NATIONAL BUREAU OF STANDARDS

The National Bureau of Standards¹ was established by an act of Congress March 3, 1901. The Bureau's overall goal is to strengthen and advance the Nation's science and technology and facilitate their effective application for public benefit. To this end, the Bureau conducts research and provides: (1) a basis for the Nation's physical measurement system, (2) scientific and technological services for industry and government, (3) a technical basis for equity in trade, and (4) technical services to promote public safety. The Bureau consists of the Institute for Basic Standards, the Institute for Materials Research, the Institute for Applied Technology, the Institute for Computer Sciences and Technology, and the Office for Information Programs.

THE INSTITUTE FOR BASIC STANDARDS provides the central basis within the United States of a complete and consistent system of physical measurement; coordinates that system with measurement systems of other nations; and furnishes essential services leading to accurate and uniform physical measurements throughout the Nation's scientific community, industry, and commerce. The Institute consists of a Center for Radiation Research, an Office of Measurement Services and the following divisions:

Applied Mathematics — Electricity — Mechanics — Heat — Optical Physics — Nuclear Sciences² — Applied Radiation² — Quantum Electronics³ — Electromagnetics³ — Time and Frequency³ — Laboratory Astrophysics³ — Cryogenics³.

THE INSTITUTE FOR MATERIALS RESEARCH conducts materials research leading to improved methods of measurement, standards, and data on the properties of well-characterized materials needed by industry, commerce, educational institutions, and Government; provides advisory and research services to other Government agencies; and develops, produces, and distributes standard reference materials. The Institute consists of the Office of Standard Reference Materials and the following divisions:

Analytical Chemistry — Polymers — Metallurgy — Inorganic Materials — Reactor Radiation — Physical Chemistry.

THE INSTITUTE FOR APPLIED TECHNOLOGY provides technical services to promote the use of available technology and to facilitate technological innovation in industry and Government; cooperates with public and private organizations leading to the development of technological standards (including mandatory safety standards), codes and methods of test; and provides technical advice and services to Government agencies upon request. The Institute consists of a Center for Building Technology and the following divisions and offices:

Engineering and Product Standards — Weights and Measures — Invention and Innovation — Product Evaluation Technology — Electronic Technology — Technical Analysis — Measurement Engineering — Structures, Materials, and Life Safety⁴ — Building Environment⁴ — Technical Evaluation and Application⁴ — Fire Technology.

THE INSTITUTE FOR COMPUTER SCIENCES AND TECHNOLOGY conducts research and provides technical services designed to aid Government agencies in improving cost effectiveness in the conduct of their programs through the selection, acquisition, and effective utilization of automatic data processing equipment; and serves as the principal focus within the executive branch for the development of Federal standards for automatic data processing equipment, techniques, and computer languages. The Institute consists of the following divisions:

Computer Services — Systems and Software — Computer Systems Engineering — Information Technology.

THE OFFICE FOR INFORMATION PROGRAMS promotes optimum dissemination and accessibility of scientific information generated within NBS and other agencies of the Federal Government; promotes the development of the National Standard Reference Data System and a system of information analysis centers dealing with the broader aspects of the National Measurement System; provides appropriate services to ensure that the NBS staff has optimum accessibility to the scientific information of the world. The Office consists of the following organizational units:

Office of Standard Reference Data — Office of Information Activities — Office of Technical Publications — Library — Office of International Relations.

Foreword

The National Standard Reference Data System was established in 1963 for the purpose of promoting the critical evaluation and dissemination of numerical data of the physical sciences. The program is coordinated by the Office of Standard Reference Data of the National Bureau of Standards but involves the efforts of many groups in universities, government laboratories, and private industry. The primary aim of the program is to provide compilations of critically evaluated physical and chemical property data. These tables are published in the *Journal of Physical and Chemical Reference Data*, in the NSRDS-NBS series of the National Bureau of Standards, and through other appropriate channels.

The task of critical evaluation is carried out in various data centers, each with a well-defined technical scope. A necessary preliminary step to the critical evaluation process is the retrieval from the world scientific literature of all papers falling within the scope of the center. Each center, therefore, builds up a comprehensive well-indexed bibliographical file which forms the base for the evaluation task. Bibliographies derived from these files are published when they appear to be of value to research workers and others interested in the particular technical area.

Further information on NSRDS and the publications which form the primary output of the program may be obtained by writing to the Office of Standard Reference Data, National Bureau of Standards, Washington, DC 20234.

Soft X-Ray Emission Spectra of Metallic Solids: Critical Review of Selected Systems and Annotated Spectral Index

A. J. McAlister, R. C. Dobbyn, J. R. Cuthill, and M. L. Williams

Theory and experimental practice in the field of soft x-ray emission from metallic solids are briefly reviewed, and measurements on a number of systems (Al, Al in AuAl₂, Al and Mg in Al-Mg, Cu, Cu and Ni in Cu-Ni, Li, Mg, Na, and Ni) are critically evaluated and compared with the results of other techniques and theory with a view to establishing the pertinence of the soft x-ray measurements and indicating specific guidelines for further enhancing their value. In addition, an exhaustive annotated index of measured spectra is provided.

Key words: Alloys; critical review; emission spectra; intermetallic compounds; metals; soft x-ray; spectra.

1. Introduction

In recent years, considerable progress has been made in understanding the electronic structure of solids. On the theoretical side, within the framework of the independent particle model, the techniques of energy band theory have been developed to the extent that many experimenters are now employing them in the detailed interpretation of their own data. Ordered compounds as well as elemental materials are under investigation, and the theory of disordered systems is being actively pursued. In addition, the theory of many-body systems has progressed to the point that the general limits of validity of the independent particle approach are fairly well understood. Experimental progress has been no less dramatic. An impressive array of experimental techniques has been brought to bear on the problem. These techniques fall into two categories: Fermi level probes of metallic solids, such as the many techniques for gaging the Fermi surface, low temperature specific heat, the Knight shift; and broad probes of the electronic structure, such as optical, photoemission, soft x-ray, ion neutralization, positron annihilation, and Compton spectroscopies. All of these techniques are being applied, with ever increasing refinement, to more and more systems. The obvious price of such progress is an enormous growth of the literature and the attendant danger of individual workers losing touch even with work in their own fields. Topical reviews are much needed to ward off this danger.

The present paper is intended to fulfill a part of this need by providing a selective critical review and

literature index to one major aspect of one experimental technique. The technique is soft x-ray emission spectroscopy, a broad probe which explores the entire occupied band structure. We further restrict ourselves to metals in their pure state, in alloys, and in intermetallic compounds. We use the term "soft x-ray" in a special way. "X-ray" has its traditional sense of describing radiative transitions involving initial ion core level vacancies. But the term "soft" shall imply that the final vacancy lies within the conduction band. Thus, as illustrated in figure 1, the technique consists of producing vacancies in ion core levels and observing the spontaneous radiation emitted when electrons initially in the conduction band drop into the vacant core states. Generally, photons emitted in this process are "soft" in the usual sense of being readily absorbed by the atmosphere, and measurements are of necessity carried out in vacuum instruments. This is not always the case, however. The penetrating radiation emitted in conduction band to K level transitions in the 3d metals is "soft" by our definition. To further orient the reader unfamiliar with the field, a typical instrument is illustrated in figure 2. It consists of two major components: a sample head in which the soft x-rays are generated, and a spectrometer in which they are energy analyzed and detected. To achieve sample cleanliness and reliable, reproducible results, the sample should always be mounted in vacuum. If, as in the case illustrated, initial state ion core vacancies are prepared by electron bombardment, a vacuum system must be employed. If inner level vacancies are produced by photoemission (shining x-rays from a separate tube onto the sample,

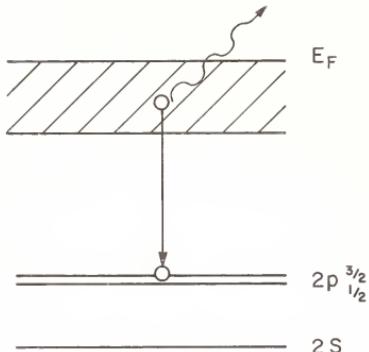

Figure 1. An energy level scheme, appropriate to 4l metal, illustrating the soft x-ray emission process. A vacancy of well defined energy is produced in some ion core level by electron beam bombardment or photoemission. An electron from the conduction band may drop into the core hole, the relaxation being accompanied by emission of soft x-ray photon. The energy distribution of the emitted photons reflects the distribution in energy in the conduction band of the particular orbital character allowed by the dipole selection rules.

for example) and penetrating radiation is produced, then the sample could be mounted in atmosphere, save for the reasons of cleanliness and reliability cited above. Figure 2 shows a particular type of spectrometer using a concave grating as the dispersing element and a driven photomultiplier as a detector. Other arrangements may be used, depending on spectral range and purpose. For instance, bent crystals and double crystals are used as dispersing elements in regions of higher photon energy. Proportional counters or photographic plates may be used as detectors as the application demands.

The major aims of this review are threefold: to promote better experimental practice by analysis of a representative sampling of systems upon which two or more measurements have been performed, to afford theorists a better understanding of the

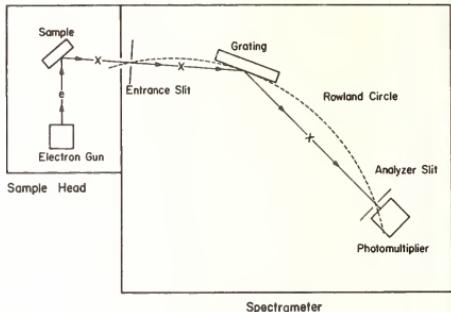

Figure 2. Any soft x-ray system must consist of (1) a sample head in which the x-rays are produced, and (2) a spectrometer in which they are energy analyzed and detected. In most practical applications, each must be mounted in vacuum since the radiation is usually easily absorbed by the atmosphere. Where the radiation is highly penetrating, it is well to keep the sample head under vacuum in the interest of sample cleanliness.

problems and limitations of the measurements, and to provide an easily used key to the literature of this subfield. The material presented to achieve these ends and its organization are as follows. In section 2, after brief surveys of the status of theory and experimental technique, we give a reasonably thorough critical review of experimental results on selected systems. Criteria for critical evaluation are developed in subsection 2.2, and cogently summarized in the introduction to subsection 2.3. In the latter segment, contact is made with theory and the results of other experimental techniques where possible. Since photoemission and ion neutralization results will be the other techniques most frequently compared, a brief description of these techniques has been provided in figure 3. Section 3 contains a comprehensive annotated index of soft x-ray emission spectra from metallic systems. The spectra are grouped according to the principal quantum number of the inner level involved (K, L, M, . . . for $n=1, 2, 3, \dots$), and listed alphabetically by elements studied (all elements permuted) within this grouping. Additionally, the spectra are separately listed alphabetically by author (all authors permuted). Also included is a chart showing the spectral ranges over which approximately 90 percent of the oscillator strength of many pure metal spectra extends.

All references in section 2 are made by author and our reference number and will be found in the author listing of section 3.

