THE CALCIUM SULFATE–WATER SYSTEM
1. DIFFERENTIAL THERMAL ANALYSIS AND PREPARATIVE STUDIES
The National Bureau of Standards was established by an act of Congress March 3, 1901. Today, in addition to serving as the Nation's central measurement laboratory, the Bureau is a principal focal point in the Federal Government for assuring maximum application of the physical and engineering sciences to the advancement of technology in industry and commerce. To this end the Bureau conducts research and provides central national services in four broad program areas. These are: (1) basic measurements and standards, (2) materials measurements and standards, (3) technological measurements and standards, and (4) transfer of technology.

The Bureau comprises the Institute for Basic Standards, the Institute for Materials Research, the Institute for Applied Technology, the Center for Radiation Research, the Center for Computer Sciences and Technology, and the Office for Information Programs.

THE INSTITUTE FOR BASIC STANDARDS provides the central basis within the United States of a complete and consistent system of physical measurement; coordinates that system with measurement systems of other nations; and furnishes essential services leading to accurate and uniform physical measurements throughout the Nation's scientific community, industry, and commerce. The Institute consists of an Office of Measurement Services and the following technical divisions:

THE INSTITUTE FOR MATERIALS RESEARCH conducts materials research leading to improved methods of measurement standards, and data on the properties of well-characterized materials needed by industry, commerce, educational institutions, and Government; develops, produces, and distributes standard reference materials; relates the physical and chemical properties of materials to their behavior and their interaction with their environments; and provides advisory and research services to other Government agencies. The Institute consists of an Office of Standard Reference Materials and the following divisions:

THE INSTITUTE FOR APPLIED TECHNOLOGY provides technical services to promote the use of available technology and to facilitate technological innovation in industry and Government; cooperates with public and private organizations in the development of technological standards, and test methodologies; and provides advisory and research services for Federal, state, and local government agencies. The Institute consists of the following technical divisions and offices:

THE CENTER FOR RADIATION RESEARCH engages in research, measurement, and application of radiation to the solution of Bureau mission problems and the problems of other agencies and institutions. The Center consists of the following divisions:

THE CENTER FOR COMPUTER SCIENCES AND TECHNOLOGY conducts research and provides technical services designed to aid Government agencies in the selection, acquisition, and effective use of automatic data processing equipment; and serves as the principal focus for the development of Federal standards for automatic data processing equipment, techniques, and computer languages. The Center consists of the following offices and divisions:

THE OFFICE FOR INFORMATION PROGRAMS promotes optimum dissemination and accessibility of scientific information generated within NBS and other agencies of the Federal government; promotes the development of the National Standard Reference Data System and a system of information analysis centers dealing with the broader aspects of the National Measurement System, and provides appropriate services to ensure that the NBS staff has optimum accessibility to the scientific information of the world. The Office consists of the following organizational units:

THE CALCIUM SULFATE–WATER SYSTEM
1. DIFFERENTIAL THERMAL ANALYSIS AND PREPARATIVE STUDIES

IMPORTANT NOTICE

Approved for public release by the director of the National Institute of Standards and Technology (NIST) on October 9, 2015

U.S. DEPARTMENT OF COMMERCE
NATIONAL BUREAU OF STANDARDS
This is the first in a series of reports on the properties of the products formed in the calcium sulfate-water system, which is part of our overall study of the properties of gypsum plaster.

Existence of two forms of calcium sulfate hemihydrate is suggested by differential thermal analysis studies. The \( \alpha \)-form can be prepared by crystallization methods whereas the \( \beta \)-form is prepared by the dehydration of calcium sulfate, either in air or in vacuo. Some preparative methods resulted in impure products.

The peak temperatures of the endothermic curves of CaSO\(_4\) \( \cdot \)2H\(_2\)O, \( \alpha \)- and \( \beta \)-CaSO\(_4\) \( \cdot \)1/2H\(_2\)O and the exothermic curve of \( \alpha \)-CaSO\(_4\) \( \cdot \)1/2H\(_2\)O are pressure dependent, shifting to lower temperatures as the gaseous pressure within the DTA cell is decreased. This phenomenon can be explained on the basis of the van't Hoff equation.

