NATIONAL BUREAU OF STANDARDS

THE NATIONAL BUREAU OF STANDARDS

Functions and Activities

The functions of the National Bureau of Standards are set forth in the Act of Congress, March 3, 1901, as amended by Congress in Public Law 619, 1950. These include the development and maintenance of the national standards of measurement and the provision of means and methods for making measurements consistent with these standards; the determination of physical constants and properties of materials; the development of methods and instruments for testing materials, devices, and structures; advisory services to government agencies on scientific and technical problems; invention and development of devices to serve special needs of the Government; and the development of standard practices, codes, and specifications. The work includes basic and applied research, development, engineering, instrumentation, testing, evaluation, calibration services, and various consultation and information services. Research projects are also performed for other government agencies when the work relates to and supplements the basic program of the Bureau or when the Bureau's unique competence is required. The scope of activities is suggested by the listing of divisions and sections on the inside of the back cover.

Publications

The results of the Bureau's work take the form of either actual equipment and devices or published papers. These papers appear either in the Bureau's own series of publications or in the journals of professional and scientific societies. The Bureau itself publishes three periodicals available from the Government Printing Office: The Journal of Research, published in four separate sections, presents complete scientific and technical papers; the Technical News Bulletin presents summary and preliminary reports on work in progress; and Basic Radio Propagation Predictions provides data for determining the best frequencies to use for radio communications throughout the world. There are also five series of nonperiodical publications: Monographs, Applied Mathematics Series, Handbooks, Miscellaneous Publications, and Technical Notes.

Information on the Bureau's publications can be found in NBS Circular 460, Publications of the National Bureau of Standards (\$1.25) and its Supplement (\$1.50), available from the Superintendent of Documents, Government Printing Office, Washington 25, D.C.

IMPORTANT NOTICE

NATIONAL BUREAU OF STANDARDS
Intended for use within the Government. This report is not to be distributed outside the Government without the approval of the Director, National Bureau of Standards. It is not to be reproduced, stored in a retrieval system, or transmitted, in any form or by any means, electronic, mechanical, photocopying, recording, or by any information storage and retrieval system, without the prior written permission of the National Bureau of Standards.

Approved for public release by the
director of the National Institute of
Standards and Technology (NIST)
on October 9, 2015

Progress accounting documents
are not to be published. It is subjected
to production, or open-literature
production. If obtained in writing from
the National Bureau of Standards,
such permission is not needed,
except as noted on the title page.

U. S. DEPARTMENT OF COMMERCE
NATIONAL BUREAU OF STANDARDS

Report on the Design and Calibration
of
Luminance Standards
for
P₄ Phosphor

1. Scope

This report describes the design and calibration of luminance standards for the calibration of instruments which are used for measuring the luminance of television tubes with P₄ phosphor. One of these standards, designated as a "master" standard, is retained at the National Bureau of Standards. Similar calibrated standards are available for purchase from the NBS.

2. Description of the Luminance Standards

A complete luminance standard consists of: (1) a 500-watt lamp, (2) a 3 1/8-inch square of flashed opal glass bound to a 3 1/8-inch square of Corning 5900 daylight glass. In accordance with the request of the Joint Electron Tube Engineering Council, the relative spectral radiance of the standard is designed to match approximately the relative spectral radiance of a blackbody at a color temperature of 10,000°K. The relative spectral radiances of a blackbody at 10,000°K and of the standards are shown on the accompanying curve sheet.

The lamp is operated at a color temperature of 3000°K and the Corning 5900 daylight glass raises the color temperature of the light from the lamp, transmitted by the opal glass, to approximately 10,000°K.

3. Calibration

3.1 The lamps.

A 500-watt, T20-bulb, inside-frosted lamp having a filament specially constructed for photometric standards is supplied as a part of each luminance standard. The voltage across each lamp required to produce a color temperature of 3000°K was determined by comparing each lamp according to a substitution method with NBS working standards of color temperature. The comparisons were made visually by using the 9° x 13° field of a Lummer-Brodhun photometer.

The luminous intensity and the current for each lamp was then measured at the voltage which had been determined for the 3000°K color temperature. The luminous intensity measurements were made by means of a physical photometer. The physical photometer consists of a thermopile and luminosity filter and is a modified form of the one described in NBS J. Research 27 217 (September 1941) RPL415. For the luminous intensity measurement each lamp was burned base down. The orientation was such that the plane containing the two filament supports was perpendicular to the axis of the photometer. The side of the lamp where the number AA850 is stamped on

the bottom of the bulb was turned away from the photometer. The bottom of the bulb was 4 inches below the photometer axis and the photometric distance (measured to the filament supports) was 1 meter. The voltage, current, and luminous intensity for 3000°K color temperature for each lamp are given in the individual report accompanying each luminance standard.

