**This work was performed on a National Bureau of Standards contract with the University of California, Los Angeles, and was sponsored (in part) by the Office of Scientific Research, USAF.
INTRODUCTION

1. Let M be a metric space of points a, b, ..., with the distance from a to b denoted by ab. Let A be a given subset of M. If p and p' are points of M such that

\[ \forall x \in A, \quad px > p'x, \]

we say that p' is point-wise closer than p to the set A. We say that p is a point-wise closest point to the set A if no point p' exists which is point-wise closer than p to A. For brevity we shall also refer to a point-wise closest point to the set A as a minimal point of the set A. The set of minimal points of A will be called the Fejér set of A and denoted by F(A). This set is never void since \( F(A) \supseteq A \). F(A) is a monotone set function since

\[ A_1 \subseteq A_2 \implies F(A_1) \subseteq F(A_2). \]

Let p, p' be distinct points of M. The set of points x such that

\[ px \preceq p'x \]

is called a half-space of M and denoted by the symbol \( H = H(p, p') \); p, p' are its defining points or foci, p being exterior to H, p' interior. The convex hull K(A) of a given set A is defined as follows: If A is not contained in any half-space, we set \( K(A) = M \). If there exist half-spaces containing A, then K(A) is defined as the intersection of all such half-spaces:

\[ K(A) = \bigcap_{H \ni A} H. \]
Notice that $K(A)$ is always closed and $A \subseteq K(A)$. A further general inclusion is

\[(h) \quad K(A) \subseteq F(A) .\]

Indeed, if $p \in F(A)$, then a point $p'$ exists such that (1) holds. This implies $A \subseteq H = H(p, p')$ while evidently $p \in H$. By (3) $p \in K(A)$ and (h) is established.

2. In 1922 Fejér [9], noticed the interesting fact that in the euclidean plane $M = E_2$ we have

\[(5) \quad F(A) = K(A) .\]

One half of Fejér's own argument has just been used to establish (h) for any metric space. The other half of his proof in $E_2$ is as follows. Let us show that $F(A) \subseteq K(A)$. Indeed, if $p \in K(A)$, then there exists a half-plane $H \subseteq E_2$ such that $p \in H$, $A \subseteq H$. If $p'$ is the point of $H$ which is nearest to $p$, then (1) evidently holds showing that $p \in F(A)$.

The last paragraph allows of a wider setting. Let $M$ be a real inner-product space. By this we mean that $M$ is a real linear space whose norm springs from an inner product $(a, b)$ and that $M$ is complete with respect to the metric just described. Under these assumptions the convex hull $K(A)$ is found to be identical with the least closed and linearly connected set containing $A$. Fejér's argument applies unchanged to prove the following

**THEOREM 1.** If $M$ is a real inner-product space and $A \subseteq M$, then

\[(6) \quad F(A) = K(A) .\]
3. In Parts I and II we investigate the Fejér sets of finite sets of points in Banach spaces. The notion of the global distribution of points on spheres is introduced (Definition 1) and Fejér sets are described in terms of this concept (Theorem 5). Fejér's result is shown to hold in rather arbitrary 2-dimensional Banach spaces (Theorem 6). The situation is quite different for dimensions exceeding two. A very weak form (2.1) of Fejér's result is shown to imply that the Banach space is an inner-product space. In Part III we determine the Fejér set of a subset of spherical space.

I. ON FEJÉR SETS OF FINITE SETS OF POINTS IN BANACH SPACES

1. An application of Helly's theorem. Let $B$ be a Banach space to be also denoted by $B_n$ in case its dimension $n$ happens to be finite. The Fejér set $F(a,b)$ of two points is described by

**THEOREM 2.** In any space $B$ we have that

\[(1.1) \quad F(a,b) = E(x; \|a-x\| + \|x-b\| = \|a-b\|).\]

**Proof:** Indeed, a point $x$ of $E$ is clearly minimal for the set $\{a,b\}$, because the existence of a point $x'$ point-wise closer than $x$ to $\{a,b\}$ would violate the triangle inequality. On the other hand, if $\|a-x\| + \|x-b\| > \|a-b\|$, we can find a point $x'$ on the segment joining $a$ to $b$ such that $\|a-x\| > \|a-x'\|, \|b-x\| > \|b-x'\|$. This proves (1.1).