1. INTRODUCTION

In the CaSO\(_4\) \( \cdot \)nH\(_2\)O system (designates number of H\(_2\)O molecules) three kinds of products are generally recognized with \( n = 2, 1/2 \) and 0. The existence of two forms of CaSO\(_4\) \( \cdot \)1/2H\(_2\)O, \( \alpha \) and \( \beta \), however, has not been firmly established. Apparent slight differences in densities [1] \(^1/\), heat of formations [2] and differential thermal analysis curves [3] have been cited as evidence for the existence of two forms. Gay [4] reported that the similarity in the x-ray diffraction patterns of the two supposed forms, however, suggests the lack of polymorphism.

There are conflicting interpretations of the binding of water in the hemi-hydrate (\( n = 1/2 \)). Some investigators believe that the water is zeolitic and, therefore, moves freely through the lattice (in which case \( n \) can have varying values), while others contend that the water occupies energetically favorable lattice sites [4].

\(^1/\) Numbers in brackets refer to references given at the end of this report.
It is surprising that the properties of \( \text{CaSO}_4 \cdot \frac{1}{2}\text{H}_2\text{O} \) have not been better characterized, since the \( \text{CaSO}_4 \cdot n\text{H}_2\text{O} \) system has been the subject of numerous studies. This can possibly be attributed to both the study of impure products, which will be explored in the present work, and the limited scope of previous studies.

The purpose of the present work is to characterize well some preparative methods and the properties of \( \text{CaSO}_4 \cdot \frac{1}{2}\text{H}_2\text{O} \), and to ascertain if two forms exist. If two forms are found to exist the preparation of two forms of gypsum \((n = 2)\) will be undertaken by allowing \( \alpha \)-and \( \beta \)-\( \text{CaSO}_4 \cdot \frac{1}{2}\text{H}_2\text{O} \) to hydrate under controlled conditions.

Results of preparative studies of the supposed \( \alpha \)-and \( \beta \)-forms of \( \text{CaSO}_4 \cdot \frac{1}{2}\text{H}_2\text{O} \), along with the differential thermal analysis curves (hereafter termed DTA curves) of the products, are presented and interpreted in this report. Throughout this and future reports the unqualified use of the \( \alpha \) and \( \beta \) terminology does not imply that the existence of two forms of \( \text{CaSO}_4 \cdot \frac{1}{2}\text{H}_2\text{O} \) has been proven.

2. EXPERIMENTAL

2.1 DTA Methods

The DTA curves were recorded using a DuPont Model 900 DTA instrument equipped with a micro-sample standard cell. The reference material was anhydrous \( \text{Al}_2\text{O}_3 \) (Baker and Adamson Reagent Grade) heated to 400°C for an hour and stored in a vacuum desiccator over phosphorus (v) oxide until used. Gaseous pressures within the DTA cell were measured with the gauge accompanying the instrument, and are not claimed to be highly accurate, possibly varying by \( \pm 8\% \). Temperature measurements were made using chromel alumel thermocouples, with a reference junction temperature of 0°C, and are accurate to \( \pm 5\% \). The ultimate vacuum of the system was estimated to reduce the residual pressure in the DTA cell to about 1 Torr.
Evaluation of atmospheric conditions within the specimen compartment was complicated by the furnace and sample housing arrangement of the DTA cell. Samples were loaded into small Pyrex glass tubes, which were closed at one end and the thermocouple wires were inserted into the tubes above the sample, with the thermocouple joint being embedded in the sample. The thermocouple wires fitted tightly in the tube, thereby hindering the diffusion of water vapor from samples and increasing the partial pressure of water vapor in the specimen tube above that in the bulk atmosphere. Furthermore, allowing nitrogen gas to flow into the DTA cell probably did not produce dynamic conditions within the specimen tubes, as the nitrogen gas was prevented by the tight fit to be an effective purging agent. For the same reasons, in studies carried out with reduced pressures the water vapor pressures within sample tubes were probably much greater than the bulk residual pressures.

2.2 Materials
The CaSO$_4$·2H$_2$O (Baker and Adamson Reagent Grade) used in this study was found, by dehydration at 375°C, to contain the stoichiometric percentage of water (theoretical 20.9%, found 21.0%). All other chemicals used in this study were of reagent grade.

