U. S. DEPARTMENT OF COMMERCE
NATIONAL BUREAU OF STANDARDS
THE NATIONAL BUREAU OF STANDARDS

Functions and Activities

The functions of the National Bureau of Standards are set forth in the Act of Congress, March 3, 1901, as amended by Congress in Public Law 619, 1950. These include the development and maintenance of the national standards of measurement and the provision of means and methods for making measurements consistent with these standards; the determination of physical constants and properties of materials; the development of methods and instruments for testing materials, devices, and structures; advisory services to Government Agencies on scientific and technical problems; invention and development of devices to serve special needs of the Government; and the development of standard practices, codes, and specifications. The work includes basic and applied research, development, engineering, instrumentation, testing, evaluation, calibration services, and various consultation and information services. A major portion of the Bureau’s work is performed for other Government Agencies, particularly the Department of Defense and the Atomic Energy Commission. The scope of activities is suggested by the listing of divisions and sections on the inside of the back cover.

Reports and Publications

The results of the Bureau’s work take the form of either actual equipment and devices or published papers and reports. Reports are issued to the sponsoring agency of a particular project or program. Published papers appear either in the Bureau’s own series of publications or in the journals of professional and scientific societies. The Bureau itself publishes three monthly periodicals, available from the Government Printing Office: The Journal of Research, which presents complete papers reporting technical investigations; the Technical News Bulletin, which presents summary and preliminary reports on work in progress; and Basic Radio Propagation Predictions, which provides data for determining the best frequencies to use for radio communications throughout the world. There are also five series of nonperiodical publications: The Applied Mathematics Series, Circulars, Handbooks, Building Materials and Structures Reports, and Miscellaneous Publications.

Information on the Bureau’s publications can be found in NBS Circular 460, Publications of the National Bureau of Standards ($1.25) and its Supplement ($0.75), available from the Superintendent of Documents, Government Printing Office, Washington 25, D. C.

Inquiries regarding the Bureau’s reports should be addressed to the Office of Technical Information, National Bureau of Standards, Washington 25, D. C.

U.S. DEPARTMENT OF COMMERCE
NATIONAL BUREAU OF STANDARDS
PREFACE

This report describes a method that greatly facilitates the analysis of many factorial designs and is expected to be especially helpful in developing a catalogue of fractional factorial experiment designs for use in experiments in which some factors are to be studied at two conditions and others at three conditions. This work is under the immediate direction of W. S. Connor and M. Zelen. Professor R. C. Bose of the University of North Carolina is serving as consultant.
Introduction.

The problem of constructing fractional factorial designs for the $2^m3^n$ series has not received much attention in the statistical literature (see, e.g., [1]). Accordingly, before preparing a catalogue, it is desirable to study methods of construction.

Such a study is now in progress. The first major problem encountered was the formation of the normal equations which correspond to any particular design. Although it is known from the general theory of least squares how to form the equations of expectation, and from them the normal equations, we were still faced with the difficult problem of implementing the theory. We recognized that progress would be very slow indeed unless some short cuts could be found.

Fortunately, we have found a very effective method for forming the normal equations. The method is described in this report, and is applied to a $1/2$ replicate of the $2^33^2$ design. The use of this fractional replicate is illustrated by application to some real experimental data.

The method is so general that it applies to the analysis of all factorial experiments. It can be used for analyzing fractional factorials of any mixed series - not merely the $2^m3^n$ series. Another use is for complete or fractional factorials with repetitions of some treatment combinations.
We are now engaged in using the method to study various designs for several fractions of the $2^m3^n$ series. Certain considerations of symmetry suggest that particular designs are optimum in the sense of providing estimates which are not highly correlated. However, these estimates may be arithmetically more complicated than the estimates which are provided by other less symmetrical arrangements. Thus, designs which are optimum in one sense are not necessarily optimum in some other sense.

We plan to program the method for use on the National Bureau of Standards electronic computer. We then shall be able to progress rapidly in the evaluation of the comparative merits of various contending designs. From these we shall select "optimum" designs for inclusion in the catalogue.
The method of forming the design

We partition the \( N \) factors into two collections, \( C_1 \) and \( C_2 \), containing \( c_1 \) and \( c_2 \) factors, respectively, \((c_1+c_2 = N)\).

