## THE NATIONAL BUREAU OF STANDARDS

#### Abstract

The National Bureau of Standards is a principal focal point in the Federal Government for assuring maximum application of the physical and engineering sciences to the advancement of technology in industry and commerce. Its responsibilities include development and maintenance of the national standards of measurement, and the provisions of means for making measurements consistent with those standards; determination of physical constants and properties of materials; development of methods for testing materials, mechanisms, and structures, and making such tests as may be necessary, particularly for government agencies; cooperation in the establishment of standard practices for incorporation in codes and specifications; advisory service to government agencies on scientific and technical problems; invention and development of devices to serve special needs of the Government; assistance to industry, business, and consumers in the development and acceptance of commercial standards and simplified trade practice recommendations; administration of programs in cooperation with United States business groups and standards organizations for the development of international standards of practice; and maintenance of a clearinghouse for the collection and dissemination of scientific, technical, and engineering information. The scope of the Bureau's activities is suggested in the following listing of its three Institutes and their organizational units. Institute for Basic Standards. Applied Mathematics. Electricity. Metrology. Mechanics. Heat. Atomic Physics. Physical Chemistry. Laboratory Astrophysics.* Radiation Physics. Radio Standards Laboratory:* Radio Standards Physics; Radio Standards Engineering. Office of Standard Reference Data. Institute for Materials Research. Analytical Chemistry. Polymers. Metallurgy. Inorganic Materials. Reactor Radiations. Cryogenics.* Materials Evaluation Laboratory. Office of Standard Reference Materials. Institute for Applied Technology. Building Research. Information Technology. Performance Test Development. Electronic Instrumentation. Textile and Apparel Technology Center. Technical Analysis. Office of Weights and Measures. Office of Engineering Standards. Offce of Invention and Innovation. Office of Technical Resources. Clearinghouse for Federal Scientific and Technical Information.**

# ANALYSIS OF A MARKET-SPLIT MODEL 

A.J. Goldman, J.M. McLynn

P.R. Meyers, R.H. Watkins

ABSTRACT

A mathematical analysis is given for a class of models describing how the market might divide its patronage among $p$ competing products ( $p>1$ ). The distinctive feature is that the elasticities of the split fractions, with respect to changes in the parameters characterizing the products, are assumed equal to linear or separable functions of the split fractions themselves. (The permitted functional forms are actually somewhat more general.) The self-consistent models of this type are determined (for $p>2$ they are linear), and their solutions derived.

# ANALYSIS OF A MARKET SPLIT MODEL ${ }^{(1)}$ 

## by

A.J. Goldman, J.M. McLynn (2)<br>P.R. Meyers, R.H. Watkins (2)

## 1. INTRODUCTION

This paper is concerned with a class of mathematical models for how the "market" (i.e., the consuming public) might divide itself among several ( $p>1$ ) competing products. For $j=1,2, \ldots, p$, we set

$$
w_{j}=\text { fraction of market which selects the } j \text {-th product, }
$$

so that

$$
\begin{gather*}
w_{j} \geq 0 \quad(j=1,2, \ldots, p),  \tag{2}\\
\sum_{j=1}^{j} w_{j}=1 \tag{3}
\end{gather*}
$$

The choice-influencing attributes of the $j$-th product are described by the numerical values of certain parameters $x_{1 j}, x_{2 j}, \ldots, x_{n}(j), j$. Since the market share of the j-th product depends on the relative attractiveness of the other products, the split fraction $w_{j}$ is a function not only of the $x_{i j}$ 's, but also of the $x_{i k}$ 's for $k \neq j$, i.e. of all the $x^{\prime}$ s.

(2) Davidson, Talbird and McLynn, Bethesda, Md.

We assume that the $\underline{x}^{\prime}$ s have been redefined (if necessary) so that

$$
\begin{equation*}
x_{i j}>0 \tag{4}
\end{equation*}
$$

and so that increasing $x_{i j}$ makes the $j$-th product less attractive (or at least no more attractivid), thus tending to decrease ${ }^{W} j$ and increase the other $\mathrm{w}_{\mathrm{k}}$ 's. Formally,

$$
\begin{align*}
& \partial w_{j} / \partial x_{i j} \leq 0,  \tag{5}\\
& \partial w_{k} / \partial x_{i j} \geq 0 \quad \text { for } k \neq j . \tag{6}
\end{align*}
$$

Let $\vec{x}$ denote the ensemble of $\underline{x}^{\prime}$ s, while $\vec{w}=\left(w_{1}, \ldots, w_{p}\right)$. An additional assumption about $\overrightarrow{\mathrm{w}}(\overrightarrow{\mathrm{x}})$ is that, for each $j$, there exists at least one $\vec{x}$ for which

$$
\begin{equation*}
w_{j}(\vec{x})=1, \quad w_{k}(\vec{x})=0 \quad \text { for } k \neq j \tag{7}
\end{equation*}
$$

The intended interpretation is that none of the products has a guaranteed minimum market share, nor is any of them artificially precluded from gaining the entire market if its superiority would lead to this result. We shall also need the stronger hypothesis, that for any $w$ with $0 \leq w \leq l$ and any ( $j, k$ ) with $j \neq k$ there exists at least one $\vec{x}$ such that

$$
\begin{equation*}
w_{j}(\vec{x})=w, \quad w_{k}(\vec{x})=l-w, \quad w_{q}(\vec{x})=0 \quad \text { for } \quad q \neq j, k \tag{8}
\end{equation*}
$$

(It suffices to assume that $\overrightarrow{\mathrm{X}}^{\prime} \mathrm{s}$ can be chosen so as to bring $\overrightarrow{\mathrm{w}}$ arbitrarily close to satisfying (7) or (8).)

It is traditional in economics to consider the elasticities

$$
\begin{equation*}
E_{i j k}=\left(\partial w_{k} / \partial x_{i j}\right) /\left(w_{k} / x_{i j}\right) ; \tag{9}
\end{equation*}
$$

$E_{i j k}$ is the rate of relative change in $w_{k}$, $\left(d w_{k} / w_{k}\right)$, per unit relative change in $x_{i j},\left(d x_{i j} / x_{i j}\right)$, for either $k=j$ (self-elasticity of $j$-th product) or $k \neq j$ (cross-elasticity). We introduce the variables

$$
\begin{equation*}
y_{i j}=\log x_{i j} \tag{10}
\end{equation*}
$$

in order to simplify (9) to

$$
\begin{equation*}
E_{i j k}=w_{k}^{-l}\left(\partial w_{k} / \partial y_{i j}\right) \tag{11}
\end{equation*}
$$

Note that (5) and (6) imply

$$
\begin{align*}
& \partial w_{j} / \partial y_{i j} \leq 0,  \tag{12}\\
& \partial w_{k} / \partial y_{i j} \geq 0 \quad \text { for } k \neq j \tag{13}
\end{align*}
$$

The elasticities are (initially unknown) functions of the $\sum_{j=1}^{p} n(j)$ components of $\vec{x}$, but it would clearly be much more convenient if components of $\overrightarrow{\mathrm{w}}$ ) . This suggests examining models of the form

$$
E_{i j k}=F_{i j k}(\vec{w})
$$

which by (11) is equivalent to the system

$$
\begin{equation*}
\partial w_{k} / \partial y_{i j}=w_{k} F_{i j k}(\vec{w}) \tag{14}
\end{equation*}
$$

of partial differential equations.

