PREFACE

We dedicate this volume to the memory of the late F. Russell Petersen, who was one of three original members of the project and who made invaluable contributions until his untimely demise in 1983. Russ was known for his CO₂ laser expertise, but his contributions and knowledge of physics extended over a much wider range. His dedication to manuscripts was meticulous, his wry humor was uplifting, and his presence tended to put things in the proper perspective. On occasion when debating whether a measurement was of sufficient accuracy, he would remark, "All we can do is the best we can." We have attempted to carry the work forward with this attitude. He left a legacy not only of his CO₂ lasers which are still in use, but also a sense of inspiration to those of us in the Time and Frequency Division of the National Institute of Standards and Technology (NIST).

We are grateful to our colleague of many years, D. A. Jennings, for his contributions which included writing the frequency synthesis programs, collaboration on some TDL measurements and some experiments with nonlinear crystals, as well as various discussions in general. M. D. Vanek has also been an especially valuable coworker in the past few years. We gratefully acknowledge the contributions of various visiting physicists who worked on the tunable diode laser (TDL) heterodyne measurements. The first was D. J. Sukle of Front Range Community College in Westminster, Colo. More recently guest researchers, A. Hinz and M. Schneider, from Prof. W. Urban's group in the Institut für Angewandte Physik of the Univ. of Bonn, have made especially valuable contributions in experiments with the liquid-nitrogen-cooled CO laser. L. Zink was also an important contributor following completion of his Ph.D. at the Univ. of Colorado. It was a pleasure working with every one of these Time and Frequency Division visiting scientists.

Of special value were the contributions by our friend, C. R. Pollock, during his tenure as a post doctoral fellow at NIST. These included not only his color center expertise in improving CO₂ frequencies, but also measurements at 2.3 μm on CO, and N₂O.

The results of other types of measurements were used in conjunction with the heterodyne measurements. We thank W. B. Olson, formerly of the NIST Molecular Physics Division, especially for his Fourier transform spectroscopy (FTS) measurements. Other major contributors to the accumulation of data upon which we also drew include A. Fayt, G. Guelachvili, J. W. C. Johns, and J. Kauppinen.

We are also very appreciative of the long term support of the measurement program and the encouragement to aggregate the results in book form by the chiefs of our organizational units, D. B. Sullivan of the Time and Frequency Division and A. Weber of the Molecular Physics Division. We thank J. Burkholder of NOAA and D. A. Jennings and M. Young of NIST for helpful comments regarding the manuscript. We gratefully acknowledge the partial support of this program over the past decade by the Upper Atmospheric Research Office of the National Aeronautics and Space Agency.

ABSTRACT

This new calibration atlas is based on frequency rather than wavelength calibration techniques for absolute references. Since a limited number of absolute frequency measurements is possible, additional data from alternate methodology are used for difference frequency measurements within each band investigated by frequency measurement techniques. Data from these complementary techniques include the best Fourier transform measurements available. Included in the text portion of the atlas are a description of the heterodyne frequency measurement techniques, details of the analysis including the Hamiltonians and least-squares-fitting and calculation procedures. Also included are other relevant considerations such as intensities and lineshape parameters. A 350-entry bibliography which contains all data sources used and a subsequent section on errors conclude the text portion.

The larger portion of the atlas consists of several hundred spectral-maps/facing-tables pages for the various calibration molecules. The spectral maps (as well as the facing tables) are calculated from the molecular constants derived for the work. The primary calibration molecules are the linear triatomics, carbonyl sulfide and nitrous oxide, which cover portions of the infrared spectrum ranging from 488 to 3120 cm⁻¹. Some gaps in the coverage afforded by OCS and N₂O are partially covered by NO, CO, and CS₂. An additional region from 4000 to 4400 cm⁻¹ based on CO is also included.

Key words: calibration atlas; carbonyl sulfide; carbon monoxide; carbon disulfide; IR frequency calibrations; IR wavenumber calibrations; nitric oxide; nitrous oxide; wavenumber tables.

Chapter I

INTRODUCTION

The primary purpose of this book is to provide an atlas of molecular spectra and associated tables of wavenumbers to be used for the calibration of infrared spectrometers. A secondary purpose is to furnish a detailed description of the infrared heterodyne frequency measurement techniques developed for this work. Additionally, we provide a bibliography of all the measurements used in producing these tables, as well as to provide a description of how those measurements were combined to calculate energy levels, transitions and uncertainties. We also provide useful related information such as line intensities, pressure broadening coefficients, and estimates of pressure shifts of spectral lines. This book does not include an exhaustive list of all the weaker transition frequencies currently available, especially for the less abundant molecular species. Such a list, containing over 10 000 transitions for OCS, is available, however, in floppy disk form from the authors. To put this book in proper perspective, some background, philosophy, and the status of existing atlases are discussed in the following sections.

Over the last 35 years (since the work of Downie *et al.* [1.1]) several compilations of infrared absorption spectra intended for the calibration of infrared spectrometers have appeared. Two compilations have been published by the International Union of Pure and Applied Chemistry (IUPAC) [1.2,1.3] and contain sections pertaining to the calibration of fairly low resolution (0.5 cm^{-1}) instruments. Other compilations [1.4-1.7] and other sections of the IUPAC compilations [1.2,1.3] were devoted to data intended for the calibration of high resolution instruments (resolution better than 0.5 cm^{-1}). This book falls into the latter category. Of the earlier compilations, only the work of Guelachvili and Rao [1.7] provides calibration data that are consistently more accurate than $\pm 0.01\text{ cm}^{-1}$.

A number of commercially available infrared spectrometers are capable of recording spectra with a resolution of 0.06 cm^{-1} or better. For the calibration of such spectrometers, one needs calibration data with an uncertainty smaller than 1/30th of the spectral linewidth. For a resolution of 0.06 cm^{-1} this means an accuracy of 0.002 cm^{-1} . For Doppler-limited resolution at room temperatures, a calibration accuracy of 0.0002 cm^{-1} or better would be desirable. The present work responds to these needs, even though it was recognized that state-of-the-art instrumentation (for sub-Doppler measurements, for example) could use even more accurate calibration data.

Most high resolution spectrometers are not capable of broad frequency scans. For the most accurate measurements the calibration should be applied to each spectral scan. This requires that at least one and preferably several calibration points be available within the scanning range of the spectrometer. For tunable diode laser spectrometers, a single scan may cover only 0.5 cm^{-1} , while for a Fourier transform spectrometer (FTS) a high resolution scan may cover hundreds of wavenumbers. This means that for many purposes calibration standards should be no more than 100 cm^{-1} apart, while for other purposes standards no more than 0.5 cm^{-1} apart are required throughout the infrared region of interest. Our work here presents a compromise between these two requirements.

In our opinion, all previous compilations of infrared wavenumber standards have suffered from the lack of a consistent effort to draw together a number of experimental measurements to arrive at a well determined set of molecular energy levels which could be used to determine frequency (or wavenumber) standards for a number of bands throughout the infrared spectral region. The present compilation provides a model for producing such frequency or wavenumber calibration data.

It is appropriate at this point to define some of the terminology used in this book clarifying an important distinction: in some places emphasis is placed on the difference between frequency measurements and wavelength measurements. All measurements that can be reduced to counting frequencies or frequency differences are frequency measurements, while all measurements that are

really comparisons of wavelengths (or wavenumbers), including counting fringes, are wavelength measurements. Fourier transform measurements, for instance are truly wavelength measurements even though counting (of fringes of a laser beam passed through the spectrometer for, example) may be involved.

Most measurements of infrared absorption spectra are made using grating or Fourier transform spectrometers. These measurements are truly wavelength measurements. They rely for calibration on measuring the difference in wavelength of some calibration feature and the feature of the spectrum to be determined. For FTS instruments, the position of the moveable mirror must be determined, while for grating instruments one is essentially calibrating the grating angle and the spacing of the grooves of the grating. Very often these instruments use more than one beam and compare the wavelength of a calibration beam with the beam carrying the spectra of interest. With FTS instruments a helium-neon laser beam is often used to monitor the mirror position. In other cases a single beam is used, but one cannot be certain that the beam properties are independent of wavelength. With all wavelength measuring instruments, it is extremely important that the calibration light beam follow precisely the same path through the spectrometer as the beam of light being measured. Problems of wavelength-dependent diffraction effects become very important for measurements intended to approach or exceed one part in 10^7 . One of the most insidious problems with wavelength measurements is the risk (or ease) of incurring systematic errors and the virtual impossibility of detecting them.

The great advantage of frequency measurements is that they simply depend on frequency counting techniques. Over the years considerable attention has been given to electronic techniques of frequency counting, and simple, accurate, well calibrated devices are readily available. The accuracy of frequency techniques does not depend on whether or not the beams are perfectly collinear or have parallel wavefronts. If a countable signal (25 dB signal-to-noise ratio) is obtained, it will be correct. The frequency of light does not depend on the medium, nor does it depend on the angle from which it is viewed.

Over the past decade we have striven to provide infrared heterodyne frequency measurements on the transitions and energy levels of several simple molecules, which are good candidates for frequency calibration standards. OCS, CO, and N₂O were chosen because they are stable, safe to handle, easily obtainable, and well documented in terms of good measurements reported in existing literature. Furthermore, they are particularly amenable to the accurate calculation of energy levels from a relatively simple Hamiltonian.

For these molecules a least-squares fit of many transitions (over 3000 OCS lines for example) has permitted the determination of all of the lower energy separations, using frequency differences referred to the primary cesium frequency standard. Due to statistical improvements from a large data base, transition frequencies between these energy levels can be calculated with greater accuracy than any single measurement with its attendant random errors.

Although we have had to use some FTS (wavelength) measurements to help define certain higher order rotational constants, for the most part the energy levels were determined from *frequency* measurements because they are less susceptible to unknown systematic errors than are wavelength measurements. Particular importance was attached to estimating the uncertainties in the transition wavenumbers; see the discussion in the chapter on errors (Chapter IV).

As with any good calibration standard, a number of different measurements were used in determining the energy levels and transition frequencies. However, only a few laboratories have used frequency measurement techniques in the infrared region and very few of the more accurate sub-Doppler frequency measurements have been made, so it is somewhat premature to claim the level of accuracy that we desire for infrared standards. Nevertheless we are encouraged by the convergence of different FTS measurements on the same values for the band centers as frequency measurements. Our publication of this atlas at this time is dictated by the need to provide good calibration data now, rather than await the arrival of a perfect atlas.

Of course the combination of OCS, CO, and N₂O gases is insufficient to provide calibration data everywhere within the infrared, so we have had to provide heterodyne measurements on other molecular species, such as CS₂ and NO in order to fill some of the gaps. The user will still note that many gaps remain in the coverage appearing by these tables. To some extent these gaps may be filled by using the data provided by the compilation of Guelachvili and Rao [1.6]. We also expect that future measurements will provide calibration data where none are currently available.

Since most workers are more comfortable with calibration data given in wavenumber units, the tables in this book are given in wavenumbers (cm⁻¹) even though the values were primarily determined from frequency measurements. The conversion from frequency units to wavenumber units was made by using the defined value of the velocity of light, c = 299 792 458 m/s. Since the tables are given in wavenumbers, we often use the terms wavenumber and frequency interchangeably in the text, but the term wavelength is reserved for quantities determined by wavelength measurements and must not be confused with frequency measurements.

Chapter II

TECHNIQUES USED FOR INFRARED HETERODYNE FREQUENCY MEASUREMENTS

Preliminary Considerations

At the present time the only frequency measurements that have been made on infrared absorption spectra of molecules treated in this book are those made in the NIST Boulder Laboratories [5.73]¹, the Harry Diamond Laboratories [5.88], the University of Lille [5.126], and University of Bonn [5.321]. The measurements of the N₂O laser transition frequencies made at the National Research Council of Canada [5.183] were also used here. This chapter describes the techniques that have been used in the NIST Boulder frequency measurements in order to familiarize the reader with the techniques that have evolved. We hope that such familiarity will give greater confidence in the accuracy of the results.

The first heterodyne frequency measurements on carbonyl sulfide (OCS) were made in the NIST Boulder Labs. A frequency-stabilized CO₂ laser served as the local oscillator for these heterodyne measurements. For this chapter, the term local oscillator is reserved for the fixed-frequency oscillator which carries the reference frequency information (near the frequency of the molecular transition to be measured) to the mixer or heterodyne detector. For each OCS measurement, the frequency of a tunable diode laser (TDL) was locked to the peak of a selected (OCS) absorption line with an assigned uncertainty, δ_{lock} , given by $\pm \frac{1}{2} \Delta\nu_{\text{Dopp}} / \text{SNR}$, where $\Delta\nu_{\text{Dopp}}$ is the full Doppler width at half maximum and SNR is the signal-to-noise ratio of the first derivative lock signal. The frequency of the locked TDL was compared with the frequency of the CO₂ laser frequency standard by mixing the TDL and CO₂ laser radiation in a fast (1 GHz, 3 dB bandwidth) HgCdTe detector. The resulting difference-frequency beatnote was measured with the aid of a spectrum analyzer and a marker oscillator (a conventional oscillator whose frequency was tuned to the center of the beatnote). The frequency of the OCS transition was the sum of the CO₂ laser frequency and the appropriately signed beatnote frequency.

Similar sets of measurements have also been made in which the TDL was heterodyned against a CO laser local oscillator (or transfer oscillator). In these cases the frequency of the CO laser was simultaneously measured relative to a frequency synthesized from combinations of CO₂ laser standard frequencies [5.94]. In a third type of measurement, a tunable color center laser (CCL) was the local oscillator. In this case, the CCL (which was locked to the transition of interest) was heterodyned directly with a frequency synthesized from CO₂ laser standards [5.304]. All three techniques are discussed in detail later in this chapter.

The determination of the spectroscopic constants for a particular band of a selected molecule was based on a number of measurements such as those described above. Some preliminary considerations for selection of the particular transitions to be measured were as follows. A review of the set of transitions of a particular band of interest served as a starting point. This set was reduced immediately to those transitions whose frequencies were within 10 GHz (the approximate combined bandpass limit of the HgCdTe detector-rf-amplifier that was used) of the frequency of a CO₂ laser or a CO laser transition frequency. Those transitions which were blended with nearby transitions from other bands or isotopic species of the molecule of interest were deleted from this subset. An attempt was then made to select (from the candidates available at this point) and measure those transitions which permitted the best determination of the constants. As a minimal set, these included low-*J* transitions in both the *P*- and *R*-branches in order to determine the band center, intermediate-*J*

¹ Rather than repeat references given in the bibliography (Chapter V), they are referenced as [5.XX]. The references at the end of Chapter II are referenced as [2.XX], etc.

transitions for determining the *B*-value, and high-*J* (60 to 100 depending on the particular band strength) transitions for the centrifugal distortion constants. If possible, additional measurements were made in order to cover the entire band with the smallest gaps possible. This served to increase the redundancy and to minimize extrapolated values in the calculated frequencies.

In some instances, it was not possible to realize the above goals. The region of interest often covered 100 cm⁻¹ or so and typical TDL frequency coverage (guaranteed by the vendor) was 15 cm⁻¹, although many times the coverage turned out to be larger. Within the 15 cm⁻¹ region, there were usually holes in coverage and it was necessary to buy the TDLs in pairs. An additional factor which was not within the experimenter's control concerned frequency holes (regions where the beatnote was not discernible) in the bandpass of the combination of the HgCdTe detector and the rf amplifiers which follow it. These two factors were the final restrictions on the set of measurements which were used to determine the spectroscopic constants for the band.

CO₂ Laser Standard Frequencies

The 1.25 m long CO₂ lasers used in these measurements were constructed by the late F. R. Petersen [2.1]. These had gratings for line selection and output mirrors typically coated for 85% transmission. In order to render the output beams nearly parallel, compensated output coupling mirrors were utilized. By compensated, we mean that the anti-reflection coated surface of the mirror was formed with a smaller radius of curvature than the reflecting concave surface. Irises at both ends were available for mode discrimination and control of the power output, which was 1 to 3 W. These lasers were equipped with internal absorption cells (filled to a pressure of 5.3 Pa (40 mTorr) of carbon dioxide) to provide frequency stabilization by the Freed-Javan technique [2.2]. Although some seven isotopic combinations of CO₂ have been the object of extensive frequency measurements, only three isotopes have been used for the NIST heterodyne frequency measurements. These were ¹²C¹⁶O₂ (626), ¹³C¹⁶O₂ (636) and ¹²C¹⁸O₂ (828). [The shorthand notation used here involves the last digits in the rounded nuclear masses for the three atoms, O, C, and O. For example, the ¹⁶O¹²C¹⁶O laser is designated (626).] In addition to the 1.25 m lasers, a 2 m laser with a similar grating and compensated output mirror (but with an external absorption cell for stabilization) was used for high-*J* and hot band transitions. This longer laser has been operated with the three different isotopic gases.

The frequencies of the CO₂ transitions were initially related to the cesium standard in an NBS experiment published in 1973 (Evenson *et al.* [2.1]). This was an experiment in which the frequency of the methane stabilized HeNe laser was measured. A new wavelength measurement (Barger and Hall [2.3]) of the same methane transition was concurrently completed. The combination of these two quantities led to a new (at that time) value for the speed of light, 299 792 456.2(1.1) m/s [2.4].

Figure 1a shows a block diagram of the frequency chain used in the methane frequency measurement. For the sake of brevity, the values of the offset frequencies in that experiment are not discussed here; the interested reader is referred to the original paper [2.1]. The essential details of the chain are as follows. An X-band klystron was phase-locked to a quartz crystal oscillator and the X-band frequency was accurately measured by a counter which was referred to the cesium standard. The seventh harmonic of the X-band frequency was used to phase-lock a 74 GHz klystron. The twelfth harmonic of the 74 GHz oscillator was used as a reference to frequency lock an HCN laser. The twelfth harmonic of the HCN laser frequency was close enough to the frequency of the 28 μm water vapor laser for the difference to be made up by the frequency from a phase-locked klystron. Three harmonics of the water vapor laser and another phase-locked klystron frequency moved the chain up to the CO₂ laser region, to the transition R₁₁(10). Another frequency from a phase-locked klystron moved the chain from the 9.3 μm band to the 10.6 μm band, to R₁(30) in particular. Three harmonics of the frequency of the R₁(30) transition brought the chain up near the frequency of the methane-stabilized HeNe laser. (The measured values for these transitions are indicated in the boxes in Fig. 1a and the values are given in terahertz.) Petersen *et al.* [2.5] subsequently used the measured

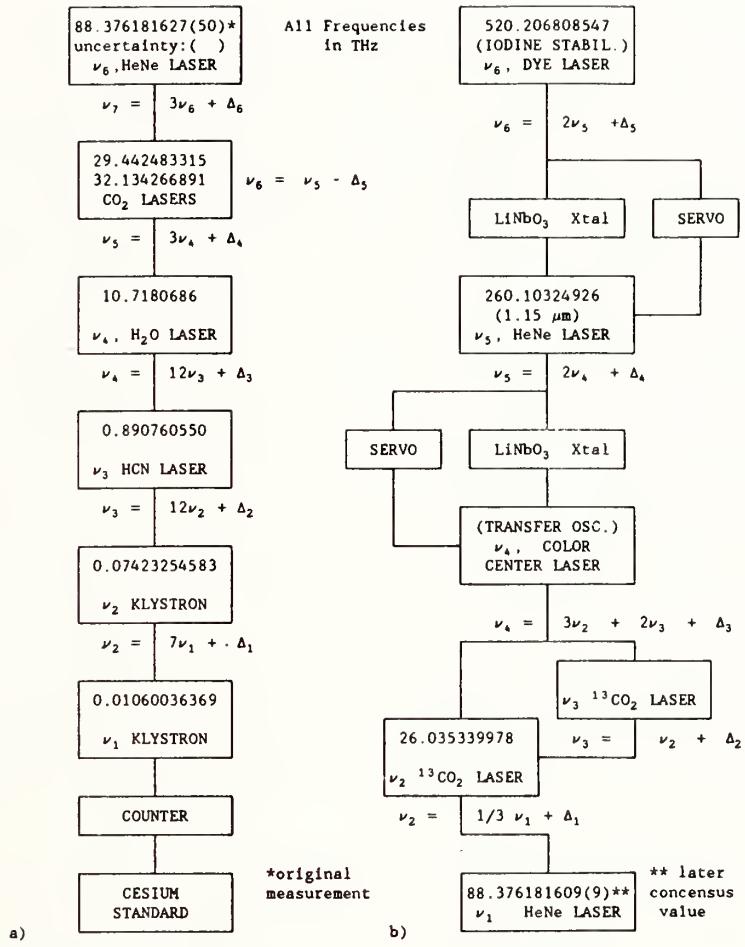

Fig. 1. Diagrams of Schemes Relating CO₂ Frequencies to the Cesium Standard.

values for these two transitions to make additional CO₂ laser frequency measurements and to generate tables of transitions for both the I and II branches.

Since 1973 several different international laboratories have repeated this frequency measurement experiment with minor variations and confirmative measurements have led to a new value for the speed of light which is now defined to be 299 792 458 m/s [2.6]. The proposal and expected acceptance of this new definition provided impetus to extend frequency measurements to the visible portion of the spectrum. Major efforts at NIST-Boulder accomplished this objective and experiments were published in 1983 by Pollock *et al.* [2.7], and by Jennings *et al.* [2.8].

Figure 1b shows a diagram of the chain used to measure the iodine transition at 520 THz (576 nm) [2.7]. The details of this chain are of secondary importance for purposes here, but a sketch will be provided. The starting point was the stabilized HeNe laser at 3.39 μm . A best value for this transition was determined from the most accurate results of the international measurements. The P_i(50) transition of a stabilized ¹³CO₂ laser was measured relative to the stabilized HeNe laser, which was assumed to oscillate at the frequency 88 376 181.609 \pm 0.009 MHz. The frequency resetability of the CO₂ laser was reported to be within 5 parts in 10¹¹, which is better than the 1 part in 10¹⁰ uncertainty in the frequency of the HeNe laser. (Petersen *et al.* [2.9] later used this accurately measured P_i(50) transition to measure other CO₂ transitions and to generate improved calibration tables.)

To continue with the sketch, we note that a second $^{13}\text{CO}_2$ transition $P_1(52)$ was phase-locked to $P_1(50)$ by means of a stabilized 62 GHz klystron. The synthesis scheme used to arrive at the CCL frequency is indicated in Fig. 1b. The remainder of the chain was locked from the top down. That is, the second harmonic of the 1.15 μm HeNe laser frequency was locked to the frequency of the dye laser, which was in turn locked to the frequency of the "o" hyperfine component of the visible (576 nm) $^{127}\text{I}_2$ 17-1 P(62) transition. The CCL was in turn locked to the frequency of the 1.15 μm HeNe laser. Both the HeNe and the CCL served as transfer oscillators in this scheme. The comparison was made at the CCL- CO_2 laser point of the chain. In a separate experiment, the HeNe laser was locked to its Lamb dip and that frequency was determined. The $^{13}\text{CO}_2$ frequency listed in Fig. 1b is the frequency used in the 520 THz determination (it was frequency-offset-locked from a stabilized CO_2 laser to remove the dither) and is not the frequency of the center of the transition. The values for the two higher frequencies are given in Fig. 1b. Additional details may be found in Ref. [2.7].