Then, for each collection separately, we form \( w \) sets of treatment combinations. It is not required that all of the treatment combinations be included in some set, nor is there any restriction as to the number of sets which contain any particular treatment combination. Also, a treatment combination may occur more than once in a set.

We denote the sets for collection \( C_1 \) by \( m_1, m_2, \ldots, m_w \) and their respective numbers of treatment combinations by \( u_1, u_2, \ldots, u_w \). Similarly, we denote the sets for collection \( C_2 \) by \( n_1, n_2, \ldots, n_w \) and their respective numbers of treatment combinations by \( v_1, v_2, \ldots, v_w \).

The design consists of adjoining every treatment combination of set \( m_i \) to every treatment combination of set \( n_i \), \((i=1, \ldots, w)\). This produces sets \( p_i \) which contain \( u_i v_i \) treatment combinations for all \( N \) factors.

To illustrate, let there be \( N=3 \) factors \( A, B, \) and \( \alpha \), all having two levels. Let \( C_1 \) consist of \( A \) and \( B \); and \( C_2 \) consist of \( \alpha \). We may choose the sets \( m_i \) and \( n_i \) as follows:
The design $D$ consists of the following treatment combinations:

$m_1$: \[
\begin{array}{ccc}
A & B & \alpha \\
0 & 0 & 0 \\
0 & 0 & 0 \\
\end{array}
\] ($u_1=2$)

$m_2$: \[
\begin{array}{ccc}
A & B & \alpha \\
0 & 0 & 0 \\
1 & 1 & 1 \\
\end{array}
\] ($u_2=2$)

$m_3$: \[
\begin{array}{ccc}
A & B & \alpha \\
1 & 0 & 0 \\
\end{array}
\] ($u_3=1$)

$p_1$: \[
\begin{array}{ccc}
A & B & \alpha \\
0 & 0 & 0 \\
0 & 0 & 0 \\
\end{array}
\] ($u_1v_1=2$)

$p_2$: \[
\begin{array}{ccc}
A & B & \alpha \\
0 & 0 & 0 \\
0 & 0 & 1 \\
1 & 1 & 0 \\
1 & 1 & 1 \\
\end{array}
\] ($u_2v_2=4$)

$p_3$: \[
\begin{array}{ccc}
A & B & \alpha \\
1 & 0 & 1 \\
\end{array}
\] ($u_3v_3=1$)
Equations of expectation and normal equations

We introduce column vectors of expected responses $\eta(m_i)$ and $\eta(n_i)$, and write the equations of expectation as

$$\eta(m_i) = M_i \begin{bmatrix} g \\ p \end{bmatrix}$$

and

$$\eta(n_i) = N_i \begin{bmatrix} g \\ q \end{bmatrix}$$

where $g$ denotes the grand mean, $p$ is a column vector of $s$ parameters, $q$ is a column vector of $t$ parameters; and $M_i$ is a $u_i \times (s+1)$ matrix of coefficients and $N_i$ is a $v_i \times (t+1)$ matrix of coefficients.

We now are ready to consider the equations of expectation and the normal equations for the design $D$. For this purpose, we introduce

$$y(D) = \begin{bmatrix} y(p_{1l}) \\ \vdots \\ y(p_{wl}) \end{bmatrix}$$

a column vector of the responses of the treatment combinations of $D$, $\eta(D)$, a column vector of the corresponding expected responses, and $r$, a column vector of $st$ parameters.

