMPLING AND TESTING

10. Sampling and testing of cold-drawn steel wire fabric for concrete reinforcement shall be done in accordance with the tentative standard methods for sampling and testing of the American Association of State Highway Officials.

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR BILLET-STEEL CONCRETE REINFORCEMENT BARS, 1920

BILLET-STEEL CONCRETE REINFORCEMENT BARS
 MATERIAL COVERED

- 1. (a) These specifications cover two classes of billet-steel concrete reinforcement bars, namely, plain and deformed.
- (b) Plain and deformed bars are of three grades, namely, structural-steel, intermediate, and hard.
- (c) Twisted bars will not be accepted under these specifications.

BASIS OF PURCHASE

2. The structural-steel grade shall be used unless otherwise specified.

MANUFACTURE

- Process—
- 3. (a) The steel shall be made by the open-hearth process.
 - (b) The bars shall be rolled from new billets. No rerolled material will be accepted.

LADLE AND CHECK ANALYSES

(Conform to Association of American Steel Manufacturers, below.)

TENSILE PROPERTIES

(Conform to Association of American Steel Manufacturers, below, except that here the tensile strength in pounds per square inch for both plain and deformed bars of the intermediate grade ranges from 70,000 to 85,000 instead of from 70,000 to 90,000.)

MODIFICATIONS IN ELONGATION

(Conform to Association of American Steel Manufacturers, below.)

BEND TESTS AND BEND-TEST REQUIREMENTS

(Conform to Association of American Steel Manufacturers, below, except that cold-twisted bars are omitted from the A. R. E. A. specification.)

TEST SPECIMENS

(Conform to Association of American Steel Manufacturers, below, except for the omission of machining in the A. R. E. A. specification.)

NUMBER OF TESTS

(Conform to Association of American Steel Manufacturers, below, except for the omission of substitution of another test specimen in the A. R. E. A. specification.)

PERMISSIBLE VARIATIONS IN WEIGHT

(Conform to Association of American Steel Manufacturers, below.)
 (Requirements covering finish, inspection, rejection, and reheating conform to those specified in A. S. T. M. standard specifications for steel. See 605.0, p. 247.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR BILLET-STEEL CONCRETE REINFORCEMENT BARS, DESIGNATION A15-30, 1930

BILLET-STEEL REINFORCEMENT BARS

(Same as Association of American Steel Manufacturers' specification, given below.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR RAIL-STEEL CONCRETE REINFORCEMENT BARS, DESIGNATION A16-14, 1914

RAIL-STEEL REINFORCEMENT BARS

(Same as Association of American Steel Manufacturers' specification, given below.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR COLD-DRAWN STEEL WIRE FOR CONCRETE REINFORCEMENT, DESIGNATION A82-27, 1927

STEEL WIRE FOR CONCRETE REINFORCEMENT
 SCOPE

1. These specifications cover cold-drawn steel wire to be used as such, or in fabricated form, for the reinforcement of concrete, in gages not less than 0.080 inch nor greater than 0.625 inch.

BASIS OF PURCHASE

2. When wire is ordered by gage number the following relation between number and diameter, in inches, shall apply unless otherwise specified:

Gage No.	Equivalent diameter	Gage No.	Equivalent diameter
	<i>Inch</i>		<i>Inch</i>
0000000	0.4900	5	0.2070
000000	.4615	6	.1920
00000	.4305	7	.1770
0000	.3938	8	.1620
000	.3625	9	.1483
00	.3310	10	.1350
0	.3065	11	.1205
1	.2830	12	.1055
2	.2625	13	.0915
3	.2437	14	.0800
4	.2253		

MANUFACTURE

- 3. (a) The steel shall be made by either or both the following processes: Bessemer or open-hearth.
- (b) The wire shall be cold-drawn from rods hot-rolled from billets.

PHYSICAL PROPERTIES AND TESTS

4. (a) The wire, except as specified in paragraphs (b) and (c), shall conform to the following minimum requirements as to tensile properties:

Tensile strength.....	lbs./in. ² ..	80,000
Reduction of area.....	per cent..	30

(b) For wire to be used in the fabrication of mesh a minimum tensile strength of 70,000 pounds per square inch shall be permitted.

(c) For wire testing over 100,000 pounds per square inch tensile strength, the reduction of area shall be not less than 25 per cent.

5. The test specimen shall stand being bent cold through 180° without cracking on the outside of the bent portion, as follows:

For wire 0.3 inch in diameter or under, around a pin the diameter of which is equal to the diameter of the specimen.

For wire over 0.3 inch in diameter, around a pin the diameter of which is equal to twice the diameter of the specimen.

6. Tension and bend test specimens shall be of the full-size section of the wire as drawn.

7. (a) One tension and one bend test shall be made for each 10 tons or less of each size of wire.

(b) If any test specimen shows defects or develops flaws, it may be discarded and another specimen substituted.

PERMISSIBLE VARIATIONS IN GAGE

8. The diameter of the wire shall not vary more than 0.003 inch from the size ordered.

FINISH

9. The finished wire shall be free from injurious defects and shall have a workmanlike finish with smooth surface.

INSPECTION AND REJECTION

10. The manufacturer shall afford the inspector, without charge, all reasonable facilities to satisfy him that the wire is being furnished in accordance with these specifications. All tests and inspection shall be made at the place of manufacture prior to shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

11. Wire which shows injurious defects subsequent to its acceptance at the manufacturer's works will be rejected, and the manufacturer shall be notified.

ASSOCIATION OF AMERICAN STEEL MANUFACTURERS, STANDARD SPECIFICATIONS FOR CONCRETE REINFORCEMENT BARS ROLLED FROM BILLETS, 1928

BILLET-STEEL REINFORCEMENT BARS

1. *Scope.*—(a) These specifications cover three classes of billet-steel concrete reinforcement bars: Plain, deformed, and cold-twisted.

(b) Plain and deformed bars are of three grades: Structural-steel, intermediate, and hard.

2. *Purchase conditions.*—(a) Orders should specify the class and grade desired.

(b) Open-hearth and Bessemer steel may be furnished.

(c) If desired, the acceptance of cold-twisted bars may be based on testing the bars before twisting, in which case the requirements for plain bars of structural-steel grade shall govern and orders shall so specify.

3. *Manufacture.*—(a) The steel shall be made by the open-hearth or the Bessemer process.

(b) The bars shall be rolled from billets.

(c) Cold-twisted bars shall be twisted cold with one complete twist in a length not over twelve times the thickness of the bar.

4. *Chemical composition.*—The steel shall conform to the following requirements as to chemical composition:

Phosphorus:	Per cent
Bessemer, not over.....	0.10
Open-hearth, basic, not over.....	.05
Open-hearth, acid, not over.....	.08

5. *Ladle analysis.*—(a) For Bessemer steel, a carbon determination shall be made of each melt; and determinations for manganese, phosphorus and sulphur, representing the average of the melts made in each 12-hour period.

(b) For open-hearth steel an analysis of each melt shall be made for carbon, manganese, phosphorus, and sulphur.

(c) These analyses shall be made by the manufacturer from test ingots taken during the pouring of each melt. The chemical composition thus determined shall be reported to the purchaser or his representative. The phosphorus content shall conform to the requirements of section 4.

6. *Check analyses.*—Analyses may be made by the purchaser from finished bars representing each melt of open-hearth steel, and each melt, or lot of 10 tons, of Bessemer steel. The phosphorus content thus determined shall not exceed that specified in section 4 by more than 25 per cent.

7. *Tension tests.*—(a) The bars shall conform to the following requirements as to tensile properties:

Tensile properties

Classes and grades	Yield point	Tensile strength	Elongation in 8 inches ^a
	Lbs./in. ²	Lbs./in. ²	Per cent
Plain bars:	33,000	55,000-70,000	1,400,000
			Tensile strength minimum 16 per cent. 1,300,000
Intermediate.....	40,000	70,000-90,000	Tensile strength minimum 16 per cent. 1,200,000
Hard.....	50,000	(Min.) 80,000	Tensile strength minimum 14 per cent. 1,000,000
Deformed bars:	33,000	55,000-70,000	1,250,000
			Tensile strength minimum 14 per cent. 1,125,000
Intermediate.....	40,000	70,000-90,000	Tensile strength minimum 14 per cent. 1,000,000
Hard.....	50,000	(Min.) 80,000	Tensile strength 5
Cold-twisted bars.....	55,000	(^b)	5

^a See sec. 8.

^b Recorded only.

(b) The yield point shall be determined by the drop of the beam of the testing machine.

8. *Modifications in elongation.*—(a) For plain and deformed bars over three-fourths inch in thickness or diameter, a deduction from the percentages of elongation specified in section 7 (a) of 0.25 per cent shall be made for each increase of one-thirty-second inch of the specified thickness or diameter above three-fourths inch.

(b) For plain and deformed bars under seven-sixteenths inch in thickness or diameter, a deduction from the percentages of elongation specified in section 7 (a) of 0.5 per cent shall be made for each decrease of one-thirty-second inch of the specified thickness or diameter below seven-sixteenths inch.

9. *Bend tests.*—The test specimen shall bend cold around a pin, without cracking on the outside of the bent portion, as follows:

Bend test requirements

Thickness or diameter of bar	Plain bars			Deformed bars			Cold-twisted bars
	Structural-steel grade	Intermediate grade	Hard grade	Structural-steel grade	Intermediate grade	Hard grade	
Under ¾ inch..	180° d=t	180° d=2t	180° d=3t	180° d=t	180° d=3t	180° d=4t	180° d=2t
¾ inch or over.	180° d=t	180° d=2t	180° d=3t	180° d=2t	180° d=3t	180° d=4t	180° d=3t

d=the diameter of pin about which the specimen is bent.
t=the thickness or diameter of the specimen.

10. *Test specimens.*—(a) Tension and bend test specimens for plain and deformed bars shall be taken from the finished bars, and shall be of the full thickness or diameter of bars as rolled; except that the specimens for deformed bars may be machined for a length of at least 9 inches, if deemed necessary by the manufacturer to obtain uniform cross section.

(b) Tension and bend test specimens for cold-twisted bars shall be taken from the finished bars, without further treatment; except as specified in section 2 (c).

11. *Number of tests.*—(a) One tension and one bend test shall be made from each melt of open-hearth steel, and from each melt, or lot of 10 tons of Bessemer steel; except that if material from any such test lots differs three-eighths inch or more in thickness or diameter, one tension and one bend test shall be made from both the thickest and the thinnest material rolled.

(b) If any test specimen shows defective machining or develops flaws, it may be discarded and another specimen substituted.

(c) If the percentage of elongation of any tension test specimen is less than that specified in section 7 (a) and any part of the fracture is outside the middle third of the gage length, as indicated by scribe scratches marked on the specimen before testing, a retest shall be allowed.

12. *Permissible variations.*—The weight of any lot of bars shall not vary more than 5 per cent from the theoretical weight of that lot.

NOTE.—The term "lot" used in this paragraph means all the bars of the same nominal weight per linear foot in a carload.

(Requirements covering finish, inspection, rejection, and reheating conform with those specified in A. S. T. M. standard specifications for steel. See 605.0, p. 247.)

ASSOCIATION OF AMERICAN STEEL MANUFACTURERS, STANDARD SPECIFICATIONS FOR RAIL-STEEL CONCRETE REINFORCEMENT BARS, 1914

RAIL-STEEL REINFORCEMENT BARS

MANUFACTURE

1. All steel shall be rolled from standard section T rails.

PHYSICAL PROPERTIES

2. The physical properties shall conform to the following limits:

Properties considered	Rail steel, grade	
	Plain bars	Deformed and hot-twisted bars
Ultimate tensile strength, minimum.....lbs./in. ²	80,000	80,000
Yield point, minimum.....lbs./in. ²	50,000	50,000
Elongation, in 8-inch minimum.....per cent.....	1,200,000	1,000,000
	Tensile strength	Tensile strength
Cold bend without fracture: Bars under ¾ inch in diameter.....	180° d=3t	180° d=4t
Bars ¾ inch in diameter or thickness and over.....	90° d=3t	90° d=4t

YIELD POINT

3. For the purposes of these specifications, the yield point shall be determined by careful observation of the drop of the beam of the testing machine or by other equally accurate method.

FORM OF SPECIMENS

4. (a) Tensile and bending test specimens may be cut from the bars as rolled, but tensile and bending test specimens of deformed bars may be planed or turned for a length of at least 9 inches if deemed necessary by the manufacturer in order to obtain uniform cross section.

(b) Tensile and bending test specimens of hot-twisted bars shall be cut from the bars after twisting and shall be tested in full size without further treatment, unless otherwise specified.

NUMBER OF TESTS

5. (a) One tensile and one bending test shall be made from each lot of 10 tons or less of each size of bar rolled from rails varying not more than 10 pounds per yard in nominal weight. Should a test specimen develop flaws, or should the tensile-test specimen break outside of the middle third of its gaged length, it may be discarded and another test specimen substituted therefor. In case a tensile specimen does not meet the specifications, an additional test may be made.

(b) The bending test may be made by pressure or by light blows.

MODIFICATIONS IN ELONGATION FOR THIN AND THICK MATERIAL

6. For bars less than seven-sixteenths inch and more than three-fourths inch nominal diameter or thickness, the following modifications shall be made in the requirements for elongation:

(a) For each increase of one-eighth inch in diameter or thickness above three-fourths inch, a deduction of 1 shall be made from the specified percentage of elongation.

(b) For each decrease of one-sixteenth inch in diameter or thickness below seven-sixteenths inch, a deduction of 1 shall be made from the specified percentage of elongation.

NUMBER OF TWISTS

7. Hot-twisted bars of rail carbon steel shall be twisted with one complete twist in a length equal to not more than twelve times the thickness of the bar.

FINISH

8. Material must be free from injurious seams, flaws, or cracks, and have a workmanlike finish.

VARIATION IN WEIGHT

9. Bars for reinforcement are subject to rejection if the actual weight of any lot varies more than 5 per cent over or under the theoretical weight of that lot.

CONCRETE REINFORCING STEEL INSTITUTE, STANDARDS FOR CONCRETE-REINFORCING BARS; TABLE OF STANDARD SIZES, AREAS, AND WEIGHTS, 1930

CONCRETE-REINFORCING BARS

(Conforms to Simplified Practice Recommendation No. R26-30 of the United States Department of Commerce in respect to area and size, see below. The weights for squares and rounds are as follows:)

Size (in inches)	Weight	Size (in inches)	Weight
	Lbs./ft.		Lbs./ft.
¼ round.....	0.17	7/8 round.....	2.07
⅜ round.....	.38	1 round.....	2.70
½ round.....	.68	1 square.....	3.44
⅝ square.....	.86	1½ square.....	4.35
¾ square.....	1.06	1¾ square.....	5.37
¾ round.....	1.52		

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, SIMPLIFIED PRACTICE RECOMMENDATION R26-30, APRIL 1, 1930

STEEL REINFORCING BARS

The industry has accepted the following simplified list of cross-sectional areas:

Cross-sectional areas

[In square inches]

0.05	0.31	1.00
.11	.44	1.27
.20	.60	1.56
.25	.79	-----

Table of typical equivalents

(The following table is for informational purposes and is not a part of the simplified practice recommendation.)

Area (in square inches)	Sizes of square and round bars (in inches)
0.05	¼ round.
.11	⅜ round.
.20	½ round.
.25	½ square.
.31	⅝ round.
.44	¾ round.
.60	⅞ round.
.79	1 round.
1.00	1 square.
1.27	1¼ square.
1.56	1½ square.

Pitch of spirals for various percentages of four standard rod sizes

[The following table shows the application of the sizes of simplified reinforcing spirals to all normal column core diameters with ¼-inch intervals of vertical spacing between successive turns]

Core diameter	Rod diameter (inches)													
	¼				⅜				½				⅝	
	Percentage of spiral reinforcement													
	½	¾	1	1½	½	¾	1	1½	2	1	1½	2	1½	2
	Pitch of spirals													
Inches	Inches	Inches	Inches	Inches	Inches	Inches	Inches	Inches	Inches	Inches	Inches	Inches	Inches	Inches
9					1½									
10					1¼									
11			1¾		1¼									
12			1½							1¾				
13		2	1½						2¼	1¾				
14		1¾	1¼						2	1½				
15	2½	1¾							2	1½			2½	
16	2½	1½						2¾	1¾				2½	
17	2¼	1½						2½	1¾				2¼	
18	2¼	1¼						2½	1¾				3	2½
19	2					3	2¼	1½				2¾	2	
20	2					3	2¼	1½				2½	2	
21	1¾					2¾	2					2½	1¾	3
22	1¾					2¾	2					2½	1¾	2¾
23	1¾					2½	2					2¼	1¾	2¾
24	1½							1¾				2¼	1½	
25	1½							1¾				2	1½	
26	1½							1¾				3	2	1½
27	1½							1½				3	2	1½
28						2	1½					2¾	1¾	3
29						3	2	1½				2¾	1¾	2¾
30						3	2	1½				2¾	1¾	2¾
31						2¾	2					2½	1¾	2
32						2¾	1¾					2½	1½	2
33						2¾	1¾					2½	1½	1¾
34						2½	1¾					2¼	1½	1¾
35						2½	1¾					2¼	1½	1¾
36						2½	1½					2¼	1½	1¾
37						2¼	1½					2	1½	1¾
38						2¼	1½					2	1½	1½
39						2¼	1½					2	1½	1½

NOTES—Pitches not greater than one-sixth of core diameter nor greater than 3 inches. (See joint building code of American Concrete Institute and Concrete Reinforcing Steel Institute.)
 Pitches not shown for smaller core diameters must be checked by above rule to determine minimum spacing.
 Pitches less than 1½ inches not recommended except for ¼-inch rods.
 Pitch of 1¼ inches may be used for ¼-inch rods where absolutely necessary but no smaller spacing recommended.
 Pitch variation by ¼-inch intervals recommended.

This recommendation, subject to annual revision by the standing committee of the industry, is effective from September 2, 1930.

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, SIMPLIFIED PRACTICE RECOMMENDATION FOR STEEL SPIRAL RODS FOR CONCRETE REINFORCEMENT, R53-31, SEPTEMBER 30, 1931

SPIRAL REINFORCEMENT RODS

(Simplified practice recommended and accepted by industry establishing a limited list of standard sizes of round bars for reinforcing spirals.)

Diameters and areas of spiral rods (plain rounds)

Diameters of round bars	Areas
Inch	Square inch
¼	0.05
⅜	.11
½	.20
⅝	.31

NOTE.—See following table of rod spacings which is for informational purposes and covers the normal conditions for use of spiral rods.

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR BARS, REINFORCEMENT, CONCRETE, NO. 350a, 1929. (CURRENT DESIGNATION, QQ-B-71)

REINFORCEMENT BARS

I. GENERAL SPECIFICATIONS

United States Government general specification for metals, Federal Specifications Board specification No. 339a (QQ-M-151), in effect on date of invitation for bids, shall form part of this specification. (See 600.0, p. 3.)

II. TYPES, GRADES, AND CLASSES

1. Concrete reinforcement bars shall be of four types: A, plain; B, deformed; C, hot twisted; and D, cold twisted.

2. Concrete reinforcement bars shall be of four grades: (1) Structural billet steel, (2) intermediate billet steel, (3) hard billet steel, and (4) hard rail steel.

3. Concrete reinforcement bars shall be of three classes: (a) Open-hearth steel, basic; (b) open-hearth steel, acid; and (c) Bessemer steel.

III. MATERIAL AND WORKMANSHIP

The finished material shall be free from injurious defects and shall have a workmanlike finish.

IV. GENERAL REQUIREMENTS

1. Bars of grades 1, 2, and 3 shall be rolled only from billets. Bars of grade 4 shall be rolled only from standard section T rails.

2. Cold-twisted bars shall be twisted cold and hot-twisted bars shall be twisted hot. Each shall have one complete twist in a length of not over twelve times the thickness of the bar.

3. *Permissible variations.*—The weight of any lot of bars shall not vary more than 5 per cent from the theoretical weight of that lot. No bar shall have a minimum cross section over 6 per cent less than the theoretical cross section. If 5 per cent or more of the bars in any lot fail to meet this requirement, the lot shall be rejected. The term "lot" in this section shall be taken to include all bars of the same nominal weight per linear foot contained in a carload and represented by one invoice.

V. DETAIL REQUIREMENTS

1. *Chemical composition.*—The phosphorus content of grades 1, 2, and 3 steel shall not exceed 0.070, 0.100, and 0.125 per cent for classes (a), (b), and (c), respectively. Grade 4 steel shall not be subjected to any chemical tests.

2. *Manufacturers' analyses.*—For grades 1, 2, and 3, the manufacturer shall furnish the analyses given in Section V, 2 (a) and (b). The phosphorus content shall not exceed that specified in Section V, 1.

(a) *Open-hearth steel.*—An analysis of each melt of steel showing the percentages of carbon, manganese, phosphorus, and sulphur.

(b) *Bessemer steel.*—An analysis of each melt, or lot of 10 tons, showing the percentage of carbon, and also an analysis for each 12-hour period showing the percentages of manganese, phosphorus, and sulphur. This shall be considered as representing all melts poured during this period.

3. *Tension and bend tests.*—(a) The bars shall conform to the requirements given in Tables 1 and 2 as to tension properties and bend test requirements, respectively.

(b) The yield point shall be determined by the drop of the beam of the testing machine.

VI. METHODS OF INSPECTION AND TESTS

1. *Number of tests.*—(a) For billet steel, two tension and two bend tests shall be made from each melt, unless the finished material from a melt is less than 25 short tons, when one tension and one bend test shall be sufficient. For Bessemer billet steel, one tension and one bend test shall be made from each lot of 10 short tons or less when the melts can not be identified. If, however, material from one melt or test lot differs three-eighths inch or more in thickness, the thickest and thinnest material rolled shall each be represented by one tension and one bend test, regardless of the weight of the melt or test lot.

(b) For rail steel, one tension and one bend test shall be made from each lot of 10 short tons or less of each size of bar rolled from rails varying not more than 10 pounds per yard in nominal weight.

2. *Test specimens.*—(a) Tension and bend test specimens for plain and deformed bars shall be taken from the finished bars, and shall be of the full thickness or diameter of bars as rolled; except that the specimens for deformed bars may be machined for a length of at least 9 inches, if deemed necessary to obtain uniform cross section.

(b) Tension and bend test specimens for cold-twisted bars shall be taken from the finished bars without further treatment, except as specified in Section VIII, 3. Tension and bend test specimens for hot-twisted bars shall be taken from the finished bars without further treatment.

3. *Bend tests.*—The test specimen shall bend cold around a pin without cracking on the outside of the bent portion, as specified in Table 2.

TABLE 1.—*Tensile properties*

(This table is the same as the two tables given in the two specifications of the Association of American Steel Manufacturers for billet steel and for rail steel reinforcement bars, tensile properties. See 605.25, above.)

TABLE 2.—*Bend-test requirements*

(This table is the same as the two tables given for bend-test requirements in the two specifications of the A. A. S. M. for billet steel and for rail steel reinforcement bars. See 605.25, above.)

VII. PACKING AND MARKING OF SHIPMENTS

Bars shall be made up in bundles, securely wired, as specified in the contract or purchase order. A metal tag shall be affixed to each bundle upon which shall be stamped data, as directed.

VIII. NOTES

1. When specifying material in accordance with this specification, the type (A, B, C, or D), the grade (1, 2, 3, or 4), and the class (a, b, or c), should be definitely stated.

2. Type A, plain bars and type B, deformed bars, may be obtained in any of the four grades specified in Section II, 2.

3. Type D, cold-twisted bars, in addition to being obtainable in accordance with the properties after twisting as specified herein, may be purchased on the basis of tests of the hot-rolled bars before twisting, in which case these latter tests shall govern and shall conform to the requirements specified for type A, plain bars of grade 1, structural steel.

4. While type C, hot-twisted bars, are obtainable in any of the four grades, 1, 2, 3, and 4, they are usually purchased only in grades 3 and 4.

5. The areas (with their equivalent sizes of square and round bars) given in Simplified Practice Recommendation No. R26-30 of the United States Department of Commerce are given above.

606. RAILWAY TRACK MATERIAL

606.0 GENERAL ITEMS.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, STANDARDS, RECOMMENDATIONS, AND MISCELLANEOUS METHODS AND PRACTICES DEALING WITH THE GENERAL SUBJECT OF WAY MATTERS

TRACK CONSTRUCTION

(These specifications do not concern themselves with the manufacture of materials, but with the utilization of manufactured materials in track-work construction.)

Serial No.	Date	Subject matter
W2-15----	1915	Definitions of bond and third-rail gage.
W3-15----	1915	Location of and clearances for third-rail working conductors, structures, and rolling equipment.
W10-21----	1921	Tongue switch construction.
W12-23----	1923	Method of designating compromise joints.
W13-28----	1928	Special track-work layouts.
W14-22----	1922	Location of tongue switches.
W35-28----	1928	Uniform track center distances.
W40-28----	1928	Determination of flange ways and gages on curves.
W101-15--	1915	Third-rail guards.
W113-28--	1928	Street railway track construction.

AMERICAN MINING CONGRESS, MINE TRACKS, SIGNALS, AND SWITCHES, M7A-1927

[Approved as American Tentative Standard by the American Standards Association, May 13, 1927]

MINE TRACKS, SIGNALS, AND SWITCHES

GAGE

1. The standard track gage shall be 42 inches.
2. A 42-inch gage forms the best radii of curves with useful frog angles to suit the majority of coal-mine work.
3. Under certain conditions, such as demands the use of cars to meet low-roof mines, etc., a gage of 42 inches may be prohibitive, and if necessary that it be other than standard the alternatives shall be in steps of 6 inches above or below, such as 30, 36, or 48 inches.
4. In addition to the above, an extra alternate of 4 feet 8½ inch gage is allowed, as some mines find it an advantage to have equipment that will roll on standard railroad tracks. Regardless of the alternates, the standard gage of 42 inches shall be used whenever possible.

RAIL

5. The rails covered by these standards shall be from 16 to 70 pounds per yard, inclusive, with room tracks limited to 45 pounds and below.

DRILLING

6. The drilling of rails or spacing and size of holes for splice bars shall be as follows:

Rails (in pounds)	Spacing		Diameter of hole
	Inches		
16 to 25-----	2	4	5/8
30 and 35-----	2	4	3/4
40 and 45-----	2½	5	7/8
50 and 70-----	2½	5	1

7. In the spacing given, the first dimension is the distance from end of rail to center of first hole, and the second dimension is the distance from center of first to center of second hole.

FROG NUMBERS (ANGLES)

8. Standard frog numbers and angles shall be as follows:

No.	Degrees	Minutes	Seconds
2	28	04	21
3	18	55	29
4	14	15	00
5	11	25	16
6	9	31	38

No. 2 frog is for room turnouts. No. 3 frog is for turnouts between room entries and face or panel entries. No. 4 frog is for turnouts between face and panel entries and in some cases for main haulage. Nos. 5 and 6 frogs are for turnouts for main-line haulage only, and especially where traffic is fast.

SWITCH LENGTHS

9. Lengths of switches and the number of frog with which they are to be used shall be as follows:

- 3 foot 6 inch switch for use with No. 2 frog.
- 5-foot switch for use with Nos. 3 and 4 frogs.
- 7 foot 6 inch switch for use with Nos. 5 and 6 frogs.

SWITCH HEEL SPREADS

10. Heel spreads of switches shall be such as to present the sharpest angle and still allow room for spike holes in heel plates. The spreads are governed by size of rail and not by lengths of switches, and shall be as listed below:

Rails (in pounds)	Heel spread
16 to 45-----	Inches 4½
50 to 60-----	5
65 and 70-----	5½

SWITCH TYPES

11. Switches shall be of two types—light and heavy duty. The light-duty switch shall be only for rails from 16 to 35 pounds and lengths of 3 feet 6 inches and 5 feet.

AMERICAN RAILWAY ASSOCIATION, MECHANICAL DIVISION, WHEELS AND TRACK, TERMS AND GAGING POINTS FOR, 1894

WHEELS AND TRACK GAGE

1. *Track rails* are the two main rails forming the track.
2. *Gage of track* is the shortest distance between the heads of track rails.
3. *Base line*, for wheel gages, is a line parallel to the axis of the wheels drawn through the point of intersection of tread with a line perpendicular to the axis, and passing through the center of the throat curve.
4. *Inside gage of flanges* is the distance between backs of flanges of a pair of mounted wheels measured on the base line.
5. *Gage of wheels* is the distance between the outside face of flanges of a pair of mounted wheels

Girder-guard rails shall be class A.

Plain and grooved girder rails under 135 pounds in weight per yard shall be specified as either class A or class B.

Plain and grooved girder rails of 135 pounds in weight per yard and heavier shall be class C, unless otherwise specified.

I. MANUFACTURE

101. The steel shall be made by the open-hearth process. The entire process of manufacture and testing shall be in accordance with the best current practice.

102. Bled ingots and ingots or blooms which show the effects of injurious treatment shall not be used.

103. A sufficient discard from the top of each ingot shall be made at any stage of the manufacture to obtain sound rails. When finished rails show piping, they may be cut to shorter lengths until all evidence of this is removed.

II. CHEMICAL PROPERTIES AND TESTS

201. The steel shall conform to the following requirements as to chemical compositions, according to the class specified in the order:

	Class A	Class B	Class C
	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>
Carbon.....	0.60-0.75	0.70-0.85	0.75-0.90
Manganese.....	.60-.90	.60-.90	.60-.90
Silicon.....	.15-.40	.15-.40	.15-.40
Phosphorus, not over.....	.04	.04	.04

202. To determine whether the material conforms to the requirements specified in section 201, an analysis shall be made by the manufacturer from a test ingot taken during the pouring of each melt. Drillings for analysis shall be taken not less than one-eighth inch beneath the surface of the test ingot. A copy of this analysis shall be given to the purchaser or his representative.

203. A check analysis may be made as information from time to time by the purchaser from a test ingot or drillings therefrom furnished by the manufacturer.

III. PHYSICAL PROPERTIES AND TESTS

301. (a) Four representative sections of rail from each melt shall be selected by the inspector as test specimens.

(b) Excess scale on the head or web of the sections shall be carefully removed.

302. (a) The head of each specimen shall be subjected to a pressure of 100,000 pounds (45,359 kg) for a period of 15 seconds, applied through a hardened steel ball 0.75 inch (19.05 mm) in diameter.

(b) The steel test ball shall have a minimum Brinell hardness of 600 and it shall not be possible to attack the surface of the ball with an American Swiss pillar file No. 2.

(c) When fractured, the ball shall show a fine uniform grain, and the fracture shall resist file attack for at least one-third of its depth from the surface of the ball. The permissible variation in the diameter of the ball shall not be greater than 0.002 inch over or under the standard size, and the permanent deformation under the required loading shall not be greater than 0.003 inch.

(d) The average depth of impression obtained on the four specimens shall not be more than 0.1496 inch (3.8 mm) for class A rails, 0.1391 inch (3.5 mm) for class B rails, and 0.1338 inch (3.4 mm) for class C rails.

303. If the average of the impression tests on the head of the section from any melt fails to conform to the requirements specified in section 302 (d) the manufacturer may at his option test each rail from such melt by making an impression test on the web, as described in section 302 (a). Rails so retested which conform to the requirements as to depths of impression specified in section 302 (d) shall be accepted.

IV. STANDARD SECTIONS, LENGTHS, AND WEIGHTS

401. (a) The cold template of the manufacturer shall conform to the specified section as shown in detail on the drawing of the purchaser and shall at all times be maintained perfect.

(b) The section of the rail shall conform as accurately as possible to the template, and within the following permissible variations:

(1) The height shall not vary more than one-sixty-fourth inch under nor more than one-thirty-second inch over that specified.

(2) The over-all width of head and tram shall not vary more than one-eighth inch from that specified. Any variation which would affect the gage line more than one-thirty-second inch will not be allowed.

(3) The over-all width of base shall not vary more than one-eighth inch under that specified for widths less than 6½ inches; three-sixteenths inch under for a width of 6½ inches, and one-fourth inch under for a width of 7 inches.

(4) No changes will be allowed in dimensions affecting the fit of splice bars except that the fishing template approved by the purchaser may stand out not to exceed three-thirty-seconds inch laterally.

(5) The base of the rail shall be at right angles to the web; and the convexity shall not exceed one-thirty-second inch.

(c) When necessary on account of the type of track construction, and notice to that effect has been given to the manufacturer, special care shall be taken to maintain the proper position of the gage line with respect to the outer edge of the base.

402. (a) Unless otherwise specified, the lengths of rails at a temperature of 60° F. (15.5° C.) shall be 60 and 62 feet for those sections in which the weight per yard will permit; except girder-guard rails, which shall be 30 and 32 feet, unless otherwise specified.

(b) The lengths shall not vary more than one-fourth inch from those specified.

(c) Shorter lengths, varying by 1 foot down to 40 feet for plain and grooved girder rails and 24 feet for girder-guard rails, will be accepted to the extent of 10 per cent by weight of each class on the order.

403. (a) The weight of the rails per yard as calculated shall be maintained as nearly as possible after conforming to the requirements specified in section 401.

(b) A variation of 0.5 per cent from the calculated weight of section as applied to the entire order will be allowed.

(c) Rails accepted will be paid for according to actual weight.

V. WORKMANSHIP AND FINISH

501. (a) Rails on the hot beds shall be protected from water or snow and shall be carefully handled to minimize cold straightening.

(b) The distance between the rail supports in the cold-straightening presses shall not be less than 42 inches, except as may be necessary near the ends of the rails. The gag shall have rounded corners to avoid injury to the rails.

VIII. MARKING AND LOADING

(c) Rails heard to snap or check while being straightened shall be at once rejected.

502. (a) Rails shall be smooth on the head, straight in line and surface without any twists, waves, or kinks, particular attention being given to having the ends without kinks or droop.

(b) All burrs or flow caused by drilling or sawing shall be carefully removed.

(c) Rails shall be free from gag marks and other injurious defects of cold straightening.

(d) Any rails to be cold straightened showing sharp kinks or greater camber than that indicated by the middle ordinate of 18 inches in 60 feet shall be classed as No. 2 rails.

VI. DRILLING, MILLING, AND PUNCHING

601. (a) Circular holes for splice bar bolts, bonds, and tie rods shall be drilled to conform to the drawings and dimensions furnished by the purchaser and within the following permissible variations:

(b) The diameter of bolt holes shall not vary more than one-thirty-second inch over or under that specified. The diameter of bond holes shall not be over the size specified, but may be one-thirty-second inch under. The diameter of the tie-rod holes shall not be less than that specified but may be one-sixteenth inch over.

(c) The location of bolt and bond holes shall not vary more than one-sixteenth inch either longitudinally or vertically from that specified. The location of the tie-rod holes shall not vary more than one-fourth inch vertically and not more than one-half inch longitudinally from that specified.

(d) Bond holes shall be truly cylindrical and not conical.

602. The ends of the rail shall be milled. The plane of the finished end surface shall, in the direction of the width of the rail, be at right angles to the gage with a permissible variation of one-thirty-second inch in 6 inches, and in the direction of the height of the rail, be inclined to the plane of the base so that the top edge of the head will project beyond the bottom edge of the base not less than one-thirty-second inch nor more than three-thirty-seconds inch.