It is natural to begin with the simple case in which each $F_{i j k}$ is
(14) becomes linear, so that (14) becomes

$$
\begin{equation*}
\partial w_{k} / \partial y_{i j}=\sum_{m=1}^{p} b_{i, j k m} W_{k} W_{m} \tag{15}
\end{equation*}
$$

where the $\underline{b}$ 's are constants. We shall deal with a generalization

$$
\begin{equation*}
\partial w_{k} / \partial y_{i j}=\sum_{m=1}^{p} b_{i j k m} f_{k}\left(w_{k}\right) g_{m}\left(w_{m}\right) \tag{16}
\end{equation*}
$$

where the functions $f_{k}$ and $g_{k}(k=1,2, \ldots, p)$, defined on $0 \leq w \leq 1$, satisfy

$$
\begin{equation*}
f_{k}(0)=g_{k}(0)=0 \tag{17}
\end{equation*}
$$

and have continuous derivatives $f_{k}^{\prime}, g_{k}^{\prime}$ such that

$$
\begin{equation*}
f_{k}^{\prime}>0, g_{k}^{\prime}>0 \tag{18}
\end{equation*}
$$

These last two conditions are of course satisfied for the particular choices

$$
f_{k}(w)=g_{k}(w)=w
$$

which specialize (16) to (15). It will be clear from the proofs to come that (18) need only be required to hold on a "sufficiently large" subset of $0 \leq w \leq 1$ 。

There are three reasons for passing from the linear model (15) to the (possibly) nonlinear (16). One is simply intellectual curiousity as to how the generalization will affect the analysis. Second is the possibility that some special insight into the competitive situation will strongly suggest that linearity is implausible. Third, if it should prove impossible to obtain a satisfactory "fit" to empirical data using the linear model, then perhaps more parameters (which can be adjusted to improve the fit) can be smuggled in via the $f_{k}$ 's and $g_{k}{ }^{\prime} s$. Our conclusions, however, will show that the second and third of these hopes are in vain (for $p>2$ ).

In the application motivating this work, the "market" in question is to consist of a single "cell" in some stratification of the population of travellers between a particular origin and a particular destination. The "products" are the services offered by the various transport alternatives; the latter might be taken as the traditional transportation "modes" (air, rail, bus, private auto) plus whatever novelties social and technological change may produce, or might reflect a finer classification
(e.g. particular auto routes, particular airlines, first-class vs. coach service). The components of $\vec{x}$ might be measures of trip time, trip cost, variability from published schedules, trip fatigue, frequency and severity of accidents, etc. Validation and subsequent use (for prediction) of such a model would of course require operationally meaningful specifications of the transport alternatives (more generally, the products) and of the $\underline{x}^{\text {is }}$, and also appropriate "calibration" based on empirical data. In the present paper, however, we are solely concerned with the mathematical consequences of the model's assumptions.

It will be shown in what follows that among the models described by (16) and the other assumptions listed above, the only ones which are consistent (have a solution $\overrightarrow{\mathrm{w}}(\overrightarrow{\mathrm{x}})$ ) are a subclass of the linear models given by (15). For this subclass, the general solution will be derived in closed form. The principal results appear in displays (42) and (45)-(48).

These conclusions only hold for $p>2$, however. For $p=2$, the class of consistent models is shown in Section 4 to contain many nonlinear ones, and for these the general solution is derived in semi-explicit form.

Call two of the $p$ products connected if, roughly speaking, the parameters of the first influence the elasticities of the second. The analyses of Sections 3 and 4 are carried out under a "connectivity hypothesis" which requires that each pair of products is connected. In Section 5 the results of dropping this hypothesis are investigated. For $\mathrm{p}=2$, there is no essential change in the nature of the consistent models or their solutions. For $p>2$, it is shown that the hypothesis must hold; disconnectedness would lead to a contradiction of our previous assumption (7). This suggests that it may be desirable to analyze the effects of replacing (7) and (8) by weaker assumptions about what market splits are theoretically "attainable".

## 2. PRELIMINARIES

We observe first that the g's can be assumed normalized so that

$$
\begin{equation*}
g_{j}(l)=1 . \tag{19}
\end{equation*}
$$

For, (17) and (18) imply that all $g_{m}(1)>0$, so that in (16) we could replace each $g_{m}$ by $g_{m} / g_{m}(l)$ and each $b_{i j k m}$ by $g_{m}(l) b_{i j k m}$.

From (3) we have

$$
\sum_{k=1}^{p} \partial_{w_{k}} / \partial y_{i j}=\partial\left(\Gamma_{k} w_{k}\right) / \partial y_{i j}=0
$$

Substituting (16) into this, we obtain

$$
\begin{equation*}
\sum_{k} \sum_{m} b_{i j k m} f_{k}\left(w_{k}\right) g_{m}\left(w_{m}\right)=0 \tag{20}
\end{equation*}
$$

By $(7), \vec{x}$ can be chosen so that $w_{k}(\vec{x})=1$ and therefore $W_{m}(\vec{x})=0$ for $m \neq k$. Applying this and (17) to (20) gives

$$
b_{i j k k} f_{k}(l)=0
$$

and since (17) and (18) imply $f_{k}(1)>0$, it follows that

$$
\begin{equation*}
\mathrm{b}_{i j k k}=0 \tag{21}
\end{equation*}
$$

Next, for any $w$ with $0 \leq w \leq l$ and any ( $k, m$ ) with $k \neq m$, we can by (8) choose $\vec{x}$ so that

$$
w_{k}(\vec{x})=w, \quad w_{m}(\vec{x})=l-w, w_{q}(\vec{x})=0 \text { for } q \neq k, m
$$

It follows from (20) that

$$
\begin{equation*}
b_{i j k m} f_{k}(w) g_{m}(l-w)+b_{i j m k} f_{m}(l-w) g_{k}(w)=0 \tag{22}
\end{equation*}
$$

By (21) this also holds for $k=m$.

Suppose now that $j, k, m$ are distinct. By (13) and (16),

$$
\sum_{m} b_{i j k m} f_{k}\left(w_{k}\right) g_{m}\left(w_{m}\right) \geq 0
$$

Choosing $\vec{x}$ as in (8), we see from this and (17) that

$$
b_{i j k m} \geq 0 \quad(j \neq k, m)
$$

Thus both $\underline{b}^{\prime}$ 's in (22) are non-negative, while for $0<w<1$ the f-values and g-valuesin (22) are positive. So (22) implies

$$
\begin{equation*}
b_{i j k m}=0 \quad(j \neq k, m) \tag{23}
\end{equation*}
$$

We conclude this section by remarking that

$$
\begin{equation*}
\partial\left(\partial w_{k} / \partial y_{i j}\right) / \partial y_{I J}=\partial\left(\partial w_{k} / \partial y_{I J}\right) / \partial y_{i j} . \tag{24}
\end{equation*}
$$

As is well-known, to prove this it suffices to show that the two second partial derivatives exist and are continuous. For the derivatives in (16) to exist, $\overrightarrow{\mathrm{w}}(\overrightarrow{\mathrm{x}})$ must be continuous. Since the $\mathrm{f}^{\prime} \mathrm{s}$ and g's are continuous, it follows from (16) that all the first partial derivatives of $\overrightarrow{\mathrm{w}}(\overrightarrow{\mathrm{x}})$ are continuous. We can evaluate the left-hand side of (24) by applying the chain rule to (16):

$$
\begin{align*}
\partial\left(\partial w_{k} / \partial y_{i j}\right) / \partial y_{I J}=\sum_{m} b_{i j k m} & \left\{f_{k}^{\prime}\left(w_{k}\right) g_{m}\left(w_{m}\right) \partial w_{k} / \partial y_{I J}\right. \\
& \left.+f_{k}\left(w_{k}\right) g_{m}^{\prime}\left(w_{m}\right) \partial w_{m} / \partial y_{I J}\right\} \tag{25}
\end{align*}
$$

Since the f's and g's and their derivatives are continuous, and the first-order parti\&l derivatives were just proved continuous, it follows that the left-hand side of (24) is continuous; similarly for the right-hand side.