We shall be concerned with the following equations of expectation for the treatment combinations of $D$:
\[
\eta(D) = \begin{bmatrix}
M_1 \otimes N_1 \\
M_2 \otimes N_2 \\
\vdots \\
M_w \otimes N_w
\end{bmatrix} \begin{bmatrix}
g \\
p \\
q \\
r
\end{bmatrix}
\]

where \( \otimes \) denotes the right direct product. The normal equations are as follows:

\[
\begin{bmatrix}
(M_1 \otimes N_1)^T \ldots (M_w \otimes N_w)^T
\end{bmatrix}
\begin{bmatrix}
(M_1 \otimes N_1) \\
\vdots \\
(M_w \otimes N_w)
\end{bmatrix}
\begin{bmatrix}
g \\
p \\
q \\
r
\end{bmatrix}
= \begin{bmatrix}
(M_1 \otimes N_1)^T \ldots (M_w \otimes N_w)^T
\end{bmatrix} y(D).
\]

By examination of the indicated operations it can be verified that

\[
(M_1 \otimes N_1)^T = M_1^T \otimes N_1
\]

and

\[
(M_1 \otimes N_1)^T (M_1 \otimes N_1) = M_1^T M_1 \otimes N_1 N_1
\]

Hence, the normal equations become

\[
\begin{bmatrix}
\Sigma_i (M_i^T \otimes N_i N_i) T
\end{bmatrix}
\begin{bmatrix}
g \\
p \\
q \\
r
\end{bmatrix}
= \Sigma_i (M_i \otimes N_i)^T y(p_i)
\]

* If \( A=(a_{ij}) \) and \( B=(b_{kl}) \), then \( A \otimes B=(a_{ij}B) \). See, e.g., [4]
Definition of the parameters.

The parameters $g$, $p$, $q$ and $r$ will be defined in terms of the expected responses in the complete factorial.

Let the equations of expectation for the complete factorial (CF) be written as

$$\eta(CF) = E \ p(CF),$$

where $\eta(CF)$ is a column vector containing $(s+1)(t+1)$ expected responses, $E$ is a square matrix of order $(s+1)(t+1)$, and $p(CF)$ is a column vector containing $(s+1)(t+1)$ parameters. If $E$ is non-singular, then the parameters $p(CF)$ are defined by

$$p(CF) = E^{-1}\eta(CF).$$

We shall define the matrix $E$ as follows. The vector of coefficients of $g$ (a column of $E$) is the unit vector.

For any factor $F$ with $i$ levels, we introduce $i-1$ parameters, which may be referred to as the linear effect, the quadratic effect, the cubic effect, etc. The elements in the vector of coefficients (a column of $E$) of each of these effects are the values of the corresponding orthogonal polynomial $[2]$.

For example, if a factor has three levels, 0, 1 and 2, then there are two parameters: the linear effect and the quadratic effect. The coefficient of the linear effect is $-1$, 0, or 1 and of the quadratic effect is $1$, $-2$ or $1$, depending on whether the factor is at level 0, 1 or 2.
Other parameters are associated with several factors simultaneously, and may be called interaction effects. The vector of coefficients of such an effect (a column of E) is obtained by taking the element by element products of the several corresponding vectors. For example, consider factors $F_1$, $F_2$ and $F_3$ which have 2, 2 and 3 levels, respectively.

The vector of coefficients of the linear by linear by quadratic effect is obtained as indicated below:

<table>
<thead>
<tr>
<th>Level</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>$F_1$</td>
<td>$F_2$</td>
</tr>
<tr>
<td>0 0 0</td>
<td>-1</td>
</tr>
<tr>
<td>0 1 0</td>
<td>-1</td>
</tr>
<tr>
<td>1 0 0</td>
<td>1</td>
</tr>
<tr>
<td>1 1 0</td>
<td>1</td>
</tr>
<tr>
<td>0 0 1</td>
<td>-1</td>
</tr>
<tr>
<td>0 1 1</td>
<td>-1</td>
</tr>
<tr>
<td>1 0 1</td>
<td>1</td>
</tr>
<tr>
<td>1 1 1</td>
<td>1</td>
</tr>
<tr>
<td>0 0 2</td>
<td>-1</td>
</tr>
<tr>
<td>0 1 2</td>
<td>-1</td>
</tr>
<tr>
<td>1 0 2</td>
<td>1</td>
</tr>
<tr>
<td>1 1 2</td>
<td>1</td>
</tr>
</tbody>
</table>