The frequencies currently used for the $^{12}\text{C}^{16}\text{O}_2$ isotope are based on the most recent values (which made use of the above results) which were published in 1983 by Petersen *et al.* [2.9]. The stated 1 sigma uncertainties for the calculated tables based on these measurements are smaller than 5 kHz for the CO_2 transitions ($J < 40$) which were used in the infrared heterodyne measurements. Subsequent CO_2 measurements relative to the values of Petersen were made by Freed and coworkers at MIT [2.10]. The uncertainties in the MIT values are also less than 5 kHz for the $^{13}\text{C}^{16}\text{O}_2$ transitions (and less than 10 kHz for the $^{12}\text{C}^{18}\text{O}_2$ transitions) used here. Note that the 1.25 m CO_2 lasers used in the TDL measurements were first generation lasers and that the numbers given in Tables 1, 2, and 3 were obtained using second generation lasers. Even if the reproducibility in the laser lock for the older lasers were somewhat poorer (an uncertainty of about 50 kHz was allowed for the realization of the frequencies) it would be of negligible consequence for the results presented here. The transition frequency values (for the three carbon dioxide isotopes) which were used are given in Tables 1, 2, and 3.

Listed in Table 4 are the frequencies and wavenumbers for some transitions of the $^{13}\text{CO}_2$ hot band ($01^11-[11^10,03^10]$,) which extend the useful range of standard reference frequencies. These frequencies were determined from NIST measurements in which the 2 m CO_2 laser and an external reference cell were used. While measurements were made on both the 636 and 626 isotopes [2.11, 2.12], only the 636 frequencies were used for subsequent TDL measurements. The two sigma uncertainties for the transitions used for OCS measurements were less than 80 kHz.

For the measurements in the CO_2 laser region, the CO_2 frequencies given in some of our papers were rounded to the nearest 0.1 MHz. However, the full accuracy of the CO_2 frequencies was retained for calculating or synthesizing the CO frequencies and the CO frequency was then rounded to the nearest 0.1 MHz.

Heterodyne Frequency Measurements with the TDL and CO_2 Laser (860 to 1120 cm^{-1})

The measurement procedure has evolved over the course of this work [5.73, 5.83, 5.87, 5.221, 5.230, 5.243]. A brief history of the TDL refrigeration evolution and the details of the apparatus and procedure currently in use will be described here. For considerations involving the TDL, refer to Fig. 2, which is a block diagram of the measurement scheme recently used for some N_2O measurements [5.243].

The first commercially available TDL spectrometers featured liquid helium Dewars as the refrigeration system. Our initial system used a 4 l helium Dewar. It was necessary to use an assortment of stainless steel shims between the Dewar's OFHC (oxygen free high conductivity) copper cold surface and the TDL in order to vary the temperature (and operating wavenumber) of the TDL. The use of liquid helium was inconvenient, changing shims was cumbersome, and the resulting temperature cycling of the TDLs was reputed to shorten their lifetime; nevertheless a narrow TDL linewidth was generally observed.

Table 1. Frequencies (MHz) for the 626 carbon dioxide laser.

a) The number in parentheses is the estimated $1-\sigma$ uncertainty in the last digits.

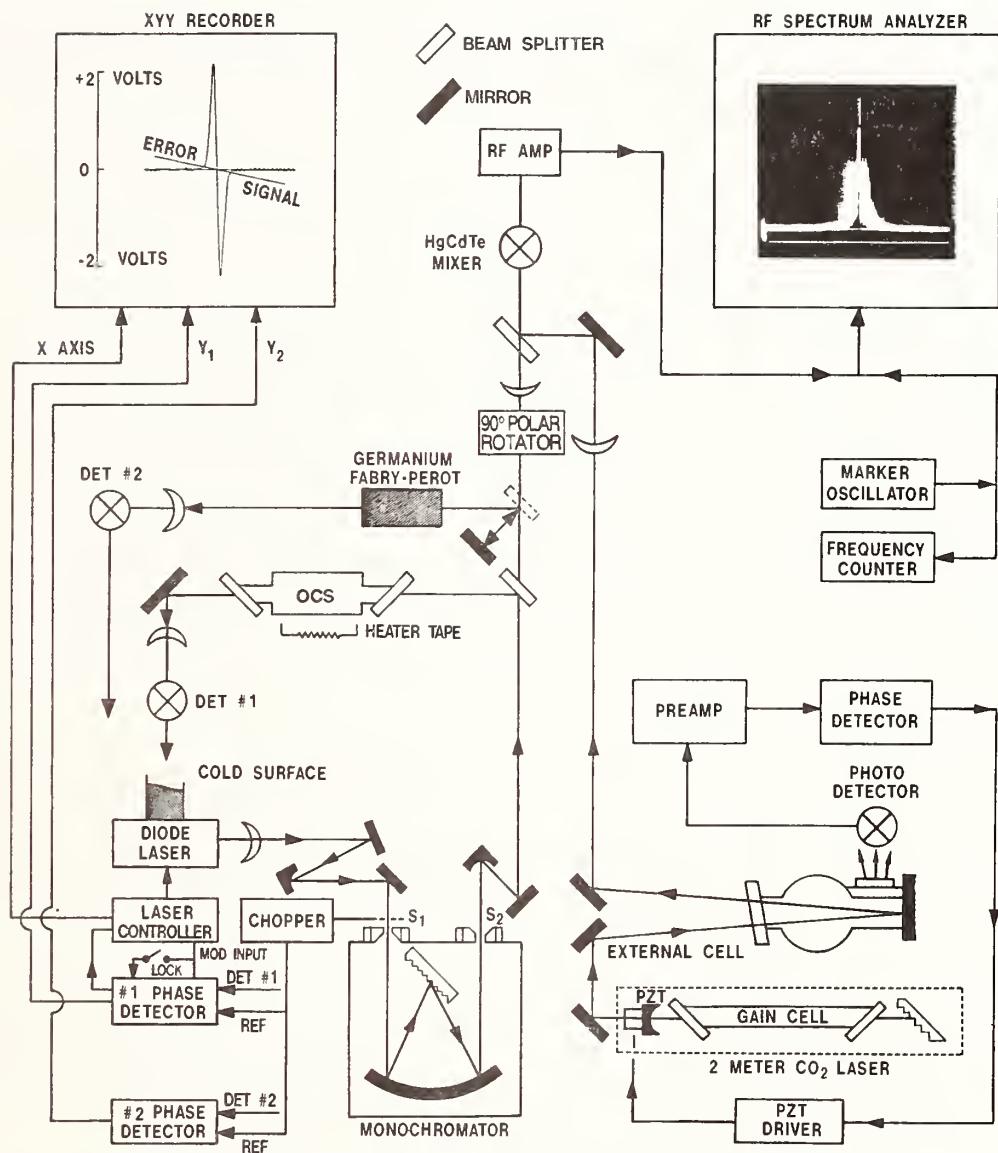

Fig. 2. Block diagram of scheme used for heterodyne measurements with a CO₂ laser.

As the demand for TDLs increased, vendors began experiencing difficulties in growing semiconductors that would meet the customers' specified frequency region while operating in the 4 to 10 K range. The materials problem became more tractable as the temperature constraint was removed by selling to the customers closed-cycle coolers with 10 to 70 K operating capabilities. Soon it became nearly impossible to obtain TDLs operable at helium temperatures. Most of our measurements were made using a closed-cycle cooler. This was an improvement in many areas, however in spite of an isolation scheme, some residual vibrations from the cooler's piston were transmitted to the TDL, resulting in the famous jitter linewidth which is familiar to all TDL users. The vendor has made two additional isolation improvement schemes available and while these appear worthwhile, they are still not the ultimate solution.

Currently, the NIST liquid helium Dewar has been modified to accommodate a four-laser mounting platform (including the heater coils and temperature sensing diodes) from a closed-cycle

cooler. While helium consumption is too high for most of the TDLs available to us, this does offer promise with the recent advent of the higher temperature MBE (molecular beam epitaxy) TDLs. A few of these are now available and operate in the temperature range accessible with liquid nitrogen (70 K to 120 K if a heater is available).

Both the Dewar and closed-cycle refrigerator are interchangeable in that they were compatible with the laser control module (current controller) and temperature control system. Both the control module and temperature controller have also been upgraded to reduce current noise and temperature instabilities; these upgrades have proved worthwhile. The particular type of refrigeration is not specified in Fig. 2.

After passing through the AR-coated ZnSe window of the refrigeration stage, the TDL radiation was collimated with an AR-coated $f/1$ lens and directed with a flat mirror and off-axis parabolic mirror into a 0.8 m Ebert-Fastie monochromator. A second off-axis parabolic mirror recollimated the TDL beam after it emerged from the monochromator. A portion of the beam was split off and passed through an absorption cell (containing the molecule of interest, N_2O in this case) to a detector which was used initially in recording the spectra and later for the TDL locking procedure. The monochromator and a solid three inch germanium etalon were used to help identify the particular molecular transition of interest. Once the transition had been identified, the kinematic mirror mount directing the TDL beam through the etalon was removed and the TDL beam was then focused on the HgCdTe mixer element. At this time, both the entrance and exit slits were removed from the monochromator, in order to eliminate the fringes or channel spectra which the slits may cause via feedback to the laser.

At this point in the procedure, it was useful to measure the TDL linewidth by heterodyning its output with that from a CO_2 laser (or CO laser as described in the next section). TDL linewidths of several hundred megahertz are not uncommon at higher currents (higher gains) when viewed for integration times of several seconds. Next, the current was reduced (while increasing the temperature to maintain frequency) until an acceptable (10 to 30 MHz), or at least the narrowest attainable, linewidth was achieved for a measurement.

TDL Locking Procedure and Minimization of Error

Assuming the best conditions, that is, a strong TDL (0.5 mW for example) with a single mode that has a flat power versus wavelength curve, a narrow TDL linewidth, and a well isolated and intense line for a locking reference, we could likely make a measurement with an uncertainty of less than 1 MHz. While these conditions sometimes prevail, more often, they do not.

It is germane to discuss here the TDL locking procedure and some of the ways we have minimized errors that can creep into a measurement. After the chopper was removed from the TDL beam path, the TDL was frequency-modulated at 4.5 kHz and a first derivative scheme was used to lock the TDL frequency. In this procedure, the frequency of the radiation output of the TDL was tuned from well below the molecular transition to well above it, and the resulting derivative signal (including the baseline and the absorption line) was traced by the recorder. (See derivative trace in the xyy recorder box in Fig. 2.) The frequency was returned to the low value and then the recorder signal monitored as the trace was followed to the derivative midpoint for locking. [Note: The derivative trace in Fig. 2 has a line labeled "error signal" superimposed on it. This error signal was recorded while scanning the TDL current both up and down while the laser was locked with moderate gain. For "infinite gain" the line becomes horizontal, or zero volts everywhere; for nearly zero gain, the line has a slope near that of the derivative signal. The slope of the error signal may be chosen (by adjusting the loop gain) to any value between these limits. By proper adjustments of the gain value and the TDL current the TDL may be "locked" (or stabilized) to nonzero values.] A low gain was used in the lock loop and the recorder pen position was monitored during the measurement. One of the reasons for this was that the TDL mode generally was not flat over the region of the line of

interest. Rather than locking the TDL to the zero-voltage point, the TDL frequency was locked to a point where the derivative signal crossed the existing baseline derivative. The sources of error to be avoided are not only sloping background (with resultant zero offset in the derivative signal), but also possible instrumental zero offsets from the lock-in amplifier. Both sources become magnified when dealing with weaker TDL modes or low level absorption and a very high sensitivity on the lock-in amplifier, and the procedure outlined above was essential.

Since the background slopes may have either sign and compensation for zero offsets may be either too large or too small, these errors are random when spread over measurements of several different lines. In the case of strong absorption lines and a powerful TDL mode, the difference between the lock point and 0 V was generally negligible compared to other sources of error.

Another obvious source of error in determining the location of the center of the molecular absorption line was noise. In addition to TDL amplitude fluctuations and detector noise, feedback fringes or channel spectra are also included, although some of amplitude noise can be attributable to feedback. Several techniques were used to minimize sources of error. The frequency of the TDL modulation was chosen to be higher than that of the TDL amplitude fluctuations and higher than the upper frequency of typical detector noise. The usual techniques for fringe reduction, including the monochromator slit removal alluded to earlier, tilting of various optical elements in the TDL beam path (particularly the detectors) were all employed. Cells of absorbing gases (for isolation) were placed in the TDL beam path in a few instances although it was not possible for most spectral regions.

Measurement of the Difference Frequency between the TDL and Gas (CO_2 or CO) Laser

The portion of the TDL beam passing through the first beam splitter in Fig. 2 has its polarization rotated by 90° to be parallel to the gas laser beam polarization. (The TDL polarization was assumed to be in the plane of the junction; however, a sizeable perpendicular component may also exist.) The TDL beam was then focused (typically, $FL = 12.5$ cm) through a second beam splitter onto the HgCdTe fast detector or mixer which had an element with an area of 0.1 mm^2 . The 3 dB bandwidth of this detector was 1 GHz. Power from the gas laser was focused with a 40 cm focal length lens and then reflected off the beam splitter (NaCl was chosen to keep the local oscillator power below 10 mW) in such manner as to make the gas laser beam collinear with the TDL beam and to make the beam waists coincide.

After initial observation of the beatnote, the amplitude was maximized by fine adjustment of the focusing lenses. It was also necessary to ascertain that the beatnote observed on the spectrum analyzer was the one of interest. This was particularly relevant when using the CO laser. On some occasions, the first beatnote observed was due to the TDL radiation mixing with that from a nearby unintended CO transition which could not be prevented from lasing along with the CO transition of interest. Multimode TDLs are also the source of extraneous beatnotes.

Once we determined that the observed beatnote was the one of interest, the TDL frequency was scanned by changing the current and the beatnote was followed on the spectrum analyzer from zero frequency up (or down) to the molecular feature to be measured. The scan rate was reduced to a lower value and the progress of the beatnote carefully monitored relative to the derivative signal. The TDL frequency was then locked to the desired point on the derivative signal which was displayed on the recorder. The beatnote was then averaged with the persistent screen averaging feature of the spectrum analyzer, and a marker oscillator was adjusted to the center of this averaged display. (A representative beat note is shown in the right hand portion of Fig. 2. Here the frequency span of the spectrum analyzer display was 100 MHz.) The marker oscillator frequency was counted and the measurement repeated a number of times (10 to 20, depending on the reproducibility of the measurements).

Minimization of the Difference Frequency Uncertainties

Ideally, the best method to determine the difference frequency between the TDL and the gas laser would be to use an electronic counter. However, the signal-to-noise ratio (S/N) of the beatnote and the frequency modulation associated with the cold head and compressor generally precluded this approach. The next best approach is that described in the preceding paragraph.

The best measurements were those made with a liquid helium Dewar; the beatnote was essentially stationary on the spectrum analyzer. However, the rapid He consumption rates for higher temperature TDLs made this choice impractical as well as inconvenient. When the compressor was used, the beatnote had a jitter linewidth associated with it and its frequency fluctuations made determination of the beatnote center more difficult. A wide variation of jitter linewidths from many different TDLs has been observed over an extended period. The current tuning rates (60 to 1600 MHz/ma) and linewidths due to current noise vary widely from one TDL to another. In a similar fashion the jitter linewidth varies greatly from one laser to the next, due to varying sensitivity to vibrations associated with the compressor/coldhead. Sometimes an apparent jitter linewidth was due to feedback, however this was generally recognized and steps were taken to minimize it. Beatnotes ranging in width from a few megahertz (10 μm TDLs in a liquid helium Dewar) to 60 to 100 MHz (6 μm TDLs in a closed-cycle cooler) were observed during the measurements. However the larger values (in the 5 to 6 μm region) were observed prior to the currently implemented improvements in the vibration isolation system. The most recent approach was to adjust the current modulation for the derivative lock such that the beatnote linewidth was not broadened beyond the jitter linewidth. (This was subject to retention of a suitable S/N for the lock signal.)

The frequency-modulated beatnote was observed at a repetitive rate on the spectrum analyzer. The pulse rate of the closed-cycle cooler was asynchronous with both the modulation rate and the spectrum analyzer sweep rate. As a result, the beatnote observed on the spectrum analyzer made small and slowly varying excursions about an average value. This led to some scatter in the measured value for the beatnote center frequency. Some experiments were conducted to check the compressor-induced fluctuations as a source of systematic error. Typically, 20 measurements were made with the compressor on, and the marker oscillator frequency was adjusted to the resultant average value. The TDL lock point was then rechecked and the compressor was turned off (eliminating the jitter from the beatnote) momentarily. The jitter-free beatnote was observed for a few seconds in this configuration. To date no appreciable deviation of the jitter-free beatnote from the marker oscillator has been observed.

On some occasions, the beatnote envelope was slightly asymmetric. Generally, two different operators have determined the center value and some subjective disagreement was apparent. In a recent set of measurements of 20 transitions the average value of 10 measurements each from two operators varied by 2.5 MHz. This was well within the assigned uncertainty of 7 MHz for the measurement. More often, the average values from different operators agree within a fraction of 1 MHz.

Another difficulty in these measurements was the presence of "holes" in the frequency coverage of the detector-rf-amplifier combination. In some instances, these frequency holes were associated with connector lengths and their effect could be minimized (by moving the hole to another frequency) by using line stretchers or by changing cables. Some holes were associated with lengths of connecting elements in the detector, and for practical purposes could not be eliminated. In other cases, holes were associated with amplifiers themselves; sometimes they precluded making measurements. In a few instances shallow holes have led to systematic errors. This occurred when only very weak TDL modes were available and the S/N for the beatnote was small (3 to 4 dB for example). Often the beatnote envelope was fairly wide (50 MHz or greater). In cases like these, one side of the beatnote envelope can overlap a hole and the apparent line center will be shifted. This has happened in a few instances but the error was apparent in the fitting process. In these cases, a repetition of the measurement with

a different TDL and a much stronger beatnote gave a different and better fitting result. Such holes generally remain at the same frequency and experience has shown which frequency regions to avoid.

Measurements with a CO Laser Transfer Oscillator and CO₂ Laser Synthesizer

Near the inception of this program, a CO laser stabilization scheme on low pressure CO laser discharges had been demonstrated by Freed [2.13]. More recently, a stabilization scheme using optogalvanic detection has been reported by Schneider *et al.* [2.14]; neither of these schemes was operable over the entire range required for our measurements. Some values of CO frequencies in the literature (available when the measurements in this region began) were in error by over 50 MHz. Since the goal of this measurement program was to be able to make measurements with a 3 MHz uncertainty, it was necessary to measure the frequency of the CO laser at the same time that the CO laser-TDL difference frequency measurements were made on N₂O and OCS transitions. This process required the use of the CO laser as a transfer oscillator, and the CO laser frequency was measured relative to a frequency generated by a CO₂ laser synthesizer [5.94, 5.221, 2.15].

Two different CO lasers were used in this manner. One was a sealed-off laser which was cooled by flowing alcohol through dry ice and then through a jacket around the discharge tube. This operated over the frequency range from 1600 to 1900 cm⁻¹ (corresponding to lower vibrational quantum numbers ranging from $v'' = 20$ to $v'' = 6$). The second CO laser was a flowing gas laser which was cooled by liquid-nitrogen and operated from 1220 to 1600 cm⁻¹ ($v'' = 36$ to $v'' = 20$). After installation of a shorter wavelength grating and an appropriate output mirror, operation was extended to the 1900 to 2080 cm⁻¹ region ($v'' = 6$ to $v'' = 1$). Additional details regarding the liquid-nitrogen cooled CO laser may be found in the literature [5.125, 5.224, 5.231].

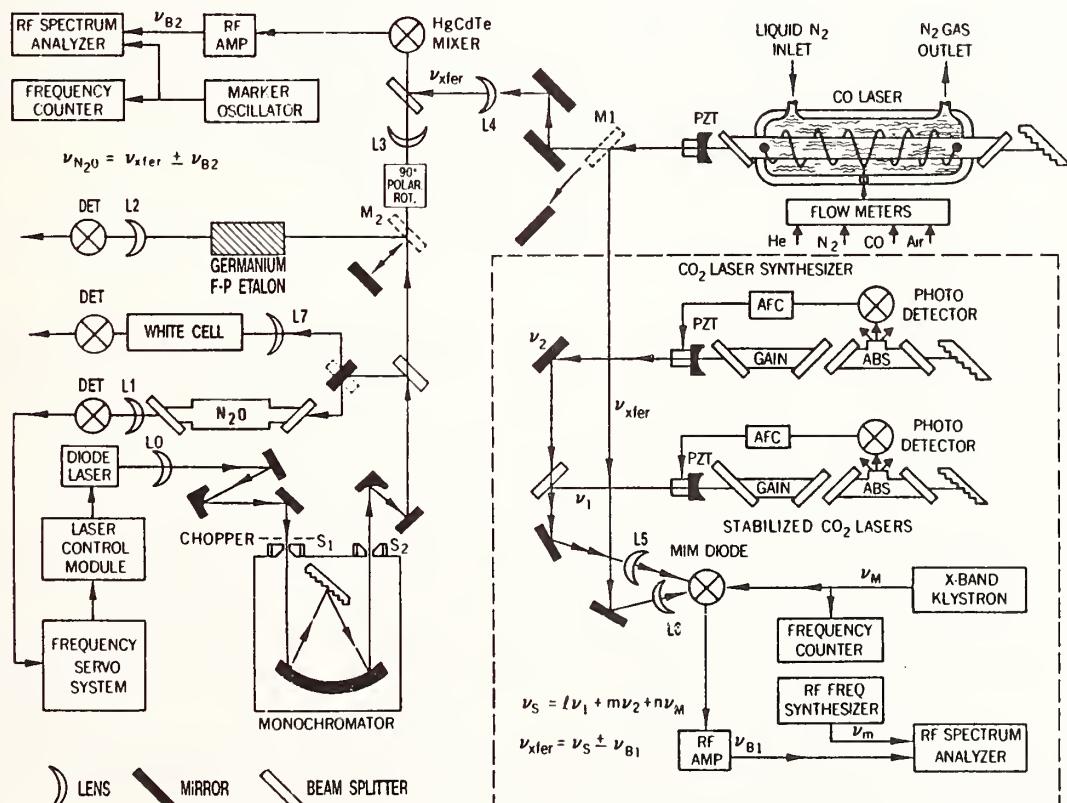

Fig. 3. Block diagram of scheme used to make heterodyne frequency measurements with a CO laser. The CO₂ laser synthesizer is shown in the dashed box.

Figure 3 shows a block diagram for making frequency measurements with the CO laser. The dashed outline shows the kinematically mounted mirror, M_1 , in position for measuring the CO laser frequency relative to the CO_2 synthesizer, which is shown enclosed in the large dashed box. The synthesizer consists of two stabilized CO_2 lasers, a phase-locked microwave oscillator and frequency counter, a metal-insulator-metal (MIM) diode, and a combination of an rf amplifier, rf spectrum analyzer, and a 0 to 1.0 GHz rf frequency synthesizer. When radiation from the two CO_2 lasers and the microwave oscillator were coupled to the MIM diode, currents were generated at a synthesized frequency, ν_s , given by

$$\nu_s = \ell\nu_1 + m\nu_2 + n\nu_M,$$

where ν_1 and ν_2 were the frequencies of the CO_2 laser frequency standards, and ν_M was a microwave frequency. The quantities ℓ , m , and n are integers which are allowed both positive and negative values. The quantity $[1 + |\ell| + |m| + |n|]$ is called the mixing order; the synthesized currents generally become weaker as the mixing order is increased. Mixing orders vary from 3 or 4 near 50 THz to 7 or 8 near 38 THz, the frequency at the longest wavelength operation of the CO laser used in these measurements. Typical values might be $\ell = 3$ or 4 , $m = -2$ or -3 , and (with the use of an X-band klystron) n was restricted to 0 , ± 1 , or ± 2 .

When the CO laser radiation was focused on the MIM diode, an additional current at the CO laser frequency, ν_{CO} , was generated in the diode and it combined with the synthesized frequency, ν_s , to produce a difference frequency beatnote at a frequency, ν_{B1} . (The microwave frequency was chosen so that this beatnote was within the 1.2 GHz range of the spectrum analyzer in use.) The beatnote was amplified, displayed on the spectrum analyzer, and its excursion was noted as the CO laser was tuned through its gain bandwidth. The beatnote was positioned at the center of this excursion (a determination of the frequency of the CO transition was a secondary objective) and a marker signal from the rf synthesizer was used to mark this frequency point on the spectrum analyzer. The rf synthesizer reading was then used as the value for ν_{B1} and the CO laser (which was not locked) was periodically readjusted to return the beatnote to the assigned frequency.

