Progress Report on CRYSTALLINE DIMETHACRYLATE MONOMERS

U.S. DEPARTMENT OF COMMERCE NATIONAL BUREAU OF STANDARDS

#### NATIONAL BUREAU OF STANDARDS

The National Bureau of Standards <sup>1</sup> was established by an act of Congress March 3, 1901. Today, in addition to serving as the Nation's central measurement laboratory, the Bureau is a principal focal point in the Federal Government for assuring maximum application of the physical and engineering sciences to the advancement of technology in industry and commerce. To this end the Bureau conducts research and provides central national services in four broad program areas. These are: (1) basic measurements and standards, (2) materials measurements and standards, (3) technological measurements and standards, and (4) transfer of technology.

The Bureau comprises the Institute for Basic Standards, the Institute for Materials Research, the Institute for Applied Technology, the Center for Radiation Research, the Center for Computer Sciences and Technology, and the Office for Information Programs.

THE INSTITUTE FOR BASIC STANDARDS provides the central basis within the United States of a complete and consistent system of physical measurement; coordinates that system with measurement systems of other nations; and furnishes essential services leading to accurate and uniform physical measurements throughout the Nation's scientific community, industry, and commerce. The Institute consists of an Office of Measurement Services and the following technical divisions:

Applied Mathematics—Electricity—Metrology—Mechanics—Heat—Atomic and Molecular Physics—Radio Physics "—Radio Engineering "—Time and Frequency "—Astrophysics "—Cryogenics."

THE INSTITUTE FOR MATERIALS RESEARCH conducts materials research leading to improved methods of measurement standards, and data on the properties of well-characterized materials needed by industry, commerce, educational institutions, and Government; develops, produces, and distributes standard reference materials; relates the physical and chemical properties of materials to their behavior and their interaction with their environments; and provides advisory and research services to other Government agencies. The Institute consists of an Office of Standard Reference Materials and the following divisions:

Analytical Chemistry—Polymers—Metallurgy—Inorganic Materials—Physical Chemistry. **THE INSTITUTE FOR APPLIED TECHNOLOGY** provides technical services to promote the use of available technology and to facilitate technological innovation in industry and Government; cooperates with public and private organizations in the development of technological standards, and test methodologies; and provides advisory and research services for Federal, state, and local government agencies. The Institute consists of the following technical divisions and offices:

Engineering Standards—Weights and Measures — Invention and Innovation — Vehicle Systems Research—Product Evaluation—Building Research—Instrument Shops—Measurement Engineering—Electronic Technology—Technical Analysis.

THE CENTER FOR RADIATION RESEARCH engages in research, measurement, and application of radiation to the solution of Bureau mission problems and the problems of other agencies and institutions. The Center consists of the following divisions:

Reactor Radiation-Linac Radiation-Nuclear Radiation-Applied Radiation.

THE CENTER FOR COMPUTER SCIENCES AND TECHNOLOGY conducts research and provides technical services designed to aid Government agencies in the selection, acquisition, and effective use of automatic data processing equipment; and serves as the principal focus for the development of Federal standards for automatic data processing equipment, techniques, and computer languages. The Center consists of the following offices and divisions:

Information Processing Standards—Computer Information — Computer Services — Systems Development—Information Processing Technology.

THE OFFICE FOR INFORMATION PROGRAMS promotes optimum dissemination and accessibility of scientific information generated within NBS and other agencies of the Federal government; promotes the development of the National Standard Reference Data System and a system of information analysis centers dealing with the broader aspects of the National Measurement System, and provides appropriate services to ensure that the NBS staff has optimum accessibility to the scientific information of the world. The Office consists of the following organizational units:

Office of Standard Reference Data—Clearinghouse for Federal Scientifie and Technical Information "—Office of Technical Information and Publications—Library—Office of Public Information—Office of International Relations.

(Abstract)

#### CRYSTALLINE DIMETHACRYLATE MONOMERS

Certain dimethacrylate monomers can be prepared and purified by recrystallization. Upon mixing, the crystals liquify by forming a ternary eutectic. The colorless oily liquid is suitable for use in composite formulations.

\*

Previously, BIS-GMA<sup>1</sup> (a dimethacrylate monomer, the reaction product of an epoxy resin and methacrylic acid or of 4,4'isopropylidenediphenol and glycidyl methacrylate)<sup>2</sup> was developed for use as a binder for reinforcing fillers. This dimethacrylate monomer, shown in Figure 1, has had widespread use in current commercial dental composite restorative materials. However, BIS-GMA is not completely color-stable and is too viscous for use without being thinned with methyl methacrylate or other comonomers of low viscosity. Furthermore, it cannot be purified by distillation or by crystallization since it is a mixture of high-molecular-weight optical isomers.