## 3. MAIN ANALYSIS

Throughout this section, we shall impose two additional restrictions. The first is that at least three products are involved, i.e. p > 2 . The second might be called a connectivity condition; it asserts that for each pair of distinct products $P_{j}$ and $P_{k}(k \neq j)$, there is an index i such that

$$
\begin{equation*}
\mathrm{b}_{i j k j} \neq 0 \tag{26}
\end{equation*}
$$

The situations in which these restrictions are not satisfied will be discussed later.

Suppose (j,k,J) distinct. Then use of (23) simplifies (25) to

$$
\begin{aligned}
\partial\left(\partial w_{k} / \partial y_{i j}\right) / \partial y_{I J}=b_{i j k j} & \left\{f_{k}^{\prime}\left(w_{k}\right) g_{j}\left(w_{j}\right) \partial w_{k} / \partial y_{I J}\right. \\
& \left.+f_{k}\left(w_{k}\right) g_{j}^{\prime}\left(w_{j}\right) \partial w_{j} / \partial y_{I J}\right\}
\end{aligned}
$$

By (16) an $\bar{\alpha}$ (23)

$$
\begin{aligned}
& \partial w_{k} / \partial y_{I J}=b_{I J K J} f_{k}\left(w_{k}\right) g_{J}\left(w_{J}\right), \\
& \partial w_{j} / \partial y_{I J}=b_{I J j J} f_{j}\left(w_{j}\right) g_{J}\left(w_{J}\right),
\end{aligned}
$$

so that the expression for the left-hand side of (24) becomes

$$
\begin{align*}
\partial\left(\partial w_{k} / \partial y_{i j}\right) / \partial y_{I J}=b_{i j k j} f_{k}\left(w_{k}\right) g_{J}\left(w_{J}\right) & \left\{b_{I J_{k} J^{f}} f_{k}^{\prime}\left(w_{k}\right) g_{j}\left(w_{j}\right)\right. \\
& \left.+b_{I J j J} f_{j}\left(w_{j}\right) g_{j}^{\prime}\left(w_{j}\right)\right\} \tag{26a}
\end{align*}
$$

The expression for the right-hand side can be obtained by interchanging (i,j) and (I,J):

$$
\begin{aligned}
\partial\left(\partial w_{k} / \partial y_{I J}\right) / \partial y_{i j}=b_{I J k J} f_{k}\left(w_{k}\right) g_{j}\left(w_{j}\right) & \left\{b_{i j k j} f_{k}^{\prime}\left(w_{k}\right) g_{J}\left(w_{J}\right)\right. \\
& \left.+b_{i j J j} f_{J}\left(w_{J}\right) g_{J}^{\prime}\left(w_{J}\right)\right\} .
\end{aligned}
$$

Equating the two, we find that for $\mathrm{w}_{\mathrm{k}}>0$ (and hence, by continuity, for $W_{k}=0$ as well)

$$
b_{i j k j} b_{I J j J} g_{J}\left(w_{J}\right) f_{j}\left(w_{j}\right) g_{j}^{\prime}\left(w_{j}\right)=b_{I J k J}{ }_{i j J j} g_{j}\left(w_{j}\right) f_{J}\left(w_{J}\right) g_{J}^{\prime}\left(w_{J}\right)
$$

Thus for ${ }^{W}{ }_{j}>0$ and ${ }_{\mathrm{w}}^{\mathrm{J}}$ >0,

$$
\begin{equation*}
b_{i j k j} b_{I J j J} f_{j}\left(w_{j}\right) g_{j}^{\prime}\left(w_{j}\right) / g_{j}\left(w_{j}\right)=b_{I J k J} b_{i j J j}{ }^{f}\left(w_{J}\right) g_{J}^{\prime}\left(w_{J}\right) / g_{J}\left(w_{J}\right) . \tag{27}
\end{equation*}
$$

The left-hand side is a function of ${ }^{w}{ }_{j}$, the right-hand one a function of ${ }^{w} \mathrm{~J}$. Hence ${ }^{(3)}$ each is constant.

We wish to deduce from this the existence of constants $d_{j}$ (necessarily positive) such that for ${ }^{w}>0$

$$
\begin{equation*}
f_{j}\left(w_{j}\right) g_{j}^{\prime}\left(w_{j}\right) / g_{j}\left(w_{j}\right)=d_{j}, \tag{28}
\end{equation*}
$$

i.e. (by continuity for $w_{j}=0$ also)

$$
\begin{equation*}
f_{j}=d_{j} g_{j} / g_{j}^{\prime} . \tag{29}
\end{equation*}
$$

(3) Note the implicit use of the hypothesis $\mathrm{p}>2$.

This would not be justified if $b_{i j k j}{ }^{b} I J j J=0$ in (27) could not be avoided. The connectivity condition ensures that $i$ and $I$ can be chosen so as to permit passing from (27) to (28). Thus the $f^{\prime}$ s are uniquely determined by the g's (in a consistent model).

Now we return to (22), set $m=j$ and assume ( $j, k$ ) distinct, and apply (29) to obtain

$$
\left(b_{i j k j} d_{k} g_{k}(w) g_{j}(l-w) / g_{k}^{\prime}(w)\right)+\left(b_{i j j k} d_{j} g_{j}(l-w) g_{k}(w) / g_{j}^{\prime}(l-w)\right)=0 .
$$

Thus, for $0 \leq w<l$, and hence by continuity for $w=1$ as well,

$$
\begin{equation*}
b_{i j k j} d_{k} g_{j}^{\prime}(l-w)+b_{i j j k} d_{j} g_{k}^{\prime}(w)=0 . \tag{30}
\end{equation*}
$$

Indefinite integration with lower limit zero gives

$$
\begin{equation*}
\mathrm{b}_{i j j k} \mathrm{~d}_{j} \mathrm{~g}_{\mathrm{k}}(\mathrm{w})-\mathrm{b}_{i j k j} \mathrm{~d}_{k} \mathrm{~g}_{j}(1-w)=-\mathrm{b}_{i j k j} \mathrm{~d}_{\mathrm{k}} . \tag{3I}
\end{equation*}
$$

Setting w=l, we have

$$
\begin{equation*}
\mathrm{b}_{i j j k}{ }^{\mathrm{d}}{ }^{2}=-\mathrm{b}_{i j k j} \mathrm{a}_{k} . \tag{32}
\end{equation*}
$$

Substitution into (30) and (31), and use of the connetivity condition, yields

$$
\begin{align*}
& g_{j}^{\prime}(1-w)-g_{k}^{\prime}(w)=0, \\
& g_{j}(1-w)+g_{k}(w)=1, \tag{33}
\end{align*}
$$

for $k \neq j$. Since $p>2$, there follows from (33) the existence of a function $g(w)$ such that

$$
\begin{equation*}
g_{j}(w)=g(w) \quad \text { for } \quad l \leq j \leq p \tag{34}
\end{equation*}
$$

That is, the $\mathrm{g}^{\prime}$ s coincide. In some of the analysis below, however, we shall keep subscripts on the g's to make the derivations easier to follow.