2.3 Preparation of CaSO$_4$·1/2H$_2$O

2.3.1 $\gamma$-CaSO$_4$·1/2H$_2$O
$\gamma$-CaSO$_4$·1/2H$_2$O was prepared from CaSO$_4$·2H$_2$O by two dehydration methods. In one method samples of CaSO$_4$·2H$_2$O were dehydrated in an air oven at 150 to 175°C for 3 to 12 hours. Then $\gamma$-CaSO$_4$ was allowed to equilibrate with 50% laboratory air at room temperature. This resulted in the uptake of water with the final product having slightly more than the stoichiometric amount of H$_2$O, as n ranged from 0.54 to 0.57. An alternate method was the removal of 1 1/2 molecules of H$_2$O from

2/ Bulk atmosphere denotes the average atmosphere within the DTA cell.
CaSO_4·2H_2O by vacuum line techniques, at 100°C. The product was then annealed for 60 hours by heating at 100°C in a closed system. This preparative method was also carried out at temperatures of 50, 75 and 100°C with the annealing process being eliminated.

2.3.2 \( \alpha \)-CaSO_4·1/2H_2O

\( \alpha \)-CaSO_4·1/2H_2O was prepared by modifying the method of Weiser and Milligan [5]. Mixed together were 210 ml of 16.3 M HNO_3, 3 ml of 18 M H_2SO_4 and 60 ml of distilled H_2O. Added slowly to this mixture was a solution of 45.3 g of Ca(NO_3)_2·4H_2O dissolved in 100 ml of distilled H_2O. The final solution was transferred to a glass-stoppered glass-chemical-bottle and heated at 50°C in an air oven. A white precipitate formed after about three hours and was allowed to age for 14 days. Then, the precipitate was separated from the supernatant liquid by decanting the liquid. The solid product was washed four times with about 50 ml of absolute ethanol, pressed between filter paper, and finally air dried. The white product contained the stoichiometric amount of H_2O (theoretical 6.62%, found 6.68%) and gave the DTA curve ascribed to \( \alpha \)-CaSO_4·1/2H_2O [3]. The effects of changing both the aging time and aging temperature were studied. In one run the aging temperature was increased to 70°C and the aging time was kept at 14 days. While in another study the product was separated from the supernatant liquid after an aging time of 4 hours at 50°C.

2.4 Dehydration Process of CaSO_4·2H_2O with External Water Vapor

Known amounts of CaSO_4·2H_2O (between 0.0419 g, 0.243 millimoles, and 0.166 g, 0.963 millimoles) were transferred to pyrex reaction tubes. The pyrex reaction tubes were sealed at one end and had a standard tapered joint at the opposite end for attachment to the vacuum line. Their volumes were about 100 cm³. A quantity of distilled H_2O calculated to give a desired gaseous water pressure at 165°C was
transferred to the reaction tubes containing CaSO₄·2H₂O. The reaction tubes were connected, through a closed stopcock, to the vacuum line, the tubes were cooled with liquid nitrogen, and deaerated by opening the stopcock. While exposed to the vacuum system the reaction tubes were sealed using an oxygen torch. Sealed tubes were placed in an air oven, 165°C, for heating periods of either 66 hours or 19 days. After the tubes had cooled to room temperature, the uncombined water was separated from the product by condensing it in the opposite end of the tubes. The tubes were then opened and the white products were air-dried.

3. RESULTS

3.1 DTA Curves of CaSO₄·2H₂O
The differential thermograms of CaSO₄·2H₂O, with several different bulk atmospheric conditions in the DTA cell, are reproduced in Figures 1 and 2. A decrease in the peak temperatures, T<sub>peaks</sub>, of the two endothermic peaks was observed when the gaseous pressure in the cell was reduced and when the residual pressure approached 1 Torr the second endothermic peak had shifted sufficiently to merge with the first peak. Peak temperatures are listed in Table 1. Peak temperature is the temperature of the maximum point in an exothermic curve or the minimum point in an endothermic curve and is used in this report since the merging tendency of the two peaks makes the estimation of the incipient temperatures difficult. DTA curves obtained under static conditions of nitrogen flow were similar to those observed with supposed dynamic nitrogen flow.