**THEOREM 3.** Let $A$ be a finite set of points of $B_n$ (n finite) and let us assume that $A$ contains at least $n+1$ points. Then

\[(1.2) \quad F(A) = \bigcup F(p_1, p_2, \ldots, p_n), \quad (p_1 \in A),\]
where the elements of the union are formed for every combination of \( n+1 \) distinct points of \( A \).

**Proof:** Let \( G(A) \) denote the set on the right-hand side of (1.2). By (2) we have

\[
G(A) \subseteq F(A)
\]

Assume now that

\[
p \notin G(A)
\]

and let us show that \( p \notin F(A) \), i.e., that \( p \) is not minimal. For every point \( a \in A \) we consider the open sphere

\[
S_a : \|x-a\| < \|p-a\|
\]

Let \( p_0, p_1, \ldots, p_n \) be any distinct points of \( A \). By (1.1)

\[p \in F(p_0, p_1, \ldots, p_n)\]

This means that a point-wise closer point exists for the set \( \{p_0, p_1, \ldots, p_n\} \), or

\[
S_{p_0} \cap S_{p_1} \cap \cdots \cap S_{p_n} \neq \emptyset
\]

The spheres \( S_a \) are convex sets, finite in number, every \( n+1 \) of which have a common point, in view of (1.6). By Helly's theorem (see [5])

\[
\bigcap_{a \in A} S_a \neq \emptyset
\]

If \( p' \in \bigcap S_a \), then \( p' \in S_a \), for every \( a \), or \( \|p-a\| > \|p'-a\| \) for every \( a \in A \). Hence \( p \notin F(A) \). Thus \( G(A) \supseteq F(A) \). In view of (1.3), the identity (1.2) is established.

**An example.** Let \( B_n = l^n \) be the Minkowski space of points \( x = (x_1, \ldots, x_n) \) with the "cubical" norm \( \|x\| = \max_{i} |x_i| \). In this particular case the result of Theorem 2 may be improved as follows:
If \( A \) is a finite set of points in \( M_n \) then

\[(1.7) \quad F(A) = \bigcup F(p_0, p_1), \]

where the union is formed for all pairs of distinct points of \( A \).

Indeed, in this special case the spheres \((1.5)\) are open cubes with edges parallel to the axes of coordinates. On repeating the argument used in proving Theorem 3 we find that every two among the cubes have a common point. If follows that the projections of the cubes on each coordinate axis have a common point and that therefore also all cubes have a common point.

Let \( n = 3 \) and let \( A = \{a, b, c\} \), where

\[(1.8) \quad a = (2, 0, 0), \quad b = (0, 2, 0), \quad c = (0, 0, 2). \]

By \((1.7)\) we have

\[F(a, b, c) = F(a, b) + F(a, c) + F(b, c).\]

The inspection of a diagram will show that the three right-hand side sets are lozenges: \( F(a, b) \) is the lozenge of consecutive vertices \((2, 0, 0), (1, 1, 1), (0, 2, 0), (1, 1, -1)\). Notice in particular the curious fact that the centroid \((2/3, 2/3, 2/3)\) of the triangle \( \Delta(a, b, c) \) is not a point of the Fejér set \( F(a, b, c) \). However the point \( p = (1, 1, 1) \) does belong to \( F(a, b, c) \). We shall say that \( a, b, c \) are globally distributed on the sphere \( \|x-p\|=1 \) and investigate the general concept in our next section.

5. On points globally distributed on spheres and their characterization. DEFINITION 1. Let \( B \) be a Banach space and let

\[(1.9) \quad S : \|x-c\| = r.\]
be the surface of the sphere of radius \( r \) and center at \( c \). Let \( p_1, p_2, \ldots, p_k \) be \( k \) points of \( S \). We shall say that the points \( p_1, \ldots, p_k \) are globally distributed on \( S \) provided

\[
(1.10) \quad c \in \mathcal{F}(p_1, p_2, \ldots, p_k)
\]

In other words: There is no solid sphere \( \|x-c'\| \leq r' \), of a smaller radius \( r' < r \), which covers all points \( p_1, \ldots, p_k \).

In what follows we denote by \([a,b)\) the half-open segment of points \( a(1-t) + bt \) \((0 \leq t < 1)\), joining \( a \) with \( b \), and use similar notations \([a,b], (a,b)\) for closed or open segments.