The frequency of the CO laser (transfer oscillator) was then

$$\nu_{\text{CO}} = \nu_{\text{transfer}} = \nu_s \pm \nu_{B1}.$$

The full accuracy of CO_2 frequencies was used for the ν_s calculation. An uncertainty of 0.3 MHz (which includes allowance for drift between readjustments) in the transfer oscillator was included in the measurement uncertainty of the molecular transition, which was given by

$$\nu_{\text{mol}} = \nu_{\text{transfer}} \pm \nu_{B2},$$

where ν_{B2} was the beatnote between the TDL and the transfer oscillator. The transfer oscillator frequency and beatnote frequency are both rounded to the nearest 0.1 MHz. The main uncertainty was again due to the TDL linewidth which was discussed in the early part of the chapter.

The most recent advance in making heterodyne frequency measurements with TDL's involves a computer-controlled, frequency offset-locking (CCFOL) scheme. Freed *et al.* [2.16] demonstrated the use of a frequency offset lock combined with a frequency synthesizer to control the output frequency of the TDL. We have combined that technique with the scanning and data-logging technology used in this laboratory for other measurements [2.17-2.19] to obtain accurate data on $d\nu/dP$, the pressure-induced frequency shifts, in the rovibrational spectrum of OCS. The potential for better absolute frequency measurements was also demonstrated.

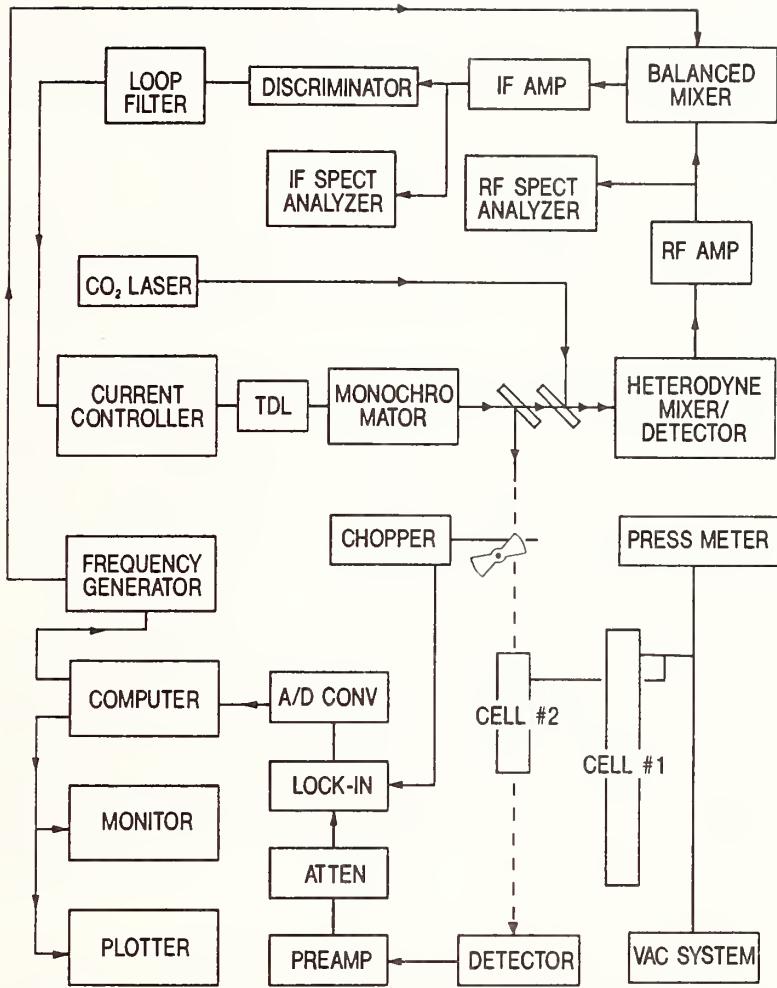

Fig. 4. Block diagram of a computer controlled frequency offset-locked spectrometer.

Figure 4 shows a block diagram of the apparatus used for this type of measurement. The output beams from a TDL and a CO₂ laser frequency standard were focused with separate lenses and then combined with a ZnSe beam splitter and directed to a HgCdTe heterodyne mixer/detector which produced a beatnote at the difference frequency, ν_B , between the two lasers. The beatnote was amplified in an rf amplifier and displayed on an rf spectrum analyzer. A balanced mixer was used to down-convert the beatnote at frequency ν_B to a nominal 160 MHz, the region of operation of the IF amplifier and discriminator. The beatnote was fed to one input arm of the balanced mixer, and the output of the sweepable frequency generator, at frequency ν_{sw} , was fed to the other input arm (the local oscillator arm). The frequency ν_{sw} was adjusted such that $|\nu_{sw} - \nu_B|$ was nominally 160 MHz, and this resulting output signal was fed to the discriminator which had a sensitivity of 0.1 V/MHz and an 80 MHz bandwidth.

After the switch in the loop filter was closed, the discriminator-based locking loop adjusted the TDL frequency to insure that the beatnote ν_B was locked at a frequency ν_{DO} away from ν_{sw} . That is,

$$\nu_{DO} = |\nu_{sw} - \nu_B|,$$

where ν_{DO} is close but (due to the presence of various zero offsets in the locking loop) not necessarily equal to 160 MHz. For frequency shift and lineshape measurements, the important point is that the frequency ν_{DO} must remain fixed, whatever value it assumes. If a frequency measurement is the objective, it becomes necessary to measure ν_{DO} . Frequency of the CCFOL TDL is then given by

$$\nu_{\text{TDL}} = \nu_{\text{CO}_2} \pm \nu_{\text{SW}} \pm \nu_{\text{DO}}.$$

Two frequency measurements were made with an uncertainty of ± 2 MHz, which was almost entirely due to the TDL linewidth. By narrowing the TDL linewidth with a faster loop filter, one should be able to use an electronic counter to measure ν_{DO} and make measurements with uncertainties the order of 0.2 MHz.

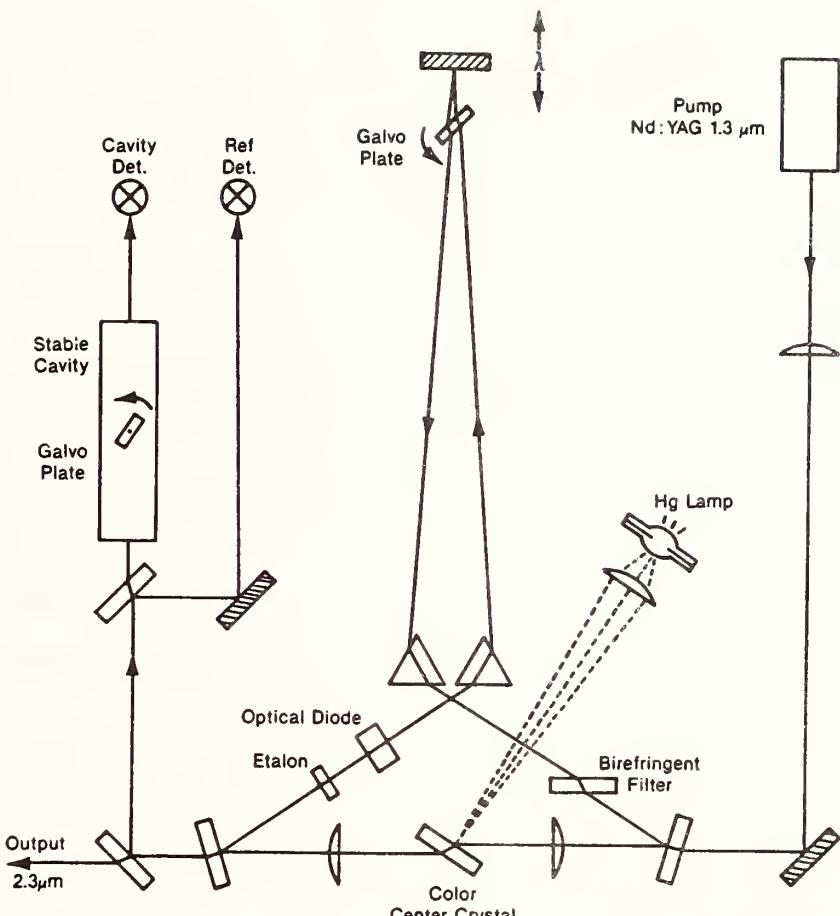

We have restricted our initial experiments to those OCS transitions which lie within 2000 MHz of a CO₂ laser transition because the lock loop requires a beatnote with a good S/N and the beatnote signal decreases with increasing frequency. This is also the band limit of our most convenient rf amplifier. We chose from the available TDLs those with sufficient power to give a beatnote with a S/N of about 30 dB. For the present measurements a 400 ms integration time was used and 640 points were recorded in each direction. Recording in both directions is a good way to cancel certain types of systematic errors. Generally only one round trip pass was made per measurement but as many passes could be made as required to give a good S/N.

A large number of measurements have been made with the older technique and these have been combined with FTS measurements, particularly the high quality measurements made recently. As the situation stands now good molecular constants exist, with the band centers currently having the largest uncertainties. The number of measurements left to be made is a relatively small number of high quality. The best approach is to make sub-Doppler or saturated measurements, however, the accidental overlaps required are rather infrequent. We believe the CCFOL approach is the next best option and several strategic overlaps occur in the 2 GHz range.

Measurements with the Color Center Laser

Pollock *et al.* [5.219] used a color center laser (CCL) to perform a set of experiments on N₂O. A brief description of their work and some related work concludes the summary of heterodyne techniques. It is of interest to compare and contrast some of the salient features of the TDL and the CCL. The tuning range of a TDL mode was 15 to 30 GHz; that of the CCL was less than 1 GHz. The linewidth of the TDL in the best instances was a few MHz, that of the CCL was 10 kHz. Perhaps the most important feature of the CCL was a large power output (in excess of 10 mW), which along with its beam quality permitted a direct coupling of the CCL output to the MIM diode, and subsequent synthesis measurements without a transfer oscillator. This relatively large power and narrow linewidth made it an ideal tool to use for some saturated absorption measurements by Pollock *et al.* on CO [5.304]. Sub-Doppler measurements could not be made on the N₂O band studied, and uncertainties of 4 to 8 MHz (at 130 to 140 THz) were reported. This uncertainty was due to the uncertainty in locating the center of the transition and was due in part to the small free spectral range of the tuning element of the CCL, which frequently prevented us from sweeping over the entire line and was also insufficient to sweep far enough on either side of an absorption line to determine a background slope.

Shown in Fig. 5 is a block diagram of the ring configuration color center laser developed by Pollock and Jennings [2.20]. The lasing entity in the lithium-doped potassium chloride crystal was an (F⁺₂)_A center. The centers were optically pumped with the 3 W power output from an Nd:YAG laser operating in a TEM₀₀ mode at 1.3 μm. These color centers were continuously replenished by uv radiation from a Hg lamp.

COLOR CENTER RING LASER

Fig. 5. Block diagram of color center laser in ring configuration.

Two Brewster's angle sapphire prisms, a single plate birefringent filter and one etalon comprised the tuning elements. The ring was constrained to operate in a unidirectional manner by an optical diode consisting of an AR-coated YIG plate in a 0.1 tesla magnetic field and a Brewster-cut quartz plate reciprocal rotator. One portion of the output radiation was used for stabilization to the side of a fringe in a passively stabilized optical cavity. The cavity was scanned by tuning a Galvo plate inside this reference cavity. Corrections were applied to the Galvo plate (slow) and to the PZT driving the tuning mirror (fast) in the laser resonator; this narrowed the CCL linewidth to 10 kHz. A second portion of the beam was split off and sent through a cell containing CO. The Galvo plate in the reference cavity was modulated at 7 kHz and slowly scanned to observe the first derivative signal, which was used to lock the CCL to the CO lines of interest.

A third portion of the CCL radiation was directed to the CO₂ synthesizer (more specifically the MIM diode portion) for a simultaneous measurement of the CO frequency. Typical synthesis schemes used $5\nu_1$, $4\nu_1 + \nu_2$, or $3\nu_1 + \nu_2$, where ν_1 and ν_2 are different CO₂ laser frequencies. No microwave oscillators were required, and the ν_{B1} type beatnotes fell within 2 GHz. In contrast to the TDL measurements, the measurement uncertainty was entirely the uncertainty in locating the center of the absorption line.

CHAPTER III

FORMULAS AND DATA SOURCES USED TO PREPARE THE TABLES

Expressions Used for Fitting the Frequency Data and for Calculating the Transition Wavenumbers

For diatomic molecules and for linear triatomic molecules in ${}^1\Sigma$ electronic states the energy levels are generally given by

$$E_{vJl} = G_v + B_v J(J+1) - D_v [J(J+1)-l^2]^2 + H_v [J(J+1)-l^2]^3 \\ + L_v [J(J+1)-l^2]^4 + \text{higher terms}, \quad (3.1)$$

where J is the quantum number for overall rotational angular momentum and l is the quantum number for vibrational angular momentum. Diatomic molecules have no vibrational angular momentum; that is, $l = 0$. In this work no higher order terms were needed and even the H_v and L_v terms were either poorly determined or not determinable.

For diatomic molecules, an alternative formulation is often given for the energy levels,

$$E_{vJ} = \sum_{ij} Y_{ij} (v+\frac{1}{2})^i [J(J+1)]^j. \quad (3.2)$$

Dunham [3.1] has related the Y_{ij} constants to the potential function of a diatomic molecule in a ${}^1\Sigma$ state. Most of the papers reporting constants for CO use Eq. (3.2). The ground state of the NO molecule is a ${}^3\Pi$ state and is treated differently [5.371].

Transitional frequencies, ν_{calc} , are calculated as differences between energy levels

$$\nu_{\text{calc}} = E_{vJl'}' - E_{vJl''}'. \quad (3.3)$$

In this book the band centers, ν_0 , are defined by

$$\nu_0 = G_v' - G_v''. \quad (3.4)$$

For linear triatomic molecules two types of perturbations are commonly encountered that affect the importance of higher order terms in Eq. (3.1), l -type resonance and Fermi resonance. Because it has a large effect on the centrifugal distortion constants, l -type resonance was treated explicitly in the analysis of the OCS and N₂O spectra. Both l -type doubling and l -type resonance are manifestations of the same matrix element that couples levels that differ only in the value of the l quantum number, where l is treated as a signed quantum number. In this book, both effects are treated under the general title of l -type resonance. If the bending vibrational quantum number, v_2 , is greater than zero, l -type resonance will be present and is usually noticeable.

When $v_2 \neq 0$, the l -type resonance was taken into account by diagonalizing the energy matrix which includes the matrix elements coupling l levels with $l \pm 2$ levels. The form of these matrices has been described in Refs. [5.120] and [3.2] but we shall repeat that description for a specific case.

For $v_2 = 3$, there are four possible values of l , $l = 3$, $l = 1$, $l = -1$, and $l = -3$. The l -doubling constant, q_v , represented by

$$q_v = q_v^0 - q_{vJ} J(J+1) + q_{vJJ} J^2 (J+1)^2, \quad (3.5)$$

couples these levels through the matrix element

$$W_{l_2,l} = W_{l,l_2} = \langle v, l | H | v, l-2 \rangle = \frac{1}{4} q_v \{ [v_2 + l] [v_2 - l + 2] \\ \times [J(J+1) - l(l-1)] [J(J+1) - (l-1)(l-2)] \}^{1/2}. \quad (3.6)$$

For each J level the form of the energy matrix for $v_2 = 3$ is

$$\begin{vmatrix} E^0(v, l=3) & W_{3,1} & 0 & 0 \\ W_{1,3} & E^0(v, l=1) & W_{1,-1} & 0 \\ 0 & W_{-1,1} & E^0(v, l=-1) & W_{-1,-3} \\ 0 & 0 & W_{-3,-1} & E^0(v, l=-3) \end{vmatrix}. \quad (3.7)$$

Here, the matrix elements are given by Eq. (3.1) (where $E_{vv} \equiv E^0$) and Eq. (3.6). $J = 0$ is not allowed and for $J < 3$ only the central two-by-two matrix is allowed. Higher order terms coupling l and $l \pm 4$ levels are sometimes important but were not necessary for the present calculations.

In general the l -type resonance calculation requires the use of a matrix of dimension $v_2 + 1$ by $v_2 + 1$. Since this is a nonlinear system, a nonlinear least-squares fitting technique was needed to fit the experimental data to determine the best constants, as explained later.

Most other workers have only used Eq. (3.1) to fit the data of OCS and N₂O. That has the effect of absorbing the l -type resonance into the effective B_v , D_v , and H_v values. While such a treatment is quite reasonable, the effective values of the higher order constants are quite different from the ground state values, and the level at which Eq. (3.1) is truncated has an important effect on both interpolation and extrapolation. By treating the l -type resonance explicitly, we bring the effective values for D_v and H_v much closer to the ground state values. This model gives a better approximation to the true Hamiltonian than the model that only uses Eq. (3.1). This improvement in the model used for fitting the data improves the reliability of the least-squares fits and gives more accurate uncertainties for the calculated transition frequencies.

For each value of $|l|$ (except $l = 0$) the states with $v_2 > 0$ are split into e and f components. For OCS and N₂O the $l = 0$ states (${}^1\Sigma^+$ states) always have the same symmetry (or parity) as the e states. These e and f components have been assigned in accordance with the convention established by Brown *et al.* [3.3]. That convention leads to the selection rules:

$$\Delta J = 0, e \leftrightarrow f$$

$$\Delta J = \pm 1, e \leftrightarrow e, \text{ and } f \leftrightarrow f$$

for electric dipole transitions. These selection rules are obeyed even when the normal rule, $\Delta l = 0, \pm 1$, is broken because perturbations always connect e to e and f to f .

All of the l -type resonance energy matrices, like Eq. (3.7), may be factored into two submatrices which represent the e levels in one case and the f levels in the other case. We have used the full matrix, as indicated by Eq. (3.7), rather than a factored form, because it is more convenient for obtaining the eigenvectors needed to calculate the intensities of the transitions.

The present analysis ignores the Fermi resonance that couples the levels $(v_1, v_2 + 2, l, v_3 - 1, J)$ and (v_1, v_2, l, v_3, J) of OCS and N₂O. In OCS the unperturbed Fermi resonance levels are far apart, so there is very little change in the resonance across a band. This results in only small changes in the effective values of D_v , H_v , and L_v . Such small changes can be accommodated by Eq. (3.1) without affecting either the accuracy of the least-squares fits or the accuracy of the calculated values. In N₂O the Fermi resonance is expected to be more important but again the effective values of D_v , H_v , and L_v are only slightly changed from the unperturbed values.

Since the Fermi resonance coupling is different for different values of $|l|$, it gives rise to different effective values of the constants q_v , B_v , etc. for levels that differ only in the value of $|l|$. Consequently, in Eq. (3.7) one must use two values for B_v , one for the $|l|=1$ states and one for the $|l|=3$ states. Similarly, two values are needed for D_v , H_v , and L_v . There will also be two different off-diagonal coupling constants, q_v , in Eq. (3.7), one for the $W_{3,1}$, $W_{1,3}$, $W_{-1,-3}$, and $W_{-3,-1}$ terms and a slightly different one for the $W_{1,-1}$ and $W_{-1,1}$ terms. However, these small differences in q_v are difficult to separate from the differences in B_v and D_v . Consequently, we have been forced to use a single value of q_v for a given vibrational state irrespective of differences in the value of the l quantum number.

In analyzing the spectral data to get the rovibrational constants for calculating the most accurate transition frequencies of OCS and N₂O, a large body of data on many different types of transitions was fit. Because of the form of the energy matrix for l -type resonance, it was not possible to use a linear least-squares technique to fit the data. Instead, an iterative nonlinear least-squares fitting procedure was used. In this procedure it was necessary to approximate the derivative of the transition frequency with respect to each constant by applying the technique described by Rowe and Wilson [3.4].

A similar nonlinear least-squares fitting procedure was used for NO but the energy matrix was somewhat different from Eq. (3.7). For a complete description of the energy matrix for NO one should refer to the work of Hinz *et al.* [5.371].

In order to calculate the statistical uncertainties in the calculated wavenumbers given in these tables it was necessary to use the variance-covariance matrix, given by the least-squares analysis, and the derivative of the transition frequency with respect to each constant. The uncertainty, or estimated standard error, given by $\sigma(\nu)$ was then determined by the double summation,

$$\sigma(\nu) = \sum_i \sum_j V_{ij} (\partial\nu/\partial c_i)(\partial\nu/\partial c_j), \quad (3.8)$$

where V_{ij} is a particular element of the variance-covariance matrix and $\partial\nu/\partial c_i$ and $\partial\nu/\partial c_j$ are the derivatives of the transition frequency with respect to the rovibrational constants c_i and c_j respectively.

Data Sources Used for Fitting the Frequency Data and for Calculating the Transition Wavenumbers

OCS

All of the OCS transitions to be used for calibration (shown with an asterisk in the atlas) were calculated by means of constants and a variance-covariance matrix given by a single least-squares fit that included all of the frequency measurements given in the literature. The equations used in this fit were described in the preceding section. In this section we indicate what references provided the data that went into that fit and give a few more details about the fit and the selection of data.

The rotational spectrum of OCS has been extensively studied by microwave and sub-millimeter wave techniques. These measurements use frequency techniques for calibration and have uncertainties on the order of ± 0.05 MHz and in some cases even smaller uncertainties. Such measurements are blessed with small line widths and are made at low pressures which contribute to the accuracy of the

measurements. The three most abundant isotopic species of OCS have no fine structure due to quadrupole effects.

Some microwave measurements [5.43, 5.79] extend to fairly high J values so they are able to give accurate values for B_v and D_{vv} . In addition, the heterodyne measurements made by Vanek *et al.* [5.124] on high- J transitions were used in the analysis. Although there are a great many measurements of rotational transitions for the lower vibrational states, Bogey and Bauer [5.78] and Tanaka *et al.* [5.98] have given measurements of rotational transitions for fairly high vibrational states, up to 4100 cm^{-1} . Some transitions show the splitting due to l -type resonance and for a few vibrational states, 01^1O [5.32, 5.47], 02^2O [5.54], and 03^1O [5.54], the transitions between split levels have been observed.

Altogether 333 frequency measurements of rotational transitions, taken from the above references as well as from Refs. [5.5, 5.29, 5.30, 5.37, 5.41, 5.48, 5.55, 5.66, 5.119], were included in the least-squares fit that determined the rovibrational constants given in Tables 5 and 6. When possible these measurements were given uncertainties suggested in the original papers. In some cases the uncertainty was estimated by us, based on other work from that time or from that laboratory, or based on the goodness of the fit.

With three exceptions, all of the infrared heterodyne frequency measurements came from a series of papers from the same laboratory at the National Institute of Standards and Technology in Boulder, Colorado [5.73, 5.83, 5.87, 5.94, 5.107, 5.120-5.122, 5.125, 5.129]. The exceptions are the measurements on the $02^0\text{O}-00^0\text{O}$ band and accompanying hot bands made in the Harry Diamond Laboratory by Sattler *et al.* [5.88], the measurements in the same frequency region made at the University of Lille by Fayt *et al.* [5.126], and the preliminary measurements from the University of Bonn [5.137a]. From the root-mean-square (rms) deviations of the NIST measurements it was obvious that their assigned uncertainties were too large by approximately a factor of two. This reflected caution in allowing for systematic errors which would not be revealed by the least-squares analysis.

