U.S. DEPARTMENT OF COMMERCE
NATIONAL BUREAU OF STANDARDS

NATIONAL BUREAU OF STANDARDS

The National Bureau of Standards¹ was established by an act of Congress March 3, 1901. Today, in addition to serving as the Nation's central measurement laboratory, the Bureau is a principal focal point in the Federal Government for assuring maximum application of the physical and engineering sciences to the advancement of technology in industry and commerce. To this end the Bureau conducts research and provides central national services in four broad program areas. These are: (1) basic measurements and standards, (2) materials measurements and standards, (3) technological measurements and standards, and (4) transfer of technology.

The Bureau comprises the Institute for Basic Standards, the Institute for Materials Research, the Institute for Applied Technology, the Center for Radiation Research, the Center for Computer Sciences and Technology, and the Office for Information Programs.

THE INSTITUTE FOR BASIC STANDARDS provides the central basis within the United States of a complete and consistent system of physical measurement; coordinates that system with measurement systems of other nations; and furnishes essential services leading to accurate and uniform physical measurements throughout the Nation's scientific community, industry, and commerce. The Institute consists of an Office of Measurement Services and the following technical divisions:

Applied Mathematics—Electricity—Metrology—Mechanics—Heat—Atomic and Molecular Physics—Radio Physics²—Radio Engineering²—Time and Frequency²—Astrophysics²—Cryogenics.²

THE INSTITUTE FOR MATERIALS RESEARCH conducts materials research leading to improved methods of measurement standards, and data on the properties of well-characterized materials needed by industry, commerce, educational institutions, and Government; develops, produces, and distributes standard reference materials; relates the physical and chemical properties of materials to their behavior and their interaction with their environments; and provides advisory and research services to other Government agencies. The Institute consists of an Office of Standard Reference Materials and the following divisions:

Analytical Chemistry—Polymers—Metallurgy—Inorganic Materials—Physical Chemistry.

THE INSTITUTE FOR APPLIED TECHNOLOGY provides technical services to promote the use of available technology and to facilitate technological innovation in industry and Government; cooperates with public and private organizations in the development of technological standards, and test methodologies; and provides advisory and research services for Federal, state, and local government agencies. The Institute consists of the following technical divisions and offices:

Engineering Standards—Weights and Measures—Invention and Innovation—Vehicle Systems Research—Product Evaluation—Building Research—Instrument Shops—Measurement Engineering—Electronic Technology—Technical Analysis.

THE CENTER FOR RADIATION RESEARCH engages in research, measurement, and application of radiation to the solution of Bureau mission problems and the problems of other agencies and institutions. The Center consists of the following divisions:

Reactor Radiation—Linac Radiation—Nuclear Radiation—Applied Radiation.

THE CENTER FOR COMPUTER SCIENCES AND TECHNOLOGY conducts research and provides technical services designed to aid Government agencies in the selection, acquisition, and effective use of automatic data processing equipment; and serves as the principal focus for the development of Federal standards for automatic data processing equipment, techniques, and computer languages. The Center consists of the following offices and divisions:

Information Processing Standards—Computer Information—Computer Services—Systems Development—Information Processing Technology.

THE OFFICE FOR INFORMATION PROGRAMS promotes optimum dissemination and accessibility of scientific information generated within NBS and other agencies of the Federal government; promotes the development of the National Standard Reference Data System and a system of information analysis centers dealing with the broader aspects of the National Measurement System, and provides appropriate services to ensure that the NBS staff has optimum accessibility to the scientific information of the world. The Office consists of the following organizational units:

Office of Standard Reference Data—Clearinghouse for Federal Scientific and Technical Information³—Office of Technical Information and Publications—Library—Office of Public Information—Office of International Relations.

¹ Headquarters and Laboratories at Gaithersburg, Maryland, unless otherwise noted; mailing address Washington, D.C. 20234.

² Located at Boulder, Colorado 80302.

³ Located at 5285 Port Royal Road, Springfield, Virginia 22151.

U.S. DEPARTMENT OF COMMERCE

NATIONAL BUREAU OF STANDARDS

ABSTRACT

A major step in the process of the elimination of lead paint poisoning is the detection of the lead hazard. The National Bureau of Standards is investigating twelve methods for the detection of lead in building materials. The total cost associated with each method is dependent on the type of equipment used, the skills required and other pertinent considerations. This report describes the factors that influence the cost of each lead detection method and presents tentative data for the costs of each method under various conditions.