3.2 DTA Curves of f-CaSO₄·1/2H₂O
In Figures 3 and 4 are reproduced the DTA curves of f-CaSO₄·1/2H₂O recorded, respectively, with a dynamic N₂ atmosphere and a small residual pressure (ca. 1 Torr) in the DTA cell. The endothermic peak has the same temperature-pressure behavior (Table 2) as previously noted for the second endothermic curve of CaSO₄·2H₂O. The position and shape of the small exothermic peak, T<sub>peak</sub> = 375°C, was not affected by changes in the atmospheric conditions in the DTA cell.
3.3 DTA Curves of $\alpha$-CaSO$_4 \cdot 1/2$H$_2$O
The DTA curve of $\alpha$-CaSO$_4 \cdot 1/2$H$_2$O, with a N$_2$ atmosphere in the DTA cell is shown in Figure 5. Results of pressure dependence studies on the shape and position of the curves are reproduced in Figure 6 and $T_{\text{peak}}$ are listed in Table 2. The position of the endothermic peak of $\alpha$-CaSO$_4 \cdot 1/2$H$_2$O shifts to lower temperatures with reductions in the gaseous pressure in the DTA cell. The small exothermic peak, also, has the same temperature-pressure behavior.

3.4 DTA Curve of Mixture of $\alpha$- and $\beta$-CaSO$_4 \cdot 1/2$H$_2$O
The DTA curve of an equal molar mixture of $\alpha$- and $\beta$-CaSO$_4 \cdot 1/2$H$_2$O includes the small exothermic peak of the respective components (Fig. 7), which indicates that this method can be used to identify the two forms in the presence of each other.

3.5 Preparation of $\beta$-CaSO$_4 \cdot 1/2$H$_2$O
A simple and reproducible preparative method for $\beta$-CaSO$_4 \cdot 1/2$H$_2$O was the complete dehydration of CaSO$_4 \cdot 2$H$_2$O, at 150° to 175°C, and the subsequent rehydration of $\gamma$-CaSO$_4$ to $\beta$-CaSO$_4 \cdot 1/2$H$_2$O at room temperature at 50% R.H. This method resulted in a product containing slightly more than the stoichiometric amount of water with $n$ ranging from 0.54 to 0.57. It was not practical to remove the stoichiometric amount of H$_2$O from CaSO$_4 \cdot 2$H$_2$O to directly form $\beta$-CaSO$_4 \cdot 1/2$H$_2$O by this method.

An alternate method was the removal, by vacuum line techniques, of the stoichiometric amount of H$_2$O from CaSO$_4 \cdot 2$H$_2$O to directly form $\beta$-CaSO$_4 \cdot 1/2$H$_2$O. This method was studied using dehydration temperatures of 50, 75 and 100°C, with and without annealing the product. DTA curves of the products are represented in Figure 8. Products were found to be impure, containing CaSO$_4 \cdot 2$H$_2$O, $\gamma$-CaSO$_4$ as well as $\beta$-CaSO$_4 \cdot 1/2$H$_2$O. The DTA curve of the unannealed product formed by dehydration at 50°C has a strange endothermic peak with a $T_{\text{peak}}$ of 120°C, the origin of which is unknown.
3.6 Preparation of $\alpha$-CaSO$_4 \cdot 1/2$H$_2$O

Increasing the aging temperature had an inverse effect on the yield of $\alpha$-CaSO$_4 \cdot 1/2$H$_2$O. The yield was estimated to be four-fold greater with an aging temperature of 50°C as compared with 70°C.

An aging time of 14 days at 50°C resulted in a pure product, according to the DTA analysis. Shortening the aging time to 4 hours at 50°C, did result in a product that was slightly impure as indicated by the indentation at about 155°C in the DTA curve, Figure 9. This impurity, possibly, could be occluded CaSO$_4 \cdot 2$H$_2$O.

