FOREWORD

The tabulation of the first moment of ranked extremes will considerably simplify the use of certain methods of analyzing extreme-value data. The present table was computed by the Computation Laboratory of the National Applied Mathematics Laboratories, National Bureau of Standards, at the suggestion of Bradford F. Kimball, who developed the necessary formulas.

This table is one item of a project aimed at the improved application of the theory of extreme values to the analysis of gust loads of airplanes. This program of the Statistical Engineering Laboratory (Section 3 of the National Applied Mathematics Laboratories, Division 11, NBS) is supported by the National Advisory Committee for Aeronautics.

TABLE OF THE FIRST MOMENT OF RANKED EXTREMES

This table gives the expected values of order statistics from the distribution of largest values $\text{Prob}\{Y \leq y\} = \exp(-e^{-y})$. The entries were computed from the formula given by B.F. Kimball*

$$E(y_r) = C + \sum_{t=0}^r (-1)^t \binom{r}{t} \Delta^t \ln(n-t)$$

where $y_0 \geq y_1 \geq \dots \geq y_r \geq \dots \geq y_{n-1}$ denote the n order statistics in a sample of n values and C is Euler's constant (.57722...). The expected values of y_r , $E(y_r)$, are given in the table for

$$r = 0(1)n-1 \text{ or } 25, \text{ whichever is smaller}$$

$$n = 1(1)10(5)60(10)100.$$

The table has two important uses. One, described by Kimball (ibid), is in connection with a method of graphical analysis of an ordered sample of extremes.

A second use relates to determination of the "best" linear unbiased estimator T of the mode u of the distribution of largest values, $\text{Prob}\{X \leq x\} = \exp(-e^{-y})$, where $y = a(x - u)$, regardless of whether or not the parameter a is known. If

*Kimball, B. F.: Assignment of Frequencies to a Completely Ordered Set of Sample Data, *Trans. Amer. Geophysical Union*, vol. 27, no. 6, 1946, pp. 843-846. See also discussion of this article in vol. 28, no. 6, 1947, pp. 951-953.

Faint, illegible text, possibly bleed-through from the reverse side of the page. The text is too light to transcribe accurately.

$T = \sum_{i=0}^{n-1} \tau_i x_i$, where the x_i are n ordered sample values (order

statistics) $x_0 \geq x_1 \geq \dots \geq x_{n-1}$ from this distribution, then

one set of conditions on the unknowns τ_i is given by the vanishing of the bias of T , that is, $E(T) - u = 0$ identically in u .

From the above linear relation between x and y , we have

$E(y_i) = a[E(x_i) - u]$, whence

$$E(T) - u = \sum \tau_i E(x_i) - u = \sum \tau_i [u + \frac{1}{a} E(y_i)] - u,$$

whose vanishing requires that the τ_i satisfy the two conditions

$\sum \tau_i = 1$, $\sum \tau_i E(y_i) = 0$. In order to determine the "best" or

most efficient linear estimator T (i.e., the one with smallest

variance), the τ_i must be determined by further conditions so

that the variance of T , $\sigma^2(T)$, is a minimum. This will require

the computation of a table of variances and covariances of

ranked extremes, $\sigma(y_i y_j)$.

Faint, illegible text, possibly bleed-through from the reverse side of the page. The text is arranged in several paragraphs and is mostly centered.

$$g(y_n) = C + \sum_{t=0}^n (-1)^t \binom{n}{t} \Delta^t \ln(n-t), \text{ where } C = 801.2157$$