An extensive set of laser-Stark resonance measurements have been made by Fayt and others [5.105, 5.106, 5.111, 5.112] and by Tanaka *et al.* [5.71, 5.97]. This is a type of frequency measurement that should be quite accurate but we have not included those data in this least-squares fit as they would introduce the additional complications of determining dipole-moment functions and assessing the accuracy of the electric field measurements. In the case of measurements using CO laser transitions there is an additional uncertainty in the laser frequency.

In order to determine the most accurate centrifugal distortion constants, some of the better diode laser and FTS measurements were included in the least-squares fits. For the most part the diode laser measurements given in Refs. [5.83, 5.88, 5.94] were calibrated with the heterodyne measurements and probably had systematic errors much smaller than the dispersion shown by the least-squares fit.

Except for the weakest transitions, the FTS measurements were more precise than any of the other infrared measurements. The high precision, however, does not necessarily imply high accuracy. The FTS data used in the analysis for these tables were taken from Refs. [5.75, 5.101, 5.102, 5.120, 5.122, 5.128, 5.132, 5.135, 5.136] or from private communication with the authors of those papers in the cases where the original data were not published.

The FTS measurements were given uncertainties equal to the rms deviations of the fits on a band-by-band basis. In order to keep the FTS measurements from affecting the determination of the vibrational energy levels, they were fitted to the same rotational constants as the other data, but to different band centers. All of the recommended calibration data were based on vibrational energy levels determined only from frequency measurements, not from FTS or ordinary diode-laser measurements.

For the less abundant isotopomers of OCS many of the above papers plus a few additional papers [5.5, 5.52, 5.82, 5.84] give microwave and sub-millimeter wave measurements of rotational transitions. Some of the infrared heterodyne measurements also included transitions for the less abundant isotopomers of OCS [5.73, 5.87, 5.94, 5.120, 5.122, 5.125]. A few transitions of $^{16}\text{O}^{13}\text{C}^{32}\text{S}$

and ¹⁶O¹²C³⁴S have enough frequency measurements to warrant being considered as possible calibration transitions. In most cases, however, transitions of the rarer isotopomers are only included in the atlas to help in identifying the other, more useful transitions.

A good many wavelength measurements have been made on the less abundant isotopomers, and they can be found in the bibliography, Chapter V. The most important sources of information on infrared measurements of the less abundant species are Refs. [5.45, 5.65, 5.76, 5.101, 5.109, 5.111, 5.128].

N₂O

The microwave data on N₂O are not so extensive as for OCS but a great many measurements are still available. The early work of Pearson *et al.* [5.161] and of Lafferty and Lide [5.156] were very useful as were other early measurements given in the review by Lovas [5.5], namely the data given in Refs. [5.138, 5.139, 5.146, 5.148, 5.159, 5.162]. The ν_1 rotational transitions given by Bogey [5.186] and the high-*J* transitions given by Andreev *et al.* [5.194], by Burenin *et al.* [5.179], and by Vanek *et al.* [5.242] were of particular value for better determining the centrifugal distortion contribution to the line positions.

All of the heterodyne measurements involving N₂O have come from two laboratories, NRC in Canada, and NIST in the U.S. The only saturated absorption measurements were those of Whitford *et al.* [5.183] on the laser transitions, 10⁰0-00⁰1, near 930 cm⁻¹. The other infrared heterodyne measurements were made by Wells and co-workers in a series of papers, Refs. [5.219, 5.221, 5.224, 5.230, 5.231, 5.241, 5.243].

There have been a great many measurements on infrared bands of N₂O using either grating instruments or, more recently, FTS instruments. Some of the more important measurements which were used in the least squares refinement of the constants, but did not contribute to the band centers for the recommended calibration lines, were given in Refs. [5.191-5.193, 5.213, 5.215, 5.220, 5.225, 5.229].

All these data were fit in the same way as was done for OCS. The constants given by the least-squares fit are given in Tables 7 and 8.

For N₂O the Fermi resonance is much more important than for OCS; nevertheless, the Fermi resonance was ignored in the fits and only the *l*-type resonance was included in the analysis. For some levels the Fermi resonance causes an effective centrifugal distortion quite different from that of the ground state.

c) Also included in the fit was a higher order term $q_{vJ} = -0.224(102) \times 10^{-13}$.

d) Also included in the fit was a higher order term $q_{vJ} = 1.109(32) \times 10^{-13}$.

In order to show the position of some of the hot band lines in the spectra, it was necessary to use constants for some levels not included in Tables 7 and 8. The wavenumbers for those lines were calculated by taking the constants for the upper state reported in Refs. [5.191, 5.213, 5.215, 5.229].

For the less abundant isotopic species, the microwave data given in Refs. [5.194, 5.227] were used in preparing these tables. One paper has reported heterodyne frequency measurements in the infrared for $^{15}\text{N}^{14}\text{N}^{16}\text{O}$ and $^{14}\text{N}^{15}\text{N}^{16}\text{O}$ [5.231]. For the most part the data for the rarer isotopic species were taken from Refs. [1.7, 5.173, 5.184, 5.192, 5.193, 5.213, 5.215, 5.225, 5.229].

CS_2

Since carbon disulfide (CS_2) is a symmetric linear molecule, it is nonpolar and has no microwave spectrum. There are, however, several high resolution infrared studies of its spectrum in the 1450 to 1550 cm^{-1} region [5.383, 5.386, 5.389] in addition to the heterodyne measurements made by Wells *et al.* [5.390]. A number of other measurements have been made on CS_2 so that the ground state constants, B_0 and D_0 , are quite well determined for both the $^{12}\text{C}^{32}\text{S}_2$ and $^{13}\text{C}^{32}\text{S}_2$ isotopic species.

The analysis of the ν_3 band of CS_2 is uncomplicated by either Fermi resonance or *l*-type resonance. The analysis used Eqs. (3.1)-(3.3) as described in detail by Wells *et al.* [5.390]. The recommended calibration frequencies are based on the constants given in their paper. Only the 00⁰1-00⁰0 transitions of $^{12}\text{C}^{32}\text{S}_2$ and $^{13}\text{C}^{32}\text{S}_2$ should be used for calibration. The other line wavenumbers given in the tables are for identification purposes and to show how close some weaker lines may be to the calibration lines. The wavenumbers of the other lines were calculated from the constants given by Winther *et al.* [5.389] and may be in error by as much as 0.01 cm^{-1} . In the spectral maps some lines may not be shown in the region below 1505 cm^{-1} because they arise from transitions not included in the data base.

CO

The carbon monoxide (CO) wavenumbers for the calibration lines given in the atlas were calculated from the constants given in Table 9 and based on Eqs. (3.2) and (3.3). Only the wavenumbers given for the $^{12}\text{C}^{16}\text{O}$ molecule were determined adequately by frequency measurements and so they are the only wavenumbers that should be used for frequency (wavenumber) calibration. There are a few frequency measurements for the other isotopomers, but not enough to provide good calibration.

For the $^{12}\text{C}^{16}\text{O}$ molecule the ground state constants are primarily based on the sub-millimeter wave measurements given by Gordy and Cowan [5.250], Rosenblum *et al.* [5.253], and Helminger *et al.* [5.266] and on the far-infrared heterodyne measurements of Nolt *et al.* [5.309] and Varberg and Evenson [5.320]. Also included in the fit were microwave measurements of the $J = 1 \leftarrow 0$ transitions in the first two vibrationally excited states as reported by Dixon [5.288]. Aside from these two measurements the upper state constants are based primarily on the heterodyne measurements of the 1-0 band given by Schneider *et al.* [5.314] and by Maki *et al.* [5.316] and the 2-0 band given by Pollock *et al.* [5.304]. Also used was one sub-Doppler measurement of the 1-0 band communicated to us by Urban [5.321].

Other data included in the analysis to determine the best constants were some heterodyne laser measurements given by Schneider *et al.* [5.313] and some FTS measurements from Guelachvili *et al.* [5.289, 5.301, 5.307] and Brown and Toth [5.306]. The FTS measurements were used to help

Excess digits are given to avoid round-off errors.

determine the best centrifugal distortion constants for the $v = 1, 2$, and 3 states. Only heterodyne frequency measurements were used to determine the vibrational frequencies.

The analysis of the CO data was carried out in the same way as described by Maki *et al.* [5.316] except that new data have been included [5.320, 5.321]. In order to avoid the possibility of problems with the potential function model, the lowest order constants, Y_{10} , Y_{20} , Y_{01} , Y_{11} , Y_{21} , Y_{02} , Y_{12} , and Y_{03} were fit to data for only the $v = 0, 1$, and 2 states. The other constants were constrained to values given by earlier fits which included data for higher vibrational states, as described by Schneider *et al.* [5.314].

The uncertainties given for the calibration wavenumbers are based on the variance-covariance matrix given by the least-squares fit with the higher order constants constrained.

The wavenumbers for the other isotopic species of CO were calculated from constants given by Guelachvili *et al.* [5.301], but corrected to agree with the offset observed in the wavenumbers for the $^{12}\text{C}^{16}\text{O}$ species. The wavenumbers for the rarer isotopic species are given to help in correctly identifying the calibration lines.

NO

The wavenumbers of the line positions used to produce the NO atlas were calculated using the constants given by Hinz *et al.* [5.371] for the $^{14}\text{N}^{16}\text{O}$ species. The constants given by Amiot and Guelachvili [5.355] were used for $^{15}\text{N}^{16}\text{O}$ and those given by Amiot *et al.* [5.350] were used for $^{14}\text{N}^{18}\text{O}$. Those were the only transitions strong enough to show on the spectral plots. The uncertainties given in the tables are only estimates based on the accuracy of other heterodyne measurements and an estimate of the accuracy of the Hamiltonian used to fit the data.

The tables only give the wavenumber values for lines of $^{14}\text{N}^{16}\text{O}$. Because only one paper [5.371] reports infrared frequency measurements for NO, the NO lines are not recommended for calibration in those regions where either OCS or N_2O transitions are available for calibration. For many spectrometers most of the NO transitions are unresolved doublets. At low pressures the doublets will have equal intensities and widths so that no appreciable errors will be incurred by using the average frequency of the doublet. A few of the low- J transitions, especially for the Q -branch lines, will have additional structure due to the interaction of the nuclear electric quadrupole moment of the nitrogen atom with the surrounding charge distribution. Such small splittings will be no larger than a few megahertz and the average line positions given in the tables will not be affected.

Intensity Calculations

This section is intended to show how the transition intensities were calculated and how the intensity was defined. This will enable users to determine the intensity to be expected for conditions other than those used to prepare the atlas. In order to estimate the appearance of the spectrum under conditions of pressure broadening and spectrometer resolution different from that used to produce the atlas figures, it is also necessary to consider the line shapes and the effect of finite slit functions. Such effects are discussed in Chapter IV.

The integrated intensity of an individual line representing a single rovibrational transition is independent of the line shape. For this atlas we take the integrated line intensity, S , to mean

$$S = \int_{-\infty}^{+\infty} k(\nu) d\nu = (1/pl) \int_{-\infty}^{+\infty} \ln(I_0/I) d\nu, \quad (3.9)$$

where $k(\nu)$ is the absorption coefficient at frequency ν , p is the partial pressure of the gas, l is the length of the absorption path, I_0 is the intensity of radiation without absorption from the line in

question, and I is the intensity of radiation after absorption by the line. Note that Eq. (3.9) is only concerned with the absorption due to a particular transition.

The integrated intensities, as given in this atlas, were calculated by using the equation

$$S = \exp(-E''/kT) [1 - \exp(-\nu/0.69504T)] [N_i/Q_v Q_R] \\ \times \nu C |R_{v''l''j''}^{v'l'j'}|^2 S_v^2 S_R^2, \quad (3.10)$$

where C is a proportionality constant that includes the factors $8\pi^3/3hc$ and other factors, such as the Loschmidt constant ($2.686\ 763 \times 10^{25}$ molecules/m³), required to give S in appropriate units. If S is in units of cm/molecule at STP, C is $4.162\ 38 \times 10^{-19}$ cm²D²/molecule. If S is in units of cm²atm⁻¹ at temperature T , C would be $3054.7262/T$ cm¹D²atm⁻¹. In Eq. (3.10) $|R_{v''l''j''}^{v'l'j'}|$ is the vibrational transition moment or dipole derivative in debye units (1 debye = $3.335\ 64 \times 10^{-30}$ C m), ν is the transition wavenumber in units of cm⁻¹, T is the temperature in kelvin, N_i is the concentration of the isotopic species under consideration, Q_v and Q_R are the vibrational and rotational partition functions respectively, and S_v and S_R are vibrational and rotational strength factors that should be included in the intensity. Some workers prefer to include S_v in the transition moment but we prefer to express it separately so the transition moment can be seen to be nearly the same for the ground state transitions and the accompanying hot bands. S_R is also called the direction cosine matrix element. The intensities given in these tables were calculated for a temperature of 296 K.

In Eq (3.10) the term $N_i/Q_v Q_R$ compensates for the fact that the pressure used in Eq. (3.9) is the total pressure of the gas being measured, including all isotopic species. That is to say, the pressure does not take into account the isotopic concentration or the number of molecules in different states.

Table 10. Percent isotopic abundances.

¹² C	98.90
¹³ C	1.10
¹⁴ N	99.634
¹⁵ N	0.366
¹⁶ O	99.762
¹⁷ O	0.038
¹⁸ O	0.200
³² S	95.02
³³ S	0.75
³⁴ S	4.21
³⁶ S	0.02

The values of N_i were calculated from the isotopic abundances given in Table 10 and taken from Refs. [3.5, 3.6]. The vibrational partition function was calculated by summing the Boltzmann population of the vibrational energy levels. The vibrational partition functions are given in Table 11.

The rotational partition functions were calculated from the equations given by McDowell [3.7]. A different rotational partition function was calculated for each vibrational energy level and for each isotopomer.

Some workers like to use $S^0 = S/N_i$ for S because S^0 seems to be a more appropriate molecular property. On the other hand, S is more useful for analytical purposes, such as the determination of the amount of CO in the atmosphere. Actually, it is $|R|$ or $|R|^2$, rather than S , that is the true molecular property in Eq. (3.10), and, as suggested by Toth [5.218], all intensity measurements should

Table 11. Vibrational partition function and natural abundance for the various isotopic species found in the calibration atlas.

report the value of $|R|$, or $|R|^2$. Unfortunately, some authors have left out the N_i term and report values of $|R|$ that are not true molecular properties relatable to the electron distribution in the molecule.

In the infancy of infrared spectroscopy the instrumentation was unable to resolve individual rovibrational transitions, so many early papers measured the intensity of entire vibrational bands. Those papers measured band intensities by using a modification of Eq. (3.9) in which the integration was over the entire band rather than over a single line. The fine points of isotopic concentration and vibrational hot bands were ignored. Even today integrated band intensities are often measured for heavier molecules for which the density of lines is very high.

From those early measurements the term *band intensity* came to mean the intensity of all the lines in a band including all isotopes present in a normal sample and all hot bands. As a first approximation such a band intensity can be calculated from Eq. (3.10) if the terms S_v^2 , S_R^2 , and $N_i/Q_v Q_R$ are all omitted and ν is set equal to the center of the band. This band intensity will generally be within a few percent of the intensity obtained by adding all the line intensities for the band. To be faithful to the original meaning, the true band intensity should be the sum of the intensities of all the lines in the band, including all isotopes and all hot bands.

Calculation of the strength factors

The vibrational strength factors were slightly different for even and odd values of Δv_2 . For simplicity the strength factor was broken into two factors such that

$$S_v^2 = S_{13}^2 S_2^2 \quad (3.11)$$

with

$$S_{13}^2 = (v_1 + \Delta v_1)! (v_3 + \Delta v_3)! / (v_1! v_3! \Delta v_1! \Delta v_3!) \quad (3.12)$$

and for Δv_2 even (or zero)

$$\begin{aligned} S_2^2 = & [1/2(v_2 + l + \Delta v_2)]! [1/2(v_2 - l + \Delta v_2)]! / \{[1/2(v_2 + l)]! [1/2(v_2 - l)]! \\ & \times \{[1/2(\Delta v_2)]!\}^2\}, \end{aligned} \quad (3.13)$$

while for Δv_2 odd

$$S_v^2 = [\frac{1}{2}(v_2+l+\Delta v_2-1)]! [\frac{1}{2}(v_2-l+\Delta v_2-1)]! (v_2+l\Delta l+\Delta v_2+1) \\ / \left\{ [\frac{1}{2}(v_2+l)]! [\frac{1}{2}(v_2-l)]! \{[\frac{1}{2}(\Delta v_2-1)]!\}^2 (\Delta v_2+1) \right\}. \quad (3.14)$$

In both cases $S_v = 0$ if $|\Delta l| > 1$. In Eqs. (3.12)-(3.14) the smaller of v' and v'' is used for v , $\Delta v = |v' - v''|$, $l = l''$, and $\Delta l = l' - l''$. For the present calculations, S_v can be taken as the positive square-root of Eqs. (3.13) and (3.14).

Equation (3.12) was derived from the properties of harmonic oscillator wave functions such as can be found, among other places, in Appendix III of Ref. [3.8]. Equations (3.13) and (3.14) were derived from the properties of the two-dimensional harmonic oscillator wave functions given by Moffitt and Liehr [3.9].

Note that S_v^2 is normalized so that transitions from the ground state always have $S_v^2 = 1$. For certain hot bands, such as $2\nu_1 - \nu_1$, $S_v^2 = 2$, while for the hot band $3\nu_1 - \nu_1$, $S_v^2 = 3$. Other authors sometimes include S_v in the transition moment, $|R|$, in which case the transition moment for certain hot bands will be very different from the transition moment for the ground state transitions.

For transitions for which $v_2 = 0$ (and $l = 0$) the rotational strength factors are given by

$$S_R^2 = |m| \text{ for } \Delta J = \pm 1$$

and

$$S_R^2 = 0 \text{ for } \Delta J = 0,$$

where m has the usual meaning of $-J''$ for $\Delta J = -1$ and $J'' + 1$ for $\Delta J = +1$.

If $v_2 \neq 0$, the l -type resonance energy matrix was used and the intensity was obtained by multiplying each term of the eigenvector, for the appropriate eigenvalue, by the appropriate intensity factor given by $S_v S_R$ where S_R was determined from Table 2.1 of Gordy and Cook [3.11], or Table 4-4 of Townes and Schawlow [3.12]. Di Lauro and Mills [3.13] describe a similar procedure for determining intensities of transitions in Coriolis coupled levels of a symmetric rotor. For the specific cases of l -type resonance, this procedure was described by Maki *et al.* [3.14] although they dealt with the symmetry factored matrix whereas the present calculations used the unfactored matrix, such as Eq. (3.7).

To understand this intensity calculation let us consider a transition from an unperturbed lower state (v_1, v_2, l, v_3, J) to an upper state that is involved in l -type resonance, $(v'_1, v'_2, l', v'_3, J') = (v_1 + \Delta v_1, v_2 + \Delta v_2, l + \Delta l, v_3 + \Delta v_3, J')$. The upper state energy is given by a particular eigenvalue, E_1 . The eigenvector for this eigenvalue gives the mixing coefficients a_{11} , a_{12} , a_{13} , etc. that measure the contribution of each unperturbed state to the perturbed state. The transition intensity is given by

$$| \langle v_1 + \Delta v_1, v_2 + \Delta v_2, l + \Delta l, v_3 + \Delta v_3, J + \Delta J | \mu | v_1, v_2, l, v_3, J \rangle |^2 = \\ | a_{11} \langle v_1 + \Delta v_1, v_2 + \Delta v_2, l' = v_2 + \Delta v_2, v_3 + \Delta v_3, J + \Delta J | \mu | v_1, v_2, l, v_3, J \rangle \\ + a_{12} \langle v_1 + \Delta v_1, v_2 + \Delta v_2, l' = v_2 + \Delta v_2 - 2, v_3 + \Delta v_3, J + \Delta J | \mu | v_1, v_2, l, v_3, J \rangle \\ + a_{13} \langle v_1 + \Delta v_1, v_2 + \Delta v_2, l' = v_2 + \Delta v_2 - 4, v_3 + \Delta v_3, J + \Delta J | \mu | v_1, v_2, l, v_3, J \rangle \\ \dots |^2. \quad (3.15)$$

All the upper state quantum numbers on the left side of Eq. (3.15) are the same as those on the right side except the l' values. The l -type resonance mixes levels that differ only in the value of l .

If one assumes that the transition moment, or dipole derivative, is the same for all values of l , then Eq. (3.15) can be rewritten

$$\begin{aligned} |\mathbf{R}|^2 S_v^2 S_R^2 = & \quad |\mathbf{R}|^2 S_{13}^2 \{ a_{11} S_2 S_R(v_2 + \Delta v_2, l = v_2 + \Delta v_2, J' \leftarrow v_2, l'', J'') \\ & + a_{12} S_2 S_R(v_2 + \Delta v_2, l = v_2 + \Delta v_2 - 2, J' \leftarrow v_2, l'', J'') \\ & + a_{13} \dots \}^2. \end{aligned} \quad (3.16)$$

Each term within the curly brackets on the right side of Eq. (3.16) has a different value for S_2 and S_R depending on the unperturbed transition to which they apply. In many cases they will be zero because they apply to $|\Delta l| > 1$. In Eqs. (3.12)-(3.14) we have already given the formulas for the values of S_{13}^2 and S_2^2 .

The only nonzero values of S_R are given below.

For $\Delta l = 0$, the $\Delta J = 0$ transitions have

$$S_R = [(2J+1)l^2/J(J+1)]^{1/2} \quad (3.17)$$

and the $\Delta J = \pm 1$ transitions have

$$S_R = [(|m|^2 - l^2)/|m|]^{1/2}. \quad (3.18)$$

For $\Delta l = \pm 1$, the expressions for $\Delta J = 0$ were

$$S_R = 1/2[(2J+1)(J+l)(J-l+1)/J(J+1)]^{1/2}, \quad (3.19)$$

where l is the larger of l' and l'' . For $\Delta l = +1$ and $\Delta J = +1$,

$$S_R = -1/2[(J+l)(J+l+1)/J]^{1/2}; \quad (3.20)$$

for $\Delta l = +1$ and $\Delta J = -1$,

$$S_R = 1/2[(-J+l)(-J+l+1)/J]^{1/2}; \quad (3.21)$$

for $\Delta l = -1$ and $\Delta J = +1$,

$$S_R = 1/2[(J-l)(J-l+1)/J]^{1/2}; \quad (3.22)$$

and for $\Delta l = -1$ and $\Delta J = -1$,

$$S_R = -1/2[(-J-l)(-J-l+1)/J]^{1/2}. \quad (3.23)$$

In Eqs. (3.19)-(3.23) J is the larger of J' and J'' but l is always l'' .

When both the upper and lower states are involved in l -type resonance, Eqs. (3.15) and (3.16) must be modified to include the eigenvectors for both the upper and lower states, otherwise the treatment is the same.

Herman-Wallis terms

Sometimes it is necessary to divide $|R_{v''r''J''}^{v'J'}|^2$ into two terms such that

$$|R_{v''r''J''}^{v'J'}|^2 = |R_{v''r''}^{v'J'}|^2 F_{J''}^{J'}, \quad (3.24)$$

where $F_{J''}^{J'}$ is similar to the Herman-Wallis term [3.15, 3.16]. There are several forms that have been used for the $F_{J''}^{J'}$ term. For the overtone of CO the form used was

$$F_{J''}^{J'} = 1 + C_1 m + C_2 m^2. \quad (3.25)$$

Toth [5.218], in his extensive intensity measurements for N₂O, has given the values for the Herman-Wallis constants for several bands. Toth has used several formulations such as Eq. (3.25) above and also

$$F_{J''}^{J'} = [1 + aJ(J+1) + bJ^2(J+1)^2] \quad (3.26)$$

$$F_{J''}^{J'} = [1 + a_1 m + a_2 J'(J'+1)]^2 \quad (3.27)$$

$$F_{J''}^{J'} = [1 + \xi_1 m + \xi_2 m^2]^2. \quad (3.28)$$

In the case of OCS, Dang-Nhu and Guelachvili [5.104] used the form of Eq. (3.25) for the 11¹0-00⁰0 band. The same constant was also used to calculate the intensities of the hot bands for which $\Delta v_1 = 1$ and $\Delta v_2 = 1$. The same form and, coincidentally, almost the same value for the Herman-Wallis term was used for the v_2 band system. As recommended by Maki *et al.* [5.132], we used

$$F_{J''}^{J'} = [1 + a_3 J'(J'+1)] \quad (3.29)$$

for the hot bands 10²2-00⁰1 and 04⁰2-00⁰1 in order to allow for the resonance interaction of the upper states. For the other transitions, there seemed to be no need for using a Herman-Wallis term in the intensity calculations.

