## U. S. DEPARTMENT OF COMMERCE

NATIONAL BUREAU OF STANDARDS

This is the sixth report on the current experimental, theoretical, and evaluative program, at the National Bureau of Standards, on the thermodynamic properties of selected light-olement and other compounds of primary interest in high-temperature research. The emphasis in the NBS work has been on the simpler substances-metals and alloys, a few of the oxidizer compounds, and especially the combustion products. The first part of the report discusses the accomplishments of the various NBS groups in the program during the past year and their plans for the coming year. The development of new apparatus and special techniques is fast apbroaching the stage where they can yield original data. A method recently developed in the program is described for the calibration, to an accuracy of 1 to $2 \%$, of the electrical-energy input to an exploding wire.

During its first two years the program was limited in scope to the compounds of $\mathrm{Li}, \mathrm{Be}, \mathrm{Mg}, \mathrm{Al}$, and Ti with the elements $\mathrm{H}, \mathrm{O}, \mathrm{F}, \mathrm{Cl}, \mathrm{N}$, and C. During the past year practical considerations have made it desirable to expand the coverage to include (a) "mixed" systems of the simpler compounds of interest (principally, compounds containing pairs of the above metallic elements), and (b) compounds of a number of other elements (especially $\mathrm{Zr}, \mathrm{Hg}, \mathrm{Pb}, \mathrm{W}, \mathrm{K}, \mathrm{Br}, \mathrm{I}, \mathrm{B}$, and Si ).

Several surveys of the existing thermodynamic data on the expanded ensemble of substances were initiated. These are up-to-date, but in most cases critical evaluation is still lacking. Preliminary results were given six months ago (in NBS Report 7093). The coverage in the present report includes: (a) the borates of $\mathrm{Li}, \mathrm{Na}, \mathrm{K}, \mathrm{Ca}$, and Pb (with "best" values for the heats of formation of about 25); (b) heats of formation of "mixed" oxides (with data on about 25); (c) the heats of formation of inorganic fluorine compounds of all the elements (covering several hundred substances); (d) low-temperature heat-capacity data on various compounds containing $\mathrm{W}, \mathrm{Pb}, \mathrm{Br}$, or I (with discussions of about 20); (e) high-temperature heat-content data (references and temperature ranges for several hundred substances); and ( $f$ ) phase relations, x-ray parameters, and heats of formation of intermetallic compounds in about 12 binary systems of the elements $\mathrm{Al}, \mathrm{Li}, \mathrm{Mg}, \mathrm{Si}, \mathrm{Ti}$, and Zr 。 Also included are tables of ideal-gas thermodynamic functions of $\mathrm{NF}_{2}, \mathrm{~N}_{2} \mathrm{~F}_{4}$, and (up to $10,000^{\circ} \mathrm{K}$ ) the single-charge positive ions of approximately 25 monatomic gases.

## INTRODUCTION

From the first the NBS program was planned and implemented to evaluate and provide, so far as possible, all the major thermodynamic properties contributing to chemical propulsion under equilibrium conditions. The first phase of the program, now largely completed, is the evaluation of existing data and the computation of the best tables possible therefrom. The second phase, active from the beginning and now the principal one, is the measurement of new data, both with existing apparatus and with new apparatus that has had to be developed.

With the aim of maximizing the number of important chemical systems for which there will exist a complete set of satisfactory thermodynamic properties, the experimental program is with few exceptions being deliberately limited to the simpler compounds involving $\mathrm{Be}, \mathrm{Al}, \mathrm{Li}, \mathrm{Zr}$, $\mathrm{H}, \mathrm{F}, \mathrm{O}, \mathrm{Cl}$, and N (potential fuel components such as hydrides and free metals, potential oxidizer components, and resulting combustion products such as metal fluorides and oxides). As the data status on two-element compounds has improved, the NBS program has been shifting its scope of research to include an increasing number of the numerous compounds of "mixed" type (such as intermetallic compounds, double fluorides, and oxyfluorides) which are inevitably important when, as is often the case, the fuel or oxidizer contains two oxidizable or two oxidizing elements.

The behavior of a given substance in propulsion depends on the simultaneous operation of a number of complementary thermodynamic properties, with no regard to the different techniques by which these properties are separately measured in the laboratory. For this reason the following summary of plans for further NBS work during the next fifteen months is subdivided by class of substance instead of by property or method of measurement. In this summary, the plans for future work are described in relation to the most important data gaps believed to exist at present. Following the summary is a more detailed account of the accomplishments during the past year of each working group, and of its plans for the next fifteen months.

## Metal Hydrides and Intermetallic Compounds

Except with discriminating methods like spectroscopy, accurate measurements are of limited value except on samples which are either highly pure or else well characterized. This problem has been most acute with some of the metal hydrides. A series of NBS measurements of the heat of formation of one hydride, probably the most accurate presently in existence for this compound, is nearly completed and will be extended only in the event that better samples become available. It is planned to make a systematic survey of the available data on light-metal hydrides to see
where further research is most needed. Those of next priority seem to be the "two-metal" hydrides. Previously unknown entropies of relatively stable hydrides will be available through NBS low-temperature calorimetry almost completed on LiH and $\mathrm{LiAlH}_{4}$, and were recently calculated for several zirconium-hydride compositions from earlier NBS work in another program.

The four metals being emphasized ( Li , Be, Al, Zr ) form six possible pairs, but the available data indicate that $B e$ forms no intermetallic compounds or solid alloys with Al or Li. Upon completion of the current survey, priority will be assigned to two of the remaining four pairs ( $\mathrm{Al}-\mathrm{Zr}$ and $\mathrm{Al}-\mathrm{Li}$ ). The corresponding intermetallic compounds will be studied, with analysis and possibly density measurements on those samples which can be procured.

## Oxidizer Compounds

Accurate heats of formation were measured earlier in the program for several solid perchlorates (those of armonium, lithium, sodium, and potassium), and that of nitronium perchlorate ( $\mathrm{NO}_{2} \mathrm{ClO}_{4}$ ) is expected to be completed soon. Proposed plans for subsequent work on a few additional compounds which may be classed as oxidizers include not solids, but rather, typical simple substances in the N-O-F system. There are several practical reasons why their heats of formation need careful determination, especially the following: (1) In the absence of actual data, the heats of formation of larger molecules containing N-F or $0-F$ bonds must often be estimated and compared using bond energies derived from the simpler molecules. (2) For many of the simpler compounds in the N-O-F system, no data exist or those that do exist disagree seriously--e.g., the values for $\mathrm{OF}_{2}$ cover a range of 14 kilocalories per mole.

It is planned that after the combustion calorimetry on aluminum and beryllium in fluorine discussed below have been completed, the heat of formation of the gas $\mathrm{OF}_{2}$ will be measured by flame calorimetry. However, if a sample of $\mathrm{OF}_{2}$ is unavailable the compound NOF may be substituted. Two important simple N-F compounds are $\mathrm{NF}_{3}$ and $\mathrm{N}_{2} \mathrm{~F}_{4}$. Their heats of formation were measured at the Bureau in other programs, which will sponsor further measurements on $\mathrm{N}_{2} \mathrm{~F}_{4}$ (heat of formation, low-temperature heat capacity and entropy, and the $\frac{4}{m i c r o w a v e ~ s p e c t r u m ~ o f ~ t h e ~} \mathrm{NF}_{2}$ produced by its dissociation) when purer samples become available. However, shockwave techniques have already reached a state of refinement at the Bureau, and the present program plans to include during the next year an extension of this method to the rate of dissociation of a simple $N-F$ compound such as $\mathrm{N}_{2} \mathrm{~F}_{4}$ or $\mathrm{NF}_{3}$, with accompanying spectroscopic determinations of the composition.

## Metal Fluorides and Chlorides

The planned continuation of this phase of the experimental program is based on priority of materials to be measured in the order (a) onemetal fluorides (as $\mathrm{AlF}_{3}$ ), (b) two-metal fluorides (as Li3 $\mathrm{AlF}_{6}$ ), and (c) chlorides (as $\mathrm{BeCl}_{2}$ ). Work on these substances involves four different apparatuses and methods already in use to measure heats of formation, entropies, and heat capacities of solids (and liquids), and three in the last stages of testing before being ready for measurements to define the composition and the heat and free energy of formation of the corresponding vapors. While individual problems (such as the tendency of $\mathrm{BeF}_{2}$ to solidify as a glass, and the common complexity of most of the metal-halide vapors) create difficulties, the above techniques are virtually capable of giving a complete set of thermodynamic properties for this class of substances.

The one-metal fluorides and chlorides whose heats of formation have been seriously in doubt have been $\mathrm{AlF}_{3}, \mathrm{BeF}_{2}$, and $\mathrm{BeCl}{ }_{2}$. Earlier experimental work in the program provided what seems to be an accurate value for $\mathrm{BeCl}_{2}$, and is expected to do so very soon for $\mathrm{AlF}_{3}$. The existing published values for $\mathrm{BeF}_{2}$ cover a range of 17 kilocalories per mole. It is planned to measure the heat of formation of this compound by direct combustion of the metal in fluorine, with the prospect that the technique successfully developed earlier for $\mathrm{AlF}_{3}$ will yield so near complete combustion as to give an unambiguous result for $\mathrm{BeF}_{2}$.

The low- and high-temperature heat capacities of the one-metal fluorides and chlorides are generally well-known except for those of beryllium. (The accepted high-temperature results for LiF and LiCl resulted from NBS measurements several years ago.) Low-temperature measurements are planned on $\mathrm{AlCl}_{3}$, and also on $\mathrm{BeF}_{2}$ and $\mathrm{BeCl}_{2}$ if samples can be obtained. Heat-capacity measurements on some two-metal fluorides also are tentatively planned: At low temperatures, on $\mathrm{Li}_{3} \mathrm{AlF}_{6}$ or $\mathrm{Li}_{2} \mathrm{BeF}_{4}$; at high temperatures, $\mathrm{Li}_{3} \mathrm{AlF}_{6}$ is expected to be completed soon. These mixed fluorides will be synthesized by melting together their components unless, as seems likely, an external source of pure samples becomes available. Although the important $\mathrm{AlF}_{3}-\mathrm{ZrF}_{4}$ system is believed to form no stable "mixed-metal" compound, an effort is being made to verify this fact.

With the above types of thermal data avallable, the vapor-pressure curves form the most reliable source of the heats of formation of the vapors of such relatively involatile compounds as the metal halides when the vapor composition is unambiguous or can be determined independently. A new vapor-pressure apparatus of the transpiration type, now being tested, will be used. The vapor pressure of $\mathrm{BeF}_{2}$ and LiF have been measured with fairly good precision elsewhere, although the composition of LiF vapor is complex and still in considerable doubt. Measurements are planned on $\mathrm{AlF}_{3}$ in inert atmospheres and also in an atmosphere of HF, to detect and measure the possible formation of Al-H-F gas species. If the latter search gives negative results, it is planned to make measurements on $\mathrm{ZrF}_{4}$, because there are serious discrepancies in the existing data.

The extension of the thermodynamic properties of metal-halide vapors to very high temperatures requires an accurate knowledge of their molecular structure, and for this purpose a microwave spectrometer which will operate up to about $1200^{\circ} \mathrm{K}$ is being constructed. If high-temperature tests in the near future show as satisfactory sensitivity as the instrument has shown at room temperature, measurements will be made on fluorides and chlorides of aluminum and beryllium. Diatomic species such as AlF are believed to be within the range of the apparatus, and the spectra of more complex molecules such as $\mathrm{AlClF}_{2}$ and corresponding beryllium species will be sought for study.

## Metal Oxides, Hydroxides, and Oxyfluorides

The heats of formation of $\mathrm{Al}_{2} \mathrm{O}_{3}, \mathrm{ZrO}_{2}, \mathrm{Li}_{2} \mathrm{O}$, and LiOH are believed to be known reliably. It is planned, however, to measure that of BeO , since it is presently uncertain by several kilocalories per mole. Although some attention has been devoted to the possibility of obtaining values for the "two-metal" oxides (such as $\mathrm{Al}_{2} \mathrm{O}_{3} \cdot \mathrm{BeO}$, for which a rather uncertain value is available by an indirect method), no plans were made for such work owing to the apparent lack of straightforward techniques and the priority of other tasks. The entropies and heat capacities of the onemetal oxides are generally well known to near the respective melting points. It is planned to measure the heat capacity of BeO from $1200^{\circ}$ to $1800^{\circ} \mathrm{K}$, and that of $\mathrm{BeO} \cdot \mathrm{Al}_{2} \mathrm{O}_{3}$ from room temperature to $1800^{\circ} \mathrm{K}$, as recent attempts to procure pure samples of macroscopic particle-size promise to be successful. The entropies of these two compounds are in doubt, so that heat-capacity measurements may be carried out over the low-temperature range too.

The properties of oxide, hydroxide, and oxyfluoride gaseous species of the above metals are unknown or far more uncertain, and several apparatuses are being developed to measure them at the high temperatures required. High priority will be given to obtaining results with a newly acquired mass spectrometer, with investigation first of the Be-0-F system. If beryllium oxyfluoride molecules are detected, it should be possible to evaluate their relative importance at different temperatures and pressures. Since such gaseous systems will almost certainly contain also $\mathrm{Be}-0$ and $\mathrm{Be}-\mathrm{F}$ species, it is planned to perform similar complementary experiments on $\mathrm{BeF}_{2}$ alone and BeO alone. Some work on these two compounds has appeared in the literature; further work on $\mathrm{BeF}_{2}$ will serve to check the apparatus and method, and work on BeO is expected to be more reliable than the earlier results by allowing the vapors to diffuse from relatively inert rhenium containers. If definitive results are obtained on the $\mathrm{Be}-0-\mathrm{F}$ system soon enough, additional tasks undertaken will be (1) measurement of the rate of vaporization of $\mathrm{Al}_{2} \mathrm{O}_{3}$ in vacuo and in the presence of water vapor under pseudo-equilibrium conditions, using the existing arc-image furnace, and (2) mass-spectrometric studies of the $\mathrm{Al}-\mathrm{O}-\mathrm{F}$ system. Important gaseous aluminum-hydroxide species would undoubtedly be present in the former system.

The exploding-wire experiment is another method currently under development to study metal-oxide gas systems (such as $\mathrm{Al}-0$ and $\mathrm{Zr}-0$ ) at still higher temperatures $\left(2000^{\circ}-6000^{\circ} \mathrm{K}\right)$ and up to pressures as high as 100 atmospheres. The apparatus has been built and is now in operation, but before measurements on the extremely transient and unusually complex hot system can be converted into reliable thermodynamic data, the detailed instrumentation and conditions of operation must be carefully investigated along several separate lines. High-speed photographic observations and pressure measurements are now well in hand, and during the past year a major goal was achieved when the accuracy of measuring the total electrical energy entering an exploding wire was verified. Two independent types of comparison with the heat energy produced gave agreement to better than 2 percent, which is considered unusually good for such short time intervals (a few microseconds). The additional phases of measurement also have been under study, but need much more work which is expected to occupy the next year. These phases are as follows: (1) Time- and space-resolved vapor-density measurements will be undertaken with X-rays (both soft and hard to accommodate systems containing different metals). (2) The metal vapor and surrounding gas must mix thoroughly. The hydrodynamic and diffusion aspects of this problem are being investigated theoretically. The experimental approach will seek empirically the conditions of power input, wire shape, etc. needed for uniform explosion, using photographic, X-ray, and chemical analytical criteria. (3) To determine the chemical composition of the vapor, it is planned to modify an existing type of grating spectrograph to provide adequate time and space resolution.

## Other Substances; Additional Tables

Light-metal compounds containing $\mathrm{B}, \mathrm{N}, \mathrm{C}, \mathrm{Mg}$, and Ti will receive considerably less priority than those discussed above. Among the nitrides and carbides, $\mathrm{Be}_{3} \mathrm{~N}_{2}$ and $\mathrm{Al}_{4} \mathrm{C}_{3}$ are two of the most important lacking heatcapacity data, and there are tentative plans for a series of measurements on each. In addition, heats of reaction of certain beryllium alkyls are planned in order to determine the strength of the $\mathrm{Be}-\mathrm{C}$ bond. Methods for preparing pure samples were reviewed earlier in the program. The thermodynamic properties of numerous non-metal boron compounds have been measured and reviewed thoroughly in earlier programs at the Bureau; and in a new program supported by the Air Force the heats of formation of the borides of aluminum and other metals will be measured by fluorine calorimetry. Tables of the thermodynamic functions of approximately 125 solids, liquids, and gases have been computed and issued earlier in the present program, and those for which better data become available will be revised.

## 1. THERMOCHEMLSTRY

## Experimental Thermochemical Studies:

Measurement of the heat of hydrolysis of nitronium perchlorate, $\mathrm{NO}_{2} \mathrm{ClO}_{4}$, has been started. These results will be combined with data previously determined in this Laboratory on other perchlorates to yield the heat of formation of nitronium perchlorate.

Future plans include measurements on the heat of solution of $\mathrm{BeCl}_{2}$ in order to resolve the apparent discrepancy in the heat of formation of the solid compound between the work of this Laboratory and unpublished data from Dow Chemical Company. Planned for measurement are also heats of reaction of certain beryllium alkyls to determine the strength of the Be-C bond, and the heat of formation of beryllium oxide.

## Tables of Thermodynamic Properties and of Heats of Formation:

The available thermochemical and thermodynamic data on the compounds of boron with hydrogen, oxygen, fluorine, chlorine, and bromine were reviewed, and a revised set of selected "best" heats of formation prepared. In addition, 49 tables of thermodynamic functions were calculated for individual boron compounds as either ideal gases or condensed phases. A critical discussion of the data used was included, to serve as a guide to the reliability of the values, and to indicate areas where additional work is needed.

Future activities of the compilation group will be directed toward a comprehensive review of the available thermochemical data for a complete revision of NBS Circular 500. This will include all of the compounds of the elements of interest, as part of the systematic coverage of the data. Special reports covering particular substances will be prepared as the data are reviewed.

## 2. FLUORINE CALORIMETRY

The heats of combustion of teflon and of aluminum-teflon mixtures in fluorine have been determined in a series of experiments. At the present, only preliminary values can be cited for the heats of these reactions as some calculations remain to be made and some of the corrections are not completely under control. The energy in the bomb process (constant volume) for the reaction of fluorine with the teflon used was found to be $10.344 \mathrm{kj} / \mathrm{gram}$ as the mean of five experiments with a standard
deviation of the mean of $0.007 \mathrm{kj} / \mathrm{gram}$. For the se reactions fluorine was injitially present at about 21 atm pressure and the product was $\mathrm{CF}_{4}$ with no higher fluorocarbons being observed. About 4 grams of teflon in the form of a powder were burned in each experiment.

For the combustion of aluminum-teflon mixtures, powdered materials were mixed in a proportion of about 1 part aluminum to 4 parts teflon by weight, the amounts being sufficient to cause a total heat release of about 43 kj . In these experiments, the teflon is burned essentially completely to $\mathrm{CF}_{4}$ - The solid product $\left(\mathrm{AlF}_{3}\right)$ is white except for scattered traces of gray material. It is found on all the bomb walls, indicating that at least part of the reaction occurs in the vapor phase. The product is a fine powder, of which the particle size has not been determined. The most successful combustions have been carried out with the pellet of aluminum-teflon mixture in a shallow recess in a nickel or monel plate resting on the bottom of the bomb. Rapid thermal equilibration was found to occur in this system, whereas in some earlier arrangements, the equilibration had been very slow. Using the energy of combustion of teflon described above, the energy of combustion of aluminum in fluorine under the bomb conditions (i.e., constant volume, and 21 atm of $F_{2}$ ) is in the neighborhood of $1,490 \mathrm{kj} /$ mole ( $357 \mathrm{kcal} / \mathrm{mole}$ ). Because of uncertainties in some of the corrections, at the time of writing, an uncertainty of about one percent must be attached to this value. The principal uncertainty appears to be in a determination of the heat to be attributed to combustion of the fuse. A nichrome fuse with aluminum supports was used, and combustion of the fuse was not complete in every case. The quantity of reaction is based upon the sample weight. Our preliminary value, which is the average of six measurements, agrees with that determined by Gross and co-workers within the experimental errors as known at this time.

Material of value to the work of this project in the critical evaluation of heats of formation of fluorine compounds, has been obtained in an independent project, in which a complete survey of material related to the heats of formation of inorganic fluorine compounds of all elements has been made, covering the period since 1948. That is, it begins at the close of the literature compiled for NBS Circular 500.

The combustion of aluminum in fluorine and the determination of the heat of formation of aluminum fluoride has proceeded to a point where it can be stated definitely that the work will be completed by September 30, 1961. The study of beryllium combustion will then begin, and the heat of formation of beryllium fluoride will be determined by a similar approach. The heat of formation of lithium fluoride (crystal) is not subject to uncertainties as large as those which we have named, and we will not expect to determine it. If time and personnel assignments permit, we shall undertake a study of the heat of formation of $\mathrm{OF}_{2}(\mathrm{~g})$ or of $\operatorname{NOF}(\mathrm{g})$, depending partly upon the availability of samples.

## 3. LOW-TEMPERATURE CALORIMETRY

The primary functions of the low-temperature heat-capacity phase of the program are the accurate measurement of the heat capacity of substances of interest in the condensed phases from about $15^{\circ}$ to $400^{\circ} \mathrm{K}$ and the calculation of the thermal functions from the results of the measurements. During the period July 1, 1960 to July 31, 1961, the efforts of the group have been directed also, with the increase in the number of elemental species important to the program, to literature survey. Investigations of methods of preparation and of sources of procurement were made of those substances where heat data were lacking or considered questionable. Low-temperature heat-capacity data were analyzed wherever available and joined smoothly with high-temperature heat-content data, and the thermal functions were calculated from the results of the analysis.

Measurements were completed on a high-purity ( 99.9 percent) BeO sample in the form of pellets prepared by compressing and sintering a powder of "sub-micron" size. The material did not sinter as well as materials of lower purity are known to sinter. The pellets were very fragile and broke readily into fine particles. The analysis of the heat data showed significant deviation from results previously published. In order to ascertain whether the difference is caused by the effect of particle size, further measurements are planned on BeO of larger particle size as soon as a sample becomes available.

Gross (sample-plus-container) measurements on LiAlH 4 have been completed from $15^{\circ}$ to $320^{\circ} \mathrm{K}$, and the measurements on the empty container are in progress. Similar to LiBH , no solid-phase transition was observed. Heat measurements on $\mathrm{K}_{4} \mathrm{H}_{4}$, if available, would be interesting since $\mathrm{KBH}_{4}$ as well as other alkali borohydrides are known to have solid phase transitions. The gross measurements on a LiH sample have also been completed. Measurements on the empty container are expected to start soon. Apparatus was designed for the purification of $\mathrm{AlCl}_{3}$ and for the subsequent transfer in the liquid phase to a platinum sample container. The purification of $\mathrm{AlCl}_{3}$ is in progress.

Recently published low-temperature heat-capacity data on Li and LiCl were analyzed and revised tables of their thermal functions were obtained. Analysis and calculation of thermal functions were extended to the following compounds: $\mathrm{TiO}, \mathrm{Ti}_{2} \mathrm{O}_{3}, \mathrm{Ti}_{3} \mathrm{O}_{5}, \mathrm{TiO} 2$ (rutile and anatase), $\mathrm{Zr}, \mathrm{ZrO}_{2}, \mathrm{ZrN}$, and $\mathrm{ZrCl}_{4}$. These tables were issued in NBS Report No. 7093 (Jãnuary 1, 1961). ${ }^{4}$

The phase behavior of binary systems of $\mathrm{Li}, \mathrm{Al}, \mathrm{Be}, \mathrm{Mg}$, and Zr fluorides and chlorides was investigated preparatory to possible procurement of mixed binary compounds of these halides for heat measurements. The results of this study were given in NBS Report No. 7093. Literature survey of heat data has been extended to compounds of lead and tungsten, and these results are given elsewhere in this report.

During the next year heat-capacity measurements in progress on LiH and $\mathrm{LiAlH}_{4}$ will be completed. Measurements will be completed on $\mathrm{AlCl}_{3}$ which is now being prepared for the measurements. A sample of BeO of large crystal size will be investigated whenever it becomes available. Measurements will also be made on an $\mathrm{Al}_{4} \mathrm{C}_{3}$ sample now on hand. Depending upon the complexity of each task about two to four of the following substances are planned for study:
a) Li3 $\mathrm{HAFF}_{6}$. This substance may be prepared by heating stoichiometric portions of LiF and $\mathrm{AlF}_{3}$ to a temperature above the melting point of LiF ( $848^{\circ} \mathrm{C}$ ). The melting point of Li3 $\mathrm{AlF}_{6}$ is $790^{\circ} \mathrm{C}$. The subsequent cooling of the melt should yield crystaline $\mathrm{Li}_{3} \mathrm{AlF}_{6}$. To save time it is hoped that this material could be prepared elsewhere for us. Meanwhile, samples of $\mathrm{AlF}_{3}$ and LiF will be obtained for possible preparation of $\mathrm{Li}_{3} \mathrm{AlF}_{6}$. A furnace for this purpose has been obtained.
b) $\mathrm{BeCl}_{2}$. A group willing to supply a vacuum-sublimed sample free of $\mathrm{AlCl}_{3}, \mathrm{FeCl}_{3}$, and BeO was located. As soon as the total purity of the sample that group intends to supply can be firmly established, a sample will be purchased.
c) BeF2. The commercial process used to obtain $\mathrm{BeF}_{2}$ by thermal decomposition of $\left(\mathrm{NH}_{4}\right) \mathrm{BeF}_{4}$ at about $1000^{\circ} \mathrm{C}$ yields a glassy material. Sublimation of $\mathrm{BeF}_{2}$ and decomposition of $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{BeF}_{4}$ below the melting point of $\mathrm{BeF}_{2}\left(548^{\circ} \mathrm{C}\right)$ are known to yield crystalline BeF2. Crystalli-
 crystalline $\mathrm{BeF}_{2}$. A possible source of crystalline $\mathrm{BeF}_{2}$ is being contacted.
d) $\mathrm{BeO} \cdot \mathrm{Al}_{2} \mathrm{O}_{3}$. Work is in progress at NBS to prepare this material, probably by heating a stoichiometric mixture to about $1900^{\circ} \mathrm{C}$.
e) $2 \mathrm{LiF} \cdot \mathrm{BeF}_{2}$. This material can be prepared by heating a stoichiometric mixume to about $500^{\circ}$ to $600^{\circ} \mathrm{C}$. Efforts are being made to have a sample prepared. If unavailable, the substance will be prepared in the furnace mentioned earlier. Samples of LiF and $\mathrm{BeF}_{2}$ are available.
f) $\mathrm{AlF}_{3}-\mathrm{ZrF}_{4}$ and $\mathrm{Al}_{2} \mathrm{O}_{3}-\mathrm{ZrO}_{2}$. Compounds of these binary systems are not knowno Eutectic nixtities of these systems may be investigated.
g) $\mathrm{Be}_{3} \mathrm{~N}_{2}$ and $\mathrm{Li}_{3} \mathrm{~N}$. These substances can be prepared directly from the elements. Efforts will be made to prepare $\mathrm{Be}_{3} \mathrm{~N}_{2}$ and, if time permits, $\mathrm{Li}_{3} \mathrm{~N}$ for heat measurements.
h) Others. The interest of the program has extended to compounds of $\mathrm{K}, \mathrm{Br}, \mathrm{I}, \mathrm{Hg}, \mathrm{Pb}$, and W . Possible heat measurenents on some of these compounds are being considered with, however, a low priority in mind.

## 4. HIGH-TEMPERATURE CALORTMETRY

These measurements supplement low-temperature calorimetry in providing enthalpy-temperature data on which the thermodynamic functions of solids and liquids are based and, in many cases, estimated by extrapolation to still higher temperatures if the actual data are reliable. In contrast to the work at low temperatures, the high-temperature calorimetry conducted in the present program uses the "drop method" exclusively. The two available apparatuses are adapted to two adjoining temperature ranges ( $300^{\circ}$ $1200^{\circ} \mathrm{K}$ and $1200^{\circ}-1800^{\circ} \mathrm{K}$ ). Although some work was done with both apparatuses during the past year, no new final data were obtained owing to difficulties of the three most formidable types commonly encountered in high-temperature measurements of this kind. These three problems; which are discussed below under separate headings, are believed to be under sufficient control for reliable measurements soon.

## Finding Inert Container Materials:

Measurements on $\mathrm{Li}_{3} \mathrm{AlF}_{6}$ over the range $273^{\circ}-1200^{\circ} \mathrm{K}$ were undertaken. Since it had proved difficult to procure a sample of this congruently melting compound, samples were synthesized by melting together, directly in the sealed calorimetric container, high-purity LiF and sublimed $\mathrm{AlF}_{3}$ in stoichiometric proportions. The thermodynamic properties indicate that a silver container would be inert to the sample. The apparatus did not permit exceeding the high melting point of $\mathrm{AlF}_{3}$. But there was good reason to believe that in a reasonable time at $1173^{\circ} \mathrm{K}$ this solid would completely dissolve in the molten LiF to form the pure liquid mixed fluoride, and that completion of this process would be verified by lack of upward drift with time of subsequent enthalpy measurements, owing to the considerable heat of fusion of aluminum fluoride.

After a few hours of such heating, three subsequent enthalpy measurements at the same temperature showed no appreciable drift and thus indicated success in forming the pure sample. However, a welded seal of the silver container opened, so that a considerable amount of the sample escaped by vaporization during each run, making the corrections too large to be reliable. A Pt-10\%Rh container, next tried, was tight for awhile, but sprang a leak before any measurements could be made. This parallels a report in the literature that this alloy failed to contain molten $\mathrm{Na}_{3} \mathrm{AlF}_{6}$ above $1373^{\circ} \mathrm{K}$, as well as earlier difficulties in this laboratory in containing molten NaOH , and is believed to be due to intergranular penetration of the metal without the occurrence of chemical corrosion. Further work with $\mathrm{Li}_{3} \mathrm{AlF}_{6}$ has been postponed till a pre-formed sample can be procured that requires no prolonged heating in the calorimetric apparatus.

## Accurate Measurement of Sample Temperatures in the Furnace:

This is no problem with the lower-temperature apparatus, owing to the large isothermal region afforded by a massive silver core. In the case
of the higher-temperature furnace, where silver cannot be used for this purpose, an alumina insert was procured and installed in the center of the core to reduce to 1 mm or less the gap between wall and suspended sample. While no tests of the modified arrangement have yet been made, it is believed that the improved heat conduction will hold the sample much closer to the measured wall temperature than earlier tests had shown.