**DEFINITION 2.** Let \( p_1, \ldots, p_k \) be \( k \) points on the sphere (1.9) of Definition 1. We say that the points \( p_1, \ldots, p_k \) are well visible provided there exists a point \( q \) outside \( S \), \( \|q-c\| > r \), such that the segments \([q,p_i]\) contain only points exterior to \( S \) and that there are points \( s_i \), such that \( p_i \in (q,s_i) \) and that the segments \([p_i, s_i]\) have only points interior to \( S \).

**Example.** In \( E_2 \) \( k \) points on a circle \( \|x-c\| = r \) are well visible if and only if they are contained in an open half-circle. The general relation between Definitions 1 and 2 is shown by the following

**THEOREM 4.** The points \( p_1, p_2, \ldots, p_k \) on \( S \) are globally distributed on \( S \) if and only if they are not well visible.

**Proof:** a. The condition is necessary. Indeed, suppose that our condition is not satisfied and, on the contrary, the points \( p_i \) are well visible from the outside point \( q \). By Definition 2 we can extend the segment \([q,p_i]\) by a segment \([p_i, s_i]\) all points of which are interior to \( S \). Let us now "shrink" \( S \) from the center of similitude \( q \) in the ratio \( 1: \lambda \) \((0 < \lambda < 1)\), obtaining a new sphere
S' of radius \( r' = r \lambda < r \). Let the segment \((p_i, s_i)\) be transformed into \((p'_i, s'_i)\) by this similitude transformation. Since \((p_i, s_i)\) is interior to \(S\), \((p'_i, s'_i)\) will be interior to \(S'\). It is clear that

\[ p_i \in (p'_i, s'_i), \quad (i = 1, \ldots, k), \]

provided that \( \lambda \) is sufficiently close to unity. But then all \( p_i \) are inside \( S' \), showing that \( p_1, \ldots, p_k \) are not globally distributed on \( S \).

b. The condition is sufficient. Indeed, let us assume that \( p_1, \ldots, p_k \) are not globally distributed on \( S \) and let us conclude that they are well visible. Accordingly, let \( p_i \) be covered by a sphere \( S_1 \) of radius \( r_1 < r \). Inflate \( S_1 \) slightly from its center into a larger sphere of radius \( r' < r \). Now all points \( p_i \) are interior to \( S \). Let \( c' \) be the center of the sphere \( S' \). Since the \( p_i \) are on \( S \) and inside \( S' \), we must have \( c' \neq c \). The spheres \( S \) and \( S' \) are similar with respect to the (exterior) center of similitude

\[ q = \frac{rc' - r'c}{r - r'} \]

We denote by \( p' = Tp \) the similitude transformation with center at \( q \) and ratio \( r : r' \). Let \( p'_i = Tp_i \). Since \( p_i \) is on \( S \), \( p'_i \) is on \( S' \). But \( p_i \) is by construction inside \( S' \). It follows that all points of \((p'_i, p_i)\) are inside \( S' \). Let \( s_i \) be such that

\[ p_i = Ts_i \]

Now \((p_i, s_i)\) goes over into \((p'_i, p_i)\) by our transformation. Since \((p'_i, p_i)\) was shown to be inside \( S' \), it follows that \((p_i, s_i)\) has only points interior to \( S \). We now claim that all points of \([q, p_i)\)
are outside $S$. For if any point of this segment were inside or on $S$, the fact that $s_i$ is inside $S$ would imply that also $p_i$ were inside $S$, which is not the case. We have just shown that $[q, p_i]$ is outside $S$, $(p_i, s_i]$ is inside $S$, $(i = 1, \ldots, k)$. But this is precisely what we mean when we say that the points $p_i$ are well visible from $q$.

6. A description of Fejér sets in terms of global distribution.

**THEOREM 5.** Let $A = \{p_1, \ldots, p_k\}$ be a finite set of points of $B$. Let $p \in A$. Draw about $p$ as center a sphere

$$S : \|x-p\| = r$$

and project $p_i$ from $p$ onto the surface $S$ into $q_i$. Denote by $F_1(A)$ the set of those points $p$ such that the points $q_1, q_2, \ldots, q_k$ are globally distributed on $S$. Then

(1.11) $$F(A) = A + F_1(A)$$

**Proof:** We have to show that $p \in F(A)$ if and only if the $q_i$ are globally distributed on $S$ or equivalently:

(1.12) $$p \in F(A)$$

if and only if

(1.13) $$q_1, \ldots, q_k$$

are not globally distributed on $S$.