For the 03¹0-01¹0 band of OCS, Depannemaeker and Lemaire [5.118] found that the first term, C_1 , in Eq. (3.25) was needed although no Herman-Wallis term was needed for the 02⁰0-00⁰0 band. On the other hand, the more extensive measurements of Blanquet *et al.* [5.134] showed that a Herman-Wallis term would improve the intensity fit for 02⁰0-00⁰0.

Data Sources for Intensity Calculations

OCS

Only a small number of intensity measurements have been published for OCS. Most of them are measurements of integrated band intensities including transitions from the ground state as well as from other low energy states populated at room temperature, hot bands. The most thorough studies of band intensities are those of Foord and Whiffen [5.49] and Kagann [5.89] where references to earlier work may be found. Kagann's values were consistently smaller by 11 to 15 percent except for the strongest band near 2062 cm⁻¹ for which Kagann found an intensity that was 18 percent *larger*.

There have been only 9 papers reporting intensity measurements of individual rovibrational transitions [5.73, 5.74, 5.83, 5.85, 5.103, 5.104, 5.118, 5.127, 5.134] and the first three of those papers are considerably less thorough than the others. In addition, there are two papers that give information on the relative intensities of well resolved rovibrational transitions without making absolute intensity measurements [5.101, 5.132].

Several papers [5.49, 5.97, 5.100, 5.106, 5.112] have used intensity and/or dipole moment measurements to derive a dipole moment function for OCS. At the present time the dipole function of OCS can be used to predict the dipole moment of OCS in different vibrational states, but it is not very useful for predicting transition intensities. The accuracy of the dipole moment function for predicting dipole moments is due largely to the fact that it is based on very accurate laser-Stark measurements involving many vibrational states.

Table 12 summarizes the intensity measurements reported in the literature. Table 12 also gives the transition moments used in the calculations for this atlas and the integrated intensity of each

band as obtained by actually summing all of the transitions within each band, including all hot bands and all isotopic species. In a few cases, where indicated by a footnote, the integrated intensity given in the literature and reported in Table 12 does not include the hot band intensity. In those cases Table 12 gives the intensity calculated without including the contribution from hot bands in order to more easily compare the intensity used in this atlas with what was reported in the literature.

Only a few bands of OCS show any need for Herman-Wallis terms. As is usually the case, the two perpendicular bands, ν_2 and $\nu_1 + \nu_2$, required a small Herman-Wallis term, $C_1 = 0.0045$ and 0.00463 for the two bands, respectively. The Herman-Wallis term is defined by Eqs. (3.24) and (3.25). For ν_2 it was estimated by us from inspection of the experimental spectrum and is not a very accurate value. The H.-W. term for $\nu_1 + \nu_2$ was measured by Dang-Nhu and Guelachvili [5.104]. Although the Herman-Wallis term is likely to be somewhat different for different isotopes and for hot bands, the same term was used for all bands involving the same quantum number changes unless indicated in the key that accompanies the tables.

The only other bands that were given nonzero Herman-Wallis constants were some of the hot bands that go with $2\nu_2$ and the hot bands 04^02-00^01 and 10^02-00^01 which involve resonance coupled upper states. Depannemaeker and Lemaire [5.118] determined that $C_1 = 0.0019$ gives the best fit to their intensity data for 03^10-01^10 transitions. We have used the same H.-W. term for most of the other hot bands accompanying $2\nu_2$; see the descriptive key accompanying the 1000 cm^{-1} to 1095 cm^{-1} tables. Maki *et al.* [5.132] have given effective constants $a_3 = 0.00105$ and $a_3 = -0.00034$, respectively, to the resonance coupled transitions. The latter constants are based on Eqs. (3.24) and (3.29).

After the tables were prepared the new intensity measurements of Blanquet *et al.* [5.134] became available and it leads us to believe that the intensity values in the tables are too high by about 7 percent because we assumed that the dipole derivative given by Depannemaeker and Lemaire took into account the isotopic abundance. Any revised intensity calculations for the $2\nu_2$ band should also include the Herman-Wallis constant measured by Blanquet *et al.* [5.134].

N_2O

A great many intensity measurements have been made on the various bands of N_2O given in this atlas. Not all the measurements are given in Table 13, but the most important or most recent measurements are given there.

As was the case for OCS, the earlier measurements were of the intensity of the unresolved bands. Such measurements included all hot bands and all isotopic species present in a normal sample. One of the more complete sets of measurements is that reported by Kagann [5.214]. Many earlier measurements are summarized in that paper. Kobayashi and Suzuki [5.228] have fit the available data on intensities to a dipole moment function from which they calculate transition moments and Herman-Wallis constants. More measurements are needed to evaluate the accuracy of the constants calculated from their dipole moment function.

Because of the interest in N_2O as an atmospheric gas, the more recent intensity measurements involve spectra with resolved rotational structure and individual rovibrational lines have been measured. In many places in Table 13 we give both the intensity of the transitions from the ground state and the intensity of all transitions with the same change of quantum numbers regardless of the lower state. That allows one to compare our intensities with those reported in the literature.

For most of the transitions we have tried to use what we judge to be the best measurements for the intensity but in a few cases we have departed from the literature values in order to give a more realistic appearance to the spectrum. For example, we have used the transition moment given by Toth [5.218] for the ν_3 band near 1270 cm^{-1} , but the transition moment given for the $2\nu_2$ band did not give a calculated spectrum that matched the observed spectrum where the two bands overlap. This mismatch caused us to use a slightly smaller value for the transition moment for $2\nu_2$ than that given by Toth. It is possible that either the Herman-Wallis constants or the intensity of the ν_3 band should

Table 13 Integrated intensities and transition moments for N₂O.

- a) Unless indicated otherwise (see footnote f), the integrated intensities are given only for the vibrational transition from the ground state.
- b) See Eq. (3.24) for definition of |R_{v'v''}^{t'}|.
- c) 1 cm⁻²atm⁻¹ at 296 K = 4.0335 × 10⁻²⁰ cm/molecule.
- d) 1 debye = 3.336 × 10⁻³⁰ C m.
- e) The uncertainties in the last digits are given in parentheses.
- f) All hot bands and isotopes are included.

have been changed. The more reasonable thing seemed to be to change the intensity of the weaker band. We have also recognized that Toth has included the vibrational factors in the dipole moment matrix elements that he reported, whereas Eq. (3.10) treats that as a separate term that multiplies the transition moment.

The two bands $2\nu_2 + \nu_3$ and $2\nu_3$ also overlap and again there was some modification of the literature values for the intensities in order to get a good agreement between the calculated spectrum and that obtained experimentally.

We know of no intensity measurements for the $\nu_1-2\nu_2$ transitions between 990 and 1090 cm⁻¹; consequently, we have estimated the intensity for that region. The true intensity could be quite different from what we have estimated, but the relative intensities of the lines in that region are probably good enough to recognize and assign the lines needed for calibration. That band is so weak that it is probably useless as a source of calibration for many workers, but it was included because it is based on frequency measurements. Since the lower energy level of the band is quite high, heating the absorption cell will make a large difference in the intensity.

Please see Eqs. (3.24) to (3.29) for the definition of the various Herman-Wallis constants used in this work. In his intensity studies [5.218, 5.185] Toth has given Herman-Wallis terms for all the bands. For the most part we have used those constants in the intensity calculations for the tables and figures. Several exceptions were made, however. For the $03^{\circ}0-01^{\circ}0$ hot band we have used the same Herman-Wallis terms as given by Toth for the $02^{\circ}0-00^{\circ}0$ band. For the other transitions involving $\Delta v_2=2$, we have estimated the intensity constants to be used for the calculations because they were not included in Toth's tables.

There seems to be no determination of a Herman-Wallis constant for the $\Delta v_2=1$ transitions, therefore, we used $a_1 = 0.0016$ which was estimated from the experimental spectrum. This value was estimated from laboratory spectra that were compared with the calculated spectrum. The intensities of the lines in the bands in the 1835-1925 cm⁻¹ region were all calculated with $\xi_1 = -0.0107$ as measured by Toth and Farmer [5.185]. The two Herman-Wallis constants measured by Boissy *et al.* [5.187] for the ν_1 band, were used for all the $\Delta v_1 = 1$ transitions including hot bands and different isotopomers used in the tables. The $2\nu_2 + \nu_3$ band also seemed to require a Herman-Wallis term although the spectra were better matched with a value of $\xi_2 = 0.3 \times 10^{-4}$ rather than the term given by Levy *et al.* [5.216]. No Herman-Wallis terms were used in the intensity calculations for the $\nu_1-\nu_3$, $\nu_1-2\nu_2$, $2\nu_3$, and $\nu_1+\nu_2$ bands and the hot bands that accompany them.

CS₂

Only a few intensity measurements have been made on the ν_3 band of CS₂ [5.375, 5.377, 5.378, 5.379]. There seem to be no measurements of individually resolved rovibrational transitions, only integrated band intensities. For the purposes of this atlas we have calculated all hot band and isotopomer transitions with the same transition moment, 0.27 debye, and with no Herman-Wallis terms. The integrated intensity for the 1500 cm⁻¹ band region of CS₂ is 9.309×10^{-17} cm/molecule (2308 cm²atm⁻¹ at 296 K) as determined from adding all the line intensities including hot bands and different isotopes. This may be compared to the value 9.55×10^{-17} cm/molecule given by McKean *et al.* [5.378], 9.38×10^{-17} cm/molecule given by Robinson [5.375], 9.23×10^{-17} cm/molecule given by Kiyama and Ozawa [5.377], and 9.13×10^{-17} cm/molecule given by Person and Hall [5.379].

CO

fundamental band

Because of the large spacing between lines, CO was one of the first molecules for which individual line intensities were measured [5.255]. More recent measurements are tabulated in the review article by Smith *et al.* [5.2]. For the fundamental band near 2143 cm⁻¹ it is difficult to determine which measurements are best but most of the recent measurements give integrated band intensities close to 1.027×10^{-17} cm/molecule (276 cm²atm⁻¹ at 273.15 K). For this atlas we have used a dipole transition moment of 0.1073 D which gives a total band intensity of 1.03×10^{-17} cm/molecule (276 cm²atm⁻¹ at 273.15 K or 255 cm²atm⁻¹ at 296 K). The changes in the matrix elements for the less abundant isotopic species were taken from the theoretical calculations of Chackerian and Tipping

[5.305]. The isotopic abundance was taken from Table 11. The uncertainty in the total band intensity seems to be about 3 percent. The intensity measurements of Chackerian *et al.* [5.300] (1.027×10^{-17} cm/molecule) are in agreement with other recent measurements for the main isotopic species and they also have studied the intensity of the weaker isotopic transitions. They gave transition intensities calculated from the electric dipole moment function given by Chackerian and Tipping [5.305]. Their calculated intensities seem to include a weak Herman-Wallis effect but they do not give any explicit constants for easily calculating that effect. A calculation that duplicates their temperature and dipole derivative agrees with their values to within one percent (for $J < 35$) even without including a Herman-Wallis effect.

In an earlier paper [5.282] Tipping gave calculated values for the Herman-Wallis constants but they were small enough to ignore for this atlas. Bouanich [5.310] has also given calculated values for the Herman-Wallis constants. Apparently there are only two experimental determinations of Herman-Wallis constants that have been reported for the fundamental band of CO [5.261, 5.318]. The earlier work is subject to question because of the sensitivity to temperature errors. The most recent measurement was reported after this work was done and would change the intensities by no more than one percent. The intensity calculations used for the atlas did not include a Herman-Wallis effect for the fundamental band.

first overtone

Fewer intensity measurements have been made on individual lines of the overtone band near 4260 cm^{-1} . A good average of the more recent values seems to give an integrated band intensity of 7.78×10^{-20} cm/molecule ($2.09\text{ cm}^{-2}\text{ atm}^{-1}$ at 273.15 K) with an uncertainty of about six percent. This is equivalent to a transition dipole matrix element of 0.0066 D.

The Herman-Wallis effect is significant for the first overtone band and has been included in the intensity calculation for the atlas. The constants given by Tipping [5.282], $C_1 = 0.005$ and $C_2 = 0.000\ 034$ [see Eq. (3.25)], were used for the calculation of the intensities of the first overtone transitions. Those calculated Herman-Wallis constants were in agreement with three experimental determinations [5.265, 5.271, 5.295] as well as with the calculation of Toth *et al.* [5.265].

NO

A transition moment of 0.00412 debye was used to calculate the line intensities given in the tables. This gives an integrated band intensity of about 5.04×10^{-18} cm/molecule ($125\text{ cm}^{-2}\text{ atm}^{-1}$ at 296 K) which agrees with the measurements of King and Crawford [5.330], Mandin *et al.* [5.359], and Holland *et al.* [5.368]. Some earlier measurements [5.326, 5.344, 5.347, 5.364, 5.367] and even some recent measurements [5.374] indicate that the intensity might be more like 4.44 to 4.64×10^{-18} cm/molecule (110 to $115\text{ cm}^{-2}\text{ atm}^{-1}$ at 296 K) so the intensities given in the tables may be too large by about ten percent. We have taken the higher intensity value because NO is prone to having impurities that are hard to remove, thus giving low intensity readings.

Other Line Parameters

Lineshape and pressure broadening

Smith *et al.* [5.2] have given a good discussion of lineshapes and the determination of pressure broadening coefficients. We shall give here only a brief description to ensure that the reader understands the principal equations describing these effects. For a more complete understanding of the subject one should refer to the work of Smith *et al.* [5.2] and the papers to which they refer.

For a static gas in a field-free environment at pressures below one atmosphere, there are four major factors that might contribute to the shapes of infrared absorption lines, (1) lifetime broadening, (2) Doppler broadening, (3) pressure broadening, and (4) collisional narrowing.

lifetime broadening

The lifetime broadening of a state n is given by

$$\gamma_n = h/2\pi\tau_n,$$

where γ_n is the half-width of the state and τ_n is the lifetime of that state. For a transition $i \rightarrow j$ between two states, i and j , the transition linewidth will be given by the lifetime of both upper and lower states,

$$\gamma_{i \rightarrow j} = (1/\tau_i + 1/\tau_j)h/2\pi.$$

For most stable molecules in the ground electronic state the radiative lifetime in a given rovibrational state will be on the order of 1 ms or more which gives a linewidth of about 1×10^{-8} cm $^{-1}$ (0.16 kHz) or less. This is much smaller than the Doppler width even at temperatures on the order of 5 K. For Doppler-free measurements the effect of lifetime broadening could be important even for stable molecules although various instrumental effects, such as beam width or beam collimation, usually limit the effective linewidth. Transit time broadening is a variation of lifetime broadening where the lifetime is the time that the molecule is in the lightbeam.

Doppler broadening

The Doppler width is the result of the random motion of the molecules in a gas sample and is given by

$$\gamma_D = 3.581 \times 10^{-7} \nu (T/M)^{1/2}, \quad (3.30)$$

where ν is the wavenumber or frequency of the transition, T is the temperature of the gas in kelvin, M is the relative molecular mass of the molecule in atomic mass units, and γ_D is half the width of the transition at half the intensity (half-width at half height or HWHH). Since spectrometer resolution is often expressed in terms of the full width at half the line height (FWHH), the Doppler width is sometimes given by $2\gamma_D$.

For most gases at ambient temperatures and pressures below 2 kPa (15 Torr), the true lineshape (that is, the lineshape that would be observed with an instrument with infinite resolution) is dominated by the Doppler effect. For some molecules the effect of collisional narrowing, see below, is also important in that pressure regime. The Doppler effect gives a Gaussian lineshape which is described by the function

$$f(\nu) = \{[(\ln 2)/\pi]^{1/2}/\gamma_D\} \exp\{-(\ln 2)[(\nu - \nu_0)/\gamma_D]^2\}, \quad (3.31)$$

where ν_0 is the frequency (or wavenumber) of the center of the line.

In Eq. (3.31) the Gaussian shape function $f(\nu)$ has been normalized so that

$$\int_{-\infty}^{+\infty} f(\nu) d\nu = 1. \quad (3.32)$$

Consequently, since

$$k(\nu) = Sf(\nu), \quad (3.33)$$

integrating both sides of Eq. (3.33) over all frequency space gives

$$\int_{-\infty}^{+\infty} k(\nu) d\nu = \int_{-\infty}^{+\infty} S f(\nu) d\nu = S. \quad (3.34)$$

Here $k(\nu)$ is the absorption coefficient at frequency ν and S is the integrated line intensity given earlier in Eq. (3.9).

One important characteristic of the Gaussian lineshape is the small wing absorption due to the exponential reduction in absorption as one gets farther from the center of the line. As pointed out by Korb *et al.* [5.263], accurate intensity measurements are more easily made when the wing absorption is small. Another characteristic of the Gaussian shape is the bluntness at the center of the line.

pressure broadening

Pressure broadening gives rise to lines with a Lorentzian lineshape for which the normalized shape function has the form

$$f(\nu) = (\gamma_L/\pi) / [(\nu - \nu_0)^2 + \gamma_L^2], \quad (3.35)$$

where γ_L is half the width of the line at the half intensity point. When pressure broadening is the dominant effect determining the lineshape, then Eq. (3.35) must be used in Eqs. (3.33) and (3.34).

Pressure broadening is an additive effect, therefore, the broadening of each gas in a mixture depends only on the partial pressure, P_x , of that gas. The total broadening in a mixture is the sum of the broadening of each gas. Thus, for gases a and b with broadening coefficients c_a and c_b , the total pressure broadened width will be $\gamma_L = c_a P_a + c_b P_b$. The broadening coefficient is unique to each absorbing molecule and to each collision partner. The broadening coefficient is a function of the temperature as one might expect since the average collision velocity changes with temperature. The broadening coefficient is also different for each rotational transition although the changes are systematic with the rotational quantum numbers.

The pressure broadening coefficients generally have values in the range of 400 to 1300 MHz/Pa (3 to 10 MHz/Torr) and are greatest for molecules that have large dipole moments. The pressure broadening coefficients are generally smallest for those rotational energy levels that are at relatively high energy.

In contrast to Gaussian shaped lines, the Lorentzian shaped lines are sharper at the line center but have very extensive wings. For very strong lines it is possible to have significant absorption intensity twenty half-widths from the line center. This is noticeable in the CO atlas where there is only a small amount of pressure broadening and yet the strong lines have very noticeable wings. If there were no pressure broadening, the wings of the strong lines would not be so prominent.

Voigt profile

In many cases the lineshape is determined both by the Doppler effect and by the effects of pressure broadening. In such cases the lineshape is more accurately given by a Voigt profile which is a convolution of the Gaussian and Lorentzian profiles. There is no good single closed-form expression for the Voigt profile. Rather, the Voigt shape function is given by the integral expression

$$f(\nu) = (Bx/\pi) \int_{-\infty}^{+\infty} [\exp(-y^2)] / [x^2 + (z-y)^2] dy \quad (3.36)$$

and various approximations to that integral. Equation (3.36) has been simplified by using

$$B = (1/\gamma_D)[(\ln 2)/\pi]^{\frac{1}{2}},$$

$$x = (\gamma_L/\gamma_D)(\ln 2)^{\frac{1}{2}},$$

$$z = [(\nu - \nu_0)/\gamma_D](\ln 2)^{\frac{1}{2}}.$$

and

There are a number of good computer programs [3.17, 3.18] for evaluating the Voigt shape function.

collisional narrowing

Collisional narrowing or Dicke narrowing [3.19-3.21] has only recently been measured for a few molecules, but its effects have been observed for NO [5.370]. Collisional narrowing has the effect of reducing the size of the Gaussian linewidth γ_D . In other words, it makes the line appear to have a Doppler width that is smaller than that calculated by Eq. (3.30). For NO, the effective Gaussian width is about 9 percent smaller than the Doppler width at a pressure of 6.6 kPa (50 Torr). Since collisional narrowing is primarily a kinetic collisional effect (sometimes described in terms of hard and soft collision models), it is not expected to depend on the rotational or vibrational levels involved in the transition. There is, however, a weak dependence on the transition assignment as shown by Pine and Looney's work on HCl and HF [3.22].

Estimating peak intensities

From tables of line intensities, such as are given in this atlas, it is possible to estimate the pressure-pathlength product needed to obtain a spectrum with adequate intensity. For this purpose we consider the two limiting cases of Doppler (or Gaussian) shaped lines at low pressures and the pressure broadened Lorentzian lines for high pressures.

If the effect of pressure broadening is negligible and the lineshape is determined by the Doppler width rather than the spectrometer slit function, the percent transmission at the center of a line is given by

$$\% \text{ transmission} = 100 \exp(-CSlp/\gamma), \quad (3.37)$$

where C is 1.1494×10^{14} if S is the intensity given in the tables (in units of cm/molecule), γ is the Doppler width [given by Eq. (3.30)], l is the pathlength in centimeters, and p is the pressure in pascals (Pa). (If p is measured in Torr, then $C = 1.5324 \times 10^{16}$.) Note that C has been evaluated for a temperature of 296 K, which is the temperature for which the intensities have been calculated in this atlas.

If the lineshape is dominated by pressure broadening, the percent transmission is again given by Eq. (3.37), but γ should be the pressure-broadened linewidth, γ_L , and C will be 7.789×10^{13} if p is in Pa (1.038×10^{16} if p is in Torr).

For the same linewidth and integrated intensity a Doppler-broadened line will have a peak intensity 1.476 times greater than a pressure-broadened line, even though the pressure broadened line is sharper.

For intermediate pressures the peak intensity can be more accurately estimated by modifying Eq. (3.37) so as to add the approximate contribution of both shapes according to

$$\% \text{ transmission} = 100 \exp\{-Slp[(1.1494 \times 10^{14}\gamma_D + 7.789 \times 10^{13}\gamma_L)/(\gamma_D^2 + \gamma_L^2)]\}. \quad (3.38)$$

Equation (3.38) reduces to Eq. (3.37) when either γ_D or γ_L dominates the lineshape.

The peak intensity observed with an instrument that introduces any instrumental broadening will, of course, be smaller than that calculated with either Eq.(3.37) or (3.38). As a rule of thumb, the peak intensity will be diminished by more than the ratio γ/γ_s , where γ is the true linewidth and γ_s is the width of the instrumental resolution function. Thus, for an instrument with a resolution

function that is ten times greater than the "true" linewidth, an absorption line will appear at least ten times weaker than what is calculated by either Eq. (3.37) or Eq. (3.38), provided the line is not saturated.

Pressure induced lineshifts

A good frequency calibration standard is one whose frequency is not changed as the measurement conditions are varied. Some of the absorption lines given in this atlas are weak enough to require that either long pathlengths or moderate pressures, 0.3 to 1.3 Pa (2 to 10 Torr), be used. It is important that one recognize the additional calibration uncertainty introduced by using pressures that are too high. Although pressure induced shifts in the frequency of the absorption lines are poorly understood and measurements are few and not very accurate, it is possible to estimate the approximate effect of moderate pressures on the frequencies of these calibration standards.