During the past year this apparatus (for enthalpy measurements up to $1800^{\circ} \mathrm{K}$ ) was described in very extensive detail in an NBS publication.* The top of the ice calorimeter had been constructed of an $\mathrm{Fe}-\mathrm{Co}-\mathrm{Ni}$ alloy to approximate the thermal expansion of the glass container, but on standing for many months in ice or cold water, this alloy began to corrode seriously. The rate of corrosion was recently reduced considerably by the well-known expedient of setting up a permanent electrical potential which keeps the alloy cathodic.

## Procurement and Analysis of Pure Samples:

The availability of pure samples, or accurately analyzed ones whose impurities can be corrected for, is necessary for accurate measurements. The NBS Applied Analytical Research Section has recently been able to begin the careful analysis of samples of $\mathrm{AlF}_{3}$ and $\mathrm{Al}_{4} \mathrm{C}_{3}$. An extensive search was recently made for sources of the best samples of the substances listed in the next section. Members of the Reactor Chemistry Division, Oak Ridge National Laboratory, have kindly offered to assist so far as possible in the problem of obtaining pure samples of metal fluorides and mixed metal fluorides for this program. In a long-term program of their own they have had extensive experience in determining the exact phase relations of metal fluoride systems, and may be able to make a few tests soon for the existence of stable mixed fluorides in some of the heretofore uninvestigated systems of primary chemical-propulsion interest. In addition, the Oak Ridge National Laboratory has recently been able to produce BeO of relatively large particle size which may be available on a limited scale for NBS measurements. The NBS Engineering Ceramics Section is cooperating by investigating alternative methods of preparing the pure mixed oxide $\mathrm{BeO} \cdot \mathrm{Al}_{2} \mathrm{O}_{3}$ from the two binary oxides, with x-ray examination as a criterion of complete compound formation. It appears feasible to use similar tests to look for compound formation in the $\mathrm{Al}_{2} \mathrm{O}_{3}-\mathrm{ZrO}_{2}$ system.

[^0]If present tests of apparatus performance progress as expected, the enthalpy of $\mathrm{Al}, \mathrm{C}_{3}$ over the range $273^{\circ}-1200^{\circ} \mathrm{K}$ will be measured within the next three months. The high-temperature measurements of enthalpy planned for the following year consist of $\mathrm{BeO} \cdot \mathrm{Al}_{2} \mathrm{O}_{3}\left(273^{\circ}-1800^{\circ} \mathrm{K}\right)$, $\mathrm{Li}_{3} \mathrm{AlF}_{6}\left(273^{\circ}-1200^{\circ} \mathrm{K}\right)$, and $\mathrm{BeO}\left(1200^{\circ}-1800^{\circ} \mathrm{K}\right)$. But in the unlikely event that tests described in the preceding section reveal stable compounds in the $\mathrm{AlF}_{3}-\mathrm{ZrF}_{4}$ and $\mathrm{Al}_{2} \mathrm{O}_{3}-\mathrm{ZrO}_{2}$ systems, enthalpy measurements on them will be given high priority if samples can be obtained.

## 5. HYDRIDES AND INTERMETALLIC COMPOUNDS OF LIGHT ELEMENTS

The work on the light metal hydrides was continued. Improvements in synthetic and analytical techniques have provided a better insight into the nature of the structure of these materials. However, there are still some disturbing facts which indicate that the presently accepted structures are not perfect. Most of the samples of the light-metal hydrides were used by the group making heat-of-formation measurements. This work will be summarized completely in a separate report.

The studies of the aluminum hydride-trimethylamine adducts were reported suspended as of June 1960. However, one preparation was made of aluminum hydride-bis-trimethylamine, but the product was not considered pure enough for further vapor-equilibrium studies.

A survey has been made of the alloys and intermetallic compounds of aluminum, beryllium, lithium, and magnesium with each other and with silicon, titanium and zirconium. This survey contains primarily phase-composition relations, crystallographic data, density and volume data, and heats of formation. The material on the beryllium alloys was reported in the last semi-annual report (NBS Report 7093, January 1, 1961). The data on the other systems is included as a separate chapter in this report.

Due to activation of projects elsewhere, the preparation of binary light-metal hydrides will be deemphasized at the Bureau. Small amounts of these materials will be prepared as required by other groups in the Bureau or by the over-all ARPA program. Searches will be continued for better methods of preparing and analyzing the light hydrides, and liaison will be maintained with other laboratories with the aim of finding realistic structures for these materials. As an aid to the calculation of heats of formation of these materials, samples of the related organometallic compounds, free of polar adduct, will be prepared for heat-of-formation studies. Research will be performed on the preparation of mixed hydrides of the light elements.

Since a satisfactory heat of formation has not been obtained for aluminum hydride, it has been suggested that a study be made of the trimethylamine adducts of aluminum hydride using mass-spectrometric techniques. By this means, vapor and decomposition pressures may be obtained, along with decomposition potentials and mass data for the adduct. By using the heat of addition of the trimethylamine moiety to the aluminum hydride it should be possible to arrive at a heat of formation of aluminum hydride. It will be the responsibility of this group to prepare or procure, purify, and analyze the aluminum-hydride adduct, and to coordinate the program on this compound.

The survey of alloys and intermetallic compounds of the light elements will continue. The study of specific systems will be pursued. This phase of the program will include procurement and analysis of samples, and determination and calculation of properties. For the present, these studies will be limited to one system.

Purification work as required by other groups will be carried out on request.

## 6. LIGFT-ELEMENT EQUATION OF STATE

The over all objective of this project is to determine, by experimental measurements, the equation of state of selected elements (Be, Al and Zr ) and their compounds at temperatures between 2000 and $6000^{\circ} \mathrm{K}$ and pressures up to 100 atmospheres. The immediate objective is the systematic exploration of the exploding wire method as the means for producing a two-component (e.g. Al vapor and oxygen), high temperature, high pressure system so that the thermodynamic properties of the system under quasi-equilibrium conditions may be measured. Thus far, this study of the feasibility of the exploding wire method has entailed the design, construction and instrumentation of an experimental apparatus. It has also required the exploration and development of techniques of high-speed observation and measurement, so as to permit a time-resolved study of the state of the exploding wire system. These tasks are in various stages of completion, and will be continued during the next year.

Activity Summary - July 1, 1960 to June 30, 1961
The basic design of the experimental setup and the experimental method are described in some detail in NBS Report 6484 (July 1, 1959). During the past year, because of difficulties with unreliable triggering, the experimental setup was modified in several ways. The two parallel spark gaps used earlier were replaced with a new, single gap which is housed in a sealed chamber. This chamber is charged with nitrogen or argon in order to reduce the problem of electrode erosion by oxidation.

The new electrodes are made of a copper alloy, tipped with a tungstencopper material known as "elkonite". Tests showed that these electrodes withstood the high current (220,000 amps peak) discharges somewhat better than the smaller tungsten-tipped electrodes used earlier. The electronic triggering circuit was also modified. The trigger spark gap and the trigger condensers were removed, and a high-energy pulse from a thyratrontriggered, 15 kv pulse generator is now used directly for breaking down the spark gap. Test results show this new setup to be more reliable. The jitter is about 1 to 2 microseconds.

The main effort during the past year was concentrated on the development of techniques of high-speed measurement for determining the state of the exploding wire system under transient conditions. The techniques for measuring the current and the voltage in the discharge circuit received the major attention. A new coaxial shunt and a special low inductance voltage divider, designed and constructed for this experiment by Mr. John H. Park of the Electrical Instruments Section of this Bureau, were installed. In addition, a calorimetric method for calibrating the total electrical energy dissipated in the discharge was developed. Using this method, we were able to achieve agreement to within 1 to 2 percent between the measured electrical energy (obtained from the voltage and current measurements) and the measured calorimetric heating energy. This work is described in detail in Part B of this report. A full report is soon to be submitted for publication in the NBS Journal of Research.

Considerable effort was also devoted to the development of techniques suitable for high-speed photographic observation of the exploding wire. A Beckman and Whitley, Model 189 Framing Camera was installed, and has been used to make preliminary observations of the explosion phenomena. The problem of multiple exposure imposed by the camera's slow ( $1 / 25 \mathrm{sec}$ ) mechanical shutter has been overcome by the development of a high-speed shutter. This shutter is made up of two parts: a fast-opening part and a fast-closing part. The fast-closing action is obtained from the blackening of a window by exploding a series of parallel lead wires. This was first developed by H. E. Edgerton (Review of Scientific Instruments, Vol. 27, No. 3, March, 1956). The fast-opening part of the shutter was developed specifically for this experiment and represents an original contribution. It consists of a piece of aluminum foil (approximately 1 in . X 3 in .) placed directly in front of the framing camera's diamond-shaped stop so that no light may pass into the camera. The opening action is obtained when a capacitor, charged to high voltage, is suddenly discharged through the foil. During the discharge the magnetic forces set up by the passage of current compress the fojl toward its center line, thus allowing light to pass into the camera. Experiments showed that the shutter is $75 \%$ open in $60-80$ microseconds. At the present time, another shutter of this type is under development. In this case two slightly overlapping foils are used to prevent passage of light into the camera. The foils are arranged to form the two arms of a loop circuit. Here the increased magnetic forces inside the foil
loop may be expected to give still faster opening action. The use of this combination fast-opening, fast-closing shutter with the framing camera will permit high-speed, time-resolved photographic observation of any portion of the exploding wire phenomenon.

For the pressure measurement, the transient pressure in the exploding wire vessel during the explosion was measured by means of a water-cooled, strain-gauge type pressure transducer. Although there was some difficulty with arcing from the exploding wire to the transducer, this technique may be considered fairly well developed.

For the density measurements, a simulated $x$-ray system was set up for working out the various problems associated with measuring the density of the exploded wire vapor by soft x-ray absorption. In this system, different thicknesses of Al foil are used to simulate the variable-density Al vapor. The time features of the experiment are simulated by passing the x-ray beam through a hole in a rotating wheel. The intensity of the transmitted beam is detected by means of a NaI crystal bonded to a photomultiplier, the output of which is displayed on an oscilloscope. This system has not progressed to a point where it can be applied to the exploding wire experiment. In addition to this soft x-ray work, a four-channel flash x-ray system was ordered. This unit will be used to study the density distribution of heavier vapors (such as zirconium and titanium) and the breakup process of the wire in the solid and liquid states.

Some work has also been done toward modifying a Jarrell-Ash spectrograph for the time-resolved determination of composition in the exploding wire system by spectrographic studies.

Another phase of our work, a theoretical stuay of the hydrodynamic aspect of the exploding wire system, was initiated during the past year. This study will concentrate primarily on the analysis of the flow field surrounding the exploding wire and the diffusion at the interface between the expanding wire vapor and the surrounding gas. Thus far this work has included a review of the open literature on related problems with cylindrical shocks.

## Plans for Period July 1, 1961 to September 30, 1962

The work in this next period will be a continuation of all phases of the work described above. Special attention will be given-to the remaining problems in the determination of the density and composition of the wire vapor as a function of space and time, by means of x-ray and spectrographic measurements. Concentrated effort will also be devoted to the problem of mixing of the metal vapor and the surrounding gas. It is hoped that the solution to these problems can be worked out in sufficient detail in the next 15 months, so that a full-scale effort may later be made in the determination of the data of state of the mixed system under conditions of high temperature and high pressure.

#### Abstract

The objective of the NBS shock tube progrom is the determination of thermodynamic and rate data for atmospheric gases (air, $\mathrm{O}_{2}, \mathrm{~N}_{2}$, NO) by the method of shock wave compression. In the next fiscal year part of the effort will be devoted to research on one of the simple $N \sim F$ compounds such as $\mathrm{N}_{2} \mathrm{~F}_{4}$ or $\mathrm{NF}_{3}$. Most of the previous activity in this program has been concerned with the refinement of techniques for the measurement of data for the gas behind the shock wave. In preliminary experiments with Mach 1.6 to 2.0 shocks in air the density (interferometric) and shock velocity (with light screens) were determined with an accuracy of 1 percent; pressure measurements (with a pressure transducer) were accurate to 3 percent. Similar measurements along with spectroscopic composition determinstions will be employed in an investigation of the rate of dissociation of $\mathrm{N}_{2} \mathrm{~F}_{4}$ behind weak shock waves. Plans were made to set-up the spectroscopic equipment soon after July l, 1961.

## 8. HIGH-TEMP ERATURE MICROWAVE SPECTROSCOPY

Microwave spectroscopy offers considerable promise for obtaining detailed structural information on some of the simpler molecular species which exist in high-temperature systems. The microwave spectrun provides very accurate values of the moments of inertia of a molecule, as well as information on vibrational energy levels and other molecular properties. A microwave spectrometer which will operate up to $800^{\circ}$ $1000^{\circ} \mathrm{C}$ has been under construction for this project. The spectrometer consists of a folded nickel waveguide suspended in an evacuated tank. The nickel Stark electrodes are supported by ceramic spacers. Resistance heating elements are mounted parallel to the waveguide. The various components have been assembled and tested at room temperature. The spectrometer showed satisfactory sensitivity and resolution in these room-temperature tests, which indicates that the waveguide design is probably suitable for high-temperature operation.

As soon as the final engineering details are taken care of, preliminary heating tests will be made. The spectrometer performance at high temperatures will be checked by observing the known spectra of suitable salts. The first new systems to be studied will probably involve the halides of aluminum and beryllium. The three most promising systems for the initial studies are: (1) the $\mathrm{Al}-\mathrm{AlCl}_{3}$ system, where it should be possible to detect the spectrum of AlCl , and possibly that of AlCl ; (2) the $\mathrm{Al}-\mathrm{AlF} 3$ system, where similar studies could be made; (3) the $\mathrm{BeCl}_{2}-\mathrm{BeF}_{2}$ system, where there is a chance of detecting the spectrum of BeFC .

## 9。 HALIDE SOLID-VAPOR EQUILIBRIA (TRANSPIRATION METHOD)

Construction of a transpiration apparatus and associated controlling mechanisms has been completed. Preliminary measurements of the vapor pressure of Calorimetry-Conference Standard-Sample benzoic acid at $100^{\circ} \mathrm{C}$ have been started. These measurements will permit evaluation of the behavior of the flow apparatus independently of the furnace.

It is the purpose of this section to describe the new apparatus with special emphasis on those features by which it differs from previous transpiration equipment.

## Furnace:

The $\mathrm{Pt}-20 \% \mathrm{Rh}$ wire wound resistance furnace is one meter long with a $42-\mathrm{cm}$ copper cylinder at the center designed to minimize temperature gradients. Preliminary experiments indicate that the gradients over this 42 cm region can be held to about $0.5^{\circ} \mathrm{C}$ by supplying heat to the ends of the furnace by other heaters associated with 5 cm -long-copper cylinders. The copper is contained in an inert gas to prevent corrosion and consequent reduction in thermal conductivity and melting point. An alternative nickel core has been made to permit furnace operation up to $1700^{\circ} \mathrm{K}$. Furnace temperatures are measured by $\mathrm{Pt} / \mathrm{Pt}-10 \% \mathrm{Rh}$ thermocouples and controlled to $\pm 0.15^{\circ}$ by Leeds and Northrop three-mode controllers feeding to magnetic amplifiers.

## Flow System:

The inert gas flow into the transpiration apparatus is monitored qualitatively by two National Instrument Laboratories Vol-0-Flo meters with ranges of 3 to 100 and 10 to $300 \mathrm{ml} / \mathrm{min}$. These meters can be read to about $0.2 \%$ of the full scale deflection.

After passing through the vapor cell and condenser the inert gas is collected in an American Meter Company 60-liter "meter prover" which measures the total volume continuously at a pressure within $0.002 \%$ of atmospheric pressure. The "prover" volume can be measured with a precision of $0.03 \%$ or better for a normal experiment. The gas is collected over vacuum-pump oil, with precautions to minimize absorption of gas by the oil.

## Vapor Cell Condenser:

The vapor cell and condenser are made of $\mathrm{Pt}-10 \% \mathrm{Rh}$. The essential features of the design are concentric construction (after Beusman*) and the use of pyrolytic graphite to prevent sticking of metal surfaces at high temperatures. The vapor cell is 20 cm long and 1.1 cm in diameter. The two sample boats are made of $\mathrm{Pt}-10 \% \mathrm{Rh}$.

[^1]The concentric design aids in bringing the flow gas to the furnace temperature. A l-mm-I. D. capillary of 10 cm length separates the vapor cell from the condenser and minimizes vapor transport by diffusion and heat loss out the ends by radiation. The major features of the apparatus are illustrated in the accompanying figure.

## Measurements on Benzoic Acid:

The few preliminary measurements which have been made on benzoic acid indicate the following advantageous features of the present design.
(1) The sample mass lost from the boats can be compared with the mass gained by the condenser. Preliminary experiments indicate that these two methods agree within the precision of weighing the condenser.
(2) The use of two boats of nearly identical dimensions permits extrapolation to low flow rates for measurements at flow rates too high for attainment of saturation. This may eliminate the need for complete saturation in an actual experiment if this is inconvenient to achieve.
(3) The vapor cell design will permit saturation of the flow gas at flow rates which are relatively high for a transpiration measurement. The present measurements indicate that $99 \%$ of saturation is achieved for benzoic acid at $100^{\circ} \mathrm{C}$ (vapor pressure about 1 mm ) with an argon flow rate of $35 \mathrm{ml} / \mathrm{min}$.

The values for the vapor pressure of benzoic acid determined by these measurements agree with those obtained by Davies and Jones* within the estimated precision of either experiment (about 1\%). The tests on benzoic acid will be continued in order to evaluate other features of the apparatus such as reproducibility of measurements and starting and stopping errors. Certain improvements in the apparatus are already planned as a result of these preliminary tests.

## Future Plans:

Following completion of the benzoic acid tests the system (AlF3 + argon) will be studied between $1150^{\circ}$ and $1400^{\circ} \mathrm{K}$. It is believed that this study may help to clarify the problem of association in saturated aluminum fluoride vapor.

Modifications in the existing flow system will precede study of the ( $\mathrm{AlF}_{3}+\mathrm{HF}$ ) system. Preliminary order-of-magnitude experiments are planhed. If these indicate appreciable reaction, quantitative measurements will be made. It is anticipated that empirical volatility data itself would have practical utility, but in addition it is hoped that such data would be interpretable in terms of heats and equilibrium constants of speciaic chemical reactions.
*M. Davies and J. Ifor Jones, Trans. Faraday Soc. 50, 1042 (1954).

Since the existing vapor pressure data for $\mathrm{ZrF}_{4}$ indicate considerable uncertainty as to pressure and vapor composition, it is planned to study the system ( $\mathrm{ZrF}_{4}+$ argon) between $925^{\circ}$ and $1200^{\circ} \mathrm{K}$.

## 10. VAPORIZATION OF REFRACTORY SUBSTANCES

The general philosophy of the experimental program to study the vaporization of refractory oxides and similar substances was discussed in the Fourth Technical Summary Report, NBS Report No. 6928, page 12 (July 1, 1960). The discussion centered around four measuring techniques which were under development at that time. Progress in the development of the techniques and changes of emphasis during the ensuing period are summarized below. Plans for continuing the activity during the forthcoming year are then presented.

## Statement of Accomplishments July 1, 1960 - June 30, 1961:

1. Mass Spectrometric Technique.

Owing to the importance of this approach, much of the experimental
work of the group has been subordinated to the task of expediting the construction, installation, and testing of this apparatus, and to training personnel. The direction-focussing mass spectrometer, custom built by Nuclide Analysis Associates, State College, Pa., has now been installed at NBS. During the year preliminary testing of the apparatus was carried out at State College, and one member of the group also spent a threemonth training period with W. A. Chupka at the Argonne National Laboratory. The last few months since installation have been devoted to a final checking of the instrument, to the removal of minor "bugs" or inconveniences in its operation, and to calibration of the Knudsen-cell inlet system. A temperature controller for use with the Knudsen cell, primarily in the $1800-2500^{\circ} \mathrm{C}$ temperature range, has yet to be obtained. Data on the power requirements of the electron-bombardment heat source have also been obtained, and will be used as basis for designing the controller. The apparatus is now ready for definitive measurementstobemade on selected systems, at least in the temperature range up to $1800^{\circ} \mathrm{C}$.

## 2. Image Furnace Technique.

Initial effort was devoted to the adaption or modification of the commercial arc image furnace in order to make measurements of rate of vaporization within reasonably well defined limits of precision. Two modifications permitted the arc to be operated at 300 amps 。 without overheating the ellipsoidal mirror. The measurement of the temperature of the heated sample was a major problem, but the overall uncertainty of corrected values has been considerably reduced: Visual flicker when observing the surface with an optical pyrometer has been eliminated by speeding up the beam-chopping mechanism. The rotating shutter and sector disc
which form integral parts of the mechanism were redesigned to give a more uniform chopping action. A technique was also developed for obtaining an approximate value of the emittance of the surface and will be useful in converting observed brightness temperatures to true temperatures.

Measurements of the rate of vaporization of aluminum oxide as a function of the pressure and composition of a surrounding gas phase have cormenced. Assuming the heated surface is always the same, the precision of measured rates of vaporization in vacuo is about $\pm 50 \%$. Temperature fluctuations account for much of the uncertainty, but better measurement and control of the area of the heated surface can be readily effected and should lead to a significant improvement in the precision. In the meantime, exploration of the problems involved in introducing controlled partial pressures of other gases, such as $\mathrm{H}_{2} \mathrm{O}$, into the system is progressing, and preliminary data is being obtained.

Using the arc image furnace, a technique has also been developed for vacuum-sealing a piece of tungsten inside an aluminum oxide sample. The usefulness of this type of sample is under investigation, as discussed below.

## 3. Microbalance Technique.

By vacuum-sealing a piece of tungsten inside an aluminum oxide sample (as mentioned above) it has been found possible to obtain rates of vaporization of the sample by suspending it in vacuum from a microbalance and heating it by induction. This method is comparatively free of the errors which were encountered when the sample was enclosed with an external heater, but it is too early to define how far the approach will be limited by diffusion of tungsten through the alumina. Measurements up to about $1700^{\circ} \mathrm{C}$ have so far been made, but they will be extended to higher temperatures before a full analysis of the data is made.
4. Knudsen Effusion Technique.

Little progress with this technique has been made, owing to the transfer of personnel to the mass spectrometric technique. Measurements of absolute effusion rates of the equilibrium vapors is, however, not outmoded by the mass spectrometric approach, because the accuracy of the latter method is limited by approximate values of the ionization cross-sections of the molecules. Interest in the technique is being maintained, therefore, but an active program is severely restricted by man-power shortages. In particular, the long-standing search for rhenium Knudsen cells has continued. A suitable composition from which to produce the cell is believed to have been found, and fabrication work on a cell is in progress.

## Program Plans July 1, 1961 - October 1, 1962

The following summarizes in order of priority the plans for the next 15 months. The plans reflect the current belief that major experimental problems will not restrict progress, except as indicated.

## Mass Spectrometric Technique.

1. Identification of gaseous species and determination of their equilibrium partial pressures in the following systems:
(a) $\mathrm{Be}-\mathrm{F}$
(b) $\mathrm{Be}-\mathrm{O}-\mathrm{F}$
(c) $\mathrm{Be}-\mathrm{O}$ (in W and Re Knudsen cells).
2. Of high priority, but subject to technique development, comparable studies to those listed above on the $\mathrm{Al}_{2} \mathrm{O}_{3}-\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{BeO}-\mathrm{H}_{2} \mathrm{O}$ systems.
3. Similar studies to those given under 1。) on Al-0-F systems.

Arc Image Furnace Technique.
4. Measurements of rates of vaporization of $\mathrm{Al}_{2} \mathrm{O}_{3}$ under pseudoequilibrium conditions.in
(a) Various partial pressures of $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$
(b) Other gases ( $\mathrm{A}, \mathrm{H}_{2}, \mathrm{O}_{2}$; etc.).

## Microbalance Techniaue.

5. Completion of measurements of rate of vaporization of $\mathrm{Al}_{2} \mathrm{O}_{3}$ in vacuum. It is not anticipated that this activity will continue beyond September 30, 1961.

Knudsen Cell Technique.
6. Absolute effusion measurements of BeO and $\mathrm{Al}_{2} \mathrm{O}_{3}$ from W and Re cells. Activity to be held in abeyance pending availability of adequate man-power.

## CHAPTER 1

PRELIMINARY REPORT ON THE CALORIMETRIC CALIBRATION OF THE ELECTRICAL ENERGY MEASUREMENT IN AN EXPLODING WIRE EXPERIMENT

by D. H. Tsai and J. H. Park

A discussion is present on the requirements and the methods for measuring the current and voltage during the transient discharge of a capacitor bank employed in an exploding wire experiment (see Part A, Section 6 of this report). A method is described for accurately calibrating the measured current, voltage and electrical energy by comparing the calorimetric heating of a fixed resistance element with the electrical energy dissipated in the element. Preliminary results here show that the accuracy of the energy measurement is about $1-2 \%$. Work is in progress to study the refinement of measurement techniques and sources of error.

## 1. Introduction

The present investigation has been carried out in connection with an exploding wire experiment, which involves the vaporization and explosion of a thin metallic wire by means of a sudden discharge of electrical energy through the wire. In order to understand and explain the temperature and energy relations in the exploding wire system, the propagation of the shock wave, and other related problems, it is important to be able to measure accurately the energy dissipated during the transient discharge. Such energy measurements are also needed in other applications of capacitor discharge experiments such as: (1) magnetic confinement in plasma experiments, (2) high-speed impact studies, (3) heat capacity measurement using a pulsed technique, (4) high voltage or high current impulse testing, and others.

This report described some results of an investigation of a calorimetric method for calibrating the electrical measurement of total energy dissipated in a fixed resistance element under the transient conditions of a capacitor-bank discharge. This method employed the fixed resistance element as a calorimeter, and compared the total heat energy measured by the calorimeter with the electrical energy obtained from the measured current through the element and the measured voltage drop across the element. Since the current and the voltage drop were measured independently of each other, the calibration also provided a separate check on these measurements. The check on the current measurement was especially interesting, because some confirmatory data were obtained on the performance of a coaxial shunt [I] ${ }^{1}$ that was used in this investigation.
$I_{\text {Figures }}$ in brackets indicate the literature references at the end of this paper.

Since the publication of reference [1], there have been some doubts expressed about the high-frequency performance of a shunt of this design. Although the present experiment was quite limited in frequency range, the method employed here was perfectly general, and obyiously could be applied in a higher frequency range.

The present results are of a preliminary nature. Only one sample test will be described to indicate the accuracy of the measurement. Further refinement of the experimental technique is being developed, and a study of the measurement accuracy under different test conditions is in progress. The final results will be given in a full report, and will be submitted for publication in the open literature.

## 2. Calorimetric Calibration

The basic principle of the calorimetric calibration is straightforward. The energy involved in the calorimetric heating of the resistance element is

$$
M C_{p} \Delta T,
$$

where $M$ is the mass of the element, $C_{p}$ its specific heat at constant pressure, and $\Delta T$ the temperature rise due to heating. The ohmic heating of the element is

$$
\int R i^{2} d t,
$$

where $R$ is the resistance of the element, $i$ the instantaneous current, and $t$ the time of heating, the integration being performed over the entire period of heating, usually from $t=0$ to $t=\infty$ in a discharge experiment. The instantaneous electrical energy involved is

$$
\text { e } 1 \mathrm{dt},
$$

where e is the voltage drop across the element. For an oscillatory discharge the area under the curve of ei vso $t$ goes alternately positive and negative as the energy is stored alternately in the magnetic and electric field. The total energy dissipated in the resistance element is

$$
\int_{0}^{\infty} e i d t,
$$

i.e., the net algebraic sum of the total area under the ei curve.

It there were no energy loss by heat conduction, convection or radiation, then

$$
M C_{p} \Delta T=\int_{0}^{\infty} R i^{2} d t=\int_{0}^{\infty} e i d t
$$

This equation is the basis for the calorimetric calibration investigated. The problems involved are two-fold. First is the achievement of the experimental conditions under which this equation holds true, and second is the accurate measurement of the various parameters. These are discussed below.

Requirements for Galorimeter. The exploding wire apparatus used in this investigation is shown in Fig. 1. This apparatus is similar to the one described in reference [2], except for minor modifications. For the present purpose, the fixed-resistance element (calorimeter) is installed in place of the exploding wire vessel. This arrangement preserves the symmetry of the current path, and allows the study of the problems of voltage measurement under conditions closely similar to those encountered in an actual exploding wire experiment. In addition to the geometrical requirements, the requirements of good calorimetry are: (I) Uniform heating along the entire length of the resistance element so that a representative temperature change may be obtained. (2) Small or known heat loss from the calorimeter. (3) Accurately known mass, heat capacity, and electrical resistance of the resistance element. (4) Accurate temperature measurement.

To satisfy requirements (1) and (2), the resistance element should be of a uniform cross-section, with known current paths along the entire length of the element, including the ends. To minimize the skin effect, (in order to achieve uniform current density over the cross-sectional area) the element should be cylindrical, with a wall thickness small compared to the diameter. To minimize the heat loss by conduction, the length of the element should be long compared to the diameter and tre wall thickness, and the temperature should be measured near the midpoint of the length. to minimize the heat loss by radiation and convection, the surface of the resistance element should be smooth and polished. In addition to the above physical characteristics, the mass and the resistance of the element and the energy input to the element should be so chosen that the temperature rise of the element is not too high. A high temperature rise not only would increase the heat loss, but also would, in general, affect the specific heat and resistance (requirement 3) of the element, and thus make it very difficult to determine both the heat energy in the calorimeter and the ohmic heating. On the other hand, too small a temperature rise would result in greater percentage error in the temperature measurement (requirement 4) and adversely affect the accuracy of the calorimetric heat energy measurement. Also, for maximum accuracy, the damping of the discharge circuit as a whole should not be too low, for then the discharge would be more oscillaroty, and it would be correspondingly more difficult to obtain an accurate measurement of the net area under the ei vs. $t$ curve.

The above are some of the more important general requirements in the design of the resistance calorimeter. In the present preliminary experiment, these requirements were only partially satisfied. However, in the experiments being planned, an effort is being made to satisfy the se requirements more fully.