So far (24) has been exploited with (j,k,J) distinct. Now we apply it with $j=k \neq J$. The left-hand side is, by (25),

$$
\begin{aligned}
\sum_{m} b_{i j j m} & \left\{f_{j}^{\prime}\left(w_{j}\right) g_{m}\left(w_{m}\right) b_{I J j J} f_{j}\left(w_{j}\right) g_{J}\left(w_{J}\right)\right. \\
& \left.+f_{j}\left(w_{j}\right) g_{m}^{\prime}\left(w_{m}\right) \sum_{n} b_{I J m n} f_{m}\left(w_{m}\right) g_{n}\left(w_{n}\right)\right\}
\end{aligned}
$$

The right-hand side, by (23), is

$$
\begin{aligned}
& \partial\left(b_{I J j J} f_{j}\left(w_{j}\right) g_{J}\left(w_{J}\right)\right) / \partial y_{i j} \\
& \quad=b_{I J j J}\left\{f_{j}^{\prime}\left(w_{j}\right) g_{J}\left(w_{J}\right) \partial_{j} / \partial y_{i j}+f_{j}\left(w_{j}\right) g_{J}^{\prime}\left(w_{J}\right) \partial w_{J} / \partial y_{i j}\right\} \\
& =b_{I J j J J} f_{j}\left(w_{j}\right)\left\{f_{j}^{\prime}\left(w_{j}\right) g_{J}\left(w_{J}\right) \sum_{m} b_{i j j m} g_{m}\left(w_{m}\right)\right. \\
& \\
& \left.\quad+g_{J}^{\prime}\left(w_{J}\right) b_{i j J j}{ }^{f}\left(w_{J}\right) g_{j}\left(w_{j}\right)\right\}
\end{aligned}
$$

Equating the two yields

$$
\sum_{m} \sum_{n} b_{i j j m} b_{I J m n} g_{m}^{\prime}\left(w_{m}\right) f_{m}\left(w_{m}\right) g_{n}\left(w_{n}\right)=b_{I J j J} b_{i j J j} g_{J}^{i}\left(w_{J}\right) f_{J}\left(w_{J}\right) g_{j}\left(w_{j}\right)
$$

Since, by (28),

$$
\begin{aligned}
& g_{m}^{\prime}\left(w_{m}\right) f_{m}\left(w_{m}\right)=d_{m} g_{m}\left(w_{m}\right), \\
& g_{J}^{\prime}\left(w_{J}\right) f_{J}\left(w_{J}\right)=d_{J} g_{J}\left(w_{J}\right),
\end{aligned}
$$

the last equation becomes

$$
\begin{gathered}
\sum_{m} \sum_{n} b_{i j j m} b_{I J m n}{ }_{m} g_{m}\left(w_{m}\right) g_{n}\left(w_{n}\right)=b_{I J j J} b_{i j J j} d_{J} g_{J}\left(w_{J}\right) g_{j}\left(w_{j}\right) \\
-13-
\end{gathered}
$$

Application of (23) reduces this to

$$
\begin{equation*}
\Sigma_{m}\left\{b_{i j j J}{ }^{b} I J J m{ }^{d} J+b_{i j j m}{ }^{b} I J m J_{m}^{d}\right\} g_{m}\left(w_{m}\right)=b_{I J j J}{ }_{i j J j j} d_{J} g_{j}\left(w_{j}\right) \tag{35}
\end{equation*}
$$

By (32), however,

$$
\mathrm{b}_{I J m J} \mathrm{~d}_{\mathrm{m}}=-\mathrm{b}_{I J J m} \mathrm{~d}_{J},
$$

and so (33) becomes

$$
\begin{equation*}
\sum_{m}\left(b_{i j j J}-b_{i j j m}\right) b_{I J J m} g_{m}\left(w_{m}\right)=b_{I J j J} b_{i j J j} g_{j}\left(w_{j}\right) \tag{36}
\end{equation*}
$$

Choose $k$ distinct from $j$ and $J$, and choose $\vec{x}$ so that $w_{k}(\vec{x})=1$. Then it follows from (36) that

$$
\begin{equation*}
\left(b_{i j j J}-b_{i j j k}\right) b_{I J J k}=0 \quad(j, J, k \text { distinct }) . \tag{37}
\end{equation*}
$$

This and the connectivity hypothesis imply the existence of constants $b_{i j}$ such that

$$
\begin{equation*}
b_{i j j k}=b_{i j} \quad \text { for all } k \neq j \tag{38}
\end{equation*}
$$

Next we employ (20), which by (21) and (23) can be written

$$
\sum_{m \neq j} b_{i j j m^{f}}{ }_{j}\left(w_{j}\right) g_{m}\left(w_{m}\right)+\sum_{k \neq j} b_{i j k j} f_{k}\left(w_{k}\right) g_{j}\left(w_{j}\right)=0
$$

A neater form is

$$
\sum_{k \neq j}\left\{b_{i j j k} f_{j}\left(w_{j}\right) g_{k}\left(w_{k}\right)+b_{i j k j} f_{k}\left(w_{k}\right) g_{j}\left(w_{j}\right)\right\}=0
$$

Application of (29) and (38) yields

$$
g_{j}\left(w_{j}\right) \sum_{k \neq j}\left\{b_{i j} d_{j} g_{k}\left(w_{k}\right) / g_{j}^{\prime}\left(w_{j}\right)+b_{i j k j} d_{k} g_{k}\left(w_{k}\right) / g_{k}^{\prime}\left(w_{k}\right)\right\}=0,
$$

which with the aid of (32) becomes

$$
b_{i j} d_{j} g_{j}\left(w_{j}\right) \sum_{k \neq j} g_{k}\left(w_{k}\right)\left\{I / g_{j}^{\prime}\left(w_{j}\right)-I / g_{k}^{\prime}\left(w_{k}\right)\right\}=0
$$

Now $d_{j}>0$, and the connectivity hypothesis permits choosing $\underline{i}$ so that $b_{i, j} \neq 0$. Hence

$$
\begin{equation*}
\sum_{k \neq j} g_{k}\left(w_{k}\right)\left\{I / g^{\prime}{ }_{j}\left(w_{j}\right)-I / g_{k}^{\prime}\left(w_{k}\right)\right\}=0 \tag{39}
\end{equation*}
$$

Choose $k$ and $m$ so that $(j, k, m)$ are distinct, and observe that $\overrightarrow{\mathrm{x}}$ can be chosen as in (8). Thus (39) implies that

$$
g_{k}(w)\left\{I / g_{j}^{\prime}(0)-I / g_{k}^{\prime}(w)\right\}+g_{m}(l-w)\left\{l / g_{j}^{\prime}(0)-I / g_{m}^{\prime}(l-w)\right\}=0 .
$$