As a general rule, pressure induced frequency shifts are at least an order of magnitude smaller than pressure induced broadening. For the overtone of CO, Pollock *et al.* [5.304] found a pressure shift (due to CO) on the order of -2 ± 1.5 kHz/Pa (-0.3 ± 0.2 MHz/Torr). Bouanich [5.302] found pressure shifts on the order of -1.2 ± 0.3 kHz/Pa (-0.16 ± 0.04 MHz/Torr). He seems to have observed a significant rotational dependence, but we only quote an average value. For the overtone of NO, Pine *et al.* [5.370] found a self-induced pressure shift of -1.1 ± 0.3 kHz/Pa (-0.15 ± 0.04 MHz/Torr). They found that there may be a weak rotational dependence but it was obscured by experimental error.

For N₂O an attempt to measure the self-induced pressure shift in the rotational spectrum resulted in an estimate of an upper limit of 0.75 kHz/Pa [5.201]. The pressure shift of several lines of N₂O were measured near 4500 cm⁻¹ and an average value of -1.2 ± 0.3 kHz/Pa (-0.16 ± 0.04 MHz/Torr) was found [5.219]. The pressure shift caused by N₂ and O₂ on the ν_3 band of N₂O near 1280 cm⁻¹ was measured by Varanasi and Chudamani [5.238]. Their diode laser measurements gave an average value of about -0.6 ± 0.15 kHz/Pa (-0.08 MHz/Torr) for several lines between 1250 and 1300 cm⁻¹.

More pressure shift measurements seem to have been made on OCS than on any of the other molecules in this atlas. The earlier measurements indicated that the pressure shift was on the order of 0.5 MHz/Torr or less [5.94]. Later this estimate was improved by new measurements that gave an average value of -0.4 ± 1.5 kHz/Pa (-0.05 ± 0.20 MHz/Torr) [5.120]. The most recent measurements at about 1000 cm⁻¹ [5.133] indicate that the self-shift is -0.37 ± 0.04 kHz/Pa (-0.049 ± 0.005 MHz/Torr). Recent measurements of the self-shift of microwave transitions [5.119] found that the shift was too small to measure, 0.000 ± 0.04 kHz/Pa or 0.000 ± 0.006 MHz/Torr.

Kou and Guelachvili [3.23] have recently measured the self-induced pressure shift for the CO₂ laser lines near 1000 cm⁻¹. They found the shift to be on the order of -1.05 ± 0.2 kHz/Pa (-0.14 ± 0.03 MHz/Torr) with no evidence of a *J*-dependence. One might expect that the self-induced pressure-shift of CO₂ would be similar to that of the molecules used in the present compilation.

Since the pressure shift is a shift in the energy levels, it is likely to be greater as one goes to higher energy levels. As a first approximation one can probably assume that the shift is proportional to the frequency. It is also possible that for polyatomic molecules, the pressure shift may depend, to a large extent, on the vibrational mode involved.

For purposes of estimating the maximum error that could be introduced in a calibration measurement using any of the data given in this atlas, one should treat the frequencies given in this book as applying for a pressure below 130 Pa (1 Torr). For each increase in pressure of 130 Pa (1 Torr) the uncertainty in the frequency for N₂O, NO, CO, and CS₂ should be increased by 0.3 MHz unless the pressure shift is added to the frequencies given in these tables or unless more accurate values for the pressure shift become available. For OCS the uncertainty should be increased by about 0.1 MHz/Torr. Note that the pressure shift seems to be negative for all the molecules in this atlas.

Chapter IV

ERROR ANALYSIS

The standards presented in this book are based on data derived in large part from frequency measurements because such measurements are less prone to systematic errors. In assessing the uncertainties that should be assigned to the recommended calibration frequencies, we must consider five major factors that may contribute to error in the determination of the line frequencies.

1. The accuracy of the calibration source.
2. The uncertainty in locating the center of the absorption line.
3. The accuracy of transferring the calibration to the line center measurement.
4. Errors caused by environmental effects.
5. Model errors, or uncertainties in the application of least-squares techniques to obtain the best estimate of the correct line frequency.

In succeeding paragraphs of this section each of these factors will be examined in relation to the calibration frequencies recommended in this book.

Accuracy of the Calibration Source

Much of the primary infrared data used for these tables originated at the NIST laboratory in Boulder, Colorado. Two other laboratories have reported heterodyne frequency measurements on the $2\nu_2$ band of OCS, [5.88, 5.126]. The most important of these were two saturated absorption measurements made by Fayt *et al.* [5.126] which considerably reduce the uncertainty in the frequencies for $2\nu_2$. The measurement of the laser transitions of N₂O by Whittford *et al.* [5.183] gave accurate frequencies for the separation of the ν_1 and ν_3 states which were useful for the tables between 880 and 980 cm⁻¹. Recently frequency measurements have been made by Urban and co-workers [5.321, 5.137a].

The NIST measurements used well characterized CO₂ lasers that were virtually identical to the lasers used by Petersen *et al.* [2.9, 2.11, 2.12] in the last major determination of the CO₂ laser frequencies. Since much of the laser technology that went into the determination of the CO₂ laser frequencies was developed in the same laboratory where the heterodyne measurements were made, one can be sure of the accuracy of the calibration source. These lasers have been described in Chapter II. The CO₂ laser frequencies are good to at least ± 0.05 MHz and are not a significant source of error for the Doppler limited heterodyne measurements.

Uncertainty in Locating the Line Center

Two major factors contribute to errors in the location or determination of absorption line centers: the signal-to-noise ratio, and the slope or other irregularities in the background.

For the infrared measurements the slope or irregular background in the radiation being absorbed was only a minor contributor to error since its effect could be practically eliminated, as described in Chapter II.

In some cases imperfectly resolved or overlapping lines were measured. In cases where the lines are close doublets, the measurement represents the center of gravity of the doublets, and the least-squares analysis took that into account. If the lines were partially resolved, that was taken into account in assigning the uncertainty for the measurement. In most cases partially resolved lines that have unequal intensities should not be used unless a very generous allowance is made for the uncertainty since the resulting error is not random, but is in a particular direction. OCS, CO, and CS₂ are good molecules to use for standards because they have no quadrupole fine structure. N₂O is not as good

because all of its transitions have a small quadrupole splitting. Since the splitting for N₂O is never greater than 4 MHz and diminishes rapidly with increasing *J*-values and since the Doppler full-width of N₂O at 500 cm⁻¹ is 28 MHz, the splitting should not affect the use of N₂O for most infrared calibration purposes.

For each infrared heterodyne frequency measurement two line centers must be measured: the absorption line center, and the center of the difference frequency (between the TDL and the local oscillator). The location of the absorption line center is determined by the technique used to lock the TDL to the absorption line as described in Chapter II. The uncertainty assigned to the line-center lock is given by half the Doppler-width of the line divided by the signal-to-noise ratio of the derivative signal for the line. Because of modulation broadening the linewidth is slightly greater than the Doppler-width but this approximation to the lock uncertainty is adequate. The lock error is random and is reflected in the statistical analysis of the least-squares fit of many measurements.

More important than the uncertainty in locking to the line center is the uncertainty in the difference frequency measurements. That uncertainty is given by one-tenth the beat note linewidth, or by half the beat note width divided by the signal-to-noise ratio, whichever is larger. We believe this covers both random and residual systematic errors for a single measurement. In most of our measurements, this has been the predominant uncertainty and the lock uncertainty has been negligible by comparison.

One source of error in the heterodyne measurements that has no direct counterpart in wavelength measurements is due to frequency-dependent differences in the transmission or amplification components involved in the heterodyne frequency measurements. This frequency dependence sometimes presented an additional distortion to the heterodyne frequency lineshape as displayed by the spectrum analyzer. Fortunately this error, which would be systematic for all measurements of the same heterodyne frequency, becomes randomized if enough different lines are measured. In most cases this problem was recognized and was taken into account in estimating the uncertainty of each measurement.

Examination of our results over the past decade indicates that the procedure outlined above for assigning the uncertainty produced values which turned out to be close to a two sigma uncertainty.

For the microwave and sub-millimeter wave measurements used to prepare these tables, the uncertainties given in the literature are generally accurate enough although we have increased the uncertainties slightly in a few cases. There may be some systematic error due to incomplete modulation when Stark modulation was used, but this is compensated by the much smaller linewidths, and the smaller frequency dependent irregularities, compared to the infrared measurements.

Accuracy of Transferring the Calibration to the Line Center Measurement

The primary difference in the reliability of wavelength and frequency measurements is in the accuracy of transferring the calibration to the measurement. In frequency measurements the accuracy of the measurements is not affected by beam dimensions, by wavefront mismatch or other misalignments, or by refractive index effects. The frequency of the radiation is always the same no matter what the medium may be, or how it is measured. Modern electronics excel at counting, and that is how frequency is determined. With frequency measurements, if a measurement can be made at all, the uncertainty must come from the four other sources of error discussed in this chapter.

On the other hand, wavelength comparisons are susceptible to many different wavelength-dependent errors, errors due to misalignment, errors due to differences in the ratio of the dimensions of the optical elements (or of the optical beam), to the wavelength. The best wavelength measurements use a calibration that is nearly the same wavelength and intensity as the feature to be calibrated. Each type of wavelength measurement has its own peculiarities.

The present tables are based in part on higher order centrifugal distortion constants determined to some extent by FTS measurements which are essentially wavelength measurements. These

measurements were all internally calibrated by means of lines whose frequency could be determined by heterodyne frequency measurements. These calibration features were always within the approximately 120 cm^{-1} band-pass of the FTS measurements. For the FTS measurements there may be a phase error which is different for weak features and for strong features and that is one reason why greater emphasis was placed on the use of frequency measurements of pure rotational transitions to determine the rotational constants wherever possible. In no case were FTS measurements used to determine the band centers or vibrational levels for the lines recommended as frequency standards.

Errors Caused by Environmental Effects

For closed shell molecules the only significant environmental effects are due to pressure shifts and electric field effects such as either the *ac* or *dc* Stark effects. As long as the radiation field (for absorption spectra) is too low to give saturated absorption effects, the *ac* Stark effect can be ignored in its effect on the absorption line center. Even the *dc* Stark effect can be ignored for most work since stray electric fields are generally too small to give noticeable Stark shifts.

We believe that even in the case of the saturated absorption measurements on the 2-0 band of CO, the shift due to the *ac* Stark effect will be smaller than a tenth of the linewidth, or less than 0.2 MHz.

The *ac* Stark effect may have a small effect on the frequency of the CO₂ lasers but, since those lasers have the same characteristics as the lasers used in the original measurements against the cesium frequency standard, the effect of the shift will already be included in the frequency assigned to the laser lines. In the case of the CO transfer oscillators, the CO frequencies are measured at the same time as the beat note frequency measurement and any *ac* shift is included in the measurement.

On the other hand, the effect of pressure induced shifts is potentially significant and deserves serious consideration. Pressure-induced shifts in infrared spectra have not been extensively studied, so there is no experimentally confirmed theory that one can use to calculate the pressure shifts to be expected for much of the data given in the present tables. All of the pressure shift measurements seem to indicate that the shift for the transitions given in these tables may be on the order of -2.2kHz/Pa (-0.3 MHz/Torr) or less. Only in the case of the measurements given by Vanek *et al.* [9.133] is the shift of $-0.37 \pm 0.04\text{ kHz/Pa}$ ($-49 \pm 5\text{ kHz/Torr}$) reliably given for the $2\nu_2$ band of OCS. Since neither the frequency dependence nor the rotational or vibrational dependence of the pressure shift is known, this remains one of the most important uncertainties in the application of these tables to real measurements.

Uncertainties in the Application of Least-squares Techniques

Because individual measurements of infrared absorption lines by heterodyne measurement techniques are not very precise (uncertainties of the order of 5 to 10 MHz for some regions) and only a small number of transitions can be measured, it is necessary to use least-squares techniques to combine all available measurements to yield calculated transitions that are considerably more accurate than any one measurement. Such fitting techniques can be no more accurate than the equations used to describe the transitions (the Hamiltonian). The molecules and the particular transitions in these tables were chosen in part because of the reliability of the Hamiltonian as shown by extensive studies reported in the literature. Although certain interactions, such as Fermi resonance, affect the constants used in the effective Hamiltonian, such resonances can be ignored, provided that measurements are available for a wide range of rotational levels for each vibrational state. In the analysis used in this book the effect of *l*-type resonance was included because it represents the largest resonance effect and it can be reliably estimated, thereby giving the correct functional form to the centrifugal distortion constants. The details of the fitting procedure and Hamiltonian are given in Chapter III.

The variance-covariance matrix determined by the least-squares fit gives a reliable estimate of the uncertainties of the transitions in the range of rotational levels for which there are good measurements. The calculated uncertainties get large quite rapidly for transitions extrapolated beyond the range of measured energy levels, but the reliability of those calculated uncertainties deteriorates even more quickly. For that reason we have terminated the recommended calibration standard indication at the highest J -value for which there are good measurements. Higher transitions are given in the tables but their accuracy is less certain.

Summary

Of the five sources of error identified above, the first (the accuracy of the calibration source) does not contribute significantly to the uncertainties in the calibration frequencies given in these tables. For frequency measurements the second and third source (uncertainty in locating the line center and accuracy of transferring the calibration) will appear as random errors and so will be given by the statistical analysis of the least-squares fit of the measurements. For the molecules and bands represented in these tables the uncertainties contributed by model errors are small and likely to show as deviations that are included in the statistical analysis.

In conclusion we think that the uncertainties given by the statistical analysis are adequate to describe the errors in the frequency measurements that might arise from all causes except errors due to pressure-induced frequency shifts. Most of the heterodyne measurements were made at low pressures but some measurements of weaker transitions were made at pressures as great as 1200 Pa (9 Torr). To allow an extra margin of error due to pressure shifts, the uncertainties assigned to the heterodyne frequency measurement data used in the fit were about twice as large as the rms deviation. Primarily, this had the effect of increasing the uncertainty in the vibrational energy levels.

Chapter V BIBLIOGRAPHY

We attempt here to list all references to papers giving infrared or microwave frequency (or wavenumber) measurements, as well as lineshape and intensity measurements that are relevant to this atlas. Papers involving bands not included in this atlas may be missing from this bibliography. Some papers are not included if they involve foreign gas broadening measurements only. For a more complete listing of pressure broadening papers see the review given by Smith *et al.* [5.2]. When completely superseded, some of the older papers may not appear in this bibliography but they can be found referenced in the more recent papers. The references are grouped by molecule and arranged in chronological order for each molecule. At the end of each reference is a list of initials that indicate the subject matter covered by the reference as follows:

- F - frequency measurements,
- FB - foreign gas broadening measurements,
- I - intensity measurements,
- LS - laser-Stark measurements,
- PS - pressure shift measurements,
- SB - self-broadening measurements,
- T - theory, and
- W - wavenumber or wavelength measurements.

CHAPTER VI

ATLAS AND WAVENUMBER TABLES

Description

Throughout the wavenumber tables the lines that are suitable for use as wavenumber standards are indicated by an asterisk (*) following the wavenumber and its uncertainty. In assigning the asterisks no consideration was given to problems related to overlapping with other transitions. The tables list nearby lines that may cause problems with overlapping. The user must exercise judgment in determining if such overlapping will impair the accuracy of the measurement. The asterisk only certifies the accuracy of the line position in the hypothetical absence of any other nearby lines. Obviously, the resolution of the instrumentation being used will determine if a nearby line might invalidate the accuracy of a calibration line.

The uncertainties of the wavenumbers are given in parentheses after the wavenumbers in those cases where there is reason to believe that a good estimate of the uncertainty can be made. Even so, the uncertainty in the lines not designated as calibration lines should be taken with some degree of skepticism.

The uncertainties given in the tables are twice the estimated standard error as calculated from the variance-covariance matrix given by the least-squares fit that determined the constants used to calculate the wavenumbers. The uncertainties refer to the accuracy of each individual transition. In general, the wavenumber separation of two nearby lines for the same vibrational transition of the same molecular species will be given more accurately than the uncertainty given in parentheses might lead one to believe. That is because the relative differences between the rotational energy levels are usually known more accurately than the differences in the vibrational energy levels.

On the other hand, the separation of two lines that are due to absorption from two different isotopic species is probably known no more accurately than the uncertainty (given in parentheses) would lead us to believe.

The wavenumbers given in the tables are calculated wavenumbers because they are more reliable than individual line measurements and the uncertainties in the calculated wavenumbers can be accurately estimated.

The wavenumber tables also contain a column for the intensity estimated for each transition at a temperature of 296 K. The format for the intensity values is the standard computer format consisting of a decimal value followed by the exponent (the power of ten multiplying the decimal value). The intensities given in the wavenumber tables are represented by S in Eq. (3.10) and are integrated line intensities rather than peak intensities.

In the sections giving discussions and equations on intensity calculations and on pressure broadening (Chapter III), equations are given for estimating the appearance of the spectrum for different experimental conditions. In particular, Eq. (3.37) can be used to estimate the percent transmission at the center of a line under different conditions of pressure and pathlength. As an aid in calculating intensities at different temperatures the tables for OCS and N₂O also contain a column giving the separation (in cm⁻¹) of the lower state energy level from the ground state. The units given in the tables can be converted to the more common units of cm⁻² atm⁻¹ at 296 K by multiplying by 2.479×10^{19} . To convert to intensities at some other temperature one should refer to Eq. (3.10). Smith *et al.* [5.2] give a table for converting to other units.

The intensity values given in this book are only given as an aid in estimating the appearance of the spectrum, they should not be treated as well determined values. The intensities given for weak lines and especially for the rarer isotopes may be in error by 50 percent or more.

The spectral illustrations were actually calculated spectra rather than reproductions of real measurements. This gave us more flexibility in choosing effective pressures and pathlengths that seemed most appropriate to illustrate even the weak lines. As with any digitized spectrum, regardless of whether it is calculated or measured, the peak intensity of sharp lines may show some irregularity depending on whether the true peak falls on a digitized point or slightly misses it. The spectra were plotted with a digitizing interval of about 0.0005 to 0.001 cm⁻¹. Close doublets that should have the same intensity may show slight intensity differences because of this digitizing effect.

Comparison with real spectra measured in our own laboratory or illustrated in published works (such as Refs. [5.101, 5.102, 5.307]) showed that the spectra given in this book are adequate for identifying the calibration lines. Some weak transitions may be absent from the calculated spectrum even though they might be found in a real spectrum of comparable pressure and pathlength. Certainly, absorption due to common impurities such as H₂O or CO₂ will not be found in these spectra.

The spectra used in the illustrations for CO were calculated for infinite resolution but the lines were given widths dictated by the Doppler width of the line convolved with the pressure broadened width. For the CO spectra the shape of the weak lines is dominated by the Doppler width which is 0.0047 cm⁻¹ (FWHH) at 2000 cm⁻¹ and 0.0093 cm⁻¹ at 4000 cm⁻¹. For the conditions chosen for the atlas illustrations, the strong CO lines are much broader than the weak ones and show pronounced shoulders due to the effect of even a very small pressure broadening.

The figures used for illustrating the OCS and N₂O spectra were calculated for spectrometer resolutions on the order of 0.003 cm⁻¹. Again the expected Doppler and pressure-broadened lineshapes were used in calculating the spectra. The atlas for OCS and N₂O is divided into sections according to the vibrational transitions involved. At the beginning of each section the parameters (slit width, dipole derivative, Herman-Wallis constants) used in calculating the spectra are given as well as a key to the abbreviations used for the vibrational transitions in the atlas.

In calculating the pressure-broadened width, a single value for the pressure broadening was used for all lines in a spectrum. It is well known that such an assumption is incorrect and therein lies one reason for the illustration to depart slightly from a true spectrum.

The spectra overlap slightly in order to show the relationship of the lines near the ends of each panel. At the top of each spectrum fiducial marks indicate which lines are given in the accompanying wavenumber tables. Every fifth line is indicated with a darker and longer mark. In the tables, every fifth line is set apart by a following blank line. Even though the panels overlap, each line is identified by a fiducial mark only once.

Diskettes with Detailed Linelist

In preparing the tables for this atlas, far more transitions were calculated than could possibly be published. A complete list of transitions calculated for this work is available from the authors in the form of four floppy diskettes readable on a personal computer (PC) capable of reading 5½ inch high-density floppy discs generated by DOS-5.0. These diskettes are written in ASCII and contain the following information: wavenumber (cm⁻¹), uncertainty, lower state energy (cm⁻¹), intensity (cm/molecule), vibrational assignment, rotational assignment, date of data entry, isotopic species, and band designation according to the keys given in this book. The authors intend to update these discs as new data become available. Persons interested in obtaining the most up-to-date calibration data should contact the authors for the most recent version of these discs.