One additional point is worth noting. In this investigation, the temperature of the resistance element was measured by means of a pair of thermocouple wires welded individually to the element at two

FIGURE I SCHEMATIC DIAGRAM OF EXPERIMENTAL APPARATUS

FIGURE 2 BALANCED CABLE CONNECTIONS FOR REDUCING GROUND CURRENT EFFECT
neighboring points at the mid-section of the element. During an oscillatory discharge, the potential at the thermocouple functions coild be as high as several thousand volts above or below ground potential. It was therefore necessary to disconnect the thermocouple circuit from the main discharge circuit during the discharge, and to re-connect the thermocouple circuit for temperature measurement after the discharge was over. The measured temperature therefore was not the instantaneous temperature. The maximum temperature rise was obtained by extrapolating the recorded temperature during the cooling period to the time just after the discharge took place. Fortunately, under the experimental conditions encountered, the error introduced by this.method was small.

Requirements for current and voltage measurements. The requirements for the accuratie measurement of current and of voltage have been studied in detail by Park in references [1] and [3]. For the present purpose, it was convenient to borrow directly from the earlier results, and make use of the coaxial shunt described in [I] for current measurement, and the non-inductive resistance divider described in [3] for voltage measurement.

As in references [1] and [3], the main difficulty in measurement arises from the high current flowing in the main discharge circuit and the high rate of change of this current with time. A part of this current flows through the ground system of the measuring circuits as well, and induces extraneous voltage signals which may be several times higher than the true voltage signals.

The effect of the ground current on a measuring circuit may be tested by disconnecting the center conductor of the coaxial cable at the input end ${ }^{2}$ and shorting it to the cable sheath. Then any signal in the measuring circuit produced by the discharge of the main circuit would be an extraneous signal.

It was found that the ground-current effect could be largely eliminated by measuring only the difference between the total voltage and the voltage induced by the ground current. This was done by using two identical cables in the measuring circuit connected to the same point at the input end by means of a "T" connector, except that one cable was connected in the "normal" manner for measuring the total voltage, and the other was connected in the "shorted" manner described above for measuring the induced voltage (see Fig。2). The signals from these two cables were fed into a differential amplifier (of a cathode ray oscilloscope) which then measured only the difference between the two signals.

The foregoing method of using this" "balanced" arrangement of the measuring cables did not completely eliminate the extraneous signals.
$2^{2}$ This is the end where the cable is normally connected to the shunt or the voltage divider.

This was probably due to some slight mismatch of the cables, and to the lack of symmetry of the current paths, especially at the input end of the cables. A further source of difficulty was the inter-connected ground system. In the present case a dual-beam oscilloscope was used for simultaneous measurement of the current and the voltage. The current and voltage measuring cables were therefore grounded to a common point at the oscilloscope end. However, at the input end, these cables were grounded to different points of the main discharge circuit, because the construction of the current shunt and of the voltage divider did not permit a common connection. Thus the ground potential at the oscilloscope must fluctuate during a discharge of the main circuit. This would cause ground currents to flow in the chassis of the oscilloscope which could induce extraneous voltages in the amplifier input circuits. In addition to the above mentioned difficulties, the pairs of cables in the two measuring circuits formed two loops which were inductively coupled to the main discharge circuit. The voltages induced in these loops were able to cause currents producing iR drops in the cables which were not self-cancelling in the present balanced arrangement for measuring the differential voltages.

No quantitative data has been obtained on the errors arising from each of these sources (cable mismatch, lack of symmetry of current paths, etc.). However, the total error could be measured rather easily by shorting all the cables at the input ends, and by repeating the discharge under identical conditions.

## 3. Experimental Apparatus and Instrumentation

The major components of the experimental apparatus are shown schematically in Figure 1. The capacitance of the condenser bank was $400 \mu \mathrm{f}$, and at the maximun voltage of 10 kv , the stored energy was 20,000 joules. When installed as in Fig. 1, the natural frequency of the discharge circuit was 11.4 kc .

The spark gap and the triggering system were similar to those described in reference [4]. The electrodes were tipped with a tungstencopper alloy (Elkonite). The spark gap was assembled in a transparent enclosure, which could be charged with nitrogen or argon at different pressures for better control of the timing of the discharge. The nitrogen or argon atmosphere presumably also cut down the erosion of the electrodes due to oxidation.

The resistance element was made of a Ni-Cr-Fe alloy (inconel) tubing 10 in. long, $1.051 \mathrm{in} .0 . \mathrm{d}_{0}, 0.912 \mathrm{in}$. i.d. The ends of this piece of tubing were silver-soldered to clamps for connection to the main circuit at points 1 and 2 (Fig. 1). The soldered joints were lap joints, each 1/4 in. wide. The effective length of the tubing was taken as the length between the mid-sections of the two lap joints, or 9.75 in . long. The mass of the tubing based on this length was 288.9 grams. The specific heat at constant pressure $\left(C_{p}\right)$ for the inconel was taken from reference [5]
as $0.1074 \mathrm{cal} / \mathrm{gram-deg} C$ (average of three inconel samples) at $40 \mathrm{deg} C$ average temperature. (This was based on a temperature rise of about 30 $\operatorname{deg}($ from a room temperature of $25 \mathrm{deg} \mathrm{C}$. )

The temperature of the inconel tubing was measured by means of an iron-constantan thermocouple, with No. 28 wires, welded directly to the inconel tubing at two neighboring points, $1 / 4 \mathrm{in}$. apart, at the midsection of the tubing. The temperature recorder was a Leeds and Northrup millivolt recorder, with a full-scale response time of about $1 / 2$ second. The thermocouple circuit was conventional, except for the switching device mentioned earlier for isolating the recorder from the high potential at the resistance element during a discharge.

The resistances of the various parts of the circuit (between points l to 5) were determined by the Electricity Division at the NBS by means of a Kelvin double bridge. These resistances were as follows:

| Between Points | Component | Resistance, ohms |
| :---: | :---: | :---: |
| 1-2 | Resistance element (calorimeter) | 0.001803 |
| 2-3 | Coaxial shunt | 0.000325 |
| 1-2-3-5 |  | 0.002180 |
| 1-4 | High-side of voltage divider | 202.60 |
| 4-5 | Low-side of voltage divider | 1.1054 |

The high-side of the voltage divider, made up of a ribbon-wound noninductive resistor [3], was mounted at an angle relative to the common axis of the inconel tubing and of the outer cylinder (see Fig. 1) which served as the current return passage. This was done in order to reduce the capacitance between this resistor and the rest of the circuit near-by. Except for this part, the main discharge circuit around the inconel element preserved a cylindrical symmetry. The low-side of the voltage divider was made up of low-inductive carbon resistors, arranged symmetrically in a small cylindrical housing in order to keep the inductive effect to a minimum. The voltage measured was the voltage drop between points 1 and 5 . If this is denoted by $e_{1-5}$, then the electrical energy associated with this part of the circuit would be

$$
\int_{0}^{\infty} e_{1-5^{i}} d t .
$$

The electrical energy associated with the inconel element would then be

$$
\frac{R_{1-2}}{R_{1-2-3-5}} \int_{0}^{\infty} e_{1-5} i d t,
$$

where $R$ is the resistance of the part of the circuit denoted by the subscripts.

For the measuring circuit, the cables used were four RG58/U coaxial cables, each 11 ft . in length. These cables were not terminated with matched impedance because of the relatively low frequency ( 11.4 kc ) involved. The oscilloscope was a Tektronix Model 555 Dual-beam
oscilloscope, equipped with two type G differential pre-amplifiers. The vertical scales (voltage scales) were calibrated against the calibration signals provided in the oscilloscope, and the horizontal scale (time scale) was calibrated against the NBS Standard 100 kc frequency.

## 4. Results

Fig. 3 shows a representative series of measurements obtained on the experimental set-up described in the preceding section. The conditions of the test are given in the figure caption. Fig. 3a was obtained with the balanced arrangement of the measuring cables described earlier. The top trace of Fig. 3a shows the measured current through the circuit, the bottom trace shows the measured voltage drop between points 1 and 5 of Fig. l. Fig. 3b was obtained with the measuring cables shorted to ground at the input end. The top trace shows the ground current effect in the current measuring circuit, the bottom trace shows the same effect in the voltage measuring circuit. (Note the difference in the vertical scales in these figures.)

From these data, the ohmic heating and the electrical energy were obtained by evaluating the integrals $\int_{R i}{ }^{2} d t$ and Seidt. This was done both graphically with the aid of a planimeter, and numerically with the aid of an automatic digital computer (at a step size of $3 \mu \mathrm{sec}$ in dt ). In both cases, the Seidt integral was evaluated twice: once without the correction for the ground-current effect on the voltage curve, and once with the correction. No correction was made on the current curve, because the gr-und current effect on the current-measuring circuit appeared to be negligible.

The results are tabulated below. The percentage figures show the percent difference compared with the measured calorimetric heating. The calorimetric heating did not include the heat losses by convection, radiation and conduction. With a temperature rise of about 30 deg $C$, the convective heat loss was about 4 joules/sec. The radiative and conductive heat losses were both negligible.

|  | Calorimetric <br> Heating, <br> joules | $\mathrm{S} \mathrm{i}^{2} \mathrm{dt}$ <br> joules | Without Correction <br> for Ground <br> Current Effect |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Graphicai <br> Method <br> Numerical <br> Method | 4076 | $4082+0.1 \%$ | With Correction <br> for Ground <br> Current Effect |  |  |

These results show the importance of the correction for the ground-current effect on the measured voltage. This was somewhat surprising, because Fig. 3b shows that this effect amounted to only about $2 \%$ (in maximum amplitude) of the measured voltage shown in Fig. 3a. The differences between the graphical method and the numerical method are not conclusive. Further work is needed to investigate the accuracy of both methods.

## 5. Conclusions

The results so far have indicated that the equipment and the methods described here for meauring the current and voltage during the transient discharge of a capacitor bank are capable of yielding results which are in fair agreement with the result obtained independently from a calorimetric method. These results therefore suggest that it will be worthwhile to refine the experimental technique by a more careful calibration procedure, and a more detailed investigation of the sources of error and the experimental range in which the technique is applicable. These investigations are now in progress, and appropriate reports will be issued as the results become available.

EXPLANATORY NOTES FOR TABLES OF IDEAL-GAS THERMODYNAMIC FUNCTIONS OF $\mathrm{N}_{2} \mathrm{~F}_{4} \mathrm{AND} \mathrm{NF}_{2}$
by D. R. Lide, Jr.

Tables of ideal-gas thermodynamic functions are given in Appendix A for $N_{2} \mathrm{~F}_{4}$ (Table $\mathrm{A}-71$ ) and for $\mathrm{NF}_{2}$ (Table $\mathrm{A}-70$ ). The basis of arriving at each of the molecular constants underlying these two tables is as follows.

Since the microwave spectrum ${ }^{1}$ of $\mathrm{N}_{2} \mathrm{~F}_{4}$ shows that the gaushe form ( $C_{2}$ symmetry, with internal rotation angle of approximately $65^{\circ}$ ) is a major constituent at ordinary temperatures, and since the infrared spectrum ${ }^{2}$ indicates that there is only one form present in significant amounts, we have assumed for purposes of calculation that $\mathrm{N}_{2} \mathrm{~F}_{4}$ exists entirely as the gaushe isomer. The principgl moments of inertia ( $15.0517,26.2484$ and $29.8378 \times 10^{-39} \mathrm{gm} \mathrm{cm}^{2}$ ) are experimental values determined from the microwave spectrum. The estimated vibrational frequencies are based on infrared measurements of M. K. Wilson ${ }^{2}$, which have been confirmed by L. J. Schoen of NBS. While a detailed assignment has not been made, it is reasonable to associate bands at 1011, 962, 933 , and $850 \mathrm{~cm}^{-1}$ with the NF stretching modes. Infrared bands at $736,589,537,517,500$ (estimated), and $390 \mathrm{~cm}^{-1}$ apparently correspond to the $\mathrm{NF}_{2}$ deformations and to the twisting and wagging modes. In view of the low $\mathrm{N}-\mathrm{N}$ bond energy ${ }^{3}$, the band at $285 \mathrm{~cm}^{-1}$ is a reasonable choice for the $\mathbb{N}-\mathbb{N}$ stretch. The remaining fundemental is the torsion about the $N-\mathbb{N}$ bond, which has been estimated as about $100 \mathrm{~cm}^{-1}$ from the microwave spectrum. The major uncertainty in the ideal-gas thermal functions results from this frequency; for example, the calculated entropy at $300^{\circ} \mathrm{K}$ would be off by about l eu if the estimated torsional frequency is in error by $50 \mathrm{~cm}^{-1}$, which is entirely possible.

The $\mathrm{NF}_{2}$ molecule is a bent triatomic with vertex, angle of $104^{\circ}$ according to the infrared results of Schoen, Lide, and Mann ${ }^{4}$. The stretching frequencies of 1075 and $940 \mathrm{~cm}^{-1}$ have been observed, while the bending mode was estimated as $510 \mathrm{~cm}^{-1}$ from a force-constant $\mathrm{ct}^{\text {treatment }} 4$. The moments of inertia ( $1.2037,7.3748$, and $8.5702 \times 10^{-39} \mathrm{gm} \mathrm{cm}^{2}$ ) were calculated from the single rotational constant obtained from a resolved infrared bend ${ }^{4}$ on the assumption that the N-F bond distance is 1.370 A. Since the molecule contains an odd number of electrons, an electronic multiplicity of 2 has been assumed.

The entropy change for the dissociation

$$
\mathrm{N}_{2} \mathrm{~F}_{4} \rightarrow 2 \mathrm{NF}_{2}
$$

is calculated from Tables A-70 and A-71 to be 45.6 eu at $400^{\circ} \mathrm{K}$. From measurements of the dissociation constant of $\mathrm{N}_{2} \mathrm{~F}_{4}$ in the $350^{\circ}-450^{\circ} \mathrm{K}$ region Colburn and Johnson ${ }^{3}$ have obtained $\Delta S$ vaIues ranging from 38 to 45 eu .

# ALLOYS AND INTERSTITIAL COMPOUNDS OF ALUMINUM, LITHIUM, AND MAGNESIUM WITH EACH OTHER AND WITH SILICON, TITANIUM, AND ZIRCONIUM <br> by Thomas W. Mears 

The alloys and interstitial compounds of beryllium with aluminum, lithium, magnesium, silicon, titanium, and zirconium were surveyed in the last semi-annual report (NBS Report 7093, 1 January 1961). In the present survey, the alloys and interstitial compounds of aluminum, lithium, and magnesium with each other and with silicon, titanium, and zirconium are covered. The phase diagrams of most of these systems were reproduced from Hansen [1] in the last semi-annual report and will be alluded to throughout this survey. ${ }^{\text {a }}$

When alloy and intermetallic compounds are formed, it is often the case that the material formed will be more dense than that calculated from partial atomic volumes. Unfortunately, it is also true that energy is lost as heat of mixing (formation) of the alloy or interstitial compound. Further, it is generally true that the greater the density of the alloy as compared to the elements, the greater the heat of mixing. This heat of mixing may be partially, completely, or even excessively offset by the heats of mixing of the mixed combustion products. However, if the heats of mixing do not cancel out, there would be no advantage in using an alloy or interstitial compound over the mixture of elements, unless a possible improvement in the kinetics of combustion is to be had.

## Aluminum-1ithium system

A partially complete phase diagram for the aluminum-1ithium system is given in Hansen [1]. This diagram is reproduced as figure 3, p. 189 of the last semi-annual report. This diagram shows two intermediate phases LiA1 and $L i_{2} A 1$. The lattice spacings of aluminum solid solutions in lithium are [2]:

| At. \% of 玉1 | a (kXat $25^{\circ} \mathrm{C}$ ) |
| :---: | :---: |
| 0 | 4.04134 |
| 3.44 | 4.03967 |
| 4.83 | 4.03927 |
| 7.11 | 4.0382 |

[^2]The average coefficient of expansion of an alloy containing 4.83
at. percent lithium is [3].
$\alpha=24.3 \times 10^{-6}\left(-50^{\circ} \mathrm{C}\right.$ to $\left.25^{\circ} \mathrm{C}\right)$
Lattice spacings: 4.03196 at $-50^{\circ} \mathrm{C}$ 4.0393 at $25^{\circ} \mathrm{C}$

Alli melts at a maximum in the liquidus at approximately $718^{\circ} \mathrm{C}$ and exists over a range of composition [4]. It exists as a face-centered cube of $B 32$ type structure, $a=6.360 \mathrm{KX}$, and the $x$-ray density is $1.75 \mathrm{~g} / \mathrm{cm}^{3}$ [5]. Its heat of formation ${ }^{\text {a }}$ is $-6.0 \mathrm{Kcal} / \mathrm{g}$. atom ( $-12 \mathrm{Kcal} / \mathrm{mole}$ ) [6].

A1Li $2_{2}$ forms peritectically at $523^{\circ} \mathrm{C}$ [5].

## Aluminum-magnesium system

The phase diagram for the aluminum-magnesium system bas been worked out by Eickhoff and Vosskuhler [7] and augmented by Clark and Rhines [8]. This is attached as figure 1. A similar phase diagram from Hansen [1] is given as figure 4, p. 190 of the last semi-annual report. The Bphase, $\mathrm{Al}_{3} \mathrm{Mg}_{2}$ melts at a maxima from the liquidus at $451.5^{\circ} \mathrm{C}$. The $\gamma$ phase, Al 12 Mg 17 melts at a maxima at $462^{\circ} \mathrm{C}$. The $\epsilon-$ phase, $\mathrm{Al}_{4} \mathrm{Mg}_{3}$ (?), exists between a eutectoid at $210^{\circ} \mathrm{C}$ and a peritectoid at $390^{\circ} \mathrm{C}$.

The lattice spacings of solid solutions of magnesium in aluminum have been measured by many workers $[2,3,9,10,11,12,13,14,15]$. A composite graph of these values is attached as figure 2. The thermal expansion of solutions of approximately the same composition have also been measured [3], and are listed in the following table.

| At. \%Mg | $-50^{\circ} \mathrm{C}$ | $+25^{\circ} \mathrm{C}$ | $+200^{\circ} \mathrm{C}$ | $a_{-50 \times 10^{6}}^{25}$ | $\chi^{2000}{ }_{2}^{0} \times 10^{6}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 4.0347 | 4.04142 |  |  |  |
| 2.35 | 4.04275 | 4.0496 |  | 22.7 |  |
| 6.36 | 4.0614 | 4.0685 | 4.0858 | 23.2 | 24.7 |
| 10.56 | 4.0782 | 4.0861 | 4.10375 | 25.9 | 26.7 |

The ${ }_{+} \beta$-phase, $\mathrm{Al}_{3} \mathrm{Mg}_{2}$, has a face-centered cubic unit cell, with $a=28.16 \pm 2 \mathrm{KX}, \mathrm{Dm}=2.23 \mathrm{~g} / \mathrm{cm}^{3}, \mathrm{Dx}=2.28 \mathrm{~g} / \mathrm{cm}^{3}$ for an alloy containing 35 atomic percent magnesium $[16,17]$. The heat of formation ${ }^{a}$ is $-0.37 \mathrm{Kcal} / \mathrm{mole}$ [8].

The $\gamma$-phase, $\mathrm{Al}_{12} \mathrm{Mg}_{17}$, occurs in the region 50 to 60 atomic percent (theory 58.6 at. percent) magnesium. It is a body-centered cubic in which $a=10.54-2 \mathrm{KX}$, and the macroscopic density is $2.068 \mathrm{~g} / \mathrm{cm}^{3}$ at $21^{\circ} \mathrm{C}$ [18]. The lattice spacings and densities have been determined for this region [19,20] and are shown graphically in figure 3 .

The $\epsilon-p h a s e$ at approximately 43 atomic percent aluminum has not been characterized. The empirical formula corresponds to about $\mathrm{Mg}_{4} \mathrm{Al}_{3}$.

[^3]The lattice spacings of solid solutions of aluminum in magnesium are shown in figure 4 [21,22,23].

The heats of formation of the aluminum-magnesium system hate been determined by Kubashewski: and Catterall [6] as follows:

| At. $\% \mathrm{Mg}$ | $\Delta \mathrm{H}_{3}(\mathrm{kcal} / \mathrm{mole})$ |
| :---: | :---: |
| 10 | -.140 |
| 40 | -.390 |
| 50 | -.620 |

## Aluminum-silicon system

Not much work has been done on the aluminum-silicon system because of the mutual insolubility in the solid state. There is little evidence of compound formation. The phase diagram is given by Hansen [1]. This diagram was reproduced as figure 5 on p. 191 in the last semiannual report. This shows a eutectic at 11.3 atom percent silicon at $577^{\circ} \mathrm{C}$. There is some slight evidence of terminal solubility. Lattice spacings for silicon concentrations up to 1 percent are reported by Axon and Hume-Rothery [2].

## Aluminum-titanium system

The phase diagram from Hansen [1] for the aluminum-titanium system was reproduced in the previous semi-annual report. The $\alpha$-solid solution transforms into the $\beta$-solid solution at temperatures ranging from $882^{\circ} \mathrm{C}$ for pure titanium to $1240^{\circ} \mathrm{C}$ for solution containing 42 atom percent (29 weight percent) aluminum. The $\gamma$-form, A1Ti, forms peritectically at $1460^{\circ} \mathrm{C}$. $\mathrm{A} 3_{3} \mathrm{Ti}$ forms peritectically at $1340^{\circ} \mathrm{C}$ and has invariant composition [24].

The solid solubility of titanium in aluminum is very small. Supersaturated solutions were obtained by rapid quenching and the lattices determined [25].

| At. \%Ti | a (kX) |
| :---: | :--- |
| 0 | 4.0415 |
| 0.085 | 4.04054 |
| 0.090 | 4.0405 |
| 0.20 | 4.0395 |

The solid solution of aluminum in titanium is much broader than the aluminum solutions. Several workers [24,26,27] have prepared these alloys and determined their crystal lattices. These data are combined in figure 5. The humps at $10-14$ atomic percent aluminum may be due to oxide or nitride impurities [28].
$\mathrm{Al}_{3} \mathrm{Ti}$ is a body-centered, tetragonal DO 22 type of structure, where $a=3.84 \mathrm{kX}, \quad c=8.579 \mathrm{KX}, \mathrm{c} / \mathrm{a}=2.234, \mathrm{Dm}=3.31 \mathrm{~g} / \mathrm{cm}^{3}$, and $\mathrm{Dx}-\mathrm{ray}=3.37 \mathrm{~g} / \mathrm{cm}^{3}[29,30]$.

The alloy may be prepared by heating aluminum with potassium fluotitanate at $1200^{\circ} \mathrm{C}$, cooling slowly, and dissolving away the excess aluminum. Calculations have also been made [31] where $\mathrm{A} 1_{3} \mathrm{Ti}$ is considered as a face-centered tetragonal cell in which case a $=5.424 \mathrm{Kx}$, $f_{+}=8.574 \mathrm{Kx}$, and $\mathrm{c} / \mathrm{a}=1.58$. The heat of formation ${ }^{\text {a }}$ is given as -35.3 - $1.2 \mathrm{kcal} / \mathrm{mole}$ ( 8.8 Kcal per atom) [32].

A1Ti has an ordered cubic $\mathrm{L} 1_{0}$ structure where $a=3.997 \mathrm{KX}, \mathrm{c}=4.062 \mathrm{KX}$, $c / a=1.02$ at the stoichimetric 50 percent point [33). The alloy is prepared by arc melting "iodine" titanium with aluminum. The heat of forma$t^{2} \mathrm{n}^{\text {a }}$ of AlTi is given as $-19.3 \pm 0.05 \mathrm{Kcal} / \mathrm{mole}(-9.7 \mathrm{Kcal} / \mathrm{g}$ atom) [32].

## Aluminum-zirconium system

The aluminum-zirconium system is quite complex as shown by the phase diagram from Hansen [1] which was reproduced as figure 7 on p. 193 of the last semi-annual report. There are three phases which melt at maxima in the liquidus, namely $\mathrm{Al}_{3} \mathrm{Zr}_{\mathrm{r}}$ at $1580^{\circ} \mathrm{C}, \mathrm{Al}_{2} \mathrm{Zr}$ at $1645^{\circ} \mathrm{C}$, and $\mathrm{Al}_{3} \mathrm{Zr}$ at $1530^{\circ} \mathrm{C}$ a Possibly six others form peritectically; $\mathrm{Al}_{3} \mathrm{Zr}_{2}{ }^{3}$ (?) at $15950 \mathrm{C}, \mathrm{A1} \mathrm{Zr}_{3}$ at $1480^{\circ} \mathrm{C}, \mathrm{Al}_{3} \mathrm{Zr}_{5}$ at $1395^{\circ} \mathrm{C}, \mathrm{AlZr}_{2}$ at $1250^{\circ} \mathrm{C}$ $\mathrm{AlZr}_{3}{ }^{2}$ at $975^{\circ} \mathrm{C}$ and A1Zr at ${ }^{3} 250^{\circ} \mathrm{C}$ [34].
$\mathrm{Al}_{2} \mathrm{Zr}_{3}$ is a tetragonal unit cell $, \quad a=7.630 \pm 0.001 \mathrm{~A}^{\circ}, \quad c=6.998$ $\pm 0.001 \mathrm{~A}^{\mathrm{G}}, \mathrm{B} / \mathrm{a}=0.9054, \mathrm{Dx}=5.34{ }_{3} \mathrm{~g} / \mathrm{cm}^{3}$ on the basis of $4 \mathrm{Zr}^{\prime} \mathrm{A}^{2}$ units per unit cell, and $\mathrm{Dm}=5.35 \mathrm{~g} / \mathrm{cm}$. The sample was prepared by arc melting under argon and annealing for two weeks at $1100^{\circ} \mathrm{C}$ [35].
$\mathrm{Al}_{3} \mathrm{Zr}_{5}$ is an hexagonal structure with an x-ray density of $5.43 \mathrm{~g} / \mathrm{cm}^{3}$ [36].
A1 Zr has an ordered cubic structure with $a=4.372 \mathrm{~A}^{\circ}$ and $\mathrm{Dx}=5.976$ $\pm 0.013 \mathrm{~g} / \mathrm{cm}^{3}$ [37].
$\mathrm{Al}_{3} \mathrm{Zr}$ is a body-centered tetragonal ( $\mathrm{DO}_{23}$ ) type of structure, where $A^{3}=4.005 \mathrm{KX}, \quad c=17.285 \mathrm{KX}, \quad c / a=4.316, D^{23}=4.11 \mathrm{~g} / \mathrm{cm}^{3}$, and $D^{\circ} \mathrm{m}=4.11 \mathrm{~g} / \mathrm{cm}^{3}$ [30, 35, 21]
$\mathrm{Al}_{2} \mathrm{Zr}$ has an orthorhomble unit cel1, where $\mathrm{a}=1040 \mathrm{KX}, \mathrm{b}=7.21 \mathrm{KX}$, and $c=4.97 \mathrm{KX}$ for an alloy containing 37.6 weight percent aluminum [34]. The heat of formation is given as $-30.0 \mathrm{Kcal} / \mathrm{mole}(-10.0 \mathrm{Kcal} / \mathrm{g}$ atom) [6].

AlZr , was prepared by arc melting and annealing for three weeks at $900^{\circ} \mathrm{C}$. It has been indexed as an hexagpnal unit cell where $a=4.8939 \pm 0.005 \mathrm{~A}$, $c=5.9283-0.0005 \mathrm{~A},{ }_{3} c / a=1.211-0.001$ and $D x=5.67 \mathrm{~g} / \mathrm{cm}$. A macroscopic density of $5.78 \mathrm{~g} / \mathrm{cm}$ was obtained, but the sample was contaminated with $\mathrm{Zr}_{3} \mathrm{Al}$ whose density is $5.98 \mathrm{~g} / \mathrm{cm}^{3}$. [39].
$\mathrm{Al}_{3} \mathrm{Zr}_{4}$ was also prepared by arc melting undeq argon. It is indexed ${ }^{3} \mathrm{as}^{4}$ an hexagonal unit cell, where $a=5.433 \geq 0.002 \mathrm{~A}$ and
$c=5.390 \pm 0.0$ Q2A. On the basis of one $\mathrm{Al}_{3} \mathrm{Zr}_{4}$ unit per unit cell, ${ }_{3}$ $\mathrm{Dx}=5.37 \mathrm{~g} / \mathrm{cm}^{3}$. The macroscopic density was measured at $5.28 \mathrm{~g} / \mathrm{cm}^{3}$ [35].

## Lithium-magnesium system

The diagram for the lithium-magnesium system given by Hansen [1] was reproduced as figure 12 on p. 198 in the last report. This curve shows a eutectic at 77 atom percent ( 92 weight percent) magnesium at $588^{\circ} \mathrm{C}$. The lithium solid solution extends to 75.5 atomic percent (91 weight percent) magnesium at $588^{\circ} \mathrm{C}$ and 70.1 atomic percent ( 89 weight percent magnesium at $100^{\circ} \mathrm{C}$. The magnesium solid solution extends to 83.0 atomic percent ( 94.5 weight percent) magnesium at $588^{\circ} \mathrm{C}$ and 82 atomic percent ( 94.3 weight percent) at $300^{\circ} \mathrm{C}$. Apparently no intermetallic compounds are formed.

## Magnesium-silicon system

The magnesium-silicon phase diagram given by Hansen [1] was reproduced as figure 13 on p. 199 of the last semi-annual report. This shows the existence of a compound $\mathrm{Mg}_{2} \mathrm{Si}$ which melts at a maximum at $1102^{\circ} \mathrm{C}$. Eutectics occur at 53 atom percent ( 50.5 weight percent) silicon at approximately $950^{\circ} \mathrm{C}$ and at 1.16 atom percent ( 1.34 weight percent) silicon at $637.6^{\circ} \mathrm{C}$. There is very little termina solubility.

The lattice spacing of a two-phase alloy quenched from just below the melting point gave the lattices: $a=3.2026, c=5.1998 \mathrm{KX}$ and $\mathrm{c} / \mathrm{a}=1.6236$ at $25^{\circ} \mathrm{C}$ as compared withpowdered magnesium metal with lattices a $=3.2023$, $c=5.1994 \mathrm{kx}$, and $\mathrm{c} / \mathrm{a}=1.6234$ [21].
$\mathrm{Mg}_{2} \mathrm{Si}$ is a face-centered cubic (C1) type structure with a $=6.338$ $\pm .002 \mathrm{KX}$ [40]. Thẹ density calculates to $1.95 \mathrm{~g} / \mathrm{cm}^{3}$. The heat of formation ${ }^{\text {is }}-19.0 \pm 1.0 \mathrm{Kcal} / \mathrm{mole}(-6.16 \mathrm{Kcal} / \mathrm{g}$ atom) [41].