603. Unless otherwise specified by the purchaser, the tie-rod holes in class A rails may be punched, and, when so made, they shall be free from burrs, fins, etc. Punched tie-rod holes shall not be less in diameter than specified but may be not over one-eighth inch oversize.

VII. CLASSIFICATION OF RAILS

701. Rails which are free from injurious defects and flaws of all kinds shall be classed as No. 1 rails.

702. (a) Rails which are rough on the head or which by reason of surface or other imperfections are not classed as No. 1 rails shall be classed as No. 2 rails; provided they do not, in the judgment of the inspector, contain imperfections in such number and of such character as to render them unfit for No. 2 rail uses, and provided they conform to the requirements specified in section 401.

(b) No. 2 rails will be accepted to the extent of 10 per cent by weight of the entire order.

801. (a) The name or brand of the manufacturer, the year and month of manufacture, the letters "O. H.," the weight of the rail, and the section number shall be legibly rolled in raised letters and figures on the web. The melt number shall be legibly stamped on each rail where it will not be covered subsequently by the splice bars.

(b) Both ends of all short-length No. 1 rails shall be painted green. Both ends of all No. 2 rails shall be painted white and shall have two heavy center-punch marks on the web at each end at such a distance from the end that they will not be covered subsequently by the splice bars.

802. (a) Rails shall be loaded in the presence of the inspector, and shall be handled in such a manner as not to bruise the flanges or cause other injuries.

(b) Loadings of each class shall be placed together in loadings.

(c) Rails shall be paired as to length before shipment.

IX. INSPECTION

(Conforms with paragraph 7 in A. S. T. M. standard specifications for steel. See 605.0, p. 247.)

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, STANDARD DESIGN FOR 7-INCH GIRDER-GROOVED RAIL, W6-31, 1931

7-INCH GIRDER-GROOVED RAIL

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR DROP-TEST MACHINE, 1910

DROP-TEST MACHINE

A drop-test machine conforming essentially to the manufacturers' plans and specifications and in general accord with the following requirements will give satisfactory results:

1. The machine shall be arranged to allow a 2,000-pound tup to fall freely at least 25 feet on the center of a rail resting on supports that can be adjusted to spans varying from 3 feet to 4 feet 6 inches.

2. The anvil shall be a solid casting, weighing, with the attachments that move with it, 20,000 pounds. It shall be free to move vertically independent of the lead columns. It shall be supported on 20 springs known as the standard "C" spring, without center coil, as employed by the A. R. A. mechanical division. (See fig. 175.) This spring has a free length of 8 3/4 inches, an outside diameter of 5 1/16 inches, and is made from a bar having a diameter of 1 1/16 inches. These springs shall be arranged in groups of five at each corner of the anvil. They shall be held in place by hubs raised on the top of the base plate, and by circular pockets on the underside of the anvil. The anvil shall be guided in its vertical movement by removable finished wearing strips. These wearing strips shall be suitably attached to the finished edges of the column base.

3. The base plate shall be of cast iron or cast steel 8 inches thick in the area covered by the anvil. It shall be firmly secured to the substructure by four bolts 2 inches in diameter.

4. The substructure shall consist of a timber grillage resting on a masonry foundation. The grillage shall project 9 inches beyond the ends of the base plate, and clear the columns at the side. It shall consist of one course of 12 by 12 inch sound oak or southern yellow pine, preferably creosoted, laid close and well bolted together. The masonry, preferably concrete, shall be not less than 5 feet deep below the grillage, suitably supported on the subsoil.

Weight, 2 bars, each 26 inches long.....	Pounds
Weight of bolts.....	65.5
Total weight, 2 bars and 6 bolts.....	77.0

5. The pedestals for supporting the test rail shall be substantial castings. The surface of the anvil between these pedestals shall be formed to receive a wooden block to absorb shock under broken test pieces, the rail having an upper cylindrical bearing surface, with a radius of 5 inches. The pedestals shall be adjustable to spans varying from 3 feet minimum to 4 feet 6 inches maximum between centers. They shall be securely held together, and so fixed to the anvil as to insure that the center of the span shall always coincide with the center between leads.

6. The leads shall be firmly connected to the column base and well braced. They shall be long enough to provide the prescribed free fall of the tup. They shall be provided with a convenient ladder and a plainly marked gage, divided into 1-foot intervals. The zero of this gage shall be 5 1/4 inches above the top of the rail support. The specified height of drop shall

LENGTH OF SPLICE BARS AND SPACING OF HOLES

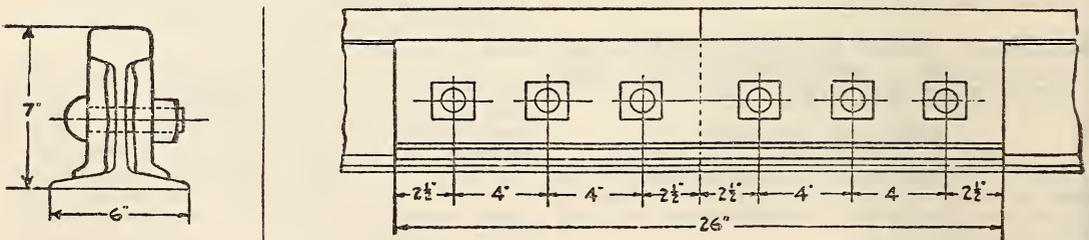

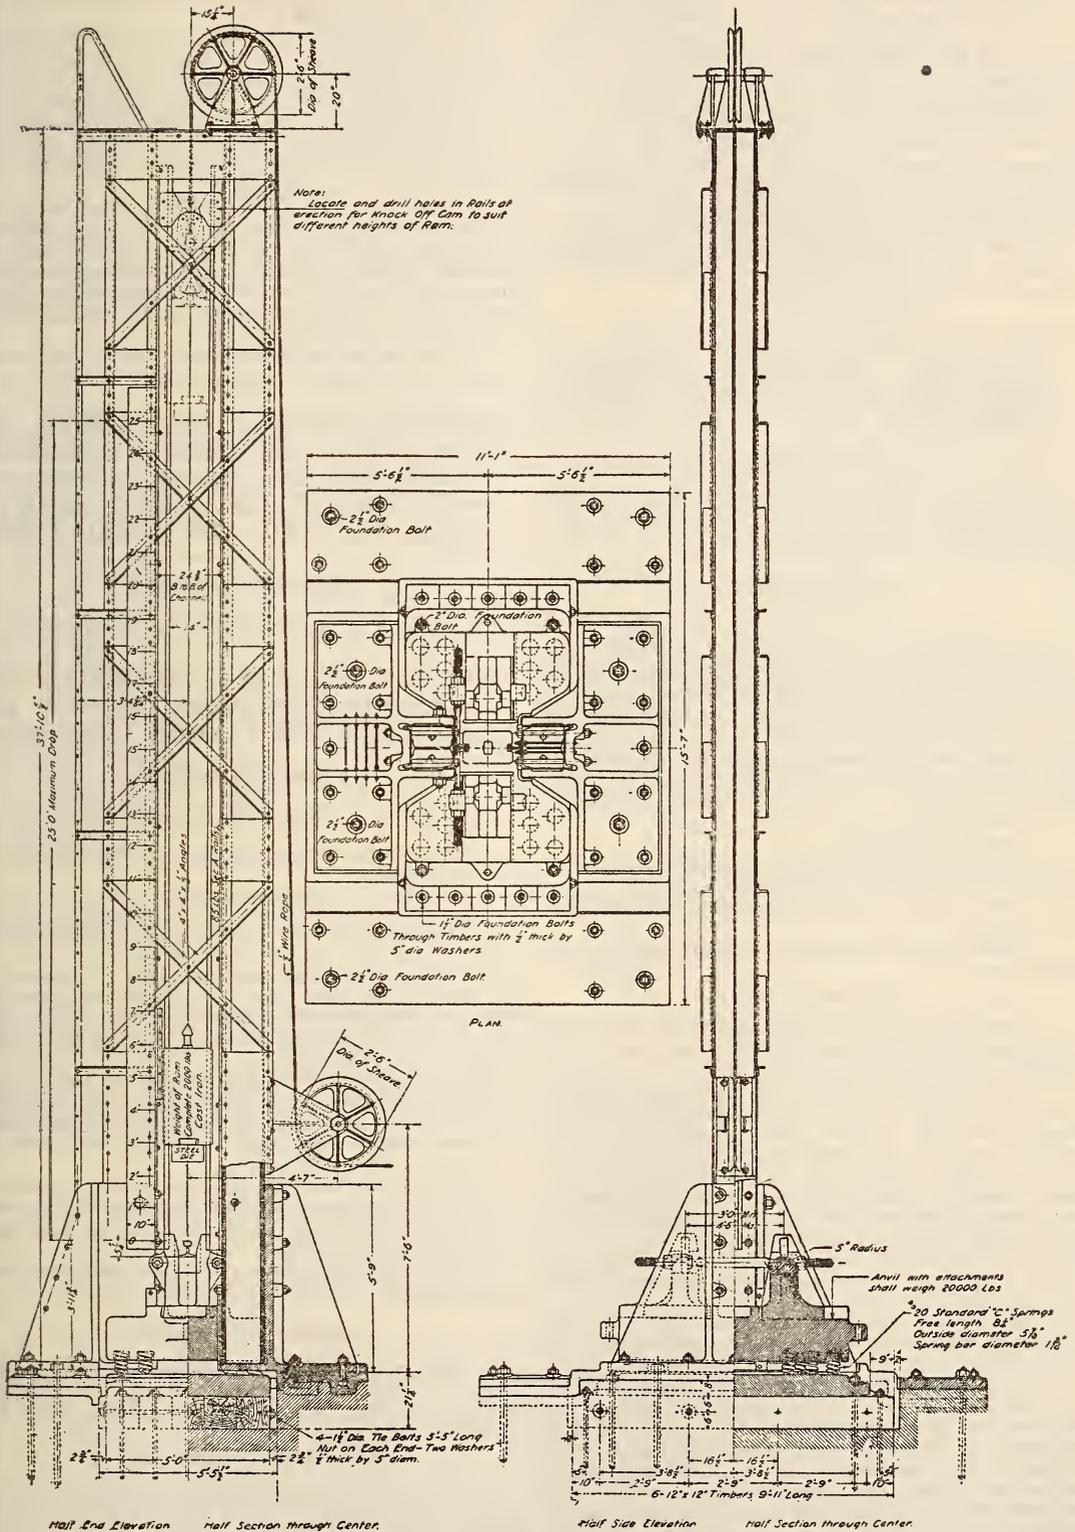

FIGURE 174.—26-inch splice bar for 7-inch plain girder rails (figures 168, 170 and 172) showing hole spacing and size of bolts

be measured from this zero, irrespective of the height of the rail being tested. One of the guides shall have a movable section 6 feet long at the bottom, so that the tup or tripping block may be readily removed.

7. The tup shall weigh, with the accessories that drop with it, 2,000 pounds. The striking die shall be of steel, having a cylindrical striking face, with a radius of 5 inches and a length of 12 inches. The guide grooves shall have finished surfaces. The tripping head shall allow a grip of the tongs that will release at the exact height for which the tripping device is set, and that will be safe from accidental release while the test piece is being shifted.

8. The tongs and tripping device shall be arranged to release the tup automatically only. No manual releasing will be allowed. The tripping device shall be easily adjusted at 1-foot intervals.

AMERICAN RAILWAY ENGINEERING ASSOCIATION, STANDARD SPECIFICATIONS FOR OPEN-HEARTH CARBON-STEEL RAILS, 1925

CARBON-STEEL RAILS

(Identical in substance with A. S. T. M. A1-30, given below, with the addition of the following requirements covering inspection:)

RAIL INSPECTION

I. Inspection Force

Rail inspectors shall be selected with care and men not familiar with rolling-mill practice shall not be sent to inspect rails except under the supervision of an experienced rail inspector. As far as possible the inspections shall be made by the same men, as they then become familiar with the methods of manufacture peculiar to each mill, for no two mills follow the same procedure even though owned by the same company.

1. Chief rail inspector.
2. Three or more assistant inspectors as size of mill and rate of rolling may require.
3. One or more checkers, depending upon rapidity of loading.
4. One chemist if check analyses are made in mill laboratory.

II. Duties of Inspectors

1. The chief rail inspector shall supervise the inspection force, mill practice, drop tests and make records.
2. One assistant inspector shall follow the mill practice closely, i. e., time of charging, time of tapping, cutting of tests, etc.; record any irregularities, such as too rapid pouring, charging cold ingots, rolling cold bloom, low finishing temperature, behavior of rails under straightening presses or any other departures from good mill practice which may affect the service of the rails.
3. One assistant inspector for night duty shall make drop tests if necessary, and follow the mill practice.
4. One or more assistant inspectors shall inspect the rails on the loading beds for surface defects, straightness, etc.
5. One or more checkers shall record the number of rails of each heat accepted and loaded in each car. A record of the car number and the number of rails of each heat in the car shall be sent to the division engineer, the supervisor, the road master or other officer to whom the rails are consigned. This prevents the loading of rails rolled from odd ingots, or the loading of more rails than were originally rolled in a heat, or the loading of rails from rejected

heats. It also furnishes a check record of the location of the rails if at any time in the future it is desired to remove the rails of a particular heat for any cause whatever.

6. A chemist shall make check analysis of drillings taken from corner of head of the rail, no rails being loaded until the check analysis is finished.

7. The office to which the rail inspection force reports shall keep a record of the history of each heat in a convenient form, so the results obtained from the service of the rails may be traced to the manufacture of the steel or rails.

8. Acceptance of heats meeting the technical requirements of specifications, but in the judgment of the inspector of inferior quality, shall be deferred pending decision of engineer of tests after full report and review of conditions; conversely, rejections of heats whose deficiencies may be technical only shall be similarly governed.

9. The inspectors can not be too careful and must exercise good judgment and all possible tact.

AMERICAN RAILWAY ENGINEERING ASSOCIATION, STANDARD SPECIFICATIONS FOR THE MANUFACTURE OF OPEN-HEARTH STEEL GIRDER RAILS OF PLAIN, GROOVED, AND GUARD TYPES, 1929

STEEL GIRDER RAILS

(Same as A. E. R. E. A., W1-31, given above.)

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR RELAYER RAIL FOR VARIOUS USES, 1920

RELAYER RAIL

DEFINITION

1. Worn rails suitable for use in track are known as relayer rails.

CLASSIFICATION

2. Relayer rails shall be classified according to the wear on the side and top of the head:

(a) Side wear shall be represented by figures: 0 representing no side wear; 1, 2, 3, etc., representing the number of sixteenths of an inch wear on the side of the head at the gage five-eighths inch below the original top of the rail.

(b) Top wear shall be represented by capital letters: O representing no top wear; A representing one-thirty-second inch; B, two-thirty-second inch; C, three-thirty-second inch, etc., wear, measured at the center of the rail.

(c) If the rail head is worn on both sides, the first figure shall represent the side showing the greater wear, the letter the top wear, and the figure following the lesser side wear.

(d) The maximum wear allowed in each case shall be specified by the user or the purchaser.

PROCESS AND SECTION

3. The process, as Bessemer, open-hearth, special alloy, or process steel, the section, the original weight per yard, and the splice drilling shall be specified.

MAIN-TRACK RELAYER RAILS

4. *Grade 1.*—Used rails suitable for main track on main or branch lines. They must be free from all physical defects and shall pass the A. R. E. A. specifications for carbon-steel rail (see above) in all re-

spects except wear. The surface of the rails of this grade must be fairly smooth and shall not have flat spots or wheel burns. They shall be sawed at the ends, not cut with a chisel. Drillings shall be uniform. Chemical analysis, or the specifications under which the rails were originally purchased, shall be furnished when requested by the purchaser. There shall be full-length pieces, 30, 33, or 39 feet long, and not over 10 per cent of shorts varying in length by one foot, with a minimum length of 22 feet.

RESAWING RAILS

5. *Grade 2.*—All rails with battered or otherwise defective ends, which if resawed would meet the grade 1 requirements, shall be graded as "resawed main-track relayer rails." In this case 90 per cent of the rails shall be of uniform length, 27 feet or over.

SIDE-TRACK RELAYER RAILS

6. *Grade 3.*—All used rails suitable for side tracks shall be included in this grade. They shall be not less than 15 feet long. Rails too badly out of line or surface to be included in grade 1, but straight enough to be easily spiked to line and gage shall be accepted. Drilling shall be uniform. Base shall be full or uniform width.

Any physical defects, such as broken lower flange, corroded, curved ends, burnt, ends battered, ends down, flat spots, head flow, line bent, piped, pitted, short, split end, split head, surface bent, twisted, worn under head, shall be specified where they occur and the extent of the defect shall be represented by the use of the term "slight," "moderate," or "bad."

SCRAP RAILS (ROLLING-MILL RAILS)

7. *Grade 4.*—Rails of standard section not suitable for use as relayer rails. They shall be not less than 6 feet long and shall be free from pipes, split heads, and similar defects. Badly twisted rails or bent rails, frogs, switches, and guard rails will not be accepted.

SCRAP RAILS

8. *Grade 5.*—All used rails of any length or condition not meeting the above specifications shall be designated as grade 5.

MARKING AND SHIPPING

9. Rails when classified shall be marked with white paint on the web about 3 feet from the end. The figure and letter representing the side and top wear shall be painted first, followed by a dash (—) and the grade number, except scrap rails shall be marked by the grade number only. No two grades of rails shall be loaded in the same car.

EXAMPLES

10. (a) Main-track relayer rails having $\frac{1}{16}$ -inch side wear and $\frac{3}{32}$ -inch top wear would be classified and marked "3 C—1."

(b) Resawed main-track relayer rails having $\frac{1}{4}$ -inch side wear and $\frac{3}{32}$ -inch top wear would be classified and marked "4 C—2."

(c) Side-track relayer rails having $\frac{1}{2}$ -inch side wear and $\frac{1}{8}$ -inch top wear would be classified and marked "8 D—." If there are any physical defects, as curved ends, line bent, pitted, etc., they should be so classified and the extent of the defects specified as "slight," "moderate," or "bad."

(d) Side-track relayer rails having $\frac{1}{2}$ -inch side wear on one side and $\frac{3}{8}$ -inch side wear on the other side, $\frac{1}{8}$ -inch top wear, would be classified and marked "8 D 6—3." If there are any physical defects, as curved ends, line bent, pitted, etc., they should be so classified and the extent of the defect specified as "slight," "moderate," or "bad."

AMERICAN RAILWAY ENGINEERING ASSOCIATION, STANDARD RAIL SECTIONS, 1924

STANDARD RAIL SECTIONS

(Rail section A.—R. A. A—90 pounds is identical with that of A. E. R. E. A. shown in Figure 165.)

(See figs. 176 to 181, inclusive.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR OPEN-HEARTH CARBON-STEEL RAILS, DESIGNATION A1-30, 1930

CARBON-STEEL RAILS

MANUFACTURE

1. (a) The entire process of manufacture shall be in accordance with the best current state of the art. It is expected that thoroughly deoxidized dead setting steel will be furnished and that in every stage of manufacture strict adherence to the standards of best practice of the individual mill will be observed.

(b) Should anything occur in the process of manufacture, which, in the judgment of the inspector, varies detrimentally from regular care and practice, the inspector will immediately notify the chief inspector and the general superintendent of the mill, confirming such report in writing. If, after full investigation, the inspector is not satisfied as to the good quality of the rails in question, and the rail, complying in other respects to these specifications, be loaded for shipment, the inspector will immediately forward a copy of this report to the purchaser.

2. Sufficient discard shall be taken from the ingot to insure freedom from injurious segregation and pipe.

CHEMICAL PROPERTIES AND TESTS

3. The steel shall conform to the following requirements as to chemical composition:

Elements considered	Weight (pounds per yard)				
	50-69	70-84	85-100	101-120	121-140
Carbon.....	Per cent 0.50-0.63	Per cent 0.53-0.70	Per cent 0.62-0.77	Per cent 0.67-0.83	Per cent 0.72-0.89
Manganese.....	.60-.90	.60-.90	.60-.90	.50-.90	.50-.90
Phosphorus, maximum.....	.04	.04	.04	.04	.04
Silicon, minimum.....	.15	.15	.15	.15	.15

4. (a) In any rolling, it is desired that the number of heats above the mean carbon percentage of the specific range shall be at least equal to the number of heats below the mean, and that the average carbon shall be as high as the mean.

(b) For information only, the manufacturer shall furnish the carbon and manganese analysis on drillings taken from both the "O" and "M" positions of the head at the top end of the "A" rail of the last full ingot rolled on each tenth heat.

5. Separate analyses shall be made from drillings taken from test ingots representing the second and one of the last full ingots of the heat to determine the percentages of carbon and manganese. The percentages of phosphorus, sulphur, and silicon shall be determined on equally mixed drillings from the test ingots. The average analysis of the ladle test ingots shall conform to the chemical requirements. A portion of the drillings shall be furnished to the inspector upon request for check analysis.

PHYSICAL PROPERTIES AND TESTS

6. (a) Ductility and resistance to impact will be determined by the standard A. R. E. A. drop-testing machine, with test specimens from 4 feet to 6 feet long cut from the top of the "A" rails from the second, middle, and last full ingots of each heat. These specimens shall be marked on the base with gage marks 1 inch apart for 3 inches each side of the center of the test specimens for measuring the ductility of the metal. The distance between supports shall be 3 feet for sections under 106 pounds. For sections 106 pounds and over it shall be 4 feet.

8. (a) If all three of the specimens endure the above tests without fracture, all the rails of the melt will be accepted subject to final inspection for surface, section, and finish.

(b) If one of the three specimens fails, all the "A" rails of the heat will be rejected. Specimens shall then be cut from the bottom end of the same "A" rails or the top end of the "B" rails and tested.

(c) If any of these test specimens fail, the "B" rails of the heat will be rejected. Three additional specimens shall then be taken from the bottom end of the "B" rails or the top end of the "C" rails. If

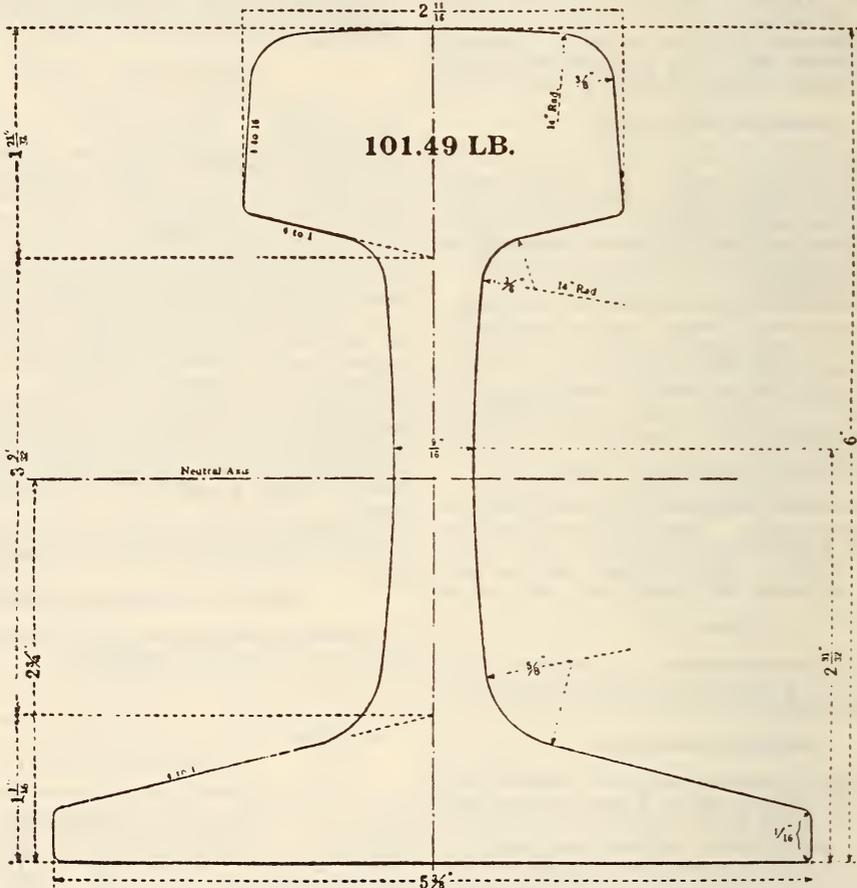

FIGURE 176.—Rail section, R. E., 100 pounds

Area:	Square inches	Per cent	Moment of inertia.....	49.0
Head.....	3.80	38.2	Section modulus, head.....	15.1

Base.....	3.90	39.2	Ratio M. I. to area.....	4.92
Total.....	9.95	100.0	Ratio section modulus to area.....	1.52

(b) The temperature of the test specimens shall not exceed 38° C. (100° F.)

7. The test specimens shall be placed head upwards on the supports and subjected to one blow from the tup falling free from the following heights:

Weight of rail (in pounds per yard)	Height of drop
	Feet
50 to 60, inclusive.....	16
61 to 80, inclusive.....	17
81 to 90, inclusive.....	18
91 to 100, inclusive.....	19
101 to 120, inclusive.....	20
121 to 140, inclusive.....	

all these test specimens endure the test, the balance of the heat will be accepted. If any of these tests specimens fail, the entire heat shall be rejected.

9. (a) One of the three test specimens shall be given a sufficient number of blows to determine, for information only, the exhausted ductility, reported inch by inch over the entire 6 inches gaged. No ductility readings will be taken between blows. The other two specimens shall be nicked and broken. The fracture of each specimen shall be examined to determine if the fracture conforms to the requirements of section 10.

(b) For information only, the permanent set measured by middle ordinate in inches in length of 3 feet shall be recorded after the first blow on all test specimens.

(c) For information only, one of the three test specimens shall be tested by Brinell indentation upon the head of the rail, and the diameter of the indentation shall be entered on the test record. The ball shall be 19 mm in diameter and the pressure 100,000 pounds.

10. If the fracture on any test specimen exhibits seams, laminations, cavities, interposed foreign matter, or a distinctly bright or fine-grained struc-

ture, that on 15 per cent of the order a variation of seven-sixteenths inch will be allowed.

When the specified length is 33 feet, 10 per cent of the entire order will be accepted in shorter lengths varying by 1 foot from 32 feet to 25 feet, and a variation of one-fourth inch from the specified length will be allowed, except that on 15 per cent of the order a variation of three-eighths inch will be allowed.

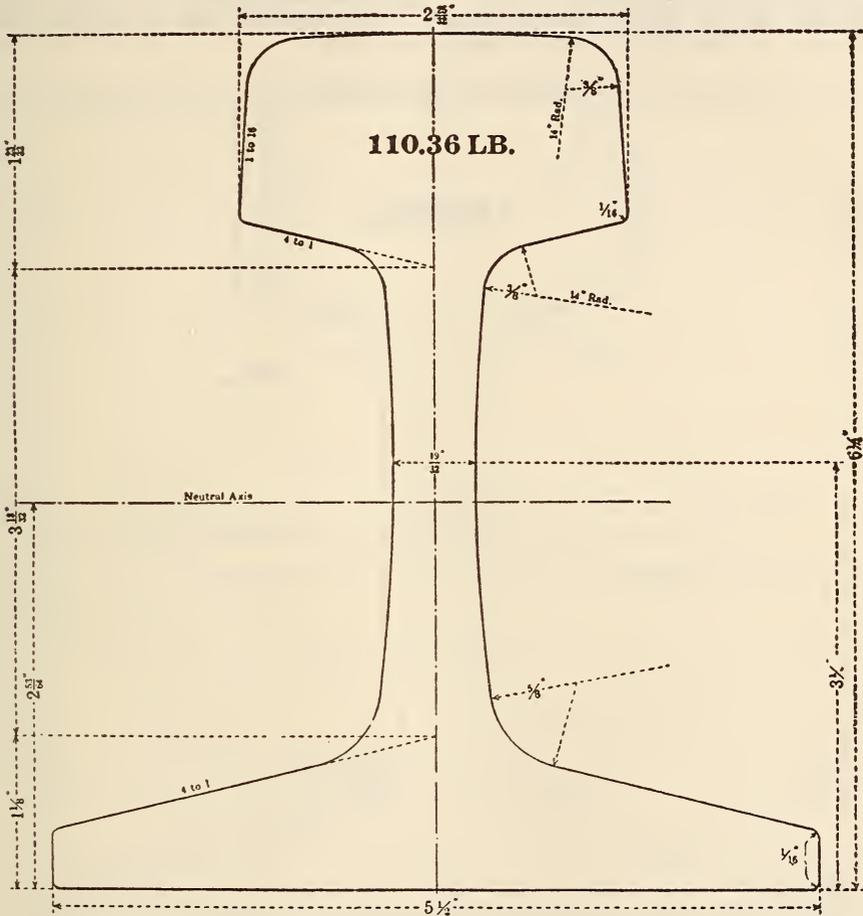

FIGURE 177.—Rail section, R. E., 110 pounds

ture, all top rails represented shall be classified as "X-rays."

STANDARD SECTION, LENGTH AND WEIGHT

11. The standard length of rails shall be 39 feet or 33 1/2 feet, as ordered, when measured at a temperature of 15.5° C. (60° F.). When the length specified is 39 1/2 feet, 11 per cent of the entire order will be accepted in shorter lengths varying by 1 foot from 38 feet to 25 feet, and a variation of three-eighths inch from the specified length will be allowed, except

12. The section of the rails shall conform as accurately as possible to the templets furnished by the purchaser. A variation of one sixty-fourth inch less or one thirty-second inch greater than the specified height will be permitted. A variation of one-sixteenth inch in the length of either flange will be permitted, but the variation in total width of base must not exceed one sixteenth inch. No variation will be allowed in dimensions affecting the fit of the joint bars, except that the fishing template approved by the purchaser may stand out not to exceed one-sixteenth inch laterally.

13. A variation of 0.5 per cent from the calculated weight of section as applied to the entire order will be allowed.

WORKMANSHIP AND FINISH

14. Circular holes for joint bolts shall be drilled to conform to the drawings and dimensions furnished by the purchaser. A variation of one thirty-second inch in the size and location of bolt holes will be allowed.

15. (a) All rails shall be smooth on the heads, straight in line, and without twists, waves, or kinks.

be reconditioned by the mill, provided they can be made fully to meet the requirements.

(c) When any finished rail shows conditions as described in section 10 at either end or at any drilled hole, it shall be cut back to sound metal, and accepted as an "X-rayl."

CLASSIFICATION OF RAILS

16. No. 1 rails shall be free from injurious defects and flaws of all kinds.

17. X-rayls are rails as described in sections 10 and 15 (c).

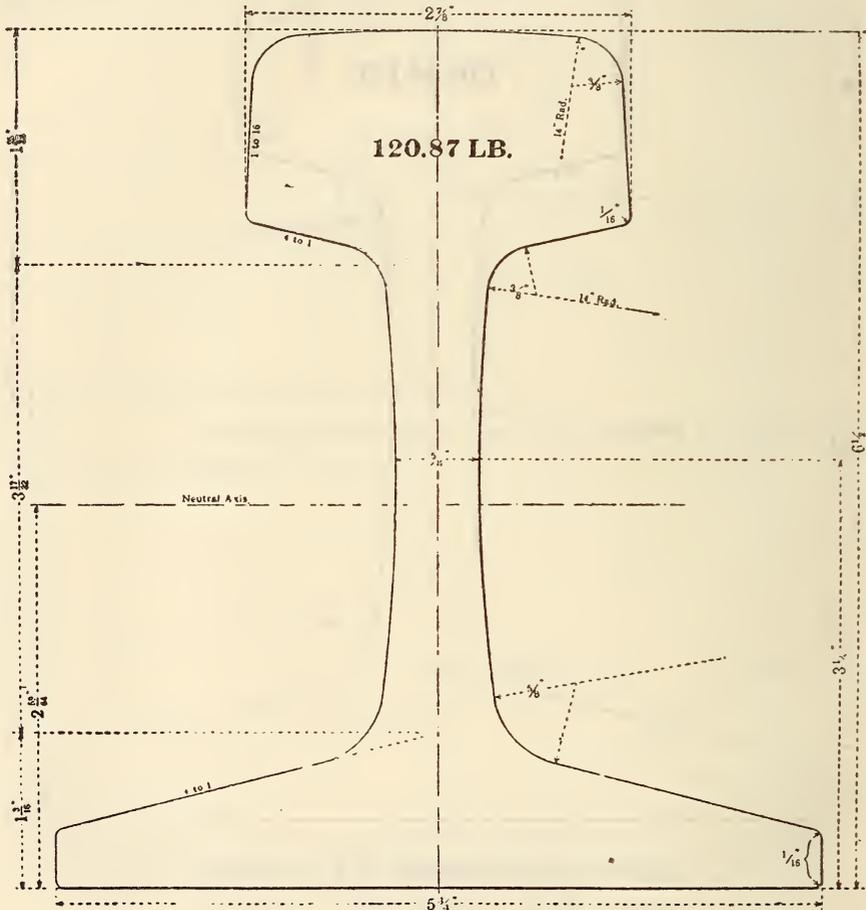

FIGURE 178.—Rail section, R. E., 120 pounds

				1.59

The supports for rails in the straightening presses shall have flat surfaces and be free from hollow places, bends, or crooks, and shall be spaced not less than 60 inches. When placed head up on a horizontal surface, rails that are slightly higher at the ends than the middle will be accepted, provided they contain a uniform sweep, the middle ordinate of which does not exceed one and one-fourth inches in 39 feet. They shall be sawed square at the ends, a variation of not more than one thirty-second inch being allowed, and burrs shall be entirely removed.

(b) Rails presented for inspection which do not conform to the requirements of paragraph (a) may

18. Rails which conform to the following requirements will be accepted as No. 2 rails:

(a) Rails which do not contain surface imperfections in such number or of such character as will in the judgment of the inspector render them unfit for recognized uses.

(b) Rails of A. R. A. type of sections arriving at the straightening presses with sharp kinks or greater camber than that indicated by a middle ordinate of 6 inches in 39 feet or 4 inches in 33 feet. Rails of A. S. C. E. type of sections arriving at the straightening presses with sharp kinks or greater camber than

that indicated by a middle ordinate of 7 inches in 39 feet or 5 inches in 33 feet.

MARKING

19. Brands made so plain and sharp that they may be read as long as the rails are in service shall be rolled on or hot stamped into the side of the web of each rail in accordance with the following requirements, and to indicate:

(a) Name of the manufacturer, the month and year of manufacture, and the weight and type of section of rail as rolled.

(d) All rails shall be branded "O. H." in addition to other marks.

20. (a) Rails accepted as No. 2 rails shall have the ends painted white and shall be stamped with the figure 2 on both end faces.

(b) Rails accepted as "X-rays" shall have the ends painted brown and shall be stamped with the letter "X" on both end faces.

(c) "A" rails shall have both ends painted yellow.

(d) No. 1 rails less than 39 feet long shall have both ends painted green.