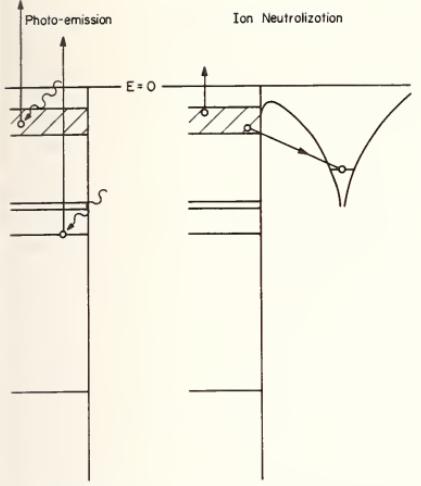

Figure 3. Photoemission (x-ray or UV induced): An incoming mono-energetic photon beam ejects electrons from the metal. If UV photons are used, only conduction band states are accessible for study; if x-rays are used, core states may be studied as well. The kinetic energy spectrum of ejected electrons yields information on the fold of occupied and unoccupied states. The two may be sorted out by varying the exciting photon beam energy.

Ion neutralization: A low energy beam of noble gas ions impinges on the metal surface. If a vacant ion state lies below the conduction band of the metal, an Auger relaxation may occur at the surface, one electron of the Auger pair filling the ion vacancy, and the other being raised to an excited state whence it may escape from the metal. The energy spectrum of ejected electrons contains information on the state density, though probably only near the surface.

core levels is low enough that the probability of their interacting is negligible. Thus, the dimensions of the radiating system are small compared to a wavelength, and the dipole approximation is valid. One can then write for the photon emission rate

$$R(\omega) \propto \omega/l \sum_{i,f} |\langle \psi_f | \sum_k \mathbf{p}_k | \psi_i \rangle|^2 \delta(\hbar\omega - E_i + E_f)$$

where \mathbf{p} is electron momentum. The k sum ranges over all electrons of the system, the i sum over l initial states, and the f sum over all final states. ψ_i and ψ_f are exact state vectors; E_i and E_f their energies. The usual dipole selection rules apply, and thus the emitted spectrum depends on the orbital symmetry of the inner level: a K level samples only the p-orbital admixture of the conduction band; L₂ and L₃ levels, the s and d orbital admixture.

The above expression for the soft x-ray emission spectrum is exact so far as the crystalline states are concerned. It can be solved in several approximations, in the simplest of which dynamic interactions between the electrons and local charge reorganization due to the presence of the core hole are ignored. ψ_i and ψ_f are approximated by antisymmetric linear combinations of single particle wave functions, ψ_i describing N conduction states plus a core with a vacancy, ψ_f an excited state containing $N-1$ conduction states and a full core. If the initial and final states are represented by linear combinations constructed from the same orthonormal set, the matrix element reduces to a sum of terms involving only single initial core and final band states. In the first attempt at this sort of analysis, Houston (319000) used free electron wave functions for the conduction band states, an approach which ignores the fact that the strongly localized core functions sample the band states near the nucleus where free electron waves form a very poor approximation to the Bloch states. This factor and an approximate accounting of the effect of crystal symmetry on the orbital admixture of the band states were introduced by Jones, Mott, and Skinner (349000). Only recently have attempts been made to carry this one-electron approach further by detailed calculations based on band theoretical results. While only a few systems have as yet been studied in this way—pure Al and Cu, Al in AuAl₂, all discussed in some detail in section 2.3. below—structural agreement with experiment is remarkably good.

A number of features of the observed emission profiles cannot be explained by the one-electron model described above. Broad low energy tails and

2. Review of Soft X-ray Emission Spectra from Metallic Systems

2.1. Theoretical Situation

Conduction band emission spectroscopy is carried out by preparing vacancies in ion core levels, in the manner outlined in the previous section, and then observing the energy distribution of photons spontaneously emitted as electrons initially in conduction band states drop into vacant core levels. Since the core levels are relatively sharp, some picture of the distribution of the conduction band states in energy is expected to emerge. To proceed further, we note that the core states are compact, normally occupying much less than a unit cell volume. Furthermore, in typical experiments, the density of ions with vacant

weak satellites on the low energy side, shifted down from the main band by the plasmon energy, are obvious examples. Moreover, while structural features such as peaks and edges occur at predicted locations, their observed amplitudes and sharpness differ from the simple one electron prediction, and seem to require screening and lifetime effects for their explanation. A number of workers have examined the effects of charge reorganization about the core hole in the one-electron approximation—Friedel (520032), Goodings (659065), Allotey (679087)—emphasizing light metal spectra, particularly the Li K spectrum [Tomboulian and Bedo (589030)], which displays a puzzling early peak, about 0.6 eV below the high energy edge. It seems fair to say that their results, while plausible, offer no definitive explanation of the observed profiles. (See particularly the discussion of the Li K spectrum given below). The first attempt to account for the effects of the electron-electron interaction (beyond the usual effective potential of the one-electron approach) was carried out by Landsberg (499007), who used a static screened interaction to compute the energy dependent lifetime of final state conduction band holes. In this way, he was able to account for the broad low energy tail of the Na L_{2,3} spectrum. Despite the rather good fit obtained, this result was defective in several respects. Since a static interaction was used, the method could not handle the plasmon satellite [observed later; see Rooke (639085)]. The small pip seen at the high energy edge [Skinner (409005) and later work discussed below] remained unexplained. Landsberg adjusted the screening length to give best fit. The length giving optimum fit was significantly shorter than that computed from the Bohm-Pines theory (539018). This situation worsened when Pirenne and Longe (649108) introduced the further effect of electrons virtually scattered from the core defect. Energy must be supplied to make the virtual processes real when a photon is emitted and further broadening is introduced. The static screening length needed to fit the experiment when this process is introduced results in further deviation from the Bohm-Pines length. A successful resolution of the plasmon and screening length difficulties was given by Glick and Longe (659075), who calculated the intensity of the tailing, including the plasmon satellite, of the Na L_{2,3} spectrum by carrying out a many-body perturbation estimate of the matrix elements, including only the lowest order terms contributing to the tail region.

The earlier discrepancy with the Bohm-Pines theory was found to have resulted from omission of certain cross terms in the static approximation. The Glick-Longe first order theory, however, diverged in the main band. Together with Bose (689344), they extended the work to the main band by summing over certain classes of terms in the many-body expansion. A notable result of this latter work was a distinct enhancement of intensity at the high energy edge resulting from a heavy production of virtual electron-hole pairs via dynamic scattering from the core hole. This provides a natural explanation for the emission edge pip observed in the Na spectrum, and agrees well with the independent analyses of the effects of sudden decay (or build up) of screening charge about the ion core defect upon emission (or absorption) edge intensities by Mahan (679320) and Nozières and de Dominicis (699051). Particular attention should be called to the work of Hedin and Lundqvist (699354), whose work on the relation between structural peaks in the spectral distribution function of the interacting electron gas, the eigenenergies of one-electron theory, and the results of a variety of experiments, including soft x-ray emission spectroscopy, provides the most convincing theoretical rationalization of the agreement cited above between one-electron estimates of soft x-ray profiles and experiment.

2.2. Remarks on Experimental Practices

It is not our purpose here to discuss instrumental details and technique. The interested reader will find much useful information and many references in Parratt's classic review (599072), the Strathclyde Conference Proceedings, edited by Fabian (689336), and the recent text by Samson (679056). Rather, we focus attention on those aspects of current experimental practice which most directly affect interpretation of emission band spectra. It is important to note, however, that the true emission spectrum is not measured, but rather the quantity

$$R_m(\omega_s) = \int_{-\infty}^{\infty} d\omega R(\omega)S(\omega)\rho(\omega)W(\omega - \omega_s)$$

where R_m is the measured emission rate at frequency setting ω_s , $R(\omega)$ the true emission spectrum at frequency ω , $S(\omega)$ the fraction of emitted photons escaping the sample (self-absorption factor), $\rho(\omega)$ the probability of a photon of energy $\hbar\omega$ being detected, and $W(\omega - \omega_s)$ the instrumental window function. The true emission rate $R(\omega)$ may not be (in fact,

probably is never) the precise quantity theory would predict and experiment determine. Bulk or surface contaminants could well contribute a spurious component. More typically, overlapping contributions may arise when several initial states not widely separated in energy occur. Thus, for instance, the measured L profile of Al inevitably consists of strongly overlapping L_2 and L_3 profiles, accompanied by a negligibly weak partially overlapping high energy satellite as well (Neddermeyer and Wiech, 709000). These problems are more pronounced in the M spectra of Cu and Ni, and are discussed in the following subsection. They can be dealt with in some cases, but their existence and the problems involved in correcting data for their presence should be borne in mind by the reader and stressed by the experimenter in reporting his results.

A number of advances have been made in experimental technique over the last decade. The use of improved vacuum technique lends greater confidence in the more current results. Two other advances are perhaps more significant. The introduction of photon counting techniques and digital recording systems has resulted in accurately linear response and known statistical confidence levels. Such work as Rooke's study of the plasmon satellites of the light metals (639085) and the identification of 3d-band structural features in the M_3 emission spectra of Cu (Dobbyn et al., 709080) and Ni (Cuthill et al., 679300) would not have been possible without this technique. Equally important is the growing realization of the effects of self-absorption on emission profiles. In this regard, Bonnelle (649057) demonstrated the utility of optimizing x-ray takeoff and exciting electron beam incidence angles. Liefeld (689330, 709116) has demonstrated that the many discrepancies among recorded 3d-metal L_3 emission profiles arose mainly from differences in satellite and self-absorption weightings due to differences in excitation conditions. It is of interest to note that the threshold effects observed in available Na L and Li K emission spectra (see the discussion in the next subsection), so important to the verification of current theory, may be affected to a significant degree by self absorption. Of course, when excitation conditions are accurately known and, in addition, the absorption coefficient of the sample is known over the appropriate spectral range (the latter is not usually the case), self-absorbed spectra can be theoretically corrected. (For instance, see Yakowitz and Heinrich (689304).)

Systematic uncertainties still remain a problem in the field. (For instance, see the discussion of Al profiles in the following subsection.) We address ourselves here, if not to their complete elimination, at least to the suggestion that measurements be reported in sufficient detail that their importance can be assessed by the reader. The major reasons for this problem are evidently the unique character of each instrument in use and the lack of any standard instrumental comparison technique. The major difficulties appear to be as follows. The frequency response $\rho(\omega)$ of dispersing elements and detectors is seldom known. Measurements on the same material are often made under different excitation conditions; not only does the intensity of excitation vary (exciting voltage and current density, say, in the case of electronic excitation), but the excitation geometry (exciting beam incidence and x-ray takeoff angles) usually differs as well. Hence $S(\omega)$ and satellite contributions to $R(\omega)$ can vary from measurement to measurement. Removal of background from electronically excited spectra is complicated by all of these factors. And too often, statements of slit settings and estimates of the inherent, varying instrumental resolution, $W(\omega - \omega_s)$ (the spectral window), are omitted, not surprisingly in the case of grating instruments where no simple experimental method of estimating W is available. These problems are not insuperable, of course, but in most cases their complete solution involves considerable difficulty. When painstaking efforts have been made to assess the instrumental response, as in the work of Neddermeyer and Wiech on Al (709000) and Neddermeyer on Mg (709115), then a detailed report of spectra measured on the calibrated instrument should serve as a valuable secondary calibration standard. However, the low L_2/L_3 intensity ratios observed in these measurements indicate that they have been made at low x-ray takeoff and high electron incidence angles. The authors do not give these numbers. (They can be found in Neddermeyer's thesis (699355); however, they are not cited in the published papers.) Now one must either reproduce their excitation conditions or, knowing the appropriate absorption coefficients, correct for differences in excitation conditions when using their data for calibration. Thus, the utility of their results as a secondary calibration standard is limited, not by the presence of self absorption in the profile, but by the authors' omission of a conveniently accessible complete summary of the conditions under which the measurements were made.