The size of the radius $r > 0$ is clearly immaterial.

a. Let us assume (1.13) and prove (1.12). Choose $r$ such that

$$r < \min \|p-p_i\|_i.$$
The assumption (1.13) means that $p \nin F(q_1, \ldots, q_k)$. Therefore there exists a point $p'$ such that

$$
\|q_i - p\| > \|q_i - p'\|,
$$
(i = 1, \ldots, k).

But then

$$
\|p_i - p\| = \|p_i - q_i\| + \|q_i - p\| > \|p_i - q_i\| + \|q_i - p'\| \geq \|p_i - p'\|
$$
or

$$
\|p_i - p\| > \|p_i - p'\|. 
$$
which proves (1.12).

b. We now assume that (1.12) holds and wish to prove (1.13). Choose $r$ such that

$$
r > \max_i \|p - p_i\|.
$$

By (1.12) there is a point $p'$ such that

$$
\|p - p_i\| > \|p' - p_i\|, \text{ for all } i.
$$

Hence

$$
r = \|p - q_i\| = \|p - p_i\| + \|p_i - q_i\| > \|p' - p_i\| + \|p_i - q_i\| \geq \|p' - q_i\|
$$
or

$$
\|p' - q_i\| < r, \text{ for all } i.
$$

Setting

$$
r' = \max_i \|p' - q_i\| < r
$$
we see that the smaller sphere $\|x - p'\| \leq r'$ will cover all points $q_i$, which proves (1.13).

7. **On Fejér sets in $B_2$.** As an application of Theorem 4 we wish to describe the Fejér sets of finite sets of points in a
Minkowski plane $B_2$. By Theorem 2 we conclude the following: The Fejer set $F(a, b)$ is identical with the segment $[a, b]$, for every pair of points $a, b$, if and only if the norm of $B_2$ has the property:

$$\|p\| + \|q\| = \|p + q\|, \quad p \neq 0, \quad q \neq 0$$

(1.1h)

imply that $p = \alpha q$, $(\alpha > 0)$.

It is known that (1.1h) holds if and only if the gauge-curve $\|x\|=1$ contains no segment, in which case the curve $\|x\|=1$ may be described as being "round."

We assume (1.1h) to hold and consider in $B_2$ a set $A = \{p_1, p_2, p_3\}$ of three points. Let $p \in A$ and let $q_1, q_2, q_3$ be the points on the gauge-curve $S$ as described in Theorem 4. By Theorem 5 $p \in F(p_1, p_2, p_3)$ if and only if $q_1, q_2, q_3$ are not globally distributed on $S$. By Theorem 4 this is the case if and only if $q_1, q_2, q_3$ are well visible (from a point $q$ outside $S$). $S$ being "round," this is evidently the case if and only if $p$ is outside the closed triangle $\Delta(q_1, q_2, q_3)$ or, equivalently, outside the triangle $\Delta(p_1, p_2, p_3)$. Thus

$$F(p_1, p_2, p_3) = \Delta(p_1, p_2, p_3).$$

Applying Theorem 3 we obtain

**THEOREM 6.** Let $B_2$ be a Minkowski plane with the property (1.1h). The Fejér set of a finite set of points is identical with the closed convex polygon spanned by the set.

This result is a special property of 2-dimensional Banach spaces as will be shown in Part II.
II. A CHARACTERIZATION OF INNER-PRODUCT SPACES

8. The main theorem. Let $M$ be the inner-product space of Theorem 1 and let the set $A$ consist of three points, $p_1, p_2, p_3$, distinct or not. Then $K(A)$, being identical with the least closed and linearly connected set containing these points, is evidently the triangle $\Delta(p_1, p_2, p_3)$ having as vertices the points $p_1, p_2, p_3$. By Theorem 1 we have

$$F(p_1, p_2, p_3) = \Delta(p_1, p_2, p_3).$$

Let now $M$ be an arbitrary Banach space. By Theorem 6 we know that (2.1) again holds provided that $B = B_2$ is 2-dimensional and that its metric has the property (1.11). Which higher-dimensional Banach spaces $B$ enjoy the property (2.1)? An answer is given by the following

THEOREM 7. A space $B$ of dimension $\geq 3$ has the property (2.1) if and only if it is an inner-product space.

9. A few lemmas. For the proof of Theorem 7 we need a number of results concerning the 3-dimensional euclidean space $E_3$.