Magnesium-titanium and magnesium-zirconium systems
The systems for both magnesium-titanium and magnesium-zirconium have only been studied slightly. The very limited curves given by Hansen [1] are reproduced as figures 14 and 15 on ps. 200 and 201 of the last semi-annual report.

The lattice spacings of a two-phase alloy containing 1 weight percent titanium and annealed just below the solidus show lattices of $\mathrm{a}=3.2025, \mathrm{c}=5.2017 \mathrm{KX}$ and $\mathrm{c} / \mathrm{a}=1.6242$ at $25^{\circ} \mathrm{C}$ as compared to pure magnesium with $a=3.2023, c=5.1994 \mathrm{kX}$, and $\mathrm{c} / \mathrm{a}=1.6236$ at $25^{\circ} \mathrm{C}$ [21]. Titanium apparently does not dissolve in magnesium [42], but both $\alpha$ and $\beta$-titanium dissolve magnesium to the extent of not more than 1.5 weight percent [43].

No intermediate phases have been found for the magnesium-zirconium system [44]. The lattice spacings for a two-phase alloy containing 1 weight percent zirconium quenched just below the solidus are

## ${ }^{\text {a }} \Delta_{\mathrm{Hf}}$

The various heat, volume, and density data available are tabulated in table 1. For information, the data on the beryllium alloys given in the last semi-annual report is also tabulated. Also included are values for several of the zirconium-silicon alloys, the heat data for which is reported by Robins and Jenkins [45]. The atomic volumes for the elements used in the calculation were taken from Heslop and Robinson [46]. Certain of the molecular volume data for silicon-titanium and silicon-zirconium systems are from VanArkle's recent paper [47]. The percent increase in volume values are probably good to 1 percent in the case of aluminum alloys and 3 percent in the remainder of the cases. It should be stressed that these percent increases are small differences in larger numbers and should be considered accordingly.

# LITERATURE SURVEY ON LOW-TEMPERATURE HEAT CAPACITY AND ENTROPY 

AT $298.15^{\circ} \mathrm{K}$ OF W AND Pb AND SOME OF THEIR COMPOUNDS<br>AND OF THE BROMIDES AND IODIDES OF $\mathrm{Li}, \mathrm{Be}, \mathrm{Mg}$, and Al<br>by George T. Furukawa

The substances of interest to the program have increased. As a part of the program to determine the thermodynamic properties of these substances, a literature survey was made on the low-temperature heat capacity of tungsten and lead and some of their compounds with oxygen and the halogens. A literature survey was made also on the bromides and iodides of lithium, beryllium, magnesium and aluminum, and found that no heat-capacity data on these substances exist. The Bureau of Mines (BM) Bulletin 592 [22] ${ }^{1}$ and the Ohio State University [2] bibliography on low-temperature calorimetry were used to locate references to experimental measurements. The Annual Review of Physical Chemistry, Volumes 10 and 11 [38,27] and the bibliography compilation for 1960 by Zwolinski and Danti [43], that appeared in the Bulletin of Chemical Thermodynamics, No. 4, 1961 in advance of its publication in the 1961 issue of the Annual Review of Physical Chemistry, were also examined for experimental data. The Bulletin of Chemical Thermodynamics No. 4, 1961 [5] was consulted for sources of unpublished measurements. The original papers were examined and the data evaluated. Time was, however, insufficient to obtain smoothed values of heat capacities at equally spaced temperature intervals from which the various thermal functiona would be derived. For this report, values of heat capacity selected from a largescale plot were compared with those given in the BM Bulletin 592 [22]. When the experimental data are reliable, the selected values of heat capacity were found to be in good agreement with those given in the BM Bulletin 592 [22]. Wherever the investigator evaluated the entropy at $298.15^{\circ} \mathrm{K}$ (Sg98), the value was compared with that given in the BM Bulletin 592 [22] and in the Natignal Bureau of Standards (NBS) Circular 500 [34]. The adopted values of $\mathrm{S}_{298}$ were taken from the above compilations or from the original publications.

The substances are discussed. separately after listing the lowtemperature heat-capacity measurements in chronological order, with the reference and the temperature range of each investigation. Information on the chemical and physical state of the substance is given wherever available. Tables of the adopted values of $S_{298}$ are given at the end of the discussion. References given in the tables are those from which the adopted values were obtained.
${ }^{I_{\text {Numbers }}}$ in brackets refer to literature references at the end of this chapter.

Measurements of the heat capacity of tungsten metal have-been reported by a number of investigators: Nordmeyer and Bernoulli [32] (-1850 to $20^{\circ} \mathrm{C}$ ) ; Dewar [10] ( $20^{\circ}$ to $80^{\circ} \mathrm{K}$ ); Lange [25] ( $26^{\circ}$ to $91^{\circ} \mathrm{K}$ ); Zwikker and Schmidt [41,42] ( 920 to $2521^{\circ} \mathrm{K}$ ); Bronson, Chisholm, and Dockerty [3] $\left(-20^{\circ}\right.$ to $\left.501^{\circ} \mathrm{C}\right)$; Silvidi and Daunt [37] (1. $5^{\circ}$ to 3.00 K); Horowitz and Daunt [15] ( $0.03^{\circ}$ to $0.34^{\circ} \mathrm{K}$ ); Rayne [33] ( $0.2^{\circ}$ to $1^{\circ} \mathrm{K}$ ); Waite, Craig, and Wallace [39] ( $4^{\circ}$ to $15^{\circ} \mathrm{K}$ ); DeSorbo [9] (13 0 to $93^{\circ} \mathrm{K}$ ); Clusius and Franzosini [7] ( $12^{\circ}$ to $274^{\circ} \mathrm{K}$ ). The extensive measurements of Clusius and Franzosini [7] were based on a sample of 99.99 percent purity. $S_{298}=7.83$ eu reported by Clusius and Franzosini [7] was adopted. DeSorbo [9] reported $S_{298}=8.2 \pm 0.2$ eu. Kelley and King [22] give $S_{298}^{\circ}=7.80 \pm$ 0.10 eu and the NBS Circular 500 [34] 8.0 eu.

## Tungsten Dioxide, $\mathrm{WO}_{2} 215.86$

Heat-capacity measurements on tungsten dioxide have been reported by King, Weller, and Christensen [24] (520 to $297^{\circ} \mathrm{K}$ ). The sample was prepared from pure tungstic acid by reduction with hydrogen at $600^{\circ}$ to $625^{\circ} \mathrm{C}$. The product from eight separate preparations were mixed and heated for 11 hours in helium at $990^{\circ} \mathrm{C}$. The analysis of the final product was reported to be 14.80 percent oxygen (theoretical $=14,82$ percent). The x-ray diffraction pattern was reported to agree with that given for $\mathrm{TiO}_{2}$ in the A.S.T.M. catalog. The value $\mathrm{S}_{298}^{0}=12.08 \pm 0.07$ eu obtained by Kîng et al. [24] was adopted.

Tungsten Trioxide, $\mathrm{WO}_{3}, 231.86$
Heat-capacity measurements on tungsten trioxide have been reported by Russell [35] ( -1890 to $47^{\circ} \mathrm{C}$ ); by Seltz, Dunkerley, and DeWitt [36] ( $63^{\circ}$ to $299^{\circ} \mathrm{K}$ ) ; and by King, Weller, and Christensen [24] ( $53^{\circ}$ to $297^{\circ} \mathrm{K}$ ). The $\mathrm{WO}_{3}$ sample investigated by King et al. [24] was prepared from reagent-grade tungstic acid by heating at $770^{\circ} \mathrm{C}$ for 16 hours. The analysis of the product by hydrogen reduction was reported to be 20.72 percent oxygen (theoretical $=20.70$ percent). The value $S_{298}^{0}=18.15 \pm 0.12$ eu obtained by King et al. [24] was adopted.

Lead, $\mathrm{Pb}, 207.21$
Heat-capacity measurements on lead have been reported by Nernst [30] ( $23^{\circ}$ to $273^{\circ} \mathrm{K}$ ) ; Hacken and Schwers [12] ( 160 to 2760 K ); Griffiths and Griffiths [14] ( $23^{\circ}$ to $380^{\circ} \mathrm{K}$ ); Keesom and Onnes [20] ( $14^{\circ}$ to $80^{\circ} \mathrm{K}$ ); Keesom and Andrews [17] ( $2^{\circ}$ to $21^{\circ} \mathrm{K}$ ); Keesom and Ende [18,19] ( $2^{\circ}$ to $20^{\circ} \mathrm{K}$ ) ; Bronson and Wilson [4] ( $-80^{\circ}$ to $120^{\circ} \mathrm{C}$ ); Meads, Forsythe and Giauque [28] ( $14^{\circ}$ to $300^{\circ} \mathrm{K}$ ); Clement and Quinnell [6] ( 60 to 80 K ) ; and Horowitz, Silvidi, Malaker, and Daunt [16] ( 10 to $75^{\circ} \mathrm{K}$ ). Measurements of Meads et al. [28] and Horowitz et al. [16] which together cover the range $1^{\circ}$ to $300^{\circ} \mathrm{K}$, join fairly continuously. Meads $\frac{\text { et }}{15}$ al. [28] calculated $S_{298}^{0}$ to be 15.51 eu. Kelley and King [22] give $15.49 \pm 0.05 \mathrm{eu} . \mathrm{NBS}$ Circuiar 500 [34] lists $S_{298}^{0}=15.51 \mathrm{eu}$, which was adopted.

## Lead Monoxide (yellow, rhombic), $\mathrm{PbO}, 223.21$

Nernst and Schwers [31] ( $21^{\circ}$ to $93^{\circ} \mathrm{K}$ ), Russell [35] (-1910 to $44^{\circ}$ C), and King [23] ( $54^{\circ}$ to $296^{\circ} \mathrm{K}$ ) measured the heat-capacity of the rhombic, high-temperature form of PbO . The sample investigated by King [23] was prepared by heating lead carbonate, precipitated by treating a solution of reagent grade lead nitrate with an excess of ammonium carbonate solution, for 10 hours at $725^{\circ} \mathrm{C}$ and quenching to room temperature. Analysis of the sample was reported to be 92.84 percent. lead (theoretical $=92.83$ percent). No reconversion to the red PbO was observed. The x-ray diffraction pattern for the sample was reported to be in agreement with that listed for yellow PbO in the ASTM catalog. King [23] reported $\mathrm{S}_{298}^{\circ}=16.1 \pm 0.2 \mathrm{eu}$, which was adopted.

## Lead Monoxide (red, tetragonal), $\mathrm{PbO}, 223.21$

King [23] $\$ 53^{\circ}$ to $296^{\circ} \mathrm{K}$ ) measured the heat capacity of the tetragonal, low-temperature form of PbO . The sample of red PbO was prepared by heating electrolytic $\mathrm{PbO}_{2}$ under vacuum at $430^{\circ}$ to $480^{\circ} \mathrm{C}$ for about 8 weeks, The chemical analysis on the sample was reported to be 92.69 percent lead (theoretical $=92.83$ percent). X-ray diffraction pattern was reported to indicate a presence of a small amount of yellow Pbo. King [23] reported $S_{298}^{\circ}=15.6 \pm 0.2$ eu, which was adopted.

Lead Orthoplumbate, $\mathrm{Pb}_{3} \mathrm{O}_{4}, 685.63$
Millar [29] ( $72^{\circ}$ to $293^{\circ} \mathrm{K}$ ) reported heat-capacity measurements on lead orthoplumbate. The sample was prepared by thermal decomposition of $\mathrm{PbO}_{2}$ at $460^{\circ} \mathrm{C}$. An average of five analyses for active oxygen on the product indicated 97 percent of the theoretical quantity. The analysis for the lead content was reported to be 90.62 percent (theoretical $=90.66$ percent). Millar [29] reported $S_{298}^{0}=60.53$ eu. Kelley and King [22] lists $50.5 \pm 1.6$ eu. In an earlier bulletin No. 350 Kelley [21] pointed out an arithematic error in Millar's value for entropy. NBS Circular 500 [34] lists 50.5 eu. The value 50.5 eu was adopted.

Lead Sesquioxide, $\mathrm{Pb}_{2} \mathrm{O}_{3}, 462.42$
King [23] ( $53^{\circ}$ to $297^{\circ} \mathrm{K}$ ) measured the heat capacity of $\mathrm{Pb}_{2} \mathrm{O}_{3}$. The sample was prepared by heating in air $\mathrm{PbCO}_{3}$, precipitated from a solution of reagent grade $\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}$ with an excess of $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{CO}_{3}$ solution, for 40 hours at $290^{\circ} \mathrm{C}, 64$ hours at $310^{\circ} \mathrm{C}$, and 10 days at $320^{\circ} \mathrm{C}$. Chemical analysis of the product was reported to be 89.64 percent lead (theoretical $=89.62$ percent). The $x$-ray diffraction pattern was reported to agree with that listed in the ASTM catalog. King [23] reported $S_{298}^{\circ}=36.3 \pm 0.7$ eu, which was adopted.

Russell [35] ( $-188^{\circ}$ to $46^{\circ} \mathrm{C}$ ) and Millar [29] ( $70^{\circ}$ to $297^{\circ} \mathrm{K}$ ) reported heat-capacity measurements on lead dioxide. The sample investigated by Millar [29] was prepared by electrolysis of an acidic solution of lead nitrate. The average of three analyses for active oxygen on the product indicated 99.5 percent of the theoretical quantity. Millar [29] reported $\mathrm{S}_{298}^{\circ}=18.27 \mathrm{eu}$. Kelley and King [22] lists $18.3 \pm 0.5 \mathrm{eu}$, which was adopted. NBS Circular 500 [34] lists 18.3 eu.

Lead Fluoride, $\mathrm{PbF}_{2}, 241.21$
No low-temperature heat-capacity data were found. NBS Circular 500 [34] lists an estimated $S_{298}^{2}=29$ eu。 Kelley and King [22] estimated $S_{298}^{\circ}=23.0 \pm 0.5 \mathrm{eu}$, which was adopted.

Lead Chloride, $\mathrm{PbCl}_{2}, 278.124$
Eucken [11] (at three mean temperatures: $+17.5^{\circ},-67.5^{\circ}$, and $-166.5^{\circ} \mathrm{C}$ ) and Nernst [30] ( $16^{\circ}$ to $880^{\circ} \mathrm{K}$ ) measured the heat capacity of $\mathrm{PbCl}_{2}$. The purity of the samples investigated is not known. From these measurements Kelley and King [22] estimated $\mathrm{S}_{298}=34.0 \pm 1.082$. From cell measurements, Gerke [13] obtained $\Delta S_{298}^{\circ}=-8.58$ eu for the reaction:

$$
\mathrm{Pb}(\mathrm{c})+\mathrm{AgCl}(\mathrm{c})=\mathrm{PbCl}_{2}(\mathrm{c})+2 \mathrm{Ag}(\mathrm{c})
$$

and $\Delta S_{298}^{\circ}=6.70$ eu for the reaction:

$$
\mathrm{Pb}(\mathrm{c})+2 \mathrm{HgCl}(\mathrm{c})=\mathrm{PbCl}_{\mathrm{Z}}(\mathrm{c})+2 \mathrm{Hg}(1) .
$$

The entropies at $298.15^{\circ} \mathrm{K}$ of $\mathrm{PbCl}_{2}(\mathrm{c})$ corresponding to the above reactions calculated by Kelley and King [22] are $32.5 \pm 0.5$ and $32.2 \pm 1.0$ eu, respectively. NBS Circular 500 [34] lists $\mathrm{S}_{298}=32.6$ eu. This value was adopted.

Lead Bromide, $\mathrm{PbBr}_{2}, 367.042$
Heat measurements on $\mathrm{PbBr}_{2}$ have been reported by Barschall [1] ( $-183^{\circ}$ to $-75^{\circ} \mathrm{C}$ ) and by Latimer and Hoenshel [26] (180 to $297^{\circ} \mathrm{K}$ ). Latimer and Hoenshel [26] prepared the $\mathrm{PbBr}_{2}$ sample from $\mathrm{c} \cdot \mathrm{p} . \mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}$ and KBr by precipitation. The $\mathrm{PbBr}_{2}$ precipitate was washed and finaliy dried at $120^{\circ} \mathrm{C}$. Latimer and Hoenshel [26] reported $\mathrm{S}_{298}^{\circ}=39.7 \pm 0.45$ eu. Kelley and King [22] calculated $S_{298}^{0}=38.6 \pm 0.5$ eu on the basis of the same data. NBS Circular 500 [34] 1ists $S_{298}^{\circ}=38.6$ eu, which was adopted.

Lead Iodide, $\mathrm{PbI}_{2}, 461.03$
Nernst and Schwers [31] ( $22^{\circ}$ to 960 K ) measured the heat capacity of $\mathrm{PbI}_{2}$. Recently, Westrum [40] measured the heat capacity of this substance in the range 60 to $300^{\circ} \mathrm{K}$. The latter results, however, have not been published as yet. Kelley and King [22] estimated $S_{298}^{a}=41.3 \pm 1.5$ eu based on the measurements of Nernst and Schwers [31]. Gerke [13] obtained $\Delta S 299=-1.20$ for the reaction:

$$
\mathrm{Pb}(\mathrm{c})+\mathrm{I}_{2}(\mathrm{c})+\mathrm{PbI}_{2}(\mathrm{c})
$$

from cell measurements, from which Kelley and King [22] calculated $\mathrm{S}_{298}^{0}=$ $42.2 \pm 0.5$ eu for $\mathrm{PbI}_{2}(\mathrm{c})$. NBS Circular 500 [34] Iists $\mathrm{S}_{298}^{\circ}=42.3$ eu。 The latter value was tentatively adopted until Westrum's low-temperature heat-capacity data become available.

## Lithium Bromide, $\mathrm{LiBr}, 86.856$

No low-temperature heat-capacity data have been found. Kelley and King [22] give an estimated value of $S_{298}^{0}=16.0 \pm 0.5 \mathrm{eu}$, which was tentatively adopted.

Lithium Iodide, LiI, 143.850
No low-temperature heat-capacity data have been found. Kelley and King [22] give an estimated value of $\mathrm{S}_{298}=17.5 \pm 0.5 \mathrm{eu}$, which was tentatively adopted.

Beryllium Bromide, $\mathrm{BeBr}_{2}, 168.845$
No low-temperature heat-capacıty data have been found.
Beryllium Iodide, $\mathrm{BeI}_{2}, 262.833$
No low-temperature heat-capacity data have been found.
Magnesium Bromide, $\mathrm{MgBr}_{2}$, 184.152
No low-temperature heat-capacity data have been found. Kelley and King [22] give an estimated value of $S_{298}^{\circ}=28.0 \pm 1.0 \mathrm{eu}$, which was tentatively adopted.

Magnesium Iodide, $\mathrm{MgI}_{2}, 278.14$
No low-temperature heat-capacity data have been found. Kelley and King [22] give an estimated value of $S_{298}^{\circ}=31.0 \pm 1.0$ eu, which was tentatively adopted.

Aluminum Bromide, $\mathrm{AlBr}_{3}, 266.728$
No low-temperature heat-capacity data have been found. NBS Circular 500 [34] lists an estimated value of $S_{298}=44$ eu, which was tentatively adopted。

Aluminum Iodide, $\mathrm{AlI}_{3}, 407.71$
No low-temperature heat-capacity data have been found. Corbett and Gregory [8] investigated the equilibrium of the reaction:
$\mathrm{AlI}_{3}(\mathrm{c})+3 \mathrm{HCl}(\mathrm{g})+\mathrm{AlCl}_{3}(\mathrm{c})+3 \mathrm{HI}(\mathrm{g})$
and obtained $\Delta F_{298}^{0}=-8.7 \pm 0.2 \mathrm{kcal}$ for the reaction. Using values of $\Delta F_{f}^{\circ}$ (at $298.150^{\circ} \mathrm{K}$ ) given in NBS Circular 500 [34], Corbett and Gregory [8] calculated $\Delta F_{f}^{\circ}$ (at $298.15^{\circ} \mathrm{K}$ ) for $\mathrm{AlI}_{3}(\mathrm{c})$ to be -74.4 kcal . NBS Circular 500 [34] Iists -75.0 kcal for this quantity. Corbett and Gregory [8] calculated $S_{298}^{0}=46.0$ eu. Kelley and King [22] assigned the uncertainty $\pm 2.0$ eu to this. 18 Circular 500 [34] lists an estimated value of $S_{298}^{\circ}=48$ eu. The value $\mathrm{S}_{298}^{2}=46.0 \pm 2.0$ eu was adopted.

A RECENT SURVEY OF REPORTED HIGH-TEMPERATURE

## HEAT CONTENTS AND HEAT CAPACITIES

by Thomas B. Douglas and Willis R. Thurber

Beginning with the first report of this series (NBS Report 6297, January 1, 1959), heat-content and heat-capacity data on condensed phases of propulsion interest have been compiled. It was not, however, until the second report (NBS Report 6484, July 1, 1959) that the extensive task was seriously begun to select "best" values of these properties and to make adjustments of the values such that the resulting tables of thermodynamic functions would not have discontinuities reflecting the many obvious discordances of data covering different temperature ranges. All the tables of thermodynamic functions of condensed phases issued so far in our NBS program are to be found in the fourth and fifth reports (NBS Report 6928, 1 July 1960; NBS Report 7093, I January 1960).

Because new data are constantly being reported, and also especially because additional elements and their compounds have acquired considerable propulsion interest, we recently began an up-to-date survey of the available data on heat contents and heat capacities of a selected list of light-element substances "at high temperatures" (above the ice-point, $273^{\circ} \mathrm{K}$ ). The results thus far obtained are tabulated below (Table 1). They are preliminary and incomplete in two respects: (1) We have made no attempt so far to assess many of the data and arrive at "best" values, and (2) the sources of information covered, while complete in principle, do not include such obvious alternative sources as abstract journals (except in the case of a few substances). The survey began with a welld known critical compilation (U. S. Bur. Mines Bulletin 584), and to that extent (1) covers all early data still considered of value, and (2) includes values for gases based on published experimental or estimated molecular constants.

With the following specific statement of substances and sources of information covered, the table should be useful as a starting point for more detailed surveys, and also by indicating in which cases hightemperature heat-content data are probably inadequate or totally lacking.

Substances Covered, and Order of Listing -- Table 1 is divided into twelve sections. Each section covers one of the following elements and its compounds (listed in the order of presentation): $\mathrm{Al}, \mathrm{Be}, \mathrm{B}, \mathrm{Hf}, \mathrm{Pb}$, $\mathrm{Li}, \mathrm{Mg}, \mathrm{Hg}, \mathrm{K}, \mathrm{Ti}, \mathrm{W}$, and Zr . (All compounds including two of these elements are listed twice -- i.e., in the sections for both elementso) For each of these elements are included only the free element, compounds with others of the above elements, and compounds with $\mathrm{H}, \mathrm{O}, \mathrm{F}, \mathrm{Cl}, \mathrm{Br}$,

I, N, C, and/or Si. For each substance the reported investigations are listed in chronological order, on the basis that a later investigation is often (though frequently not) more accurate or more extensive than an earlier one.

Sources of Information Covered -- The dates in parentheses indicate the period of time for which literature coverage is claimed by the given reference source.

1. U. S. Bureau of Mines Bulletin 584, 1960 (same as reference [37]) (to September 1958).
2. "Annual Review of Physical Chemistry," Volume 10--chapter entitled "Thermochemistry and Thermodynamic Properties of Substances," by J. M. Sturtevant -- Annual Reviews, Inc., Palo Alto, Calif., 1959, pp. 1-30 (Dec. 1957 to Dec. 1958).
3. NAnnual Review of Physical Chemistry," Volume ll -- chapter entitled "Thermochemistry and Thermodynamic Properties of Substances," by J. P. McCullough -- Annual Reviews, Inc., Palo Alto, Calif., 1960, pp. 1-20 (Dec. 1958 to Dec. 1959).
4. "Bibliography on the High Temperature Chemistry and Physics of Materials in the Condensed State" (covering the literature of several countries), International Union of Pure and Applied Chemistry, Commission on High Temperatures and Refractories, Sub-Commission on Condensed States, Jan. 1960 through Mar. 1961 (5 issues), 172 pages.
5. Journal of Physical Chemistry, Jan. 1959 through June 1961.
6. Journal of Chemical Physics, Jan. 1959 through June 1961.
7. Journal of the American Chemical Society, July 5, 1960, through June 5, 1961.
8. Bulletin of Chemical Thermodynamics, "No. 4, 1961," March 20, 1961 (same as reference [38]).

Further Comments on Table 1 -- As is customary, the empirical formulas are given for condensed states, but the true molecular formulas are given for gases. The physical state is designated as crystalline(c), liquid ( $\ell$ ), gas ( g ), amorphous, or glass, with a distinction among different crystalline forms if the existence of more than one is recognized. The actual temperature range of measurements on a condensed phase is given where it was possible to ascertain it in the time available, with an attempt to indicate the cases where the temperature scale referred to is ambiguous. Even the sources of information listed above were not covered completely with respect to "low-temperature" measurements which extend only up to or slightly above room temperature, as this temperature region has been covered thoroughly for many of the elements listed above (but yet incompletely for many of the other elements) by another group in the NBS program. Finally, it may be mentioned that the absence from the table of the description "critical compilation" is in some cases due to lack of information rather than real evidence that critical selection was not used.

For the substances covered in the present survey, all individual investigations included in U. S. Bureau of Mines Bulletin 584 have been given separately in the table below, but the Bulletin must be consulted for the original references. For each particular substance and state where that Bulletin lists more than one reference, the column "Rating by Bulletin 584" lists "1" if the Bulletin italicized the reference ("given greatest weight") or " 2 " if not italicized ("not given greatest weight").

Heat Content, Melting Point, and Heat of Fusion of Beryllium Oxide -- As noted in Table 1, measurements of the heat content of Be 0 from $1200^{\circ} \mathrm{K}$ to the melting point have recently been reported by Kandyba, Kantor, Krasovitskaya, and Fomichev [14]. The samples, $99.9 \% \mathrm{BeO}$ after sintering finally at $1800^{\circ} \mathrm{C}$, were contained in molybdenum below $2400^{\circ} \mathrm{K}$ and in tungsten above this temper ature. They used a vacuum furnace, measured temperatures with an optical pyrometer, and reported they found the melting point of BeO to be $2820^{\circ} \pm 9^{\circ} \mathrm{K}$, which agrees with earlier measurements within the stated precisions. Their smoothed values of the heat content of BeO (c) are represented by the equation (in cal/mole at $\left.T^{\circ} \mathrm{K}\right)\left(1200^{\circ}-2820^{\circ} \mathrm{K}\right)$

$$
\mathrm{H}_{\mathrm{T}}-\mathrm{H}_{298.16}=9.471 \mathrm{~T}+1.045\left(10^{-3}\right) \mathrm{T}^{2}-3540
$$

The above results may be compared with values in NBS Report 6484 (July 1, 1959), which gave (in Table 2-8) thermodynamic functions for BeO (c) up to $2800^{\circ} \mathrm{K}$ based on the long and hence inaccurate extrapolation of the heat capacity from precise measurements made only up to $1200^{\circ} \mathrm{K}$. The smoothed heat capacities of KKKF are $1.8 \%$ lower at $1200^{\circ} \mathrm{K}, 4.4 \%$ higher at $2000^{\circ} \mathrm{K}$, and $13.5 \%$ higher at $2800^{\circ} \mathrm{K}$ and should of course be more reliable than the estimated values at the higher temperatures.

In the same report (NBS Report 6484, p.59), the heat of fusion of BeO was estimated as being about $17 \mathrm{kcal} /$ mole by analogy with the entropies of fusion of MgO and FeO . Although KKKF's heat-content data obviously reflect varying amounts of melting at $2820^{\circ}$, $2822^{\circ}$, and $2840^{\circ} \mathrm{K}$, if fusion were complete at the last temperature (which they apparently do not claim), their data would give a heat of fusion of $15 \mathrm{kcal} / \mathrm{mole}$. Although based on a single experimental heat-content value in the liquid range, this value thus represents a lower limit to the true heat of fusion.

TABLE 1. REPORTED INVESTIGATIONS OF THE HIGH-TEMPERATURE
HEAT CONTENTS AND HEAT CAPACITIES OF SELECTED SUBSTANCES

## CHAPTER 6

## THERMODYNAMIC PROPERTIES OF BORATES

by William H. Evans

The available data leading to values for the heats of formation at $25^{\circ} \mathrm{C}$ of the crystalline borates have been reviewed, and "best" values are summarized below.
$\underline{\mathrm{Li}_{2} \mathrm{O}-\mathrm{B}_{2} \mathrm{O}_{3} \text { system }}$
$\Delta H f \mathrm{~B}_{2} \mathrm{O}_{3}(\mathrm{c})=-305.34 \pm 0.3 \mathrm{kcal} / \mathrm{mole}$ (NBS Report 7093)
$\Delta H f \mathrm{Li}_{2} \mathrm{O}(\mathrm{c})=-142.4 \pm 0.8 \mathrm{kcal} / \mathrm{mole}$ (NBS Circular 500)
Based on heats of solution in $2 \mathrm{~N}_{\mathrm{HNO}_{3}}$, reported by $\mathrm{L}_{0}$ Shartsis and W. Capps (J. Am. Ceram. Soc. 37, 27 (1954)) and G. S. Smith (Ph.D. Thesis, Penn. State Univ. (1959)). The agreement is good ( $0.1 \%$ ) in $\Delta H f$.
$\left.\mathrm{Li}_{2} \mathrm{O}^{-\mathrm{B}_{2} \mathrm{O}_{3} \quad[2 \mathrm{LiBO}}{ }_{2}\right]$ (extrapolated)
$\Delta H f=-40.4+1.0 \mathrm{kcal} / \mathrm{mole} \quad$ from oxides

$$
=-488.2 \pm 1.3 \mathrm{kcal} / \mathrm{mole} \quad \text { from elements }
$$

$\mathrm{Li}_{2} \mathrm{O} \cdot 2 \mathrm{~B}_{2} \mathrm{O}_{3}\left[\mathrm{Li}_{2} \mathrm{~B}_{4} \mathrm{O}_{7}\right]$
$\Delta H f=-54.9 \pm 0.7 \mathrm{kcal} / \mathrm{mole} \quad$ from oxides $=-808.0 \pm 1.4 \mathrm{kcal} / \mathrm{mole}$
from elements
$\mathrm{Li}_{2} \mathrm{O} \cdot 3 \mathrm{~B}_{2} \mathrm{O}_{3}$
$\Delta H f=-58.6 \pm 1.0 \mathrm{kcal} / \mathrm{mole}$ $=-1117.0 \pm 1.6 \mathrm{kcal} / \mathrm{mole}$
from oxides from elements
$\mathrm{Li}_{2} \mathrm{O} \cdot 4 \mathrm{~B}_{2} \mathrm{O}_{3}$
$\Delta H f=-56.9 \pm 1.3 \mathrm{kcal} / \mathrm{mole} \quad$ from oxides $=-1420.7 \pm 1.9 \mathrm{kcal} / \mathrm{mole}$
from elements
Shartsis and Capps, and Smith both give data for glasses.
$\xrightarrow{\mathrm{Na}_{2}{ }^{0}-\mathrm{B}_{2} \mathrm{O}_{3} \text { system }}$
$\Delta H f \mathrm{~B}_{2} \mathrm{O}_{3}(\mathrm{c})=-305.34 \pm 0.3 \mathrm{kcal} / \mathrm{mole}$ (NBS Report 7093)
$\Delta H f \mathrm{Na}_{2} \mathrm{O}(\mathrm{c})=-99.4 \pm 0.5 \mathrm{kcal} / \mathrm{mole}$ (NBS Circular 500)
Based on heats of solution in $2 \mathrm{~N}_{\mathrm{HNO}}^{3}$, reported by L. Shartsis and W. Capps (J. Am. Ceram. Soc. 37, 27 (1954)), G. S. Smith (Ph. D. Thesis, Penn. State Univ. (1959)), and by G. Grenier and D. White (J. Phys. Chem. 61, 1681 (1957)).