Other examples could be cited but these few seem sufficient basis for recommending that the following guidelines be followed by all workers in reporting emission spectra. This information should be given or some readily accessible source cited in all papers.

A. The Instrument

- (i) Method of calibration.
- (ii) Estimates of frequency response. If none, give type and nature of dispersing element, settings.
- (iii) Report of resolution tests.
- (iv) Type of detector and recording system.

B. Excitation

- (i) Type: x-ray or electron. Monochromaticity. Current density and voltage.
- (ii) Geometry: beam incidence and x-ray takeoff angles.

C. Sample

- (i) Preparation: purity, method.
- (ii) Characterization: type of tests and results. *Particularly important for alloys and compounds.*
- (iii) Handling: before mounting; in vacuum before and during measurements. Tests made in instrument (e.g., scans for C and O K emission bands).

D. Data Treatment

- (i) Explain everything clearly—all corrections, smoothings, unfoldings.
- (ii) Show raw measured data, indicating statistical confidence level.

2.3. Critical Survey of Selected Main Band Results

In the following critical survey, we deal with complete transcribed spectral profiles rather than such commonly used spectroscopic parameters as peak position, half-width, and asymmetry index. We do so because such parameters can be strongly affected by the experimental problems cited above and because it is the existence or otherwise of characteristic structure in the profiles, rather than coarse general features, which is of most interest to the student of electronic structure. Only main bands will be presented. Unless otherwise indicated, the ordinate is [Rate ($h\nu$) per unit energy]/ ν^2 , as given by the author or so corrected. The abscissa is $E-E_F$ in eV, where E_F is the estimated position of the Fermi level. All curves are normalized at peak ordinate value.

This is not the best choice in all cases; in some, it will, in fact, overemphasize discrepancies. Additionally, the curves are corrected for background, usually by the author, but by us (using a simple linear approximation) if he has not done so. All alloy concentrations are given in atomic percent.

The criteria for value judgments between measured profiles are those established in section 2.2. An ideal measurement will have been made on a clean, well characterized sample in an instrument with accurate energy calibration, known frequency response, and a sharp, known spectral window. Electromagnetic detection will have been used, and data of known statistical confidence level presented. Excitation conditions will have been clearly stated, and self-absorption effects will be, if not eliminated, of readily assessible extent. In cases where many measurements have been made, we select for display those few which come closest to the ideal. (An occasional good measurement, in particularly close agreement with one of those displayed, may be omitted for the sake of clarity in the figures; such an omission will be noted in the text.) Where only two or three measurements are available, we show all which are free of obvious catastrophic error.

a. Al

In figure 4 are presented a number of results, experimental and theoretical, on the $L_{2,3}$ and K emission bands of metallic Al, the material most frequently studied by soft x-ray spectroscopists, as well as the photoemission spectrum recorded by Wooten et al. (659084) at $h\nu = 11.3$ eV.

The $L_{2,3}$ measurements are from Fomichev (679102) (background corrected); Neddermeyer and Wiech (709000 and 699355); and Rooke (689154). All used electromagnetic detection. Neddermeyer and Wiech present an average of strip chart records; Fomichev (679102) total counts, accumulated point by point; Rooke total counts, accumulated by summing many digitally recorded continuous sweeps of the spectrum. Fomichev and Neddermeyer and Wiech used Au coated, blazed gratings, and have made measurements of and corrected for grating frequency response. Neddermeyer and Wiech argue for a smooth, relatively flat detector response. Rooke used an unblazed glass grating and did not make response measurements. No sample temperatures were reported; Fomichev notes use of a water-cooled anode. The curves have been shifted slightly to coincide at $Y=0.6$ on the leading edge (a Fermi energy

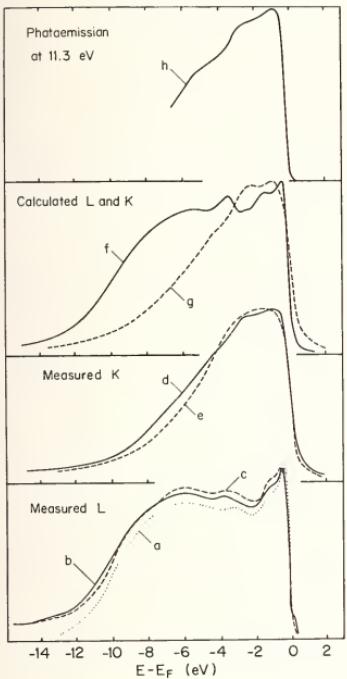

Figure 4. Al Measured $L_{2,3}$ spectra: (a) Fomichev, (b) Neddermeyer and Wiech, (c) Rooke. Measured K spectra: (d) Deslattes, (e) Sénemaud. Calculated spectra of McAlister: (f) L, (g) K. Measured photoemission spectrum at 11.6 eV, (h) Wooten et al.

estimate suggested by calculations cited below). All three are electronically excited. All appear to be rather strongly self absorbed at the edge. Fomichev and Neddermeyer and Wiech have achieved better resolution than Rooke, and their profiles are more intense at the band edge. Normalization to peak intensity, therefore, makes their curves appear weaker in the lower reaches of the emission band. The definition of the $L_{2,3}$ edges of Fomichev and Neddermeyer and Wiech suggests that about the same resolution was achieved. In light of their attempts at determining instrumental frequency response, the discrepancies between Fomichev and Neddermeyer and Wiech are puzzling. In any case, all three spectra show the same type of structure, as do the available band theoretical estimates of the profile [Rooke (689153), Smrcka (719187), and McAlister (unpublished)]. Other measurements showing the same structure have been reported: Sagawa (689323);

Appleton and Curry (659066); Dimond (679063), (the latter in close agreement with Rooke's measurements). Earlier work, in various respects less satisfactory than those cited above, by Catterall and Trotter (639087), Skinner (409005), and Cady and Tomboulian (419001), is in essential agreement. Discrepancies certainly exist among the various measurements of the $L_{2,3}$ spectral profile. Their source is not clear. Temperature differences could play a role. The exact location of the deeper lying structure is liable to uncertainty from inherent noise, mode of data presentation, variations in instrumental response, and errors in estimating spectral dispersion. It seems safe to conclude, however, from the weight of experimental evidence, that the structure observed is real, though at present not perfectly characterized and, from the calculations, that it arises from band structure effects. Neither the calculations nor the measurements are sufficiently refined at present to ascertain the need for invoking singular edge behavior.

The two K profiles are from Deslattes (unpublished) and Sénemaud (see Cauchois, 689326). (The latter is a revision of earlier work by Sénemaud (669142).) Deslattes used a two-crystal spectrometer and digital, stepwise recording of the output of an electromagnetic detector. (The curve shown here was obtained by averaging two raw spectra, kindly supplied us by Dr. Deslattes, and subtracting a constant background correction.) Sénemaud used a bent crystal instrument and photographic recording, and employed photoexcitation rather than electron beam excitation. The results of Sénemaud, therefore, needed no background correction. The overall shapes of the spectra are in good accord, particularly in view of our rough background correction to Deslattes results. The results of Deslattes show weak but clear structural features which are in quite good agreement with the calculated result, curve g of figure 4. The failure of Sénemaud (and other experimenters as well) to observe the structure in the K spectrum is in all likelihood due to the use of photographic detection (with only marginal response linearity) and the somewhat poorer resolution of the spectrometers employed.

The calculated profiles of McAlister (unpublished) are shown here; the L profile labeled f, the K profile g. Of the three available estimates, we believe this one to have determined the orbital character of the band wave functions most accurately. As noted above, the evident structural correlation between the

calculated and measured profiles strongly suggests that band structure effects are being observed. The further structural correlation with the ultraviolet photoemission spectrum lends additional weight to this suggestion.

b. Al in AuAl₂

The measured L_{2,3} profiles of Al from AuAl₂ shown in figure 5 are from Williams et al. (709081)

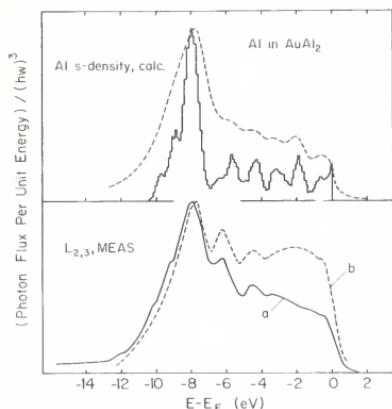

FIGURE 5. Al in AuAl₂. Lower curves, measured Al L_{2,3} spectra; (a) Williams et al., (b) Curry and Harrison. Upper solid curve: calculated s-like state density at Al sites. Upper dashed curve: s-like state density at Al sites subjected to Landsberg smear.

and Curry and Harrison (709016). Williams et al. used photoelectric detection and summed many scans of the spectrum. Curry and Harrison averaged several photographic records. The structural agreement between the two spectra is quite good. Comparison of L_{2,3} spectra of pure Al from the two groups with other results [see above, and Appleton and Curry (659066)] suggests that the overall difference between the profiles is due to spectrometer frequency response, the results of Curry and Harrison being more severely affected. Williams et al. appears to have achieved more nearly linear intensity response and spent greater effort on specimen characterization. The upper curves of figure 5 give some theoretical estimate of the Al L_{2,3} profile from the compound. The solid curve is Switendick's (709113) estimate of the density of s-like states at Al sites. This has been shown [Goodings and Harris (699161);

Bennett et al. (709082); Dobbyn et al. (709080)] to be the leading term in a band theoretical estimate of the profile. The dashed curve is the result of applying an approximate Landsberg fold (499007) to the Al s-density. The agreement seen between the calculation and the measured profiles is quite striking, as good in fact as that noted between measured and calculated pure Al L_{2,3} spectra above.

c. Al and Mg in Al-Mg

In figures 6 and 7 are compared Al (fig. 6) and Mg (fig. 7) L_{2,3} emission spectra from the pure metals

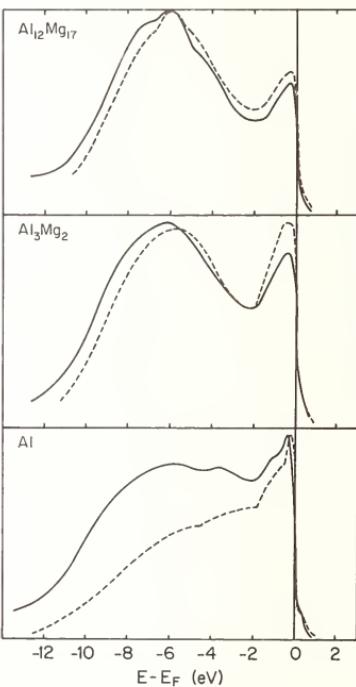

Figure 6. Al in Al-Mg. Measured Al L_{2,3} emission spectra from Al and two Al-Mg Compounds.

and the compounds Al₃Mg₂ and Al₁₂Mg₁₇. The data are from Neddermeyer (709115), solid curves, and Appleton and Curry (659066), dashed curves. Both used electron beam excitation; Neddermeyer at 2.0 keV, Appleton and Curry at 3.5 keV. Neither reported electron impingement or x-ray takeoff angles.