3.7 Studies of the Dehydration of CaSO$_4 \cdot 2$H$_2$O in Reaction Tubes

In a typical study, a reaction tube containing 0.243 millimoles of CaSO$_4 \cdot 2$H$_2$O was heated at 165°C for 66 hours with an internal water vapor pressure of 730 Torr. Thermograms were recorded on the same day the sample was removed from the reaction tube and at 4, 5, 6 and 40 days. A wide endothermic curve with $T_{\text{peak}}$ of 320°C was initially observed (Figure 10). During exposure to laboratory air at 50% R.H. the $T_{\text{peak}}$ of the curve increased and its width decreased until after 40 days the curve had disappeared. TGA studies (to be discussed in a later report) indicated that the endothermic reaction was not accompanied by a weight loss and, therefore, must be associated with a phase transition. Other studies conducted with different gaseous water pressures, 375 to 1520 Torr, and heating times, 19 days, gave similar results.

4. DISCUSSION

4.1 DTA Curves of CaSO$_4 \cdot n$H$_2$O

4.1.1 Nitrogen Gas at 760 Torr in DTA Cell

The differential thermogram of CaSO$_4 \cdot 2$H$_2$O, recorded with a nitrogen atmosphere in the DTA cell (Figure 1) can be understood on the basis of three transformation steps with peak temperatures of 150, 197 and 380°C:
(1) \( \text{CaSO}_4 \cdot 2\text{H}_2\text{O} (s) \xrightarrow{150^\circ\text{C}} \beta\text{-CaSO}_4 \cdot 1/2\text{H}_2\text{O} (s) + 3/2\text{H}_2\text{O} (v) \)

(2) \( \beta\text{-CaSO}_4 \cdot 1/2\text{H}_2\text{O} (s) \xrightarrow{197^\circ\text{C}} \gamma\text{-CaSO}_4 (s) + 1/2\text{H}_2\text{O} (v) \)

(3) \( \gamma\text{-CaSO}_4 (s) \xrightarrow{380^\circ\text{C}} \beta\text{-CaSO}_4 (s) \).

Steps (1) and (2) are dehydration processes and, consequently, result in endothermic curves, while step (3) is exothermic and is attributed to a lattice modification. The above assignments infer that reaction (1) is completed before reaction (2) commences, however, some overlapping does take place. The extent of overlapping is smaller in the present study, probably because of using micro samples, than previously reported [6].

The solid product formed in reaction step (1) is presumed to be \( \beta\text{-CaSO}_4 \cdot 1/2\text{H}_2\text{O} \) since the curves of steps (2) and (3) are identical to those observed in the differential thermogram of pure \( \beta\text{-CaSO}_4 \cdot 1/2\text{H}_2\text{O} \) (Figure 3). Furthermore, pure \( \beta\text{-CaSO}_4 \cdot 1/2\text{H}_2\text{O} \) can be prepared by removal of the stoichiometric amount of \( \text{H}_2\text{O} \) from \( \text{CaSO}_4 \cdot 2\text{H}_2\text{O} \), if followed by an annealing treatment. The necessity of the annealing treatment does, however, suggest a more complicated reaction sequence could be taking place than the scheme outlined by steps (1) and (2).

The endothermic curve in the differential thermogram of \( \alpha\text{-CaSO}_4 \cdot 1/2\text{H}_2\text{O} \) (Figure 5) has the same shape and \( T_{\text{peak}} \) as the endothermic curve of \( \beta\text{-CaSO}_4 \cdot 1/2\text{H}_2\text{O} \). The endothermic curve of \( \alpha\text{-CaSO}_4 \cdot 1/2\text{H}_2\text{O} \), however, is closely followed by an exothermic curve with \( T_{\text{peak}} \) of 217°C. Another difference is the lack of the exothermic curve of \( \beta\text{-CaSO}_4 \cdot 1/2\text{H}_2\text{O} \) with \( T_{\text{peak}} = 380^\circ\text{C} \), in the thermogram of \( \alpha\text{-CaSO}_4 \cdot 1/2\text{H}_2\text{O} \). From the basis of DTA studies, however, no definite conclusions on structural differences between the two forms can be made.
4.1.2 Reduced Atmospheric Pressure in the DTA Cell

The effect of decreasing the bulk atmospheric pressure in the DTA cell on the differential thermograms of CaSO$_4 \cdot$2H$_2$O, and $\alpha$- and $\beta$-CaSO$_4 \cdot$1/2H$_2$O is discussed in this section. It is instructive to first examine the thermogram of CaSO$_4 \cdot$2H$_2$O and then compare the thermograms of $\alpha$- and $\beta$-CaSO$_4 \cdot$1/2H$_2$O.