The data of Grenier and White, measured directly on the compound, lead to $\Delta H f=-472.0 \pm 1.3 \mathrm{kcal} / \mathrm{mole}$ (from elements). The extrapolated data of Shartsis and Capps (which agree very well with the data of Smith for $\mathrm{Na}_{2} \mathrm{O} \cdot 2 \mathrm{~B}_{2} \mathrm{O}_{3}$ and $\mathrm{Na} \mathrm{NO}^{2} \cdot 3 \mathrm{~B}_{2} \mathrm{O}_{3}$ ) lead to $-462.7 \pm 1.4 \mathrm{kcal} / \mathrm{mole}$. The value from Grenier andWhite seems to be too negative; it leads to a value, from the oxides, of $-67.3 \mathrm{kcal} / \mathrm{mole}$, which gives $-16.8 \mathrm{kcal} / \mathrm{gram}$-atom oxygen. The corresponding Li and $K$ values are -10.1 and -18.4 ; the extrapolated value for Na is $\mathbf{- 1 4 . 5}$. For consistency, we select the extrapolated value.
$\mathrm{Na}_{2} \mathrm{O}^{\circ} \cdot \mathrm{B}_{2} \mathrm{O}_{3} \quad\left[2 \mathrm{NaBO}_{2}\right]$ (extrapolated)

$$
\begin{aligned}
\Delta H f & =-58.0 \pm 1.0 \mathrm{kcal} / \mathrm{mole} & & \text { from oxides } \\
& =-462.7 \pm 1.4 \mathrm{kcal} / \mathrm{mole} & & \text { from element }
\end{aligned}
$$

$\mathrm{Na}_{2} \mathrm{O} \cdot 2 \mathrm{~B}_{2} \mathrm{O}_{3}\left[\mathrm{Na}_{2} \mathrm{~B}_{4} \mathrm{O}_{7}\right]$

$$
\Delta H f=-76.1 \pm 0.7 \mathrm{kcal} / \mathrm{mole} \quad \text { from oxides }
$$

$$
=-786.2 \pm 1.1 \mathrm{kcal} / \mathrm{mole} \quad \text { from elements }
$$

$\mathrm{Na}_{2} \mathrm{O} \cdot 3 \mathrm{~B}_{2} \mathrm{O}_{3}$

```
\(\Delta H f=-85.3 \pm 1.0 \mathrm{kcal} / \mathrm{mole} \quad\) from oxides
    \(=-1100.7 \pm 1.5 \mathrm{kcal} / \mathrm{mole}\)
from elements
```

$\mathrm{Na} \mathrm{a}_{2} \cdot 4 \mathrm{~B}_{2} \mathrm{O}_{3}$

$$
\begin{aligned}
\Delta H f & =-91.5 \pm 1.3 \mathrm{kcal} / \mathrm{mole} & & \text { from oxides } \\
& =-1412.3 \pm 1.8 \mathrm{kcal} / \mathrm{mole} & & \text { from elements }
\end{aligned}
$$

Shartsis and Capps, and Smith both give data for glasses.
Entropies have been reported for

(Grenier and Westrum, J. Am. Chem. Soc. 78, 6226 (1956))
$\mathrm{Na}_{2} \mathrm{O} \cdot 2 \mathrm{~B}_{2} \mathrm{O}_{3} \quad \mathrm{~S}_{2 \mathrm{Lag}}^{\circ}=45.30 \mathrm{cal} / \mathrm{deg} \mathrm{mole}$
(Westrum and Grenier, J. Am. Chem. Soc. 79, 1799 (1957))
$\underline{\mathrm{K}_{2} \mathrm{O}-\mathrm{B}_{2} \mathrm{O}_{3} \text { system }}$
$\Delta \mathrm{Hff} \mathrm{B}_{2} \mathrm{O}_{3}(\mathrm{c})=-305.34 \pm 0.3$ (NBS Report 7093)
$\Delta H f K_{2} O(c)=-86.4 \pm 0.5 \mathrm{kcal} / \mathrm{mole}$ (NBS Circular 500)
Based on heats of solution in $2 \mathrm{NHNO}_{3}$, reported by L. Shartsis and W. Capps (J. Am. Ceram. Soc. 37, 27 (1954)).
$\mathrm{K}_{2} \mathrm{O}^{\circ} \mathrm{B}_{2} \mathrm{O}_{3}\left[2 \mathrm{KBO}_{2}\right]$ (extrapolated)

$$
\begin{aligned}
\Delta H f & =-73.5 \pm 1.0 \mathrm{kcal} / \mathrm{mole} \mathrm{~K}_{2} \mathrm{O}^{\circ} \mathrm{B}_{2} \mathrm{O}_{3} & & \text { from oxides } \\
& =-465.2 \pm 1.2 \mathrm{kcal} / \mathrm{mole} & & \text { from elements }
\end{aligned}
$$

$\mathrm{K}_{2} \mathrm{O} \cdot 2 \mathrm{~B}_{2} \mathrm{O}_{3} \quad\left[\mathrm{~K}_{2} \mathrm{~B}_{4} \mathrm{O}_{7}\right]$

$$
\begin{aligned}
\Delta H f & =-99.3 \pm 0.7 \mathrm{kcal} / \mathrm{mole} & & \text { from oxides } \\
& =-796.3 \pm 1.1 \mathrm{kcal} / \mathrm{mole} & & \text { from elements }
\end{aligned}
$$

$\mathrm{K}_{2} \mathrm{O} \cdot 3 \mathrm{~B}_{2} \mathrm{O}_{3}$
$\Delta H f=-110.1 \pm 1.0 \mathrm{kcal} / \mathrm{mole} \quad$ from oxides $=-1112.5 \pm 1.5 \mathrm{kcal} / \mathrm{mole}$ from elements
$\mathrm{K}_{2} \mathrm{O} \cdot 4 \mathrm{~B}_{2} \mathrm{O}_{3}$
$\Delta H f=-118.3 \pm 1.3 \mathrm{kcal} / \mathrm{mole} \quad$ from oxides

$$
=-1426.1 \pm 1.8 \mathrm{kcal} / \mathrm{mole}
$$

from elements
Shartsis and Capps also give data for glasses.

## $\mathrm{CaO}-\mathrm{B}_{2} \mathrm{O}_{3}$ system

$\Delta \mathrm{Hf} \mathrm{CaO}(\mathrm{c})=-151.9 \pm 0.3 \mathrm{kcal} / \mathrm{mole}$ (NBS Circular 500)
$\Delta H f \mathrm{~B}_{2} \mathrm{O}_{3}(\mathrm{c})=-305.34 \pm 0.3 \mathrm{kcal} / \mathrm{mole}$ (NBS Report 7093)
Heats of solution in IN HCl are reported by D. R. Torgeson and C. H. Shomate (J. Am. Chem. Soc. 69, 2103 (1947)).

$$
\mathrm{CaO} \cdot \mathrm{~B}_{2} \mathrm{O}_{3} \quad\left[\mathrm{Ca}\left(\mathrm{BO}_{2}\right)_{2}\right]
$$

$$

\end{aligned}
$$

Assuming $\quad \Delta \mathrm{Hm}=7.0 \mathrm{kcal} / \mathrm{mole}$, these become for $\mathrm{PbO} \cdot \mathrm{B}_{2} \mathrm{O}_{3}(\mathrm{c})$
$\Delta H f=-16.2 \pm 1.3 \mathrm{kcal} / \mathrm{mole}$
$=-366.6 \pm 1.4 \mathrm{kcal} / \mathrm{mole}$
from oxides
from elements
$\mathrm{PbO} \cdot 2 \mathrm{R}_{2} \mathrm{O}_{3} \quad(\mathrm{gls}) \quad\left[\mathrm{PbB}_{4} \mathrm{O}_{7}\right]$
$\begin{aligned} \Delta H f & =-11.9 \pm 0.7 \mathrm{kcal} / \mathrm{mole} \\ & =-667.7 \pm 1.0 \mathrm{kcal} / \mathrm{mole}\end{aligned}$
from oxides from elements
$\mathrm{PbO} \cdot 2 \mathrm{~B}_{2} \mathrm{O}_{3}$ (c), estimating the heat of fusion

$$
\begin{aligned}
\Delta H f & =-23.3 \pm 1.3 \mathrm{kcal} / \mathrm{mole} \\
& =-689.1 \pm 1.5 \mathrm{kcal} / \mathrm{mole}
\end{aligned}
$$

from oxides from elements
$\mathrm{PbO} \cdot 3 \mathrm{~B}_{2} \mathrm{O}_{3}$ (gls)
$\Delta H f=-24.5 \pm 1.0 \mathrm{kcal} / \mathrm{mole} \quad$ from oxides $=-961.1 \pm 1.4 \mathrm{kcal} / \mathrm{mole}$
from elements
$\mathrm{PbO} \cdot 3 \mathrm{~B}_{2} \mathrm{O}_{3}(\mathrm{c})$, estimating the heat of fusion,
$\Delta H f=-40.5 \pm 1.5 \mathrm{kcal} / \mathrm{mole}$
$=-977 . \pm 2 . \mathrm{kcal} / \mathrm{mole}$
from oxides
from elements
$2 \mathrm{PbO} \cdot 5 \mathrm{~B}_{2} \mathrm{O}_{3}(\mathrm{gls})$
$\begin{aligned} \Delta H f & =-45.2 \pm 1.8 \mathrm{kcal} / \mathrm{mole} \\ & =-1662.12 .\end{aligned}$ $=-1662.1 \pm 2.3 \mathrm{kcal} / \mathrm{mole}$

from oxides from elements

$2 \mathrm{PbO} \cdot 5 \mathrm{~B}_{2} \mathrm{O}_{3}$ (c), estimating the heat of fusion,
$\Delta \mathrm{Hf}=-72 . \pm 3 . \mathrm{kcal} / \mathrm{mole}$
from oxides $=-1689 . \pm 3.5 \mathrm{kcal} / \mathrm{mole}$ from elements

The values for the glasses should be rather good; those for the crystalline oxides include an estimated - very roughly - heat of fusion, which may be several kcal/mole in error.

Lepinskikh and Esin (Zhur. Neorg. Khim。6, 1223 (1961)) have studied the systems $\mathrm{PbO}-\mathrm{B}_{2} \mathrm{O}_{3}$ and $\mathrm{MnO}-\mathrm{B}_{2} \mathrm{O}_{3}$ at $1000^{\circ}$ with cells of the type $\mathrm{Pb}($ liq $)\left|\mathrm{PbO}, \mathrm{B}_{2} \mathrm{O}_{3}\right| \mathrm{Pt} \mid \mathrm{O}_{2}(\mathrm{~g})$. Their results for the $\mathrm{PbO}-\mathrm{B}_{2} \mathrm{O}_{3}$ system are in fair agreement with the results of Shartsis and Newman.

# HEATS OF FORMATION OF BINARY MIXED-OXIDE SYSTEMS OIHER THAN BORATES 

by R. F. Walker, E. S. Newman, and T. B. Douglas

## 1. Introduction

A more thorough search of the literature has been undertaken to survey data on the heats of mixing of binary systems of oxides or to find thermodynamic data from which the heats may be computed. Studies of compound formation in binary systems of the oxides of $\mathrm{Hi}, \mathrm{Be}, \mathrm{Mg}, \mathrm{Al}, \mathrm{Ti}$ and Zr were surveyed and available phase diagrams were presented in the last report (NBS NO. 7093). Many compounds are identified on the diagrams for which no thermodynamic data is available. Furthermore, it is probable that the existence of many new compounds will be established during future phase equilibrium studies. In general it can be said that data on heats of formation of the compounds are scarce and even then not of high accuracy. In order to provide additional background in the evaluation of the heats of mixing, data on binary systems containing $\mathrm{BaO}, \mathrm{CaO}$ and $\mathrm{Na}_{2} \mathrm{O}$ have also been noted. Furthermore, the current interest of Si to the program fas also led to the inclusion of data on binary systems with $\mathrm{SiO}_{2}$.

A prime reason for the lack of data has probably been lack of motivation. However, there are two major obstacles to ready experimental measurement: First, the preparation of pure, stoichiometric samples in sufficient quantity to make measurements worthwhile may often be the most difficult part of an investigation. Secondly, the heat of mixing of few oxides can be measured directly; hence, another reaction which the reactant and compound oxides will undergo must be found. The difference between the heats of reaction of the compound and of the reactants is then the required heat of formation of the compound from the oxides. If the difference is small, high precision in the individual measurements is necessary to obtain meaningful data. A brief discussion of calorimetric methods of measuring the heats is given later.

In principle, the phase diagrams can be used to determine heats of mixing. However, the data and phase boundaries given on most high-temperature diagrams are not usually known with sufficient accuracy to yield reliable heats.

## 2. Heats of Formation of Binary Oxides

Available data on the heats of formation of the mixed oxide systems ( $\mathrm{Al}, \mathrm{Be}$, $\mathrm{Ca}, \mathrm{Mg}, \mathrm{Na}, \mathrm{Si}, \mathrm{Ti}$ and Zr ) are summarized in Table I. In the literature search, Metallurgical Thermochemistry by Kubaschewski and Evans [1] was taken as the point of departure. Data given in the compilations of that volume were checked with original literature. The references to this and other literature are summarized in Table I. The following discussion amplifies some of the background to the selection of the values given in Table I.

* Heats of formation of the many oxide systems were taken from NBS Report 6928 (July 1, 1960) and NBS Circular 500.
** Numbers in brackets refer to literature references.

Altman and Searcy [2] have recently reported measurements of the vapor pressure of MgO vaporizing from $\mathrm{Al}_{2} \mathrm{O}_{3}$ Knudsen cells. During the experiments the $\mathrm{Al}_{2} \mathrm{O}_{3}$ and MgO reacted to form the spinel $\mathrm{MgO} \cdot \mathrm{Al}_{2} \mathrm{O}_{3} 3^{\circ}$ The weight loss from the cell during the runs ylelding nearly stoichiometric spinel suggested that its heat of formation is close to zero.

A recent value of the heat of formation obtained by Grjotheim, Herstad and Toguri [16] from a study of the reaction:

$$
4 \mathrm{MgO}(\mathrm{c})+2 \mathrm{Al}(\mathrm{l})=\mathrm{MgAl}_{2} \mathrm{O}_{4}(\mathrm{c})+3 \mathrm{Mg}(\mathrm{~g})
$$

is in good agreement with Altman and Searcy's result. Grjotheim et al's value of +1.1 kcals/mole is subject to accumulated experiment errors in the heats of formation of reactants and products, and the removal of these errors could easily result in a small negative value for the heat of formation of $\mathrm{MgO} \cdot \mathrm{Al}_{2} \mathrm{O}_{3}$.

## $\mathrm{Al}_{2} \mathrm{O}_{3}-\mathrm{ZrO}_{2}$ System

The rates of vaporization of $\mathrm{Al}_{2} \mathrm{O}_{3}$ and $\mathrm{Al}_{2} \mathrm{O}_{3}-\mathrm{ZrO}_{2}$ mixtures have been crudely investigated at NBS in recent months. Much additional work is necessary before definitive conclusions can be drawn. An x-ray examination of mixtures fused in vacuo with an arc image furnace ylelded no evidence of new compound formation beyond a small quantity of stabilized, cubic $\mathrm{ZrO}_{2}$. Corundum and the monoclinic form of $\mathrm{ZrO}_{2}$ formed the bulk of the fused mixture.

The previously published phase diagrams on ternary systems containing $\mathrm{Al}_{2} \mathrm{O}_{3}$ and $\mathrm{ZrO}_{2}$ were summarized in the last report (NBS No. 7093). The diagrams show no evidence of compound formation between the oxides. The liquid curve of the binary system was reported by von Wartenberg and Reusch [3] and shows a single minimum, suggesting lack of congruent-melting compounds. The reliability of the curve may be questionable, but the consensus of available evidence is that there is no stable compound formation in the $\mathrm{Al}_{2} \mathrm{O}_{3}-\mathrm{ZrO}_{2}$ system.

The question may be posed as to how much the total heat of combustion of given amounts of Al and Zr depends on whether the metals are burned separately or together. Numerous intermetallic compounds of the two metals are known, and if the metals are present in such a form, the heat of formation of the intermetallic compound would make a direct additive contribution. For the sake of simplicity, it will be assumed that the Al and Zr are present as a mere mixture of the two elemental phases. The heat of formation of the product compared with the sum of the heats for the separate oxides is then the remaining consideration.

The above evidence of no stable compound between $\mathrm{Al}_{2} \mathrm{O}_{3}$ and $\mathrm{ZrO}_{2}$ does not preclude the possibility that the two oxides may be formed together under such rapid conditions that metastable compounds or solid solutions may form and be "frozen" into permanence. Two theoretical factors enter here: (a) the crystal radii。 of $\mathrm{Al}^{+++}$and $\mathrm{Zr}^{++++}$differ substantially (Pauling [4] gives 0.50 and 0.80 A respectively), a fact which would lead to considerable strain energy and
a corresponding lower heat of combustion, and (b) the difference in valence would lead to a considerable concentration of lattice vacancies, which energetically are equivalent to lattice strains. At a given temperature the equilibrium concentrations of such vacancies and "foreign" ions varies more or less exponentially with the added energy, so that the gross enhancement of energy would decrease rapidly with increase in strain energy per foreign ion or vacancy; and, at least qualitatively, one would expect a similar rough parallel for given non-equilibrium conditions. There are methods, at least in principle, for calculating such lattice strains. However, the kinetics of the problem are probably of equal importance, and suggest that empirical tests may, after all, be the simplest and most reliable way to settle the question.
$\mathrm{Al}_{2} \mathrm{O}_{3}$ and $\mathrm{ZrO}_{2}$ both form several phases which have appreciably different energies, and there is at least some evidence to show that simultaneous crystallization of the oxides can result in a different proportion of these forms than when they crystallize separately. Furthermore it is possible that different crystal sizes may result from simultaneous quenching of the oxides. Liquid eutectic compositions often crystallize in finely-divided form, and their surface energies could conceivably be different.

No information is at hand as to whether studies of the surface energies of $\mathrm{Al}_{2} \mathrm{O}_{3}, \mathrm{ZrO}_{2}$, or comparable substances have been made. Considerable experimental and theoretical work is available for the alkali halides, however, and a rough analogy may be useful. It is worth observing that the experimentally determined surface tensions (and hence, surface energies) of liquid salts are in comparative agreement with the theoretical values.

Numerous investigators have calculated the surface energies of crystalline alkali halides, with and without various refinements. Benson, Balk and White [5]; and Benson, Dempsey, and Balk [6] have given more refined calculations for all the alkali halides, including the effects of van der Waals attraction, polarization, and shifts in position of the surface ions. For NaCl, e.g., they calculate surface energies of 124 and $307 \mathrm{ergs} / \mathrm{cm}^{2}$ for the 100 and 110 planes, respectively; and they find that these values agree with the experimental ones if it be assumed that the experiments were conducted on fine crystals with $75 \%$ of the faces as 110 and $25 \%$ as 100 - obviously not an equilibrium state.

We may try to apply these results to $\mathrm{Al}_{2} \mathrm{O}_{3}$ and $\mathrm{ZrO}_{2}$ in a very rough way, and examine the result. Let us assume for simplicity that these two oxides are formed as uniform cubes each $x$ microns on an edge. The application of a simple Born treatment is known to give a surprisingly good lattice energy for $\mathrm{Al}_{2} \mathrm{O}_{3}$, and it may be assumed that the effective valence product for the two oxides is several times as great as for the (univalent) alkali halides. The molal volumes of $\mathrm{Al}_{2} \mathrm{O}_{3}$ and $\mathrm{ZrO}_{2}$ average about $25 \mathrm{~cm}^{3} / \mathrm{mole}$. If we assume a surface energy of $2000 \mathrm{ergs} / \mathrm{cm}^{2} 2^{3}$, we then get a surface of $1.5\left(10^{6}\right) / \mathrm{x} \mathrm{cm}^{2}$ per mole and a surface energy of $0.08 / \mathrm{x}$ kcal./mole. The heats of formation of $\mathrm{Al}_{2} \mathrm{O}_{3}$ and $\mathrm{ZrO}_{2}$ average $33 \mathrm{lkcal} / \mathrm{mole}$, and if we assume a particle size $x$ of 0.1 micron (equivalent to several hundred atoms per edge), this calculation gives a surface-energy contribution of $0.8 \mathrm{kcal} / \mathrm{mole}$,
or only about $0.2 \%$ of the total heat of combustion. Unless the particles are considerably smaller than 0.1 micron, it thus seems unlikely that the surface energy makes a contribution to the heat of combustion of much practical importrance.

It is presently believed that the system $\mathrm{AlF}_{3}-\mathrm{ZrF} \mathrm{F}_{4}$ forms no solid compounds. If this is true, similar conclusions may be drawn about the combustion of Al-Zr mixtures in fluorine.

In conclusion, the available evidence indicates that in the combustion of Al-Zr mixtures (to form oxides or fluorides) the heat produced is not likely to be much different from the additively calculated equilibrium values for the separate systems, being more likely to be less than greater.

## $\xrightarrow[\mathrm{Al}_{2} \mathrm{O}_{3}-\mathrm{BeO} \text { System }]{ }$

Young [7] studied by transpiration experiments what seem to be the following three reactions, obtaining for $\Delta \mathrm{H}^{\circ} 167$ the following respective values. (Tolerances stated refer to precision only.)
(1) $\mathrm{BeO}(\mathrm{c})+\mathrm{H}_{2} \mathrm{O}(\mathrm{g})=\mathrm{Be}(\mathrm{OH})_{2}(\mathrm{~g})$
(2) $(3 / 2) \mathrm{BeO}^{2} \cdot \mathrm{Al}_{2} \mathrm{O}_{3}(\mathrm{c})+\mathrm{H}_{2} \mathrm{O}(\mathrm{g})=(1 / 2) \mathrm{BeO} \cdot 3 \mathrm{Al}_{2} \mathrm{O}_{3}(\mathrm{c})+\mathrm{Be}(\mathrm{OH})_{2}(\mathrm{~g})$
$42.5 \pm 0.4$
(3) $\mathrm{BeO} \cdot 3 \mathrm{Al}_{2} \mathrm{O}_{3}(\mathrm{c})+\mathrm{H}_{2} \mathrm{O}(\mathrm{g})=3 \mathrm{Al}_{2} \mathrm{O}_{3}(\mathrm{c})+\mathrm{Be}(\mathrm{OH})_{2}(\mathrm{~g})$
$49.4 \pm 0.6$
$43.2 \pm 0.8$
Linear combination of these results gives
(4) $\mathrm{BeO}(\mathrm{c})+\mathrm{Al}_{2} \mathrm{O}_{3}(\mathrm{c})=\mathrm{BeO} \cdot \mathrm{Al}_{2} \mathrm{O}_{3}$ (c)
(5) $\mathrm{BeO}(\mathrm{c})+3 \mathrm{Al}_{2} \mathrm{O}_{3}(\mathrm{c})=\mathrm{BeO} \cdot 3 \mathrm{Al}_{2} \mathrm{O}_{3}(\mathrm{c})$
$-4.8 \pm 0.6$
$-0.7 \pm 0.9$

The data yield also, for $\Delta F_{1673}^{\circ},-3.2 \pm 1.1 \mathrm{kcal}$. for reaction (4) and $-3.7 \pm 1.7$ kcal. for reaction (5). There are insufficient data on the heat capacities of these mixed oxides for correction of these heats of reaction to $298^{\circ} \mathrm{K}$. According to early data of Nelson and Peterson [8] on the heat capacity of $\mathrm{BeO} \cdot \mathrm{Al}_{2} \mathrm{O}_{3}(\mathrm{c})$, for reaction (4) $\Delta C_{p}=-1.2$ between $273^{\circ}$ and $373^{\circ} \mathrm{K}$; if half this value were assumed for the interval from $298^{\circ}$ to $1673^{\circ} \mathrm{K}$ one would obtain $\Delta H_{298}^{\circ}=-4.0 \mathrm{kcal}$. for reaction (4).

As Young implies, his assumption that reactions (2) and (3) represent his experiments, and under equilibrium conditions, is subject to some uncertainty, particularly since each equilibrium involved two solid phases. However, considering his qualitative $x$-ray evidence and the fact that this part of the $\mathrm{BeO}_{-\mathrm{Al}_{2} \mathrm{O}_{3}}$ phase diagram has been well investigated [9, 10], it seems likely that these were the principal reactions occurring in Young's experiments. Unless future solution calorimetry or other relatively straightforward techniques reveal substantially different heats of formation of these mixed oxides, it must be concluded on experimental grounds that the heat of combustion of mixtures of beryllium and aluminum metals in oxygen is not increased more than about one percent through formation of these "mixed" oxides.

## $\mathrm{Al}_{2} \mathrm{O}_{3}-\mathrm{SiO}_{2}$ System

The three crystalline forms of aluminum monosilicate are naturallyoccurring minerals, which are believed to be formed only under high pressure. In addition, there is some evidence to suggest that impurities may act as "mineralizers," speeding up, if not being essential to, the formation of phases. In the laboratory the minerals can be synthesized in the $700-900^{\circ} \mathrm{C}$ temperature range and under pressures of $10,000-20,000$ atmos. The formation of andalusite and sillimanite in particular appears to be controlled by chemical factors. According to evidence at hand, andalusite has not been formed in the absence of sodium, although one might suspect that lithium would be an alternative; sillimanite has not been formed in the absence of fluorine, and forms a complete series of solid solutions with topaz, $\mathrm{Al}_{2} \mathrm{SiO}_{4}(\mathrm{~F}, \mathrm{OH})_{2}$. Kyanite is the only phase relatively insensitive to the composition of the reaction mixture.

The only aluminum silicate formed at atmospheric pressure is mullite, $3 \mathrm{Al}_{2} \mathrm{O}_{3}$ : $2 \mathrm{SiO}_{2}$, for which no heat of formation has yet been located. Another silicate, $\mathrm{AI}_{2}^{2} \mathrm{O}_{3} \cdot 3 \mathrm{SiO}_{2}$, forms at $900^{\circ} \mathrm{C}$ under 40,000 atm. pressure.
$\xrightarrow[\mathrm{Al}_{2} \mathrm{O}_{3}-\mathrm{IH}_{2} \mathrm{O} \text { and } \mathrm{IH}_{2} \mathrm{O}-\mathrm{SiO}_{2} \text { Systems }]{ }$
Recent data on these systems have been published by Fedorov and Shamrai [17]. This paper has been seen in abstract form only, and the abstract contains some ambiguity of notation. It appears that a heat of formation of $26 \mathrm{kcals} / \mathrm{mole}$ was determined for either $\mathrm{Li}_{2} \mathrm{O} \cdot \mathrm{SiO}_{2},{ }_{2 \mathrm{Ii}_{2}} \mathrm{O} \cdot \mathrm{SiO}_{2}$ or $3 \mathrm{Li}_{2} \mathrm{O} \cdot \mathrm{SiO}_{2}$. For lithium monoaluminate (presumably $\mathrm{Al}_{2}^{2} \mathrm{O}_{3} \cdot \mathrm{Ii}_{2}{ }^{2}$ ), a heat $\mathrm{cf} 27 \mathrm{kcals} / \mathrm{mole}$ is given. This value compares favorably with the value given in table I, but may not refer to $298^{\circ} \mathrm{K}$. Examination of the actual paper is necessary to resolve these uncertainties, and the data have not, therefore, been included in Taible I.

## 3. Possible Measuring Techniques for Determining Additional Heats of Formation

The literature has been surveyed to determine what calorimetric techniques have been used in recent years to determine heats of formation and to evaluate prospects for applying the techniques to the mixed oxides discussed in this chapter.

Probably, the most common calorimetric reaction studied is that of combustion. In many cases, the heat of the reaction of metals with oxygen, or other substances, can be determined directly, and this process has been studied in the calorimeter over many years. A great deal of the data on the heats of formation of the oxides of metals has been determined in this manner, many references and much expert knowledge is available, and no further attention will be given to heats of combustion in the present discussion.

A second very common calorimetric reaction is that of solution in water or in aqueous or other solutions, and it is to this reaction that attention is mainly directed. Some refractory oxides, similar to those of concern to this program, are soluble directly in acids or acid mixtures, or their heats of
solution in acid can be calculated fairly directly from the heats of solution of the metals themselves and their heats of combustion. In this manner the heats of formation of calcium [18], barium [14], and strontium aluminates have been determined by measurement of their heats of solution in hydrochloric acid solutions at room temperature, although $\mathrm{Al}_{2} \mathrm{O}_{3}$ has not been dissolved directly.