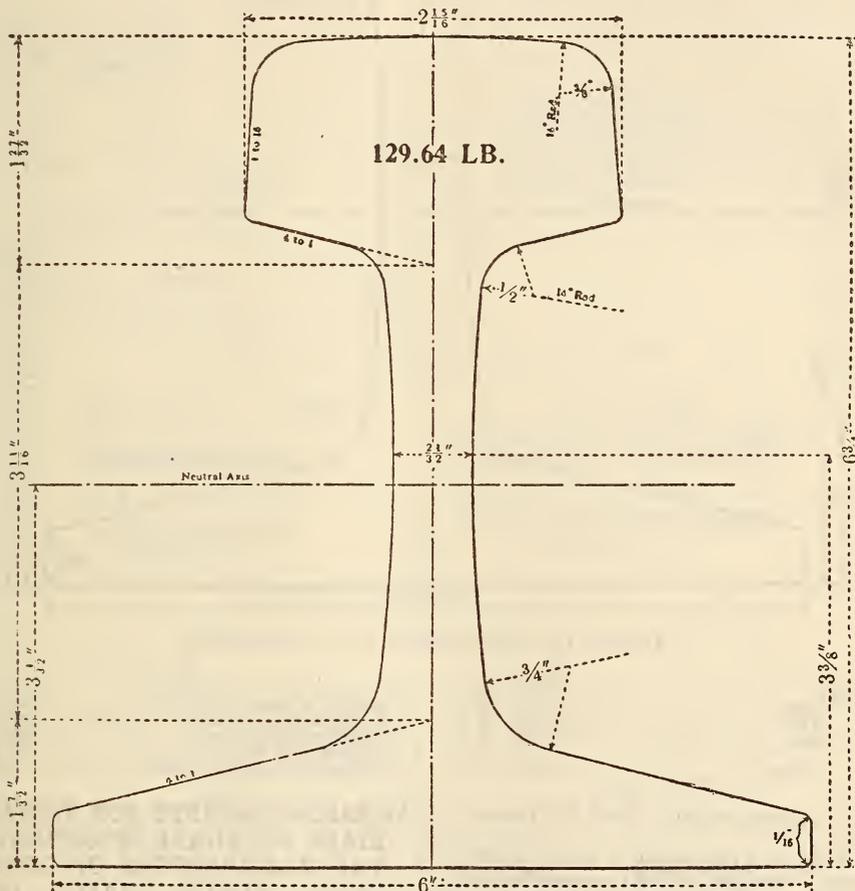

FIGURE 179.—Rail section, R. E., 130 pounds

Section modulus, base.....	25.6
Ratio M. I. to area.....	6.09
Ratio section modulus to area.....	1.64

(b) The heat number and the ingot number as rolled shall be stamped in the web of each rail where it will not be covered by the joint bars.

(c) The top rails shall normally be lettered "A" and the succeeding ones "B," "C," "D," "E," etc., consecutively, but in case the top discard is greater than normal, the rail lettering shall conform to the amount of discard, the top rail becoming "B" or other succeeding letter to suit the condition.

Only the "A," "B," and "C" rails are required to be lettered when the normal weight per yard is less than 70 pounds.

(e) All rails of heats the carbon content of which exceeds the mean carbon percentage of the specific range shall have both ends painted blue.

Individual rails shall be painted only one color, according to the order of precedence listed above.

LOADING

21. Rails shall be carefully handled in such manner as to avoid injury and shall be loaded as follows:

(a) No. 1 low-carbon rails shall be loaded in separate cars.

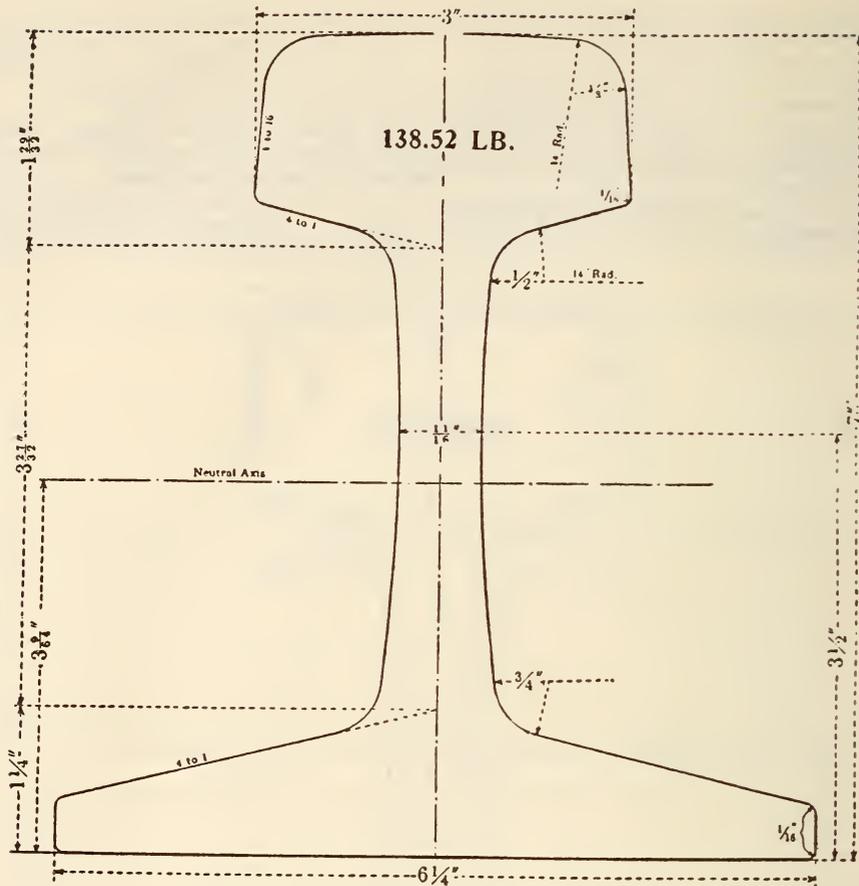

FIGURE 180.—Rail section, R. E., 140 pounds

Area:	Square inches	Per cent

(b) No. 1 high-carbon rails shall be loaded in separate cars.

(c) No. 2 rails shall be loaded in separate cars.

(d) "X-rays" shall be loaded in separate cars.

(e) No. 1 "A" rails shall be loaded in separate cars.

(f) No. 1 short rails shall be loaded in separate cars. No subdivision by classification markings other than listed above is necessary for separate loading.

INSPECTION AND REJECTION

22. Inspection and tests shall be made at the works of the manufacturer before shipment, and the works management shall afford all reasonable facilities for determining the satisfactory quality of the rails accepted.

23. (a) In order to be accepted, the rails offered shall fulfill all the requirements of these specifications.

(b) No. 2 rails will be accepted to the extent of 8 per cent of the whole order of 39-foot standard length rails and 5 per cent of the whole order of 33-foot standard length rails.

(c) Rails accepted will be paid for according to actual weights.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, DESIGN OF PLAIN GIRDER RAILS AND SPLICE BARS, W31-31, 1931

PLAIN GIRDER RAILS AND SPLICE BARS

(See 606.1, p. 316.)

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR HIGH-CARBON-STEEL JOINT BARS, 1915

HIGH-CARBON-STEEL JOINT BARS

(In respect to material, chemical properties, physical properties and tests, and inspection, this specification conforms to A. S. T. M., A5, given below, except that under chemical composition no reference is made to percentage of carbon content, and under physical properties the minimum elongation in 2 inches is 16 per cent instead of 14 per cent as in A5. It also carries the same reference to ladle and check analysis as A5. Otherwise it provides as follows:)

VI. GENERAL REQUIREMENTS

8. The different sections of joint bars shall be rolled to dimensions specified in drawing furnished by the purchaser. No variation will be allowed in the dimensions affecting the fit and the fishing spaces of the rail. The maximum camber on either plane shall not exceed one-thirty-second inch in 24 inches.

9. The joint bars shall be sheared to the length prescribed by the purchaser and shall not vary therefrom by more than one-eighth inch.

10. (a) All joint bars shall be punched, slotted, and shaped at a temperature of not less than 1,470° F. (800° C.).

(b) All bolt holes shall be punched in one operation, without bulging or distorting the section, and the bars shall be slotted for spikes when required, in accordance with the drawings, the slotting being done in one operation; a variation of one thirty-second inch in the size and location of the holes will be allowed.

11. All joint bars must be finished smooth and true, without swelling over or under the bolt holes, and be free from flaws, seams, checks, or fins, and the fishing angles must be fully maintained.

12. The manufacturer's identification symbol, kind of material, month and year rolled, and number of design shall be rolled in raised letters and figures on each bar. The number of the melt shall be plainly stenciled on each lot of joint bars.

VI. INSPECTION

13. The joint bars from each melt shall be piled separately until tested and inspected by the purchaser's inspector. One joint bar for tension test shall be selected by the inspector for each melt represented in finished bars, or by agreement specimens for tension test may be cut from the bar as rolled. One joint bar for bend test shall be selected by the inspector for each lot of 1,000 bars or less presented.

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR MALLEABLE-IRON TIE PLATES, 1920

MALLEABLE-IRON TIE PLATES

I. MATERIAL

1. Plates shall be made from furnace malleable iron.

II. PHYSICAL REQUIREMENTS

2. *Tension tests.*—The tension-test specimens specified in section 4 shall conform to the following minimum requirements as to tensile properties:

Tensile strength.....	lbs./in. ² ..	45,000
Elongation in 2 inches.....	per cent..	7.5

3. *Special tests.*—(a) All tie plates shall have cast thereon test lugs of a size proportional to the thickness of the tie plate, but not exceeding 5/8 by 3/4 inch in cross section. These lugs shall be attached to the tie plate at such a point that they will not interfere with the assembling of the tie plates, and may be broken off by the inspector.

(b) If the purchaser or his representative so desires, a tie plate may be tested to destruction.

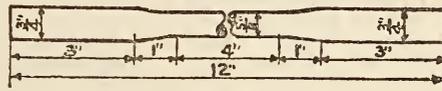

FIGURE 184

Such a tie plate shall show good, tough malleable iron.

4. *Tension-test specimens.*—(a) Tension-test specimens shall be of the form and dimensions shown in figure 184. Specimens whose mean diameter at the smallest section is less than nineteen thirty-seconds inch will not be accepted for test.

(b) A set of three tension-test specimens shall be cast from each melt, without chills, using risers of sufficient height to secure sound bars.

The specimens shall be suitably marked for identification with the melt. Each set of specimens so cast shall be placed in some one oven containing tie plates to be annealed.

5. *Number of tests.*—(a) After annealing, three tension-test specimens shall be selected by the inspector as representing the tie plates in the oven from which these specimens are taken.

(b) If the first specimen conforms to the specified requirements, or if, in the event of failure of the first specimen, the second and third specimens conform to the requirements, the tie plates in that oven shall be accepted, except that any tie plate may be rejected if its test lug shows that it has not been properly annealed. If either the second or third specimen fails to conform to the requirements, the entire contents of that oven shall be rejected.

6. *Reannealing.*—Any tie plates rejected for insufficient annealing may be reannealed once. The reannealed tie plates shall be inspected and if the remaining test lugs or tie plates broken as specimens show the tie plates to be thoroughly annealed, they shall be accepted; if not, they shall be finally rejected.

III. DESIGN

7. *Plan.*—Tie plates shall conform to the drawing submitted to the manufacturer, with the following permissible variations:

Variation.—(a) The length and width shall not vary more than one-eighth inch from the dimensions shown.

(b) The thickness shall not vary more than one thirty-second inch from the dimensions shown.

IV. MANUFACTURE

8. *Workmanship.*—The plates shall be straight and out of wind on the surface which forms the bearing for the rail, and shall be made in a workmanlike manner.

9. *Finish.*—The finished tie-plate shall be well cleaned and free from warping, shrinkage, cracks, blowholes, fins, and other imperfections.

10. *Marking.*—The manufacturer's identification mark and the pattern numbers assigned by the purchaser shall be cast on all tie-plates in such positions that they will not interfere with the service of the tie plate.

V. INSPECTION

11. *Inspection.*—(a) (Same as paragraph 7 of A. S. T. M. standard specifications for steel. See 605.0, p. 247.)

(b) The manufacturer shall be required to keep a record of each melt, from which tie-plates are produced, showing tensile strength and elongation of test specimens cast from such melts. These records shall be available and shown to the inspector whenever required.

12. *Rejection.*—Tie-plates which show injurious defects subsequent to their acceptance at the manufacturer's works may be rejected, and, if rejected, shall be replaced by the manufacturer free of cost to the purchaser.

VI. SHIPMENT

Packing.—(Same as for wrought-iron tie-plates, given below.)

Table of dimensions for tie-plates

Length of plates	Range of rail bases	Same for flat and canted plates			Flat plates	Canted 1 in 40		Canted 1 in 20	
		A	B	C	D and E	D	E	D	E
<i>inches</i>	<i>inches</i>	<i>ins.</i>	<i>ins.</i>	<i>in.</i>	<i>inch</i>	<i>inch</i>	<i>inch</i>	<i>inch</i>	<i>inch</i>

11½	5¾-6¼	3½	6½	5½	¾	¾	1½	1½	1½
12	6-6½	3¾	6½	5½	¾	¾	1½	1½	1½

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR QUENCHED CARBON-STEEL JOINT BARS, 1924

QUENCHED CARBON-STEEL JOINT BARS

(This specification conforms to the A. S. T. M. specifications given below and to B11 in 641.21, p. 1176, in respect to the following items in each specification:)

- A3..... Ladle and check analyses; marking; finish.
- A4..... Test specimens; number of tests.
- A5..... Bend tests; optional bend tests.
- A49..... Material; chemical requirements; retests.
- B11..... Inspection and rejection.

(The text of specifications A3, A4, A5, and A49 is given below. Otherwise this specification provides as follows:)

III. PHYSICAL REQUIREMENTS

5. (a) The joint bars shall conform to the following minimum requirements as to tensile properties:

Tensile strength.....	lbs./in. ² ..	100,000
Yield point.....	lbs./in. ² ..	70,000
Elongation in 2 inches.....	per cent..	1,600,000 Tensile strength
But in no case under		12 per cent.
Reduction of area.....	per cent..	3,500,000 Tensile strength
But in no case under		25 per cent.

(b) The yield point shall be determined by the drop of the beam of the testing machine.

IV. DESIGN AND TOLERANCE

11. The splice bars shall be smoothly rolled, true to templet, and shall accurately fit the rails for which they are intended. The bars shall be sheared to length, and the punching and notching shall conform to the dimensions specified by the purchaser. A variation of one thirty-second inch from the specified size of holes, of one-sixteenth inch from the specified location of holes, and of one-eighth inch from the specified length of splice bar, will be permitted. Bars shall be straight without camber in either plane and with outside surface of web parallel to the axis of rail.

V. MANUFACTURE

13. Joint bars shall be punched, slotted, and shaped at a temperature of not less than 1,470° F. (800° C.) and subsequently quenched from a temperature of 810° C. (1,490° F.).

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR STEEL TIE PLATES, 1926

STEEL TIE PLATES

(Identical with A. S. T. M., A67-30, given below.)

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR WROUGHT-IRON TIE PLATES, 1920

WROUGHT-IRON TIE PLATES

I. MATERIAL

1. Plates shall be made of all-pig puddled iron.

II. PHYSICAL REQUIREMENTS

2. The material shall conform to the following minimum requirements as to tensile properties:

Tensile strength.....	lbs./in. ² ..	48,000
Yield point.....	do.....	0.6 Tensile strength.
Elongation in 2 inches.....	per cent..	23
Elongation in 8 inches.....	do.....	25
Reduction of area.....	do.....	37

3. *Bend tests.*—The bend-test specimen shall bend cold through 180° without fracture around a pin, the diameter of which is equal to the thickness of the specimen.

4. *Test specimens.*—(a) The tension-test specimen shall be taken from the finished tie plates, or from the rolled bar. They shall be cut so that the sides of the specimens are parallel to the direction in which the tie plates have been rolled.

(b) Tension-test specimens may conform to the essential dimensions shown in Figures 128 and 129 in A. S. T. M. standard specifications for steel (see 605.0, p. 247). The 2-inch specimen shall have filleted shoulders, or threaded ends, to fit into the holders on the testing machine in such a way that the line of action of the force exerted by the testing machine shall coincide with the axis of the specimen.

5. *Number of tests.*—(a) One tension test and one bend test shall be made from each lot of 1,000 tie plates.

(b) If any test specimen from either of the bars originally selected to represent a lot of material contains surface defects not visible before testing, but visible after testing, or if a tension-test specimen breaks outside the middle third of the gage length, the individual bar shall be rejected and one retest from a different bar will be allowed.

III. DESIGN

6. *Plan.*—The tie plates shall conform to the drawings submitted to the manufacturer, with the following permissible variations:

Variations.—(a) For plates with shoulders parallel to the direction of rolling, a variation of one-thirty-second inch in thickness, one-eighth inch in rolled width, and three-sixteenths inch in sheared length will be permitted.

(b) For plates with shoulders perpendicular to the direction of rolling, a variation of one thirty-second inch in thickness, one-eighth inch in rolled width and one-fourth inch in sheared length will be permitted. The distance from the face of the shoulder to the outside end of plate shall not vary more than one-fourth inch, and from the face of the shoulder to the inside end not more than one-half inch.

IV. MANUFACTURE

7. *Workmanship.*—The tie plate shall be smoothly rolled, true to templet, and shall be straight and out of wind on the surface which will form the bearings for the rail, and have a workmanlike finish.

8. *Finish.*—The finished tie plates shall be free from burs and other surface deformations caused by the shearing and punching; they shall also be free from slivers, depressions, seams, crop ends, and evidences of being burnt.

Marking.—(Same as A. S. T. M., A3, given below.)

Inspection.—(Same as paragraph 7 of A. S. T. M. standard specifications for steel. See 605.0, p. 247.)

11. *Rejection.*—If either of the test bars selected to represent a lot does not conform to the requirements specified in sections 2, 3, 4, and 5, the lot will be rejected.

12. *Packing.*—Tie plates shall be wired together in bundles of uniform number, weighing not to exceed 100 pounds for shipment, unless otherwise specified.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR LOW-CARBON-STEEL SPLICE BARS, DESIGNATION A3-24, 1924

LOW-CARBON-STEEL SPLICE BARS

MANUFACTURE

1. The steel shall be made by either or both the following processes: Bessemer or open hearth.

CHEMICAL PROPERTIES AND TESTS

2. The steel shall conform to the following requirements as to chemical composition:

Phosphorus: —————	Per cent
Bessemer, not over.....	0.10
Open hearth, not over.....	.05

3. (a) A carbon determination shall be made of each melt of Bessemer steel, and two analyses every 24 hours representing the average of the elements carbon, manganese, phosphorus, and sulphur contained in the steel, one for each 12-hour period, respectively. These analyses shall be made from drillings taken at least one-eighth inch beneath the surface of a test ingot obtained during the pouring of the melts. The chemical composition thus determined shall be reported to the purchaser or his representative and shall conform to the requirements specified in section 2.

(b) An analysis of each melt of open-hearth steel shall be made by the manufacturer to determine the percentages of carbon, manganese, phosphorus, and sulphur. This analysis shall be made from drillings taken at least one-eighth inch beneath the surface of a test ingot obtained during the pouring of the melt. The chemical composition thus determined shall be reported to the purchaser or his representative and shall conform to the requirements specified in section 2.

4. An analysis may be made by the purchaser from a finished splice bar representing each melt. The phosphorus content thus determined shall not exceed that specified in section 2 by more than 25 per cent.

PHYSICAL PROPERTIES AND TESTS

5. The splice bars shall conform to the following requirements as to tensile properties:

Tensile strength.....	lbs./in. ² ..	55,000-65,000
Elongation in 8-inch, minimum.....	per cent..	25

6. The test specimen shall stand being bent cold through 180° flat on itself without cracking on the outside of the bent portion.

7. Tension and bend test specimens shall be taken from the finished rolled bars. Tension-test specimens shall be of eight-inch gage length. Bend tests may be made of an unpunched splice bar, flattened if necessary.

8. (a) One tension and one bend test shall be made from each melt.

(b) If any test specimen shows defective machining or develops flaws, it may be discarded and another specimen substituted.

(c) If the percentage of elongation of any tension-test specimen is less than that specified in section 5 and any part of the fracture is outside the middle third of the gage length, as indicated by scribe scratches marked on the specimen before testing, a retest shall be allowed.

WORKMANSHIP AND FINISH

9. (a) The splice bars shall be smoothly rolled, true to template, and shall accurately fit the rails for which they are intended. The bars shall be sheared to length, and the punching and notching shall conform to the dimensions specified by the purchaser. A variation of one thirty-second inch from the specified size and location of holes and of one-eighth inch from the specified length of splice bar will be permitted. Any variation from a straight line in a vertical plane shall be such as will make the bars high in the center. The maximum camber in either plane shall not exceed one-sixteenth inch in 24 inches, except as specified in paragraph (b).

(b) For splice bars for girder and high T rails, any variation from a straight line in a vertical plane shall be such as will make the bars high in the center, and the maximum camber in this plane shall not exceed three sixty-fourths inch in 24 inches. Any variation from a straight line in a horizontal plane shall be such as will make the bars convex toward the web of the rail, and the maximum camber in this plane shall not exceed one-sixteenth inch in 24 inches.

10. The finished splice bars shall be free from injurious defects and shall have a workmanlike finish.

MARKING

11. The name or brand of the manufacturer and the year of manufacture shall be rolled in raised letters and figures on the side of the rolled bars, and a portion of this marking shall appear on each finished splice bar.

INSPECTION AND REJECTION

(Same as A. S. T. M., B11-18. See 641.21, p. 1176.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR MEDIUM-CARBON-STEEL SPLICE BARS, DESIGNATION A4-14, 1914

MEDIUM-CARBON-STEEL SPLICE BARS

MANUFACTURE

1. The steel shall be made by the open-hearth process.

2. (a) The splice bars may be punched, slotted, and, in the case of special designs, shaped either hot or cold.

(b) Bars that are punched, slotted, or shaped cold shall be subsequently annealed.

CHEMICAL PROPERTIES AND TESTS

3. The steel shall conform to the following requirements as to chemical composition:

	Per cent
Carbon, not under.....	0.30
Phosphorus, not over.....	.04

LADLE AND CHECK ANALYSES

(Same as A. S. T. M., A3, given above.)

PHYSICAL PROPERTIES AND TESTS

6. The splice bars shall conform to the following minimum requirements as to tensile properties:

Tensile strength.....	lbs./in. ² ..	68,000
Elongation in 2 inches.....	per cent..	$\frac{1,600,000}{\text{Tensile strength}}$

But in no case under 20 per cent.

7. The bend-test specimen specified in section 8 shall bend cold through 180° around a pin, the diameter of which is equal to twice the thickness of the specimen, without cracking on the outside of the bent portion.

8. Tension and bend-test specimens shall be taken from the finished bars. Tension-test specimens shall conform to the dimensions shown in Figure 129 in A. S. T. M. standard specifications for steel. (See 605.0, p. 247.) The ends shall be of a form to fit the holders of the testing machine in such a way that the load shall be axial. Bend-test specimens may be one-half inch square in section or rectangular in section with two parallel faces as rolled.

9. If preferred by the manufacturer and approved by the purchaser, the following bend test may be substituted for that described in section 7: A piece of the finished bar shall bend cold through 90° around a pin the diameter of which is equal to twice the greatest thickness of the section, without cracking on the outside of the bent portion.

10. (a) One tension and one bend test shall be made from each melt.

(b) If any test specimen shows defective machining or develops flaws, it may be discarded and another specimen substituted.

(c) If the percentage of elongation of any tension-test specimen is less than that specified in section 6 and any part of the fracture is more than three-fourth inch from the center of the gage length, as indicated by scribe scratches marked on the specimen before testing, a retest shall be allowed.

WORKMANSHIP AND FINISH, AND MARKING

(Same as A. S. T. M., A3, given above.)

INSPECTION AND REJECTION

(Same as A. S. T. M., B11-18. See 641.21, p. 1176.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR HIGH-CARBON-STEEL SPLICE BARS, DESIGNATION A5-14, 1914

HIGH-CARBON-STEEL SPLICE BARS

1. The steel shall be made by the open-hearth process.

2. The splice bars shall be punched, slotted, and in the case of special designs, shaped at a temperature not less than 750° C.

CHEMICAL PROPERTIES AND TESTS

3. The steel shall conform to the following requirements as to chemical composition:

	Per cent
Carbon, not under.....	0.45
Phosphorus, not over.....	.04

LADLE AND CHECK ANALYSES

(Same as A. S. T. M. A3, given above.)

PHYSICAL PROPERTIES AND TESTS

6. The splice bars shall conform to the following minimum requirements as to tensile properties:

Tensile strength.....	lbs./in. ² ..	85,000
Elongation in 2 inches.....	per cent..	14

7. The bend-test specimen specified in section 8 shall stand being bent cold through 90° around a pin the diameter of which is equal to three times the thickness of the specimen, without cracking on the outside of the bent portion.

(Paragraph 8 is identical with paragraph 8 in A4, given above.)

9. If preferred by the manufacturer and approved by the purchaser, the following bend test may be substituted for that described in section 7: A piece of the finished bar shall stand being bent cold through 45° around a pin the diameter of which is equal to three times the greatest thickness of the section, without cracking on the outside of the bent portion.

NUMBER OF TESTS

(Identical with paragraphs 10 (a), (b), and (c) in A4, given above.)

WORKMANSHIP AND FINISH, AND MARKING

(Same as A. S. T. M. A3, given above.)

INSPECTION AND REJECTION

(Same as A. S. T. M. B11-18. See 641.21, p. 1176.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR QUENCHED HIGH-CARBON-STEEL SPLICE BARS, DESIGNATION A49-21, 1921

QUENCHED HIGH-CARBON-STEEL SPLICE BARS

1. The steel shall be made by the open-hearth process.
2. The splice bars shall be punched, slotted, and, in the case of special designs, shaped at a temperature not less than 750° C., and subsequently quenched.

CHEMICAL PROPERTIES AND TESTS

3. The steel shall conform to the following requirements as to chemical composition:

	Per cent
Carbon, not over.....	0.60
Manganese, not over.....	.80
Phosphorus, not over.....	.04

LADLE AND CHECK ANALYSES

(Same as A. S. T. M. A3, given above.)

PHYSICAL PROPERTIES AND TESTS

6. (a) The splice bars shall conform to the following minimum requirements as to tensile properties:

Tensile strength.....	lbs./in. ²	100,000
Yield point.....	lbs./in. ²	65,000
Elongation in 2 inches.....	per cent.....	10

- (b) The yield point shall be determined by the drop of the beam of the testing machine.
(Paragraph 7 is identical with paragraph 7 in A5, given above.)
(Paragraph 8 is identical with paragraph 8 in A4, given above, except that bend test specimens have the corners rounded to a radius not over 1/16 inch.)
(Paragraph 9 is identical with paragraph 9 in A5, given above.)

NUMBER OF TESTS

- (Identical with paragraphs 10 (a), (b), and (c) in A4, given above.)

RETESTS

11. If the results of the physical tests of any test lot do not conform to the requirements specified, the manufacturer may re-treat such lot one or more times, in which case two additional tension and two additional bend tests shall be made from such lot, all of which shall conform to the requirements specified.

WORKMANSHIP AND FINISH, AND MARKING

- (Same as A. S. T. M. A3, given above, except that no reference is made to splice bars for girder and high T rails.)

INSPECTION

(Same as A. S. T. M. B11-18. See 641.21, p. 1176.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR STEEL TIE PLATES, DESIGNATION A67-30, 1930

STEEL TIE PLATES

1. These specifications cover two grades of steel tie plates, namely, soft and medium. The soft grade will be used unless otherwise specified.

MANUFACTURE

2. The steel shall be made by one or more of the following processes: Open-hearth, electric furnace, or acid Bessemer.

CHEMICAL PROPERTIES AND TESTS

3. (a) The steel shall conform to the following requirement as to limitation of phosphorus content:

	Bessemer	Open-hearth
Phosphorus, not over.....	Per cent 0.10	Per cent 0.05
Copper, when copper-steel is specified, per cent, not under 0.20.		

- (b) Unless otherwise specified, the steel shall be furnished according to chemical composition only, in which case the minimum carbon content shall be as follows:

	Bessemer	Open-hearth
Carbon:	Per cent	Per cent
Soft grade, not under.....	0.08	0.15
Medium grade, not under.....	.12	.20

4. (a) A carbon determination shall be made of each melt of Bessemer steel, and three analyses every 24 hours representing the average of the elements carbon and phosphorus, and also copper, where copper-steel is specified, contained in the steel, one for each 8-hour turn respectively. These analyses shall be made from drillings taken at least one-eighth inch beneath the surface of a test ingot obtained during the pouring of the melts. The chemical composition thus determined shall be reported to the purchaser or his representative, and shall conform to the requirements specified in section 3.

- (b) An analysis of each melt of open-hearth steel shall be made by the manufacturer to determine the percentages of carbon and phosphorus; also copper when copper-steel is specified. This analysis shall be made from drillings taken at least one-eighth inch beneath the surface of a test ingot obtained during the pouring of the melt. The chemical composition thus determined shall be reported to the purchaser or his representative, and shall conform to the requirements specified in section 3.

5. An analysis may be made by the purchaser from a finished tie plate representing each melt of open-hearth steel, and each melt or lot of 10 tons of Bessemer steel. The carbon content thus determined shall not be less than that specified in section 3, and the phosphorus content shall not exceed that specified in section 3 by more than 25 per cent.

PHYSICAL PROPERTIES AND TESTS

6. The bend-test specimens specified in section 7 shall stand being bent cold through 180° around a pin the diameter of which is equal to the thickness of the specimen for the soft grade, and to twice the thickness of the specimen for the medium grade, without cracking on the outside of the bent portion.

7. Bend-test specimens shall be taken from the finished tie plates, or from the rolled bars, and longitudinally with the rolling. They shall be rectangular in section, not less than one-half inch in width between the planed sides, and shall have two faces as rolled. They shall be free from ribs or projections. Where the design of the tie plates

is such that the specimen can not be taken between the ribs or projections, these ribs or projections shall, in preparing the specimen, be planed off even with the main surface of the tie plate.

8. If preferred by the manufacturer and approved by the purchaser, the following bend test may be substituted for that described in section 6:

A piece of the rolled bar shall stand being bent cold through 90° around a pin the diameter of which is equal to the thickness of the section where bent for the soft grade, and to twice the thickness of the section where bent for the medium grade, without cracking on the outside of the bent portion.

9. (a) One bend test shall be made from each melt of open-hearth steel, or from each melt or lot of 10 tons of Bessemer steel.

(b) If any test specimen shows defective machining or develops flaws, it may be discarded and another specimen substituted.

WORKMANSHIP AND FINISH

10. The tie-plates shall conform to the dimensions specified by the purchaser, with the following permissible variations:

(a) For plates with shoulders parallel to the direction of rolling, a variation of one thirty-second inch in thickness, one-eighth inch in rolled width, and three-sixteenths inch in sheared length will be permitted.

(b) For plates with shoulders perpendicular to the direction of rolling, a variation of one twenty-second inch in thickness, three-sixteenths inch in rolled width, and one-fourth inch in sheared length will be permitted. The distance from the face of shoulder to the outside end of the plate shall not vary more than one-eighth inch, and from the face of shoulder to the inside end not more than one-fourth inch.

(c) A variation of not more than one thirty-second inch in the location of spike holes and in the length of their sides will be permitted.

11. The tie-plate shall be smoothly rolled, true to template, and shall be straight and out of wind on the surface which will form the bearings for the rail.

12. The finished tie-plates shall be free from burrs and other surface deformities caused by the shearing and punching; they shall also be free from other injurious defects and shall have a workman-like finish.

MARKING

13. The name or brand of the manufacturer, the section of the tie-plate and the year of manufacture shall be rolled in raised letters and figures on the outside of the shoulder of the plates, and a portion of this marking shall appear on each finished tie-plate.

(Requirements covering inspection, rejection, and reheating conform with those specified in A. S. T. M. standard specifications for steel. (See 605.0, p. 247.)

ASSOCIATION OF AMERICAN STEEL MANUFACTURERS, STANDARD SPECIFICATIONS FOR STEEL TIE-PLATES, 1923

STEEL TIE-PLATES

1. *Material covered.*—These specifications cover three grades of steel tie-plates, namely, soft, medium,

and hard. The purchaser shall specify on the order which grade is desired.

2. *Process.*—Steel for the soft and medium grades may be made by either or by both the open hearth or Bessemer processes. Steel for the hard grade shall be made by the open-hearth process.

3. *Finishing and heat treatment.*—Tie-plates of the soft and medium grades may be sheared, slotted, and punched cold, but tie-plates of the hard grade shall be sheared, slotted, and punched hot, at a temperature that will prevent injury to the steel and shall immediately thereafter be put into a closed chamber or box which will prevent rapid cooling.

4. *Chemical composition.*—The steel shall conform to the following requirements as to chemical composition, based on ladle analysis:

	Soft grade	Medium grade	Hard grade
Bessemer:	<i>Per cent</i>	<i>Per cent</i>	<i>Per cent</i>
Carbon.....	¹ 0.15	0.12-0.25	-----
Phosphorus.....	1.12	1.12	-----
Open hearth:			
Carbon.....	1.25	.20-.35	0.35-0.80
Phosphorus.....	1.06	1.06	1.06

¹ Maximum.

(Workmanship and finish conform with A. S. T. M. A67-30, given below, except that for tie-plates with shoulders parallel to the direction of rolling the variation in width permitted is three-sixteenths instead of one-eighth inch; and for tie-plates with shoulders perpendicular to the direction of rolling the distance from the face of the shoulder to the outside end of the plates shall not vary more than one-fourth inch, and from the face of the shoulder to the inside end not more than one-half inch.)

(Marking conforms with A. S. T. M. A67-30, except for the addition of the following:) Each individual tie-plate made from the hard grade of steel, hot worked, shall be stamped or branded with the letters H. W.

(Requirements covering inspection and rejection conform with those specified in A. S. T. M. standard specifications for steel. See 605.0, p. 247.)

606.3 SWITCHES AND SPECIAL TRACK WORK.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, STANDARD DIMENSIONS OF SWITCHES AND MATES, W11-30, 1930

STANDARD DIMENSIONS OF SWITCHES AND MATES

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, STANDARD SPECIFICATION FOR SOLID MANGANESE-STEEL SPECIAL TRACK WORK FOR GIRDER RAIL, W32-30, 1930

MANGANESE-STEEL TRACK WORK

(In respect to materials (except for the use of manganese steel), chemical properties and tests, physical properties and tests, design (including standard dimensions of switches and mates), workmanship, assembly for inspection, marking, and shipping, and inspection, this specification conforms to A. E. R. E. A. W33, given below, except for the following provisions:)

These specifications are intended to cover the manufacture of special track work wherein the tongue switches, mates, frogs, and crossings are made of solid manganese steel. The term "solid manganese" shall be considered as distinguishing such special track work from other types wherein manganese steel is used only for inserts at points receiving the principal wear.

MANGANESE-STEEL CASTINGS

407. Tongue switches, mates, frogs, and crossings (not steam-railroad crossings) shall be made of manganese-steel castings of uniform design, with extremities to conform to the connecting rail. The castings shall be uniform in depth of 6, 7, or 9 inches and of not less depth than the highest of the connecting rails and of a cross section in which the thickness of metal will not be under the following dimensions:

Under treads, 1½ inches.

Under grooves, seven-eighths inch.