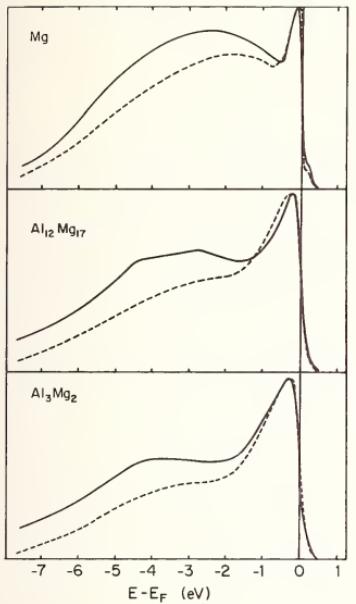

Figure 7. Mg in Al-Mg. Measured Mg $L_{2,3}$ emission spectra from Mg and two Al-Mg compounds.

No temperatures were reported, although Appleton and Curry used water-cooled targets. Stated pressures were: Neddermeyer 4×10^{-8} , and Appleton and Curry, 1×10^{-6} torr. Neddermeyer used photoelectric detection, averaged several strip chart recordings of ratemeter output, and corrected his results for the known frequency response of his Au coated, blazed grating. Appleton and Curry used an unblazed glass grating, with photographic detection. As noted above (Al in AuAl_2), and evident here, Appleton and Curry's instrumental response increases markedly with photon energy, while Neddermeyer's, because of the quantum efficiency of the photocathode used [see Samson (679056)], probably decreases slightly. Both Neddermeyer and Appleton and Curry note that their compound samples probably deviate from stoichiometry by 1 or 2 percent.

Apart from the noted difference in instrumental frequency response, these two sets of measurements are in good general agreement. Specific points of disagreement occur in the placement of the minimum of the pure Mg spectrum; the lack of structure in Appleton and Curry's Mg profile from $\text{Al}_{12}\text{Mg}_{17}$; and,

finally, in the shape of the Mg profiles from the compounds below -4.5 eV. In this energy range, Neddermeyer's curves are noticeably concave while Appleton and Curry's are slightly convex. This latter point is pertinent to understanding the electronic structure of this alloy system and needs further experimental clarification. Early measurements by Farineau of the Al and Mg K spectra from Al-Mg alloys showed equal experimental band widths for Al and Mg in the alloys, with the common band width varying smoothly from pure Al to pure Mg. More recent K measurements by Fischer and Baun (679041), under cleaner vacuum conditions, are in essential agreement with Farineau's work. (The validity of these K measurements is questionable, however, since strong self-absorption effects may mask the true behavior. Reinvestigation of the K spectra with this difficulty in mind would be of considerable interest.) The L spectra clearly behave in a radically different way, each component retaining essentially the same observed band width throughout the composition range. This behavior is clearly shown in figure 8, where Neddermeyer's Mg and Al spectra are overlaid. The compound data of figures 6 and 7 are repeated here and the results from a solid solution of 5 percent Al in Mg are shown. The latter sample was believed to be single phase. The striking difference in measured band widths seen here probably stems from the necessity of local charge neutrality in a metallic system. More charge must accumulate in regions of greatest potential, here at Al sites. Screening is evidently accomplished by states lowest in energy being heavily localized at Al sites, and perhaps being of different orbital symmetry there than at Mg sites. (This latter point is suggested by the concavity of the Mg $L_{2,3}$ from Al_3Mg_2 and $\text{Al}_{12}\text{Mg}_{17}$ below -4 eV. Normally, one anticipates convexity for L spectra in this energy range, owing to dominantly s-like local wave function character there. See Jones et al., 349000.) Direct substantiation of this picture by band computations for the compounds is ruled out at present because of their complicated crystal structure. However, a rough model computation by Jacobs (699213) suggests that it is correct. Computational evidence does exist for energy dependent charging in other alloy systems. For instance, consider the calculations for AuAl_2 by Switendick (709113) cited above, where Bloch functions of dominantly d-like character at Au sites are highly localized there and exert influence on the charge distribution at Al sites largely through hybridization effects.

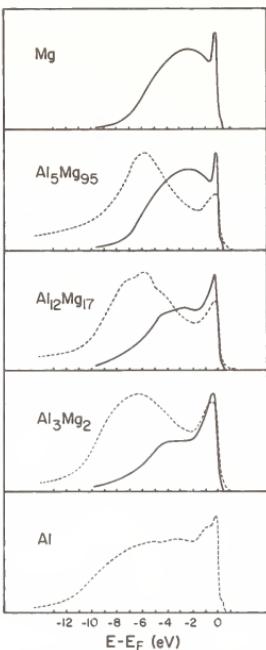

Figure 8. Al and Mg in Al-Mg. Measured Al and Mg spectra, matched in energy at the Fermi edge and overlaid. Spectra from pure metals, the compounds Al_3Mg_2 and $\text{Al}_{12}\text{Mg}_{17}$, and the solid solution 5 percent Al in Mg.

d. Cu

In figure 9, three measurements of the $\text{Cu M}_{2,3}$ spectral complex are shown. These are smoothed, background corrected spectra, as presented by the authors save for division by suitable powers of energy to reduce the data to a common plot of intensity (energy flux per unit energy) versus photon energy. The curves have been shifted by slight amounts (no more than 0.3 eV) to match in energy at peak intensity. They are otherwise faithful transcriptions of the published curves. These data are from Bedo and Tomboulian (599002), solid curve; Dobbyn et al. (709080), dash-dot curve; and Clift et al. (639083), dashed curve. Bedo and Tomboulian and Clift et al. used photographic detection; Dobbyn et al., photoelectric detection. Dobbyn et al. summed many digitally recorded scans of the spectrum and, in view of the linear response of photoelectric detection and the known standard counting error in their data (1.1

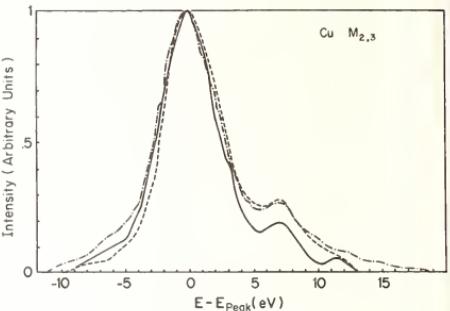

FIGURE 9. Cu. Comparison of three measurements of the $\text{Cu M}_{2,3}$ emission spectrum taken with different exciting electron beam voltages and different detection methods.

to 0.7 percent), asserted the fine structure they observed to be reliably established. Bedo and Tomboulian and Clift et al. report pressures of 1×10^{-6} torr, and used water-cooled targets. Dobbyn et al. reported a pressure of 7×10^{-8} torr, with the target at 580 °C [well above the O_2 surface cleanup temperature of 277 °C (Roberts, 609017)]. All used electron beam excitation with beam energies as follows: Bedo and Tomboulian, 1.5 keV; Dobbyn et al., 2.5 keV; and Clift et al., 3.5 keV. The grazing angles of electron beam incidence were 90, 20, and 90°; x-ray takeoff angles, 45, 90, and 32° for Bedo and Tomboulian, Dobbyn et al., and Clift et al. respectively. None attempted to assess self-absorption effects. Bedo and Tomboulian and Dobbyn et al. identify the structure above 5 eV in figure 9 as satellites, Dobbyn et al. noting that, energetically, they are likely to be double ionization satellites with the spectator hole residing in the M shell. This identification is supported by the trend in intensity of this structure relative to the main peak with exciting voltage. Dobbyn et al. (private communication) noted this same trend, comparing measurements made at 1.5 and 2.5 keV in the same instrument. Dobbyn et al. also noted that additional satellites nearer the parent bands are expected, with the spectator hole residing in the valence band. By treating the valence band satellites in a manner suggested by analysis of Liefeld's (689330) measurements of the L_2 spectra of Cu and Ni at and above the L_2 threshold excitation voltage, and the M shell satellites in the intermediate coupling approximation, Dobbyn et al. argued that the major features of the $\text{Cu M}_{2,3}$ spectrum could be approximated by

$$M_{2,3}(E) = [M_3(E) + \alpha_1 M_3(E - \epsilon) + \alpha_2 M_3(E - 2\epsilon)] \\ + [\beta_1 M_3(E - \delta - 2\epsilon/3) + \beta_2 (E - \delta + \epsilon/\sqrt{3}) \\ + \beta_3 M_3(E - \delta + 2\epsilon/3)]$$

where $M_{2,3}(E)$ is the measured spectral complex and $M_3(E)$ the true single hole M_3 emission profile. The second bracketed term on the right approximates the satellites with the spectator hole residing in the $3p$ shell; the first represents the M_3 and M_2 parents and the satellites with spectator hole in the valence band. Dobbyn et al. inverted this expression and varied ϵ , the α 's, and the β 's over reasonable ranges, and found the estimated M_3 single hole emission profile to be relatively insensitive to choice of these parameters. In figure 10, the Dobbyn et al. estimate of the M_3 profile (SXS) so obtained is compared with the results of other deep band experimental probe studies: ion neutralization (INS) by Hagstrum and Becker (679195); x-ray induced photoemission (XPS) by Fadley and Shirley (689234); and ultraviolet induced photoemission (UPS) by Eastman (699246).

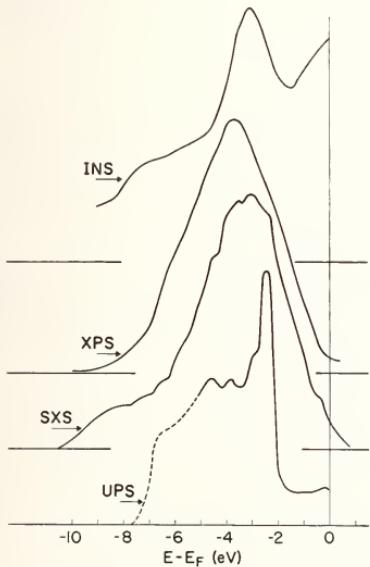

Figure 10. Cu. Comparison of various deep band probe results: ultraviolet photoemission optical density of states (UPS); reduced soft x-ray M_3 emission band (SXS); x-ray photoemission spectrum with Al $K_{2,1}$ excitation (XPS); ion neutralization unfold function (INS).

Note particularly the 1-to-1 correspondence of structural features in the main SXS and UPS humps and the agreement as to width and peak location of all four measurements.