In mixtures of nitric or hydrochloric acid with hydrofluoric acid, the heats of solution of hydrated and unhydrated calcium silicates [19, 20], as well as more complex materials [21, 22] have been determined at room temperature. Although the silicates are in many cases thus soluble, silica itself is more difficult to dissolve. To deal with $\mathrm{SiO}_{2}$, as well as minerals such as albite, $\mathrm{NaAlSi}_{3} \mathrm{O}_{8}$, nepheline, $\mathrm{NaAlSiO}_{4}$, and jadeite, $\mathrm{NaAl}\left(\mathrm{SiO}_{3}\right)_{2}$ [23] and others [24, 25], Calorimeters using HF solutions have been built to operate at temperatures in the neighborhood of $75^{\circ} \mathrm{C}$. At least one operating at room temperature, the rocking-bomb calorimeter [26], has been built, and this, it seems probable, could be used with aqueous solutions at still higher temperatures.

The oxides with which this project is most immediately concerned are $\mathrm{Li}_{2} \mathrm{O}$, $\mathrm{BeO}, \mathrm{B}_{2} \mathrm{O}_{3}, \mathrm{MgO}, \mathrm{Al}_{2} \mathrm{O}_{3}, \mathrm{TiO}_{2}, \mathrm{ZrO}_{2}$, and $\mathrm{SiO}_{2}$. Of these, BeO and $\mathrm{Al}_{2} \mathrm{O}_{3}$ are listed [27] as the least soluble in acid. It appears that with the others, choices of acids or acid mixtures and temperature of operation would permit calorimetric determinations. Certainly some of the borates should be amenable to calorimetric determination of their heats of solution.

A great deal of work has been done with heat-of-solution calorimeters at elevated temperatures, using molten metal as a solvent, for example, molten tin [28, 29, 30, 31 and 32], and molten silver [33]. Temperatures as high as $1100^{\circ} \mathrm{C}$ have been reached [33], although temperatures of 300 to $500^{\circ} \mathrm{C}$ are more commonly indicated. Molten metals are unsuited as solvents for the oxide compounds with which this project is concerned, but a few similar measurements have been made using molten salts [34, 35]. It has been found that "ih many instances fused salt mixtures are close to ideal solutions" [36]. It would seem that further work with molten salts might well make possible measurements of heats of reaction of substances impossible to dissolve calorimetrically in aqueous solutions. Beryllium oxide, for example, is said to be soluble in fused Kон [27].

Ginnings [37] has suggested the possibility of raising the temperature of a reaction mixture by electrical heating until a desired reaction occurs, carrying out the reaction in an isolated capsule in a calorimeter, and correcting for the electrical energy. Such measurements have indeed been made using a bomb calorimeter and heating the reaction mixture in its crucible [38]. The precision of the calorimetry and the definition of the final products would probably be much poorer both for this type of measurement as well as for measurements made with molten salts than for modern combustion or heat-of-solution calorimetry. Precisions of 0.2 to 1.5 per cent have been given for molten-tin calorimetry.

## CHAPTER 8

THE HEATS OF FORMATION OF INORGANIC FLUORINE COMPOUNDS -- A SURVEY by George T. Armstrong and Leslie A. Krieger

## Abstract

This paper examines the current state of measurements leading to heats of formation of the inorganic fluorine compounds, and carbon compounds of one carbon atom per molecule. It is based upon a survey of the literature from 1949 to mid-1961. A bibliography of 625 references is given. Reported values of $\Delta \mathrm{Hf}_{298}^{\circ}$, cited from the literature, are listed for individual compounds in eight tables. Related thermodynamic measurements are also listed. No attempt is made to indicate the best values to be assigned when conflicting data exist. As a group the binary fluorine compounds have been the most thoroughly studied. The availability of the thermodynamic information decreases rapidly as the complexity of the compounds increases. Recent developments in certain phases of the calorimetry of fluorine compounds are discussed.

## Acknowledgment

This survey was prepared at the National Bureau of Standards, as part of the basic program of the Heat Measurements Section, and the work was supported by Bureau RTS funds. Because of the wide interest in the material of this survey, it is incorporated in the present ARPA report.

## 1. Introduction.

This paper presents in brief review and summary form the results of a survey of the recent literature on the thermochemical properties of inorganic fluorine compounds. The purpose of the paper is to indicate the present status of the heats of formation of this group of compounds without attempting an exhaustive critical evaluation of the data.

The fluorine compounds form a group of special interest from a scientific point of view because of the extreme position of fluorine in the periodic table. For many years it received less study than this extreme position warrants, probably for two reasons: the low abundance of fluorine relative to neighboring elements in the periodic table, and the extreme reactivity of the element, which has hindered work with it. In recent years this situation has changed and a large volume of research has been carried out, leading to a rapid growth of the literature of the fluorine compounds and the publication of several general review works $[1,2,3,4,5,6,7,8]$.

## 2. Scope and Completeness of Survey.

A large amount of effort has been expended by others in searching and evaluating the literature relating to the heats of formation of fluorine compounds. In carrying out the literature search in the present survey, advantage was taken of the results of prior work whenever possible. The National Bureau of Standards Circular 500 [9] was used as a starting point. This critical evaluation was considered to be complete through the 1949 Chemical Abstracts and further search of the literature covered in [9] was thought to be unnecessary. For the period following 1949, the Chemical Abstracts was the primary source searched.

For aqueous species we have not attempted to duplicate in our references the survey on stability constants of metal ion complexes and solubility products of inorganic substances, by Bjerrum, Schwarzenbach, and Sillen [16]. Many thermodynamic studies related to heats of formation of aqueous complex ions are listed there. When reference to a source of work on an aqueous species is made by Bjerrum, et al. [16], in general we refer to [16] rather than to the original source. Material not found in Bjerrum for these species is listed in the usual manner.

A complete search of the literature pertaining to such a large group of compounds, and covering all modes of information of potential value to the calculation of heats of formation, is a complex, painstaking task. A considerable amount of ingenuity is required to ferret out sources of information. In some instances, a source may contain the only applicable information available on a particular compound, but because the article is principally about a subject other than thermochemistry, the information may not be revealed in the abstract. A search of Chemical Abstracts, therefore, can hardly be expected to be complete in itself.

For this reason use was also made of other reviews in order to complete the search. The principal published reviews searched are listed as references $[10,11,12,13,14,15,16,17]$. Of these, several may be commented on. In two lengthy reviews Brewer, Bromley, Gilles and Lofgren [12] and Brewer [13] gave the heats of formation, fusion, and vaporization and other thermodynamic properties of most of the binary fluorides for which data were available. They also estimated values for many compounds for which measurements had not been made. They discussed briefly the sources of the selected values. Their references
were essentially completed in 1946, though reference was made to some additional work published through 1948. For many values of heats of formation they depended heavily upon Bichowsky and Rossini [10].

Herzberg [11] and Gaydon [14] are standard references for the dissociation energies of diatomic molecules. Additional information on dissociation energies might have been found in Cottrell [18] which, however, was not specifically searched. Kubaschewski and Evans [15] list many heats of formation, principally of materials of interest to metallurgists. Bjerrum [16] has compiled stability constants for complex ions in aqueous solutions, summarizing a good deal of literature which should be applicable to the calculation of enthalpies and free energies of formation of aqueous ions. Fluoride ion, forming many strongly bonded complex ions, is well represented. The second edition of Lewis and Randall's Thermodynamics, revised by Pitzer and Brewer, [17] contains extensive tables of thermodynamic properties including heats of formation. Of these the values for the gaseous alkali halides, based on a recent survey by Brewer and Brackett [19], are new.

Glassner, in an informal publication [20], tabulates the heats of formation of a great many binary fluorides, including estimates for many compounds for which experimental values are lacking. Aside from the estimates he depends upon Brewer, et al. [12], Kubaschewsky and Evans [15] or NBS Circular 500 [9], and lists data from other sources only for the fluorides of polonium and the actinide elements.

The Annual Reviews of Physical Chemistry have provided a review chapter on thermodynamics and thermochemistry each year since 1950. These chapters have become more complete and more uniform in coverage so that they formed a useful source for checking the completeness of our search. In addition, chapters on heterogeneous equilibrium and phase diagrams, high temperature chemistry, and bond energies supplied useful information. Volumes 1 - 11 were examined. The Bulletin of Chemical Thermodynamics (1958-1961) has provided a guide to very recent work. The "Table of Contents" of several journals and the serial publication Current Chemical Papers have been examined for new work each month for about three years.

Advantage was also taken of the current active interest in twenty or thirty elements, particularly of the low atomic weights, as potential ingredients of rocket fuels or oxidizers. This interest has led to surveys of thermochemical properties, with emphases on compounds which could occur as ingredients, products or intermediate species. Such surveys by Sinke [21], Gordon [22], Mickle [23], Hildenbrand [24] and Gordon [25] have appeared as listed reports. Others [26,27,28,29,30,31,32] have come in the form of informal communications to the authors. Still others $[33,34,35,36,37]$ represent unpublished communications by the authors. These surveys differ widely in the extent to which they resort to the original literature or to prior surveys, and also in the extent to which they attempt to justify the values they list. The values presented include estimates of the properties of some species considered to be possible, but for which no experimental data exist. Fluorine is a prominent element in most of these surveys, and so these have been scanned for information suitable for this paper.

The search of Chemical Abstracts included a page-by-page scanning of unindexed issues, sections $1,2,3,6,9$ and 24 (Apparatus, General and Physical Chemistry, Electronic Phenomena, Inorganic Chemistry, Metallurgy, and Propellants, respectively). This portion of the search began with the 1957 volume, and is complete through 18 issues of 1961. The issues from 1950 to 1956 have been searched in the formula index for all references to fluorine compounds, excluding carbon compounds $\mathrm{C}_{2}$ or higher. In addition, a limited number of subject index headings have been searched, including the names of fluorine compounds cross-referenced from the formula index, as well as certain headings involving heat processes.

Although the search of Chemical Abstracts has been intensive and detailed, it is probable that certain sources have been missed, because of the primary dependence upon the mention of the compound and the heat measurement in the abstracts studied. It is also probable that resort to other surveys did not completely fill the gap, because the other surveys in general did not cover all the fluorine compounds in any systematic manner.

The present examination and evaluation of the sources of data on fluorine compounds are expected to continue. Therefore, information about data not referred to in this article will be welcomed by the authors.

The information selected from the various references was limited to energy changes occurring at constant temperature. In particular, this criterion excludes the listing of specific heat measurements. It permits the inclusion of energies of phase changes, free energy changes (or the related equilibrium constants), as well as enthalpy changes occurring in chemical processes of all types and determined by any means.

For the preparation of this survey gaseous ions as chemical species were not covered. It is believed, however, that all other clearly recognized classes of chemical species have been included.

## 3. Arrangement of the Tables.

The information relating to heats of formation is summarized in Tables 1 to 8. There the chemical species are separated into fluorine (Table 1), binary fluorides (Table 2), ternary fluorine compounds (containing three elements including fluorine) (Table 3), quaternary and higher fluorine compounds (containing four or more elements) (Table 4), aqueous fluoride ion (Table 5), binary aqueous species (Table 6), ternary aqueous species (Table 7), and quaternary and higher aqueous species (Table 8). Hydrates, ammoniates, and hydrofluorides are treated consistently with other compounds in these tables, in which each element that occurs is counted without regard to chemical relationships or tightness of binding. Within Tables 2 and 5, the compounds are arranged alphabetically with respect to the symbol of the non-fluorine element.

In the remaining tables, the compounds are arranged in the order of the formula index in Chemical Abstracts, with a single modification: compounds containing water or other coordinated molecules and compounds containing $C$ and $H$ are not treated as exceptions to the general rules for arrangement. The rule for arrangement of elements within a compound is that they are in alphabetical order according to their symbols. The rule for arrangement of compounds within a table is that the compounds are in alphabetical order except that for the first element in a compound, for example Al, all formulas with Al come before those with $\mathrm{Al}_{2}$ and so on. This rule is maintained for each successive
element in the formula.
When this procedure leads to a formula not easily recognizable in terms of the molecular configuration, a more conventional formula is listed in parenthesis.

A compound whose existence has not been demonstrated, but for which a heat of formation is presented is followed by the abbreviation, hyp.

Table 2 lists all binary fluorides which were encountered in the search, whether or not thermodynamic data were found. The binary compounds listed were found by scanning the formula indices of Chemical Abstracts, 1950-1957; such monographs as Simons [1] and Ryss [2]; and the recent summaries by George [4] and Peacock [5]. The practice of including compounds for which no thermochemical data have been reported is not continued in the other tables.

The data for each compound are listed according to the phase of the compound in the order gas, liquid, crystal.

The purpose of these tables is to provide a very brief summary of new data related to the heat of formation of each compound, and its relation to prior data. For this purpose, in the column labelled " $\Delta H f_{298}^{\circ}$ " are listed the experimental values for the heat of formation found in the search. In addition, the heat of formation listed in NBS Circular 500 or a more recent authoritative review is listed. References are given for each value listed. It should be emphasized that appearance of a number in the column does not mean that it has been critically evaluated, or that precedence over other values or partial data listed elsewhere in these tables is intended. In addition, no effort has been spent toward making the values consistent.

In the column headed "Remarks" are described the processes by which heats of formation have been derived. In this column are listed data which are not reported as heats of formation, but which are applicable to the evaluation of a heat of formation when the data are combined with suitable other data. Also listed are values for heats of formation given by some other reviews, and estimated values.

The usual chemical process which can be used to derive a value suitable for listing in these tables involves more than one fluorine compound. To avoid duplication, cross references are given as needed. When two phases of the same substance are involved, as in a vaporization process, any enthalpy change reported is arbitrarily listed by the substance formula in the phase that results from an increase in energy; i.e., the vapor phase in this instance. This procedure is adopted in order to avoid ambiguity in those cases in which more than one molecular formula may be found in the vaporizing gases. Vapor pressure measurements are listed for the condensed phase in equilibrium with the vapor. These vapor pressure studies may provide additional information on the heat of vaporization or sublimation.

## 4. Evaluation of the Data.

Due to the lack of time, it has not been possible in this survey to give an evaluation of the available data, or any calculation of heats of formation on a consistent and critical basis, from the reported heat measurements of particular processes, and from the reported free energy and entropy data for equilibrium processes. The values given must, therefore, be taken as citations from the original literature.

It must be left to future critical analysis to indicate the greater or lesser degree of reliability of different experimental reports; to place the calculations upon a consistent basis, particularly with regard to the values to be used for auxiliary thermodynamic quantities required in the calculation; and to apply the most appropriate schemes for correlation or analysis of the data.

Similarly, as stated earlier, it has not been possible to discriminate definitely between the listed values which were taken from various other reviews. Each value listed in the second column of the tables, as coming from a review, is, therefore, merely a recent value from a competent review, and is not to be considered as necessarily superior to other values found in other reviews listed under "Remarks". The reason for listing such a value selected from a review is to provide a fair picture of the situation with regard to compounds for which data adequate for evaluation of a heat of formation may have existed prior to the period covered by the present survey. No values are listed in this column which are based to any important degree upon estimation.

## 5. Status of Data on the Heats of Formation of Fluorine Compounds.

In the absence of a critical evaluation of the data, a judgment of the reliability of the existing thermochemical measurements on the fluorine compounds as a group will not be attempted here. Of some interest is an estimation of the extent to which thermochemical data are lacking as compared to the extent to which measurements have been made. A careful estimate of this status for all classes of inorganic compounds would require a more thorough counting of the polyatomic

Pluorine compounds than has been possible for this review. At best such a count would be incomplete at any given time because the number of know compounds is continually being augmented. It is possible, however, on the basis of the information in these tables to make some limited and tentative estimates of the situation.

Let us consider for example the binary compounds. Two hundred seventy-eight (278) compounds are listed in Table 2, an average of about three fluorides for each element. Of these we find listed in the table a value for the heat of formation based on experimental work for 93 compounds; and data, in some instances sufficient for the calculation of a heat of formation, for 32 additional compounds, a total of 125 . This leaves 153 binary compounds, somewhat more than half of all the binary fluorine compounds, with insufficient data to permit a statement of the heat of formation based upon experiment.

Estimates have been made for many of these. The adequacy of such estimates is a moot point. The possible uncertainties are suggested by a few examples from the table. For $\mathrm{AcF}_{3}$ (c) estimates of the heat of formation range from -395 to $-477 \mathrm{kcal} / \mathrm{mole}$. For $\mathrm{AlF}_{3}(\mathrm{c})$ a value of $-311 \mathrm{kcal} / \mathrm{mole}$ was given in NBS Circular 500 [9] for which an estimate of the heat of solution was used to complete a cycle of thermochemical data. A more recently measured value reported on the basis of non-aqueous reactions was $-356.2 \mathrm{kcal} / \mathrm{mole}$. A recently measured value for $\mathrm{PF}_{5}(\mathrm{~g})$ is $-381.4 \mathrm{kcal} / \mathrm{mole}$, whereas Gordon [26] estimated $-420 \mathrm{kcal} / \mathrm{mole}$, and Kapustinskii [38] estimated $-315 \mathrm{kcal} / \mathrm{mole}$. Undoubtedly some estimates are better than these; nevertheless, the illustrations given above are by no means only for exotic or exceptional compounds.

The estimates of the completeness of existing data can be extended to the case of more complex compounds only in a qualitative way. In Table 3, 147 ternary compounds are listed, for which some thermochemical data have been presented. Of these there are sufficient data for 41 compounds for us to present a value of $\Delta H f$. For the remainder some relevant data or estimates of the heats of formation are available. The various monographs on fluorine chemistry and the Chemical Abstracts indices were not scanned for the purpose of obtaining a count of ternary compounds, so we do not have even an approximate count of the total number of known ternary fluorine compounds. However, examination of a single source (George [4]) gives an approximate number of the ternary compounds involving elements of groups Vb and VIb. This source lists 45 ternary compounds involving nine elements from these two groups, compared to 17 binary compounds involving the same elements. The ratio of ternary to binary compounds is somewhat over 2.5 to 1. Assuming the same ratio to hold for the ternary and binary fluorine compounds of all the elements, we find that the total number of ternary fluorine compounds would be somewhat in excess of 700. The validity of this assumption is not easy to justify, and the number could be made very far in error by the discovery of a group of compounds such as chain linked molecules analogous to the carbon compounds. Thus estimates of the number of compounds in the area for which measurements remain to be made can only be suggestive of the magnitude of the tasks involved if measurements were contemplated on all compounds. The contrast between 41 compounds for which measurements have been made, leading to an experimental value for the heat of formation, and
approximately 700 for which measurements might be contemplated is striking, and indicates the need for a very careful consideration of the desirability of closing the gap, and of ways in which it might be done.

## 6. Some Problems and New Developments in the Calorimetry of Fluorine Compounds.

The calorimetry of fluorine compounds has been hindered by the fact that in comparison with oxygen the use of elemental fluorine in reaction is attended with difficulties due to its great reactivity and its toxicity. Procedures for reactions of oxygen have been refined to such a degree, that reaction vessels, and materials compatible with oxygen are not lacking for almost any reaction process desired, either in a flame or a bomb calorimeter. Recent developments suggest that calorimetry of fluorine will also be possible in a comparably wide range of experiments. Already promising procedures have been worked out for a very satisfying variety of measurements directly on elemental fluorine. Gross [39,40, 568] and co-workers have developed procedures for the use of fluorine at 1 to 2 atm pressure in glass vessels in which the fluorine can be kept separate from the other reactant until reaction is desired. Hubbard and co-workers [41,42,43, 44, 241, 567] have demonstrated the feasibility of fluorine-bomb calorimetry, using nickel or monel bombs. They have applied their method to measurements of metals and metalloids forming volatile fluorides, such as those of titanium and boron. Armstrong and Domalski [45] have been able to extend fluorine bomb calorimetry to metals such as aluminum, which form relatively non-volatile fluorides. Other laboratories are also attempting work in this direction [46].
: Thustior of rganic and hydrogeneous compounds in a fluorine bomb orimeter apparently has not been attempted for precise measurements. The use of hydrogenous materials offers difficulties in the great non-ideality, the probable condensation of part of the hydrogen fluoride that would be formed, as well as the extreme corrosiveness of the gas it elevated temperatures. The presence of water in the bomb $_{\text {e }}$ in to dissolve the $H F$ reduces the amount of corrosion to an extent that ma: make it tolerable, as was shown by Armstrong, Marantz and Coyle [47] smont rat, involvıng elemental fluorine. The use of water 2. esence of fluorine to dissolve the hydrogen fluoride as it is fced would be precluded by the reaction of water with fluorine. Nevertheless these difficulties may be susceptible to a careful approach. There seems to be no a priori reason why, for instance, hydrogen fluoride formed by combustion in a bomb could not be absorbed in sodium fluoride, much as it is absorbed in NaF traps in flame calorimetry experiments [48]. "Teflon" has been shown [45] to burn readily in fluorine and is now - in the wosealable thin films, from which it should be possible to fabricate sample containers for liquids or spontaneously igniting substances. Such an experiment could open up the whole field of the thermochemistry of the fluorocarbons and the partially fluorinated hydrocarbons, as well as other substances not now accessible to such reactions. Of more immediate importance to the thermochemistry of fluorocarbons has been the development of methods for the satisfactory combustion of such materials in oxygen by Good, Scott and Waddington $[49,50]$.

Of equal importance to the development of bomb calorimetric methods with fluorine has been the development of a flame calorimeter suitable for burning gaseous samples in an atmosphere of fluorine [48]. This procedure, successfully used in the combustion of methane and ammonia, should be adaptable to the combustion of other gaseous materials in which either a fluoride is formed, or a fluorine oxidizer burns another material such as hydrogen or ammonia.

The difficulties in the use of elemental fluorine are at least, in part, compensated by another aspect of fluorine thermochemistry: the very great utility of hydrofluoric acid as a solvent. It is probable that the dissolving characteristics of hydrofluoric acid solutions have not been used to their fullest extent for ths decermination of heats of formation of fluorine compounds. There have been many applications to the determination of the heats of formation of mineral products, mostly oxides and silicates. More satisfactory anả more frequent application to the determination of the heats of formation of fluorine compounds should follow a better understanding of the species equilibria and rate processes involved in solutions of complex fluoride ions.

In some areas, it is apparent that uncertainties in the heacs of various processes exert a significant effect upon the thermochemical calculations, and that there is room for improvement of some of the more basic quantities of fluorine thermochemistry. A few instances will be briefly cited.
(1) The heat of formation for $\mathrm{HF}(\mathrm{g})$ is listed in NBS Circular 500 as $\Delta H f=-64.2 \mathrm{kcal} / \mathrm{mole}$. This value is less negative than the value obtained by Von Wartenberg and Schutza [51] in their careful experiments. A more negative value is also indicated by the experiments of Armstrong and Jessup [48]. If a value as negative as -64.6 kcal/mole were the proper value, the determinations of the heat of formation of $\mathrm{CF}_{4}$ by Jessup, McCoskey and Nelson [52] and by Scott, Good and Waddington [49], would be brought into essential agreement at -220 kcal/mole and the value determined by Neugebauer and Margrave [173] would be only 1 kcal different at $-219 \mathrm{kcal} / \mathrm{mole}$ rather then these determinations being separated by 2 or 3 kilocalories.
(2) The non-ideality of hydrogen fluoride in the low pressure region is so poorly known that use of one set of P-V-T data or another can lead to differences up to nearly l kcal/mole for the heat of formation at various pressures (see [48] for a discussion).
(3) A great deal of work has been done on the dissociation energy of fluorine (Table l). Despite the large amount of work, the value which lies near $38.7 \mathrm{kcal} / \mathrm{mole}$, as indicated by most of the recent work, still has not been as precisely established as would be desirable. This value enters into all calculations of average bond energies of fluorine compounds.

| $\mathrm{F}_{6} \mathrm{Fe}_{2} \mathrm{~K}_{2} \mathrm{Mg}_{6} \mathrm{O}_{19} \mathrm{Si}_{6}(\mathrm{c})$ |  | [482] reports $\Delta H$ crystn. |

d. Compounds of seven elements.
$\mathrm{Al}_{2} \mathrm{BaCF}_{6} \mathrm{Mg}_{6} \mathrm{O}_{21} \mathrm{Si}_{6}(\mathrm{c})$
[482] reports $\Delta \mathrm{H}$ crystn.
$\mathrm{Al}_{2} \mathrm{~F}_{6} \mathrm{Fe}_{3} \mathrm{~K}_{2} \mathrm{Ng}_{3} \mathrm{O}_{19} \mathrm{Si}_{6}$ (c)
[482] reports $\Delta \mathrm{H}$ crystn.
$\mathrm{BBaF}_{2} \mathrm{LiMg}_{2} \mathrm{O}_{10} \mathrm{Si}_{3}(\mathrm{c})$
[481, 482.] report $\Delta H$ crystn.
$\mathrm{BCF}_{3} \mathrm{H}_{3} \mathrm{NOS}(\mathrm{c}) \quad$ [483] meas. dissoc. pressure for; $\mathrm{CH}_{3} \mathrm{NSO}^{2} \cdot \mathrm{BF}_{3}(\mathrm{c})=\mathrm{CH}_{3} \mathrm{NSO}(\mathrm{g})+\mathrm{BF}_{3}(\mathrm{~g})$. Using the
$\left(\mathrm{CH}_{3} \mathrm{NSO} \cdot \mathrm{BF}_{3}\right)$ data of [483], [29] reported $\Delta \mathrm{H}$ dissoc. $=32.8$. See [520].
$\mathrm{CF}_{6} \mathrm{~K}_{2} \mathrm{Mg}_{6} \mathrm{O}_{22} \mathrm{Si}_{7} \mathrm{Zn}_{2}(\mathrm{c})$
[482] reports $\Delta H$ crystn.
e. Compounds of eight elements.
$\mathrm{Al}_{4} \mathrm{CF}_{12} \mathrm{~K}_{4} \mathrm{Mg}_{12} \mathrm{NiO}_{40} \mathrm{Si}_{12}$ (c)
[482] reports $\Delta H$ crystn.
$\mathrm{B}_{2} \mathrm{Ba}_{2} \mathrm{CF}_{4} \mathrm{Li}_{2} \mathrm{Mg}_{4} \mathrm{O}_{22} \mathrm{Si}_{6}(\mathrm{c})$
[481, 482] report $\Delta \mathrm{H}$ crystn.
$\mathrm{B}_{2} \mathrm{CCO}_{2} \mathrm{~F}_{4} \mathrm{Li}_{2} \mathrm{Mg}_{4} \mathrm{O}_{22} \mathrm{Si}_{6}(\mathrm{c})$
[482] reports $\Delta \mathrm{H}$ crystn.
$\mathrm{B}_{2} \mathrm{CF}_{4} \mathrm{Li}_{2} \mathrm{NH}_{4} \mathrm{O}_{22} \mathrm{Si}_{6} \mathrm{Sr}_{2}(\mathrm{c})$
[482] reports $\Delta H$ crystn.
$\mathrm{Ca}_{3 / 2} \mathrm{FHgg}_{9 / 2} \mathrm{Mn}_{1 / 2} \mathrm{NaO}_{23} \mathrm{Si}_{8}(\mathrm{c})$
[479] meas. decomposition to pyroxene, glass, and water and reports $\Delta \mathrm{H}=6.85$.