This report describes the synthesis and properties of three dimethacrylate monomers that were synthesized in order to reduce the viscosity, improve the color and storage stability and possibly other properties associated with the resin that forms the binder of composite restorative materials. The monomers, with melting points slightly above room temperature, form a liquid when combined in

- 1 -

ternary eutectic proportions. Their purification by recrystallization provides a means of attaining desired purity and of facilitating production control.

This paper does not deal with properties of the polymer or composite materials prepared from these monomers. It encompasses only the synthesis of the monomers and the formulation of a liquid ectectic monomer based on them.

#### Materials and Methods\*

The three monomers, bis(2-methacryloxyethyl)isophthalate, (MEI); bis(2-methacryloxyethyl)terephthalate, (MET), and bis(2-methacryloxyethyl)phthalate (MEP) were condensation products of 2-hydroxyethyl methacrylate (HEMA) and the corresponding acid chlorides of the phthalic acid position isomers. Most of the compounds that were used are listed in Table 1. They were used as received.

\*Certain commercial materials and equipment are identified in this paper to specify adequately the experimental procedure. In no instance does such identification imply recommendation or endorsement by the National Bureau of Standards or that the material or equipment identified is necessarily the best available for the purpose.

- 2 -

SYNTHESIS OF MEI. ---- The synthesis was carried out in a three-neck round-bottom flask placed in a cooling bath, equipped with stirrer, thermometer, dried nitrogen inlet, and a dropping funnel. BHT (butylated hydroxytoluene; 2,6-di-t-butyl-4-methyl phenol) and di-t-butyl sulfide. each equivalent to 0.1% of the theoretical vield of monomer were placed in the flask. To this was added 194 ml of pyridine (2.4 mols) and 305 ml of HEMA (2.4 mols) with stirring. Dried nitrogen was used as the reaction atmosphere and the cooling bath maintained the temperature within the range of 10-35°C throughout the reaction. Isophthaloyl chloride (203 gm; 1 mol), dissolved in 112 gm of acetone, was added dropwise to the stirred reagents in the reaction vessel. As the reaction proceeded, a white precipitate (pyridinium chloride) formed. The acid chloride solution was added over a four-hour period. The mixture after standing overnight without stirring was vacuum filtered to remove crystals of pyridinium chloride. The residue on the filter was rinsed with additional acetone and then discarded.

- 3 -

A clear yellow filtrate containing the monomer product was obtained.\*

The filtrate was diluted with 300 ml of chloroform and washed three times in a separatory funnel using 500 ml of distilled water for each wash. The resin phase was evaporated down under vacuum to remove chloroform and water to approximately constant weight. A yellow liquid with a refractive index of  $n_D^{23.5^{\circ}C} =$ 1.5087 was obtained. The yield of this impure monomer was slightly over 90% of the theoretical. To this was added additional BHT and di-<u>t</u>-butyl sulfide (0.1% of each). The monomer was diluted with an equal volume of methanol and then cooled, with stirring, to a low temperature utilizing a dry ice bath. At a low temperature (about -20°C) the crystals formed spontaneously

\* It might be possible to crystallize the monomer directly from this acetone solution by stirring and cooling it to a low temperature (e.g. -20°C or below) with the aid of a dry-ice (solid carbon dioxide) bath, although this was not attempted.

- 4 -

and developed rapidly. This slurry of crystalline monomer was then suction filtered, the crystals of monomer being retained on the filter paper.\*

The crystals obtained were redissolved in warm methanol and recrystallized three times.

SYNTHESIS OF MET. — This compound was synthesized in essentially the same manner as MEI, with the following exceptions. Since the terephthaloyl chloride is less soluble in acetone, a larger quantity of acetone was required as a solvent and the mixture was warmed slightly.

SYNTHESIS OF MEP. — This monomer was synthesized in essentially the same manner as were MEI and MET, with the exception that no acetone was used in the synthesis since the phthaloyl chloride is liquid at room temperature and could therefore be added dropwise to the reaction flask.

\* The filtrate can then be concentrated and cooled again to obtain additional crystalline monomer and this process repeated to obtain maximum yield of crystalline product.

- 5 -

DETERMINATION OF EUTECTIC COMPOSITION. — After the individual melting points of the three recrystallized monomers had been determined, the mixed melting point (first sign of melting) was determined for the binary systems MEI-MET, MEI-MEP and MET-MEP. The proportions of the binary eutectics were calculated from the theoretical<sup>3</sup> relationship:  $X_1 = \frac{100(T_2-Te)}{T_1+T_2-2Te}$  where  $X_1$  is the melting point of the lower-melting component,  $T_2$  is the melting point of the higher-melting component, and Te is the eutectic temperature (first sign of melting of the mixture).