In figure 11, the lower set of curves compares the experimental M_3 and L_3 single hole emission profiles, the latter determined by Liefeld (689330) at threshold excitation. Note particularly the greater width of the M_3 profile in the d -hump, and its greater relative intensity below the hump. Qualitatively, these features are predicted in the one-electron transition densities calculated by Goodings and Harris (699161), but they are overridden in the total emission spectra by the E^3 dependence of the dipole emission rate expression, this factor being important to the M_3 profile only. The Goodings and Harris results for the M_3 and L_3 Cu emission profiles are shown as the middle pair of curves in figure 11, where many-body level broadening has been taken into account with Blokhin and Sachenko's approximation (609057) to the Landsberg (499007) free electron result. Dobbyn et al. (709080) noted that if emission takes place after screening of the inner level defect, one might reasonably expect large positive s -wave and small negative d -wave shifts in the screening

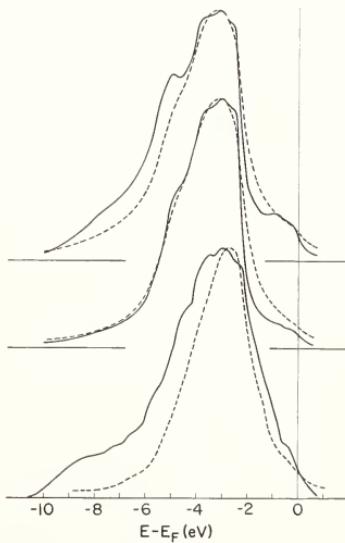

Figure 11. Cu. Comparison of measured and calculated $Cu L_3$ (dashed) and M_3 (solid) emission spectra. Lower curve, measured. Middle curve, band theory estimate; upper curve, band theory with approximate screening correction.

cloud. Thus, the *s*-like fraction of the calculated emission spectrum could be enhanced relative to the *d* by a factor in excess of 1, and the above-mentioned differences in one-electron transition rates enhanced by the screening. They tested this mechanism in a rough way by assuming various energy independent *s* to *d* enhancement factors and then recomputing the spectra. Their results for *s/d* = 5 are shown at the top of figure 11. Agreement with experiment was noticeably improved, but no rationalization of the factor used was offered.

e. Cu and Ni in Cu-Ni

Cu and Ni form a continuous series of solid solutions over the entire composition range; the lattice constant increasing by 2.7 percent from Ni to Cu. It is, therefore, an attractive system for studying the effects of substitutional disorder on the electronic structure of metals. Homogeneity is difficult to achieve, however, and for this reason some of the results presented here must be regarded with caution. (The question of homogeneity in Cu-Ni alloys has been reviewed by Seib and Spicer, 700846.) While not enough work has been done to permit intercomparison of soft x-ray results, sufficient other deep band probe studies have been made to warrant their summary. Presented here are: soft x-ray emission bands (SXS) (Clift et al., 639082); x-ray photoemission spectra (XPS) (Hüfner et al., 729038); ultraviolet photoemission (UPS) (Seib and Spicer, 700846 and 700847); soft x-ray L₃ absorption spectra (Van den Berg, 579055).

Clift et al. (639082) give (SXS) M_{2,3} emission spectra of the pure metals and both components of the alloys, in 10 percent concentration steps across the composition range. No details of sample preparation were given. Some of their results are shown in figure 12, plotted as intensity versus photon energy. The spectra were excited with a 3.5 keV electron beam normally incident on the samples. X-ray takeoff was at 30° from the sample surface. Samples were water cooled. Pressure was approximately 1×10^{-6} torr. Photographic detection was used. The plotted curves were obtained by averaging densitometer traces of several exposures at 0.5 eV intervals and drawing a smooth curve through the points. Thus, even in the pure metals, detail such as that observed by Cuthill et al. (679300) for pure Ni and Dobbyn et al. for Cu (709080) is eliminated, and no light is shed on the interesting question of its survival or change with alloying.

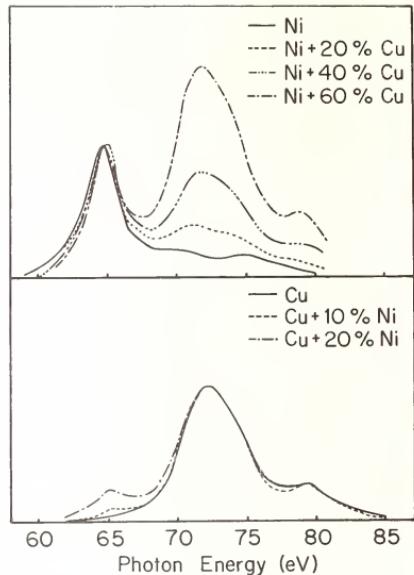

Figure 12. Cu and Ni in Cu-Ni. Soft x-ray M_{2,3} spectra from a number of alloys and the pure metals.

Hüfner et al. (729038) XPS spectra of the valence bands of Cu, Ni, and 12, 44, 46, and 74 percent of Cu in Ni are shown in figure 13. Al K_{α12} radiation was employed; resolution was approximately 1.0 eV. No details of sample preparation are given. Ar ion cleaning was employed prior to measurements.

The samples upon which Seib and Spicer (700846 and 700847) performed UPS measurements fall into three classes: 0, 13, and 23 percent Ni in Cu, single crystal, the alloys vacuum annealed at 1000 °C for 13 days and air quenched, all three cleaned in vacuum by heating to 600 °C; 0, 11, 19, and 49 percent Cu in Ni, polycrystalline, similarly heat treated, then cleaned in vacuum by successive Ar bombardments followed by 355 °C annealing; 39 and 62 percent Cu in Ni, no heat treatment, cleaned in vacuum like the latter. The alloys of 39, 49, and 62 percent Cu in Ni proved unsatisfactory in several respects and will not be discussed here. Figure 14 shows photoemission spectra from samples of 0, 13, and 23 percent Ni in Cu, taken with 10.2 eV photons; and 81, 89, and 100 percent Ni in Cu, taken with 10.0 eV photons. Resolution is about 0.2 eV.

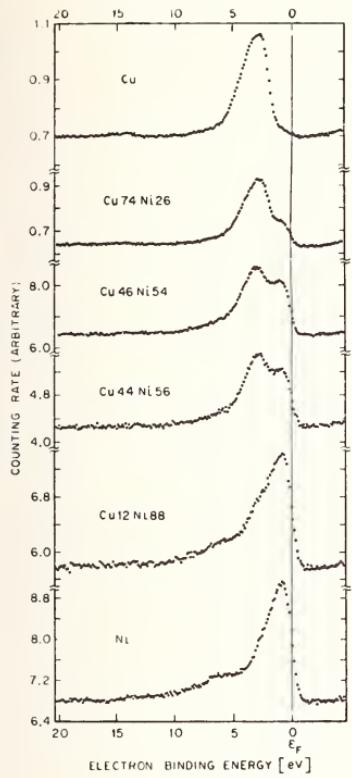

Figure 13. Cu and Ni in Cu-Ni. X-ray photoemission spectra of a number of Cu-Ni alloys.

Both Clift et al. and Hüfner et al. note that, to a good approximation, their results can be reproduced by superimposing the pure metal results. Seib and Spicer on the other hand assert that the Ni density of states is narrow (~ 1 eV) at low Ni concentrations and broadens to about 5 eV for pure Ni. There is reason to doubt the validity of this description at low Ni concentrations, however. Seib and Spicer base this assertion largely on an attempt to remove the Cu contribution to the observed spectra at 13 and 23 percent Ni by scaling the pure Cu spectrum to full experimental intensity for the alloys at -2.2 eV and subtracting. The resulting curves not only show a peak at about -1.0 eV, but an additional peak at -3.0 eV, together with a rather pathological, narrow minimum at -2.1 . Reducing the scale factor for Cu from full to about 0.7 of the experimental intensity at

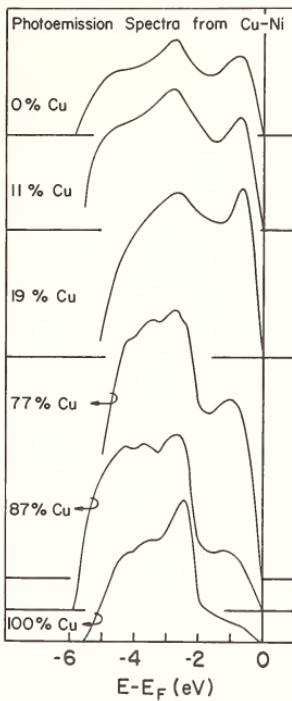

Figure 14. Cu and Ni in Cu-Ni. Ultraviolet photoemission spectra from several Cu-Ni alloys.

-2.2 largely removes the strange minimum and leaves an estimated Ni curve quite like that of pure Ni but with about a -0.2 eV chemical shift. Thus, it would appear that all three techniques can be reasonably construed to yield compatible results.

An additional interesting experimental observation is that of figure 15. Shown here are Van den Berg's (579055) measurements of the soft x-ray L absorption edge of Ni in pure Ni and 4 and 40 percent Ni in Cu. The striking feature here is the persistence of the strong peak at the edge, usually attributed to d holes above the Fermi level. This result is again consistent with those cited above, but the quality of the samples, described only as evaporated films, is open to question.

Finally, Wenger et al. (719033) have attempted to obtain a measure of the $s-d$ charge at Ni sites in Cu-Ni alloys by measuring the integrated intensity of the Ni L_{α} emission band normalized to that of the Ni L_{α} line ($3s \rightarrow 2p^{3/2}$) at 20 percent intervals across the se-

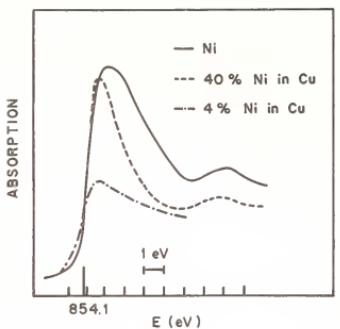

Figure 15. Ni in Cu-Ni. Soft x-ray l_3 absorption spectra of Ni in pure Ni and two Cu-Ni alloys.

ries. They found it to be constant within experimental error. No details of sample preparation were given.

Further clarification of the experimental situation is needed, particularly at low Ni concentrations. SXS measurements should be particularly valuable here because of the partial resolution of the component emission spectra, but optimum resolution, linearity, and signal-to-noise ratio must be achieved if genuine improvements are to be made.

f. Li

Figure 16 compares Li K emission profiles recorded by Crisp and Williams (619025) and Crisp (619046), and Tomboulian and Bedo (589030). These two results are quite representative of the available literature. In each case, measurements were made on samples freshly evaporated in vacuum. Pressures were approximately 10^{-5} torr during evaporation and 10^{-6} during measurement. (More recent mea-

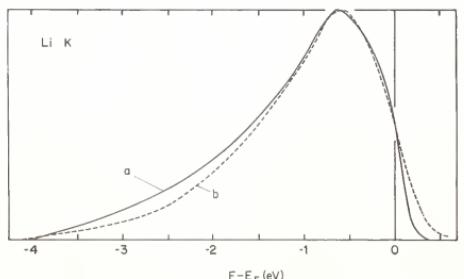

Figure 16. Li. Two measured soft x-ray Li K emission profiles: (a) Crisp and Williams, (b) Tomboulian and Bedo.

urements by Aita and Sagawa (699204), made under better vacuum, 10^{-7} to 10^{-8} torr, are compatible with these results.) Crisp and Williams used electromagnetic detection and ratemeter strip chart records. Tomboulian and Bedo used photographic detection. Sample temperature was stated by Tomboulian and Bedo as 162°C ; Crisp and Williams used a water-cooled sample but reported no temperature. In each case, the samples were metallic and retained bright metallic luster during the measurements. The only significant difference between the two profiles is in the high energy edge, the results of Crisp and Williams being noticeably sharper there. In this connection, it is worth noting differences in excitation conditions; Crisp and Williams, electron beam of 4 keV, incident at 90° , x-ray takeoff $\sim 15^\circ$; Tomboulian and Bedo (589030), electron beam of 0.75 keV at 90° , x-ray takeoff of 45° . The sharper edge of Crisp and Williams appears to be a self-absorption artifact.