Substantial decreases of the bulk atmospheric pressure within the DTA cell were found to significantly perturb the DTA curves of CaSO$_4 \cdot$2H$_2$O. Results of this study are presented in Table 1 and Figure 2. $T_{\text{peak}}$ of the first endothermic curve (CaSO$_4 \cdot$2H$_2$O(s) $\rightarrow$ $\beta$-CaSO$_4 \cdot$1/2H$_2$O(s) + H$_2$O(v)) was shifted from 150°C to 123°C when the bulk pressure was reduced from 760 Torr to near 1 Torr. $T_{\text{peak}}$ of the second endothermic curve ( $\beta$-CaSO$_4 \cdot$1/2H$_2$O(s) $\rightarrow$ $\gamma$-CaSO$_4$(s) + 1/2H$_2$O(v)) was shifted even more, being 197°C at 760 Torr and merging with the first endothermic curve when the bulk residual pressure approached 1 Torr. The position of the exothermic curve, attributed to the phase transformation of $\gamma$-CaSO$_4$ to $\beta$-CaSO$_4$, was not pressure dependent.

The mergence of the two endothermic curves of CaSO$_4 \cdot$2H$_2$O at bulk residual pressures approaching 1 Torr, is an interesting phenomenon that may be accounted for by several proposed mechanisms. According to one mechanism, two separate dehydration reactions are taking place when appreciable water vapor is in contact with the sample. Dehydration in vacuo, however, leads directly to the formation of $\gamma$-CaSO$_4$ and $\beta$-CaSO$_4 \cdot$1/2H$_2$O is not an intermediate product [7,8]. However, this is inconsistent with the findings of the present investigation that removal of 3/2 molecules of water from CaSO$_4 \cdot$2H$_2$O in vacuo yields an impure product, which is largely $\beta$-CaSO$_4 \cdot$1/2H$_2$O. Furthermore, for the reasons previously stated in the experimental section of this report, although the bulk residual pressure in the DTA cell may be near 1 Torr, the water vapor pressure in contact with the sample is probably much higher.
A more firm explanation for the merging of the two endothermic curves is based on the van't Hoff equation

\[
\frac{d\ln P}{dt} = \frac{\Delta H}{RT^2},
\]

In this equation \(\Delta H\) is the heat of reaction at temperature \(T\), and therefore is not a constant. The standard heat of reaction, \(\Delta H_0\), is introduced by using the Kirchoff equation

\[
\frac{\Delta H}{T} = \Delta C_p \frac{dT}{T},
\]

thus

\[\Delta H = \Delta H_0 + \int_{T_1}^{T_2} \Delta C_p \, dt\]

and

\[
\frac{d\ln P}{dt} = \frac{\Delta H_0}{RT^2} + \frac{1}{RT^2} \int_{T_1}^{T_2} \Delta C_p \, dt.
\]

The change in \(\Delta C_p\) with \(dT\) is small in the temperature interval encountered in the present case so the mean value, \(\Delta C_p\), is used. Then the integrated form of the above equation becomes

\[
\ln \frac{P_2}{P_1} = -\frac{\Delta H_0}{R} \left( \frac{1}{T_2} - \frac{1}{T_1} \right) + \frac{\Delta C_p}{R} \ln \frac{T_2}{T_1}.
\]

The pressure decrease necessary to shift \(T_{peak}\) of the second endothermic curve in the thermogram of \(\text{CaSO}_4 \cdot 2\text{H}_2\text{O}\) from 197°C to 123°C can now be estimated by setting \(T = T_{peak}\) and using the values of \(\Delta H_0\) and \(\Delta C_p\) reported by Kelley, Southard and Anderson [2] for the reaction

\[
\beta-\text{CaSO}_4 \cdot \frac{1}{2}\text{H}_2\text{O}(s) \rightarrow \gamma-\text{CaSO}_4(s) + \frac{1}{2}\text{H}_2\text{O}(v).
\]

The calculated value

\[\frac{P_2}{P_1} = 0.25\]

means a four fold decrease in the partial pressure of water vapor within the specimen tube can account for the shift in \(T_{peak}\) observed when the
bulk pressure is decreased from 760 Torr to about 1 Torr. This calculated value can be considered only as an approximation to the actual situation within the specimen tube because of the non-rigorous treatment.