By (33) and (34), this can be rewritten as

$$
\left.g(w)\left\{I / g^{\prime}(0)-I / g^{g}(w)\right\}+(I-g(w))\left\{I / g^{\prime}(0)\right)-I / g^{\prime}(w)\right\}=0,
$$

implying that $g^{\prime}(w)=g^{\prime}(0)$. That is, $g^{\prime}$ is constant, and so $g(w)$ is linear. Since $g(0)=0$ and $g(1)=1$, we have

$$
\begin{equation*}
g(w)=w . \tag{40}
\end{equation*}
$$

By (29),

$$
\begin{equation*}
f_{j}(w)=d_{j} w . \tag{4I}
\end{equation*}
$$

We now return to the original model equations (16). For $k \neq j$, these become

$$
\begin{aligned}
\partial W_{k} / \partial y_{i j} & =b_{i j k j} f_{k}\left(w_{k}\right) g_{j}\left(w_{j}\right) \\
& =b_{i j k j} d_{k} W_{k}{ }_{j}=-b_{i j} d_{j} W_{k} W_{j},
\end{aligned}
$$

while for $k=j$ we obtain

$$
\begin{aligned}
& \partial w_{j} / \partial y_{i j}=\sum_{m} b_{i j j m}{ }^{f}{ }_{j}\left(w_{j}\right) g_{m}\left(w_{m}\right) \\
& =\sum_{m \neq j} b_{i j}{ }^{\mathrm{d}}{ }_{j}{ }^{W}{ }^{W}{ }^{W} m \\
& =b_{i j}{ }^{d}{ }_{j}{ }^{w}{ }_{j} \sum_{m \neq j} W_{m}=b_{i j}{ }^{\mathrm{d}}{ }_{j}{ }^{w}\left(l-w_{j}\right)
\end{aligned}
$$

Both forms can be combined in

$$
\begin{equation*}
\partial w_{k} / \partial y_{i j}=b_{i j}{ }_{j}{ }_{j} w_{k}\left(\delta_{j k}-w_{j}\right) . \tag{42}
\end{equation*}
$$

From (42) we have

$$
\begin{aligned}
\left(l / w_{k}\right) d w_{k} & =\left(I / w_{k}\right) \sum_{i, j}\left(\partial w_{k} / \partial y_{i j}\right) d y_{i j} \\
& =\sum_{i, j} b_{i j} d_{j}\left(\delta_{j k}-w_{j}\right) d y_{i j}
\end{aligned}
$$

Therefore

$$
\begin{align*}
d w_{k} / w_{k}-d w_{l} / w_{l} & =\sum_{i, j} b_{i j}{ }_{j}\left(\delta_{j k}-\delta_{j l}\right) d y_{i j} \\
& =\sum_{i} b_{i k} d_{k} d y_{i k}-\sum_{i} b_{i l} d_{l} d y_{i l} . \tag{43}
\end{align*}
$$

There is therefore a constant $c_{k}$ such that

$$
\log \left(w_{k} / w_{l}\right)=\sum_{i} b_{i k} d_{k} y_{i k}-\sum_{i} b_{i l} d_{l} y_{i l}+c_{k}
$$

and hence such that

$$
\begin{equation*}
\mathrm{w}_{\mathrm{k}}=\mathrm{C}_{\mathrm{k}} \mathrm{w}_{1} \mathrm{~W}_{\mathrm{k}} / \mathrm{W}_{1}, \tag{44}
\end{equation*}
$$

where

$$
\begin{aligned}
C_{k} & =\exp \left(c_{k}\right)>0 \quad\left(C_{1}=1\right) \\
W_{k} & =\exp \left(\sum_{i} b_{i k} d_{k} y_{i k}\right)
\end{aligned}
$$

From the definition (10) of $y_{i j}$, we have

$$
\begin{equation*}
W_{k}=\left(\underset{i}{ } x_{i k}{ }^{b_{i k}}\right)^{d_{k}} \tag{45}
\end{equation*}
$$

By summing (44) over $1 \leq k \leq p$ and applying (3), we obtain

$$
\begin{align*}
& I=\left(w_{1} / W_{1}\right) \sum_{k} C_{k} W_{k} \\
& W_{k}=C_{k} W_{k} / \sum_{j} C_{j} W_{j} \tag{46}
\end{align*}
$$

We have shown that if the model (16) is to be consistent then it must have the special form (42), in which case its solutions $\overrightarrow{\mathrm{w}}(\overrightarrow{\mathrm{x}})$ must have the form given by (45) and (46). The parameters of these solutions are ${ }^{(4)}$

$$
\begin{equation*}
d_{k}>0, c_{k}>0, b_{i k} \leq 0 \tag{47}
\end{equation*}
$$

where the last inequality comes from (12). The connectivity hypothesis takes the form

$$
\begin{equation*}
\min _{i} b_{i k}<0 \text { for } a l l k \text {; } \tag{48}
\end{equation*}
$$

if it were violated for some $\underline{k}$, then from (45) and (46) we see that $\vec{W}(\vec{x})$ would not depend on the $x^{\prime}$ s of the $k$-th product.

Although (42) admits the singular solution $w_{k}(\vec{x}) \equiv 0$ corresponding to $C_{k}=0$, this is ruled out by requirements (7) and (8).

Conversely, consider any sets of $\underline{b} ' s, \underline{C}$ 's and $\underline{\text { d's }}$ satisfying (47) and (48), and define $\overrightarrow{\mathrm{w}}(\overrightarrow{\mathrm{x}})$ by (45) and (46). It is readily verified that (1), (2) and (42) are satisfied; hence (12) and (13) are satisfied. For each $\mathfrak{j}$ there is an $\underset{\underline{i}}{ }$ with $b_{i j}<0 ;(7)$ can be satisfied as closely as desired by letting the corresponding $x_{i j} \rightarrow 0$ and keeping all other $\underline{x}^{\prime}$ s fixed. Similarly, (8) can be satisfied as closely as desired. So (45) through (48) do give precisely the class of consistent models and their general solutions.
(4) Note from (45) that $d_{k}$ appears only in the products $b_{i k} d_{k}$, so that parameter-fitting to empirical data would deal with these products.

## 4. THE TWO-PRODUCT CASE

In this section we continue to impose the connectivity condition (26), but now assume $p=2$. For this case the situation will be shown to be quite different from that with $p>2$, in that there is an abundance of consistent non-linear models.