The pre-peaking of the Li K emission spectrum has not as yet received definitive explanation. It is certain that no band calculation based on Hartree-Fock type orbitals and using conventionally constructed crystal potentials will yield an early peak (McAlister, 699058). However, the new band calculational approach of Goddard (see O'Keefe and Goddard, 690254), using spin generalized rather than Hartree-Fock basis orbitals, does offer a natural one-electron explanation. Since the removal of core electron from Li constitutes an extremely large perturbation, screening effects have been plausibly invoked (Goodings, 659065; Allotey, 679087; Ausman and Glick, 699001). None of these approaches offers any explanation of the extreme overlap of the emission and absorption edges (Skinner and Johnston, 379000) and their Gaussian tails. McAlister (699058) has shown that folding one-electron estimates of the emission and absorption rates with a broad Gaussian smearing function yields good agreement with experiment. He attributes the Gaussian smear to thermal broadening of the K level by the phonon field but offers no rationalization of the large width (.3 to .4 eV) needed for a good fit.

g. Mg

Numerous measurements have been made of the Mg $L_{2,3}$ emission spectrum, all showing a rather sharp peak just below the high energy emission edge. The three measurements of figure 17 are due to Watson et al. (689324), Neddermeyer (709115), and Fomichev (699089). In no case were tempera-

See Al and Mg in Al-Mg.

i. Na

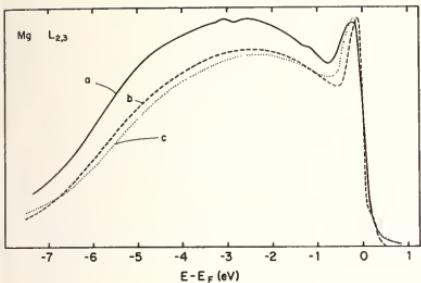

Figure 17. Mg. Three measured Mg $L_{2,3}$ soft x-ray emission profiles: (a) Watson et al., (b) Neddermeyer, (c) Fomichev.

tures stated, but water-cooled cathodes were used by Watson et al. and Fomichev. Electron beam excitation was used in each case; Watson et al., 3.0 keV; Neddermeyer, 2.0 keV; and Fomichev, not stated. None cite x-ray takeoff or electron impingement angles. Pressures cited were; Watson et al., 1×10^{-6} torr; Neddermeyer, $1-3 \times 10^{-8}$ torr; and Fomichev, not stated. All used blazed metal coated gratings; Watson et al. and Fomichev, Au coated; and Neddermeyer, Pt coated. Photoelectric detection was used in each case. Watson et al. summed many digitally recorded runs, Neddermeyer summed several strip chart recorded scans, and Fomichev used a single, stepped counting sweep. Neither Neddermeyer nor Fomichev cite noise figures for their data. Watson et al. plotted data with vertical bars representing the standard counting error, $\pm \sqrt{N}$, N being the total number of counts per channel. Their statistical noise level was sufficiently low that the small features at -1.3 and -2.9 eV appear real. Independent, unpublished measurements of Dimond, displayed by Watson et al. show like structure. An approximate theoretical analysis, similar to that by Rooke for Al (689153), was carried out by Watson et al. The analysis suggests a one-electron interpretation for the minimum at about -0.8 eV on their curve, and the feature at -1.3 eV. The analysis suggests no explanation for that at -2.9 . The calculated positions for the minimum and slope break are -0.9 and -1.7 eV respectively. The feature at -2.9 remains unexplained. Watson et al. suggest the possibility that it is an oxide structure. However, it shows no correlation with the Mg spectrum from bulk MgO [Neddermeyer (699355), Fomichev et al. (689249)].

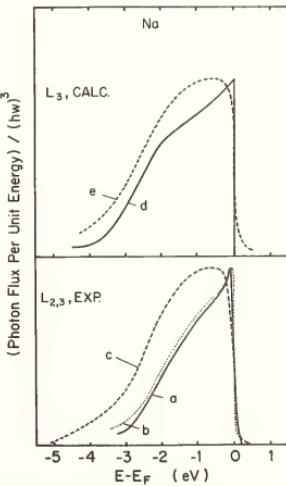

Figure 18. Na. Measured $L_{2,3}$ spectra: (a) Crisp and Williams, (b) Skinner, (c) Cady and Tomboulian. Theory: (d) many body profile; (e) band theory profile.

experimental results. However, they report an r.m.s. electron beam exciting voltage of 1.4 keV, while those of other workers range from 3.5 to 4.0 keV. Additionally, Haensel et al. (699094) have reported a measurement of the Na L_{2,3} absorption profile which shows a distinct minimum approximately 0.2 eV below the midpoint of the L₃ edge. The pip in the data of Crisp and Williams, and Skinner occurs approximately 0.15 eV below the 50 percent point of the emission edge. Unfortunately, the absorption data extend only 0.6 eV below the midpoint of the edge, and only the shape of the absorption edge, not its absolute magnitude, is reported. These factors suggest that the edge pip may be a self-absorption artifact. Further experimental work is needed to clarify this point.

The importance of answering this question is emphasized by the two theoretical estimates shown in the upper part of figure 18. In figure 18 the solid curve *d* is the result of a many-body calculation by Glick et al. (689344). It includes in a natural way the effects of the core hole and final state interactions, and shows a distinct rise in intensity just at the Fermi edge. The broken curve *e* is a band theory estimate by McAlister (unpublished), with level broadening treated in the Landsberg approximation (499007). The latter would agree fairly well with experimental curve *c* (fig. 18) if a modest degree of energy dependent enhancement by core hole screening were assumed.

j. Ni

The L₃ emission profile of Ni has been studied by many investigators (Farineau, 389001; Skinner et al., 549020; Cauchois, 539002, for example), with considerable disagreement resulting. Van den Berg (579055) made the first progress in solving the problem by noting that the measured profile depended strongly on the energy of the exciting electron beam. More recently, Bonnelle (649057) and, particularly, Liefeld and coworkers (689330, 709116) have shown the disparities to arise from the fact that satellite intensity and self-absorption effects can be very important and depend markedly on exciting electron beam energy. In figure 19 are shown results of Liefeld (689330) and Chopra and Liefeld (649160) on the L₃ profile of Ni. Measurements were made at a sample temperature of about 800 °C, at approximately 1×10^{-7} torr in a two-crystal instrument. Various exciting electron beam voltages, V_x , were used. Curve *a* (fig. 19) is typical of results with V_x

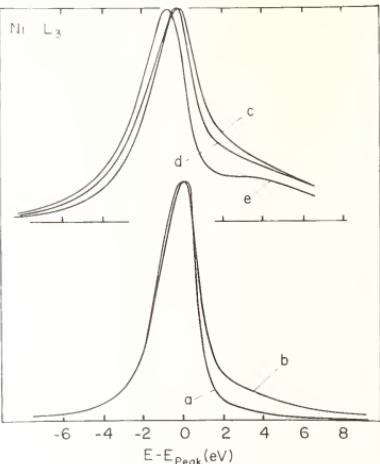

Figure 19. Ni. The Ni soft x-ray L₃ profile, measured at a number of exciting electron beam energies. The voltages are, in keV: (a) 0.86, (b) 0.92, (c) 2.0, (d) 5.1, (e) 12.5.

between the L₃ and L₂ threshold. For V_x above the L₂ threshold, holes can be created in the $2p^{1/2}$ core shell, and the Auger decay $2p^{1/2} \rightarrow 2p^{3/2}, v$, where v denotes a hole in the valence band, can occur. Radiative decay can then occur with a local, relatively high mass spectator hole in a 3d level, and high energy satellite structure appears, as in curve *b*. As one continues to raise V_x , the satellite structure increases in intensity, as in *c*. Eventually, as in curves *d* and *e*, self absorption becomes sufficiently strong to warp the measured profiles in a pronounced way. In fact, the L₃ absorption spectrum can be obtained by taking the ratio of profiles measured at two suitable values of V_x (Liefeld, 689330). Bonnelle (649057) independently demonstrated the dependence of self absorption on V_x and, in addition, showed how it can be reduced by optimizing x-ray takeoff and exciting electron beam incidence angles.

Various measurements of the Ni M_{2,3} spectrum (Tomboulian and Bedo, 619081; Skinner et al., 549020; Clift et al., 639083; Cuthill et al., 679300) have shown better agreement, the situation being comparable to that shown above for the M_{2,3} spectra of Cu. There are several probable causes for this. The M_{2,3} measurements were made over a less extreme range of V_x , 2.5 to 4.0 keV. Also, as noted above for Cu, the M-valence band satellites tend to

be degenerate in energy with the M₂ band. And, finally, self absorption should be much less severe, owing to very broad and only gently structured M_{2,3} absorption edges (Sonntag, 699356).

In figure 20, a number of deep band electronic structure probe results on Ni are compared: the M₃ profile of Cuthill et al. (679300), extracted from the M_{2,3} complex in the manner described above for Cu; the L₃ profile, measured at L₃ threshold excitation by Liefeld (709116); the ultraviolet induced photoemission optical density of states of Eastman and Krolikowski (689211), the XPS spectrum of Fadley and Shirley (689234), and the ion neutralization unfold function of Hagstrum and Becker (679195). Here, as in the case of Cu discussed above, remarkably strong structural correlations are observed, despite differences in magnetic state. The soft x-ray measurements were made on paramagnetic Ni (at 960 °C for the M, 800 °C for the L) while the photoemission and ion neutralization measurements were made at room temperature on ferromagnetic samples. Figure 21 compares the M₃ profiles of

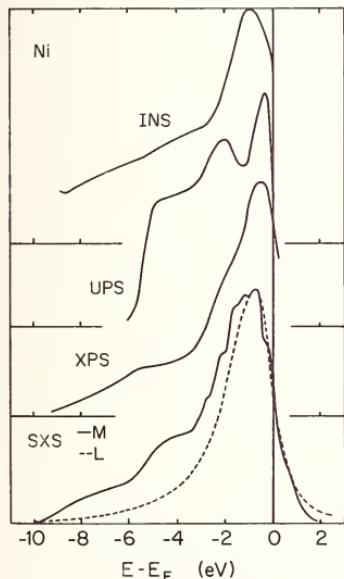

Figure 20. Comparison of various deep probe results for Ni. Lowest curves, soft x-ray L and M emission spectra (SXS). X-ray photoemission spectrum (XPS); ultraviolet photoemission optical density of states (UPS); ion neutralization unfold function (INS).

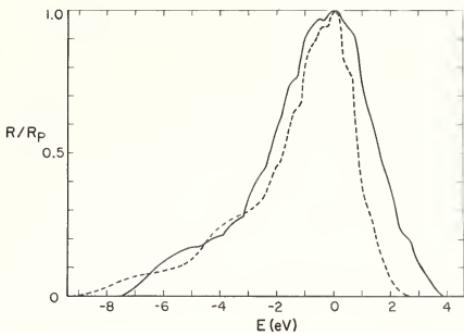

Figure 21. Ni and Cu. Comparison of Ni- and Cu-M_{2,3} emission bands, showing structural correlation.