Under grooves at flange bearing, 1½ inches.

Vertical walls or webs, five-eighths inch in double webs.

Vertical walls or webs, three-quarters inch in single web.

Base flange, one-half inch at outer edge; three-quarters inch at web.

Base flanges shall be not less than 3 inches wide on each side of double-web sections and 5 inches wide on single-web sections. Angles in castings are not permissible, all must have fillets. All holes shall be cored, and smooth and accurately located. Where drilled holes are required, soft iron or steel plugs may be inserted in the casting.

HEEL OPENINGS

408. Tongue switch and mate castings shall be open on top at the heel ends for convenience of setting joint bars.

TONGUE SWITCHES

409. The tongues in tongue switches shall be provided with lateral flanges to promote lateral stiffness, with a construction at the heel that will furnish adequate bearing and give a secure and adjustable fastening. There shall be provision for attaching throwing or controlling mechanism and the box containing same to either side of the switch. The tongue shall be arranged for such attachment when specified. Provision shall also be made for attaching a cleaning box to the switch casting opposite the throwing device and openings shall be provided in the tongue bed for proper drainage. All bearing parts of the tongue and switch bed shall be properly

finished to a good surface. The tread of the tongue shall be at least one-quarter inch above the curved tread of the switch, from 1 foot from tongue point to give an effective guard where required. Switch tongues shall be finished so that practical interchangeability is assured.

FROGS AND CROSSINGS; LENGTH OF ARMS AND CASTINGS

410. (a) The length of frog and crossing arms shall be sufficient to give at least $6\frac{1}{4}$ inches clearance between vertical webs at end of joint plates with a minimum length of 3 feet unless adjoining piece will not permit. The length and angles of frogs for turnouts and crossovers, shall be as provided in specification W15-22. (Dimensions of frogs for crossovers and turnouts given above.)

(b) Single crossings shall be cast in two pieces in angles from 90° to 60° and in four pieces for angles under 60° . In 2-piece crossings or compound pieces the length of arms shall be kept under 4 feet 6 inches. Castings shall not exceed a maximum of 16 feet in length.

JOINTS

411. Where castings connect directly with rails they shall be finished for a tight fit of standard splice bars throughout the length of such bars, and projecting portions of castings taking the place of joint plates shall be finished to a splice-bar fit. When joints are bolted up tight, the rail shall align correctly with castings with no greater variation than one thirty-second inch in either line or level. For joints between castings, special splice bars may be used only when it is impossible to apply standard bars and the finish shall then be maintained equally good. Joints shall be tight. Occasional open joints shall not exceed one-eighth inch. Manufacturers shall make note of such open joints on drawings.

COMPROMISE JOINTS

412. (a) Compromise joints shall be avoided wherever possible by shaping the ends of special pieces to match the adjoining rail, or compromise rails shall be used consisting either of steel castings or two pieces of rails connected by cast welding or other welding method, and shaped on the two ends to suit the respective sections to be joined. Such compromise rails shall be not less than 5 feet long over all.

(b) Where the foregoing practice is not specified or practicable, compromise joints shall be of forged or cast steel at least equivalent in strength to the joint for the lower rail and must be finished to a good fit so that good line and surface are obtained.

(Paragraphs (c) and (d), covering shape of guard rail and designation of compromise joints, conform to paragraphs (b) and (c), section 415, in A. E. R. E. A. W33, given below.)

PAVING FACE

413. In work specified for paved streets the angles in frogs and crossings shall be filled to provide paving faces to a width of not less than 4 inches and in switches and mates to not less than 3 inches by carrying out the castings forming the body of the piece where length of arms and points will permit. Where this is not possible, paving chocks shall be used consisting of separate iron castings which must have ample bearing on the bottom flanges of the special pieces and rails to prevent their being depressed under vehicular traffic and be so constructed as to permit their being placed and solidly grouted after the joint plates are applied.

(In respect to finish of castings, this specification conforms to A. R. E. A. track-work plans, given below, except for the following provisions:)

502. (b) Running surfaces of castings shall be finished with as good surfaces as those of rolled rail.

(c) That portion of castings which rests on ties shall be straight and out of wind and shall be free from lumps or such imperfections as would prevent a good bearing. The wind or warp in bottom surfaces of castings shall not exceed one-eighth inch in 5 feet and when work is specified for use with steel-tie structures exceptional care shall be exercised to secure practically true bearing surfaces.

FINISHING OF ENDS

503. All ends of frogs, switches, mates, crossings, or rail lengths shall be finished square to the axis of the rail unless otherwise specified. A variation of more than one thirty-second inch in the width of the head out of square will not be accepted. There shall be no variation of more than one-fourth inch from theoretical lengths, and such variations shall be noted on plans.

CURVING OF RAILS

504. All curved rails shall be so bent true to templet throughout their entire length and depth that they may rest in a horizontal plane.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, STANDARD SPECIFICATION FOR PLAIN BOLTED SPECIAL TRACK WORK, W33-30, 1930

PLAIN BOLTED SPECIAL TRACK WORK

This specification is intended to cover the manufacture of special track work wherein switches, mates, frogs, crossings, curves, guard rails and connecting rails are made of rolled steel rails properly shaped by machining or grinding and secured together by means of cast iron, cast, forged or rolled steel fillers, bolts, rivets, and plates. The term "plain bolted" shall be considered as being synonymous with the term "built up."

I. MATERIALS

101. *Conformity with association specifications.*—All work furnished under these specifications shall be manufactured of materials which are in accordance with the recommended specifications of the American Electric Railway Engineering Association for materials for use in the manufacture of special track work, W104, given below.

II. CHEMICAL PROPERTIES AND TESTS

201. *Conformity with association specifications.*—The chemical composition and tests covering each of the several materials in the special track work shall conform to the requirements of the recommended specifications of the American Electric Railway Engineering Association for materials for use in the manufacture of special track work, W104, given below.

III. PHYSICAL PROPERTIES AND TESTS

301. *Conformity with association specifications.*—The physical properties and tests covering each of the several materials in the special track work shall conform to the requirements of the recommended specifications of the American Electric Railway Engineering Association for materials for use in the manufacture of special track work, W104, given below.

IV. DESIGN

(A) General Specifications

401. *Engineering data and drawings.*—(a) The manufacturer shall obtain all necessary engineering data either in the field or from such plans and data as may be furnished by the purchaser. The manufacturer shall be held responsible only for the accuracy of such data as he may obtain which is not furnished by the purchaser.

(b) The manufacturer shall submit working drawings, showing engineering data, piece numbers, and lengths, when so specified.

(c) The drawings of the purchaser and the manufacturer's drawings approved by the purchaser shall be a part of the specifications. Anything not shown on the drawings but which is mentioned in the specifications, or vice versa, and anything not specifically set forth in either but which is reasonably implied shall be furnished the same as if specifically shown and mentioned in both. Any omissions from drawings or specifications necessary for a clear understanding of the work shall be called to the purchaser's attention promptly by the manufacturer.

402. *Grooves, flangeways, and gage.*—(a) Grooves, flangeways, and gage shall conform to the recommended practice of the American Electric Railway Engineering Association.

(b) Flangeways shall not vary from the widths and depths specified by greater amounts than allowed by the following permissible variations:

	Under	Over
Width of flangeway.....	<i>Inch</i> None.	<i>Inch</i> 3/32
Depth of flangeway:		
Flange bearing.....	1/16	1/32
Nonflange bearing.....	1/16	3/16

(c) When M. C. B. flangeways are specified, the width and depth shall not be less than 1 3/4 inches.

403. *Flange bearing.*—When flange bearing is required the depth of groove at intersections and on curved side of mate points shall be one-eighth inch less than the depth of the wheel flange except that the minimum depth of flangeway shall be nine-sixteenths inch. Wherever possible the flange bearing shall be carried to a point where the wheel will have not less than 2 inches tread bearing. The effective part of risers approaching the flange bearing shall not be steeper than one-sixteenth inch in 1 inch of length and shall be made a maximum of one thirty-second inch in 1 inch wherever possible. When so specified, continuous flange bearing shall be provided through crossings and involved special track work, except on the inner rails of curves.

404. *Wheel clearance.*—Tread clearance shall be 4 inches in width for A. E. R. E. A. wheels and 4 1/2 inches wide for M. C. B. wheels, unless otherwise specified.

405. *Line and surface.*—The line and surface of all work shall be practically true and uniform throughout, with no greater variation than one-sixteenth inch in 5 feet of length.

406. *Lengths of tongue switches and mates.*—The lengths of tongue switches and mates shall be in accordance with the following table of standard dimensions of switches and mates:

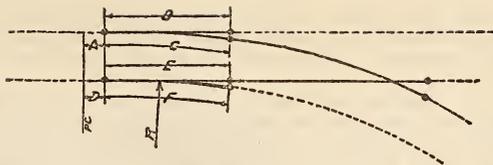

FIGURE 188

Standard dimensions of switches and mates

Standard radius	Radius for all gages R		Dimensions					
			A	B and C mate	D	E and F tongue switch		
	<i>Ft.</i>	<i>In.</i>	<i>In.</i>	<i>Ft.</i>	<i>In.</i>	<i>In.</i>	<i>Ft.</i>	<i>In.</i>
100-foot lateral.....	97	7 1/2	0	13 6	0	13 6	13 6	6
200-foot lateral.....	197	7 1/2	18	16 6	18	16 6	16 6	6
200-foot equilateral.....	197	7 1/2	0	13 6	0	13 6	13 6	6
350-foot equilateral.....	347	7 1/2	12	16 6	12	16 6	16 6	6
50-foot lateral.....	47	7 1/2	-6	10 0	-6	10 0	10 0	0
75-foot lateral.....	72	7 1/2	0	12 0	0	12 0	12 0	0
100-foot equilateral.....	97	7 1/2	-6	10 0	-6	10 0	10 0	0

NOTE.—Radii and dimensions shown in italic type are not standard and should be used only where special conditions will not permit the use of radii and dimensions shown in roman type. As it will rarely be found necessary to use other than a standard, it is recommended that the 100 and 200 foot lateral and 200-foot radius equilateral be used wherever practicable.

407. *Guards—For frogs and curves.*—(a) Frog guards shall be furnished when specified. They shall be similar in design to regular rolled rail guards in all respects. They shall be suitably flared at ends and provided with spacing blocks and braces as called for. They may be made of second-quality rails.

(b) Frog guards shall not be less than 8 feet 3 inches nor more than 16 feet 6 inches long over all.

(c) Guards for standard section rails on curves shall be of standard section rails unless rolled-shaped guards or flat-bar guards are definitely specified. If of standard section rail on sharp curves of 100-foot radius or less for wheels with flanges shallower than M. C. B. flanges, unless otherwise specified the top of the guard rail shall be raised above the level of the running rail at least five-sixteenths inch by the use of step tie-plates if guard section is same as running rail or by the use of suitable higher rail with bases set level. For M. C. B. flanges the guards shall be level with the running rail. The guard rails shall be fastened to the running rails by through bolts as specified in section 413 (a) and cast-iron or steel spacing blocks not less than 3 inches long and spaced not more than 30 inches on centers.

(d) Guard-rail joints shall have an overlapping filler with two bolts with short splice bars on the outside or joints may be the same as those used on the running rail.

408. *Rail braces.*—Rail braces shall be of pressed steel or malleable iron not less than three-eighths inch in thickness unless cast iron is specified. They shall be of approved design and have a good fit under the head and against the web of rail.

409. *Foot guards.*—Foot guards shall be furnished only when specified and shall be of approved design.

410. *Cotter pins*.—Cotter pins shall be used in all vertical bolts, pins, and through body bolts in frogs and crossings. They shall be placed close up to the nut.

411. *Washers, head locks, and nut locks*.—(a) Flat washers under the nut shall be not less than three-eighths inch thick. Angle or beveled washers and head locks shall be not less than one-eighth inch thick at the thin end. Washers other than spring-type lock washers shall be not less than 2½ inches long and of ample width to provide bearing against the head or base of rail.

(b) All main or body bolts and through bolts shall be provided with self-locking heads or with separate head locks and with approved nut locks.

412. *Sawing of rails*.—All rails whether furnished in frogs, switches, mates, crossings, or rail lengths shall be sawed square to the axis of the rail unless otherwise specified. A variation of more than one thirty-second inch in the width of the head out of square will not be accepted. There shall be no variation of more than one-fourth inch from theoretical lengths, and such variation shall be noted on plans.

413. *Minimum diameters—bolts, rivets, and rivet holes*.—(a) The minimum diameters of through bolts shall be controlled by the depth of the fishing space measured along the vertical center line of the rail as follows:

Depth of fishing space		Minimum diameters of bolts
From—	To—	
Inches	Inches	Inches
-----	2½	¾
2¾	2¾	1
2¾	3	1½
3¾	-----	1¾

(b) Joint bolts shall be of mill standard for section of rail used unless otherwise specified.

(c) The minimum diameter of rivets and bolts used for any purpose shall be five-eighths inch. The diameters of rivet holes shall not be more than one-sixteenth inch greater than the diameters of corresponding rivets.

414. *Joints*.—Joints for bolted work in streets shall be tight. Occasional open joints shall not exceed one-eighth inch. Joints for work for open tracks need not be tight, but no joint shall be more than one-eighth inch open, excepting joints designated as insulated joints. When joints are bolted tightly, the rails shall align correctly with each other with no greater variation than one thirty-second inch in either line or level. Occasional open joints in guard rails shall not exceed one-fourth inch. The manufacturer shall make note of such open joints on plans.

415. *Compromise joints*.—(a) Compromise rails shall be used instead of compromise joints wherever possible. They shall be made of steel castings, forged taper rails, or two pieces of rail connected by cast welding or other welding methods. Where this practice is not specified or practicable, compromise joints shall be of forged or cast steel at least equivalent in strength to the joint for the lower rail and must be finished to a good fit so that good line and surface are obtained.

(b) Where guard rails connect with other sections the shape of the guard shall be modified in a distance of 6 to 9 inches to conform gradually and as nearly as practicable to the contour of the connecting section.

(c) Compromise joints shall be designated in accordance with the standard method of the American Electric Railway Engineering Association W12. (See 606.0, p. 310.)

416. *Paving face*.—In work specified for paved streets the angles in switches, mates, and frogs shall be filled to provide paving faces to a width of not less than 4 inches, by means of paving chocks consisting of iron castings which must have ample bearing on the bottom flanges of the special pieces and rails to prevent their being depressed under vehicular traffic. They shall be so constructed as to permit their being placed and solidly grouted after the joint plates are applied.

417. *Split switch design*.—(a) The design shall be in accordance with Figure 189.

(b) The fixtures shall conform to the A. R. E. A. Details as per A. R. E. A. plans 201 and 202. (See A. R. E. A. track work plans given below.)

The number and kind of fixtures required shall be specified by a selection from the bill of materials applicable to the length of switch desired, given on A. R. E. A. plans Nos. 210 and 211. (See A. R. E. A. track work plans, given below.)

(B) Frogs and Accessories

418. *Lengths of frogs*.—(a) The lengths and angles of frogs for crossings and turnouts shall be in accordance with those provided in W15, given above.

(b) The lengths of spring rail frogs shall be in accordance with the standard lengths of spring rail frogs of the American Railway Engineering Association.

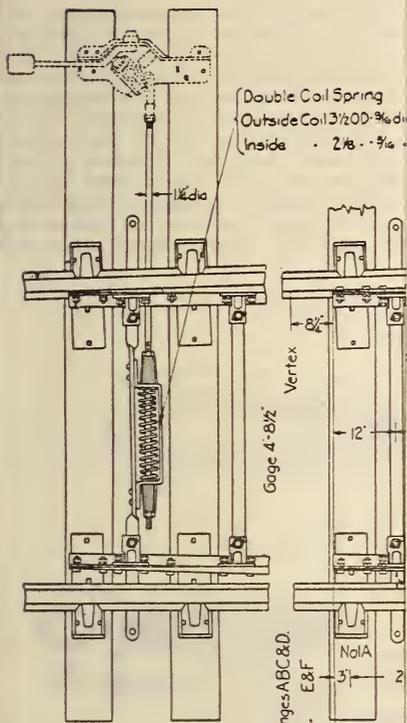

419. *Frog and crossing arms*.—Frog and crossing arms, except as provided in section 418 (a) and (b), shall in all cases be long enough to give 6¼ inches clearance between webs at end of splice bars. When adjoining pieces or combination pieces prevent a length of arm for proper joining, special pieces made of cast steel may be substituted. Minimum arm length for frogs shall be 3 feet and for crossing arms 4 feet unless adjoining pieces or other conditions will not permit.

420. *Frog points, body fillers, and wing rails*.—(a) Frogs shall be made with points formed of rails suitably planed and fitted together and securely held in correct position by main body fillers of rolled steel or cast iron of sufficient length to provide for not less than two through body bolts passing through both point rails and wing rails. Through bolts shall not be spaced more than 10 inches center to center. Wing rails shall lap the point not less than 20 inches and for frogs having an angle of 10° or less, the lap of the wing rail shall be the same as that provided in the American Railway Engineering Association standards.

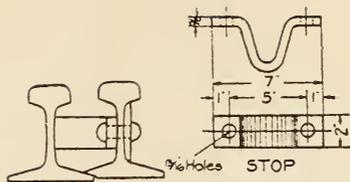

(b) The body fillers shall be of sufficient length to provide proper flange bearings where required and the surfaces for such flange bearings shall be steel, properly treated, or cast iron with chilled surface to provide hard wearing surface.

421. *Spring rail frogs*.—The design shall be in accordance with Figure 190.

422. *Girder rail frogs*.—Frogs made of grooved girder and girder guard rails shall be made with points formed by rails properly planed, shaped, and machined, securely held together by means of body fillers and through bolts. Further strength shall be provided by means of rolled steel plates not less than three-fourths inch thick, planed to fit the fishing section on the outside of the rails and through-bolted. Flange bearing when required may be provided by suitably shaping the rails.

(C) Tongue Switches, Mates, and Crossings

423. *Tongue switches.*—Tongue switches shall have a cast iron, cast steel, or rolled steel bed underneath the tongue. The tongue shall be of hard steel not less than 2 inches thick and have a substantial pivot pin. The pivot pin shall be of sufficient size to provide ample strength and not less than $2\frac{7}{16}$ inches in diameter and fitted accurately in a bored hole in the bed. The base of the tongue and the surface of the bearing bed shall be finished true and smooth so that the tongue will maintain a true bearing in any position. The tread of the tongue shall be at least one-fourth inch above the curved tread of the switch from a point 1 foot back from the point of the tongue toward the heel to provide an efficient guard where required. Tongues of switches of 200-foot radius or over may have their tops level with the curved tread surface. Provision for attachment

bolts, rivets, and bearing plates or corner plates as may be required. One line of rails shall be carried through the crossing with the heads of the through rails notched for the flangeways of the intersecting rails. The through rails may be cut through vertically at the middle of the notch. Flange bearing, when required, shall be provided by hard-steel fillers, by cast-iron fillers having chilled top surfaces, or by suitably planing the guard rails.

(b) Single crossings may be made in one or two pieces at the manufacturer's option unless otherwise specified.

(c) Crossings having an angle of 35° or less shall be made with frog-point construction as provided in section 420.

(d) Easer rails in steam tracks shall be of the same section as the main running rails and shall be full headed throughout except that the ends of easers

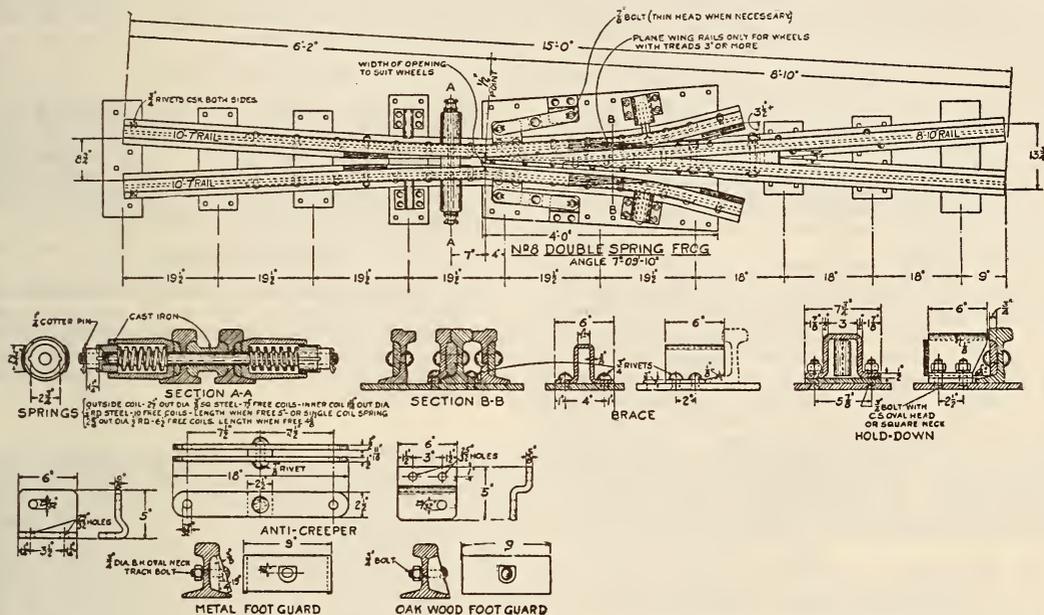

FIGURE 190.—No. 8 double spring frog. (But only partially spring acting)

of switch throwing or locking devices shall only be made when specified.

424. *Mates.*—(a) Mates shall be made with guards of sufficient length to extend beyond the point toward the heel not less than 20 inches and sufficiently toward the P. C. to guard the point of the tongue properly. Where flange bearing is required the surfaces for such flange bearing shall be steel properly treated or cast iron with chilled surface to provide a hard-wearing surface.

(b) Body fillers shall be of sufficient length properly to protect the mate point and hold it in position, with not less than four through body bolts passing through the rail forming the point.

(c) Mates made of girder grooved and girder guard rails shall be made with points formed of rails properly planed, shaped, and machined, securely held together by body fillers and through bolts. Flange bearing may be provided by suitably shaping the rails.

425. *Crossings.*—(a) Crossings of angles from 90° down to 35° shall be made of double or triple rails as specified. They shall be made of rails suitably shaped, planed, and fitted together and securely held by such main body fillers, heavy forged-steel reinforced knees, rolled-steel angle knees, through

shall be planed down one-half inch in 12 inches. They shall extend not less than 21 inches from the gauge-line intersection.

V. WORKMANSHIP, ASSEMBLY, AND FINISH

501. *Workmanship.*—Workmanship shall be first class in accordance with best current practice and the assembly of the several parts shall be such that uniformity of detail and finish will result.

502. *Bolt holes, method of drilling.*—Main or body bolts shall have a driving fit in straight true holes and surrounding metal shall be free from burrs or cracks. Holes in carbon-steel rail shall be drilled and shall be cylindrical and not conical. Drilling shall be accurately done on bevel where necessary and no punching shall be permitted except in bearing plates, tie plates, and washers. Holes for main bolts shall be one-sixteenth inch less in diameter than bolts to be used. The parts shall then be assembled and holes reamed straight and true with no offsets between adjacent parts and of such size as will give the driving fit. In lieu of this method the parts may be assembled and accurately fitted before any drilling is done; after the parts have been securely clamped in correct position the holes may

be drilled of such size as will give driving fit for their entire length.

All bolt holes through rails and fillers shall be drilled with a minimum clearance for rough bolts and they shall conform accurately to the required dimensions.

503. *Rivets and riveting.*—Rivets shall be of full diameter called for on plans, and rivet holes shall not be more than one-sixteenth inch greater in diameter. When not otherwise called for by plans or specifications, rivets shall have standard button or cone heads of uniform size for the same size of rivet. The heads shall be concentric with the holes. Countersunk rivets shall be flush with the surface and fill the countersink except that rivets through base and tie plates may have a crown of not more than one-eighth inch below the lower surface of the plate.

504. *Curving of rails.*—All curved rails shall be so bent true to templet throughout their entire length and depth that when ready for installation all parts of the undersurface of the base will rest in a plane.

505. *Set-in guards.*—Set-in guards shall be carefully fitted to the back of switch points to insure perfect line, surface, and flangeway when point is open, and accurate fit against the abutting rail when the point is closed.

506. *Bolt and rivet clearance in split switches.*—Care must be taken to provide at least one-eighth inch clearance between heads on all rivets and bolts and the adjacent rails.

507. *Fit of fillers, braces, and spacers.*—All abutting parts and pieces shall have accurate true fit. All filler and spacer blocks shall fit in the bases, heads, and webs of rails for a distance of one-half inch above the base and below the head and maintain required flangeway. Throat filler blocks shall fit sufficiently well to maintain required spacing. When the raised brand of rail interferes with fit of fillers the brand shall be removed. Fillers shall be grooved or cut to fit over rivet heads and bolt heads.

508. *Heating of rails.*—Open-hearth steel rails shall not be heated to more than a dull red color for the purpose of kinking, bending, drilling, or punching.

509. *Assembly for inspection.*—Before any of the work is shipped, the several parts shall be assembled and inspected and checked to insure proper fit and conformity with plans.

VI. MARKING AND SHIPPING

601. All material shall be given suitable shop marks by painting and die stamping for ready identification, corresponding to marks given on plans. Die-stamping figures shall not be less than five-eighths inch high. This marking shall be carefully arranged to insure proper and easy assembly of material in the field. No paint, tar, or other covering shall be used before inspection and not at any time unless definitely required by the specifications.

VII. INSPECTION

701. The inspector representing the purchaser shall have all reasonable facilities afforded him by the manufacturer to satisfy himself that the finished material is furnished in accordance with these specifications. All inspections shall be made at place of manufacture, unless otherwise arranged.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, STANDARD SPECIFICATION FOR RAIL-BOUND INSERT TYPE SPECIAL TRACK WORK, W34-30, 1930

RAIL-BOUND SPECIAL TRACK WORK

(In respect to materials, chemical properties and tests, physical properties and tests, design (including standard dimensions of switches and mates), workmanship, heating of rails and inserts, assembly for inspection, marking and shipping, and inspection, this specification conforms to A. E. R. E. A., W33, given above, except for the following provisions:)

This specification is intended to cover the manufacture of special track work wherein the switches, mates, frogs, and crossings are made of cast manganese steel inserts, at the points of greatest wear, secured in place by rolled-steel rails properly machined and bolted thereto.

FLANGE-WAY FILLERS

406. Flange-way fillers when required shall be of rolled or forged steel, cast steel, or wrought iron, or of good quality gray cast iron, as may be specified. They shall fit in the fishing space of the rail and into the fillets of the web for not less than one-half inch below the head and above the base flange.

MANGANESE INSERTS

408. The cast manganese steel inserts shall be the full height of the rail, or have a full support on the base of the rail. The sectional area shall be not less than the minimum recommended by the Manganese Track Society and the Manganese Steel Founders Society.

BASE PLATES

410. Base plates under frogs or crossing intersections shall only be furnished when specified. They shall lap the joint between the rolled rail and the manganese-steel insert, and shall not be shorter than the manganese-steel casting. They may be fastened to the structure by rivets or clip bolts. The thickness of the plate shall be not less than five-eighths inch for rails weighing less than 100 pounds per yard and three-fourths inch for rails weighing 100 pounds per yard and over.

TONGUE SWITCHES

417. (a) Tongue switches shall be made of standard rails suitably bent and fitted together to form a running surface for the straight and curved tracks, with a guard of same section bolted thereto forming a pocket for the tongue. The tongue shall be made of manganese steel or other hard steel as may be specified, not less than 2 inches thick and have a substantial pivot pin fitted accurately in a bored hole, or other approved fastening. The bed shall be of cast iron, cast steel, or rolled steel underneath the tongue. The base of the tongue and the surface of the bearing bed shall be finished true and smooth so that the tongue will maintain a true bearing in any position. The tread of the tongue shall be at least one-fourth inch above the curved tread of the switch from a point 1 foot back from the point of the tongue toward the heel to provide an efficient guard

where required. Tongues of switches of 200 feet radius or over may have their tops level with the curved tread surface. Provision for attachment of switch throwing or locking devices shall only be made when specified.

(b) Manganese-steel inserts shall be provided at either the point or the heel of the tongue, or both, as may be specified. The insert at the point shall form a pocket for the tongue and extend in front of the point not more than 6 inches, and toward the heel about one-fourth the length of the tongue and be securely bolted to main and guard rails through the webs by not less than four bolts.

The insert at the heel of the tongue shall continue the running surface of the tongue and form the junction of the running rails and guard.

MATES

418. Mates shall be made of main and guard rails, enveloping a cast manganese steel insert, and of such length as to insure wheel flange bearing in the grooves, and tread bearing on the head. The insert shall extend back of the head a sufficient distance properly to protect the mate point and hold it firmly in position by not less than four through bolts or it shall be made with a cast manganese-steel insert with guard forming integral part thereof extending in front of the point to insure full wheel tread bearing, and back of the point to the full width of the railhead and be securely bolted to the rail.

The straight rail of the mate shall be recessed in the head by planing or bending to provide a bearing on the manganese-steel insert opposite the point, for the outside edge of the wheel tread on the curve run.

(Paragraph 419, lengths of tongue switches and mates, is identical with paragraph 406 (including accompanying note) in W33, given above.)

FROGS

420. Frogs shall be made with a manganese-steel insert set between the wing rails, and securely fastened together with through bolts spaced not more than 10 inches center to center. The manganese-steel insert shall have a width across the head at the heel end of not less than 4 inches, shall extend between rails at the heel not less than 8 inches, and shall be secured to the heel rails with not less than two bolts.

The wing rails shall be recessed in the head to receive the insert and to provide a bearing on the manganese steel for the outside edge of the wheel tread opposite the point on both runs, and shall extend in front of the throat to a spread between gage lines one and one-half times the width of the groove. Where it is necessary to form a guard point on the insert, the latter shall be suitably extended.

At the heel end the wing rails shall be flared to an opening twice the width of the throat, and rolled steel or cast iron fillers shall be extended to the end of the wing rails and securely bolted thereto.

CROSSINGS

421. (a) Crossings of angles of 90° down to but not including 35° shall be made of double or triple rails as specified on either or both runs. The portion at intersections shall consist of manganese-steel inserts surrounded by the rolled rails and forged or cast steel knees, or fastened to base plates. The insert shall extend on the running surfaces to the spreads between gage lines of not less than 4 inches on electric railway track and 4¾ inches on steam railway track, and form the guard points where necessary. The rolled rails and knees shall be suitably shaped and fitted to the manganese-steel inserts and secured together by through bolts and by clip bolts to the base plate when furnished.

Single crossings may be made in one or two pieces at the option of the manufacturer, unless otherwise specified.

(b) Crossings having an angle of 35° or less shall be made of frog construction, as provided in section 420. On steam railway lines the manganese-steel insert shall extend into the wings opposite the point not less than 4 inches measured from gage lines.

FROG AND CROSSING ARMS

422. Frog and crossing arms shall in all cases be long enough to give 6¼-inch clearance between webs at end of splice bars. When adjoining pieces or combination pieces prevent a length of arm for proper joining, special pieces made of cast steel may be substituted. Minimum arm length for frogs shall be 3 feet and for crossing arms 4 feet, unless adjoining pieces or other conditions will not permit. The lengths and angles of frogs for cross-overs and turnouts shall be as provided in Engineering Manual Specification W15, Dimensions of Frogs for Crossovers and Turnouts. (See figs. 185 to 187.)

(In respect to finish of castings, this specification conforms to A. R. E. A. track-work plans, given below, except for the following provisions:)

502. (b) The running surface of manganese-steel inserts shall be finished with as good surfaces as those of the rolled rail, and portions fitting into rails or other parts shall be ground to a good fit.

(Paragraphs 503 and 504 are identical with paragraphs 503 and 504 in A. E. R. E. A., W32, given above.)

HEATING OF RAILS AND INSERTS

(Paragraph 505 (a) is identical with paragraph 508 in A. E. R. E. A. W33, given above. Paragraph 505 (b) is as follows:)

(b) Manganese steel inserts shall under no circumstances be heated to more than a light blue temper color.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, STANDARD DESIGN OF BOLTED RAIL CROSSINGS; STEAM RAILROAD OVER ELECTRIC RAILWAY, W39-28, 1928

BOLTED RAIL CROSSINGS

BOLTS

Through bolts shall be high tensile steel—1¾-inch diameter bolts for 120-pound rail and heavier; 1½-inch diameter bolts for rails less than 120 pounds and down to rails having 3-inch fishing height; 1¼-inch diameter bolts for rails having less than 3-inch fishing height, down to and including 80-pound rail. Fishing height shall be measured on vertical center line of rail.

All through bolts to have tight fit. Through bolts to have square heads and nuts, with U. S. standard thread, fitted with head locks, nut locks, and bevel washers where necessary to afford square bearing.

Suitable washers in any case shall be placed under nuts to bring same out from under head of rail, so that they may be tightened with a standard wrench.

FILLERS

Flangeway fillers shall be of rolled or forged steel on steam railroad, and on electric railway may be of rolled steel, forged steel, or cast iron, the latter to be used only when flange bearing is omitted. They shall fit closely into the fishing space of the rail, and tightly into the fillets of the web for not less than one-half inch below the head and above the base.

Third rail through fillers shall be of rolled or forged steel. Other fillers and spacer blocks may be of cast iron.

PLATES

Crossings shall be provided with base plates unless otherwise specified. Plates shall be three-fourths inch thick, of length to suit angle of crossing, and of sufficient width for attaching to crossing by clips with three-fourths-inch diameter countersunk-head bolts.

CORNER BRACES

Forged steel or iron corner braces with heavy reinforced corners shall be provided, and shall be planed to fit closely into the fishing space of the rail, and into the fillets of the web for not less than one-half inch below the head and above the base flange.

Spaces marked "X" in flangeway between rolled steel fillers on steam railroad run may be filled with either rolled-steel or cast-iron fillers, if so specified.

Third-rail fillers at "Y" may be continuous if so specified. Flange bearing on electric railway run may be omitted when so specified.

(For illustrative details of bolted rail crossings, steam railroad over electric railway, see A. R. E. A. track-work plans, plan No. 716.)

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, STANDARD DESIGN OF BOLTED RAIL CROSSINGS; STEAM RAILROAD OVER ELECTRIC RAILWAY, FOR ANGLES BELOW 50° TO 30°, INCLUSIVE, W43-28, 1928

BOLTED RAIL CROSSINGS

(Identical with A. R. E. A. track-work plans, plan No. 717.)

NOTE.—Specifications for the general character and quality of the materials and workmanship entering into bolted rail crossings are contained in specification W33-29, given above.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, STANDARD DESIGN OF BOLTED MANGANESE-STEEL CROSSINGS; STEAM RAILROAD OVER ELECTRIC RAILWAY, FOR ANGLES BELOW 45° TO 30°, INCLUSIVE, W44-28, 1928

BOLTED MANGANESE-STEEL CROSSINGS

(Identical with A. R. E. A. track-work plans, plan No. 778.)