According to the present interpretation, a two step dehydration process is still taking place in vacuo, but is obscured by the overlapping of the two endothermic curves of CaSO$_4$·2H$_2$O. The previously cited findings that $\beta$-CaSO$_4$·1/2H$_2$O is formed (among other products) from the dehydration in vacuo of CaSO$_4$·2H$_2$O, is in agreement with this interpretation.

The endothermic curves of both $\alpha$- and $\beta$-CaSO$_4$·1/2H$_2$O have similar $T_{\text{peak}}$ dependence on pressure (Table 2 and Figures 4 and 6) as the second endothermic curve of CaSO$_4$·2H$_2$O. Values of $T_{\text{peak}}$ for these curves obtained with the same pressure conditions vary, primarily, because of differences in packing characteristics.

It is surprising that the location of an exotherm attributed to a lattice change would be significantly perturbed by changes in the bulk pressure, as observed for the exothermic curve of $\alpha$-CaSO$_4$·1/2H$_2$O. Obviously, the location of this exotherm is not directly pressure dependent but apparently is determined by the degree of completion of the preceding dehydration process. When the dehydration reaction of $\alpha$-CaSO$_4$·1/2H$_2$O has reached a certain stage a thermodynamic unstable lattice structure is possibly produced which rearranges to a more stable form, giving an exothermic DTA curve.

4.2 Formation of $\alpha$- and $\beta$-CaSO$_4$·1/2H$_2$O

The present study appears to confirm the mechanisms proposed by Kuntze [9] to account for the formation of $\alpha$- and $\beta$-CaSO$_4$·1/2H$_2$O. According to his proposals, $\alpha$-CaSO$_4$·1/2H$_2$O is formed by methods involving crystallization such as precipitation from solution or autoclaving, while $\beta$-CaSO$_4$·1/2H$_2$O is formed by dehydrations methods independent of the ambient water vapor pressure.
McAdie [10] has suggested that the designations "\(\alpha\)" and "\(\beta\)" represent the terminals of a \(\text{CaSO}_4 \cdot 1/2\text{H}_2\text{O}\) series and a product would have properties of both proportional to the percentage of terminal present. By DTA techniques the presence of both forms can be identified in an artificial mixture as shown in Figure 7. It is interesting, therefore, that the DTA curves of products formed by the dehydration, in vacuo and at atmospheric pressure, of \(\text{CaSO}_4 \cdot 2\text{H}_2\text{O}\) clearly indicates lack of \(\alpha\)-\(\text{CaSO}_4 \cdot 1/2\text{H}_2\text{O}\). Although the results of the present study are inconclusive with regards to this matter, they do point to the need for further study of the \(\alpha\)- and \(\beta\)-terminal concept.

The preparation of \(\beta\)-\(\text{CaSO}_4 \cdot 1/2\text{H}_2\text{O}\) carried out by dehydrating \(\text{CaSO}_4 \cdot 2\text{H}_2\text{O}\) to anhydrous \(\gamma\)-\(\text{CaSO}_4\) which was then allowed to rehydrate at room temperature in laboratory air resulted in a product containing slightly more than the stoichiometric amount of \(\text{H}_2\text{O}\). Theoretically, \(n\) (where \(n\) is the number of \(\text{H}_2\text{O}\) molecules per molecule of \(\text{CaSO}_4\)) should be 0.50, but was found to range from 0.54 to 0.57. The extra quantity of \(\text{H}_2\text{O}\), possibly, can have zeolitic character, while the larger portion is lattice water. This interpretation agrees with the finding of Saito [11] that NMR studies suggests two forms of \(\text{H}_2\text{O}\) exist in \(\text{CaSO}_4 \cdot 1/2\text{H}_2\text{O}\), one which is zeolitic \(\text{H}_2\text{O}\).