INTERIM REPORT: LEAD PAINT DETECTION IN RESIDENTIAL DWELLINGS; A COST ANALYSES

I. INTRODUCTION

The hazardous nature of lead painted surfaces in dwelling units is an established fact. Detoxification by means of removing, covering or otherwise preventing humans from ingesting available chips or segments of a leaded wall, ceiling, or moldings depends first on the detection of the presence of lead in painted surfaces. A program goal of lead detection in old paint has been established by the U.S. Department of Housing and Urban Development. That goal specifies detection capability when lead concentrations equal or exceed 1% by dried weight of the paint.

The Analytical Chemistry Division (ACD) of the National Bureau of Standards, is identifying and analyzing various methods and equipment useful for lead detection at the 1% level. In support of the ACD, the Building Economics Group, Building Research Division, NBS, is determining the expected costs when using the various methods to detect lead content in old residential painted surfaces.

"One" best method for detection is not recommended in this report. Rather, tabulation will be provided of information describing costs, life, time, utilization profiles and so on. It is necessarily a decision of the using municipality, state or other legal body, to determine adoption of a particular methodology, rate of use, and the machinery needed. Hopefully, the tabulated data will aid in decision making.

II. THE PROBLEM

There are ten basic lead paint detection methods under consideration by analytical chemists at the National Bureau of Standards. Two of

these methods have two options based on the type of equipment required. Thus, there are a total of twelve procedures being examined by the NBS chemists to detect lead by weight of dried solids at the 1% level.

The following attributes of a lead detection test method have cost significance:

- 1) Type of equipment employed.
- 2) Useful equipment life.
- 3) Amount of expendable material used.
- 4) Personnel skills required.
- 5) The number of samples that can be analyzed per unit time.

Each detection method is different. Initial investment costs and the operating and maintenance costs are also different for each method. Furthermore, the present value (discounted cost) of each method will vary, depending on the magnitude of:

- 1) Program duration.
- 2) Wage rate.
- 3) Discount rate.
- 4) Utilization rates of the capital equipment.

III. DATA REQUIREMENTS

Preliminary cost data regarding the various lead detection methods under consideration by NBS have been provided by the Analytical Chemistry Division. Those cost data provided by ACD were converted to annual costs for purposes of analysis. Data included for each detection method are:

- 1) Equipment First Cost.
- 2) Accessory First Cost.
- 3) Life (years).

- 4) Time Required For Analysis.
- 5) Number of Samples that can be Tested Per Day.
- 6) Was the method destructive or non-destructive.
- 7) Test Site (laboratory or field).
- 8) Operator Skill Level.

Table 1 displays those data used for analyses.

IV. A COST MODEL

A simple model has been constructed to permit rapid evaluation of detection costs while varying conditions for detection. The model permits parametric variation in certain cost influencing factors while holding all other factors constant.

Basic input data to the model is found in Table 1. For analysis the following influence factors have been considered:

- 1) Depreciation.
- 2) Discount rate.
- 3) Utilization.
- 4) Wage rate.
- 5) Program length.

For preliminary analysis the following assumptions have been made:

- 1) Depreciation follows a straight line computation, i.e., investment minus salvage value divided by years of life equals annual depreciation.
- 2) The Government Discount Rate shall be permitted to vary up to 50% of the current maximum borrowing rate.
- 3) Equipment utilization shall be based on an 8 hour, 5 day week being equal to 100%.

- 4) Wage rates shall be selected as representative of the skills employed and shall be an estimated value.
- 5) Program length in months or years shall recognize policy decisions to "clean up" the lead paint within reasonable time periods.

V. RATIONALE

A particular detection method may have a lower initial investment (first cost) when compared with other methods, but it may require two or three times the expendable materials and maintenance per year to perform the chemical analysis. Dependent upon the length of the lead detection detection program, the total detection cost might be considerably less if one chose a higher first cost method having lower annual operating and maintenance costs. Thus, total program length is an important consideration. The decision maker is in a better position to decide on an approach to detection methods when costs are presented on a common datum.

Varying wage rates will determine the cost sensitivity of particular methods to labor skills and future cost escalation.

Utilization rates (percentage of time a machine is being used) are an important determinant of total cost. For example, consider a detection method that requires an expensive machine. If utilization rates are considered it might be more effective to purchase lower cost equipment. This will be dependent on a city's lead program. The lead detection method that would be best suited for a particular city depends on the magnitude of the lead poisoning problem and the resources available in that city.

The discount rate is used to equalize the initial investment cost of the base year with future cost streams, such as operating and maintenance costs, that occur over time. A dollar to be received one year from now or two years in the future, doesn't have the same value as a dollar received today. There is an opportunity cost of receiving that dollar today rather than in the future. For example, one can earn a $4\frac{1}{2}$ interest payment in one year at the local bank (\$1.045). Hence people, firms or governments are not indifferent between having to spend money today as against future monetary outlays.