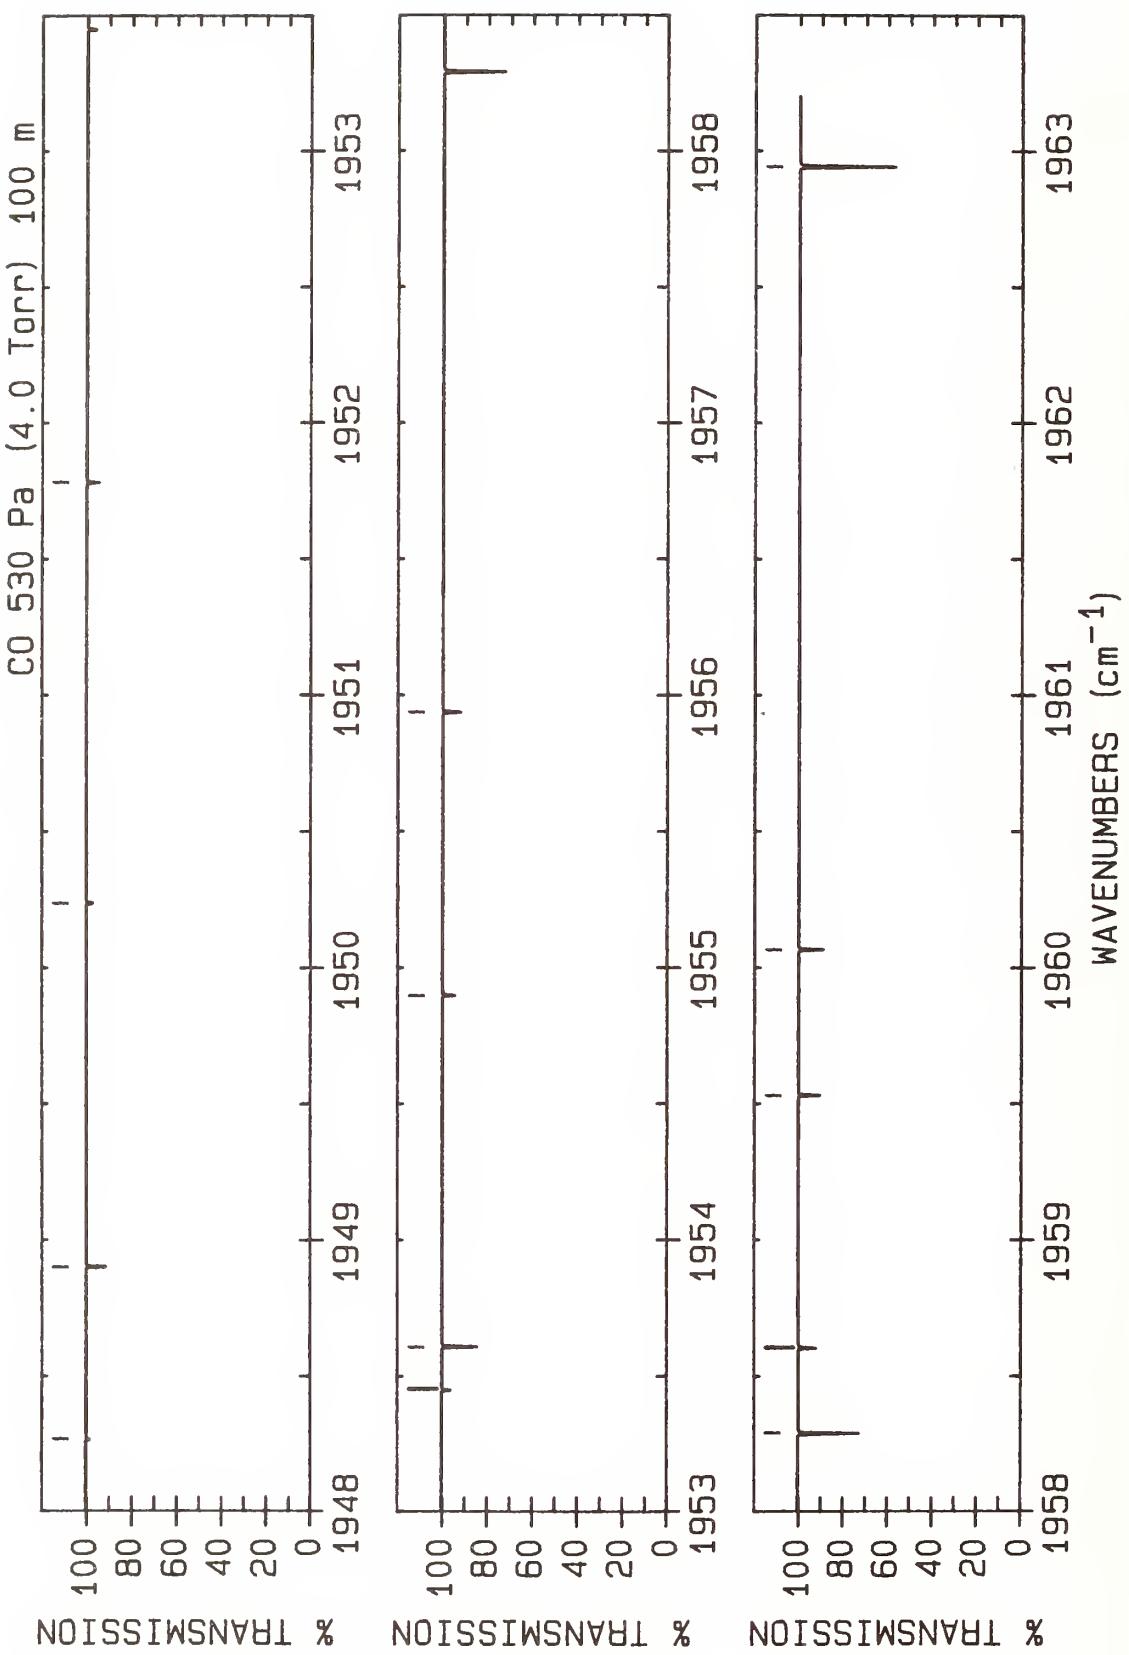

ATLAS of CO ABSORPTION LINES

from 1948 to 2275 cm⁻¹

and

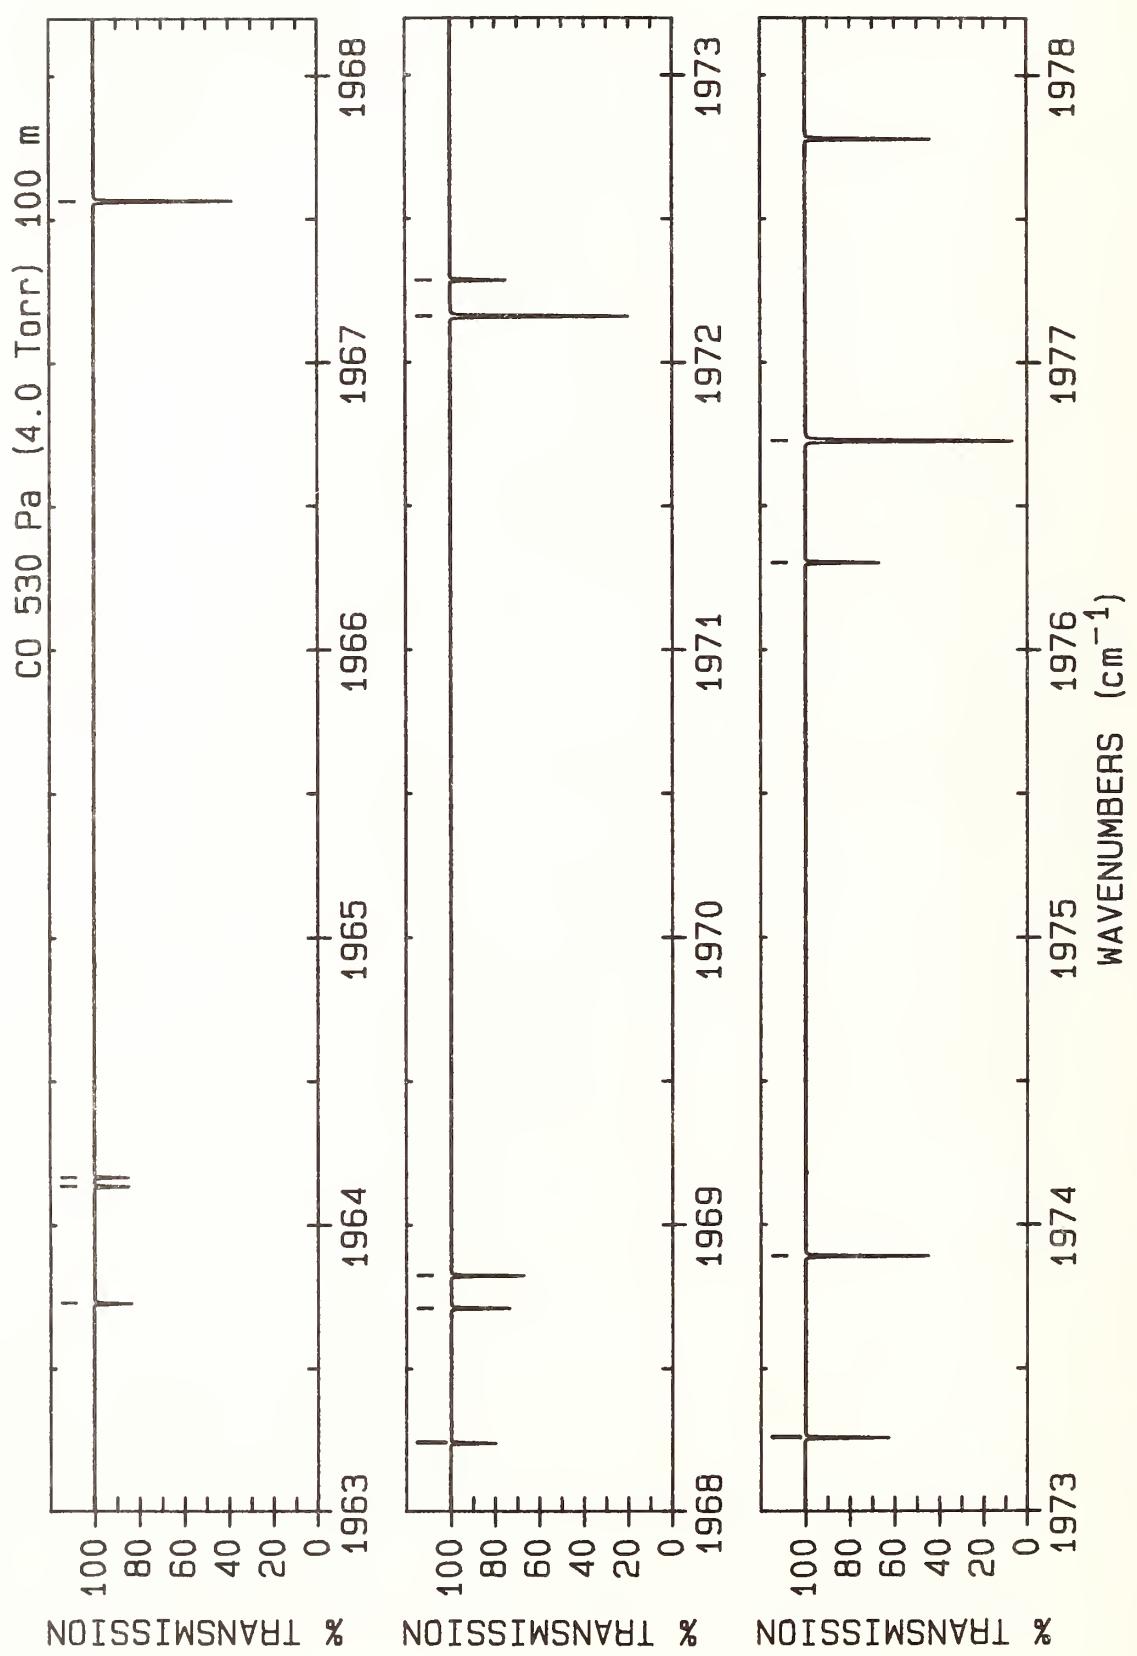

from 4071 to 4352 cm⁻¹

Spectra of the fundamental region are given for a slitwidth of < 0.001 cm⁻¹ and a transition moment of 0.1073 debye at a temperature of 296 K. For the first overtone region the transition moment was 0.0066 debye and the same narrow slitwidth was used. No Herman-Wallis constant was used for the fundamental band but the constants $C_1 = 0.005$ and $C_2 = 0.000\ 034$ were used for the first overtone band region.

S		02 ⁰ 0-01 ¹ 0
T	$^{16}\text{O}^{13}\text{C}^{32}\text{S}$	01 ¹ 0-00 ⁰ 0

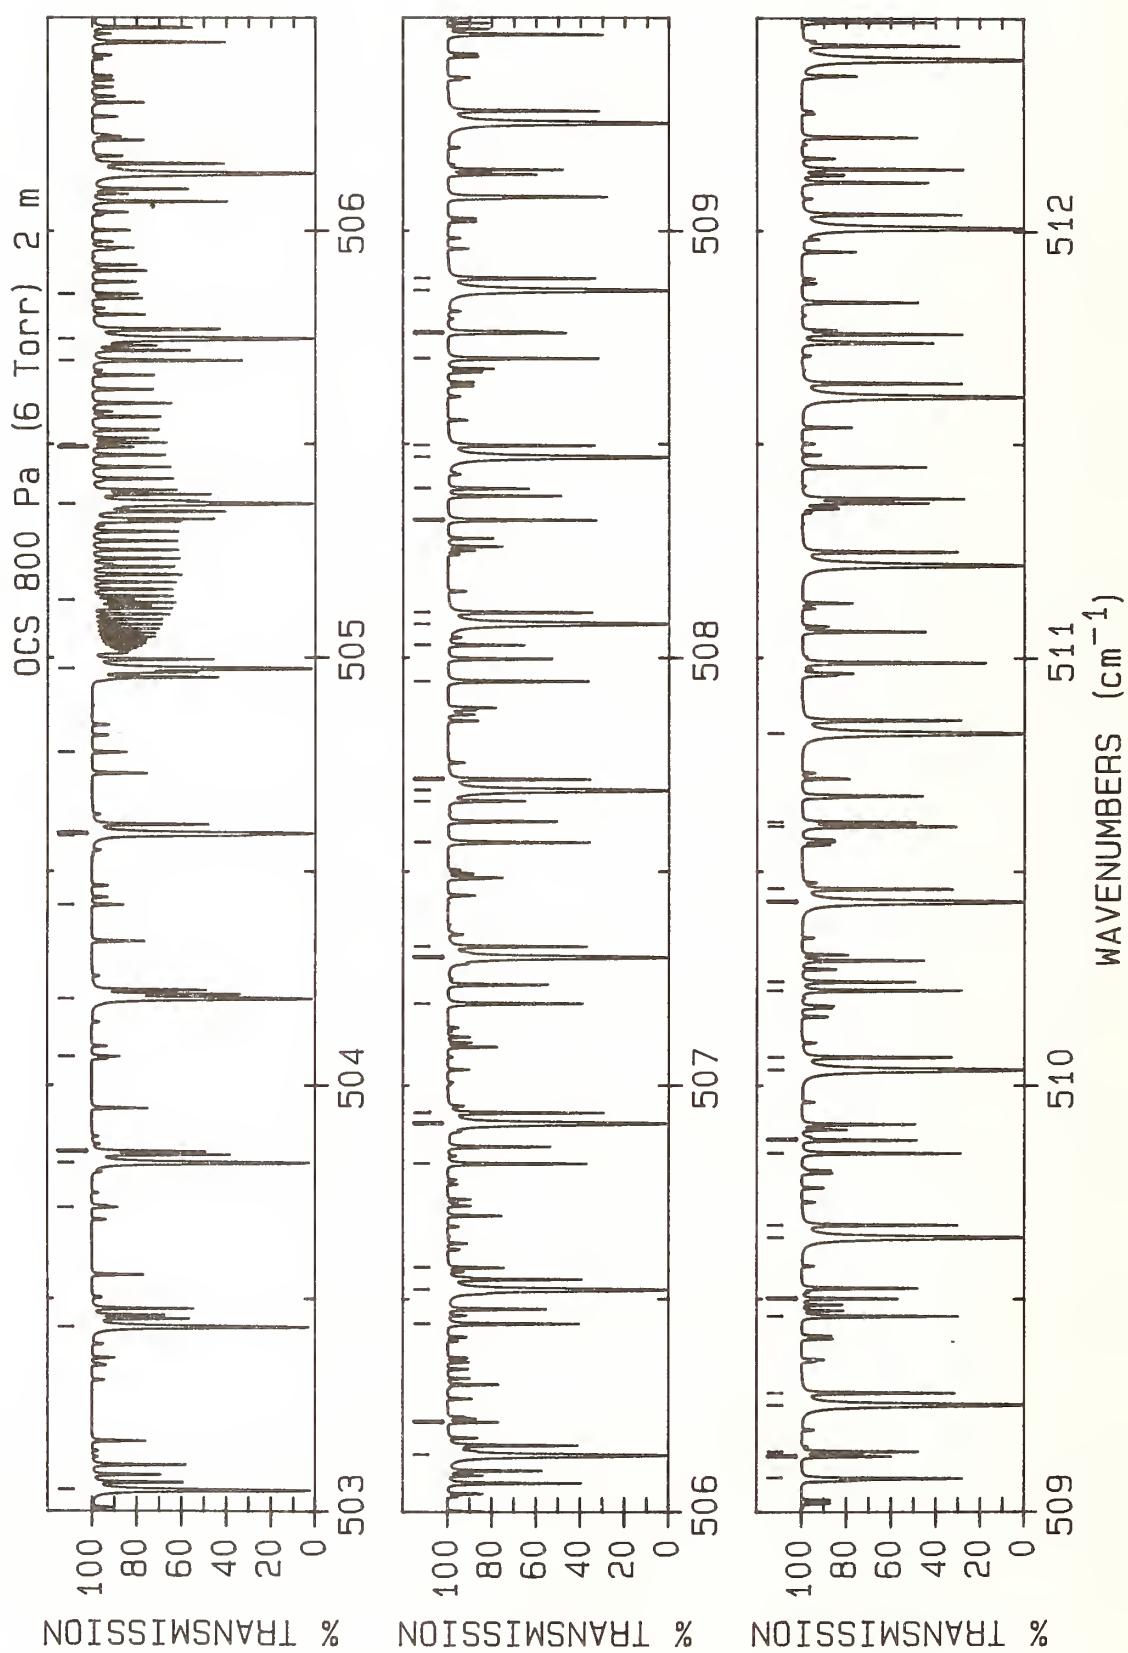

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.002 cm^{-1} and a transition moment of 0.047 debye at a temperature of 296 K. A Herman-Wallis constant of $C_1 = 0.0045$ is included in the intensity calculation for the lines of all bands.

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.002 cm^{-1} and a transition moment of 0.064 debye at a temperature of 296 K. No Herman-Wallis constant was included in the intensity calculation.

ATLAS OF OCS ABSORPTION LINES FROM 1000 cm^{-1} to 1095 cm^{-1}

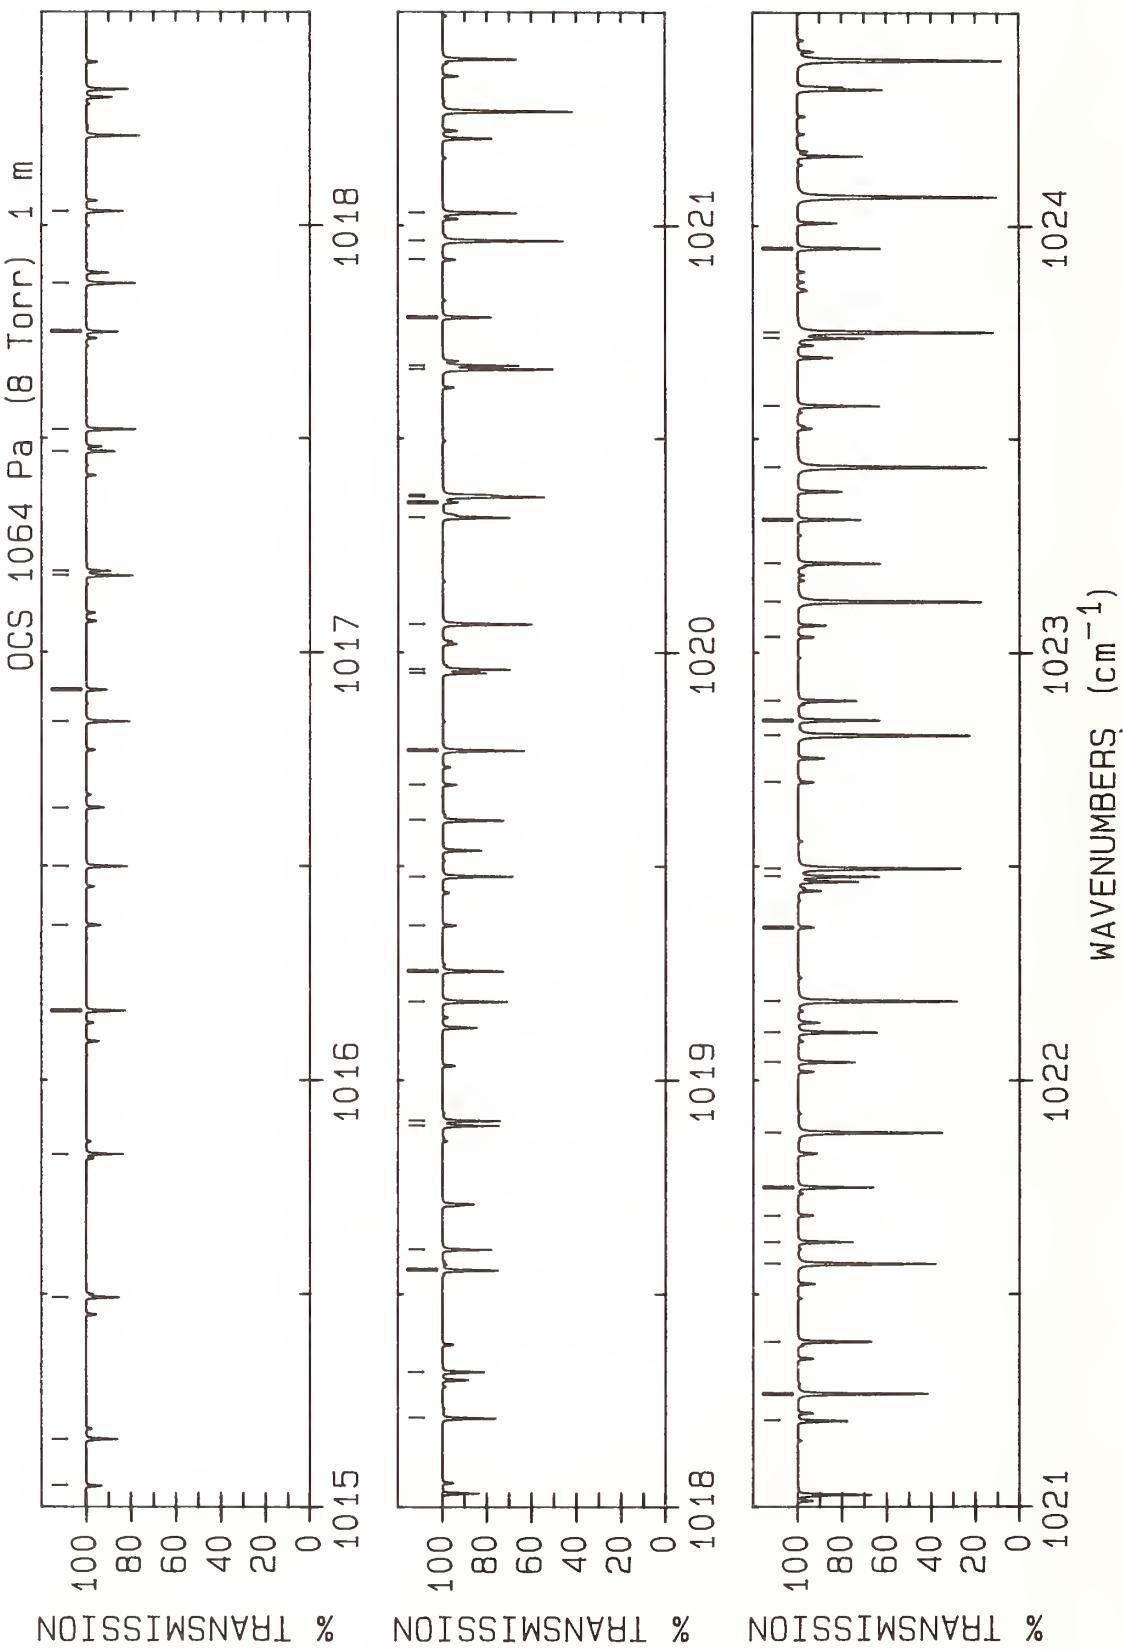

key:

Band	Isotopomer	Vibrational Transition
A	$^{16}\text{O}^{12}\text{C}^{32}\text{S}$	02^00-00^00
X		$02^{2e}0-00^00$
B		$03^10-01^{1e}0$
C		$03^10-01^{1f}0$
D		02^01-00^01
E		$04^20-02^{2e}0$
F		$04^20-02^{2f}0$
G		04^00-02^00
H		$03^{11}-01^{1e}1$
I		$03^{11}-01^{1f}1$
J		$05^30-03^{3e}0$
K		$05^30-03^{3f}0$
L		$05^10-03^{1e}0$
M		$05^10-03^{1f}0$
P	$^{16}\text{O}^{12}\text{C}^{34}\text{S}$	02^00-00^00
Q		$03^10-01^{1e}0$
R		$03^10-01^{1f}0$
T	$^{16}\text{O}^{13}\text{C}^{32}\text{S}$	02^00-00^00