We have defined $E$, and now shall examine the definitions of the parameters. We may write

$$E(dI) = C$$

where $(dI)$ is a diagonal matrix and $C$ is an orthogonal matrix. The element $d_{jj}$ of $(dI)$ is $(\sum e_{ij}^2)^{-1/2}$, where $e_{ij}$ is the element in the $i$th row and $j$th column of $E$. 
Because $E(dI)$ is orthogonal,

$$[E(dI)]^{-1} = [E(dI)]^T,$$

whence

$$E^{-1} = (dI)^2_{ET}$$

Therefore,

$$p(CF) = (dI)^2_{ET} \eta(CF).$$

This equation defines the effects in terms of the expected responses.
A one-half replicate of the $2^3 3^2$.

The following set of tables, Tables 1, ..., 8 traces the application of the method to a particular $1/2$ replicate of the $2^3 3^2$ complete factorial.

Table 1 contains the 36 treatment combinations which comprise the design, together with data for an illustrative example. There are three factors, A, B, and C which have two levels, and two factors, $\alpha$ and $\beta$, which have three levels. The collection $C_1$ contains A, B, C and the collection $C_2$ contains $\alpha$ and $\beta$. The sets of $C_1$ are

\[
\begin{array}{ccc}
A & B & C \\
0 & 0 & 0 \\
1 & 1 & 0 \\
1 & 0 & 1 \\
0 & 1 & 1 \\
\end{array}
\quad \text{and} \quad
\begin{array}{ccc}
A & B & C \\
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1 \\
1 & 1 & 1 \\
\end{array}
\]

and the sets of $C_2$ are

\[
\begin{array}{ccc}
\alpha & \beta \\
0 & 0 \\
0 & 2 \\
1 & 1 \\
\end{array}
\quad \text{and} \quad
\begin{array}{ccc}
\alpha & \beta \\
0 & 1 \\
1 & 0 \\
2 & 1 \\
\end{array}
\]

The treatment combinations of $m_1$ are adjoined to those of $n_1$, and those of $m_2$ to those of $n_2$ to form the $4 \times 5 + 4 \times 4 = 36$ treatment combinations in Table 1.

\]

\[
= \frac{1}{2^{8/3}}
\]
Tables 2 and 3 contain sketches of the equations of expectation. At the left are the expected responses $\eta(000)$, $\eta(110)$, etc., with $\eta(\ )$ omitted. The equality signs have been omitted and the parameters (effects) have been indicated at the top, instead of as column vectors. In Table 2 it is understood that the + and - are to be read as +1 and -1. The matrices $M_1$, $M_2$, $N_1$ and $N_2$ have been indicated.

The notation for the effects is as follows: The symbol $E$ denotes "effect", and the five positions correspond, in order, to A, B, C, $\alpha$ and $\beta$. The comma separates A, B, and C from $\alpha$ and $\beta$. Zero (0) in a position indicates that no effect of the corresponding factor is involved in the definition of $E(\ )$. One (1) in a position indicates that the linear effect of the corresponding factor is involved, and two (2) that the quadratic effect is involved.

The following typical examples should suffice to explain the notation:

- Grand average: $E(000,00)$
- Main effect of A: $E(100,00)$
- Interaction, A with B: $E(110,00)$
- Linear effect of $\alpha$: $E(000,10)$
- Quadratic effect of $\alpha$: $E(000,20)$
- Linear $\alpha$ by linear $\beta$: $E(000,11)$
- Linear $\alpha$ by quadratic $\beta$: $E(000,12)$
- Linear A by linear $\alpha$: $E(100,10)$
- Linear A by quadratic $\alpha$: $E(100,20)$
Tables 4 and 5 exhibit the matrices $M_1^T M_1$, $M_2^T M_2$, $N_1^T N_1$, and $N_2^T N_2$; and Table 6 displays the matrix of coefficients of the normal equations. This matrix is of order 72, and decomposes into four identical submatrices of order 18. These submatrices are of rank 9, which implies that it is impossible to uniquely estimate the 72 effects.