LEMMA 1. Let $S_2$ denote the surface of a sphere in $E_3$ with center at $o$. Let $C$ be a simple closed curve on $S_2$ and let $H_1$ and $H_2$ be the two open components of the complementary part: $S_2 = C + H_1 + H_2$. Let $K^*(H_1)$ and $K^*(H_2)$ denote the least convex sets in $E_3$ containing $H_1$ and $H_2$, respectively. If

$$o \in K^*(H_1) \cup K^*(H_2)$$

then $C$ is necessarily a great circle.
Proof: By (2.2) \( o \in K^*(H_1) \). Therefore \( o \) is either outside or on the boundary of the closed convex set

\[
K^*(H_1) = K^*(H_1 + C)
\]

We can therefore draw through \( o \) a plane \( \Pi \) which is a bounding plane or a plane of support of \( K^*(H_1 + C) \). Let \( \Gamma = S_2 \cap \Pi \) and let \( h_1 \) and \( h_2 \) denote the open half-spheres in which \( \Pi \) divides \( S_2 \):

\[
S_2 = \Gamma + h_1 + h_2.
\]

By our choice of \( \Pi \) and for a proper labelling of the \( h_i \) we have

\[
h_1 + \Gamma \supseteq H_1.
\]

Passing to complements on the sphere we see that \( h_2 \subseteq H_2 + C \), and since \( h_2 \) is open on the sphere, we have

\[
(2.3) \quad h_2 \subseteq H_2.
\]

We now claim that

\[
(2.4) \quad h_1 \cap H_2 = 0.
\]

Indeed, if \( p \in h_1 \cap H_2 \), then \( K^*(p, h_2) \) would contain the point \( o \) and by \( p \in H_2 \) and (2.3) a fortiori

\[
o \in K^*(H_2),
\]

in contradiction to (2.2). By (2.3) no point of \( C \) is in \( h_2 \) and by (2.4) no point of \( C \) is in \( h_1 \). Thus \( C \subseteq \Gamma \) and therefore \( C = \Gamma \), showing that \( C \) is a great circle.

A seemingly more general version of Lemma 1 to be used below is as follows.

**Lemma 2.** Let \( S \) be the surface of a convex body in \( E_3 \) having the point \( o \) as center of symmetry. Let \( C \) be a simple closed curve
on $S$ and let $H_1, H_2$ be the two open components of the complement: $S = C + H_1 + H_2$. Let $K^*(H_1), K^*(H_2)$ denote the least convex sets in $E_3$ containing $H_1$ and $H_2$, respectively. If

$$o \in K^*(H_1) \cup K^*(H_2)$$

then $C$ is a "great circle" of $S$, i.e., $C$ is the intersection of $S$ by a plane through $o$.

**Proof:** Draw a sphere $S_2$ with center at $o$. Central projection of $S$ only $S_2$ with the center of projection at $o$ reduces Lemma 2 to Lemma 1.

We turn to our last lemma which is due to Blaschke. Let $S$ be the surface of a convex body in $E_3$. We assume that the surface $S$ contains no segment, a fact which we describe by saying that $S$ is "round." Let $\vec{v}$ be a fixed vector and let us illuminate $S$ by rays of light all parallel to $\vec{v}$ in direction and sense. Let $C$ denote the light-shade boundary on $S$, that is, the boundary between the illuminated part of $S$ and the part of $S$ which is shaded.

We claim that $C$ is a simple closed curve. Indeed, let $\Pi$ be a fixed plane normal to $\vec{v}$. The orthogonal projection of $S$ onto $\Pi$ is a plane convex domain $D$ whose boundary curve we denote by $\Gamma$. Let $p \in \Gamma$. The point $p$ is the projection of a point $q$ of $S$. Since $S$ contains no segment this point $q$ is unique and is readily shown to vary continuously as $p$ varies continuously on $\Gamma$. As $p$ describes $\Gamma$ the point $q$ describes our curve $C$ which is clearly simple and closed.

**LEMMA 3 (Blaschke).** If $S$ has the property that the light-
shade boundary C is a plane curve for all possible directions of \( \mathbf{v} \) then S is necessarily an ellipsoid.

Blaschke proves this result ([1], pp. 157-159) by assuming that S is an "Eifläche," by which he means that S is analytic and regular at all its points and has everywhere non-vanishing curvature ([1], p. 147). However, the reader will have no difficulty in carrying through Blaschke's proof on the basis of our simplified assumption that S is "round."