NOTE.—Specifications for the general character and quality of the materials and workmanship entering into these crossings are contained in specification W34-29, given above.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, SPECIFICATION FOR MATERIALS FOR USE IN THE MANUFACTURE OF SPECIAL TRACK WORK, W104-28, 1928

[Approved as American Tentative Standard by the American Standards Association, January 23, 1929]

SPECIAL TRACK WORK MATERIALS

Part I.—INTRODUCTORY

1. Definitions—Scope—Inspection and Tests

101. *Definition of special track-work.*—All rails, track structures and fittings, other than plain unguarded track neither curved nor fabricated before laying.

102. *Scope of specifications.*—These specifications are intended to cover the manufacture, chemical and physical properties, and tests of materials entering into the manufacture and assembly of special track work for steam, electric and industrial tracks of all gauges and types, for heavy rail of 50 pounds per yard and over, under any motive power, and in either open or paved track.

103. *Principal structural items in special track work.*—Switches; mates; frogs; crossings; guarded, curved, and fabricated rails; appurtenances and fittings for the preceding items, such as plates, rods, fillers, braces, knees, guards, risers, stops, springs, housings, clips, bolts, nuts, washers, rivets, and splice bars.

104. *Principal materials used for structural items.*—

(a) *Rolled rails:*

Carbon-steel rails—

Standard T-sections.

Plain girder sections.

Girder grooved sections.

Girder guard sections.

Manganese steel rails.

(b) *Castings:*

Manganese-steel castings.

Carbon-steel castings—general.

Carbon-steel castings—hard.

Gray-iron castings—general.

Gray-iron castings—high test.

Malleable castings.

(c) *Rolled or forged material:*

Steel forgings—medium.

Steel forgings—hard.

Mild-steel bars and shapes.

Rolled-steel frog fillers.

Wrought iron—common.

Wrought iron—refined.

(d) *Springs:*

Helical springs.

(e) *Fastenings:*

Splice bars.

Bolts and nuts—general.

Bolts and nuts—high tensile.

Washers.

Nut locks.

Rivets.

105. *Selection of material to be used.*—The kind of material to be used for the various parts of special track work shall be as specified by the purchaser. If not so specified, and two or more kinds are applicable to a particular part, the selection shall be optional with the manufacturer.

106. *Application of specifications.*—Any material entering into the manufacture of special track work or parts thereof and which is covered by specifications contained (or referred to) herein, shall conform to the requirements of such specifications, unless otherwise specified by purchaser.

107. *Reference to established specifications.*—The specifications contained (or referred to) herein are based, as far as possible, on established specifications of various national associations with such additional or modified requirements, necessary to adapt the material to the manufacturing of special track work, as are particularly specified herein.

108. *Inspection and tests.*—(a) The records of any tests made by the manufacturer as his regular routine in the manufacture of materials entering into the work of the purchaser shall be open, free of charge, for the examination of the inspector representing the purchaser.

(b) The inspector representing the purchaser shall have free entry, at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturer's works, which concern the manufacture of the materials ordered. The manufacturer shall afford the inspector, without charge, all reasonable facilities to examine the work during

its progress as well as the finished product to satisfy him that the materials comply with these specifications.

(c) Other chemical and physical tests covered by the specifications shall be made when required by the purchaser. For materials originally manufactured by the special track-work manufacturer for a specific order such tests shall be made at the expense of the manufacturer when the amount of the particular kind of material is 50 tons or more; if less than 50 tons the purchaser shall pay for the expense of such tests, unless the material fails to meet the specifications, in which case the manufacturer shall bear the expense.

(d) For materials or parts of the work taken from stock or purchased from other manufacturers the special track-work manufacturer, when required, shall certify that the material conforms with these specifications. If the purchaser desires any chemical or physical tests of such materials, he shall pay the expense of such tests, unless the materials fail to meet the specifications, in which case the special track-work manufacturer shall pay the expense. For the rails used in the work the manufacturer, when requested, shall supply the purchaser with a certificate of inspection from the rail manufacturer.

(e) All inspection and tests shall be made at the place of manufacture prior to shipment and shall be so conducted as not to interfere unnecessarily with the operation of the works or the progress of the work on the purchaser's order. Chemical and physical tests may be made at a testing laboratory outside of the manufacturer's works to be agreed upon between the manufacturer and the purchaser.

(f) The acceptance of any material by an inspector shall not prevent subsequent rejection if found defective after delivery.

(g) No guarantee of specific length of service will be required. A claim for defective material and/or workmanship shall cover only such defects as will impair the life of the work.

(h) No claim for free replacement of defective material and/or workmanship shall be recognized unless made promptly and based on defects appearing within three months from date of installation and in any event within two years from date of shipment.

(i) The foregoing paragraphs cover the inspection and tests of the materials when used for special track work and take precedence over the inspection clauses contained in the various established specifications for similar materials referred to in section 107.

Part II. SPECIFICATIONS

RAILS

I. Carbon Steel Rails of Standard T-Rail Section

101. *Material covered.*—Rails of standard T-rail section weighing 50 pounds per yard or over, and of open-hearth steel (Bessemer-steel rails are not desired for special track work).

102. *Manufacture.*—Unless otherwise specified by the purchaser the rails shall be manufactured, at the option of the special track-work manufacturer, according to any one of the specifications of the American Society for Testing Materials, A1-30, the American Railway Engineering Association, 1925, or the American Electric Railway Engineering Association, W16-29 (see 606.1, p. 315), for open-hearth steel rails of the weight and section specified and conform to the following requirements:

103. *Quality.*—First quality No. 1 rails only shall be used in special track work, except that No. 2 rails may be used for guard rails and for parts of track structures where the necessary machining of the rail entirely removes any flaws or imperfections.

104. *Length.*—The standard length of full-length rails in special track work shall, at 60° F., be 30 feet, 33 feet, and 39 feet, as may be specified, and within the variations permitted by the specifications under which the rails were rolled.

105. *Drilling.*—(a) When circular holes for joint bolts, electric bonds, or tie-rods are required they shall be drilled to conform to the specifications of the purchaser and be within the following permissible variations:

(b) The diameter of the bolt holes shall not vary more than one thirty-second inch over or under that specified. The diameter of the bond holes shall not vary more than one thirty-second inch under that specified. The diameter of the tie-rod holes shall not vary more than one-sixteenth inch over or under that specified.

(c) The location of the bolt and bond holes shall not vary more than one-sixteenth inch either longitudinally or vertically from that specified. The location of the tie-rod holes shall not vary more than one-eighth inch vertically and not more than one-half inch longitudinally from that specified.

(d) The bond holes shall be truly cylindrical and not conical.

106. *Punching.*—Unless otherwise specified by the purchaser, the tie-rod holes may be punched, and when so made they shall be free from burrs, fins, etc. The permissible variation in the diameter of punched tie-rod holes shall be not more than one-eighth inch over or under that specified.

II. Open-Hearth Steel Girder Rails of the Plain, Grooved, and Guard Types

201. *Material covered.*—Girder rails of the different types for curves, turnouts, and other parts of special track work for use in paved streets.

202. *Manufacture.*—Unless otherwise specified by the purchaser, the rails shall be manufactured according to the standard specifications for open-hearth girder rails of the American Electric Railway Engineering Association W1-31, the American Society for Testing Materials A2-27, or the American Railway Engineering Association, 1926. (See 606.1, p. 311.) Where the class of the rail is optional, the special track-work manufacturer may use either class.

203. *Quality.*—First quality No. 1 rails only shall be used in special track work, except that No. 2 rails may be used for parts of track structures where the necessary machining of the rail entirely removes any flaws or imperfections.

204. *Length.*—The standard length of full-length rails in special track work shall be 30 feet and 32 feet at 60° F. and within the variations permitted by the specifications under which the rails are rolled.

205. *Drilling and punching.*—The drilling of holes for joint bolts and electric bonds and the drilling or punching of tie-rod holes shall conform to the specifications of the purchaser and be within the limits of variations permitted by the standard specifications referred to in section 202.

206. *Sawing.*—The ends of the rails shall be sawed at right angles to the gage with a permissible variation of one-sixteenth inch in 6 inches and on an incline from the vertical so that the top edge of the head will project beyond the bottom edges of the base not less than one thirty-second inch, nor more than three-sixteenths inch. The ends of the rails in special track work need not be milled unless specially called for.

III. Rolled Manganese-Steel Rails

301. *Material covered.*—Rails rolled of manganese steel for sections corresponding to sections of open-hearth rails.

302. *Manufacture.*—The process of manufacture shall be in accordance with the best current state of the art and the rail manufacturer's approved specifications No. I-B. The rails shall comply with the following requirements.

303. *Chemical compositions.*—The steel shall conform to the following requirements as to chemical composition:

	Per cent
Manganese.....	10.50-15.00
Carbon.....	.95- 1.35
Phosphorus, not over.....	.10

304. *Physical properties and tests.*—A test of the proper toughness of the rail, when required by the purchaser may consist of taking a 2-inch-long section of the rail and bending the same cold under a hammer through the flat part of the web until the head stands at an angle of 90° to its original normal position without fracture at the bend.

305. *Workmanship and finish.*—The general workmanship, finish, and classification of the rails shall be the same as required for carbon-steel rails in the recommended specifications for open-hearth steel rails of the American Society for Testing Materials, A1-30, or of the American Electric Railway Engineering Association, W16-29. (See 606.1, p. 315.)

306. *Quality.*—First class No. 1 rails only shall be used in special track work, except that No. 2 rails may be used for guard rails and for parts of track-work structures where the necessary machining entirely removes any flaws or imperfections.

307. *Punching.*—(a) Holes for joint bolts or tie-rods may be punched or drilled in location and of size specified by the purchaser.

(b) The diameter of the bolt holes shall not vary more than one thirty-second inch over or under that specified. The diameter of the bond holes shall not vary more than one thirty-second inch under that specified. The diameter of the tie-rod holes shall not vary more than one-sixteenth inch over or under that specified.

(c) The location of the bolt and bond holes shall not vary more than one-sixteenth inch either longitudinally or vertically from that specified. The location of the tie-rod holes shall not vary more than one-eighth inch vertically and not more than one-half inch longitudinally from that specified.

CASTINGS

IV. Manganese-Steel Track Castings

401. *Material covered.*—Manganese-steel castings for solid manganese-steel track structures or wearing parts of track structures.

402. *Manufacture.*—The entire process of manufacture and heat treatment shall be in accordance with the best current practice.

403. *Chemical requirements.*—The chemical composition of cast manganese steel shall be within the following limits:

Elements	Minimum	Maximum
	Per cent	Per cent
Manganese.....	10.00	14.00
Carbon.....	1.00	1.40
Phosphorus.....14

404. *Check analysis.*—Drillings from the finished articles shall be furnished for check analysis if so specified by the purchaser.

405. *Physical requirements and tests.*—When specified, a test coupon shall be cast from the same heat,

separate from the casting, key-marked by the inspector and subject to equivalent heat treatment as the special track-work casting. The coupon shall be 6 to 12 inches long by one-half by three-quarters inch; shall bend cold on the flat side around a diameter of 1 inch to an angle of 160° without fracture. The bending may be accomplished by pressure or by blows.

406. *Bend test.*—Bending test demonstration from the test coupon, if specified by the purchaser, shall be made in the presence of his representative at the foundry where the castings are made.

407. *General conditions.*—(a) Castings shall be reasonably smooth and true to patterns in accordance with good foundry practice. Large lumps, sharp fins, sand, and chills on the outside of the casting shall be removed. The castings shall be free from such blowholes, sand holes, cracks, cold shuts, and other defects which would impair their serviceability and as further specified below. Castings must be out of twist and reasonably true, both as to general surface and alignment, and must not show any signs of straining or undue denting produced in the straightening process.

(b) The bottom part of castings which rest on ties shall be reasonably straight and out of twist, and shall be free from lumps or such imperfections as would prevent a good bearing.

408. *Imperfections.*—Tread surface within 2½ inches of gage line and side of groove 1 inch down from thread shall be free from physical defects, such as shrinkage cracks, sand holes, blowholes, cold shuts or segregation of metal, unless such defects are so small that they have been practically removed by the finish grinding, and there must be no indication of unsoundness of the metal. Shrinkage cracks, cold shuts or segregations of metal will not be allowed in any part of the tread surfaces. Sand holes, blow holes, and cold shuts in portions of the casting where they will not appreciably weaken the casting, or impair its wearing qualities, will be permitted. Castings must be free from shrinkage cracks running vertically in web members of solid work or horizontally at or near the same or in corners of junction of projecting members or longitudinally in grooves. Other small shrinkage cracks which do not materially weaken the castings will be acceptable.

V. Carbon-Steel Castings

501. *Material covered.*—(a) Steel castings for general service in track work for which no physical requirements are specified, appurtenances and fittings, braces, washers, switch heel blocks, spring housings, and other parts not exposed to wheel wear, designated as "class A" castings.

(b) Carbon-steel castings for solid cast track structures or parts of track structures exposed to wheel wear, or special splice bars designated as "class B—hard" castings.

502. *Manufacture.*—(a) The steel shall be made by one or more of the following processes: Open-hearth, electric furnace, converter, or crucible.

(b) The castings shall conform in general character to the standard specifications of the American Society for Testing Materials A27-24 (see 611.41, p. 707) for steel castings of "class A" or "class B—hard" as designated and comply with the following requirements:

503. *Chemical composition.*—The chemical composition shall be as follows:

(a) For class A castings:	Per cent
Carbon, not over.....	0.45
Phosphorus:	
Acid process, not over.....	.07
Basic process, not over.....	.06

(b) For class B—hard castings:

	Not less than—	Not more than—
	Per cent	Per cent
Carbon.....	0.45	0.55
Silicon.....	.30	.45
Manganese.....	.60	.85
Sulphur.....06
Phosphorus.....05

504. *Check analysis.*—Check analysis may be made by the purchaser. The phosphorus and sulphur contents thus determined shall not exceed that specified by more than 20 per cent. Drillings for the analysis shall be taken not less than one-fourth inch beneath the surface and in such a way as not to injure the strength or usefulness of the castings.

505. *Physical requirements.*—(a) For class A castings, no test for physical properties shall be required unless otherwise specified.

(b) Class B—hard castings shall conform to the following minimum requirements as to tensile properties:

Tensile strength.....	lbs./in. ² ..	80,000
Yield point.....	lbs./in. ²
.....	0.45 tensile strength.
Elongation in 2 inches.....	per cent..	17
Reduction of area.....	do.....	25

NOTE. No maximum limit shall be placed on the tensile strength.

506. *Bend test.*—Bend test shall not be required in either class of castings.

507. *Tension test and alternative test.*—Test on class B castings, when required, to determine the tensile properties of the castings or alternative test therefor shall be made in accordance with requirements and method of procedure as per A. S. T. M. specifications referred to in section 502 (b).

508. *Annealing and heat treatment.*—(a) Class A castings coming within the desired chemical composition, need not be annealed nor heat treated unless so specified. Castings with carbon content above 0.30, but not over 0.45 may be accepted, when properly annealed.

(b) Class B—hard castings shall receive proper heat treatment in accordance with the specifications of the American Society for Testing Materials referred to in section 502 (b); the treatment depending upon the design of the casting.

509. *Workmanship.*—The castings shall conform substantially to the shapes and sizes indicated by the patterns and drawings.

510. *Finish.*—The castings shall be free from injurious defects.

511. *Welding.*—Defects which do not impair the strength or wearing qualities of the castings, except those located on the tread surface within 1½ inches of the gage line, may be welded by an approved process. The defects shall be cleaned out to the solid metal, before welding, and when so required by the inspector, shall be submitted to him in this condition for his approval. When required by the inspector, important castings shall be heat treated after welding.

VI. Gray Iron Castings

601. *Material covered.*—(a) “General” gray iron castings for switches, fillers, braces, and other general appurtenances for track work not requiring high strength.

(b) “High test” gray iron castings for parts of track work requiring high strength to sustain weight

and shock of car-wheel traffic and not requiring to be readily machinable including those generally known as “semisteel” castings.

602. *Manufacture.*—The castings may be made by the cupola or any other approved process.

603. *Chemical composition.*—(a) For “general” gray-iron castings the sulphur content of the metal shall not be over 0.10 per cent.

(b) Sulphur determination when required shall be made in accordance with the standard method of sampling and chemical analysis of pig and cast iron of the American Society for Testing Materials, A64-27. (See 601.20, p. 119.)

(c) For “high test” gray-iron casting no specific chemical composition shall be required.

604. *Physical properties and tests.*—(a) For “general” gray-iron castings no test for physical properties shall be required.

(b) “High test” gray-iron castings shall be subject to the following test when required:

(c) Transverse test specimens poured from the same heat as the castings corresponding to the standard arbitration tests bars of the American Society for Testing Materials when placed horizontally upon supports 12 inches apart and tested under a centrally applied load shall withstand a minimum load of 3,800 pounds and deflect under this load at least 0.12 inches at the center.

(d) The rate of the application of the load shall be such that the central deflection of 0.10 inch is produced in from 20 to 40 seconds.

(e) One test bar of each set of castings shall conform to the above requirements, otherwise the castings represented by such bars may be rejected.

605. *Workmanship and finish.*—The castings shall be true to pattern and free from gas holes, cracks, flaws, and excessive shrinkage and in all other respects they shall conform to whatever points may be specially agreed upon between the manufacturer and the purchaser.

VII. Malleable-Iron Castings

701. *Material covered.*—Malleable-iron castings for fittings and appurtenances for track work, braces, washers, switch clips, spring housings, and foot guards.

702. *Manufacture.*—(a) The castings shall be produced by either air furnace, open hearth, or electric furnace process.

(b) The castings shall be thoroughly annealed. Castings rejected for insufficient annealing may be reannealed once.

(c) When so specified by the purchaser the castings shall be manufactured in accordance with the standards specifications of the A. S. T. M. for malleable castings, A47-30. (See 611.21, p. 665.)

703. *Physical properties and tests.*—(a) If the purchaser or his representative so desires, a casting may be tested to destruction. Such casting shall show good, tough malleable iron. No other test shall be required unless otherwise specified.

(b) When so specified by purchaser the castings shall be subject to the test prescribed by the specification of the A. S. T. M. referred to in section 702

(c) and shall conform to the following minimum requirements as to the tensile properties:

(c) Tensile strength.....	lbs./in. ² ..	50,000
Elongation in 2 inches.....	per cent..	10.0
Yield point.....	lbs./in. ² ..	30,000

704. *Workmanship and finish.*—(a) The castings shall conform substantially to the patterns or drawings.

(b) The castings shall be made in a workmanlike manner and shall be free from injurious defects.

ROLLED OR FORGED MATERIALS

VIII. Steel Forgings

801. *Material covered.*—(a) Forgings of mild-carbon steel for knee braces, fillers and other heavy parts of trackwork not exposed to wheel wear.

(b) Forgings of hard steel for riser blocks, switch tongues, and other parts of track work exposed to wheel wear.

802. *Manufacture.*—(a) The forgings shall be made from billets or slabs manufactured in accordance with the standard specification of the American Society for Testing Materials A17-29. (A. S. A. tentative American Standards G9-1924), for carbon-steel blooms, billets, and slabs for forgings. (See 602.2, p. 131.)

(b) Hard-steel forgings if desired may be made from rail steel of the respective qualities specified for carbon steel T rails of standard sections.

803. *Chemical composition.*—The steel shall conform to the following requirements as to chemical composition:

	Mild steel	Hard steel
	<i>Per cent</i>	<i>Per cent</i>
Carbon.....	0.15-0.30	1.0-1.45
Manganese.....	.40-.80	0.60-0.90
Phosphorus.....	.05	.05
Sulphur.....	.05	.05

¹ Minimum.

² Maximum.

804. *Heat treatment.*—(a) For mild-steel forgings heat treatment shall not be required unless otherwise specified.

(b) For hard-steel forgings heat treatment, when required, shall consist of annealing or quenching and tempering as specified.

805. *Physical properties.*—Forgings except when made from rail steel shall conform after final treatment to the following requirements as to tensile properties:

	Mild steel (minimum)	Hard steel (minimum)
Tensile strength.....lbs./in. ² ..	60,000	80,000
Yield point.....do.....	30,000	40,000
Elongation in 2 inches.....per cent..	22	15
Reduction of area.....do.....	35	22

806. *Tests.*—(a) Tension test may be made when so specified.

(b) Test specimens shall be taken from a full-size prolongation of any forging and shall conform in dimensions to A. S. T. M. standard 2-inch test abr.

807. *Hardness.*—(a) Forgings exposed to wheel wear in track work shall be equal in hardness to rail steel of the weight and type of rail with which they are used.

(b) A hardness test may be made when so specified. The details of such test shall be agreed upon between the manufacturer and the purchaser.

808. *Workmanship and finish.*—The forgings shall be free from injurious defects and shall have a workmanlike finish.

IX. Mild Steel

901. *Material covered.*—Rolled-steel bars and shapes for parts of track work, hammered, pressed, or machined from such semifinished materials for fittings and appurtenances, reinforcements, tie-rods, tie-plates, base-plates, etc.

902. *Manufacture.*—(a) When made from bar steel, the same shall be of open-hearth steel conforming, in general, with standard specifications of the American Society for Testing Materials for com-

mercial quality hot-rolled bar steel A107-30 (see 603.23, p. 147), and/or the specifications of the American Railway Association, Mechanical Division, for structural steel shapes, plates, and bars, 1923. (See 605.13, p. 254.)

(b) If made from structural steel, rolled shapes, or plates, they shall be of Bessemer or open-hearth steel conforming, in general, with the standard specifications of the American Society for Testing Materials for structural steel for buildings A9-29 (see 605.12, p. 252), and complying with the following requirements:

903. *Chemical requirements.*—(a) For bar steel the chemical requirements shall be as follows:

	Per cent
Carbon.....	0.15-0.30
Phosphorus, not over.....	.045
Sulphur, not over.....	.055

(b) For structural shapes and plates the chemical requirements shall be as follows:

	Per cent
Carbon.....	Optional.
Phosphorus:	
Bessemer, not over.....	0.10
Open-hearth, not over.....	0.06

904. *Physical requirements.*—(a) The material shall conform to the following requirements as to tensile properties:

Tensile strength.....lbs./in.².. 50,000-65,000

(b) Test specimens shall bend cold through 180° without cracking on the outside of the bent portion for material up to and including 1¼ inches in thickness around a pin, the diameter of which is equal to the thickness of the specimen; and for material over 1¼ inches in thickness around a pin of a diameter equal to twice the thickness of the specimen.

905. *Tests.*—All tests, when required, shall be made in accordance with the respective specifications referred to in sections 902a and 902b.

906. *Workmanship and finish.*—(a) The permissible variations in the size and dimensions of the rolled bars and shapes shall be within the limits of the specifications referred to in sections 2a and 2b.

(b) The finished articles shall be free from injurious defects and accurately machined and otherwise finished for the purposes intended.

X. Rolled Steel Frog Fillers

1001. *Material covered.*—Rolled-steel fillers of various sections to fit T rails of standard sections.

1002. *Manufacture.*—(a) The steel shall be made by either one or both of the following processes: Bessemer or open-hearth.

(b) Bars shall be hot rolled.

1003. *Chemical composition.*—The steel shall conform to A. S. T. M. specification A107-30 (See 603.23, p. 147) for commercial steel bars of classes applicable hereto in the following grades:

	Open-hearth	Bessemer
Carbon.....	<i>Per cent</i> 0.15-0.30	<i>Per cent</i> 0.12-0.25

1004. *Workmanship and finish.*—(a) The bars shall be smooth and straight and within the following permissible variations and dimensions:

The finishing heights of the fillers shall not exceed that called for by the rail section and shall not under-run by more than three sixty-fourths inch.

Width of fillers between rail webs shall not be under, nor more than one-sixteenth inch over the dimensions called for.

Depth of the flangeway groove may be one-sixteenth inch under or one-eighth inch over dimensions called for.

XI. Wrought Iron

1101. *Material covered.*—These specifications cover wrought iron common or refined, as may be specified, for parts of track work such as rods, reinforcing, bars, fillers, and small forgings hammered or pressed.

1102. *Manufacture.*—(a) Common wrought-iron bars shall be manufactured in accordance with the standard specifications of the American Society for Testing Materials for common iron bars, A85-27. (See 603.1, p. 140.)

(b) Refined wrought iron bars shall be manufactured in accordance with the standard specifications of the American Society for Testing Materials A41-18 and/or the American Railway Association, Mechanical Division, for refined wrought iron bars. (See 603.1, p. 139.)

1103. *Physical requirements.*—The bars shall have a minimum tensile strength of 45,000 pounds per square inch.

1104. *Tests.*—(a) Tests for tensile strength and elongation may be made in accordance with the specifications referred to in section 1102b.

(b) No other test shall be required.

1105. *Workmanship and finish.*—(a) The permissible variations in size of the rolled bars shall be within the limits of the specifications referred to in section 1102.

(b) The rolled bars and the finished articles shall be smooth and free from slivers, depressions, seams, crop ends, evidence of being burned and other injurious defects.

SPRINGS

XII. Helical Springs

1201. *Material covered.*—These specifications cover helical springs for spring rail frogs and for actuating devices for switches.

1202. *Manufacture.*—The springs shall be manufactured in accordance with the specifications for helical springs for railways of the American Society for Testing Materials A61-16. (See 611.54, p. 801.)

1203. *Chemical requirements.*—The steel for the bars shall conform to the following chemical requirements:

	Per cent
Carbon.....	0.90-1.10
Manganese, maximum.....	.50
Phosphorus, maximum.....	.05
Sulphur, maximum.....	.05

1204. *Workmanship and finish.*—(a) The springs shall be of uniform pitch with ends tapered to give a reasonably firm square bearing. The point of the bars shall not protrude beyond the outside diameter of the springs.

(b) The free heights of the springs shall not vary more than one-eighth inch from that specified.

(c) The outside diameters of the springs excepting the heights shall not vary more than one-sixteenth inch from those specified.

FASTENINGS

XIII. Splice Bars

1301. *Material covered.*—(a) Rolled steel splice bars of standard design for joints in rails of standard section or girder rail sections and of the following grades:

- Low-carbon-steel splice bars.
- Medium-carbon-steel splice bars.
- High-carbon-steel splice bars.
- Extra-high-carbon-steel splice bars.

(b) Special splice bars, when standard rolled sections of splice bars are not applicable in special track work including compromise splice bars or joint fixtures.

1302. *Manufacture.*—(a) Splice bars of standard section may be manufactured in accordance with any of the standard specifications for the different grades of the A. S. T. M. A3-24, A4-14, A5-14, A6-14; A. E. R. E. A. W17-22, W18-22, W19-22, W20-22, or the A. R. E. A. (see 606.2, p. 331), as may be specified by the purchaser. When not so specified it shall be optional with the special track-work manufacturer to use bars made to either of these specifications as may be available to fit the rail sections called for at the time when the special track work is being manufactured.

(b) Special splice bars used in special track work may be machined from hard steel or may be of cast steel according to design required.

1303. *Chemical and physical properties.*—The special splice bars shall conform to the specifications herein contained or referred to, for hard steel or for steel castings—class B, according to the material that is used.

1304. *Tests.*—(a) Tests, when required, shall be made in accordance with the specifications under which the splice bars are manufactured or in case of the special splice bars according to the test required for the material from which they are made.

(b) No test shall be required for low-carbon-steel splice bars or when no higher grade is specified.

XIV. Bolts and Nuts

1401. *Material covered.*—(a) Low-carbon-steel bolts and nuts for general use in special track work including track bolts for joints as well as bolts with square or hexagon heads or other shapes of head as may be required for the various purposes.

(b) High-tensile-strength bolts and nuts of carbon steel or alloy steel whether track bolts for joints or bolts with square, hexagon, or other shaped head as may be required for the various purposes, when so specified.

(c) Low-carbon-steel bolts shall be furnished unless high-tensile-strength bolts are called for.

1402. *Manufacture.*—The manufacture of the bolts shall conform in general and as far as applicable to A. S. T. M. specification for low-carbon-steel track bolts (A76-27); high-tensile-strength bolts, either quenched-carbon-steel bolts (A50-24), or alloy-steel track bolts (A51-21); or to similar specifications of A. E. R. E. A. or A. R. E. A. (see 606.4, p. 352), at the option of the special track-work manufacturer.

XV. Nut Locks

1501. *Material covered.*—Helical spring washers. Unless otherwise specified helical spring washers shall be furnished where nut locks are called for in special track work. They shall be of two classes: High spring pressure and low spring pressure.

1502. *Manufacture.*—(a) The spring washers shall be of carbon steel or an acceptable alloy steel and shall be from lots that have passed satisfactory tests at the place of manufacture in accordance with the specifications for spring washers of the American Railway Engineering Association, adopted 1926.

(b) High-spring-pressure washers shall be used in connection with high-tensile bolts, low-spring-pressure washers with all other bolts unless otherwise specified.

XVI. Rivets

1601. *Material covered.*—These specifications cover steel rivets for general use in special track work.

1602. *Manufacture.*—The rivets shall conform in general requirements to the specification of the American Society for Testing Materials for rivets in structural steel for buildings A9-29. (See 605.12, p. 252.)

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, RECOMMENDED SPECIFICATION FOR CAST-STEEL CONSTRUCTION HARD CENTER SPECIAL TRACK WORK, W106-27, 1927

CAST-STEEL SPECIAL TRACK WORK

(In respect to materials, chemical properties and tests, physical properties and tests, design (including standard dimensions of switches and mates), workmanship, assembly for inspection, marking and shipping, and inspection, this specification conforms to A. E. R. E. A., W33, given above, except for the following provisions:)

These specifications are intended to cover the manufacture of special track work wherein the tongue switches, mates, frogs, and crossings are made of steel castings with hard centers of special steel inserted at points receiving the principal wear.

FLANGE BEARING

403. The depth of grooves at intersections and on curved side of mate points shall be one-eighth inch less than the depth of the wheel flange except that the minimum depth of flangeway shall be nine-sixteenths inch. Flange bearings and risers shall conform to the requirements of Figure 191 of A. E. R. E. A., W122, minimum dimensions for center plates for single and middle frogs, given below.

CAST-STEEL BODY DIMENSIONS

407. (a) Tongue switches, mates, frogs, and crossings (not steam railroad crossings) shall consist of cast-steel bodies, the extremities conforming to the adjoining rail and have hard steel centers secured to the bodies. The bodies shall be of uniform depth of 6, 7, or 9 inches, and be provided with a base flange not less than 3 inches wide on each side of double web sections and 5 inches wide on single web sections.

(b) The cross sections shall provide minimum thickness of metal as follows:

Thickness under groove, three-fourths inch.

Thickness under center, three-fourths inch.

Thickness of vertical walls or webs, five-eighths inch for double webs.

Thickness of vertical walls or webs, three-fourths inch single webs.

Thickness of base, one-half inch at outer edge, three-fourths inch at web.

HARD CENTERS

408. (a) Hard-center inserts shall be made of manganese steel or other hard steel as approved by the purchaser.

(b) For centers fastened along the center line of the plate, the depth shall be not less than 2 inches, and for centers designed to have fastenings on the edges of the plates the centers shall be not less than 2½ inches thick. In all cases the minimum thickness underneath the grooves shall be three-fourths inch. Minimum dimensions of all center plates shall conform to the requirements of Figure 191, W122, minimum dimensions for center plates for single and middle frogs, given below. The centers shall be fastened to the bodies by an efficient method, and in frogs and crossings shall be renewable. Hard-center inserts shall have either a partial or full machine bearing when specified. The running surface of hard centers must be finished to a true level with the adjoining body castings.

TONGUE SWITCHES

409. The switches shall be provided with a hard steel center at the point of, and a hard steel bed under the entire length of, the tongue.

(Otherwise tongue switches are identical with paragraph 409 in A. E. R. E. A., W32, given above, except that tongue is of hard steel instead of manganese steel.)

MATES

410. Mates shall have a hard steel wearing plate which shall include the guard as well as the running surfaces and be of sufficient length to provide at least a 2-inch tread at both ends. The hard steel wearing plate in mates need not be renewable.

(In respect to frogs and crossings, length of arms and castings, joints, compromise joints (including reference to paragraphs (b) and (c), section 415, in A. E. R. E. A., W33), paving face, finish of castings (including reference to A. R. E. A. track-work plans), finishing of ends (except that in W106 an allowable variation of three-fourths inch from theoretical lengths is provided for), and curving of rails, this specification conforms to A. E. R. E. A., W32, given above.)

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, RECOMMENDED SPECIFICATION FOR IRON-BOUND HARD-CENTER SPECIAL TRACK WORK, W107-29, 1929

IRON-BOUND HARD-CENTER SPECIAL TRACK WORK

(In respect to materials, chemical properties and tests, physical properties and tests, design (including standard dimensions of switches and mates), workmanship, assembly for inspection, marking and shipping, and inspection, this specification conforms to A. E. R. E. A., W33, given above, except for the following provisions:)

These specifications are intended to cover the manufacture of special track work wherein the tongue switches, mates, frogs, and crossings are made principally of rolled rail arms bound together by cast-iron bodies having recesses to receive the hard steel centers which form the running portions between the rolled rail arms, and at points receiving the principal wear.

CONSTRUCTION OF BODY CASTINGS; MINIMUM DIMENSIONS

407. (a) Tongue switches, mates, frogs, and crossings shall consist of rolled rail arms bound together by a cast body with a recess to receive a hard steel center which shall form the running portions of the structure between the rolled rail arms. The body portion shall be of a cross section giving not less than 1¼ inches thickness of metal underneath the hard steel center, not less than 1½ inches thickness of walls, and not less than 6 inches total width of bearing surface on the ties. It shall be provided with a spiking ledge on the outside. The minimum depth of the body portion shall be 7 inches.

(b) The rail arms must be secured in the body casting by proper means and an adequate amount of the cast metal along the webs of the rail to assure their being held absolutely tight and to give proper strength to both the rail arms and the body casting.

FROGS AND CROSSINGS; LENGTH OF ARMS

411. (a) Frog and crossing arms shall be long enough to give 6¼ inches clearance between webs at end of joint plates. When adjoining pieces, or a combination of pieces, prevent a length of arm for proper joining, pieces made of cast steel with hard steel center, or solid manganese steel, may be substituted at the manufacturer's option. The length and angles of frogs for crossovers and turnouts shall be as provided in W15-22, dimensions of frogs for crossovers and turnouts, given above.

(b) Crossings shall be in 1 and 2 pieces, or, in small angles, in 4 pieces, at manufacturer's option. Outside crossing arms shall be not less than 3 feet in length unless joined to other pieces necessitating shorter lengths.

(c) The hard steel center plate shall be of sufficient length in all cases to provide a full tread at the junction with the rolled rails, and no center shall be less than 12 inches long, measured on the gage line.

(In respect to flange bearing, tongue switches (including reference to A. E. R. E. A., W32), hard centers, and mates, this specification conforms to A. E. R. E. A., W106, given above.)

(In respect to joints, compromise joints (including reference to paragraphs (b) and (c), section 415, in A. E. R. E. A., W32), paving face, finish of castings (including reference to A. R. E. A. track-work plans), sawing of rails, and curving of rails, this specification conforms to A. E. R. E. A., W32, given above.)

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR FROG FILLER SECTIONS, 1926

FROG FILLER SECTIONS

I. MANUFACTURE

Process

1. The steel shall be made by either or both the following processes: Bessemer or open-hearth.
2. Bars shall be hot rolled.