It is convenient to introduce the functions

$$
\begin{align*}
& h_{1}(w)=f_{1}(w) g_{2}(1-w),  \tag{49}\\
& h_{2}(w)=f_{2}(w) g_{1}(1-w), \tag{50}
\end{align*}
$$

so that for $j=1,2$

$$
\begin{equation*}
h_{j}(0)=h_{j}(1)=0, h_{j}(w)>0 \text { for } 0<w<1 \tag{51}
\end{equation*}
$$

With the aid of (21), the model (16) is found to take the form

$$
\begin{align*}
& \partial w_{1} / \partial y_{i 1}=b_{i 112} h_{1}\left(w_{1}\right),  \tag{52}\\
& \partial w_{1} / \partial y_{i 2}=b_{i 212} h_{1}\left(w_{1}\right),  \tag{53}\\
& \partial w_{2} / \partial y_{i 1}=b_{i 121} h_{2}\left(w_{2}\right),  \tag{54}\\
& \partial w_{2} / \partial y_{i 2}=b_{i 221} h_{2}\left(w_{2}\right), \tag{55}
\end{align*}
$$

while (22) yields

$$
\begin{equation*}
b_{i j 12} h_{1}(w)+b_{i j 21} h_{2}(1-w)=0 \tag{56}
\end{equation*}
$$

Froin (56) it follows that

$$
\begin{aligned}
& \mathrm{b}_{i j 12} \mathrm{~h}_{1}(\mathrm{w})=-\mathrm{b}_{\mathrm{i}_{2} 11} \mathrm{~h}_{2}(1-w) \\
& \mathrm{b}_{\text {IJ211 }} \mathrm{h}_{2}(1-w)=-\mathrm{b}_{I_{J 12} h_{1}}(w)
\end{aligned}
$$

Multiplying these two equations together leads to

$$
\begin{equation*}
\mathrm{b}_{i j 12}{ }^{\mathrm{b}} \mathrm{IJ} 21=\mathrm{b}_{\text {ij21 }} \mathrm{b}_{\text {IJ12 }} \tag{57}
\end{equation*}
$$

Take $J^{T}=1$; then connectivity ensures the existence of an index $I$ with $\mathrm{b}_{\mathrm{T121}} \neq 0$. With

$$
\lambda=\mathrm{b}_{\mathrm{IlI2}} / \mathrm{b}_{\mathrm{I} 121}
$$

it follows from (57) that

$$
\begin{equation*}
b_{i j 12}=\lambda b_{i j 21} \tag{58}
\end{equation*}
$$

Conditions (12), (13), (52) and (54) show that $\lambda \leq 0$, and the connectivity condition (choose $j=2$ in (58)) permits sharpening this to

$$
\begin{equation*}
\lambda<0 . \tag{59}
\end{equation*}
$$

It will now be shown that model consistency places no further conditions on the $\underline{b}$ 's, and no further conditions on the $\underline{f}^{\prime} s$ and $\underline{g}$ 's except (51) and the relation

$$
\begin{equation*}
\lambda h_{1}(w)+h_{2}(l-w)=0 \tag{60}
\end{equation*}
$$

which follows from (56), (58) and the connectivity condition.

For $j=1,2$, and $0<w<1$, let

$$
\begin{equation*}
H_{j}(w)=\text { an indefinite integral of } 1 / h_{j}(w) . \tag{61}
\end{equation*}
$$

Then $H_{j}^{\prime}(w)=l / h_{j}(w)>0$, and so $u=H_{j}(w)$ has an inverse function $w=\bar{H}_{j}(u)$ defined for all real $\underline{u}$ and taking values between 0 and 1 . $\bar{H}_{j}(-\infty)=0$ and $\bar{H}_{j}(\infty)=1$. These inverse functions will be used in expressing the explicit solution of the model. Note that (60) yields

$$
\begin{equation*}
H_{l}(w)-\lambda H_{2}(1-w)=0 \tag{62}
\end{equation*}
$$

for a proper choice -- which we assume made --- of the integrals (5) $H_{j}$.

With the use of (58), the model (52)-(55) becomes

$$
\begin{aligned}
& \partial w_{1} / \partial y_{i 1}=\lambda b_{i 121} h_{1}\left(w_{1}\right), \\
& \partial w_{1} / \lambda y_{i 2}=\lambda b_{i 221} h_{1}\left(w_{1}\right), \\
& \partial w_{2} / \lambda y_{i 1}=b_{i 121} h_{2}\left(w_{2}\right), \\
& \partial w_{2} / \lambda y_{i 2}=b_{i 221} h_{2}\left(w_{2}\right)
\end{aligned}
$$

The simplifying substitutions

$$
\begin{equation*}
z_{i j}=b_{i j 21} y_{i j} \tag{63}
\end{equation*}
$$

(5) The choice is that $H_{j}\left(W_{\circ j}\right)=O(j=1,2)$ where $0<W_{o j}<1$ and $W_{01}+{ }_{W_{02}}=1$.

## transform this into

$$
\begin{align*}
& \partial w_{1} / \partial z_{i 1}=\lambda w_{1} / \lambda z_{i 2}=\lambda h_{1}\left(w_{1}\right),  \tag{64}\\
& \partial w_{2} / \partial z_{i 1}=\lambda w_{2} / \partial z_{i 2}=h_{2}\left(w_{2}\right) \tag{65}
\end{align*}
$$

If all independent variables except a particular one $z_{l l}$ are held fixed, then (64) yields the separable ordinary differential equation

$$
d w_{1} / d z_{11}=\lambda h_{1}\left(w_{1}\right)
$$

whose general solution is

$$
\begin{equation*}
H_{1}\left(w_{1}\right)=\lambda z_{11}+K_{1}\left(z_{1} z_{11}\right) \tag{66}
\end{equation*}
$$

where the arguments of the (so far arbitrary) function $K_{1}$ consist of all $\underline{z}^{\prime}$ s except ${ }^{z}$ II . We invert this solution as

$$
\begin{equation*}
\mathrm{w}_{1}=\bar{H}_{1}\left(\lambda \mathrm{z}_{11}+\mathrm{K}_{1}\left(\mathrm{z}_{1} \mathrm{z}_{11}\right)\right) \tag{67}
\end{equation*}
$$

If $n(1)>1$, we go on to $z_{21}$. It follows from (66) that $\lambda K_{1} / \lambda z_{21}$ exists. By (67),

$$
\begin{equation*}
\partial w_{1} / \partial z_{21}=\left(\lambda K_{1} / \partial z_{21}\right) \bar{H}_{1}^{\prime}\left(\lambda z_{11}+K_{1}\right) \tag{68}
\end{equation*}
$$

Since

$$
\bar{H}_{1}^{\prime}(u)=I / H_{1}^{\prime}\left(\bar{H}_{1}(u)\right)=h_{1}\left(\bar{H}_{1}(u)\right),
$$

it follows from (67) and (68) that

$$
\partial w_{1} / \partial z_{21}=\left(\partial K_{1} / \partial z_{21}\right) h_{1}\left(w_{1}\right) .
$$

Comparing this with the assertion of (64) that

$$
\partial w_{1} / \lambda z_{21}=\lambda h_{1}\left(w_{1}\right),
$$

we see that

$$
\lambda K_{1} / \lambda z_{21}=\lambda,
$$

so that there is a decomposition

$$
K_{1}\left(z_{1} z_{11}\right)=\lambda z_{21}+K_{2}\left(z \mid z_{11}, z_{21}\right)
$$

Thus (67) becomes

$$
\begin{equation*}
{ }^{w_{1}}=\bar{H}_{1}\left(\lambda\left(z_{11}+z_{21}\right)+K_{2}\left(\mathrm{Z}_{1}^{\prime} \mathrm{z}_{11}, \mathrm{z}_{21}\right)\right) . \tag{69}
\end{equation*}
$$

Repetition of this argument leads finally to

$$
\begin{equation*}
{ }^{w} 1=\bar{H}_{1}\left(\lambda \sum_{i=1}^{n(1)} z_{i 1}+\lambda \sum_{i=1}^{n(2)} z_{i 2}+c_{1}\right) \tag{70}
\end{equation*}
$$

where $c_{1}$ is a constant. Working similarly with (65) leads to

$$
\begin{equation*}
w_{2}=\bar{H}_{2}\left(\sum_{i=1}^{n(1)} z_{i 1}+\sum_{i=1}^{n(2)} z_{i 2}+c_{2}\right) \tag{71}
\end{equation*}
$$

where $c_{2}$ is a constant.