10. Proof of Theorem 7. We are to show that the property (2.1) implies that B is an inner-product space. If \( p_2 = p_3 \) then (2.1) implies that

\[
\mathbf{F}(p_1, p_2) = [p_1, p_2].
\]

The metric of B must therefore have the property (1.11): The gauge-surface

\[
\Sigma : \|x\| = 1
\]

of B is "round."

Let \( B_3 \) be an arbitrary but fixed 3-dimensional linear subspace of B. \( B_3 \) is a 3-dimensional Banach space whose gauge-surface is

\[
S = B_3 \cap \Sigma.
\]

In terms of a coordinate system in \( B_3 \) we can also think of \( B_3 \) as being a Minkowski space whose points are those of an \( E_3 \) which is metrized by means of the convex gauge-surface \( S \). By a theorem of Jordan and von Neumann [3], it suffices to show that S is an ellipsoid.

We know already that S is "round" because \( \Sigma \) has this property
Let us illuminate $S$ from a direction parallel to $\vec{v}$. Let $C$ be the light-shade boundary on $S$ and let $H_1$ be the illuminated part of $S$, $H_2$ the shaded part, $S = C + H_1 + H_2$.

We claim that

(2.5) \[ o \in K^*(H_1) \]

Indeed, let us assume for the moment $o$ to be a point of the convex set $K^*(H_1)$. $H_1$ being connected it follows, by a sharpened version of a theorem of Fenchel,¹ that $o$ is the centroid of some three points of $H_1$: $p_1, p_2, p_3$, say. Thus

(2.6) \[ p_1, p_2, p_3 \in H_1 \]

(2.7) \[ o \in A(p_1, p_2, p_3) \]

These conclusions, however, are contradictory with our previous assumptions, for on the one hand the points $p_1, p_2, p_3$ are well visible from a point at infinity in the direction $-\vec{v}$. From this it follows easily that they are well visible from a point $q$ at finite distance and sufficiently far out in the direction of $-\vec{v}$. By Theorem 1 we conclude that the points $p_1, p_2, p_3$ are not globally distributed on the sphere $S$ of the space $B_3$.

On the other hand by (2.7) and our basic assumption (2.1) we conclude that $o \in F(p_1, p_2, p_3)$. Thus $o$ is a minimal point of the set $A = \{p_1, p_2, p_3\}$ in the space $B$. It follows a fortiori that

¹The sharpened version of the theorem of Fenchel is as follows: Let $H$ be a connected subset of $E_n$ and let $K^*(H)$ be the least convex set containing $H$. Then every point of $K^*(H)$ is a centroid of some $n$ points of $H$. This result is due to L. N. H. Bunt. See [2] for Bunt's proof (pages 589-590) and for references.
that \( o \) is minimal point of \( A \) with respect to the subspace \( B_3 \). Thus \( p_1, p_2, p_3 \) are globally distributed on \( S \) in \( B_3 \), in direct contradiction to the conclusion of our previous paragraph.

This proves (2.5) and we may similarly show that

\[ o \in K^*(H_2) \]

By Lemma 2 we conclude that \( C \) is a plane curve and by Blaschke's Lemma 3 we learn that \( S \) is an ellipsoid.

**III. ON FEJÉR SETS IN SPHERICAL SPACES**

11. Let \( M \) be the real inner-product space of section 2. We are now confining our attention to the surface \( S \) of its unit sphere

\[ \|x\| = 1 \]

By the distance \( xy \) of two points of \( S \) we mean the arc defined by

\[ \cos xy = (x,y), \quad o \leq xy \leq \pi \]

If \( p \) and \( p' \) are distinct points of \( S \) then the closed half-sphere \( H(p, p') \) may be defined by the inequality \( px \geq p'x \) or equivalently by \( (p, x) \leq (p', x) \) or \( (p'-p, x) \geq 0 \). A being a given subset of \( S \) we may now define the convex hull \( K(A) \) as in section 1.