II. CHEMICAL PROPERTIES

3. Steel shall conform to A. S. T. M. specifications for commercial bar steel, in so far as they apply to this product, A. S. T. M. A107 and A108 (see 603.23, p. 147) of the following grades:

	Open-hearth	Bessemer
Carbon -----	Per cent 0.15-0.30	Per cent 0.12-0.25

III. PERMISSIBLE VARIATIONS IN DIMENSIONS

4. The fishing height of filler shall not exceed that shown in drawings by more than one sixty-fourth inch, and shall not underrun by more than one thirty-second inch.

Width of filler between rail webs shall be nothing under to one-sixteenth inch over dimensions shown.

Depth of flange-way groove may be one-sixteenth inch under or one-eighth over dimensions given on drawing.

IV. GROUPING

In order to reduce the large number of sections now rolled, fillers recommended as standard have been grouped as shown on plan 325 in A. R. E. A. track-work plans.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, RECOMMENDED DESIGN, MINIMUM DIMENSIONS FOR CENTER PLATES FOR SINGLE AND MIDDLE FROGS, W122-27, 1927

CENTER PLATES FOR SINGLE AND MIDDLE FROGS

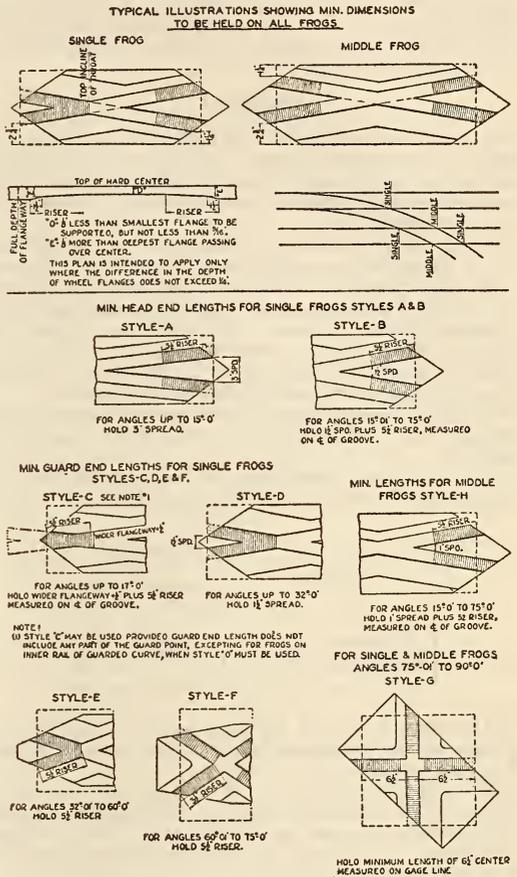

FIGURE 191.—Minimum dimensions for center plates for single and middle frogs

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR SWITCHES, FROGS, CROSSINGS, AND GUARD RAILS, A. R. E. A. TRACK-WORK PLANS, 1929

TRACK WORK

GENERAL INSTRUCTION

1. The purchaser will furnish the manufacturer specifications and drawings, giving rail sections, splice drilling, angles, alinement, and general dimensions, and such special details as may be required.

2. Unless otherwise specified the construction, design, and details shall conform to the plans adopted by the American Railway Engineering Association as recommended practice. For track structures for which no such plans have been adopted, the manufacturer shall, when requested, submit for approval detail drawings.

3. The drawings shall be part of the specifications. Anything that is not shown on the drawings, but which is mentioned in the specifications, or vice versa, or anything not expressly set forth in either, but which is reasonably implied, shall be furnished the same as if specifically shown and mentioned in both. Should anything be omitted from the drawings or specifications that is necessary for a clear understanding of the work, or should any error appear in either the drawings or specifications affecting the work, the manufacturer shall notify the purchaser and shall not proceed with the work until instructed to do so.

MATERIAL

4. *Rail*.—The rail used shall be first quality open-hearth steel of the section called for, manufactured according to A. R. E. A. specifications or to rail manufacturer's standard specifications, unless otherwise specified.

5. *Gray iron castings*.—Gray iron castings shall be of a good commercial grade of medium gray iron.

6. *Steel castings*.—Steel castings shall be of good commercial grade manufactured in accordance with standard specifications of the American Society for Testing Materials for steel castings, class B, except that steel castings exposed to wheel wear shall have a hardness approximately that of rail steel.

7. *Manganese steel track castings*.—The cast manganese steel shall conform to the following specifications.

(a) *Chemical composition*.—The chemical composition shall be within the following limits:

Elements	Percentages	
	Not less than—	Not more than—
Manganese.....	10.00	14.00
Carbon.....	1.00	1.40
Phosphorus.....		.10

Drillings from the finished articles shall be furnished to the inspector from time to time on request for check analysis.

(b) *Physical qualities*.—A rough cast specimen $\frac{3}{4}$ by $\frac{1}{2}$ inch shall bend cold on the flat side around a diameter of 1 inch to an angle of 180° without breaking. The bending may be accomplished by pressure or by blows.

Bending test demonstrations from test bars poured from the same heat as the castings, when required, shall be made in the presence of the inspector at the foundry where the castings are made.

(c) *General conditions*.—Castings shall be reasonably smooth and true to pattern in accordance with good foundry practice. Large lumps, sharp fins, sand, and chills on the outside of castings shall be removed. The castings shall be free from such blowholes, sand holes, cracks, cold shuts, and other defects which would impair their serviceability and as further specified below. Castings must be out of twist and reasonably true, both as to general service and alignment, and must not show any signs of straining or undue denting produced in the straightening process.

The bottom part of castings which rest on ties shall be reasonably straight and out of twist, and shall be free from lumps or such imperfections as would prevent a good bearing.

(d) *Imperfections*.—Tread surfaces within 2½ inches of gage line and side of groove 1 inch down from tread shall be free from physical defects such as shrinkage cracks, sand holes, blowholes, cold shuts, or segregation of metal, unless such defects

are so small that they have been practically removed by the finish grinding, and there must be no indication of unsoundness of the metal. Shrinkage cracks, cold shuts, or segregation of metal will not be allowed in any part of the tread surfaces. Sand holes, blowholes, and cold shuts in portions of the casting where they will not appreciably weaken the casting, or impair its wearing qualities, will be permitted. Castings must be free from shrinkage cracks running vertically in web members of solid work, or horizontally at or near the ends, or in corners of junction of projecting members, or longitudinally in grooves. Other small shrinkage cracks which do not materially weaken the casting will be acceptable.

8. *Malleable iron castings*.—Malleable iron castings shall be of a good commercial grade, properly annealed.

9. *Rolled or forged steel*.—Rolled or forged steel parts shall be of a medium grade of commercial mild steel. Parts exposed to wheel wear shall be equal in hardness to rail steel.

10. *Fillers*.—Fillers shall be of rolled or forged steel, wrought iron or of good quality gray cast iron as called for on plans and as specified.

11. *Heel risers*.—Heel risers shall be as called for on plans and provide wearing surface equal in hardness to rail steel.

12. *Foot guards*.—Metal foot guards as shown on plans shall be of rolled steel or malleable iron. Wooden foot guards shall be good quality hard wood. Filler blocks when acting as foot guards may be of gray iron.

13. *Bolts*.—Bolts, other than where heat-treated bolts are called for on plans or specified, shall be of mild carbon steel and shall have a tensile strength of not less than 50,000 pounds per square inch and an elongation of not less than 15 per cent in 8 inches.

Heat treated or high tensile bolts shall be of carbon or alloy steel and conform to the following minimum requirements.

Tensile strength.....	lbs./in. ²	100,000
Yield point.....	do.....	70,000
Elongation in 2 inches.....	per cent.....	15
Reduction in area.....	do.....	40

Full-size bolts shall bend cold without cracking through 180° around a pin of the same diameter as the bolt. The yield point, elongation, and reduction of area may be determined from a finished bolt or from a test piece $\frac{1}{2}$ by 2 inches turned from a finished bolt. Nuts may be Bessemer or open-hearth carbon steel not heat treated and shall be of sufficient thickness to develop the full strength of the bolt. Bolts with countersunk heads, button heads, or coneheads shall be provided with locking necks or other effective locking means to keep bolts from turning.

14. *Rivets*.—Rivets shall be made of steel manufactured in accordance with the standard specifications of the American Society for Testing Materials for rivet steel for ship or structural work.

15. *Reinforcing bars*.—Reinforcing bars shall be of wrought iron or mild open-hearth steel.

16. *Plates*.—Switch plates, special frog tie-plates, and bearing plates shall be of mild open-hearth steel.

17. *Switch clips*.—Switch clips shall be of mild open-hearth steel, except special designs which may be of cast steel or malleable iron.

18. *Switch rods*.—Switch rods shall be of mild rolled steel or wrought iron.

19. *Stops and hold-downs*.—Stops and hold-downs shall be of mild rolled steel or wrought iron.

20. *Anticreeping device*.—Anticreeping devices shall be of mild rolled steel or wrought iron.

21. *Braces*.—Braces shall be of mild rolled steel, malleable iron, or cast steel.

22. *Washers.*—Washers shall be of mild rolled steel, malleable iron, or cast steel.

23. *Spring washers.*—For heat-treated or high-tensile bolts, spring washers shown on track-work plans shall conform to specifications of the American Railway Engineering Association for high spring pressure, and where nut locks (N. L.) are specified on present track-work plans the term "spring washers" shall be understood.

24. *Switch heel blocks.*—Switch heel blocks shall be of gray iron, cast or forged steel, as specified.

25. *Springs.*—The steel in springs shall conform to the standard specifications of the American Society for Testing Materials for carbon steel bars for railway springs. Springs when forced down solid and held in the compressed position for 30 seconds, upon release, must not vary from their original free length.

26. *Spring housings.*—Spring housings shall be of gray cast iron, malleable iron, or cast steel.

27. *Forged crossing knees.*—Forged crossing knees shall be of mild rolled open-hearth steel or wrought iron.

28. *Special splice bars.*—Special splice bars shall be made of mild rolled steel or cast steel.

WORKMANSHIP

29. *Workmanship.*—Workmanship shall be first class and in accordance with best current practice. The assembly of the several parts shall be such that uniformity of detail and finish will result.

30. *Alignment and surface.*—The alignment and surface of all finished work shall be even and true and conform to the angles specified.

31. *Length.*—Length of frogs and crossing arms shall not vary more than one-fourth inch from lengths specified. Switch-point rails and guard rails shall not vary more than one-half inch from length specified. Rail ends shall be cut square to the axis of the rail unless otherwise required.

32. *Gages and flange ways.*—Track gage may be one-eighth inch under or one-sixteenth inch over that specified for manganese construction, and one-sixteenth inch under or over for bolted construction.

Guard gage (distance between guards) shall not exceed that specified, but may be one-eighth inch less. The width of flange ways may not be less than specified nor more than one-sixteenth inch wider than specified. All the above measured on the level of gage line five-eighth inch below tread surface.

Flange ways shall be not less than $1\frac{1}{8}$ inches deep measured from top of thread surfaces, unless otherwise specified.

33. *Bending.*—Bends shall be made accurately in arcs of circles and without injury to the material. It is desired that rails be bent cold. If heating of the rails is resorted to it must be done in a manner so as not to injure the metal.

34. *Planing.*—All planing must be true and all abutting surfaces must fit accurately.

35. *Grinding.*—Running surfaces of the manganese steel parts shall be ground to practically as good a surface as that of the rolled rail. Manganese steel portions fitting into rails or other parts shall be ground to a good fit.

36. *Drilling and punching.*—All holes in carbon steel rails must be drilled. In other parts all holes for turned pins or bolts and for tight fit of rough bolts must be drilled. Drilling to be done accurately, on bevel where necessary. Punching will be permitted only in wrought iron or mild steel parts for rivets, loose rough bolts, and spikes, except when such holes come so close together or close to the edge of the piece that the metal between holes or between hole and edge is less in width than the thickness of the material, in which case holes must be drilled.

37. *Fit of bolts.*—Main bolts (also referred to on plans as "through" or "body" bolts) in bolted rigid frogs and bolted rail crossings shall have a tight fit in straight, true holes. Heads and nuts shall have a square bearing. Other bolts not requiring a tight fit, unless otherwise specified, shall have a clearance of not more than one-sixteenth inch in drilled or punched holes and not more than one-eighth inch in cored holes. Holes in solid manganese steel frogs and crossings to be one-fourth inch larger than bolt diameter as specified on plans. Threads must be United States standard, accurately cut within tolerance of best practice for cut threads. Nuts must have a tight fit.

38. *Rivets.*—Rivets shall be of full diameter called for on plans, and rivet holes shall not be more than one-sixteenth inch greater in diameter. When not otherwise called for by plans or specifications, rivets shall have standard button or cone heads of uniform size for the same size rivet. The heads shall be concentric with the holes. Countersunk rivets shall be flush with the surface and fill the countersink, except that rivets through base plates and tie-plates may have a crown of not more than one-eighth inch below the lower surface of the plate.

39. *Fit of fillers, braces, and reinforcing bars.*—Fillers, except as otherwise called for or permitted by plans and specifications, shall fit closely into the fishing space of the rail and into the fillets of the web for not less than one-half inch below the head and above the base flange. When the raised brand of the rail interferes with fit of filler the brand shall be removed. Fillers shall be grooved or cut to clear rivet heads and boltheads.

Switch braces shall fit the fishing space of the rail when the brace is tight against the shoulder of the switch plate.

Reinforcing bars shall fill the height of the fishing space of the rail.

40. *Plates and bars.*—All plates must be flat and true to surface. Bars must be straight and of the full size called for.

41. *Painting.*—No paint, tar, or other covering shall be used unless specified, and, in any case, shall not be applied before final inspection.

42. *Welding.*—No welding shall be permitted on rails or on surfaces of other parts exposed to wheel wear. Welding in other portions may be permitted if in the judgment of the inspector the strength of the piece is not impaired.

43. *Marking.*—The finished articles shall be plainly stamped with $\frac{3}{4}$ -inch figures and letters for identification. The manufacturer's name or initials, section and weight of rail, and month and year of manufacture must be stamped on a rail portion of the structure not exposed to wheel wear and where marking can be plainly seen, or may be stamped on a separate rust-proof plate, riveted to the web of the rail, in which case smaller letters may be used. Frogs must be marked with the frog number. All loose parts or fixtures shall be similarly stamped with suitable size letters and figures, the stamping also to show the numbers of the parts appearing on the plan and detail number, where established. On cast parts all or part of the lettering may be cast on the piece. All heat-treated bolts shall be marked on the head with letter or symbol indicating the manufacturer.

INSPECTION

44. Material and workmanship shall be at all times subject to inspection by a duly authorized representative of the purchaser. The inspector shall have all reasonable facilities afforded to him by the manufacturer to examine the work during its progress, as well as the finished product, to satisfy himself that the work is manufactured and finished in accordance with these specifications.

45. All inspection shall be made at the place of manufacture. Tests of material may be made at the expense of the manufacturer if the amount of any particular kind of material is 50 tons or more. If less than 50 tons, the manufacturer shall certify that it is furnished in accordance with this specification; however, if the purchaser desires that a test be made he shall bear the expense of same, unless the material fails to meet the specifications, in which case the manufacturer shall stand the expense of such test. For the rails used in the work the manufacturer, when requested, shall supply the purchaser with a certificate of inspection from the rail manufacturer.

46. The acceptance of any material by an inspector shall not prevent subsequent rejection if found defective after delivery. No guarantee of specific length of service will be required. A claim for defective material and/or workmanship shall cover only such defects as will impair the life of the work.

No claim for free replacement of defective material and/or workmanship shall be recognized unless made promptly and based on defects appearing within three months from date of installation and in any event within two years from date of shipment.

(As provided for in paragraph 3 above, these specifications are accompanied by drawings which form part of the specifications. There are 190 such drawings, covering switches, rail braces, switch stands, frogs, guard rails, crossings, gages and flange ways, double-slip switches, turnouts and crossovers, movable point crossings, and track construction details. Characteristic of these drawings is drawing No. 279, showing A. R. E. A. No. 12 frogs for heavy rails, angle $4^{\circ} 46' 19''$, rail-bound manganese steel, bolted rigid, spring rail, and solid manganese steel. Part of this drawing is appended as Figure 192.

NOTES TO DRAWING NO. 279

Frogs on this plan designed for heavy rails (combined width of head and base more than $8\frac{1}{2}$ inches but not exceeding $9\frac{1}{16}$ inches); also recommended for other heavy rails $6\frac{1}{2}$ inches high and over.

The uniform tie layout shown is suitable for any type of guard rail, including 6-tie 1-piece designs with spacing 19 to 20 inches, to accommodate which the distances underlined thus ($19\frac{1}{2}$ inches) must be adhered to.

The use of plates on all ties is recommended. When specified the tie-plates shown in dotted lines shall be furnished with frog, in which event railway company shall supply details of splice bars showing spike slotting, if any. Distance X to suit spike slotting.

MANGANESE TRACK SOCIETY, SPECIFICATIONS FOR SWITCHES, FROGS, CROSSINGS, AND GUARD RAILS, TRACK-WORK PLANS, 1929

TRACK WORK

606.4 TRACK BOLTS, NUTS, AND WASHERS.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, STANDARD SPECIFICATION FOR QUENCHED CARBON-STEEL TRACK BOLTS, SERIAL NO. W21-23, 1923

TRACK BOLTS

(Identical in substance with A. S. T. M. A50, given below, including the references in A50 to A. S. T. M. A3, B11, and to standard test specimen in standard specifications for steel under 605.0.)

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, STANDARD SPECIFICATION FOR QUENCHED, ALLOY-STEEL TRACK BOLTS, W22-23, 1923

ALLOY-STEEL TRACK BOLTS

(Identical in substance with A. S. T. M. A51, given below, including the references in A51 to A. S. T. M. A3, A50, B11, and to standard test specimen in standard specifications for steel under 605.0.)

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, STANDARD SPECIFICATION FOR LOW CARBON-STEEL TRACK BOLTS, W36-28, 1928

TRACK BOLTS

(Identical in substance with A. S. T. M. A76, given below, including the references in A76 to A. S. T. M. A3, A50, and to standard test specimen, and inspection and rejection, in standard specifications for steel under 605.0.)

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR QUENCHED CARBON-STEEL AND ALLOY-STEEL TRACK BOLTS, 1924

TRACK BOLTS

(This specification is substantially the same as A. S. T. M. A50, given below, including the references in A50 to paragraphs 3 (b) and 4 in A. S. T. M. A3, and inspection and rejection in A. S. T. M. B11. It differs from A50 in the following additional requirements:)

PHYSICAL REQUIREMENTS

1. (a) The bolts shall conform to the following minimum requirements as to tensile properties:

	Carbon steel	Alloy steel
Ultimate tensile strength.....lbs./in. ² ..	100,000	110,000
Yield point.....do.....	75,000	85,000
Elongation in 2 inches.....per cent..	10	12

(b) The yield point shall be determined by the drop of the beam or by the dividers, the method being optional with the inspector and at a crosshead speed not to exceed one-eighth inch per minute. The tensile strength shall be determined at a speed not to exceed $1\frac{1}{2}$ inches per minute.

(c) The capacity of the nut in developing the full strength of the bolt shall be determined by a strip test. The threads must not strip when the bolt, with nut fully mounted, is tested in tension to its yield point, the load being applied to the head and the outside of the nut.

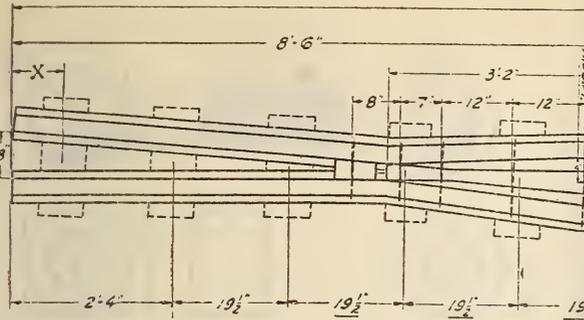

DESIGN AND TOLERANCE

2. (a) The nominal size of rolled thread bolts shall be the over-all diameter of the rolled threads.

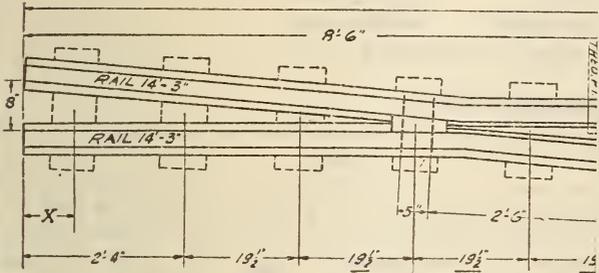

MARKING

3. (a) A letter or brand indicating the manufacturer and the initials "H T" shall be pressed on the head of the bolt when it is formed.

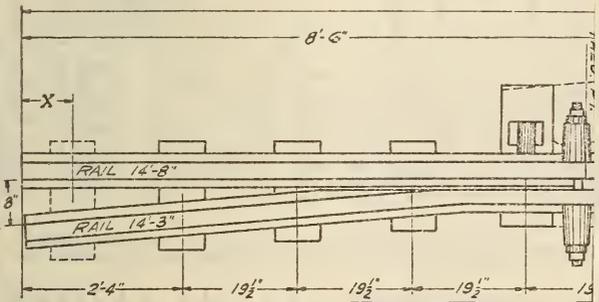

(b) All containers shall be marked by the manufacturer as follows: (1) Name of the manufacturer, (2) material (carbon or alloy steel), (3) size of bolts (diameter and length), and (4) weight.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS, AMERICAN STANDARD TRACK BOLTS AND NUTS, B18d-1930

[Approved as American standard by the American Standards Association, November, 1930]

TRACK BOLTS AND NUTS

INTRODUCTORY NOTES

Sizes.—The designation for standard track bolts is considered as the nominal diameter over the thread. The sizes vary by 1/16-inch steps, but as large quantities of certain 1/16-inch sizes are in general use,

dimensions are included for these 1/16-inch sizes. This last-named group is designated as "special sizes for use during transition period," and are for replacements in present splice bars. On new construction the 1/8-inch sizes should be used so that the standard sizes may come into general use as quickly as possible.

Heads.—Users of track bolts expressed a preference for keeping the size of the head as small as possible, and still they wish to insure that the full strength of the thread could be developed. A type of head commonly referred to as of round or button type, in which a section has the top formed to a single radius, was considered first. Tests showed that a stronger head of the same diameter would result by increasing the thickness of metal at the edges. This has been done in the present standards by use of what has been called a mushroom-type head, in which a section has the top formed by three radii. Tests with this type of head showed that the full strength of the thread could be developed without shearing off the edges of the head.

Necks.—The types of track bolts are designated as "oval neck" and "elliptic neck." The oval-neck type is in most general use, but some large systems

have found advantages in the use of the elliptic neck for their particular conditions, and this type is included to take care of their requirements. The heads for both types are the same.

Body diameters.—The tables of standard track bolts do not have the body diameter designated due to different methods of manufacture used. The type of track bolt in most general use has a thread rolled to a larger diameter than the body. Bodies of these bolts are approximately one-sixteenth inch smaller in diameter than the threaded portion. When cut threads are used the body diameter is approximately equal to the outside diameter of the threaded portion.

Threads.—Two types of threads are referred to, viz, the American National Standard with fit as specified by the customer and the Harvey grip thread. The latter has an included angle of 55°, but the angles which the two faces of the thread

make with a line perpendicular to the axis of the bolt are not equal, one being 10° the other 45°.

Nuts.—Three types of nuts are included in the standards. These are square, hexagonal, and recessed. Two thicknesses are given, common and extra thick. The width across flats agrees with the American standard for rough square and hexagonal nuts. The thickness of the "common" nut is the same as for the American standard rough square and hexagonal nuts, and the "extra thick" and "recessed" nuts are one-fourth inch thicker. The present general practice is to have nuts screwed on the track bolts before shipping.

Material.—The American Society for Testing Materials has three specifications that appear satisfactory. These cover low-carbon steel track bolts, quenched carbon-steel track bolts, and quenched alloy-steel track bolts—all of which are given below.

¹ Bearing area is equal to the area of bolthead minus the area of the oval hole in the splice bar.

² Shear area is equal to the periphery of the oval hole in the splice bar times the mean height of the head above the bearing surface.

Screw threads.—The screw threads on track bolts shall conform to the American national standard form, with fit as specified, or have the Harvey grip thread. They may be formed by cutting, drawing, or rolling.

Tolerances—Length (*L*) plus or minus 1/8 inch.
Neck (*V*, *O*, and *R*) plus or minus 1/32 inch.
Head (*A* and *H*) plus or minus 1/16 inch.

FORMULAS

$$A = 1\frac{1}{8}D + \frac{1}{16}$$

$$H = \frac{3}{8}D$$

$$r_1 = 1\frac{1}{8}D - \frac{1}{4}$$

$$r_2 = H - \frac{1}{32}$$

$$O = \begin{cases} 1\frac{1}{4}D & \text{(for } \frac{1}{16} \text{ to } \frac{3}{8} \text{ inch inclusive)} \\ 1\frac{1}{4}D + \frac{1}{8} & \text{(for } \frac{1}{16} \text{ to } 1\frac{1}{4} \text{ inches inclusive)} \end{cases}$$

$$R = O - \frac{1}{32}$$

$$P = \frac{1}{2}D + \frac{1}{16}$$

¹ The tolerance for the width across flats (W) shall be minus 0.050 D inches.

² The tolerance for the thickness of nuts (U and U₁) shall be plus or minus (0.016 D + 0.012) inches.

³ American standard rough square and hexagonal nuts.

⁴ The recessed type of nut shall have a recess of 1/8 inch minimum and 3/16 inch maximum.

NOTE.—Formulas for the width across flats are the same as given in the American standard wrench head bolts and nuts. For special sizes, the width across flats is the same as for the standard of 1/16 inch greater bolt diameter.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR QUENCHED, CARBON-STEEL TRACK BOLTS, DESIGNATION A50-24, 1924

CARBON-STEEL TRACK BOLTS

MANUFACTURE

1. (a) The steel for the bolts shall be made by the open-hearth process.

(b) The steel for the nuts shall be made by either or both the following processes: Bessemer or open-hearth.

2. The bolts shall enter the quenching medium at a temperature not less than 790° C. The threads may be rolled either hot or cold.

CHEMICAL PROPERTIES AND TESTS

3. The steel for the bolts shall conform to the following requirements as to chemical composition:

	Per cent
Carbon, not under.....	0.30
Phosphorus, not over.....	.04

(Ladle and check analyses are identical with paragraphs 3 (a), 3 (b), and 4 in A. S. T. M. A3. See 606.2, p. 331.)

PHYSICAL PROPERTIES AND TESTS

6. (a) The bolts shall conform to the following minimum requirements as to tensile properties:

Tensile strength.....	lbs./in. ² ..	100,000
Yield point.....	do.....	70,000
Elongation in 2 inches.....	per cent..	12

(b) Nuts shall be capable of developing the strength of the finished bolt up to its yield point.

(c) The yield point shall be determined by the drop of the beam of the testing machine.

7. Full-size bolts shall stand being bent cold through 45° around a pin the diameter of which is equal to the diameter of the bolt, without cracking on the outside of the bent portion.

8. Tension-test specimens shall be taken from the finished bolts and shall conform to the dimensions shown in Figure 129 in A. S. T. M. standard specifications for metals. (See 605.0, p. 247.) The ends shall be of a form to fit the holders of the testing machine in such a way that the load shall be axial.

9. (a) One tension and one bend test shall be made from each lot of 50 kegs or fraction thereof.

(b) If any test specimen shows defective machining or develops flaws, it may be discarded and another specimen substituted.

(c) If the percentage of elongation of any tension-test specimen is less than that specified in section 6 (a) and any part of the fracture is more than three-fourths inch from the center of the gage length, as indicated by scribe scratches marked on the specimen before testing, or if the bend-test specimen breaks in the threaded portion, a retest shall be allowed.

10. If the results of the physical tests of any test lot do not conform to the requirements specified, the manufacturer may re-treat such lot one or more times in which case two additional tension and two additional bend tests shall be made from such lot, all of which shall conform to the requirements specified.

PERMISSIBLE VARIATIONS

11. The bolts and nuts shall conform to the dimensions specified by the purchaser subject to the following variations: A variation of one thirty-second inch under and one sixty-fourth inch over the specified diameter of the shank of the bolt will be permitted. The diameter of rolled thread shall

not exceed the diameter of the shank more than one-sixteenth inch for bolts seven-eighths inch in diameter and under, nor more than three thirty-second inch for bolts 1 inch in diameter and over. The outside diameter of the finished rolled threads shall not exceed the diameter of the shank of a cut-thread bolt of corresponding size. The length of the bolt under the head shall not vary more than one-eighth inch from that specified. A variation in the dimensions of the elliptical shoulders under the head of one thirty-second inch and a taper of the shoulder of one thirty-second inch will be permitted.

WORKMANSHIP AND FINISH

12. The bolts and nuts shall be neatly formed and free from fins or nicking. The head of the bolt shall be concentric with and firmly joined to the shank, with the underside at right angles to the axis of the bolt. The threads shall be sharp and true to gage and of the design specified by the purchaser. The nuts shall have a hand free fit on the bolt from two to six turns, and wrench tight the balance of the screw length without distorting the threads or twisting the shank. They shall be screwed on the bolts before packing, a sufficient number of turns to hold them in place until used.

13. The finished bolts and nuts shall be free from injurious defects and shall have a workmanlike finish.

MARKING

14. A letter or brand indicating the manufacturer shall be pressed on the head of the bolt while it is being formed.

INSPECTION AND REJECTION

(Conform to A. S. T. M. B11. See 641.21, p. 1176.)

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR QUENCHED ALLOY-STEEL TRACK BOLTS, DESIGNATION A51-21, 1921

QUENCHED ALLOY-STEEL TRACK BOLTS

(This specification is identical in form with A. S. T. M. A50, given above, including references in A50 to A. S. T. M. A3, paragraphs 3 (b) and 4; standard test specimen in A. S. T. M. standard specifications for steel under 605.0; and inspection and rejection in B11. It differs from A50 in the following particulars:)

MANUFACTURE

1. (a) The steel for the bolts shall be made by either or both the following processes: Open hearth or electric furnace.

CHEMICAL PROPERTIES

2. The steel for the bolts shall conform to the following requirements as to chemical compositions:

	Per cent
Phosphorus, not over.....	0.035

PHYSICAL PROPERTIES AND TESTS

3. (a) The bolts shall conform to the following minimum requirements as to tensile properties:

Tensile strength.....	lbs./in. ² ..	110,000
Yield point.....	do.....	85,000
Elongation in 2 inches.....	per cent..	12

4. Full-size bolts shall stand being bent cold through 90° around a pin the diameter of which is equal to the diameter of the bolt, without cracking on the outside of the bent portion.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR LOW-CARBON-STEEL TRACK BOLTS, DESIGNATION A76-27, 1927

LOW-CARBON-STEEL TRACK BOLTS

MANUFACTURE

1. (a) The steel shall be made by either or both the following processes: Bessemer or open hearth.
- (b) The threads may be cut or rolled.

CHEMICAL PROPERTIES AND TESTS

2. (a) The steel for the bolts shall conform to the following requirements as to chemical composition:

Phosphorus:	Per cent
Bessemer, not over.....	0.10
Open hearth, not over.....	.05

- (b) The steel for the nuts shall be soft steel.

(Ladle and check analyses are identical with paragraphs 3 (a), 3 (b), and 4 in A. S. T. M., A3. See 606.2, p. 331.)

PHYSICAL PROPERTIES AND TESTS

5. The stock from which the bolts are made shall conform to the following requirements as to tensile properties:

Tensile strength.....lbs./in. ² ..	55,000-70,000
	1,500,000
Elongation in 8 inches, minimum per cent--	$\frac{\text{Tensile strength}}{22}$
Elongation in 2 inches, minimum...do....	22

6. The test specimen shall stand being bent cold through 180° flat on itself without cracking on the outside of the bent portion.

7. Tension and bend test specimens shall be taken from a finished bolt or from the full-size rolled bars. Tension-test specimens shall be of 8-inch gage length when taken from the rolled bars. When taken from a finished bolt the tension-test specimen shall conform to the dimensions shown in Figure 129 in A. S. T. M., standard specifications for metals. (See 605.0, p. 247.)

8. (a) One tension and one bend test shall be made from each melt of steel. When the melts can not be identified, one tension and one bend test shall be made from each lot of 10 tons or fraction thereof.

- (b) If any test specimen develops flaws, it may be discarded and another specimen substituted.

- (c) If the percentage of elongation of any tension-test specimen is less than that specified in section 5 and any part of the fracture is outside the middle third of the gage length, as indicated by scribe scratches marked on the specimen before testing, a retest shall be allowed.

(Retests, permissible variations, workmanship and finish, and marking are the same as in A. S. T. M., A50, given above, with the addition of the following requirement as to marking:)

Bolts shall be packed in serviceable packages. All packages shall be plainly marked as to material, size of bolts, and name of manufacturer.

INSPECTION AND REJECTION

(Conform to A. S. T. M. standard specifications for steel. See 605.0 p. 247.)

606.5 TRACK SPIKES.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, STANDARD SPECIFICATION FOR STEEL SCREW SPIKES, W24-23, 1923

STEEL SCREW SPIKES

STANDARD TRACK SPIKE

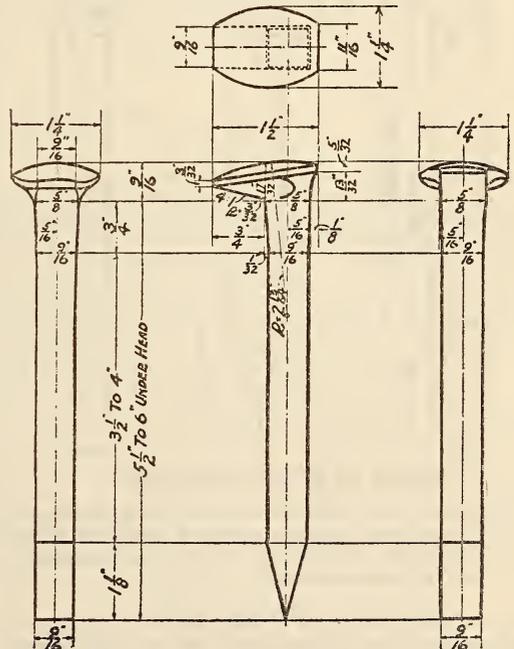

FIGURE 197.—Recommended design for 5½ by ¼ inch track spike

AMERICAN RAILWAY ENGINEERING ASSOCIATION SPECIFICATIONS FOR SOFT-STEEL CUT TRACK SPIKES, 1926

SOFT-STEEL CUT TRACK SPIKES

I. MANUFACTURE

1. The steel may be made by the Bessemer or open-hearth process, or both.

II. CHEMICAL PROPERTIES AND TESTS

2. (a) The steel shall conform to the following requirements as to chemical composition:

	Bessemer	Open-hearth
Carbon, not under.....	Per cent 0.06	Per cent 0.12

(b) A carbon determination shall be made of each melt of Bessemer steel and three determinations

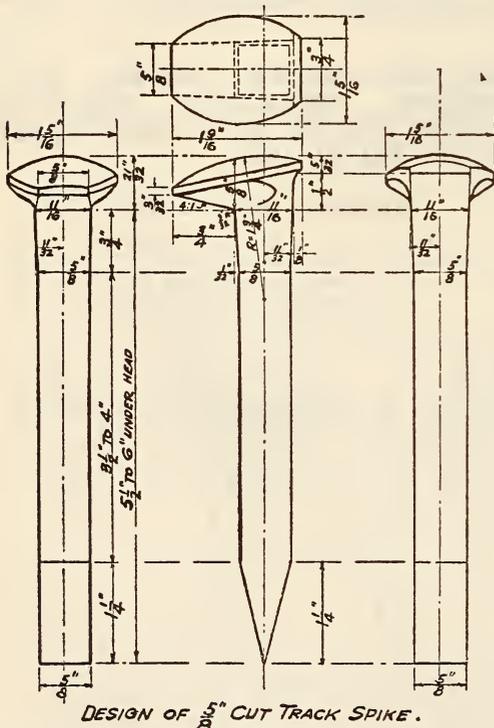

FIGURE 198.—(The dimensions of the A. R. E. A. 5/16 inch cut track spike are identical with those of the A. E. R. E. A. 5/16 inch standard track spike shown above)

shall be made every 24 hours, one for each 8-hour turn, respectively, representing the average carbon content in the steel. These analyses shall be made from drillings taken at least one-eighth inch beneath the surface of a test ingot obtained during the pouring of the melts. The chemical composition thus determined shall be reported to the purchaser or his representative, and shall conform to the requirements specified in section 2.