Cu (Dobbyn et al., 709080) and paramagnetic Ni (Cuthill et al., 679300). Structural correlation between the two spectra is evident and to be expected from their common crystal structure and valence difference of 1. Note, however, the slight shoulder on the high energy side of the d-hump in both spectra. Similar structure has been noted by the present authors in unpublished measurements of the M spectra of Cr and Fe. Liefeld and Hanzely (709116) also report like structure in their threshold measurements of the L₃ spectra of Cu, Ni, Co, and Fe. These have been plausibly interpreted as excitation features (Dobbyn, 709080; Liefeld, 709116) of the type described by Parratt (599072).

See Cu and Ni in Cu-Ni.

3. Annotated Spectral Index

3.1. Guide to the Index

This section contains an annotated index to soft x-ray emission spectra from metallic systems. As far as possible, it is complete for the literature published through 1970, with many later papers included as well. The papers are grouped according to the principal quantum number of the inner level involved (K, L, M, ... for $n = 1, 2, 3, \dots$). Within these groups, the listing is alphabetical by material (with all components of an alloy permuted). The papers are annotated according to type (E, T, or R for experiment,

theory, or review) and to content, the various properties (e.g., 5D for state density, 9S for satellite structure) being listed in appendix 1. A guide to journal name and special publication abbreviations is given in appendix 2. The year of publication is indicated by the first two digits of the file number. Boldface italics has been used to designate the elements from which spectra have been obtained. (Elements are normally denoted by chemical symbol. Occasionally, classes of materials are studied (for example, rare earths), and special class designations are used. These are listed in app. 3.) Concentrations are rounded to the nearest integer or zero. For binaries,

the composition always applies to the constituent occurring first in alphabetic order. For three or more constituents, additional entries appear, the second entry giving the concentration of the element second in alphabetic order, the third entry giving the concentration of the third in alphabetic order, etc. Specimen temperature or temperature range is assumed to be room temperature unless specified otherwise by footnote. This section closes with an index to sources of spectra, arranged alphabetically by author (all authors permuted). Included here are all references from the text above, including those which would not otherwise be listed.

3.2. Index by Inner Shell

3.4. Spectra Chart

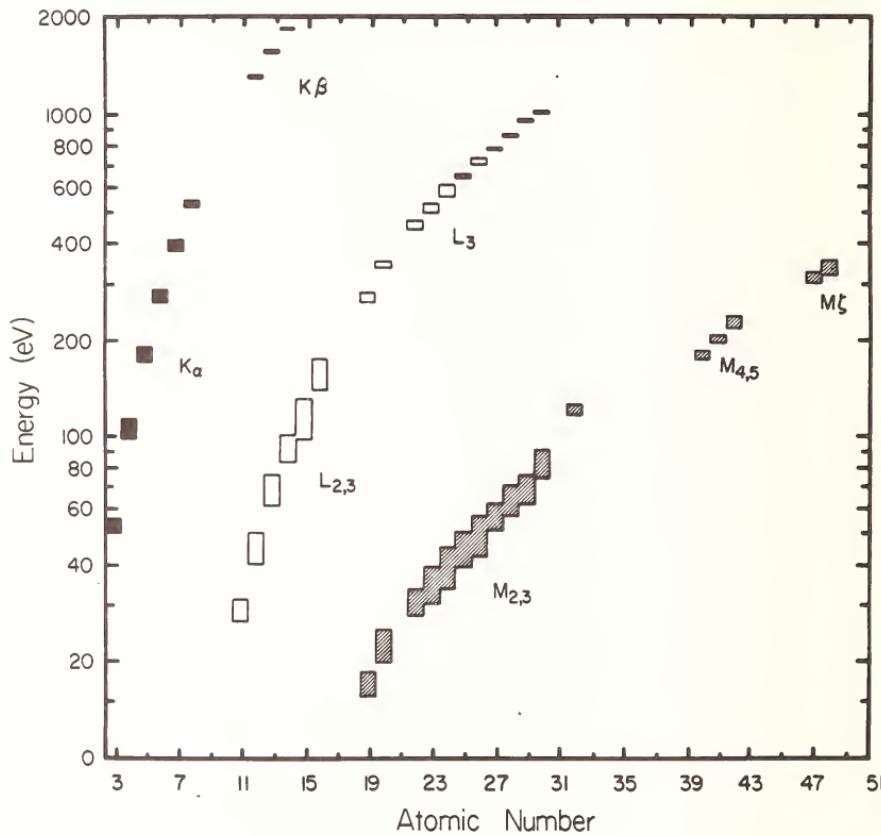

Figure 22. Chart showing the spectral location in eV of various spectra.

Bar height represents region within which approximately 90 percent of oscillator strength falls.

The authors wish to acknowledge Dr. G. C. Carter who, as Director of the NBS Alloy Data Center, devised the computerized property indexing system employed in the Spectral Index and Author Index tables. The authors also wish to thank D. Kahan of the NBS Alloy Data Center for maintenance of the computer tapes, C. Messina and M. R. Shaver for assistance in formatting the above tables for publication, and J. G. Koch for programming assistance.

Appendix 1

List of Properties by Categories

The code of the property is the category number followed by the alphabetic symbol at the left of the property. The deleted letters are open for future assignment. First we list the properties by increasing alphanumeric code number, and then alphabetically by property name.

Category 1

Electronic Transport Properties (ETP)

- A. Temperature coefficients of resistivity.
- B. Electrical resistivity; conductivity.
- C. Thermal conductivity; anharmonic force constants.
- D. Residual resistivity; mean free path; resistivity ratios.
- E. Effective number of charge carriers; number of electrons; number of holes.
- F. Ferromagnetic anisotropy of magnetoresistance. (Magnetoresistance, see Category 5.)
- H. Hall coefficients, R , R_o ; R_s .
- I. Peltier coefficient, π .
- J. Ettingshausen-Nernst effect.
- K. Thompson coefficient.
- L. Lorentz number, Wiedemann-Franz ratio.
- M. Mobility; drift velocity.
- P. Ettingshausen coefficient, P .
- Q. Nernst coefficient, Q_x .
- S. Righi-Leduc coefficient, S .
- T. Thermoelectric power, Seebeck effect.

Category 2

Magnetic Properties (MAG)

- B. Electronic magnetic moment; effective number of Bohr magnetons; local moment; (including neutron diffraction results and moments of clusters). (See NEU.)†
- C. Curie constants.
- D. Néel point; Kondo Temperature; Morin transition; other magnetic transitions, etc. (except 2T, below).
- E. Residual inductance; coercive force.
- F. Remanent magnetization; saturation remanence; etc.
- G. $(HB)_{\max}$; hysteresis.
- H. Total energy loss; loss angle; eddy current losses; quality factor, Q .
- I. Saturation magnetization; saturation moment; intrinsic moment ($\neq 2B$).
- J. Magnetic exchange energy of electrons, J .
- K. Magnetostrictive coupling constant, K (both isotropic and anisotropic).

- L. Molecular field coefficient, Weiss constant.
- M. Magnetocrystalline anisotropy constant.
- N. Magnetocaloric or magnetothermal effect (oscillatory under 5K).
- O. Electrostrictive mechanical coupling coefficient; piezoelectric effect; magnetoelectric properties.
- P. Permeability: initial; effective; maximum; reversible.
- Q. Elastoresistance.
- R. Magnetomechanical damping; magnetoelastic effect; (magnetomechanical properties).
- T. Curie temperature: paramagnetic, ferromagnetic.
- X. Susceptibility (magnetization); antiferromagnetic susceptibility.

Ferromagnetic Kerr effect, see under 6M.

Category 3

Mechanics (MEC)

- A. Electron probability density, charge density; Pauling electronegativity, charge transfer.
- B. Stacking faults and other interfacial phenomena, such as grain boundary properties of solidliquid interfaces; etc.
- C. Viscosity.
- D. Density.
- E. Acoustic and ultrasonic attenuation. (See ACO.)†
- F. Acoustic impedance. (See ACO.)†
- G. Elastic properties.
- H. Young's modulus (modulus of elasticity in tension or compression), E ; compressibility, β .
- I. Bulk modulus, K .
- J. Shear modulus, shearing modulus; torsion modulus; modulus of rigidity, G .
- K. Poisson's ratio, σ .
- L. Elastic constants, c_{ij} 's (elastic stiffness parameter, elastic coefficients); s_{ij} 's (elastic compliances).

†Single daggers in these categories refer the reader to List No. 3 for a variety of techniques and their abbreviations.

- N. Structure-sensitive properties (e.g., effect of dislocations, irradiation, etc. on physical properties).
- O. Lattice parameters, lattice constants, cell dimensions (including c/a ratios); space groups; superlattice formation; coordination number; crystal structures. (See XRA, NEU, etc.)[†]
- P. Nuclear polarization. (See NPL OVR, etc.)[†]
- R. Phonon spectra.
- S. Spin wave spectra; spin wave energy, spin wave velocity; magnon spectra. (See SPW.)[†]
- U. Form factors; structure factors; scattering factors.
- V. Sound velocity.
- W. Electron-phonon interactions; Kohn anomalies.
- X. Thermomechanical properties.

Category 4

Nuclear and Other Resonance Properties (NMR, EPR, etc.)

- A. Line width (for all spectroscopic techniques).
- B. Line shape; line intensity; enhancement factor recoilless fraction (f) (as in MOS).[†]
- C. Hyperfine field, internal field, effective field at the nucleus, etc. (no Knight shifts). (See for example THE, FNR or MOS).[†]
- E. Electric field gradient at the nucleus; electric quadrupole coupling constant.
- F. Spin-lattice relaxation time, T_1 , longitudinal relaxation time, thermal relaxation time. (See NMR).[†]
- G. Spin-spin relaxation time, T_2 , transverse relaxation time, spin-phase memory time. (See NMR).[†]
- H. Nuclear g-factor; nuclear magnetic moment dipole, quadrupole, etc.).
- J. Spin echoes, pulsed NMR techniques.
- K. Knight shift. (See NMR.)
- L. Chemical shift, paramagnetic shift in non-metals. (See NMR).[†] (This is not a metallic property, but is important in Knight shift data evaluations.)
- M. Spin diffusion.
- N. Isomer shift.
- O. Debye-Waller factor. (See MOS or XRA).[†]
- P. Ferromagnetic shift. (See FER).[†]
- Q. Electronic g-values and shifts; spectroscopic splitting factors.
- R. Nuclear coupling constants, $R-K$, A_{ij} , A_z ; hyperfine interaction constant; antishielding factors.
- T. Exchange stiffness parameter. (See FER).[†]
- X. Scattering cross-sections (including electronic, spinflip, etc.)

[†]Single daggers in these categories refer the reader to List No. 3 for a variety of techniques and their abbreviations.