TABLE 5. AQUEOUS FLUORIDE ION

| Species | $\Delta \mathrm{Hf}_{298}^{\circ}(\mathrm{kcal} / \mathrm{mole})$ | Remarks |
| :---: | :---: | :---: |
| $\mathrm{F}^{-}(\mathrm{aq})$ | -78.66 [9] | For the equilibrium: $H^{+}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nsucceq \mathrm{HF}(\mathrm{aq})$, [16] lists $\Delta H=3.05$, 3.18; $\log \mathrm{K}$ (25 values). [195, 589] calc. $\Delta \mathrm{H}$ hydration of $\mathrm{F}^{-}(\mathrm{g})$. See also $\mathrm{HF}_{2}^{-}(\mathrm{aq})$, $\mathrm{HF}(\mathrm{aq})$, and individual metal ion species. |

TABLE 6. BINARY AQUEOUS SPECIES

| Species | $\Delta \mathrm{Hr}_{298}^{\circ} \mathrm{l}$ ( $\mathrm{kcal} / \mathrm{mole}$ ) | Remarks |
| :---: | :---: | :---: |
| $\mathrm{AgF}(\mathrm{aq})$ | $\underset{(\mathrm{var})}{-53.35[9]}$ | For the equilibrium: $\mathrm{Ag}^{+}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nLeftarrow \mathrm{AgF}($. .q $), \quad[16]$ lists $\Delta H=-2.4 ;$ log K ( 5 values). |
| $\mathrm{AlF}^{+2}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{AI}^{+3}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nsubseteq A 1 \mathrm{~F}^{+2}(\mathrm{aq}),[16]$ lists $\Delta \mathrm{H}=1.15$; log K (3 values). [484] recalc. the data for this reaction and reports $\Delta H=1.17$. [488] calc. $\Delta H=1.06$. See $\mathrm{AlF}_{2}^{+}(\mathrm{aq})$. |
| $\mathrm{AlF}_{2}^{+}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{Al} \mathrm{F}^{+2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nsubseteq \mathrm{A} 1 \mathrm{~F}_{2}^{+}(\mathrm{aq}),[16]$ lists $\Delta \mathrm{H}=0.78$; log K (2 values). [488] calc. $\Delta H=0.92$. [484] recalc. data for the equilibrium: $\mathrm{Al}{ }^{+3}(\mathrm{aq})+2 \mathrm{~F}^{-}(\mathrm{aq}) \nsubseteq \mathrm{AlF}_{2}^{+}(\mathrm{aq})$, and reports $\Delta \mathrm{H}=1.97$. See $\mathrm{AlF}_{3}(\mathrm{aq})$. |
| $\mathrm{AlF}_{3}(\mathrm{aq})$ | -361.4 [9] | For the reaction: $\mathrm{Al}(\mathrm{c})+3 \mathrm{HF}(\mathrm{aq}, 12 \%)=\mathrm{AlF}_{3}(\mathrm{aq})+3 / 2 \mathrm{H}_{2}(\mathrm{~g})$, [485] meas. $\Delta \mathrm{H}=$ $-124.4 \pm 1$. For the reaction: $\mathrm{Al}(\mathrm{c})+3 \mathrm{HF}(\mathrm{aq}, 10 \mathrm{~g})=\mathrm{AlF}_{3}(\mathrm{aq})+3 / 2 \mathrm{H}_{2}(\mathrm{~g}),[486]$ meas. $\Delta H=-139.2$. For the equilibrium: $\mathrm{AlF}_{2}^{+}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{AlF}_{3}(\mathrm{aq})$, [16] lists $\Delta H=0.19 ; \log K$ (2 values). [484] calc. $\Delta H=0.18$. [484] recalc. data for the equilibrium: $\mathrm{Al}^{+3}(\mathrm{aq})+3 \mathrm{~F}^{-}(\mathrm{aq}) \nrightarrow \mathrm{AlF}_{3}(\mathrm{aq})$, and reports $\Delta \mathrm{H}=2.18$. See $\mathrm{AlF}_{4}^{-}(\mathrm{aq})$, $\left(\mathrm{Al}_{2} \mathrm{~F}_{6}\right)(\mathrm{aq})$. |
| $\mathrm{AlF}_{4}^{-}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{AlF}_{3}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{AIF}_{4}^{-}(\mathrm{aq}),[16]$ lists $\Delta H=0.28: \log \mathrm{K}$ (2 values). [488] calc.' $\Delta H=0.04$. [484] recalc. data for the equilibrium: $\mathrm{Al}{ }^{+3}(\mathrm{aq})+4 \mathrm{~F}^{-}(\mathrm{aq}) \rightleftarrows \mathrm{AlF}_{4}^{-}(\mathrm{aq})$, and reports $\Delta \mathrm{H}=2.14$. See $\mathrm{AlF}_{5}^{-2}(\mathrm{aq}), \mathrm{AlF}_{6}^{-3}(\mathrm{aq})$. |
| $\mathrm{AlF}_{5}^{-2}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{AlF}_{4}^{-}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \leftrightarrows \mathrm{AlF}_{5}^{-2}(\mathrm{aq}),[16]$ lists $\Delta H=-0.75$; $\log \mathrm{K}$ (2 values). [484] calc. $\Delta H=-0.36$. [484] recalc. data for the equilibrium: $\mathrm{Al}^{+3}(\mathrm{aq})+5 \mathrm{~F}^{-}(\mathrm{aq}) \nRightarrow \mathrm{AlF} \mathrm{F}_{5}^{-2}(\mathrm{aq})$, and reports $\Delta \mathrm{H}=2.27$. See $\mathrm{AlF}_{6}^{-3}(\mathrm{aq})$. |
| $\mathrm{AlF}_{6}^{-3}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{AlF}_{5}^{-2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{AlF}_{6}^{-3}(\mathrm{aq})$, [16] lists $\Delta H=-1.55$; log K ( 1 value). [ 488 ] discusses the equilibrium. For the equilibrium: $\mathrm{Al}^{+3}$ (aq) + $6 \mathrm{~F}^{-}(\mathrm{aq}) \nsubseteq A \mathrm{FF}_{6}^{-3}(\mathrm{aq}),[16]$ lists $\log \mathrm{K}$. [484] recalc. data for this reaction and reports $\Delta H=-1.24$. See $\mathrm{Al}_{2} \mathrm{~F}_{6}(\mathrm{aq})$. |
| $\mathrm{AlF}_{n}^{3-\mathrm{n}}(\mathrm{aq})$ |  | See [488] for a general review of Al-F complexes. |
| $\begin{aligned} & \mathrm{Al}_{2} \mathrm{~F}_{6}(\mathrm{aq}) \\ & \left(\mathrm{Al}\left(\mathrm{AIF}_{6}\right)\right) \end{aligned}$ |  | For the equilibrium: $\mathrm{Al}^{+3}(\mathrm{aq})+\mathrm{AlF}_{6}^{-3}(\mathrm{aq}) \nsucceq \mathrm{Al}\left(\mathrm{AlF} \mathrm{F}_{6}\right)(\mathrm{c})$, [16] lists log K sp (1 value). |
| $\mathrm{AmF}_{2}(\mathrm{aq})$ |  | See [106]. |
| $\mathrm{AmF}_{3}(\mathrm{aq})$ |  | See [106]. |
| $\mathrm{AuF}_{3}(\mathrm{aq})$ |  | [131] meas. $\Delta \mathrm{H}$ hydr. of $\mathrm{AuF}_{3}(\mathrm{c})$ |
| $\mathrm{BF}_{3}(\mathrm{aq})$ | $\begin{aligned} & -289.8[9] \\ & -292.2[29] \end{aligned}$ | See $\mathrm{BF}_{4}^{-}(\mathrm{aq})$. |

table 6. binary aqueous species (continued)

| Species | $\Delta H f_{298}^{\circ}(\mathrm{kcal} / \mathrm{mole})$ | Remarks |
| :---: | :---: | :---: |
| $\mathrm{BF}_{4}^{-}(\mathrm{aq})$ | $\begin{aligned} & -365[9] \\ & -371.7[29] \end{aligned}$ | [351] calc. $\Delta \mathrm{Hf}_{298}^{\circ}=-342$. For the equilibrium: $\mathrm{BF}_{3}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \neq \mathrm{BF}_{4}^{-}(\mathrm{aq})$, [16] lists $\log \mathrm{K}$. For the equilibrium: $\mathrm{BF}_{3} \mathrm{OH}^{-}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \not \underset{\mathrm{BF}}{4}-(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\ell)$, [16] lists $\Delta H=-3.23 ; \log _{K} \mathrm{~K}$ (8 values). For the equilibrium: $\mathrm{BF}_{4}^{-}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{O}(\ell) \underset{ }{\rightleftarrows}$ $\mathrm{H}_{3} \mathrm{BO}_{3}(\mathrm{aq})+3 \mathrm{H}^{+}(\mathrm{aq})+3 \mathrm{~F}^{-}(\mathrm{aq})$, [489] meas. K , and reports $\Delta \mathrm{F}$ reac., and $\Delta \mathrm{Ff}_{298}^{\circ}$ of $\mathrm{BF}_{4}^{-}(\mathrm{aq})=-352$. For this reaction, [16] lists $\log K$ (l value). |
| $\mathrm{BaF}^{+}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{Ba}^{+2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nsubseteq \mathrm{BaF}^{+}(\mathrm{aq}),[16]$ lists $\log \mathrm{K}$ (2 values). |
| $\mathrm{BaF}_{2}(\mathrm{aq})$ | -286.0 [9] | For the equilibrium: $\mathrm{Ba}^{+2}(\mathrm{aq})+2 \mathrm{~F}^{-}(\mathrm{aq}) \pm \mathrm{BaF}_{2}(\mathrm{c}),[16]$ lists $\log \mathrm{K} \mathrm{sp}$ ( 4 values). |
| $\mathrm{BeF}^{+}(\mathrm{sq})$ |  | For the equilibrium: $\mathrm{Be}^{+2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nsubseteq \mathrm{BeF}^{+}(\mathrm{aq}),[16]$ lists $\log \mathrm{K}$ (2 values). <br> For the equilibrium: $\mathrm{Be}^{+2}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \not \mathrm{BeF}^{+}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})$, [16] lists $\Delta H=-3.40$; $\log \mathrm{K}$ ( 4 values). See $\mathrm{BeF}_{2}$ (aq). |
| $\mathrm{BeF}_{2}$ (aq) | -251.4 [9] | For the equilibria: $\mathrm{BeF}^{+}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nRightarrow \mathrm{BeF}_{2}(\mathrm{aq})$, and $\mathrm{Be}^{+2}(\mathrm{aq})+2 \mathrm{~F}^{-}(\mathrm{aq}) \nRightarrow$ $\mathrm{BeF}_{2}(\mathrm{aq}),[16]$ lists $\log \mathrm{K}$ (l value, each). For the equilibrium: $\mathrm{BeF}^{+}(\mathrm{aq})+$ $\mathrm{HF}(\mathrm{aq}) \nleftarrow \mathrm{BeF}_{2}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}),[16]$ lists $\Delta H=-1.735$ : $\log \mathrm{K}$ (4 values). See $\mathrm{BeF}_{3}^{-}(\mathrm{aq})$. |
| $\mathrm{BeF}_{3}^{-}(\mathrm{aq})$ |  | For the equilibria: $\mathrm{BeF}_{2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{BeF}_{3}^{-}(\mathrm{aq})$, and $\mathrm{BeF}_{2}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \neq$ $\mathrm{BeF}_{3}^{-}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})$, [16] lists $\log \mathrm{K}$ (l and 4 values, resp.). See $\mathrm{BeF}_{4}^{-2}(\mathrm{aq})$. |
| $\mathrm{BeF}_{4}^{-2}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{BeF}_{3}^{-}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{BeF}_{4}^{-2}(\mathrm{aq}),[16]$ lists $\log \mathrm{K}$ ( 1 value). |
| $\mathrm{CaF}^{+}$(aq) |  | For the equilibrium: $\mathrm{Ca}^{+2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \pm \mathrm{CaF}^{+}(\mathrm{aq}),[16]$ lists $\log \mathrm{K}(2$ values). |
| $\mathrm{CaF}_{2}$ (aq) | -287.09 [9] | For the equilibria: $\mathrm{CaF}_{2}(\mathrm{c}) \not \mathrm{Ca}^{+2}(\mathrm{aq})+2 \mathrm{~F}^{-}(\mathrm{aq})$, and $\mathrm{CaF}_{2}(\mathrm{c})+\mathrm{H}^{+}(\mathrm{aq}) \not \ddagger$ $\mathrm{Ca}^{+2}(\mathrm{aq})+2 \mathrm{HF}(\mathrm{aq}),[16]$ lists $\log \mathrm{K}$ ( 6 values, and 2 values, resp.). |
| $\mathrm{CdF}^{+}$(aq) |  | [16] lists $\log K\left(2\right.$ values) for the equilibrium: $\mathrm{Cd}^{+}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{CdF}^{+}(\mathrm{aq})$. See $\mathrm{CdF}_{2}$ (aq). |
| $\mathrm{CaF}_{2}$ (aq) | -173.6[9] | [16] lists $\log \mathrm{K}(1 \mathrm{value})$ for the equilibrium: $\mathrm{CdF}^{+}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{CdF}_{2}(\mathrm{aq})$. |
| $\mathrm{CdF}_{12}^{-10}(\mathrm{aq})$ |  | [16] lists $\log K\left(1\right.$ value) for the equilibrium: $\mathrm{Cd}^{+2}(\mathrm{aq})+12 \mathrm{~F}^{-}(\mathrm{aq}) \neq \mathrm{CdF}_{12}^{-10}(\mathrm{aq})$. |
| $\mathrm{CeF}^{+2}$ (aq) |  | [16] lists $\log K(3$ values $)$ for the equilibrium: $\mathrm{Ce}^{+3}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{CeF}^{+2}(\mathrm{aq})$. For the equilibrium: $\mathrm{Ce}^{+3}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \not \mathrm{CeF}^{+2}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}), \quad[16]$ lists $\Delta H=-0.5$; $\log \mathrm{K}$ (l value). [181] calc. $\Delta \mathrm{Ff}_{2}^{\circ} \mathrm{og}$ of $\mathrm{CeF}^{+2}(\mathrm{aq})=-242$. |
| $\mathrm{CeF}_{3}$ (aq) |  | [181] meas. K sp for the equilibrium: $\mathrm{CeF}_{3} \cdot \frac{1}{2} \mathrm{H}_{2} \mathrm{O}(\mathrm{c}) \nRightarrow \mathrm{Ce}^{+3}(\mathrm{aq})+3 \mathrm{~F}^{-}(\mathrm{aq})+\frac{1}{2} \mathrm{H}_{2} \mathrm{O}(\ell)$. |
| $\mathrm{CmF}_{2}(\mathrm{aq})$ |  | See [106]. |
| $\mathrm{CmF}_{3}(\mathrm{aq})$ |  | See [106]. |
| $\mathrm{CoF}_{2}$ (aq) | -173.6[9] |  |
| $\mathrm{CrF}^{+2}(\mathrm{aq})$ |  | [16] lists $\log K$ (2 values) for the equilibrium: $\mathrm{Cr}^{+3}(\mathrm{aq})+\mathrm{F}^{-}$(aq) $\not \approx \mathrm{CrF}^{+2}$ (aq). For the equilibrium: $\mathrm{Cr}^{+3}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \not \mathrm{CrF}^{+2}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}),[16]$ lists $\Delta H=-0.6$; $\log K$ ( 1 value). See $\mathrm{CrF}_{2}^{+}(\mathrm{aq})$. |
| $\mathrm{CrF}_{2}^{+}(\mathrm{aq})$ |  | [16] lists $\log K$ (l value) for the equilibrium: $\mathrm{CrF}^{+2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nRightarrow \mathrm{CrF}_{2}^{+}(\mathrm{aq})$. For the equilibrium: $\operatorname{CrF}^{+2}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \nRightarrow \operatorname{CrF}_{2}^{+}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}),[16]$ lists $\Delta H=-0.1$; $\log \mathrm{K}$ (l value). See $\mathrm{CrF}_{3}(\mathrm{aq})$. |
| $\mathrm{CrF}_{3}(\mathrm{aq})$ |  | [16] lists $\log K(1$ value, each $)$ for the equilibria: $\operatorname{CrF}_{2}^{+}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nsucceq$ $\mathrm{CrF}_{3}(\mathrm{aq})$, and $\mathrm{CrF}_{2}^{+}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \nleftarrow \mathrm{CrF}_{3}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})$. |
| CsF (aq) | $\begin{gathered} -137.9[9] \\ (\mathrm{var}) \end{gathered}$ | [195, 619] calc. $\Delta H$ hydration of ions. [487] calc. free energy of hydration of ions. |

TABLE 6. BINARY AQUEOUS SPECIES (continued)

| Species | $\Delta \mathrm{Hf}_{298}^{\circ}(\mathrm{kcal} / \mathrm{mole})$ | Remarks |
| :--- | :--- | :--- |

$\mathrm{CuF}^{+}(\mathrm{aq})$
$\mathrm{FeF}^{+}(\mathrm{aq})$
$\mathrm{FeF}_{2}^{+}(\mathrm{aq})$
$\mathrm{FeF}_{2}(\mathrm{aq})$
-177.8 [9]
-243.1 [9]
$\mathrm{FeF}_{4}^{-}(\mathrm{aq})$
$\mathrm{FeF}_{5}^{-2}(\mathrm{aq})$
$\mathrm{FeF}_{6}^{-3}(\mathrm{aq})$
$\mathrm{CaF}^{+2}(\mathrm{aq})$
$\mathrm{GaF}_{2}^{+}(\mathrm{aq})$
$\mathrm{GaF}_{3}(\mathrm{aq})$

$\mathrm{HF}_{2}^{-}(\mathrm{qq})$
$\mathrm{HgF}^{+}(\mathrm{aq})$
$\mathrm{Hg}_{2} \mathrm{~F}^{+}(\mathrm{aq})$
$\mathrm{InF}^{+2}(\mathrm{aq})$

For the equilibrium: $\mathrm{Cu}^{+2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{CuF}^{+}(\mathrm{aq})$, [16] lists $\Delta \mathrm{H}=0.9 ; \log \mathrm{K}$ (5 values). [490] meas. $\Delta H=0.9 \pm 2.7$, and $K$. For the equilibrium: $\mathrm{Cu}^{+2}(\mathrm{aq})+$ $\mathrm{HF}(\mathrm{aq}) \underset{\mathrm{CuF}}{ }{ }^{+}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}),[490]$ meas. $\Delta \mathrm{H}=-2.6 \pm 2.7$, and K .
[16] lists $\log \mathrm{K}$ (l value) for the equilibrium: $\mathrm{Fe}^{+2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nRightarrow \mathrm{FeF}^{+}(\mathrm{aq})$.
For the equilibrium: $\mathrm{Fe}^{+3}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{FeF}^{+2}(\mathrm{aq})$, [16] lists $\Delta H=7.5$, and 2.33; $\log \mathrm{K}$ (ll values). For the equilibrium: $\mathrm{Fe}^{+3}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \neq \mathrm{FeF}^{+2}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})$, [484] meas. $\Delta \mathrm{H}=-0.58 \pm 0.07$. For the same reaction [16] lists $\Delta H=-0.62 ; \log$ K (5 values). [491] meas. K. See $\mathrm{FeF}_{2}^{+}(\mathrm{aq})$.

For the equilibrium: $\mathrm{FeF}^{+2}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \neq \mathrm{FeF}_{2}^{+}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}), \quad$ [484] meas. $\Delta \mathrm{H}=-1.66$ $\pm 0.1$. For the same reaction [16] lists $\Delta H=-1.65$ : log $K$ (5 values). [491] meas.
K. For the equilibrium: $\mathrm{FeF}^{+2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nsupseteq \mathrm{FeF}_{2}^{+}(\mathrm{aq})$, [16] lists $\Delta \mathrm{H}=1.77$; $\log \mathrm{K}$ ( 7 values). See $\mathrm{FeF}_{3}(\mathrm{aq})$.

For the equilibrium: $\mathrm{FeF}_{2}^{+}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \not \ddagger \mathrm{FeF}_{3}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})$, [484] meas. $\Delta \mathrm{H}=-2.03$ $\pm 0.20$. For this reaction [16] lists $\log K$ ( 5 values). [491] meas. K. For the equilibrium: $\mathrm{FeF}_{2}^{+}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \underset{\mathrm{FeF}}{3}$ (aq), [16] lists $\Delta H=2.98$; $\log \mathrm{K}$ ( 6 values). See $\mathrm{FeF}_{4}^{-}(\mathrm{aq})$.

For the equilibrium: $\mathrm{FeF}_{3}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nleftarrow \mathrm{FeF}_{4}^{-}(\mathrm{aq})$, [16] lists $\log \mathrm{K}$ (1 value). See $\mathrm{FeF}_{5}^{-2}(\mathrm{aq})$.
For the equilibrium: $\mathrm{FeF}_{4}^{-}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{FeF}_{5}^{-2}(\mathrm{aq})$, [16] Iists $\log \mathrm{K}$ (1 value).
[16] lists $\log \mathrm{K}$ for the equilibrium: $\mathrm{HFeF}_{6}^{-2}(\mathrm{aq}) \not \mathrm{FeF}_{6}^{-3}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})$.
For the equilibrium: $\mathrm{Ga}^{+3}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{GaF}^{+2}(\mathrm{aq})$, [16] lists $\log \mathrm{K}$ (2 values). For the equilibrium: $\mathrm{Ga}^{+3}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \not \mathrm{GaF}^{+2}(\mathrm{aq})+\mathrm{H}^{+}$(aq), [16] lists $\Delta H=-0.5$, and -1.30: $\log \mathrm{K}$ ( 5 values). See $\mathrm{GaF}_{2}^{+}$(aq).
For the equilibrium: $\mathrm{GaF}^{+2}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \nleftarrow \mathrm{GaF}_{2}^{+}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}), \quad$ [16] lists $\Delta H=-1.49$; $\log K$ ( 4 values). See $\mathrm{GaF}_{3}$ (aq).

For the equilibrium: $\mathrm{GaF}_{2}^{+}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \underset{\mathrm{GaF}}{3}$ (aq) $+\mathrm{H}^{+}(\mathrm{aq})$, [16] lists $\Delta H=-5.50$; $\log K$ (4 values).

For the equilibria: $\mathrm{Gd}^{+3}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{GdF}^{+2}(\mathrm{aq})$, and $\mathrm{Gd}^{+3}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \not \mathrm{GdF}^{+2}(\mathrm{aq})$ $+\mathrm{H}^{+}(\mathrm{aq})$, [16] lists $\log \mathrm{K}$ (2 values, and 1 value, resp.). [181] reports
$\Delta \mathrm{Ff}_{298}^{\circ}=-236.5$.
For the equilibrium: $H^{+}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nleftarrow \mathrm{HF}(\mathrm{aq})$, [16] lists $\Delta H=3.05$, and 3.18; log K (25 values). [491] meas. $\Delta H$ ionization. [590] meas. pH vs. concentration. Heats of soln. of various sübstances in $\mathrm{HF}(\mathrm{aq})$ have been determined by [310, 311, 498, 591, 592, 593, 594, 595, 596, 597, 598]. See $\mathrm{HF}_{2}^{-}(\mathrm{aq})$.

For the equilibrium: $\mathrm{HF}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nRightarrow \mathrm{HF}_{2}^{-}(\mathrm{aq}),[16]$ lists $\Delta H=5.07$; log K
(19 values).
For the equilibrium: $\mathrm{Hg}^{+2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \rightleftarrows \mathrm{HgF}^{+}(\mathrm{aq}),[16]$ lists $\Delta H=0.85$; log K (4 values).

For the equilibrium: $\mathrm{Hg}_{2}^{+2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nRightarrow \mathrm{Hg}_{2} \mathrm{~F}^{+}(\mathrm{aq})$, [16] lists $\log \mathrm{K}$ (2 values).
For the equilibrium: $\mathrm{In}^{+3}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{InF}^{+2}(\mathrm{aq}),[16]$ lists $\Delta H=2.47$; log K ( 6 values). For the equilibrium: $\mathrm{In}^{+3}+\mathrm{HF}(\mathrm{aq}) \not \mathrm{InF}^{+2}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})$, [16] lists $\Delta H=-0.51 ; \log K(3$ values $)$. See also [599]. See $\operatorname{InF}_{2}^{+}(\mathrm{aq})$.

TABLE 6. BINARY AQUEOUS SPECIES (continued)

| Species | $\Delta \mathrm{Hf} \mathrm{O}_{298}(\mathrm{kcal} / \mathrm{mole})$ | Remarks |
| :---: | :---: | :---: |
| $\mathrm{InF}_{2}^{+}(\mathrm{aq})$ |  | For the equilibrium: $\operatorname{InF}^{+2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \operatorname{InF}_{2}^{+}(\mathrm{aq})$, [16] lists $\Delta H=4.0$ : $\log \mathrm{K}$ (6 values). For the equilibrium: $\operatorname{InF}^{+2}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \nsucceq \mathrm{InF}_{2}^{+}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})$, [16] lists $\Delta H=1.0: \log K$ (3 values). See also [599]. See $\operatorname{InF}_{3}(\mathrm{aq})$. |
| $\mathrm{InF}_{3}(\mathrm{aq})$ |  | For the equilibrium: $\operatorname{InF}_{2}^{+}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \neq \operatorname{InF}_{3}(\mathrm{aq})$, [16] lists log K (2 values). See also [599]. See $\operatorname{InF}_{4}^{-1}(\mathrm{aq})$. |
| $\mathrm{InF}_{4}^{-}$(aq) |  | For the equilibrium: $\operatorname{InF}_{3}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nsucceq \operatorname{InF}_{4}^{-}(\mathrm{aq}),[16]$ lists $\log \mathrm{K}$ ( 1 value). See also [599]. |
| KF (aq) | $\underset{(\mathrm{var})}{-138.7}$ | [492] reports $\Delta H$ dilution. [195] calc. $\Delta H$ soln. [619] calc. $\Delta H$ hydration of ions. [487, 600] calc. $\Delta F$ hydration of ions. [601] reviews degree of dissoc. |
| $\mathrm{LaF}^{+2}(\mathrm{aq})$ |  | For the equilibria: $\mathrm{La}^{+3}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nleftarrow \mathrm{LaF}^{+2}(\mathrm{aq})$, and $\mathrm{La}^{+3}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \not \rightleftarrows$ $\operatorname{LaF}^{+2}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})$, [16] lists $\log \mathrm{K}$ (2 values and 1 value, resp.). |
| $\mathrm{LaF}_{3}(\mathrm{aq})$ |  | [181] gives K sp, and $\Delta H$ soln. |
| LiF (aq) | $\underset{(\mathrm{var})}{-145.21}[9]$ | [622] meas. $\Delta H$ neutralization of $\operatorname{LiOH}(\mathrm{aq})$ and $\mathrm{HF}(\mathrm{aq}) . \quad[622,233]$ meas. $\Delta H$ soln. [195, 619, 620] calc. $\Delta H$ hydration of ions. [487] calc. $\Delta$ F hydration of ions. |
| $\mathrm{MgF}^{+}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{Mg}^{+2}$ (aq) $+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{MgF}^{+}(\mathrm{aq}),[16]$ lists $\Delta \mathrm{H}=4$; $\log \mathrm{K}$ (3 values). See [493]. For the equilibrium: $\mathrm{Mg}^{+2}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \not \mathrm{MgF}^{+}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})$, [493] lists K. |
| $\mathrm{MgF}_{2}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{MgF}_{2}(\mathrm{c}) \nRightarrow \mathrm{Mg}^{+2}$ (aq) $+2 \mathrm{~F}^{-}$(aq), [16] lists K sp (2 values). |
| $\mathrm{MmF}^{+2}$ (aq) |  | For the equilibrium: $\mathrm{Nm}^{+3}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \neq \mathrm{NaF}^{+2}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}), \quad$ [16] lists $\log \mathrm{K}$ (l value). |
| $\mathrm{MmF}_{2}(\mathrm{aq})$ | -209.2 [9] |  |
| $\mathrm{MmF}_{3}(\mathrm{aq})$ | -260 [9] | - |
| $\mathrm{MmF}_{4}(\mathrm{aq})$ |  | [239] meas. $\Delta \mathrm{H}$ soln. of $\mathrm{MnF}_{4} \cdot 4 \mathrm{H}_{2} \mathrm{O}$. |
| $\mathrm{MoF}_{6}(\mathrm{aq})$ |  | See $\mathrm{F}_{2} \mathrm{MOO}_{2}(\mathrm{aq})$. |
| NaF (aq) | $\underset{(\mathrm{var})}{-135.94}[9]$ | [256] meas. $\Delta H$ soln. in $H C l(a q)$. [195, 619] calc. $\Delta H$ hydration of ions. [487] calc. $\Delta F$ hydration of ions. See also [258]. |
| $\mathrm{NiF}^{+}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{Ni}^{+2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{NiF}^{+}(\mathrm{aq}),[16]$ lists $\log \mathrm{K}$ ( 1 value). |
| $\mathrm{NiF}_{2}(\mathrm{aq})$ | -171.5 [9] |  |
| $\mathrm{NpF}_{6}(\mathrm{aq})$ |  | See [555]. |
| $\mathrm{PbF}^{+}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{Pb}^{+2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{PbF}^{+}(\mathrm{aq}),[16]$ lists $\log \mathrm{K}$ (2 values). See [490]. |
| $\mathrm{PbF}_{2}(\mathrm{aq})$ | -155.7 [9] | For the equilibrium: $\mathrm{PbF}_{2}(\mathrm{c}) \nsupseteq \mathrm{Pb}^{+2}(\mathrm{aq})+2 \mathrm{~F}^{-}(\mathrm{aq})$, [16] lists K sp ( 4 values). [602] meas. solubility of $\mathrm{PbF}_{2}(\mathrm{c})$. See also [282]. |
| $\mathrm{PuF}^{+3}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{Pu}^{+4}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \pm \mathrm{PuF}^{+3}(\mathrm{aq})$, [16] lists $\log \mathrm{K}$ (2 values). |
| $\mathrm{PuF}_{3}(\mathrm{aq})$ | -374.6 [9] | [288] meas. $\Delta H$ pptn of $\mathrm{PuF}_{3}(\mathrm{c})$. |
| $\mathrm{RbF}(\mathrm{aq})$ | $\underset{(\mathrm{var})}{-137.6[9]}$ | [ 195,619$]$ calc. $\Delta H$ hydration of ions. |
| $\mathrm{SbF}_{3}(\mathrm{aq})$ | -216.1 [9] |  |