The three binary diagrams were then incorporated into a triangular ternary diagram to help predict the composition of the ternary eutectic. The approximate ternary eutectic composition was determined by trial and error,<sup>3</sup> starting from the composition corresponding to the intersection of the lines normal to the sides of the triangle at the theoretical binary eutectic compositions.

Stabilizers and a polymerization accelerator<sup>4-8</sup> as given in Table 2 were added to the approximate ternary eutectic mixture. This formulation (Table 2) was sent to an independent commercial laboratory for preliminary toxicity evaluation.

#### Results

After the MEI was recrystallized three times from methanol, it was a colorless white solid having a melting point of 42.3-43.3°C. After melting, the metastable liquid had a refractive index of  $n_D^{22.4°C} = 1.5116$ .

After the MET was recrystallized four times as previously described, the white crystalline monomer had a melting point of 50-53°C, and the refractive index of the metastable liquid (measured immediately after melting) was  $n_D^{22.3°C} = 1.5135$ . The yield after t the first crystallization was greater than 55%.

After four recrystallizations, the colorless white crystals of MEP had a melting point of 39-40°C and the refractive index of the metastable liquid •

(measured immediately after melting of some of these crystals) was  $n_D^{22.3^{\circ}C} = 1.5095$ . The yield was approximately 80% of theoretical at the time of the first crystallization.

The following data are only theoretical for the binary and approximate for the ternary systems but are presented since they might be useful in practical applications. Binary eutectics:

> 36% MET - 64% MEI, 31°C 45% MEI - 55% MEP, 26°C 68% MEP - 32% MET, 29.5°C

Ternary eutectic:

47% MEI, 38% MEP, and 15% MET, (∠23°C) This ternary mixture is a colorless oily liquid at room temperature; it solidified under refrigeration (about 5°C).

TOXICITY. — The summaries of the toxicity results (on the formulation given in Table 2) are as follows: The monomer formulation was evaluated for acute oral toxicity by gastric intubation to groups of two adult male albino

rats at graded dosage levels of 1.0, 3.16, 10.0, and 31.6 ml/kg of body weight. The acute oral mediam lethal dose of the material for albino rats was 31.6 ml/kg of body weight; therefore, it is considered to be relatively harmless by the oral route.

The test material was also evaluated for acute eye irritation by a single application of 0.1 ml of the test material into one eye of each of three albino rabbits. No irritation was produced in one eye, and only slight conjuctival redness was produced in two eyes which subsided by 72 hours or day 4. The test material is considered to be essentially nonirritating to rabbit eyes.

#### Discussion

A considerable advantage of the ternary eutectic mixture prepared from the three dimethacrylate crystalline monomers as a binder for seinforcing fillers lies in the fact that its viscosity permits its use without the addition of thinners or diluents which may contribute undesirable properties. Having molecular weights of 390, the monomers of the liquid are nonvolatile and require no volatile additives. Their structural formulas are shown in Figure 2. Compared

- 9 -

with BIS-GMA it is reasonable to expect that the introduction of electron-withdrawing substituents into the aromatic ring will result in improved resistance to oxidation and subsequent color formation. Electron-withdrawing substituents deactivate aromatic nuclei thereby diminishing oxidation. Electron-donors, such as the alkyl and ether groups on the BIS-GMA rings, have the opposite effect.

Information on MEI was not found in the literature. A compound corresponding to MEP has been described.<sup>9</sup> The acidcatalyzed condensation product of methacrylic acid, ethylene glycol, and phthalic acid, and of ethylene glycol monomethacrylate and phthalic anhydride was reported.<sup>10, 11</sup> Both were reported to have  $n_D^{20} = 1.500$  and  $D_4^{20} = 1.18$ ; no mention was made of crystallization.

Crystalline products melting between 30 and 53°C have been reported to result from the reaction of bis- $\beta$ -hydroxyethyl terephthalate with the acid chloride of methacrylic acid.<sup>12</sup>

A correction of a previous report<sup>13</sup> should be made. It was stated that a liquid mixture of MEI and MET did not crystallize on standing at room temperature. This binary •

mixture did crystallize at a later date, having been metastable for a considerable period of time.

Although the work reported here is part of a larger program encompassing the development of an esthetic adhesive restorative material,<sup>14</sup> there is no reason to believe that the monomer system reported here has adhesive characteristics. To obtain adhesion, appropriate coupling agents that have been referred to previously,<sup>14</sup> are indicated.

Properties of composite materials utilizing the formulation given in Table 2, are being investigated.

#### Conclusions

Improved purity of nonvolatile monomers can be achieved readily when the molecular characteristics are such as to facilitate recrystallization. The bis(2-methacryloxyethyl) esters of phthalic, isophthalic and terephthalic acids have melting points. slightly above room temperature and they form a ternary eutectic mixture

i

that is liquid at room temperature. This colorless slightly viscous liquid appears to be suitable for formulation as the binder for composite materials for use in industry and in dentistry.