4.3 Dehydration of \(\text{CaSO}_4 \cdot 2\text{H}_2\text{O}\) under Static Conditions
Exposure of \(\text{CaSO}_4 \cdot 2\text{H}_2\text{O}\) to static conditions of temperature and water vapor pressure for extended periods resulted in complete dehydration (see Section 3.7 and Figure 10). The product can possibly be characterized as having a meta-stable lattice structure which slowly transforms into the \(\gamma\)-\(\text{CaSO}_4\) lattice. The complete dehydration at 165°C is not surprising as a calculation of \(\Delta F^o\) at 165°C for the process

\[
\text{CaSO}_4 \cdot 2\text{H}_2\text{O}(s) \rightarrow \gamma\text{-CaSO}_4(s) + 1/2\text{H}_2\text{O}(v),
\]

using the relationship of \(\Delta F^o\) versus temperature derived by Kelley, Southard and Anderson [2], gives the value of 2.2 K cal/mole. At 165°C and at standard conditions, therefore, \(\text{CaSO}_4 \cdot 2\text{H}_2\text{O}\) is thermodynamic unstable with respect to \(\gamma\)-\(\text{CaSO}_4\).
5. SUMMARY AND CONCLUSIONS

The contention that two forms of CaSO₄·1/2H₂O, \( \alpha \) and \( \beta \), exist is apparently supported by DTA Studies. However, no insight to structural differences in the two forms are obtainable by DTA studies.

The peak temperatures of the endothermic curves of CaSO₄·2H₂O, \( \alpha \) and \( \beta \)-CaSO₄·1/2H₂O, and the exothermic curve of \( \alpha \)-CaSO₄·1/2H₂O are pressure dependent, shifting to lower temperatures as the residual pressure within the DTA cell decreases. This phenomenon can be explained on the basis of the van't Hoff equation.

The \( \alpha \)-form of CaSO₄·1/2H₂O can be prepared by methods involving crystallization such as precipitation from solution. While dehydration of CaSO₄·2H₂O in air, followed by rehydration, and partial dehydration in vacuo lead to the formation of \( \beta \)-CaSO₄·1/2H₂O. The former method gives a product that contains slightly more than the theoretical amount of H₂O, for \( \beta \)-CaSO₄·1/2H₂O, the excess possibly being zeolitic water.

The analysis of every preparation of either \( \alpha \) or \( \beta \)-CaSO₄·1/2H₂O is strongly urged as it is not a simple matter to obtain pure products containing the stoichiometric amount of H₂O.

CAPTIONS FOR FIGURES

Figure 1. DTA curve of CaSO₄·2H₂O with N₂(g) at atmospheric pressure in the DTA Cell.

Figure 2. Differential thermograms of CaSO₄·2H₂O with reduce pressures in the DTA cell. The pressures with runs A, B, and C were 590, 380 and about 1 Torr, respectively.

Figure 3. DTA curve of β-CaSO₄·1/2H₂O with N₂(g) at atmospheric pressure in the DTA cell.

Figure 4. DTA curve of β-CaSO₄·1/2H₂O with a pressure near 1 Torr in the DTA cell.

Figure 5. DTA curve of α-CaSO₄·1/2H₂O with N₂(g) at atmospheric pressure in the DTA cell.

Figure 6. Differential thermograms of α-CaSO₄·1/2H₂O with reduced pressures in the DTA cell. Pressures were 380 and about 1 Torr, respectively, with runs A and B.

Figure 7. DTA curve of an equal molar mixture of α- and β-CaSO₄·1/2H₂O.

Figure 8. DTA curves of products resulting from removal, in vacuo, of stoichiometric amount of H₂O from CaSO₄·2H₂O to form β-CaSO₄·1/2H₂O. Dehydration temperatures and annealing conditions were as follows:
   A. 100°C, annealed for 60 hours;
   B. 100°C, no annealing;
   C. 75°C, no annealing;
   D. 50°C, no annealing.
Figure 9. Differential thermogram of a precipitate of $\alpha$-CaSO$_4 \cdot 1/2$H$_2$O aged for 4 hours at 50°C.

Figure 10. DTA curves of the product resulting from heating together 0.243 millimoles of CaSO$_4 \cdot 2$H$_2$O and 730 Torr of H$_2$O($v$) at 165°C for 66 hours, recorded immediately after products had cooled to room temperature (A), and at four (B), five (C), six (D), and forty days (E) later.