VI. CALCULATION OF PRESENT WORTH OF LEAD DETECTION COSTS PER SAMPLE

It was assumed that the O & M cost per year for each method would be a constant amount for all years of a given lead paint detection program. Therefore the appropriate formula for calculating the present worth of a uniform series of payments is:

$$P = R \left[\frac{(1 + i)^N - 1}{i(1 + i)^N} \right]$$

where:

P = Present worth of the future O & M costs.

N = program length of a given lead detection program in years.

i = discount rate.

R = the annual operations and maintenance costs including labor, depreciation and expendables.

The cost per sample for each detection method was computed by summing the initial investment cost in equipment and accessories (from Table 1) with the present worth of the operations and maintenance costs (O & M)

associated with each method (Tables 5-7), and dividing by the number of samples per year that each method is capable of analyzing. To this sum must be added the cost of sample collection (Tables 5-7) for those methods where it is required.

Thus the formula for computation of total cost per sample is:

$$\left(\frac{I + P}{S} \right) + C$$

where: I = Initial investment cost in equipment and accessories.

P = present worth of the O & M costs.

S = number of samples per year per lead detection method.

C = per sample cost of collection of lead paint chips.

VII. RESULTS BASED ON PRELIMINARY DATA

For each lead detection method there exists a set of present value costs determined by varying wage rates, program length, utilization rates, and discount rates. These results, classified by detection method, present an array of likely alternatives and the costs associated with each. Each critical factor (discount rate, wage rate, utilization rate, and program length) is varied while the others are held constant. The decision maker simply considers those possibilities relevant to his particular needs and budget constraints. Table 2 shows a sample output matrix.

Progress on Analysis

The values selected for the first model run were:

Factor	Units	Low	Mid	High
Wage Rate	\$/Hour	2.50	5.00	10.00
Discount Rate	%	10	15	20
Program Length	Years	3	5	10
Utilization Rate	%	100	75	50

These values were selected to represent realistic magnitudes of a low intensity, medium intensity and high intensity lead paint poisoning program. A range of options were considered dependent on the effort involved.

A computerized cost model has been developed. The program logic is presented in Table 3. This is a relatively simple program using Fortran V for batch use and Basic Language for time shared application. The computations are performed by the computer. Thus, when refined and updated cost data are received, they can be fed into the model and new lead detection method cost estimates can be immediately computed.

Typical output for a 3-year, 5-year and 10-year lead paint program are presented in Tables 5, 6, and 7.

VIII. FUTURE RESEARCH

The model has been run with preliminary cost data for this interim report. During the course of the study, efforts will be made to obtain refined and updated cost data. To insure that the sensitivity cost analysis for the final report on lead detection methods is based upon the most reliable and accurate cost data obtainable, the cost model is set up for rapid use once new cost inputs become available. The cost model will be improved and new output reports to display the cost analysis may be designed.

IX. EXAMPLES OF USE--DETERMINATION OF DETECTION COSTS PER DWELLING UNIT

To compute detection cost per dwelling unit (D.U.), one begins by entering tables 5-7 and determining the cost per sample for a particular combination of discount rate, utilization rate, and time frame for the method under consideration. As an example, select Method 2, Atomic Absorption Spectroscopy I. Assume a 75% utilization rate, 10% discount

rate and a 3-year program length. Table 5 indicates a cost per sample of \$0.62 based on the assumptions. Assuming that 20 samples are required for analysis per D.U. at \$0.62 per sample, the total cost is \$12.40. To this amount must be added the field costs to collect 20 samples. Based on survey data, it costs approximately \$40 for sample collection, including cost of equipment and transportation. Thus the total cost per D.U. for Method 2 at 75% utilization for a 3-year program would be \$52.40. For a five-year program, a 75% utilization rate and a 10% discount rate, the cost per D.U. for Method 2 would be (from Table 6): $\$0.52 \times 20 = \$10.40 + \$40.00 = \50.40 . Similarly a 10-year program at a 75% utilization rate, and 10% discount rate would cost $\$0.40 \times 20 = \$8.00 + \$40.00 = \48.00 cost per D.U. In sum, we have detection costs at 75% utilization rate, 10% discount rate, using Method 2:

3-yr. program \$52.40 cost/D.U.

5-yr. program \$50.40 cost/D.U.

10-yr. program \$48.00 cost/D.U.

Following the above procedure, one could derive the cost per D.U. for any of the 12 detection methods based upon that data provided in Tables 5-7 and in Appendix B.