3.2 The "master" standard.

The "master" standard consists of one of the lamps calibrated as described above and one of the diffusing "sandwiches". Before the parts of this "sandwich" were bound together each glass was measured separately. The spectral transmittances of the Corning 5900 daylight glass were measured on a General Electric recording spectrophotometer. From these data the transmittance of the daylight glass for light of color temperature 3000°K transmitted by the opal glass was computed. The transmittance is 0.098.

The effect of multiple reflections between the daylight glass and the opal glass on the luminance of the "sandwich" was measured as follows. The two glasses and a 500-watt projection lamp were mounted on a photometer bar with the daylight glass about midway between the lamp and the opal glass. The distance between the lamp and the opal glass was about 2 feet. The luminance of the opal glass was measured by a photoelectric photometer. The daylight glass was then placed against the opal glass and the luminance was again measured. The latter measurement was 1.012 times the former and represents the increase in luminance due to multiple reflections between the glasses.

From the transmittance of the daylight glass and the increase in luminance due to multiple reflections the luminance required on the opal glass alone to produce 20fL and 50fL on the "sandwich" when the glasses were bound together was computed. The distance between the 500-watt inside-frosted lamp which is a part of the "master" standard and the opal glass necessary to produce the computed luminance was then determined by means of a Macbeth illuminometer which had been calibrated by using the National Bureau of Standards SB3 luminance standard.

The two glasses were then bound together and used to calibrate similar "sandwiches" which are available for purchase from the National Bureau of Standards. The "master" standard is retained at the NBS and will be available for calibrating more "sandwiches" in case they are needed in the future.

3.3 The "sandwiches".

The "sandwiches" consist of 3 1/8-inch squares of Corning 5900 daylight glass and 3 1/8-inch squares of flashed opal glass similar to those used in the "master" standard. The luminance of each of the "sandwiches"

was determined relative to the luminance of the "master" standard. This was done by means of a photoelectric photometer. Each "sandwich" was placed in turn on a photometer bar at the same distance, about 15 inches, from a 500-watt inside-frosted lamp which is a part of the "master" standard. The lamp was operated at a color temperature of 3000°K and the luminance of each "sandwich" relative to the luminance of the "master" sandwich was measured. The distance required between each "sandwich" and the lamp which is supplied with it was computed from the relative luminance of the "sandwich" and the luminous intensity of the lamp. The distances required for 20fL and for 50fL do not follow precisely the inverse square law. This is to be expected because of the sizes of the components and the distances between them.

4. Using the Standard

It has been determined experimentally that for solid angles of acceptance up to and including the angle viewed by the Weston model 759 Foot Lambert meter, the standards closely approximate the angular distribution of luminance of a perfect diffuser. These standards thus serve to calibrate the Weston model 759 Foot Lambert meter or any instrument which has a smaller solid angle of acceptance; but the readings on the same diffusing area obtained by instruments with markedly different acceptance angles will agree only if that area diffuses light perfectly or nearly perfectly. To obtain by means of an instrument with a small acceptance angle a reading of an imperfect diffuser comparable to that on one with a large acceptance angle, readings on the former at several angles of view sampling the larger acceptance angle should be averaged.

When the model 759 Foot Lambert meter is used care should be taken to center the receiver on the "sandwich".

Each luminance standard when issued is accompanied by a report giving the following information.

1. Voltage and current of the lamp for 3000°K color temperature.
2. Luminous intensity of the lamp at the above voltage.
3. Distance between the lamp filament and the flashed opal side of the "sandwich" to produce 20fL.
4. Distance between the lamp filament and the flashed opal side of the "sandwich" to produce 50fL.

The lamps and the opal glass side of the "sandwiches" have been etched with identification numbers.

When a standard is used the glass "sandwich" should be illuminated from the flashed opal side and viewed from the blue-glass side. The "sandwich" should be centered on the photometer axis and the lamp aligned so that its filament supports are perpendicular to the photometer axis with the side of the lamp where the number AA850 is stamped on the bottom of the bulb turned away from the glass "sandwich". The bottom of the lamp should be 4 inches below the photometer axis. (This centers the lamp filament on the photometer axis.) The lamp voltage should be accurately set to the voltage given in the individual report. The distance between the opal glass side of the "sandwich" and the lamp filament should be accurately set to the value given in the report.

Relative Spectral Energy Distributions of a Black Body
at 10,000°K and of the Luminescence Standards

THE NATIONAL BUREAU OF STANDARDS

The scope of activities of the National Bureau of Standards at its major laboratories in Washington, D.C., and Boulder, Colorado, is suggested in the following listing of the divisions and sections engaged in technical work. In general, each section carries out specialized research, development, and engineering in the field indicated by its title. A brief description of the activities, and of the resultant publications, appears on the inside of the front cover.