Conversely, for any choices of $c_{1}$ and $c_{2},(70)$ and (71) are easily verified to yield positive-valued solutions of (64) and (65). It follows from (62) that

$$
\bar{H}_{1}(\lambda u)+\bar{H}_{2}(u)=1
$$

and so choosing

$$
\begin{equation*}
c_{1}=\lambda c_{2} \tag{72}
\end{equation*}
$$

is necessary and sufficient for the requirement $\mathrm{w}_{1}+\mathrm{w}_{2}=1$ to be satisfied. The conditions (12) and (13) follow automatically from (59) and the known signs of the b's in the display above (63). Satisfaction of (7) and (8) is easily verified.

We continue this section by illustrating the solution with the linear case

$$
f_{j}(w)=g_{j}(w)=w \quad(j=1,2),
$$

leading to

$$
h_{j}(w)=w(1-w)
$$

Choosing $w_{o j}$ with $0<w_{o j}<l$, we have

$$
\begin{aligned}
H_{j}(w) & =\int_{W}^{W}[t(1-t)\rceil^{-1} d t \\
& \left.=\log [w /(1-w)\rceil-\log \Gamma_{W_{O j}} /\left(1-W_{O j}\right)\right] .
\end{aligned}
$$

Taking $W_{\mathrm{Ol}}+\mathrm{W}_{\mathrm{O} 2}=1$ guarantees (62). Abbreviate

$$
k_{j}=\log \left[w_{o j} /\left(1-w_{o j}\right)\right] .
$$

Then from

$$
u=H_{j}=\log [w /(1-w)]-k_{j}
$$

we obtain

$$
w=\bar{H}_{j}(u)=w_{o j} \exp (u) /\left[I-w_{o j}+w_{o j} \exp (u)\right] .
$$

Thus (70) and (71) yield

$$
\begin{aligned}
& w_{1}=w_{o 1} \exp \left(u_{1}\right) /\left[w_{o 2^{+}} w_{o 1} \exp \left(u_{1}\right)\right], \\
& w_{2}=w_{o 2} \exp \left(u_{2}\right) /\left[w_{o 1}+w_{o 2} \exp \left(u_{2}\right)\right]
\end{aligned}
$$

where

$$
\begin{aligned}
& u_{2}=\sum_{i=1}^{n(1)} z_{i 1}+\sum_{i=1}^{n(2)} z_{i 2}+c_{2}, \\
& u_{1}=\lambda u_{2} .
\end{aligned}
$$

From (63) and (10) we find that

$$
\exp \left(u_{2}\right)=C_{2} P
$$

where $C_{2}=\exp \left(c_{2}\right)>0$,

$$
P=\prod_{i=1}^{n(1)}\left(x_{i 1}^{b_{i l 21}}\right) \prod_{i=1}^{n(2)}\left(x_{i 2}^{b_{i 221}}\right)
$$

Hence

$$
\exp \left(u_{1}\right)=C_{1} p^{\lambda}
$$

where $C_{1}=C_{2}^{\lambda}$ and, by (58),

$$
P^{\lambda}=\prod_{i=1}^{n(1)}\left(x_{i l}^{b_{i 112}}\right) \prod_{i=1}^{n(2)}\left(x_{i 2}^{b_{i 212}}\right)
$$

Taking $W_{o l}=w_{o 2}=l / 2$ for simplicity, we have

$$
\begin{aligned}
& { }_{w_{1}}=C_{2} \lambda_{2} \lambda /\left[1+C_{2} \lambda_{P} \lambda_{1}\right], \\
& w_{2}=C_{2} P /\left[1+C_{2} P\right\rceil .
\end{aligned}
$$

To relate this to the material of Section 3, it is simplest to compare model equations rather than solution forms. If (42) of Section 3 is specialized to $p=2$ (for which it was not proved necessary), the result is

$$
\begin{aligned}
& \partial w_{1} / \partial y_{i 1}=b_{i 1} d_{1} w_{1}\left(l-w_{1}\right), \\
& \partial w_{1} / \partial y_{i 2}=-b_{i 2} d_{2} w_{1}\left(1-w_{1}\right), \\
& \partial w_{2} / \partial y_{i 1}=-b_{i 1} d_{1} w_{2}\left(1-w_{2}\right), \\
& \partial w_{2} / \partial y_{i 1}=b_{i 2} d_{2} w_{2}\left(1-w_{2}\right)
\end{aligned}
$$

Comparing these with the corresponding specializations of the model equations before (63), we have

$$
\begin{aligned}
& \lambda b_{i 121}=b_{i 1} d_{1} \\
& \lambda b_{i 221}=-b_{i 2} d_{2} \\
& b_{i 121}=- \\
& b_{i 1} d_{i} \\
& b_{i 221}=b_{i 2} d_{2}
\end{aligned}
$$

Thus the solution form of Section 3, if applied to $p=2$, yields the special category $\lambda=(-1)$ of the subclass of "linear" models among the models considered in the present section.

One specific example of a nonlinear model for $p=2$ which is consistent (since it satisfies the conditions given above) is characterized by

$$
f_{1}(w)=f_{2}(w)=g_{1}(w)=g_{2}(w)=w^{2}
$$

and $\lambda=(-1)$.

## 5. THE DISCONNECTED CASE

Recall that the connectivity condition (26) required, for each pair of distinct products $P_{j}$ and $P_{k}(j \neq k)$, the existence of an index $i=1$ in at
such that

$$
\mathrm{b}_{i j k j} \neq 0
$$

In this concluding section, we investigate the situations in which this condition is violated. It is useful to observe in advance that

$$
\begin{align*}
& b_{i j k j}=0 \quad \text { implies } \quad b_{i j j k}=0  \tag{72}\\
& b_{i j j k}=0 \quad \text { implies } \quad b_{i j k j}=0 \tag{73}
\end{align*}
$$

These results follow from (22) with $m=j$ if $j \neq k$, or from (2l) otherwise.
As before, the case $\mathrm{p}=2$ will be considered separately. The model is given by the previous equations (52)-(55). Let us assume that the connectivity condition is violated, in that

$$
b_{i 212}=0
$$

for all i. Then by (72) it follows that $b_{i p 2}=0$ for all i so that from (52) and (54) we see that the values $\begin{aligned} & \text { il f } \\ & \end{aligned}$ have no effect on the market split. (This makes the connectivity condition an increasingly reasonable hypothesis, for $p=2$.)