TABLE 6. BINARY AQUEOUS SPECIES (continued)

| Species | $\Delta \mathrm{Hf}_{298}^{\circ}$ ( $\mathrm{kcal} / \mathrm{mole}$ ) | Remarks |
| :---: | :---: | :---: |
| $\mathrm{ScF}^{+2}(\mathrm{aq})$ |  | For the equilibrium : $\mathrm{Sc}^{+3}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{ScF}^{+2}(\mathrm{aq}),[16]$ lists $\Delta \mathrm{H}=0.40$; log K ( 4 values). See [494]. For the equilibrium: $\mathrm{Sc}^{+3}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \nsucceq \mathrm{ScF}^{+2}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})$, [ 495 ] meas. K and calc. $\Delta \mathrm{H}=-4.48 \pm 0.05$. See ScF ${ }_{2}{ }^{+}(\mathrm{eq})$. |
| $\mathrm{ScF}_{2}^{+}(\mathrm{aq})$ |  | For the equilibrium:ScF ${ }^{+2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nsucceq \mathrm{SCF}_{2}^{+}(\mathrm{aq}),[16]$ lists $\Delta H=-1.23 ; \log \mathrm{K}$ (4 velues). See [494]. For the equilibrium: $\mathrm{ScF}^{+2}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \geqq \mathrm{ScF}_{2}^{+}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})$, [495] meas. K and calc. $\Delta \mathrm{H}=-3.23 \pm 0.05$. See $\mathrm{ScF}_{3}(\mathrm{aq})$. |
| $\mathrm{ScF}_{3}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{ScF}_{2}^{+}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \neq \mathrm{ScF}_{3}(\mathrm{aq})$, [16] lists $\Delta \mathrm{H}=-1.26$; log K ( 4 values). See [494]. For the equilibrium: $\operatorname{ScF}_{2}^{+}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \nsucceq \mathrm{ScF}_{3}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})$, [495] meas. K and calc. $\Delta \mathrm{H}=-1.59 \pm 0.05$. See $\mathrm{ScF}_{4}{ }^{-}(\mathrm{aq})$. |
| $\mathrm{ScF}_{4}^{-(\mathrm{aq})}$ |  | For the equilibrium: $\mathrm{ScF}_{3}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \rightleftharpoons \mathrm{ScF}_{4}^{-}(\mathrm{aq})$, [16] iists $\log \mathrm{K}$ ( 4 values). For the equilibrium: $\mathrm{ScF}_{3}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \nsupseteq \mathrm{ScF}_{4}^{-}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}),[495]$ meas. K . |
| $\mathrm{SiF}_{4}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{Si}^{(\mathrm{OH})_{4}}+\left\langle\mathrm{HF}(\mathrm{aq}) \neq \mathrm{SiF}_{4}(\mathrm{aq})+\left\langle\mathrm{H}_{2} \mathrm{O}(\mathrm{l})\right.\right.$, [16] lists log K ( 1 value). See $\mathrm{SiF}_{6}^{-2}$ (aq). |
| $\mathrm{SiF}_{5}^{-}(\mathrm{aq})$ |  | See $\mathrm{SiF}_{6}^{-2}(\mathrm{aq}), \mathrm{Si}_{2} \mathrm{~F}_{10}^{-2}(\mathrm{aq})$. |
| $\mathrm{SiF}_{6}^{-2}(\mathrm{aq})$ | -558.5 [9] | For the equilibrium: $\mathrm{SiF}_{4}(\mathrm{aq})+2 \mathrm{~F}^{-}(\mathrm{aq}) \not \mathrm{SiF}_{6}^{-2}(\mathrm{aq}),[16]$ lists log K (2 values) derived from the equilibria: 1) $\mathrm{SiF}_{4}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \neq \mathrm{SiF}_{5}^{-}(\mathrm{aq})$; 2) $\mathrm{SiF}_{5}^{-}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq})$ $\nRightarrow \mathrm{SiF}_{6}^{-2}$ (aq). [16] lists log K for the equilibrium $\mathrm{Si}(\mathrm{OH})_{4}+6 \mathrm{HF}(\mathrm{aq}) \underset{\mathrm{C}}{\boldsymbol{S}} \mathrm{SiF}_{6}^{-2}(\mathrm{aq})+$ $2 \mathrm{H}^{+}(\mathrm{aq})+4 \mathrm{H}_{2} \mathrm{O}(\ell)$. [496] recalculated previous data for the equilibrium: <br> $\mathrm{SiF}_{6}^{-2}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \geq \mathrm{SiO}_{2}(\mathrm{aq})+4 \mathrm{H}^{+}(\mathrm{aq})+6 \mathrm{~F}^{-}(\mathrm{aq})$ and reported $\Delta \mathrm{H}_{298}=17.3$, and $\log ^{6} \mathrm{~K}$ vs.t. See $\mathrm{Si}_{2} \mathrm{~F}_{10}^{-2}(\mathrm{aq})$. |
| $\begin{aligned} & \mathrm{Si}_{2}{ }_{210}^{-2}(\mathrm{aq}) \\ & \left(\mathrm{SiFiF}_{4} \mathrm{SiF}_{6}\right) \end{aligned}$ |  | For the reaction: $4 \mathrm{H}^{+}(\mathrm{aq})+5 \mathrm{SiF}_{6}^{-2}(\mathrm{aq})+\mathrm{SiO}_{2} \neq 2 \mathrm{H}_{2} \mathrm{O}(\ell)+3\left[\mathrm{SiF}_{6}-\mathrm{SiF}_{4}\right]^{-2}(\mathrm{aq}), \quad[497]$ meas. $\Delta \mathrm{H} \cong-5 \mathrm{kcal} / \mathrm{mole} \mathrm{SiO}_{2}$, and $\log \mathrm{K}$. |
| $\mathrm{SnF}^{+}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{Sn}^{+2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{SnF}^{+}(\mathrm{aq})$, [16] lists $\log \mathrm{K}$ ( 2 values). |
| $\mathrm{SnF}_{3}^{-(\mathrm{aq})}$ |  | For the equilibrium: $\mathrm{Sn}^{+2}(\mathrm{aq})+3 \mathrm{~F}^{-}(\mathrm{aq}) \geq \mathrm{SnF}_{3}^{-}(\mathrm{aq}),[16]$ lists $\log \mathrm{K}$ ( 2 values). |
| $\mathrm{SnF}_{6}^{-2}(\mathrm{aq})$ | -474.7 [9] | For the equilibrium: $\mathrm{Sn}^{+4}(\mathrm{aq})+6 \mathrm{~F}^{-}(\mathrm{aq}) \neq \mathrm{SnF}_{6}^{-2}(\mathrm{aq}),[16]$ lists $\log \mathrm{K}$ ( 1 value). |
| $\mathrm{SrF}_{2}(\mathrm{aq})$ |  | For the equilibrium: $\operatorname{SrF}_{2}(\mathrm{c}) \neq \mathrm{Sr}^{+2}(\mathrm{aq})+2 \mathrm{~F}^{-}(\mathrm{aq}),[16]$ lists K sp ( 4 values). [603] meas. solubility. |
| $\mathrm{TaF}_{5}(\mathrm{aq})$ |  | For the reaction: $\mathrm{Ta}(\mathrm{c})+5 \mathrm{HF}\left(\mathrm{aq}, 1.7 \mathrm{H}_{2} \mathrm{O}\right)=\mathrm{TaF}_{5}(\mathrm{aq})+5 / 2 \mathrm{H}_{2}(\mathrm{~g})$ [498] meas. $\Delta \mathrm{H}=$ -99.66. |
| $\mathrm{ThF}^{+3}(\mathrm{aq})$ |  | For the equilibria: $\mathrm{Th}^{+4}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \mathrm{ThF}^{+3}(\mathrm{aq})$, and $\mathrm{mh}^{+4}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \nRightarrow$ $\mathrm{ThF}^{+3}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})$, [16] lists $\log \mathrm{K}\left(1\right.$ value and 3 values, resp.). See $\mathrm{ThF}_{2}^{+2}(\mathrm{aq})$. |
| $\mathrm{ThF}_{2}^{+2}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{ThF}^{+3}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \not \mathrm{ThF}_{2}^{+2}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}),[16]$ lists log K (2 values). For the equilibrium: $\mathrm{ThF}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right){ }_{4}(\mathrm{c})+2 \mathrm{H}^{+}(\mathrm{aq}) \rightleftarrows \mathrm{ThF}_{2}^{+2}(\mathrm{aq})+2 \mathrm{HF}(\mathrm{aq})+$ $4 \mathrm{H}_{2} \mathrm{O}(\ell)$, [16] lists $\log \mathrm{K}$ ( 1 value). See $\mathrm{ThF}_{3}^{+}(\mathrm{aq})$. |
| $\mathrm{ThF}_{3}^{+}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{ThF}_{2}^{+2}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \not \mathrm{ThF}_{3}^{+}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})$ [16] lists $\log \mathrm{K}$ (I value). |
| teF(aq) | -77.3 [9] | [16] lists $\log \mathrm{K}$ ( I value) for the equilibrium: $\mathrm{Tl}^{+}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nsubseteq \mathrm{T} \ell \mathrm{F}(\mathrm{aq})$. [56] meas. $\Delta \mathrm{H}$ soln. ( TlF in $800 \mathrm{H}_{2} \mathrm{O}$ ) $=-0.5 \pm 0.2$. |
| $\mathrm{TlF}_{3}(\mathrm{aq})$ |  | For $\Delta H$ hydrolysis [131] meas. -8.4. |
| $\mathrm{UF}^{+3}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{U}^{+4}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \geq \mathrm{UF}^{+3}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})[16]$ lists $\log \mathrm{K}$ (I value). |
| $\mathrm{uF}_{2}^{+2}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{U}^{+4}(\mathrm{aq})+2 \mathrm{HF}(\mathrm{aq}) \geq \mathrm{UF}_{2}^{+2}(\mathrm{aq})+2 \mathrm{H}^{+}(\mathrm{aq})[16]$ lists $\log \mathrm{K}$ ( 1 value). |

| Species | $\Delta 4 f_{298}^{\circ}(\mathrm{kcal} / \mathrm{mole})$ | Remarks |
| :---: | :---: | :---: |
| $\mathrm{YF}^{+2}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{Y}^{+3}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \neq \mathrm{YF}^{+2}(\mathrm{aq})$, [499] meas. K . For the reactions $\mathrm{Y}^{+3}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \nsupseteq \mathrm{YF}^{+2}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}),[499]$ meas. K and $\mathrm{calc} . \Delta \mathrm{H}=-0.93 \pm 0.55$. See $\mathrm{YF}_{2}^{+}(\mathrm{aq})$. |
| $\mathrm{YF}_{2}^{+}(\mathrm{aq})$ |  | For the equilibria; 1) $\mathrm{YF}^{+2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \neq \mathrm{YF}_{2}^{+}(\mathrm{aq})$; 2) $\mathrm{YF}^{+2}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \nRightarrow$ $\mathrm{YF}_{2}^{+}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}),[499]$ gives K . See $\mathrm{YF}_{3}(\mathrm{aq})$. |
| $\mathrm{YF}_{3}(\mathrm{aq})$ |  | For the equilibria: $\mathrm{YF}_{2}^{+}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nLeftarrow \mathrm{YF}_{3}(\mathrm{aq})$, and $\mathrm{YF}_{2}^{+}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \nRightarrow \mathrm{YF}_{3}(\mathrm{aq})+$ $\mathrm{H}^{+}(\mathrm{aq})$, [499] gives K. |
| $\mathrm{ZnF}^{+}(\mathrm{gq})$ |  | For the equilibrium: $\mathrm{Zn}^{+2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \neq \mathrm{ZnF} \mathrm{F}^{+}(\mathrm{aq}),[16]$ lists $\Delta H=1.5$; $\log \mathrm{K}$ (5 values). For $\mathrm{Zn}^{+2}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \nLeftarrow \mathrm{ZnF}^{+}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}),[490]$ meas. K and calc . $\Delta H=-2.3 \pm 2.4$. |
| $\mathrm{ZnF}_{2}(\mathrm{aq})$ | -187.9 [9] |  |
| $\mathrm{zrF}^{+3}(\mathrm{aq})$ |  | For the equilibria: $\mathrm{Zr}^{+4}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nRightarrow 2 \mathrm{rF}^{+3}(\mathrm{aq})$, and $\mathrm{Zr}^{+4}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \rightleftarrows$ $2 \mathrm{rF}^{+3}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})$, [16] lists $\log \mathrm{K}\left(1\right.$ value each). See $\mathrm{ZrF}_{2}^{+2}(\mathrm{aq})$. |
| $\mathrm{ZrF}_{2}{ }^{+2}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{ZrF}^{+3}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \neq \mathrm{ZrF}_{2}^{+2}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}),[16]$ 1ists $\log \mathrm{K}$ (I value). See $\mathrm{ZrF}_{3}^{+}(\mathrm{aq})$. |
| $\mathrm{ZrF}_{3}^{+}(\mathrm{aq})$ |  | For the equilibrium: $\mathrm{ZrF}_{2}^{+2}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \nRightarrow \mathrm{ZrF}_{3}^{+}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}),[16]$ lists log K (1 value). |

[256] meas. $\Delta \mathrm{H}$ soln. of $\mathrm{Na}_{3} \mathrm{AlF}_{6}(\mathrm{c})$.
[349] calc. $\Delta H$ soln. of $\mathrm{CsBF}_{4}(c)$ from solubility.
[604] meas. K hydr.
[349] calc. $\Delta H$ soln. of $\mathrm{KBF}_{4}(\mathrm{c})$. [351] est. $\Delta H$ soln. of $\mathrm{KBF}_{4}(\mathrm{c})$. [350] meas. $\Delta H f_{298}^{\circ}$ of $\mathrm{KBF}_{4}$ (c) from solution calorimetry.
[390] meas. $K$ sp and $\Delta F$ soln. for $\operatorname{PbClF}(c)$. [282] meas. $\Delta H$ soln. of $\mathrm{PbClF}(\mathrm{c})$.
[509] meas. K for the equilibrium: $\mathrm{CrO}_{2} \mathrm{~F}_{2}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\imath) \not \mathrm{CrO}_{3}(\mathrm{aq})+2 \mathrm{HF}(\mathrm{aq})$.
[399] calc. $\Delta F$ soln. of $\mathrm{NH}_{4} \mathrm{~F}(\mathrm{c})$.
[16] lists $\log \mathrm{K}$ (l value) for the equilibrium: $\mathrm{TiO}^{+2}(\mathrm{eq})+\mathrm{F}^{-}$(aq) $\underset{\mathrm{a}}{\mathrm{T}} \mathrm{TiO}^{+}$(aq). See $\mathrm{F}_{2} \mathrm{OTi}(\mathrm{aq}), \mathrm{F}_{3} \mathrm{OTi}^{-}(\mathrm{aq}), \mathrm{F}_{4} \mathrm{OTi}^{-2}(\mathrm{aq})$.
[16] lists $\log K(1$ value $)$ for the equilibrium: $V^{+2}(a q)+F^{-}(\mathrm{eq}) \nRightarrow \operatorname{VOF}^{+}(\mathrm{aq})$.
[16] lists $\log \mathrm{K}$ (4 values) for the equilibrium: $\mathrm{UO}_{2}^{+2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nleftarrow \mathrm{UO}_{2} \mathrm{~F}^{+}(\mathrm{aq})$. For the equilibrium: $\mathrm{UO}_{2}^{+2}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \nleftarrow \mathrm{UO}_{2} \mathrm{~F}^{+}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})$, [16] lists $\Delta H=$ -5.4 and $\log \mathrm{K}$ ( 9 values). See $\mathrm{UO}_{2} \mathrm{~F}_{2}(\mathrm{aq})$.
[462] reports $\Delta H$ hydr. of $\mathrm{SO}_{3} \mathrm{~F}^{-}$gas ion.
[605] reports solubility of KF in $\mathrm{HF}(\mathrm{aq})$.
[605] reports solubility of LiF in HF(aq).
[605] meas. solubility of NaF in HF (aq).
[9] est. $\Delta \mathrm{Hf}_{298}^{\circ}=-212.5$.

TABLE 7. TERNARY AQUEOUS SPECIES (continued)

| Species | $\Delta 4 \mathrm{~F}_{298}^{\circ}(\mathrm{kcal} / \mathrm{mole})$ | Remarks |
| :---: | :---: | :---: |
| $\begin{aligned} & \mathrm{F}_{2} \mathrm{H}_{5} \mathrm{~N}(\mathrm{aq}) \\ & \left(\mathrm{NH}_{4} \mathrm{HF}_{2}\right) \end{aligned}$ |  | [410] calorimetrically meas. $\Delta \mathrm{H}$ soln. of $\mathrm{NH}_{4} \mathrm{HF}_{2}(\mathrm{c}), \Delta \mathrm{H}$ diln. of $\mathrm{NH}_{4} \mathrm{HF}_{2}$, and $\Delta \mathrm{H}$ neutralization of $\mathrm{NH}_{3}$ and HF (1:2). |
| $\begin{aligned} & \mathrm{F}_{2} \mathrm{KOO}_{2}(\mathrm{aq}) \\ & \left(\mathrm{MoO}_{2} \mathrm{~F}_{2}\right) \end{aligned}$ |  | [509] meas. K for the equilibrium: $\mathrm{MoF}_{6}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \not \mathrm{MoO}_{2} \mathrm{~F}_{2}(\mathrm{aq})+4 \mathrm{HF}(\mathrm{aq})$. |
| $\begin{aligned} & \mathrm{F}_{2} \mathrm{OOH}_{1(\mathrm{aq})} \\ & \left(\mathrm{TiOF}_{2}\right) \end{aligned}$ |  | [618] meas. K for the equilibrium: $\mathrm{TiOF}^{+}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \geq \mathrm{TiOF}_{2}(\mathrm{aq})$. |
| $\begin{aligned} & \mathrm{F}_{2} \mathrm{O}_{2} \mathrm{U}(\mathrm{aq}) \\ & \left(\mathrm{UO}_{2} \mathrm{~F}_{2}\right) \end{aligned}$ |  | For the equilibrium: $\mathrm{UO}_{2} \mathrm{~F}^{+}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \nLeftarrow \mathrm{UO}_{2} \mathrm{~F}_{2}$ (aq), [16] lists 1 og K ( 3 values). [509] meas. K for the equilibrium: $\mathrm{UF}_{6}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\ell) \neq \mathrm{UO}_{2} \mathrm{~F}_{2}(\mathrm{aq})+4 \mathrm{HF}(\mathrm{aq})$. See $\mathrm{F}_{3} \mathrm{O}_{2} \mathrm{U}^{-}(\mathrm{aq}), \mathrm{F}_{4} \mathrm{O}_{4} \mathrm{U}_{2}(\mathrm{aq})$. |
| $\begin{aligned} & \mathrm{F}_{2} \mathrm{O}_{2} \mathrm{~W}(\mathrm{aq}) \\ & \left(\mathrm{WO}_{2} \mathrm{~F}_{2}\right) \end{aligned}$ |  | [509] meas. K for the equilibrium: $\mathrm{WF}_{6}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\ell) \not \pm \mathrm{WO}_{2} \mathrm{~F}_{2}(\mathrm{aq})+4 \mathrm{HF}(\mathrm{aq})$. |
| $\begin{aligned} & \mathrm{F}_{3} \mathrm{OTH}^{-}(\mathrm{aq}) \\ & \left(\mathrm{THOF}_{3}{ }^{-}\right) \end{aligned}$ |  | [618] meas. K for the equilibrium: $\mathrm{TiOF}^{+}(\mathrm{aq})+2 \mathrm{~F}^{-}(\mathrm{aq}) \not \pm \mathrm{THOF}_{3}{ }^{-}(\mathrm{aq})$. |
| $\begin{aligned} & \mathrm{F}_{3} \mathrm{OV}(\mathrm{aq}) \\ & \left(\mathrm{VOF}_{3}\right) \end{aligned}$ |  | [509] meas. K for the equilibrium: $2 \mathrm{VOF}_{3}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{O}(\ell) \nsupseteq \mathrm{V}_{2} \mathrm{O}_{5}(\mathrm{aq})+6 \mathrm{HF}(\mathrm{aq})$. |
| $\begin{aligned} & \mathrm{F}_{3} \mathrm{O}_{2} \mathrm{U}^{-}(\mathrm{aq}) \\ & \left(\mathrm{UO}_{2} \mathrm{~F}_{3}{ }^{-}{ }^{-}\right) \end{aligned}$ |  | [16] lists $\log \mathrm{K}$ (2 values) for the equilibrium: $\mathrm{UO}_{2} \mathrm{~F}_{2}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}) \not \pm$ $\mathrm{UO}_{2} \mathrm{~F}_{3}{ }^{-}(\mathrm{aq})$. See $\mathrm{F}_{4} \mathrm{O}_{2} \mathrm{U}^{-2}(\mathrm{aq})$. |
| $\begin{aligned} & \mathrm{F}_{4} \text { OT1 }^{-2}(\mathrm{aq}) \\ & \left(\mathrm{TiOF}_{4}{ }^{-2}\right) \end{aligned}$ |  | [618] meas. K for the equilibrium: $\mathrm{TiOF}^{+}(\mathrm{aq})+3 \mathrm{~F}^{-}(\mathrm{aq}) \not \pm \mathrm{THOF}_{4}^{-2}(\mathrm{aq})$. |
| $\mathrm{F}_{4} \mathrm{O} \mathrm{U}^{-2}$ (aq) |  | [16] lists $\log \mathrm{K}$ ( 2 values and 1 value, resp.) for the equilibria 1) $\left.\mathrm{UO}_{2} \mathrm{~F}_{3}^{-}(\mathrm{aq})+\mathrm{F}^{-} \nsupseteq \mathrm{UO}_{2} \mathrm{~F}_{4}^{-2}(\mathrm{aq}) ; 2\right) \mathrm{UO}_{2}^{+2}(\mathrm{aq})+\left\langle\mathrm{F}^{-}(\mathrm{aq}) \not \pm \mathrm{UO}_{2} \mathrm{~F}_{4}^{-2}(\mathrm{aq})\right.$. |
| $\begin{aligned} & \mathrm{F}_{4} \mathrm{O}_{4} \mathrm{U}_{2}(\mathrm{aq}) \\ & \left(\mathrm{UO}_{2} \mathrm{~F}_{2}\right)_{2} \end{aligned}$ |  | [500] meas. K for the equilibrium: $2 \mathrm{VO}_{2} \mathrm{~F}_{2}(\mathrm{aq}) \not \pm\left(\mathrm{UO}_{2} \mathrm{~F}_{2}\right)_{2}$ (aq). [501] revieus this reaction and indicates a small positive $\Delta H$ dimerization. [16] lists log $K$ 13 values) for this reaction. |
| $\begin{aligned} & \mathrm{F}_{6} \mathrm{FeH}^{-2}(\mathrm{aq}) \\ & \left(\mathrm{HFFF}_{6}^{-2}\right) \end{aligned}$ |  | See $\mathrm{FeF}_{6}{ }^{-3}(\mathrm{aq})$. |

| $\mathrm{F}_{6}^{\mathrm{F}_{6} \mathrm{H}_{3} \mathrm{Sb}(\mathrm{aq})}$ $\left(\mathrm{H}_{3} \mathrm{SbF}_{6}\right)$ | -444.3 [9] |  |
| $\begin{aligned} & \mathrm{F}_{6} \mathrm{Li}_{2} \mathrm{Si}\left(\mathrm{aq}, 1500 \mathrm{H}_{2} \mathrm{O}\right) \\ & \left(\mathrm{Li}_{2} \mathrm{SiF}_{6}\right) \end{aligned}$ |  | [9] est. $\Delta \mathrm{Hf}_{298}^{\circ}=-691.2 \mathrm{in} 1500 \mathrm{H}_{2} \mathrm{O}$. |
| $\begin{aligned} & \mathrm{F}_{6} \mathrm{Na}_{2} \mathrm{Si}\left(\mathrm{aq}, 600 \mathrm{H}_{2} \mathrm{O}\right) \\ & \left(\mathrm{Na}_{2} \mathrm{SiP}_{6}\right) \end{aligned}$ | -671.2 [9] |  |

TABLE 8. QUATERNARY AND HIGHER AQUEOUS SPECIES

| Species | $\Delta \mathrm{Hf}_{298}^{\circ} \mathrm{O}$ (kcal/mole) | Remarks |
| :---: | :---: | :---: |
| $\begin{aligned} & \mathrm{BF}_{2} \mathrm{H}_{2} \mathrm{O}_{2}^{-}(\mathrm{aq}) \\ & \left(\mathrm{BF}_{2}(\mathrm{OH})_{2}^{-}\right) \end{aligned}$ |  | See $\mathrm{BF}_{3} \mathrm{HO}^{-}(\mathrm{aq})$. |
| $\begin{aligned} & \mathrm{BF}_{3} \mathrm{HO}^{-}(\mathrm{aq}) \\ & \left(\mathrm{BF}_{3} \mathrm{OH}^{-}\right) \end{aligned}$ | -363.1 [29] | [503] meas. K for the equilibrium: $\mathrm{BF}_{2}(\mathrm{OH})_{2}^{-}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq}) \not \underset{\mathrm{H}_{2} \mathrm{O}}{ }(\ell)+\mathrm{BF}_{3} \mathrm{OH}^{-}(\mathrm{aq})$. [16] lists $\log \mathrm{K}$ (l value) for this equilibrium. For the equilibrium: $\mathrm{BF}_{3} \mathrm{OH}^{-}(\mathrm{aq})+$ $\mathrm{HF}(\mathrm{aq}) \nleftarrow \mathrm{H}_{2} \mathrm{O}(\ell)+\mathrm{BF}_{4}^{-}(\mathrm{aq})$, [16] lists $\Delta \mathrm{H}=-3.23$ and $\log \mathrm{K}$ (8 values). For the reaction: $3 \mathrm{BF}_{3} \mathrm{OH}^{-}(\mathrm{aq}) \leftrightarrows 2 \mathrm{BF}_{4}^{-}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{BO}_{3}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq}), \quad[504]$ calc. $\Delta \mathrm{H}=4.2$. For the reaction: $2 \mathrm{BF}_{3} \mathrm{OH}^{-}(\mathrm{aq}) \nleftarrow \mathrm{BF}_{2}(\mathrm{OH})_{2}^{-}(\mathrm{aq})+\mathrm{BF}_{4}^{-}(\mathrm{aq}),[504]$ calc. $\Delta \mathrm{H}<1.4$. |
| $\begin{aligned} & \mathrm{CrF}_{3} \mathrm{H}_{12} \mathrm{O}_{6}(\mathrm{aq}) \\ & \left(\left[\mathrm{Cr}\left(6 \mathrm{H}_{2} \mathrm{O}\right)\right] \mathrm{F}_{3}\right) \end{aligned}$ | -704.3 [9] |  |
| $\begin{aligned} & \mathrm{CrF}_{6} \mathrm{H}_{15} \mathrm{O}_{6}(\mathrm{aq}) \\ & \left(\mathrm{H}_{3}\left[\mathrm{Cr}\left(6 \mathrm{H}_{2} \mathrm{O}\right)\right] \mathrm{F}_{6}\right) \end{aligned}$ | -931.9 [9] |  |
| $\begin{aligned} & \mathrm{FHO}_{3} \mathrm{~S}(\mathrm{aq}) \\ & \left(\mathrm{HSO}_{3} \mathrm{~F}\right) \end{aligned}$ | -190.2[461] | [461] meas. $\Delta \mathrm{H}$ hydr. of $\mathrm{HSO}_{3} \mathrm{~F}(\ell)$. [621] meas. heat of ionization. |
| $\begin{aligned} & \mathrm{FKO}_{3} \mathrm{~S}(\mathrm{aq}) \\ & \left(\mathrm{KSO}_{3} \mathrm{~F}\right) \end{aligned}$ |  | [462] meas. $\Delta \mathrm{H}$ soln. of $\mathrm{KSO}_{3} \mathrm{~F}(\mathrm{c})$. |
| $\begin{aligned} & \mathrm{FNaO}_{3} \mathrm{~S}(\mathrm{aq}) \\ & \left(\mathrm{NaSO}_{3} \mathrm{~F}\right) \end{aligned}$ | -204.6 [461] | [461] reports $\Delta H f$ from the heat of neutralization. See also [621]. |
| $\begin{aligned} & \mathrm{FNO}_{3} \mathrm{Th}^{+2}(\mathrm{aq}) \\ & \left(\mathrm{ThFNO}_{3}^{+2}\right) \end{aligned}$ |  | [16] lists $\log \mathrm{K}$ (1 value) for the equilibrium: $\mathrm{Th}^{+4}(\mathrm{aq})+\mathrm{HF}(\mathrm{aq})+\mathrm{NO}_{3}^{-}(\mathrm{aq}) \nleftarrow$ $\mathrm{ThFNO}_{3}^{+2}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})$. |
| $\begin{aligned} & \mathrm{F}_{2} \mathrm{NO}_{3} \mathrm{Th}^{+}(\mathrm{aq}) \\ & \left(\mathrm{ThF}_{2} \mathrm{NO}_{3}^{+}\right) \end{aligned}$ |  | [16] lists $\log \mathrm{K}$ (l value) for the equilibrium: $\mathrm{Th}^{+4}(\mathrm{aq})+2 \mathrm{HF}(\mathrm{aq})+\mathrm{NO}_{3}^{-}(\mathrm{aq}) \nleftarrow$ $\mathrm{ThF}_{2} \mathrm{NO}_{3}^{+}(\mathrm{aq})+2 \mathrm{H}^{+}(\mathrm{aq})$. |
| $\begin{aligned} & \mathrm{F}_{4} \mathrm{H}_{8} \mathrm{O}_{4} \mathrm{Th}(\mathrm{aq}) \\ & \left(\mathrm{ThF}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right) \end{aligned}$ |  | [16] lists $\log \mathrm{K}$ for the equilibrium: $\mathrm{ThF}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}(\mathrm{c})+2 \mathrm{H}^{+}(\mathrm{aq}) \not \mathrm{ThF}_{2}^{+2}(\mathrm{aq})+2 \mathrm{HF}(\mathrm{aq})$ $+4 \mathrm{H}_{2} \mathrm{O}(\ell)$. |

$\mathrm{F}_{6} \mathrm{HNaSi}\left(\mathrm{aq}, 400 \mathrm{H}_{2} \mathrm{O}\right) \quad-614.1$ [9] ( $\mathrm{NaHSiF}_{6}$ )

IDEAL GAS THERMODYNAMIC FUNCTIONS
by
Joseph Hilsenrath and William H. Evans

The thermodynamic functions are given for the positive ions of the elements $\mathrm{He}^{+}$through $\mathrm{K}^{+}$; for $\mathrm{Ti}^{+}, \mathrm{Br}^{+}, \mathrm{Zr}^{+}, \mathrm{Mo}^{+}, \mathrm{I}^{+}, \mathrm{W}^{+}, \mathrm{Hg}^{+}$, and $\mathrm{Pb}^{+}$; and for the molecules $\mathrm{NF}_{2}$ and $\mathrm{N}_{2} \mathrm{~F}_{4}$. The computations were performed on the IBM 704 using the fundamental constants of Cohen, Crowe, and Dumond [1]. The tables, which extend to $6,000 \circ \mathrm{~K}$ for the molecules and to 10,000 oK for the atomic ions, are given in units of calories (4.1840 abs. joules), gram moles, and oK. Conversion factors are given to other units.

The functions for the atomic ions were computed by a summation over energy levels given in Volume I (and as corrected in Volume III) of Atomic Energy Levels [2]. The functions for the polyatomic molecules were computed on the harmonic oscillator-rigid rotator approximation using the molecular data listed with the tables. The molecular constants for the polyatomic molecules are discussed in Chapter 2 of this report.

For the first 18 elements the table number agrees with the atomic number as in the earlier NBS Report 6928 with the addition of -1 to designate the first ion. For the other ions and for the polyatomic molecules the numbers are consecutive to the last table in the earlier report.

The tables for the atomic ions were computed in connection with work at the National Bureau of Standards directed at properties of highly ionized gases under a contract with the Air Force Special Weapons Center, Kirtland Air Force Base. They are included here as a convenience to ARPA contractors. The tables are in close agreement with those of Green, Poland, and Margrave [3]

APPENDIX B
THERMODYNAMIC FUNCTIONS OF THE HYDRATES OF SODIUM,
POTASSIUM, AND AMMONIUM PENT ABORATES
by George T. Furukawa and Martin L. Reilly
As a part of an earlier program on experimental thermodynamic investigations of boron compounds, heat-capacity measurements were obtained on sodium pentaborate pentahydrate ( $\mathrm{NaB}_{5} \mathrm{O}_{8} \cdot 5 \mathrm{H}_{2} \mathrm{O}$ ), potassium pentaborate tetrahydrate $\left(\mathrm{KB}_{5} \mathrm{O}_{8} \cdot 4 \mathrm{H}_{2} \mathrm{O}\right)$, and ammonium pentaborate tetrahydrate ( $\mathrm{NH}_{4} \mathrm{~B}_{5} \mathrm{O}_{8} \cdot 4 \mathrm{H}_{2} \mathrm{O}$ ). These measurements have not as yet been published. Considering that these compounds should be of interest to the lightelements program, their thermodynamic functions from $0^{\circ}$ to $370^{\circ} \mathrm{K}$ are herewith given. The gram-formula masses used for these compounds are one-half of those often used. The values for $\mathrm{NaB}_{5} \mathrm{O}_{8} \cdot 5 \mathrm{H}_{2} \mathrm{O}$ are given only to $345^{\circ} \mathrm{K}$ because of a possible dehydration that was observed above this temperature.

The numbering of these tables is continuous with the tables given in the earlier NBS Reports 6928 and 7093. No table of this report replaces or duplicates a table of any previous report.

THERMODYNAMIC FUNCTIONS FOR SODIUM PENTABORATE PENTAHYDRATE（NA $B_{5} O_{8} \cdot 5 H_{2} O$ ）