At this point it is reasonable to equate certain effects to zero, and to solve for the remaining effects. A selection of effects to be estimated is indicated by asterisks in Table 7. (The unstarred effects are put equal to zero.) The effects to be estimated are all of the main effects and two-factor interactions.

The subsets in Table 7 correspond to the submatrices of Table 6. Solutions for the effects in subset 1 are particularly easy, because the corresponding matrix of coefficients is a diagonal matrix.

Table 8 displays the solution for the effects in subsets 2, 3 and 4. The symbol $Y(i_1 i_2 i_3, j_1 j_2)$ - where $i_1$, $i_2$, and $i_3$ take on the values 0 and 1; and $j_1$ and $j_2$ take on the values 0, 1 and 2 - denotes a linear combination of the observed responses. It occurs in the normal equation which corresponds to $E(i_1 i_2 i_3, j_1 j_2)$; and is the inner product of the vector of responses with the vector of coefficients of $E(i_1 i_2 i_3, j_1 j_2)$ in the equations of expectation.
From the inverse matrix, one may read the variances and covariances of the estimates. The maximum correlation between estimates is $18/[(36)(81)]^{1/2} = 1/3$.

There is very little correlation among the estimates. In fact, of the $27(26)/2 = 351$ pairs of estimates, there is correlation between the estimates in only 18 pairs.

If, instead of using the present design, one used the design*which is formed by adjoining the treatments of $m_1$ to those of $n_1$ and $n_2$, only 21 of the chosen effects would be estimable (the effects $E(100,00)$, $E(011,00)$, $E(010,00)$, $E(101,00)$, $E(001,00)$, and $E(110,00)$ would not be estimable).

It is interesting to compare the variances of the estimates obtained from the two designs. They are identical, except in six instances. For $\hat{E}(100,20)$, $\hat{E}(100,02)$, $\hat{E}(010,20)$, $\hat{E}(010,02)$, $\hat{E}(001,20)$, and $\hat{E}(001,02)$ the variance for the alternative design is $8/9$ as large as for the present design.

* As suggested in [1].
An illustrative example

The following example is taken from a paper by Youden and Zimmerman [3]. Youden was concerned with comparing various methods of producing tomato plant seedlings prior to transplanting in the field. Comparison was made by planting in the field and then weighing the ripe produce. Thus, the observations were pounds of tomatoes.

Although Youden used five methods of production, we shall select only three: flats, fibre pots, and fibre pots soaked in one percent sodium nitrate solution. Other factors considered were different soil conditions, different sizes of pots, different varieties of tomato, and different locations on the field. The factors and their levels are recorded below:

<table>
<thead>
<tr>
<th>Factor</th>
<th>Levels</th>
</tr>
</thead>
</table>
| Soil condition, A       | Field Soil
                          | Plus fertilizer         |
| Size of pot, B          | Three-inch
                          | Four-inch               |
| Variety of tomato, C    | Bonny Best
                          | Marglobe                |
| Method of production, α | Flat                    |
                          | Fibre                   |
                          | Fibre + NO₃             |
| Location on field, β    | 0, 1, 2                 |
The object of the experiment was to evaluate the effects of these factors on the yield of tomatoes. The observations have been recorded, along with the experiment design, in Table 1.

The first stage in the analysis is the same as for a complete factorial. We form a number of summary tables, which are given below:

**TABLE 9**
Summary Tables

</tbody>
</table>
The entry in any cell is the sum of the observations which have the row and column designations associated with the cell. For example, in the last table, the first entry is the sum of the observations in Table 1 which have \( \alpha = 0 \) and \( \beta = 0 \), i.e., the first four observations.

We calculate the Y's from the summary tables. For example, from the first summary table we compute

\[
Y(100,00) = -993.7 - 1100.7 + 1210.9 + 1415.9 = 532.4
\]
\[
Y(010,00) = -993.7 + 1100.7 - 1210.9 + 1415.9 = 312.0
\]
and \( Y(110,00) = 993.7 - 1100.7 - 1210.9 + 1415.9 = 98.0 \)

We observe that there is some repetition of Y's from the various tables. For instance, \( Y(100,00) \) is obtained from all four tables which have A as a factor. This repetition is unnecessary and in practice would be avoided. Having already calculated a Y from a previous table, we would not calculate it again.