We cannot also have

$$
\mathrm{b}_{i 121}=0
$$

for all $\frac{i}{}$, for this would make $w_{2}$ constant, in contradiction of (8). From (22), we have

$$
\begin{aligned}
& b_{i l l 2} h_{1}(w)=-b_{i l 21} h_{2}(l-w) \\
& b_{\text {Il 21 }} h_{2}(l-w)=-b_{\text {Ill 2 }} h_{1}(w)
\end{aligned}
$$

With $I$ chosen such that $\mathrm{b}_{\text {Il 21 }} \neq 0$, we can proceed just as in Section 4 except that the $y_{i l}$ and hence l the $z_{i l}$ do not appear. The result is

$$
\begin{aligned}
& w_{1}=\bar{H}_{1}\left(\lambda \sum_{i=1}^{n(2)} z_{i 2}+c_{1}\right), \\
& w_{2}=\bar{H}_{2}\left(\sum_{i=1}^{n(2)} z_{i 2}+c_{2}\right),
\end{aligned}
$$

where

$$
\lambda=\mathrm{b}_{\text {Ill2 }} / \mathrm{b}_{\text {Il21 }}<0
$$

We turn now to the case $p>2$. It can be assumed that for each pair (i,j), with $l \leq j \leq p$ and $l \leq i \leq n(j)$, there is a $k$ such that

$$
\partial \mathrm{w}_{\mathrm{k}} / \partial \mathrm{x}_{i j} \neq 0,
$$

for otherwise the parameter $x_{i j}$ would have no influence on the market split and so could (and should) have been omitted from the model. We can choose $k$ so that $k \neq j$, for if $\partial w_{k} / \partial x_{i j}$ vanished for all $k \neq j$, then so also would

$$
\partial w_{j} / \partial x_{i j}=\ni\left(1-\sum_{k \neq j} w_{k}\right) / \partial x_{i j} .
$$

By (16), (21) and (23), then, it follows that for each (i,j) there is a $k \neq j$ for which $b_{i j k j} \neq 0$.

Consider two products $P_{j}$ and $P_{J}, j \neq J$. We will call $P_{j}$ weakly (strongly) disconnected from $P_{J}$ if $b_{i j J j}=0$ holds for some $\underline{i}$ (for all i), $l \leq i \leq n(j)$. Clearly strong disconnectedness implies weak disconnectedness. It will now be shown that, conversely, weak disconnectedness implies strong disconnectedness, so that we can speak simply of "disconnectedness" and its opposite, "connectedness". It will also be shown that disconnectedness is a symmetric relation, i.e if $P_{j}$ is disconnected from $P_{J}$ then $P_{J}$ is disconnected from $P_{j}$.

For the proof, assume $b_{i j J j}=0$ for some $\underline{i}$. There is a $\underline{k}$, with $k \neq j$, such that $b_{i j k j} \neq 0$; hence $k \neq J$. Since ( $j, k, J$ ) are distinct we can apply (27)---whose derivation did not use the connectivity condition---to infer $b_{I J j J}=0$ for all $I$ with $l \leq I \leq n(J)$, i.e. $P_{J}$ strongly disconnected from $P_{j}$. Applying the same argument with $j$ and $J$ interchanged, we have $P_{j}$ strongly disconnected from $P_{J}$.

Since disconnectedness is symmetric, the same is true of connectedness. We now show that connectedness is also a transitive relation, i.e. if $P_{j}$ is connected to $P_{k}$, and $P_{k}$ to $P_{J}$, then $P_{j}$ is connected to $P_{j}(j, k, J$

For this purpose we cite the equation, derived without use of the connectivity condition, which appears several lines above (38):

$$
\sum_{m n} b_{i j j m} b_{I J m n} g_{m}^{\prime}\left(w_{m}\right) f_{m}\left(w_{m}\right) g_{n}\left(w_{n}\right)=b_{I J j J} b_{i j J j} g_{J}^{\prime}\left(w_{J}\right) f_{J}\left(w_{J}\right) g_{j}\left(w_{j}\right)
$$

for distinct $(j, J)$. By use of (2l) and (23), this can be written as

$$
\sum_{m \neq J} b_{i j j m}^{b} I J m J g_{m}^{\prime}\left(w_{m}\right) f_{m}\left(w_{m}\right) g_{J}\left(w_{J}\right)
$$

$$
+\sum_{n} b_{i j j J} J_{I J J n} g_{J}^{\prime}\left(w_{J}\right) f_{J}\left(w_{J}\right) g_{n}\left(w_{n}\right)=b_{I J j J}{ }_{i j J j} g_{J}^{\prime}\left(w_{J}\right) f_{J}\left(w_{J}\right) g_{j}\left(w_{j}\right),
$$

and terms collected to obtain

$$
\begin{aligned}
& \sum_{m \neq J, j}\left\{b_{i j j m}^{b} I J m_{I} g_{m}^{\prime}\left(w_{m}\right) f_{m}\left(w_{m}\right) g_{J}\left(w_{J}\right)+b_{i j j J}^{b} I J J m_{J} g_{J}^{\prime}\left(w_{J}\right) f_{J}\left(w_{J}\right) g_{m}\left(w_{m}\right)\right\} \\
& +b_{i j j J} b_{I J J j} g_{J}^{\prime}\left(w_{J}\right) f_{J}\left(w_{J}\right) g_{j}\left(w_{j}\right)=b_{I J j J} b_{i j J j} g_{J}^{\prime}\left(w_{J}\right) f_{J}\left(w_{J}\right) g_{j}\left(w_{j}\right)
\end{aligned}
$$

Now choose $\vec{x}$ so that $\vec{w}(\vec{x})$ has $w_{q}=0$ for $q \neq j, k, J$. Then the last equation becomes

$$
\begin{aligned}
& b_{i j j k} b_{I J K J} g_{k}^{p}\left(w_{k}\right) f_{k}\left(w_{k}\right) g_{J}\left(w_{J}\right)+b_{i j j J} b_{I J J k} g_{J}^{\eta}\left(w_{J}\right) f_{J}\left(w_{J}\right) g_{k}\left(w_{k}\right) \\
+ & b_{i j j J} b_{I J J j} g_{J}^{\eta}\left(w_{J}\right) f_{J}\left(w_{J}\right) g_{j}\left(w_{j}\right)=b_{I J j J} b_{i j J j} g_{J}^{\prime}\left(w_{J}\right) f_{J}\left(w_{J}\right) g_{j}\left(w_{j}\right) .
\end{aligned}
$$

If $P_{j}$ were disconnected from $P_{J}$, the right-hand side anā(using(72)) the last two summands on the left would vanish, leaving

$$
\begin{equation*}
b_{i j j k}{ }^{b} J_{k} J_{k}^{\prime}\left(w_{k}\right) f_{k}\left(w_{k}\right) g_{J}\left(w_{J}\right)=0 \tag{74}
\end{equation*}
$$

for $W_{j}+w_{k}+w_{J}=1$. This is impossible since the connectedness of $P_{j}$ with $P_{k}$ and $P_{k}$ with $P_{J}$ guarantees that the $b$ 's in (74) are nonzero. So $P_{j}$ and $P_{J}$ are connected.

From the fact that connectedness is both symmetric and transitive, it follows that unless the connectivity condition holds (i.e. unless any two products are connected), the set of $p$ products decomposes into two or more subsets such that
(a) any two products in the same subset are connected, but
(b) no two products in different subsets are connected.

Suppose for example that products $P_{1}$ and $P_{2}$ lie in different subsets $S_{1}$ and $S_{2}$. Then by (16) and (23) $\partial W_{1} / \partial y_{i j}=0$ unless $P_{j}$ is in $S_{1}$, i.e. $W_{l}$ depends only on the parameters of the products in $S_{1}$, and similarly for $W_{2}$ and $S_{2}$. By (7) we can choose the parameters of the products in $S_{1}$ so that $\vec{W}(\vec{x})$ has $w_{1}=1$. This is impossible because it requires $w_{2}=0$, whereas the parameters of products in $S_{1}$ cannot influence $S_{2}$. It follows from this contradiction that, for $p>2$, the connectivity condition must hold.