Category 5

Quantum Description of Solids (QDS)

- A. Fermi velocity; Fermi momentum.
- B. Band structure.
- C. Cyclotron resonance frequency.
- D. Density of states.
- E. Effective mass, m^* (as determined by different methods).
- F. Fermi surface, Fermi energy surface dimensions.
- G. Anomalous skin effect; rf size effect, Gantmakher effect.
- H. de Haas-van Alphen effect; Oscillatory susceptibility effects in other properties (e.g. oscillatory Knight shifts (4K) are indexed 4K, 5H).
- I. Magnetoresistance (nonoscillatory).
- J. Magnetic breakdown; magnetic breakthrough.
- K. Shubnikov-de Haas effect (oscillatory magnetoresistance).
- L. Oscillatory magnetostriction; oscillatory magnetocaloric effect; other oscillatory effects not listed elsewhere.
- M. Magnetoacoustic effect, geometric resonance.
- N. Screening parameter, k_F , α_{eff} ; charge oscillations, RKKY theory; virtual states.
- O. Volume per electron; radius per electron, r_s ; metallic radius.
- P. Pseudopotential, model potential.
- Q. Angular correlation or anisotropy of emitted γ rays (including POS).[†]
- R. Disordered alloys: breakdown of translational periodicity (when not otherwise noted).
- S. Madelung constant; cohesive energy; electrostatic interaction energy.
- T. Various quantum states; total electronic angular momentum, J , etc.
- U. Electronic transitions (excluding single-particle transitions, which are listed under 6T); semimetal-to-metal transitions; Mott transitions; energy gaps.
- V. Binding, or dissociation energies, including those for foreign particles, pairs, vacancies, etc.
- W. Wave functions of electrons in metals.
- X. Crystal field splitting; exchange interaction energies and splitting; other characteristic energies of electronic states.
- Y. Relaxation times, electronic or other; all except $T_1-(4F)$ and T_2 (4G)—this code includes the cross-relaxation time, T_{12} .
- Z. Electron-like quasiparticles.

Category 6

Electromagnetic Radiation (RAD)

- A. Absorptivity.
- B. Emissivity (normal spectral).
- C. Transmission.

- D. Reflectivity, percent reflectance of (polished) metal.
- E. Extinction coefficient $K(\lambda)$.
- F. Fermi edge energy, absorption and emission edge energy.
- G. Photoemission spectra. (See PES.)[†]
- H. Quantum yield.
- I. Index of refraction, $n(\lambda)$, optical and dielectric constants.
- J. Impedance; reactance (for acoustic impedance, see 3F).
- K. Photoconductivity.
- L. $L \cdot S$ splitting of energy levels. (See also 4Q.)
- M. Magneto-optical constants; magneto-optical rotation; Kerr effect (also ferromagnetic); magneto-reflectance; Faraday rotation; saturation rotation; Verdet constant.
- N. Extinction potential.
- O. Plasma oscillations and resonances.
- P. Peak energy. (See SXS.)[†]
- Q. Excitonic effects.
- S. Synchrotron radiation.
- T. Transition probability.
- U. Energy level.
- W. Work function; thermionic; photoelectric; contact potential.
- X. Piezooptical properties.

Note: for line width, see 4A; for line shape, see 4B.

Category 7

Superconductivity (SUP)

- A. a of $\left\{ \frac{C_{es}}{\gamma T_c} = a \exp\left(\frac{-bT_c}{T}\right) \right.$, where C_{es} is the electronic specific heat in the superconducting state and γ is the coefficient of the linear term of the specific heat in the normal state.
- B. b of $\left\{ \frac{C_{es}}{\gamma T_c} = a \exp\left(\frac{-bT_c}{T}\right) \right.$, where C_{es} is the electronic specific heat in the superconducting state and γ is the coefficient of the linear term of the specific heat in the normal state.
- D. Skin depth, penetration depth.
- E. Energy gap for superconducting electrons; order parameter.
- F. Penetration depth of electron pairs, λ .
- G. Flux lines; flux flow; structure of flux lines.
- H. Critical field, H_c ; H_{c1} ; H_{c2} ; H_{c3} .
- J. Critical current, I_c .
- K. Landau-Ginzburg constant, K .
- M. Magnetization in superconductors.
- S. Superconducting state (to be used only when essential for clarity).
- T. Critical temperature, T_c .

[†]Single daggers in these categories refer the reader to List No. 3 for a variety of techniques and their abbreviations.

- V. Electron-electron interaction parameter, V (multiplied by the density of states = $N(E_F)V$).

- X. Coherence distance, ξ_0 , range of coherence, correlation length.

Category 8

Thermodynamics (THE)

- A. Heat capacity, specific heat, C_r , C_p .
- B. Nuclear hyperfine structure; spin specific heat (of ions in materials, etc.), nuclear specific heat.
- C. Electronic specific heat, γ , γ_{el} .
- D. Magnetic specific heat, including that due to magnetic clustering.
- E. Stark and other specific heats.
- F. Phase transformations and diagrams.
- G. Melting point.
- H. Boiling point.
- I. Latent heats.
- J. Entropy of mixing; heat of solution.
- K. Entropy (other); enthalpy, heat content; Gibbs free energy, Helmholtz free energy; etc.
- L. Cohesion energy (as measured thermodynamically).
- M. Solubility.
- N. Vapor pressure; evaporation; sublimation.
- O. Thermal expansion.
- P. Debye temperature.
- Q. Diffusion. (See DIF.)[†]
- R. Activation energy. (See DIF.)[†]
- S. Diffusion constant. (See DIF.)[†]
- T. Fermi-Dirac degeneracy temperature.
- U. Order-disorder; clustering.

Category 9

Soft X-ray Spectroscopy (SXS)

- A. Absorption spectra.
- B. Absorption coefficient.
- C. Characteristic energy losses of electrons.
- D. Isochromat spectra.
- E. Emission spectra (i.e., characteristic or band spectra).
- F. Fine structure.
- G. Fluorescence yield (spectra).
- H. Bremsstrahlung, continuous spectra.
- I. Intensity determinations, intensity ratios (when used together with 9S).
- K. K -spectra.
- L. L -spectra.
- M. M -spectra.
- N. N -spectra.
- O. O -spectra.
- P. P -spectra.
- Q. Higher multipolarity-, forbidden-, nondiagrammatic transitions (excluding satellites, 9S).
- R. Self-absorption effects.

- S. Satellites.
- T. Auger transition; level and lifetime broadening.
(Instrumental, or environmental broadening under OD).
- U. Ion neutralization spectra. (See INS.)†
- V. X-ray photoelectron spectroscopy, electron spectroscopy for chemical analysis (ESCA).
(See also PES and XPS.)†

Appendix 3. Special Materials Symbols

A Few Generalized Names for Groups of Materials.

Material codes which have proven to be useful for the inclusion in our files of review articles theoretical papers:

A—alkali metals.

G—garnet (marginal to our scope).

IG—iron garnet (marginal to our scope).

T—transition metals.

R—rare earth metals.

X—an element (metal or non-metal). This has also used to designate complexes in salts, together the descriptor, OO.

These symbols were chosen so that they differed from those of the elements in the periodic table.

15. SUPPLEMENTARY NOTES			
16. ABSTRACT (A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here.) Theory and experimental practice in the field of soft x-ray emission from metallic solids are briefly reviewed, and measurements on a number of systems are critically evaluated and compared with the results of other techniques and theory, with a view to establishing the pertinence of the soft x-ray measurements and further indicating specific guidelines for enhancing their value. In addition, an exhaustive annotated index of measured spectra is provided.			
17. KEY WORDS (Alphabetical order, separated by semicolons) Alloys; critical review; emission spectra; intermetallic compounds; metals; soft x-ray; spectra.			
18. AVAILABILITY STATEMENT <input checked="" type="checkbox"/> UNLIMITED.		19. SECURITY CLASS (THIS REPORT) UNCLASSIFIED	21. NO. OF PAGES 176
<input type="checkbox"/> FOR OFFICIAL DISTRIBUTION. DO NOT RELEASE TO NTIS.		20. SECURITY CLASS (THIS PAGE) UNCLASSIFIED	22. Price \$1.85

NBS TECHNICAL PUBLICATIONS

PERIODICALS

JOURNAL OF RESEARCH reports National Bureau of Standards research and development in physics, mathematics, and chemistry. Comprehensive scientific papers give complete details of the work, including laboratory data, experimental procedures, and theoretical and mathematical analyses. Illustrated with photographs, drawings, and charts. Includes listings of other NBS papers as issued.

Published in two sections, available separately:

• Physics and Chemistry (Section A)

Papers of interest primarily to scientists working in these fields. This section covers a broad range of physical and chemical research, with major emphasis on standards of physical measurement, fundamental constants, and properties of matter. Issued six times a year. Annual subscription: Domestic, \$17.00; Foreign, \$21.25.

• Mathematical Sciences (Section B)

Studies and compilations designed mainly for the mathematician and theoretical physicist. Topics in mathematical statistics, theory of experiment design, numerical analysis, theoretical physics and chemistry, logical design and programming of computers and computer systems. Short numerical tables. Issued quarterly. Annual subscription: Domestic, \$9.00; Foreign, \$11.25.

DIMENSIONS, NBS

The best single source of information concerning the Bureau's measurement, research, developmental, cooperative, and publication activities, this monthly publication is designed for the layman and also for the industry-oriented individual whose daily work involves intimate contact with science and technology—for engineers, chemists, physicists, research managers, product-development managers, and company executives. Annual subscription: Domestic, \$6.50; Foreign, \$8.25.

NONPERIODICALS

Applied Mathematics Series. Mathematical tables, manuals, and studies.

Building Science Series. Research results, test methods, and performance criteria of building materials, components, systems, and structures.

Handbooks. Recommended codes of engineering and industrial practice (including safety codes) developed in cooperation with interested industries, professional organizations, and regulatory bodies.

Special Publications. Proceedings of NBS conferences, bibliographies, annual reports, wall charts, pamphlets, etc.

Monographs. Major contributions to the technical literature on various subjects related to the Bureau's scientific and technical activities.

National Standard Reference Data Series. NSRDS provides quantitative data on the physical and chemical properties of materials, compiled from the world's literature and critically evaluated.

Product Standards. Provide requirements for sizes, types, quality, and methods for testing various industrial products. These standards are developed cooperatively with interested Government and industry groups and provide the basis for common understanding of product characteristics for both buyers and sellers. Their use is voluntary.

Technical Notes. This series consists of communications and reports (covering both other-agency and NBS-sponsored work) of limited or transitory interest.

Federal Information Processing Standards Publications. This series is the official publication within the Federal Government for information on standards adopted and promulgated under the Public Law 89-306, and Bureau of the Budget Circular A-86 entitled, Standardization of Data Elements and Codes in Data Systems.

Consumer Information Series. Practical information, based on NBS research and experience, covering areas of interest to the consumer. Easily understandable language and illustrations provide useful background knowledge for shopping in today's technological marketplace.

BIBLIOGRAPHIC SUBSCRIPTION SERVICES

The following current-awareness and literature-survey bibliographies are issued periodically by the Bureau:

Cryogenic Data Center Current Awareness Service (Publications and Reports of Interest in Cryogenics). A literature survey issued weekly. Annual subscription: Domestic, \$20.00; foreign, \$25.00.

Liquefied Natural Gas. A literature survey issued quarterly. Annual subscription: \$20.00.

Superconducting Devices and Materials. A literature survey issued quarterly. Annual subscription: \$20.00. Send subscription orders and remittances for the preceding bibliographic services to the U.S. Department of Commerce, National Technical Information Service, Springfield, Va. 22151.

Electromagnetic Metrology Current Awareness Service (Abstracts of Selected Articles on Measurement Techniques and Standards of Electromagnetic Quantities from D-C to Millimeter-Wave Frequencies). Issued monthly. Annual subscription: \$100.00 (Special rates for multi-subscriptions). Send subscription order and remittance to the Electromagnetic Metrology Information Center, Electromagnetics Division, National Bureau of Standards, Boulder, Colo. 80302.

Order NBS publications (except Bibliographic Subscription Services) from: Superintendent of Documents, Government Printing Office, Washington, D.C. 20402.