(c) An analysis of each melt of open-hearth steel shall be made by the manufacturer to determine the percentage of carbon. This analysis shall be made

from drillings taken at least one-eighth inch beneath the surface of a test ingot obtained during the pouring of the melt. The chemical composition thus determined shall be reported to the purchaser or his representative, and shall conform to the requirements in section 2.

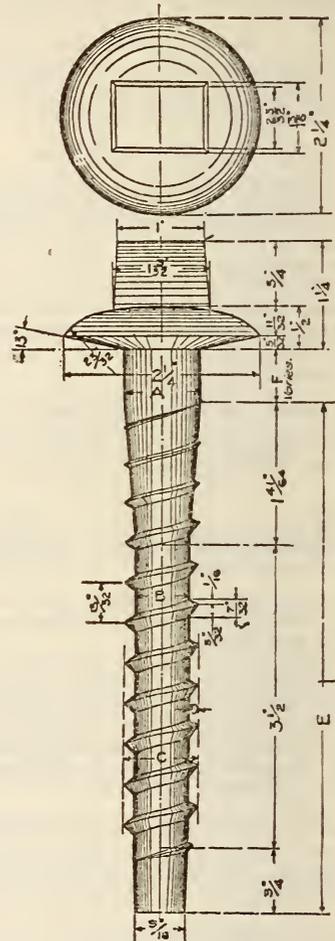

FIGURE 199.—Design of screw spike

	Letter	Maximum	Standard	Minimum
Under head.....	A	29/32	7/8	7/8
Root.....	B	27/32	3/8	3/8
Over thread.....	C	29/32	3/8	3/8
Thread.....	D	3/64	3/8	3/8
Length.....	E	6 3/64	5 57/64	5 49/64
Length under head.....	F	Varies according to thickness of rail base and tie plate.		

III. PHYSICAL PROPERTIES AND TESTS

(Same as A. S. T. M., A65, given below, in respect to bend tests. No tension tests are specified, but one bend test of each kind shall be made from each lot of 5 tons or fraction thereof.)

IV. WORKMANSHIP AND FINISH

5. (a) The spikes shall conform to the dimensions specified by the purchaser, with the following permissible variations:

(b) A variation of one thirty-second inch over and one sixty-fourth inch under the specified cross-section dimensions of the body of the spike will be permitted.

(c) A variation of three thirty-seconds inch over and one thirty-second inch under the specified dimensions of the head of the spike will be permitted.

(d) A variation of one-eighth inch from the specified length of the spike measured from the underside of the head to the point will be permitted.

(e) A variation of 1° in the specified angle of the underside of the head of the spike will be permitted.

6. The finished spikes shall be free from injurious defects and shall have a workmanlike finish.

V. INSPECTION

(Same in substance as A. S. T. M., B11, paragraphs 12 and 13 (b). See 641.21, p. 1176.)

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR STEEL SCREW TRACK SPIKES, 1920

STEEL SCREW TRACK SPIKES

(See fig. 199, p. 358)

(Identical in substance with A. S. T. M., A66, given below, including the references in A66 to A. S. T. M., A65 and B11, except for the following additions:)

SHIPMENT

When spikes are shipped they shall be properly oiled to prevent rusting and shall be packed in good, serviceable packages. All packages shall be plainly marked as to material, size of spike, and name of manufacturer unless otherwise specified.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR STEEL TRACK SPIKES, DESIGNATION A65-24, 1924

STEEL TRACK SPIKES

MANUFACTURE

1. The steel shall be made by either or both the following processes: Bessemer or open hearth.

PHYSICAL PROPERTIES AND TESTS

2. The full-size finished spikes, or the full-size bars from which the spikes are made, shall conform to the following minimum requirements as to tensile properties:

Tensile strength.....	lbs./in. ²	55,000
Yield point.....	do.....	} 0.5 tensile strength
Elongation in 2 inches.....	per cent.....	

3. (a) The body of the full-size finished spike shall stand being bent through 180° flat on itself without cracking on the outside of the bent portion.

(b) The head of the full-size finished spike shall stand being bent backward to the line of the face of the spike without cracking on the outside of the bent portion.

4. (a) One tension and one bend test of each kind shall be made from each lot of 10 tons or fraction thereof.

(b) If any test specimen develops flaws it may be discarded and another specimen substituted.

5. If any tension test specimen breaks more than three-fourths inch from the center of the gage length a retest shall be allowed.

WORKMANSHIP AND FINISH

6. The spikes shall conform to the dimensions specified by the purchaser except that a variation of one thirty-second inch over and one sixty-fourth inch under the specified dimension of the body of the spike, and a variation of one-eighth inch over and one-sixteenth inch under the specified dimension of the head of the spike will be permitted. A variation of one-fourth inch over and nothing under the specified length of the spike, measured from the underside of the head to the point, will be permitted. A variation of 1° in the specified angle of the underside of the head of the spike will be permitted.

7. The finished spikes shall be free from injurious defects and shall have a workmanlike finish.

INSPECTION AND REJECTION

(Conform to A. S. T. M., B11, paragraphs 12 and 13 (b). See 641.21, p. 1176.)

AMERICAN SOCIETY FOR TESTING MATERIALS, TENTATIVE SPECIFICATIONS FOR SOFT-STEEL TRACK SPIKES, DESIGNATION A65-26T, 1926

SOFT-STEEL TRACK SPIKES

I. MANUFACTURE

1. The steel shall be made by either or both of the following processes: Bessemer or open hearth.

II. CHEMICAL PROPERTIES AND TESTS

2. (a) The steel shall conform to the following requirements as to chemical composition:

	Bessemer	Open hearth
Carbon, minimum.....	Per cent 0.06	Per cent 0.12

3. (a) A carbon determination shall be made of each melt of Bessemer steel and three determinations shall be made every 24 hours, one for each 8-hour turn, respectively, representing the average carbon content in the steel. These analyses shall be made from drillings taken at least one-eighth inch beneath the surface of a test ingot obtained during the pouring of the melts. The chemical composition thus determined shall be reported to the purchaser or his representative, and shall conform to the requirements specified in section 2.

(b) An analysis of each melt of open-hearth steel shall be made by the manufacturer to determine the percentage of carbon. This analysis shall be made from drillings taken at least one-eighth inch beneath the surface of a test ingot obtained during the pouring of the melt. The chemical composition thus determined shall be reported to the purchaser or his representative, and shall conform to the requirements specified in section 2.

III. PHYSICAL PROPERTIES AND TESTS

4. (a) The body of the full-size finished spike shall stand being bent cold through 180° flat on itself, without cracking on the outside of the bent portion.

(b) The head of the full-size finished spike shall stand being bent backward to the line of the face of the spike, without cracking on the outside of the bent portion.

5. One bend test of each kind shall be made from each lot of 5 tons or fraction thereof.

IV. WORKMANSHIP AND FINISH

6. The spikes shall conform to the dimensions specified by the purchaser with the following permissible variations:

(a) A variation of one thirty-second inch over and one sixty-fourth inch under the specified cross-section dimensions of the body of the spike will be permitted.

(b) A variation of three thirty-seconds inch over and one thirty-second inch under the specified dimensions of the head of the spike will be permitted.

(c) A variation of one-eighth inch from the specified length of the spike measured from the underside of the head to the point will be permitted.

(d) A variation of 1 degree in the specified angle of the underside of the head of the spike will be permitted.

7. The finished spikes shall be free from injurious defects and shall have a workmanlike finish.

(Requirements covering inspection and rejection conform to paragraphs 7 and 8 of A. S. T. M. standard specifications for steel. See 605.0, p. 247.)

AMERICAN SOCIETY FOR TESTING MATERIALS, SPECIFICATION FOR STEEL SCREW SPIKES, DESIGNATION A66-21, 1921

STEEL SCREW SPIKES

(In respect to process, number of tests, retests, and finish, this specification is the same as A65-24 given above, except that under retests if the percentage of elongation of any tension test spike is less than that specified in section 3, given below, a retest shall be allowed. As in A65, inspection and rejection conform to A. S. T. M., B11, paragraphs 12 and 13 (b). Otherwise this specification provides that—

MANUFACTURE

2. The heads of the spikes shall be formed and the threads rolled at a temperature not less than 750° C.

PHYSICAL PROPERTIES AND TESTS

3. The full-size finished spikes shall conform to the following minimum requirements as to tensile properties:

Tensile strength.....	lbs./in. ²	60,000
Yield point.....	do.....	{ 0.5 tensile strength
Elongation in 2 inches.....	per cent.....	20

4. The full-size finished spikes shall bend cold through 90° around a pin the diameter of which is equal to three times the diameter of the spike, without cracking on the outside of the bent portion. One tension and one bend test shall be made from each lot of 100 kegs or fraction thereof.

WORKMANSHIP AND FINISH

7. The spikes shall conform to the dimensions specified by the purchaser. The head shall be concentric with, and firmly joined to, the body of the spike. The threads shall be sharp and true to gage and of the design specified by the purchaser. A variation of one thirty-second inch over the specified diameter of the unthreaded portion of the body of the spike will be permitted. A variation of one thirty-second inch over the specified diameter of the threaded portion of the spike will be permitted. A variation of one-sixteenth inch under and one-eighth inch over in the reach of the head of the spike will be permitted. A variation of one-eighth inch from the specified length of the spike will be permitted.

8. The finished spikes shall be free from injurious defects and shall have a workmanlike finish.

MARKING

9. A letter or brand indicating the manufacturer shall be pressed on the head of the spike while it is being formed.

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR NAILS, SPIKES, TACKS, AND STAPLES, FF-N-101, MAY 3, 1932

TRACK SPIKES

(See 608.11, p. 560.)

606.6 TRACK TIE RODS.

AMERICAN ELECTRIC RAILWAY ENGINEERING ASSOCIATION, STANDARD SPECIFICATION FOR DESIGN AND MANUFACTURE OF TIE-RODS, W42-31, 1931

TIE-RODS

This specification is intended to cover the design and manufacture of low-carbon-steel tie-rods of the round or flat types, for use in street-railway track.

I. MANUFACTURE

101. *Process*—The steel shall be made by either or both the Bessemer or open hearth process.

II. CHEMICAL PROPERTIES

201. Tie-rods shall be manufactured from commercial-quality hot-rolled bar steels conforming to A. S. T. M. specification A107-30, screw steel grades, for both open hearth and Bessemer steels, the chemical properties requirements of which are as follows:

	Carbon	Manganese	Phosphorus	Sulphur
Bessemer-screw.....	Per cent 0.08-0.16	Per cent 0.60-0.90	Per cent 0.09-0.13	Per cent 0.10-0.15
Open-hearth screw..	.15-.25	.60-.90	(Max.) .06	.075-.150

III. WORKMANSHIP AND FINISH

401. *Workmanship*.—(a) Flat-type tie rods, if manufactured from flat bars, shall be three-eighths inch by 2 inches, with the permissible variations allowed in A. S. T. M., A107 (these permissible variations will be found under Association of American Steel Manufacturers, hot-rolled bars, in 600.7, p. 116). If rolled from round stock, the thickness shall be not less than that permitted by the above specification.

(b) Tie rods of the round type and the round portion of the rods of flat type shall have an area in the unthreaded portion of not less than the area at the root of the threads.

(c) The terminals of the rods shall be fully threaded with a seven-eighths U. S. standard thread, 3 inches on one end and 6 inches on the other. The threads on the terminals shall be U. S. standard cut threads, so threaded that the inner nuts may be turned down the full length of threading specified. The full section threading of the terminal shall extend to within one-eighth inch from the end of the rod.

(d) Unless otherwise specified, each terminal shall be fitted with two hot-pressed U. S. standard square nuts, four nuts per tie rod. Nuts shall be free from burrs and fins. Inner nuts shall turn by hand;

outer nuts shall have wrench-tight fit. The steel for the nuts shall be soft steel.

402. *Lengths.*—The dimensions shall be as follows, and in accordance with Figure 200.

(a) Tie rods for use with girder rails for 4 feet 8½-inch gage shall be 61 inches long over all.

(b) Tie rods for use with plain girder and standard section rails for 4 feet 8½-inch gage shall be 63 inches long over all.

(c) Tie rods for all gages other than 4 feet 8½ inches shall have increased or decreased lengths to correspond with the increase or decrease in the track gage as specified by the purchaser.

403. *Permissible variations.*—(a) The length of the tie rod shall be not more than one-eighth inch

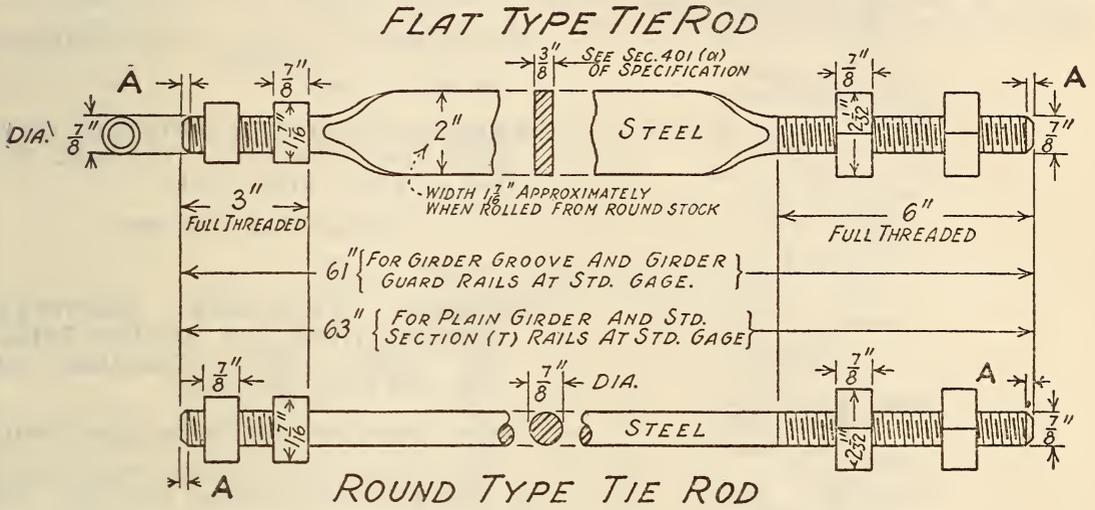

607.0 GENERAL ITEMS.

AMERICAN GAS ASSOCIATION, AMERICAN STANDARD GAS SAFETY CODE FOR INSTALLATIONS AND WORK IN BUILDINGS, K2-1927

[Approved as American Standard by the American Standard Association, 1927]

GAS SAFETY CODE

(Joint sponsor with the Bureau of Standards for safeguarding the lives, health, and property of the users of manufactured gas. This code contains

NOTES: DIMENSION A NOT MORE THAN 1/8 IN.
U.S. STD. SQ. NUTS REQUIRED UNLESS OTHERWISE SPECIFIED.
U.S. STD. 3/8 IN. CUT THREADS REQUIRED.

FIGURE 200.—Dimensions of tie rods

shorter nor more than one-fourth inch longer than that shown on the drawing.

(b) The diameter of the threaded portion or terminal shall not vary more than one sixty-fourth inch from the diameter shown on the drawing.

(c) The lengths of the threaded portions or terminal of the rod shall not vary more than one-eighth inch from those shown on the drawing.

(d) The outside dimensions of the nuts shall not vary more than one thirty-second inch from those shown on the drawing.

V. MARKING AND SHIPPING

501. *Marking and shipping.*—When the rods are shipped, they shall have the nuts applied for at least the length of the nut, and shall be properly oiled to prevent rusting. They shall be securely wired together in bundles of five rods each, and each bundle shall be plainly marked as to material, name of manufacturer, length of rods, and name and shipping address of consignee.

VI. INSPECTION

(Conforms to A. S. T. M., B11, paragraph 12. See 641.21, p. 1176.)

607. TUBULAR PRODUCTS AND FITTINGS, COCKS, AND VALVES

mandatory rules which must be followed to attain the greatest measure of safety, supplemented by a series of notes on these rules citing the dangers to be guarded against.)

AMERICAN GAS ASSOCIATION, REQUIREMENTS FOR HOUSE PIPING AND APPLIANCE INSTALLATION, 1928

GAS PIPING

(Basic requirements for house piping and appliance installation to insure safe and satisfactory service. Includes material and size of pipe, maximum gas demand required for household gas-consuming appliances, location of such appliances, recommended practice for flue connections, and diagrams picturing relative positions of gas-operated and auxiliary appliances.)

AMERICAN MARINE STANDARDS COMMITTEE, DISTINCTIVE MARKINGS FOR PIPING, O NO. 10-1926

PIPE MARKINGS

(Scheme for indicating the purpose of conveyor pipes aboard ship by suitable markings. These markings occur at intervals throughout the ship,

and involve not only the pipe itself but also the edges of flanges adjacent to valves and on such other flanges as will identify the function of the pipe. These markings are based on and coincide with the standard marking system of the U. S. Navy.)

**AMERICAN PETROLEUM INSTITUTE,
DIMENSIONAL STANDARDS FOR CABLE-
DRILLING TOOLS, A. P. I. STANDARDS
NO. 3, 1930**

BASIC THREAD FORM

Profile.—The angle between the sides of the thread is 60° measured in the axial plane, and the thread is perpendicular to the axis of the joint.

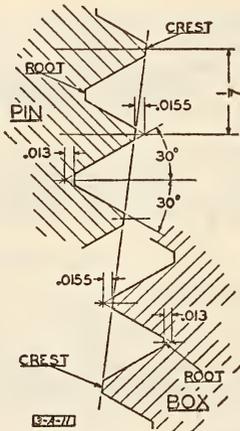

FIGURE 201.—Basic form, 7-thread

The crest on seven threads per inch is truncated parallel to the taper an amount equal to 0.0155 inch, while the root is truncated an amount equal to 0.013 inch parallel to the axis. (See fig. 201.)

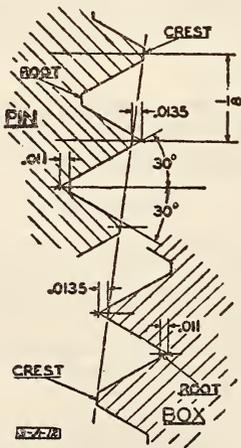

FIGURE 202.—Basic form, 8-thread

The crest on eight threads per inch is truncated parallel to the taper an amount equal to 0.0135 inch, while the root is truncated an amount equal to 0.011 inch, parallel to the axis. (See fig. 202.)

Pitch.—The number of threads per inch is seven on joints 1½ by 2½ inches and larger and the number of threads per inch is eight on joints 1½ by 2¼ inches

and smaller, both conforming to United States standard, measured in a direction parallel to the axis of the thread.

Taper of joint.—The taper of the joint is 3 inches per foot, or 1 in 4 measured on the diameter.

(Recommended practice for turning threads is included in this specification. While not forming part of the specification, these recommendations are generally accepted as productive of satisfactory results. They include setting the taper of the lathe and also setting the threading tool.)

**AMERICAN PETROLEUM INSTITUTE, PIPE
SPECIFICATIONS, STANDARD NO. 5-A
(7TH ED.), JULY, 1931**

**PIPE THREADS FOR OIL COUNTRY TUBULAR
GOODS**

PIPE SPECIFICATIONS, STANDARD NO.
5-L (4TH ED.), JULY, 1931**

THREADS FOR LINE PIPE

(See 607.4, p. 457.)

**AMERICAN PETROLEUM INSTITUTE,
SPECIFICATIONS FOR ROTARY DRILLING
TAPER JOINTS, STANDARD NO.
7-B (4TH ED.), JULY, 1931**

TAPER JOINTS FOR ROTARY DRILLING TOOLS

(This specification includes dimensional standards for taper joints, tool joints and fishtail bits, drill

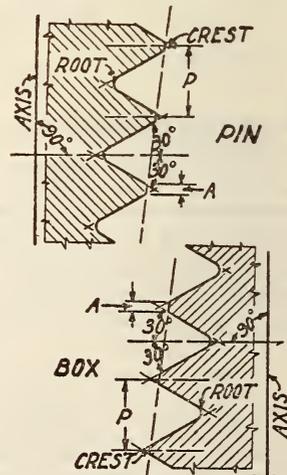

FIGURE 203.—Basic thread form

A=0.040 inch on 5-thread

A=0.050 inch on 4-thread

Truncation is parallel to taper, measured parallel to axis

collars, grief stems and couplings, and swivel gooseneck connections. Below are given the basic thread form and the dimensional standards of the standard rotary taper joint.)

TAPER JOINTS

9. (a) The sizes of taper joints shown in Table 1 and Figures 203 and 204 are standard.

(b) *Basic thread form, profile.*—The angle between the sides of the thread is 60°, measured in the axial plane, and the line bisecting this angle is perpendicular to the axis of the joint. The crest is truncated parallel to the taper to produce a flat of 0.050 inch (see "A," fig. 203) on 4-thread and similarly truncated to produce a flat of 0.040 inch on 5-thread (see "A," fig. 203), while the root is rounded a sufficient amount to clear the mating threads on both four and five threads. Both flats are measured parallel to the axis.

(c) *Pitch.*—The number of threads per inch on all sizes up to and including the 3¹/₁₆ by 4⁵/₁₆ inches is five, and on all sizes over 3¹/₁₆ by 4⁵/₁₆ inches is four, as specified, measured in a direction parallel to the axis of the thread.

(d) *Taper of joints.*—The taper of all joints is 3 inches per foot, or 1 in 4, measured on the diameter except the 5 by 6-4, which is 2 inches per foot, or 1 in 6, measured on the diameter.

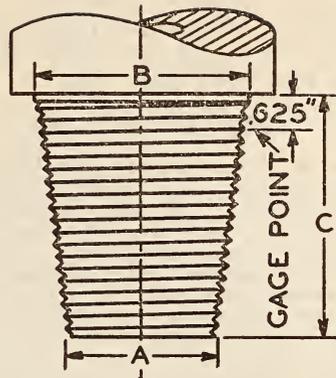

FIGURE 204

TABLE 1.—A. P. I. standard rotary taper joints

[See figs. 203 and 204]

[Taper joints shall be identified by the drill-pipe size. All dimensions in inches at 68° F.]

Size of drill pipe	Nominal size of taper joint	Small diameter of pin "A"	Large diameter of pin "B"	Length of pin "C"	Number of threads per inch	Taper of joint inches per foot	Form of thread
2 ³ / ₈	1 ⁷ / ₈ by 2 ⁵ / ₈ —5	1.875	2 ⁵ / ₈	3	5	3	V-.040 flat.
2 ⁷ / ₈	2 ¹ / ₈ by 3—5	2.125	3	3 ¹ / ₂	5	3	V-.040 flat.
3 ¹ / ₂	2 ⁹ / ₁₆ by 3 ¹ / ₂ —5	2.562	3 ¹ / ₂	3 ³ / ₄	5	3	V-.040 flat.
4 ¹ / ₂	3 ⁹ / ₁₆ by 4 ⁵ / ₁₆ —5	3.562	4 ⁵ / ₁₆	4 ¹ / ₄	5	3	V-.040 flat.
5 ¹ / ₁₆	4 ¹ / ₂ by 5 ¹ / ₂ —4	4.333	5 ¹ / ₂	4 ³ / ₄	4	3	V-.050 flat.
6 ³ / ₈	5 by 6—4	5.159	6	5	4	2	V-.050 flat.
7 ⁵ / ₈	6 by 7—4	5.6875	7	5 ¹ / ₄	4	3	V-.050 flat.
8 ⁵ / ₈	7 by 8—4	6.608	8	5 ³ / ₈	4	3	V-.050 flat.

NOTE.—Dimensions "A" and "C" for all sizes except the 5¹/₁₆, 6³/₈, and 8⁵/₈ inches are absolute dimensions from which gage values are computed. Dimensions "A" and "C" for the 5¹/₁₆, 6³/₈, and 8⁵/₈ sizes are approximately accurate.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS, SCHEME FOR THE IDENTIFICATION OF PIPING SYSTEMS, A13-1928

[Approved as American recommended practice by the American Standards Association, 1928]

IDENTIFYING PIPING SYSTEMS

(Joint sponsor with the National Safety Council for a system to indicate the purpose of conveyor pipes by suitable markings. The scheme is limited to piping systems in industrial and power plants, exclusive of electrical conduits and pipes buried in the ground. For identification purposes the piping systems are divided into five classes, viz, fire protection, dangerous materials, safe materials, protective materials, and extra valuable materials. The colors attaching to each of these classes are, respectively, red, yellow or orange, green (or the achromatic colors white, black, gray, or aluminum), bright blue, or deep purple. An appendix lists the identifying trade names of the specific five basic colors which are least affected chemically and physically by abnormal exposure conditions.)

AMERICAN SOCIETY OF MECHANICAL ENGINEERS, PIPE THREAD, NO. 3, 1919

[Approved as American standard (B2-1919) by the American Standards Association]

PIPE THREADS

(Joint sponsor with the American Gas Association under the auspices of the American Standards Association. Substantially the same as the National Screw Thread Commission report, given below.)

ASSOCIATED FACTORY MUTUAL FIRE INSURANCE COMPANIES, SPECIFICATIONS FOR FIRE HOSE, COUPLINGS, AND PLAY PIPES, 1930

(See also 645.4, p. 1232.)

THREADS FOR HOSE COUPLINGS

Threads of 2¹/₂-inch hose couplings should conform to the national (American) standard thread. (See National Screw Thread Commission, given below.)

NATIONAL BOARD OF FIRE UNDERWRITERS, INSTALLATION, MAINTENANCE, AND USE OF PIPING AND FITTINGS FOR CITY GAS, 1920

PIPING FOR CITY GAS

All pipe shall be cut square with its length, and the exact dimensions as given on the piping plans shall be followed. Pipe shall be threaded with clean-cut threads, and all burrs or other obstructions shall be removed from the pipe.

Nominal ordinary pipe sizes and Briggs' standard are understood in these regulations for all pipes and threads where not otherwise specified.

The following table specifies the number of threads to be cut and the length of section to be threaded for each size of pipe, based on Briggs' standard:

Size of pipe	Approximate length of threaded portion	Approximate number of threads to be cut
<i>Inches</i>	<i>Inches</i>	
3/8	9/16	10
1/2	3/4	10
3/4	3/4	10
1	7/8	10
1 1/4	1	11
1 1/2	1	11
2	1	11
2 1/2	1 1/2	12
3	1 1/2	12
4	1 5/8	13

Pipe with threads stripped, chipped, or damaged, or which has crooked threads, shall not be used. If the weld opens during the operation of cutting or threading, that portion of the pipe shall not be used.

When an approved jointing compound is used, it should always be applied sparingly and only to the male thread of the joint. Sealing wax or any material or compound known as "gas-fitter's cement" shall not be used in making up joints in piping systems. If material containing lead is used for a jointing material, it shall not be applied with the hand because of its poisonous nature.

POWER PIPING SOCIETY, STANDARD SPECIFICATIONS FOR POWER PIPING, 1928

POWER PIPING

(This specification contains requirements for a safe, economical, commercial installation. It has been compiled as a guide for framing actual specifications. The materials and workmanship are of higher grade than safety alone or service under the most favorable conditions might dictate, but are recommended by the Power Piping Society as the minimum permitted by good practice. The text consists of excerpts from standard specifications, each paragraph carrying an identifying letter and number. This is supplemented by a material-service index which indicates at a glance the power-piping requirements for different kinds of service. For example, superheated steam at pressures of 400 to 600 pounds per square inch, or saturated steam at a pressure of 100 pounds per square inch, requires for safe and economical service certain standards in

regard to materials, dimensions, finish and tolerances, hydrostatic tests, gate valves, globe and angle valves, nonreturn valves, blow-off valves, fittings, loose flanges, screwed unions, wrought pipe, bolting, gaskets, welding, bends, expansion, and supports. The standard requirements in each case are indicated by paragraph number and letter. By paragraph number and letter are also indicated the power-piping requirements as detailed above for superheated steam at other pressures, saturated steam at other pressures, boiler-feed water at various pressures, exhaust, service water, suction and low-pressure water, live-steam drains, low-pressure drains, boiler blow-off, fuel-oil discharge, transformer circulating oil, and fuel-oil suction. Under the head of gate valves it is provided that):

The bodies of steel gate valves of the sizes listed below shall have three bosses on each connecting end, one such boss on each side and one on the bottom. Each boss shall be of a diameter and height to permit tapping of American standard pipe threads of the following sizes. (Standard practice of the Manufacturers' Standardization Society of the valve and fitting industry.)

	<i>Inch</i>
3 inch to/and 4 inch.....	1/2
5 inch to/and 8 inch.....	3/4
10 inch and larger.....	1

SOCIETY OF AUTOMOTIVE ENGINEERS, SCREW THREADS, S. A. E. (AMERICAN) STANDARD, FEBRUARY 1924

[Approved as American Standard (B1a-1924) by the American Standards Association]

(Joint sponsor with the American Society of Mechanical Engineers under the auspices of the American Standards Association. Substantially the same as corresponding tables in United States Government, National Screw Thread Commission, Bureau of Standards Miscellaneous Publication No. 89 (see 608.0, p. 529), except for data on extra-fine-thread series, and fine-thread series over 1 1/2 inches in diameter, for which see S. A. E. (608.0, p. 517).)

SOCIETY OF AUTOMOTIVE ENGINEERS, SCREW THREADS; SCREW-THREAD-FIT APPLICATIONS, JULY, 1926

SCREW-THREAD-FIT APPLICATIONS

(A system of symbols for readily identifying the threads per inch, the series, and the fit of screw threads to be used in the different S. A. E. standards and recommended practices which do not specify screw-thread fits. These standards and recommended practices include carburetor flanges, oil and grease-cup threads, tachometer drive, and front-axle hubs.)

SOCIETY OF AUTOMOTIVE ENGINEERS, SCREW THREADS; TAPER PIPE THREADS, S. A. E. (AMERICAN) STANDARD, MARCH, 1921

TAPER PIPE THREADS

(Same as Table 44 of the National Screw Thread Commission, given below, from which it is abstracted, in pipe sizes ranging from one-eighth to 6 inches.)

UNITED STATES GOVERNMENT, DEPARTMENT OF COMMERCE, BUREAU OF STANDARDS, WROUGHT-IRON AND WROUGHT-STEEL PIPE, VALVES, AND FITTINGS, SIMPLIFIED PRACTICE RECOMMENDATION NO. 57, 1926

WROUGHT-IRON AND WROUGHT-STEEL PIPE, VALVES, AND FITTINGS

The United States Department of Commerce, through the Bureau of Standards, recommends that the sizes and dimensions of wrought-iron and wrought-steel pipe and the sizes of valves and fittings conform to the following simplified lists:

TABLE 1.—“Standard weight” pipe

Nominal inside diameter	Outside diameter	Approximate thickness	Nominal inside diameter	Outside diameter	Approximate thickness
<i>Inches</i>	<i>Inches</i>	<i>Inch</i>	<i>Inches</i>	<i>Inches</i>	<i>Inch</i>
1/8	0.405	0.068	2 1/2	2.875	0.203
1/4	.540	.088	3	3.500	.216
3/8	.675	.091	3 1/2	4.000	.226
1/2	.840	.109	4	4.500	.237
3/4	1.050	.113	5	5.563	.258
1	1.315	.133	6	6.625	.280
1 1/4	1.660	.140	8	8.625	.322
1 1/2	1.900	.145	10	10.750	.365
2	2.375	.154	12	12.750	.375

TABLE 2.—“Extra strong” pipe

NOTE.—Random lengths according to present pipe-mill practice.

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATIONS FOR PIPE THREADS, NO. 238, NOVEMBER 5, 1924. (CURRENT DESIGNATION GGG-P-351)

PIPE THREADS

TYPES

I. This specification covers taper and straight pipe threads.

MATERIAL AND WORKMANSHIP

II. 1. Threads shall be full and clean cut in conformity with best commercial practice.

GENERAL REQUIREMENTS

III. No details.

DETAIL REQUIREMENTS

IV. 1. Unless otherwise specified taper pipe threads shall apply to all pipe and pipe fittings.

2. Taper pipe threads.

(The illustrative sketch and table of taper pipe thread dimensions given in this specification are identical with the sketch and table of taper pipe thread dimensions given in the standards of the National Screw Thread Commission below, for pipe sizes up to and including 12 inches.)

3. Where straight pipe threads are specified, the following shall apply.

(a) The sizes and basic dimensions of straight pipe threads shall be as given in columns 1, 2, 3, and 11 of the N. S. T. C. table of taper-pipe-thread dimensions.

(b) Diameters of straight threads. (Determined by same formula as given in standards of N. S. T. C., see below.)

METHOD OF INSPECTION

V. 1. Gages within the tolerances specified shall be used for inspecting pipe threads. Gages approved by the purchaser shall be supplied by the vendor.

2. Gages used for inspection shall not vary from the basic dimensions more than one-half turn either way. Proper allowance shall be made for any such variation in using the gage.

3. The thread is within the extreme tolerance in the case of internal threads when the plug gage notch is within 1 1/2 turns of the coupling or fitting face, or if chamfered at the bottom of chamfer, when screwed in tightly by hand. In the case of external threads the small end of the ring gage shall be within 1 1/2 turns of the end of the pipe when screwed on tightly by hand.

PACKING AND MARKING

VI. 1. Details for packing and marking are given in the specifications for the pipe.

ADDITIONAL INFORMATION

VII. 1. For new inspection gages, a tolerance of plus or minus 0.0005 inch is allowed on the distance between the gaging notch and the small end of the inspection plug gage, or on the thickness of the inspection ring gage.

2. (For table of tolerances for use in purchasing new inspection gages, see National Screw Commission, 615.82, p. 921.)

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, SPECIFICATION FOR PLUMBING FIXTURES (FOR LAND USE), NO. 448, NOVEMBER 22, 1926. (CURRENT DESIGNATION: FF-P-451)

(See 617.73, p. 1062 and 600.3, p. 70.)