The complete list of 27 distinct Y's is given in Table 10.
TABLE 10

Values of Y's

<table>
<thead>

</tbody>
</table>

The formulae and estimates of the main and interaction effects are given in Table 11.
TABLE 11
Estimated Effects

\[ \hat{E}(000,00) = \frac{Y_1}{36} = 131.1 \]

\[ \hat{E}(000,10) = \frac{Y_8}{12} = 29.7 \]

\[ \hat{E}(000,01) = \frac{Y_{16}}{12} = 43.0 \]

\[ \hat{E}(000,20) = \frac{Y_9}{24} = 14.7 \]

\[ \hat{E}(000,02) = \frac{Y_{17}}{24} = 21.4 \]

\[ \hat{E}(000,11) = \frac{Y_{24}}{8} = -7.6 \]

\[ \hat{E}(000,21) = \frac{Y_{25}}{16} = 22.2 \]

\[ \hat{E}(000,12) = \frac{Y_{26}}{16} = -20.5 \]

\[ \hat{E}(000,22) = \frac{Y_{27}}{32} = 12.2 \]

\[ \hat{E}(100,00) = \frac{65Y_2 + 2Y_{11} + 2Y_{19} + 9Y_7}{1152} = 29.3 \]

\[ \hat{E}(100,20) = \frac{Y_2 + 18Y_{11} + 2Y_{19} + 9Y_7}{384} = -8.6 \]

\[ \hat{E}(100,02) = \frac{Y_2 + 2Y_{11} + 18Y_{19} + 9Y_7}{384} = 4.8 \]

\[ \hat{E}(011,00) = \frac{Y_2 + 2Y_{11} + 2Y_{19} + 9Y_7}{128} = -2.4 \]

\[ \hat{E}(010,00) = \frac{65Y_3 + 2Y_{13} + 2Y_{21} + 9Y_6}{1152} = 18.9 \]

\[ \hat{E}(010,20) = \frac{Y_3 + 18Y_{13} + 2Y_{21} + 9Y_6}{384} = -14.1 \]

\[ \hat{E}(010,02) = \frac{Y_3 + 2Y_{13} + 18Y_{21} + 9Y_6}{384} = -9.5 \]

\[ \hat{E}(101,00) = \frac{Y_3 + 2Y_{13} + 2Y_{21} + 9Y_6}{128} = +13.7 \]

\[ \hat{E}(001,00) = \frac{65Y_5 + 2Y_{15} + 2Y_{23} + 9Y_4}{1152} = 34.0 \]

\[ \hat{E}(001,20) = \frac{Y_5 + 18Y_{15} + 2Y_{23} + 9Y_4}{384} = -6.7 \]

\[ \hat{E}(001,02) = \frac{Y_5 + 2Y_{15} + 18Y_{23} + 9Y_4}{384} = -10.7 \]

\[ \hat{E}(110,00) = \frac{Y_5 + 2Y_{15} + 2Y_{23} + 9Y_4}{128} = 4.1 \]
These formulae have been arranged into four sets. All of the estimated effects in the first set are uncorrelated. In addition the estimated effects within any set are uncorrelated with the estimated effects in any other set.

The analysis of variance is given in Table 12.

In order to evaluate the effects, t-tests were carried out. It was found that $\hat{E}(100,00)$, $\hat{E}(001,00)$, $\hat{E}(000,10)$ and $\hat{E}(000,01)$ are significant at the .01 level of significance. There were no other significant effects.

THE NATIONAL BUREAU OF STANDARDS

The scope of activities of the National Bureau of Standards at its headquarters in Washington, D. C., and its major laboratories in Boulder, Colo., is suggested in the following listing of the divisions and sections engaged in technical work. In general, each section carries out specialized research, development, and engineering in the field indicated by its title. A brief description of the activities, and of the resultant publications, appears on the inside front cover.

WASHINGTON, D. C.

- Office of Basic Instrumentation.
- Office of Weights and Measures.

BOULDER, COLORADO