THEOREM 8. Let \( A \) be a subset of \( S \). a. If there is no open half-sphere containing \( A \) then

\[ (3.1) \quad F(A) = S \]

b. If there is an open half-sphere \( H_0 \) such that \( A \subseteq H_0 \), then

\[ (3.2) \quad F(A) = K(A) \]
Proof: a. In order to prove (3.1) we have to show that every point $p \in S$ is a minimal point of $S$. This is clear, for otherwise there would exist a point $p'$ such that (1) holds. However (1) implies that $A$ is in the open half-sphere $H_o(p, p')$ which contradicts our assumption.

b. Let us assume that

\[(3.3) \quad A \subseteq H_o\]

where $H_o$ is an open half-sphere defined by

\[(3.4) \quad H_o : (x, b) > 0\]

and let us prove (3.2). However, the inclusion

\[K(A) \subseteq F(A)\]

or (h), has already been established in section 1 for any metric space. There remains to show that

\[(3.5) \quad F(A) \subseteq K(A)\]

or that

\[(3.6) \quad p \bar{\epsilon} K(A)\]

implies

\[(3.7) \quad p \bar{\epsilon} F(A)\]

Assuming (3.6) means that there is a closed half-sphere $H$ such that

\[(3.8) \quad p \bar{\epsilon} H, \quad H \supseteq A\]

Let the half-sphere $H$ be defined by

\[(3.9) \quad H : (x, a) \geq 0\]

By the first relation (3.8) we know that $(p, a) < 0$. Choose $\varepsilon > 0$
so small as to make sure that

\[(3.10) \quad (p,a) + \epsilon(p,b) < 0 \quad . \]

Consider the open half-sphere

\[(3.11) \quad H'_0 : (x,a) + \epsilon(x,b) > 0 \quad . \]

If \( x \in A \) then \( x \in H \), by (3.8), and \( x \in H'_0 \), by (3.3). The point \( x \) thus satisfies the inequalities (3.11), (3.9) and therefore also (3.11):

\[(3.12) \quad A \subseteq H'_0 \quad . \]

On the other hand (3.10) shows that

\[
\overline{p \in H'_0}.
\]

But then clearly \( p \) is not a minimal point of \( A \). Indeed let \( p' \) be the symmetric of \( p \) with respect to the hyperplane

\[(x, a+\epsilon b) = 0 \]

which bounds \( H'_0 \). Clearly \( H'_0 = H_0(p, p') \). By (3.12) we see that \( p' \) is point-wise closer than \( p \) to \( A \). This proves (3.7) and therefore also our theorem. Notice that the dimensionality of the space \( M \), finite, denumerable or non-denumerable, does not affect our theorem.

THE NATIONAL BUREAU OF STANDARDS

Functions and Activities

The National Bureau of Standards is the principal agency of
the Federal Government for fundamental and applied research in phys-
ics, mathematics, chemistry, and engineering. Its activities range
from the determination of physical constants and properties of ma-
terials, the development and maintenance of the national standards
of measurement in the physical sciences, and the development of
methods and instruments of measurement, to the development of special
devices for the military and civilian agencies of the Government.
The work includes basic and applied research, development, engi-
neering, instrumentation, testing, evaluation, calibration services,
and various scientific and technical advisory services. A major
portion of the NBS work is performed for other government agencies,
particularly the Department of Defense and the Atomic Energy Com-
mission. The functions of the National Bureau of Standards are set
forth in the Act of Congress, March 3, 1901, as amended by Congress
in Public Law 619, 1950. The scope of activities is suggested in
the listing of divisions and sections on the inside of the front
cover.

Reports and Publications

The results of the Bureau’s work take the form of either actual
equipment and devices or published papers and reports. Reports are
issued to the sponsoring agency of a particular project or program.
Published papers appear either in the Bureau’s own series of publi-
cations or in the journals of professional and scientific societies.
The Bureau itself publishes three monthly periodicals, available
from the Government Printing Office: the Journal of Research, which
presents complete papers reporting technical investigations; the
Technical News Bulletin, which presents summary and preliminary re-
ports on work in progress; and Basic Radio Propagation Predictions,
which provides data for determining the best frequencies to use for
radio communications throughout the world. There are also five
series of nonperiodical publications: the Applied Mathematics Se-
ries, Circulars, Handbooks, Building Materials and Structures Re-
ports, and Miscellaneous Publications.

Information on the Bureau’s publications can be found in
NBS Circular 460, Publications of the National Bureau of Standards
(§1.00). Information on calibration services and fees can be found
in NBS Circular 483, Testing by the National Bureau of Standards
(25 cents). Both are available from the Government Printing Office.
Inquiries regarding the Bureau’s reports and publications should be
addressed to the Office of Scientific Publications, National Bureau
of Standards, Washington 25, D. C.