PLUMBING FIXTURES (FOR LAND USE)

UNITED STATES GOVERNMENT, NATIONAL SCREW THREAD COMMISSION, AMERICAN NATIONAL PIPE THREADS, BUREAU OF STANDARDS MISCELLANEOUS PUBLICATION NO. 89, JUNE 22, 1928

PIPE THREADS

The American national pipe-thread standard for taper-threaded pipe joints was formulated prior

to the year 1882 by Robert Briggs, of Philadelphia, Pa. This standard, with certain modifications and additions, is now in general use throughout the United States and Canada.

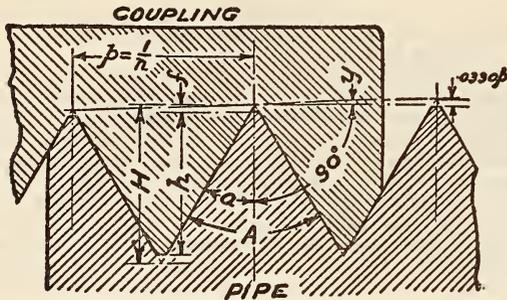

FIGURE 205.—American national taper pipe thread form and notation

$A = 60^\circ$ angle of thread.
 $a = 30^\circ$ one-half angle of thread.
 $y = 1^\circ 47'$ approximate taper angle = one-sixteenth inch per inch on diameter.
 $H = 0.866025 p$ depth of 60° sharp V thread.
 $h = 0.800000 p$ as against $H = 0.866025 p$, the value given above.
 $f = 0.923761 H$ depth of thread on work.
 $f_1 = 0.033012 p$ depth of truncation.
 $f_2 = 0.038120 H$ depth of truncation.
 $f_3 = 0.041266 h$ depth of truncation.
 $p = 1/n$ pitch.
 $n = \text{number of threads per inch.}$

For a symmetrical straight screw thread, $H = p \cot a$. For a symmetrical taper screw thread $H = \frac{p}{2}(\cot^2 a - \tan^2 y \tan a)$, so that the exact value for an American National taper pipe thread is $H = 0.865743 p$ as against $H = 0.866025 p$, the value given above. For an 8-pitch thread, which is the coarsest standard taper pipe thread pitch, the corresponding values of H are 0.108218 inch and 0.108253 inch, respectively, the difference being 0.000035 inch. This difference being too small to be significant, the value of $H = 0.866025 p$ continues in use for threads of three-fourths inch, or less, taper per foot.

FORM OF THREAD

(a) Specifications

1. Angle of thread.—The angle between the sides of the thread is 60° when measured in an axial plane.

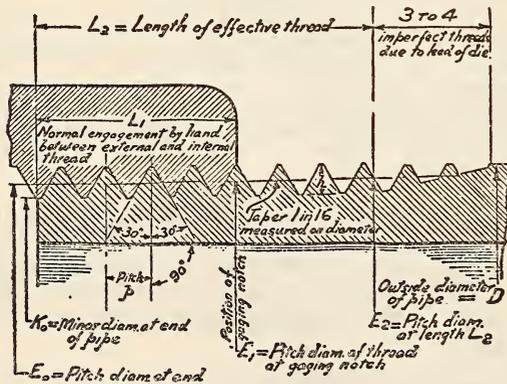

FIGURE 206.—American national taper pipe thread notation

NOTATION

$E_0 = D - (0.05D + 1.1) p$
 $E_1 = E_0 + 0.0625 L_1$
 $L_2 = p(0.8D + 6.8)$
 $h = 0.8 p$

and the line bisecting this angle is perpendicular to the axis of the pipe for either taper or straight threads.

2. Depth of thread.⁵⁸—The crest and root of the thread form are truncated an amount equal to $0.0330 p$; the depth of thread is, therefore, equal to $0.8 p$.

3. Taper of thread.—The taper of the thread is 1 in 16, or three-fourths inch per foot, measured on the diameter.

(b) Illustration

There are shown in Figure 205 the relations as specified herein for form of thread and general notation. Special notation is given in Figures 206, 207, and 209.

SYMBOLS

(The significance of symbols used in the several formulas given below are as shown in the following tabulation:)

Pitch diameter of thread at end of pipe.....	E_0
Pitch diameter of thread at gaging notch.....	E_1
Pitch diameter of thread at L_2 from end of pipe.....	E_2
Maximum pitch diameter, external locknut thread.....	E_3
Minimum pitch diameter, internal locknut thread.....	E_4
Distance from gaging notch to end of pipe = normal engagement by hand.....	L_1
Length of effective thread.....	L_2
Outside diameter of pipe = major diameter of pipe thread at L_1 from end of pipe.....	D
Internal diameter of pipe.....	d

THREAD SERIES

(a) American National Taper-Pipe Threads

Taper external and internal pipe threads are recommended for threaded pipe joints and pipe fittings for any service. The sizes and basic dimensions of the "American national taper pipe threads" are specified in Table 44.

1. Outside diameter of pipe.—The outside diameters of pipe are given in column 5 of Table 44.

2. Diameters of taper threads.—The pitch diameters of the taper threads are determined by formulas based on the outside diameter of pipe and the pitch of thread. These are as follows⁵⁹ (see Symbols above):

$$E_0 = D - (0.05 D + 1.1) p$$

$$E_1 = E_0 + 0.0625 L_1$$

3. Length of thread.—The length of the taper external thread is determined by a formula based on the outside diameter of pipe and the pitch of the thread. This is as follows⁵⁹ (see Symbols above):

$$L_2 = (0.8 D + 6.8) p$$

4. Length of engagement.—The normal length of engagement between taper external and internal threads, when screwed together by hand, is shown in column 6 of Table 44. This length is controlled by means of gages.

5. Tolerances.—The tolerance on diameter is the equivalent of the variation in diameter due to taper over one and one-half turns either way from the basic dimensions.⁶⁰

⁵⁸ While Mr. Briggs originally advocated a slightly rounded crest and root, cutting tools are actually slightly flattened at the crest and root.

⁵⁹ These formulas are not expressed in the same terms as the formulas originally established by Mr. Briggs, because they are used to determine directly the pitch diameter and the length of effective thread, which includes two threads slightly imperfect at the crest; whereas the Briggs formulas determined the major diameter and the length of perfect thread, the two threads imperfect on the crest not being included in the formula. However, both forms give identical results.

⁶⁰ On account of the gage tolerance of one-half turn on working gages, this is equivalent to one turn plus or one turn minus from the gaging notch when using working gages.

TABLE 44.—Dimensions of American national taper-pipe threads

(b) American National Straight-Pipe Threads.

The specified sizes and basic dimensions on the "American national straight-pipe threads" are given in Table 45.

1. *Diameters of straight threads.*—The basic pitch diameter of the straight thread is equal to the diameter at the gaging notch of American national taper-pipe thread, and is determined by the following formula based on the outside diameter of pipe and the pitch of thread (see Symbols above):

$$E_1 = D - (0.05 D + 1.1)p + 0.0625 L_1$$

2. *Tolerances.*—The tolerance on pitch diameter of a straight-pipe thread is the equivalent of the variation in diameter over one and one-half turns either way from the gaging notch of the American national taper-pipe thread.⁶¹ (See columns 4 and 6 of Table 45.)

3. *Application to internal threads.*—Straight-threaded internal wrought-iron or wrought-steel couplings of the weight known as standard may be

⁶¹ The coupling thread may be gaged with a taper-threaded plug gage. On account of the gage tolerance of one-half turn on working taper-pipe-thread gages, the working tolerance is equivalent to one turn either way from the gaging notch. In gaging, care must be taken to gage at the first thread and not at the end of the coupling when the thread is chamfered.

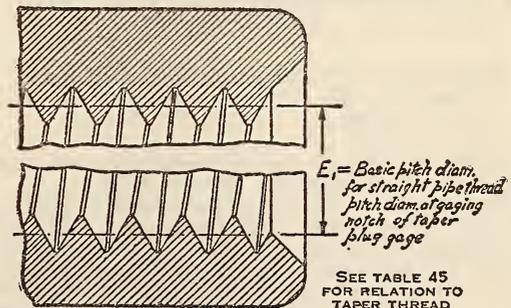

FIGURE 207.—American national straight pipe thread notation (internal)

NOTE.—This thread is gaged with the taper threaded plug gage and should gage flush at the face with the gaging notch, allowing a maximum variation of one turn plus or minus from the notch.

used with taper-threaded pipe for ordinary pressures, as they are sufficiently ductile to adjust themselves to the taper external thread when properly screwed together.

For high pressures, only taper external and internal threads should be used.

4. Application to external threads.—Straight external threads are recognized only for special applications, such as long screws and tank nipples.

TABLE 45.—Dimensions of American national straight pipe threads (for couplings)

[For notation see fig. 207]

Nominal size	Threads per inch	Major diameter, ¹ basic	Pitch diameter			Minor diameter ¹

5	8	5.48492	5.46101	5.44929	5.43757	5.34929
6	8	6.0597	6.51769	6.50597	6.49425	6.40597

¹ The American national pipe thread form is maintained; therefore, the major and minor diameters vary with the pitch diameter and are determined by the threading tools.

5. Application to long screw joints.—Long screw joints are used to a limited extent. This joint is not considered satisfactory when subjected to high temperature or pressure. In this application the coupling has a straight thread and must make a joint with an American national taper pipe thread. (See fig. 207.) It is necessary that the coupling be screwed on the straight external thread for the full length of the coupling and then back until it engages the taper external thread. The straight thread on the pipe enters the coupling freely by hand, the

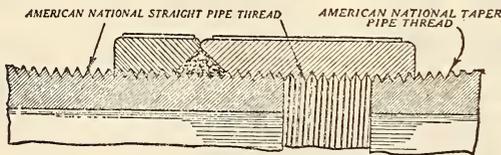

FIGURE 208.—Illustration of "long screw" joint between straight threaded coupling and taper threaded pipe

joint being made by a packing material between the locknut and the coupling. (See fig. 208.)

On account of the long engagement of thread, imperfections in pitch affect the fit when the coupling is screwed on the pipe its full length. Refinements of manufacture and gaging to insure a properly interchangeable product are more costly than the commercial use warrants; therefore, the use of this type of joint is not recommended. For this reason, specifications for tolerances and gaging are not included herein.

(c) American National Locknut Threads

Occasional requirements make it advisable to have a straight thread of the largest diameter it is possible to cut on a pipe. This practice has been standardized and is known as "maximum external and minimum internal locknut threads." For dimensions, see Table 46. The "tank nipple" shown in

Figure 210 is an example of this thread. In this application an American national standard-taper

NOTATION

E_1 = pitch diameter at gaging notch of American national taper plug gage.

$E_0 = E_1 + (4p \times 0.0625)$.

$E_1 = E_1 + (5p \times 0.0625)$.

NOTE.—See Table 46 for relation to taper pipe thread.

pipe thread is cut on the end of the pipe after having first cut the "external locknut thread."

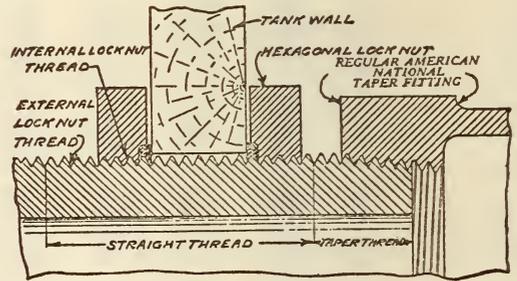

FIGURE 210.—Illustration of "tank nipple" thread

TABLE 46.—Dimensions of American national locknut threads

[For notation, see fig. 209]

Nominal size	Threads per inch	E_0 (Maximum) ¹	E_1 (Minimum) ¹	Depth of thread

12	8	12.64906	12.65688	.10000

¹ A tolerance equivalent to 1 1/2 turns of the American national taper pipe thread is recommended, the tolerance being minus on E_0 and plus on E_1 .

607.1 CAST-IRON PIPE, FITTINGS, AND CONNECTIONS.

607.10 GENERAL ITEMS.

ASSOCIATED FACTORY MUTUAL FIRE INSURANCE COMPANIES, RULES FOR LAYING CAST-IRON WATER PIPES IN FACTORY YARDS, 1931

WATER PIPES FOR FIRE PROTECTION

(These rules specify that underground pipe for fire protection should be made in accordance with the standards of the New England Water Works Association or of the American Water Works Association, class C, or the equivalent. The rules cover the depth of laying of pipe, protection against frost, care in laying, amount of jute yarn and lead required for making joints, installation of hydrants and gate valves, connections from water supplies, and testing of piping and hydrants.)

607.11 CAST-IRON PIPE CULVERTS, DRAINS, AND SEWERS.

AMERICAN ASSOCIATION OF STATE HIGHWAY OFFICIALS, METHODS OF TESTING CULVERT PIPE, TENTATIVE METHOD T-33, 1931

TESTING CAST-IRON CULVERT PIPE

PHYSICAL TESTS

Strength tests.—These methods of making strength tests are intended to apply to cast iron, vitrified clay, and concrete culvert pipe.

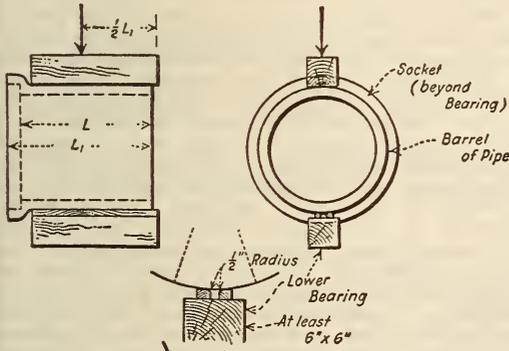

FIGURE 211.—Three-edge bearings

Pipe may be tested for strength by either the 3-edge bearing or sand-bearing method.

THREE-EDGE BEARING METHOD

When the 3-edge bearing method is used, the lower bearing for the pipe shall consist of two wooden strips with vertical sides having their interior top corners rounded to a radius of approximately one-half inch. The strips shall be straight and shall be securely fastened to a rigid block with the interior vertical sides spaced a distance apart not less than one-half inch or more than one inch for each foot of pipe diameter. The upper bearing shall be a rigid wooden block, straight and true from end to end. The upper and lower bearings shall extend the full length of pipe exclusive of bell. The pipe shall be placed symmetrically between the two bearings as illustrated in Figures 211 and 212. In testing pipe which is "out of line" the lines of the bearings chosen shall be from those which appear to give the most favorable conditions for fair test.

When the sand-bearing method is used (see figs. 213 and 214), the ends of each specimen of pipe shall be accurately marked prior to the test in quarters of the circumference. Specimens shall be carefully bedded, above and below, in sand, for

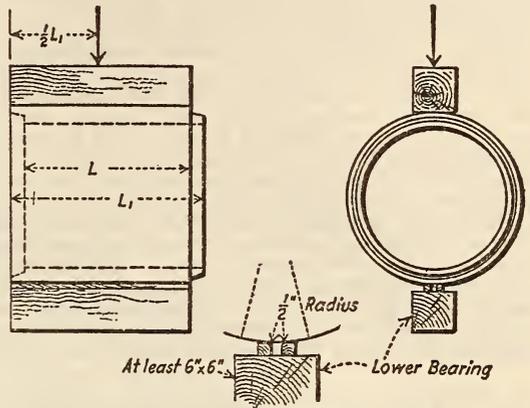

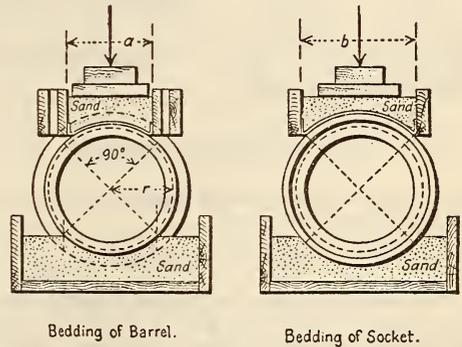

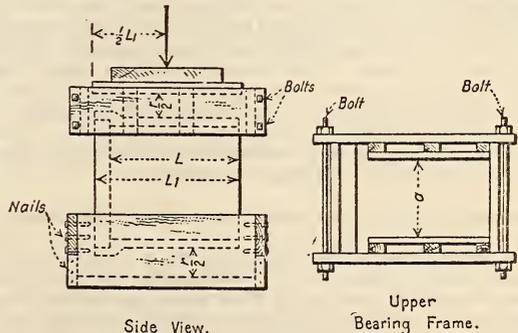

FIGURE 212.—Three-edge bearings

one-fourth the circumference of the pipe measured on the middle line of the barrel. The depth of bedding above and below the pipe at the thinnest points shall be one-half the radius of the middle line of the barrel.

Bedding of Barrel.

Bedding of Socket.

Side View.

Upper Bearing Frame.

FIGURE 213.—Sand bearings

The sand used shall be clean and moist, and shall be such as will pass a 4,760 micron (No. 4) sieve. The sand in the lower bearing shall be loose when the pipe is placed.

The top bearing frame shall not be allowed to come into contact with the pipe nor with the top bearing plate. The upper surface of the sand in the top bearing shall be struck off level with a straight-

edge, and shall be covered with a rigid top bearing plate, with lower surface a true plane, made of heavy timbers or other rigid material, capable of distributing the test load uniformly without appreciable bending. The test load shall be applied at the exact center of this top bearing plate, or in such manner as to produce uniform deflection throughout the full length of the pipe. For this purpose a spherical bearing is preferred, but two rollers at right angles may be used. The test may be made without the use of a testing machine, by piling weights directly on a platform resting on the top bearing plate; provided, however, that the weights shall be piled symmetrically about a vertical line through the center of the pipe, and that the platform shall not be allowed to touch the top bearing frame.

The frames of the top and bottom bearings shall be made of timbers so heavy as to avoid appreciable bending by the side pressure of sand. The interior surfaces of the frames shall be dressed. No frame shall come in contact with the pipe during the test. A strip of cloth may, if desired, be attached to the inside of the upper frame on each side, along the

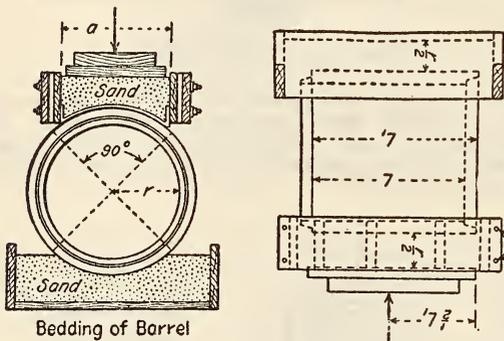

FIGURE 214.—Sand bearings

lower edge, to prevent the escape of sand between the frame and the pipe.

TESTING APPARATUS

It is desirable that the testing machine used for the strength tests shall give a uniform deflection throughout the full length of the pipe. Any mechanical or hand-power device may be used in which the head that applies the load moves at a speed of not more than 0.05 inch per minute while making the test. The testing machine shall be substantial and rigid throughout, so that the distribution of the load will not be affected appreciably by the deformation or yielding of any part. The load shall be applied continuously until the ultimate strength of the pipe is reached.

PRELIMINARY TESTS AND TESTS FOR EXTENDED DELIVERIES

Preliminary to placing an order, a purchaser of pipe whose needs require shipments at intervals over extended periods of time shall be entitled to test not more than 10 pieces of pipe covering the size in which he is interested. The test specimens shall be selected in approximately equal numbers from the larger and smaller sizes of pipe. The acceptability of the larger sizes of pipe shall not be based on the results of tests in smaller sizes. After these preliminary tests, a purchaser shall be entitled to additional tests in such numbers and at such times as he may deem necessary, provided that the total number of pipe tested shall not exceed 2 per cent of the total deliveries.

TESTS FOR OCCASIONAL ORDERS

A purchaser who places occasional orders shall be entitled to test a number of pipe equal to 2 per cent of an order but not to exceed five pieces of any one size; otherwise the number of pipe desired for testing shall be included in the order.

SELECTING TEST SPECIMENS

All pipe for testing purposes shall be selected at random by the purchaser from the stock of the manufacturer and shall be pipe which would not otherwise be rejected under these specifications. The pipe shall be free from visible moisture when tested and they shall not have been exposed to a temperature below 40° F. for the 24 hours immediately preceding the test.

Pipe shall be acceptable under the strength tests when all test specimens conform to the test requirements. Should less than 3 of the 10 preliminary test specimens, or any one of the additional test specimens provided for above in the preliminary tests, or any one specimen provided for above in tests for occasional orders, fail to meet test requirements, then the manufacturer will be allowed a retest on two like specimens for each specimen that failed, and the pipe shall be acceptable only when all of these retest specimens meet the test requirements. No further retests shall be permitted.

AMERICAN RAILWAY ENGINEERING ASSOCIATION, SPECIFICATIONS FOR CAST-IRON CULVERT PIPE, 1930

CAST-IRON CULVERT PIPE

MANUFACTURE

The pipe shall be manufactured of cast iron of good quality and of such character as to be strong, tough, and of even grain, but soft enough to admit of satisfactory drilling and cutting. The metal shall be made without any admixture of cinder iron or other inferior metal and shall be remelted in a cupola or air furnace. The pipe shall be hub and spigot style of cast-iron water pipe or cast-iron culvert pipe, or spiral corrugated cast-iron pipe, or a ribbed or corrugated cast-iron pipe of design approved by the railroad company, smooth, free from scales, lumps, blisters, and other defects impairing its strength or durability, and be round, of uniform physical character, of close grain, and cast vertically. It shall be manufactured in lengths of not less than 3 feet, and the inner and outer surfaces shall be true, whole, concentric cylinders. This pipe shall be heated to 300° F. and immersed in coal tar varnish so that the result will be a smooth coating on both the inside and outside of the pipe. This coating must be of such a nature that it will be tough, tenacious—not brittle—or have any tendency to scale when cold, and such results shall be consistent.

PHYSICAL PROPERTIES AND TESTS

Cast-iron culvert pipe shall have minimum thickness of pipe as follows:

Inside diameter	Thickness	Inside diameter	Thickness
<i>Inches</i>	<i>Inch</i>	<i>Inches</i>	<i>Inch</i>
12	$\frac{3}{16}$	24	$\frac{3}{16}$
14	$\frac{3}{16}$	30	$\frac{1}{4}$
16	$\frac{1}{2}$	36	$\frac{1}{4}$
18	$\frac{1}{2}$	42	$\frac{1}{2}$
20	$\frac{1}{2}$	48	$\frac{1}{4}$

No pipe shall be accepted the thickness of which is one-sixteenth inch less than the thickness herein specified.

The transverse test shall be used to determine the physical properties. The test bar shall be the 1 by 2 by 28 inch American Foundrymen's Association standard rectangular bar. This bar shall be cast vertically in a dry sand mold, coated with a bituminous facing and not cast until the mold is cold. The test bar shall not be tumbled or otherwise treated, but simply brushed off before testing.

The test shall be transverse with the bar placed horizontally upon supports 24 inches apart and a concentrated load applied midway between the supports.

The test shall conform to the following requirements as a minimum:

Average load at center.....pounds.. 2,200
Average deflection at center.....inches.. 0.30

From each melt, test bars shall be poured, the first one five minutes after the first tap and then one bar from each 2-hour interval or fraction thereof, throughout the heat.

The pipe shall have sufficient strength so that when tested by the 3-edge bearing method as specified in the standard specifications for drain tile C14-24, of the American Society for Testing Materials, will show a load-supporting capacity in pounds per linear foot equal to or greater than that obtained by the use of the formula, W equals $1,500 D$, in which W equals pounds per foot and D equals the inside diameter of pipe in feet. All pipe shall be carefully examined for defects and sounded with a hammer before shipment. No fillings with metal, cement, or other materials, or so-called burning on of iron, will be permitted. The castings shall be sound and free from cracks, sand holes, blowholes, and cold shuts.

INSPECTION AND REJECTION

(Conform with A. S. T. M. standard specifications for steel, paragraph 7. See 605.0, p. 247.)

AMERICAN RAILWAY ENGINEERING ASSOCIATION, PLUMBING FOR RAILWAY BUILDINGS, 1929

CAST-IRON PIPE AND FITTINGS

Concealed soil, waste, drain, sewer, and vent pipes in buildings shall be extra heavy cast-iron soil pipe. Pipe shall have the maker's name cast thereon and shall be in lengths not less than 5 feet. It shall be sound and free from defects and with the inner and outer surfaces concentric and smooth and of the following weights per linear foot:

Inches	Pounds	Inches	Pounds
2	5½	6	20
3	9½	7	27
4	13	8	33½
5	17	10	45

Fittings for cast-iron pipe shall be extra heavy cast iron of the same make as the soil pipe, and shall be of the same inside diameter as the pipe with which they are connected. Unless otherwise specified, cast-iron pipe and fittings must be coated with hot asphaltum both inside and outside by dipping. Fittings for the junction of cast and wrought iron pipe shall be cut at one end with full threads; and fittings supporting risers shall have proper shoes cast on them.

Water supply pipes larger than 2½ inches diameter located below ground shall be class B cast-iron pipe,

in accordance with the specifications of the American Water Works Association (see 607.12, p. 379), unless local conditions require the use of heavier pipe.

AMERICAN SOCIETY FOR TESTING MATERIALS, STANDARD SPECIFICATIONS FOR CAST-IRON SOIL PIPE AND FITTINGS, DESIGNATION A74-29, 1929

CAST-IRON SOIL PIPE AND FITTINGS

MANUFACTURE

1. The cast iron from which the pipe and fittings are made shall be of such composition, and the conditions of manufacture so maintained, that the castings will be of uniform physical character, close grain, and not hard, brittle, nor difficult to cut with file or chisel.

2. (a) When pipe or fittings are to be coated, coal-tar pitch shall be used, which shall contain sufficient oil to make a smooth coating. The pitch shall be tough and tenacious when cold, and not brittle nor having any tendency to scale.

(b) The varnish shall be heated to about 300° F. and shall remain at this temperature during the time the casting is immersed.

(c) Each casting shall be heated to a uniform temperature of about 300° F. immediately before it is dipped, and shall possess this temperature at the time it is put in the bath.

(d) Each casting shall remain in the bath at least two minutes.

(e) Fresh pitch and oil shall be added when necessary to keep the mixture of the proper consistency, and the vat shall be emptied of its contents and refilled with fresh pitch whenever the accumulation of sand or carbonaceous matter renders this desirable, as can be seen by the solids adhering to the under side or lower ends of the castings.

(f) After being coated, the pipe and fittings shall be carefully drained of the surplus varnish.

CHEMICAL PROPERTIES AND TESTS

3. Drillings taken from the fractured end of the arbitration test bar shall not contain over 0.10 per cent of sulphur.

PHYSICAL PROPERTIES AND TESTS

4. The transverse test specimen (arbitration test bars) specified in section 6, when placed horizontally upon supports 18 inches apart and tested under a centrally applied load, shall conform to the following minimum requirements:

Average load at center.....pound.. 1,500
Average deflection at center.....inch.. 0.20

5. All pipe shall be tested to a hydrostatic pressure of not less than 50 pounds per square inch

TABLE 1.—Weights of soil pipe

Size	Single hub		Double hub
	Per 5-foot length	Per foot, including hub	Per 5-foot length
<i>Inches</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>

3	47½	9½	47½
4	65	13	65
5	85	17	85
6	100	20	100

before coating. Any casting showing defects under this hydrostatic test shall be promptly broken and returned to the cupola.

6. The arbitration test bar shall be in accordance with the standard specifications for the arbitration test bar and tension test specimen for cast iron in A. S. T. M. A124 (sec. 600.1, p. 18).

7. From each melt of metal not less than three test specimens (arbitration test bars) shall be poured, the first of which shall be poured within five minutes after the first ladle is tapped and the remainder at intervals not exceeding one hour throughout the melt.

STANDARD SIZES AND WEIGHTS

8. (a) The inside diameter of the barrel of any pipe or fittings or branch thereof shall not vary more than one-eighth inch under the nominal size of pipe.

(b) The outside diameter of the barrel of pipe and fittings shall be one-half inch greater than its nominal inside diameter. A variation in the outside diameter of one-eighth inch over or under these figures will be permitted.

TABLE 2.—Weights of soil pipe fittings

[Only the staple fittings are shown. From the data herewith the weights of other fittings may be calculated]

[All values are in pounds]

(c) All pipe and fittings shall be of uniform thickness of wall and present true circles at the hub and spigot ends. A variation of one-sixteenth inch under the following dimensions will be permitted, but only when the actual weight is not less than the variation of the marked or estimated weight as given in Tables 1 and 2:

Thickness of barrel.....	Inch
Thickness of body of hub.....	¼
Thickness of bead of hub.....	⅜
Thickness of bead of spigot end.....	½
	⅜

9. (a) Weights and measurements of pipe and fittings shall be taken as those of plain uncoated pipe. All weights shall be given in pounds.

(b) Individual lengths of pipe and fittings may weigh 5 per cent less than designated in Tables 1 and 2, but only when the average weight of a given size and weight of pipe and fittings selected at random, is not less than that shown in Tables 1 and 2.

(c) The regular length of pipe shall be such as to lay 5 feet, including hub.

(d) The average weights of soil pipe and fittings shall not be less than those given in Tables 1 and 2.

WORKMANSHIP AND FINISH

10. (a) All pipe and fittings shall be practically straight and cylindrical and fittings true to pattern. The specified sizes shall be for the inside diameter and shall conform, within the allowable variation, to the dimensions given in the tables.

(b) All pipe and fittings shall be carefully examined for defects and sounded with a hammer before shipment. No fillings with metal, cement, or other

material, or so-called burning on of iron will be permitted. The castings shall be sound and free from cracks, sand holes, blowholes, and cold shots.

MARKING

11. All pipe and fittings shall be marked with the name of the manufacturer, or appropriate initial. Each casting shall have cast upon it the minimum or estimated weight of same as shown in Tables 1 and 2.

INSPECTION AND REJECTION

(Inspection and rejection conform to the requirements specified in A. S. T. M. standard specifications for metals. See 605.0, p. 247.)

UNITED STATES GOVERNMENT, FEDERAL SPECIFICATIONS BOARD, FEDERAL SPECIFICATION FOR PIPE AND PIPE FITTINGS, SOIL, CAST IRON, COATED AND UNCOATED, NO. 343a, AUGUST 22, 1928. (CURRENT DESIGNATION: WW-P-401)

CAST-IRON SOIL PIPE AND FITTINGS

(This specification conforms to A. S. T. M. A74, given above, except for the additional weights of fittings, the laying lengths of fittings, and the dimensions of hubs and spigots shown in the annexed tables. F. S. B. No. 343a (WW-P-401) also contains the following provisions:)

GENERAL REQUIREMENTS

Unless otherwise specified, the pipe shall be provided with a lead groove inside the hub opposite the hub band. A variation in straightness not

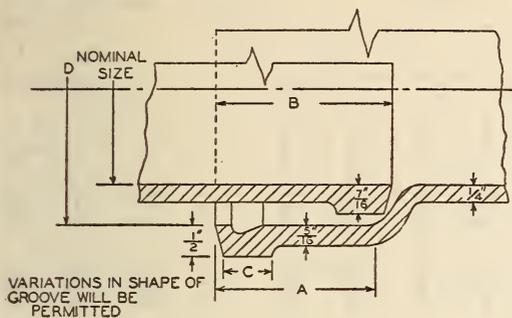

FIGURE 215

exceeding one-fourth inch per 5 feet length of pipe will be permitted;

DETAIL REQUIREMENTS

The depth of hub (see dimension A, fig. 215) shall be the distance, measured parallel to the axis of the opening, from the end of the hub to the beginning

of any offset or change of direction of the inside wall of same.

The lettered dimensions indicated in Figure 215 shall conform to the requirements as listed in Table 1.

TABLE 1

Dimension	Nominal size (inches)					
	2	3	4	5	6	8
Depth of hub A, shall be not less than.....	Ins. 2 1/4	Ins. 2 1/2	Ins. 2 3/4	Ins. 2 3/4	Ins. 2 3/4	Ins. 3
Spigot end shall telescope B not less than.....	2 1/2	2 3/4	3	3	3	3 1/4
Width of hub bead C, shall be not less than.....	5/8	1 1/16	3/4	3/4	3/4	1
Inside diameter of hub D shall be as follows.....	{ 3 3/16 ± 1/16	{ 4 3/16 ± 1/16	{ 5 3/16 ± 1/16	{ 6 3/16 ± 1/16	{ 7 3/16 ± 1/16	{ 9.625 ± 1/16

¹ Maximum.

² Minimum.

The laying length of fittings shall be in accordance with dimensions given in Table 3, with a tolerance of ± 1/4 inch.

Calking room.—The spigot end, including bead, of every fitting must be straight without offset or change in direction for at least 4 inches, except that on 3-inch bends this may be 3 1/2 inches, and on 2-inch bends, 3 inches. On all traps this must be at least 5 inches.

TABLE 2.—Weight of soil pipe fittings

[Only the single hub staple fittings are listed. From the data herewith the weights of other fittings may be calculated. All weights are in pounds. Sizes are nominal inside diameter]

METHOD OF INSPECTION AND TESTS

All pipe before coating shall be tested to a hydrostatic pressure of not less than 50 pounds per square inch. Pipe while under pressure shall be struck in three places—body, spigot, and hub—with a 1-pound hammer, using a full elbow swing. The strength of the blow shall be such as to disclose brittleness, and not break good pipe. Any casting showing defects under this test shall be rejected.

All pipe shall be surface inspected for defects before coating by rolling on suitable supports, so that the entire surface of each pipe may be properly inspected.

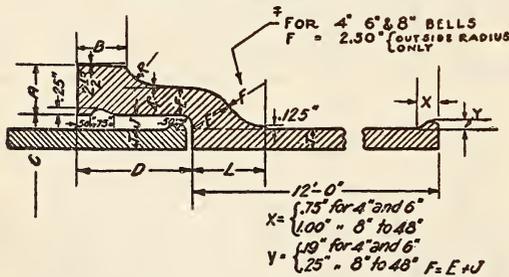

All fittings shall be subjected to the hammer test, striking each piece in body, spigots, and hubs

or bureau concerned should include such requirement in its purchase specification. Cast-iron soil pipe and fittings should be purchased by the piece and not by weight.

607.12 CAST-IRON GAS AND WATER PIPE.**AMERICAN GAS ASSOCIATION STANDARD SPECIFICATIONS FOR CAST-IRON PIPE AND SPECIAL CASTINGS, 1925****CAST-IRON PIPE AND SPECIAL CASTINGS**

(Text of specifications conforms with A. S. T. M. A44-04, given below. Weights and dimensions of bell and spigot pipe are as shown in accompanying tables. Additional tables in this specification give the weights and dimensions of the following special castings:)

¹ Weight of bell includes only metal beyond outside diameter of pipe.
² Weight per foot includes bell and bead.

NOTE.—Pipe heavier than these standards may be made by reducing the cores, or internal diameters C and D; same for specials.

Dimension L for sizes 4, 6, and 8 inches, and dimension F, shown in sketch as 2.50 (outside radius only), apply to bells of straight pipe only. For bells of special castings the correct dimensions for F and L are:

Size	F	L
4	1.09	1.90
6	1.12	2.00
8	1.19	2.10