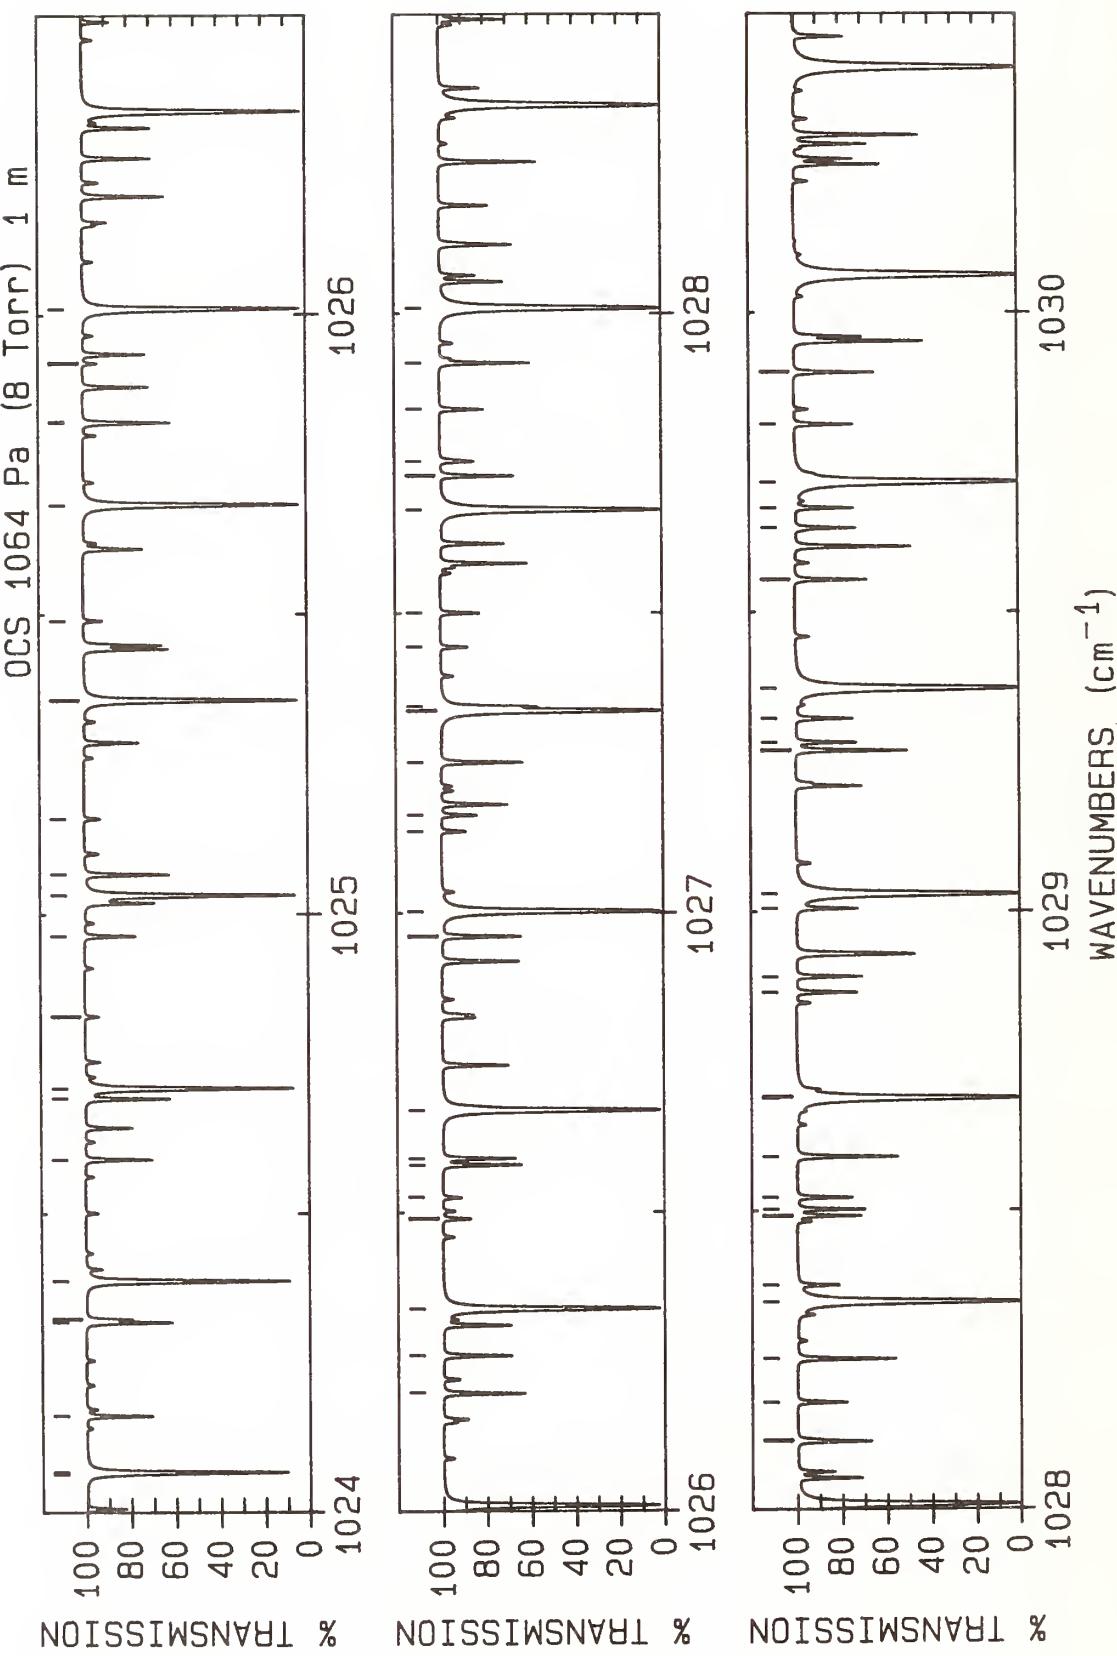

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.002 cm^{-1} and a temperature of 296 K . For the A, X, D, P, and T bands a transition moment of 0.0333 debye was used and no Herman-Wallis constant was included in the intensity calculation. For the other bands a transition moment of 0.032 debye was used with a Herman-Wallis constant of $C_1=0.0019$.

ATLAS OF OCS ABSORPTION LINES FROM 1650 cm^{-1} TO 1739 cm^{-1}

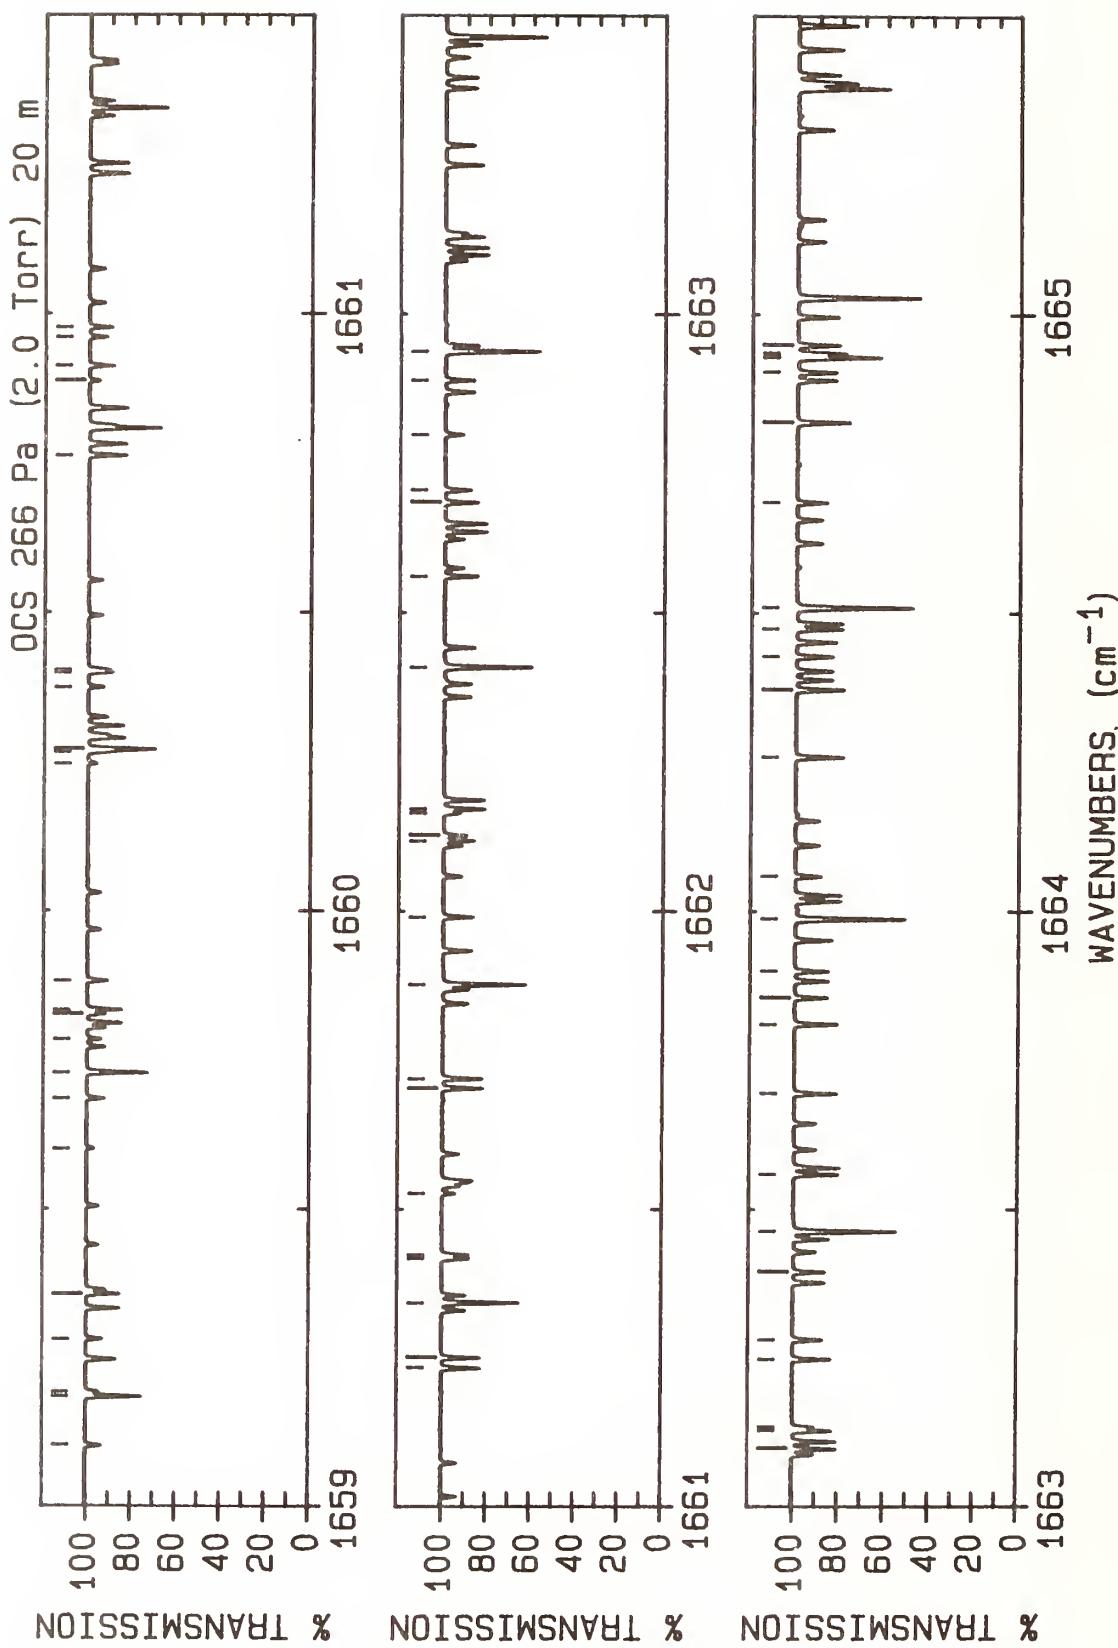

key:

Band	Isotopomer	Vibrational Transition
A	$^{16}\text{O}^{12}\text{C}^{32}\text{S}$	00^02-00^00
B		01^12-01^1e0
C		01^12-01^1f0
D		00^03-00^01
E		02^22-02^2e0
F		02^22-02^2f0
G		02^02-02^00
H		01^13-01^1e1
I		01^13-01^1f1
L	$^{16}\text{O}^{12}\text{C}^{33}\text{S}$	00^02-00^00
P	$^{16}\text{O}^{12}\text{C}^{34}\text{S}$	00^02-00^00
Q		01^12-01^1e0
R		01^12-01^1f0
T	$^{16}\text{O}^{13}\text{C}^{32}\text{S}$	00^02-00^00

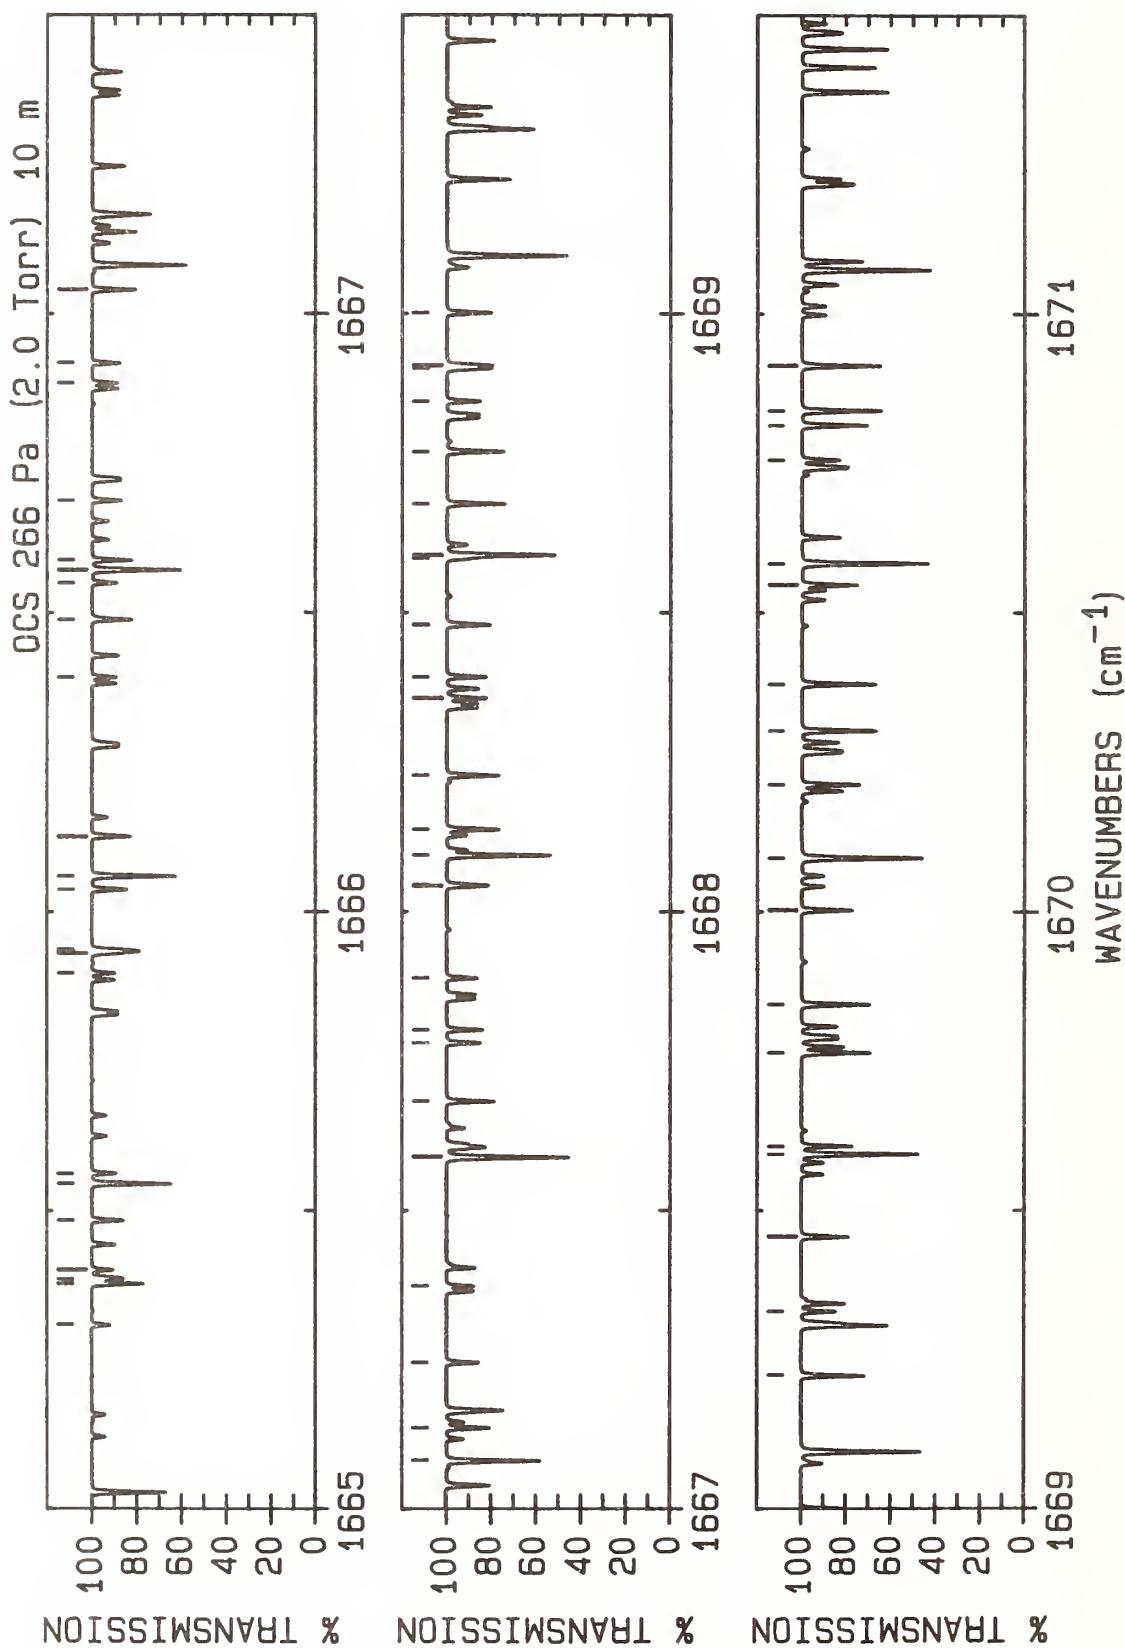

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.003 cm^{-1} , a temperature of 296 K , and a transition moment of 0.0195 debye . No Herman-Wallis constant was included in the intensity calculation.

ATLAS OF OCS ABSORPTION LINES FROM 1832 cm^{-1} to 1934 cm^{-1}

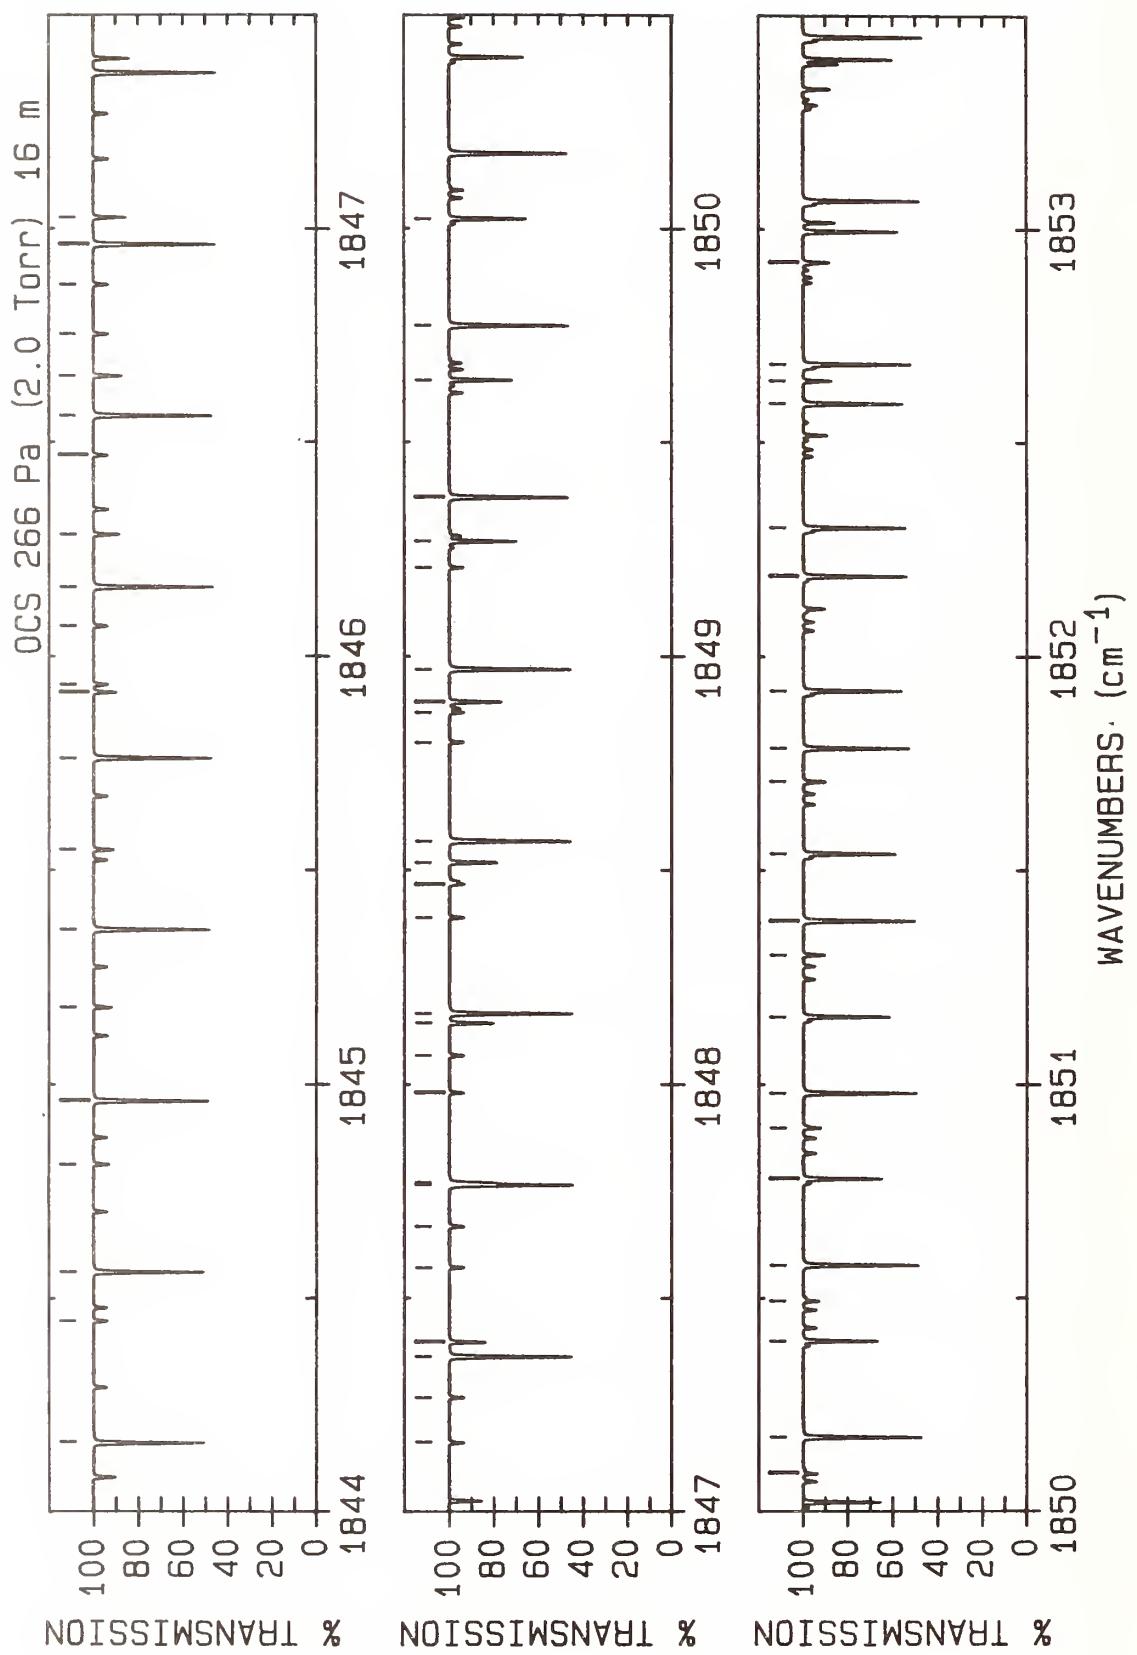

key:

Band	Isotopomer	Vibrational Transition
A	$^{16}\text{O}^{12}\text{C}^{32}\text{S}$	02 ⁰ 1-00 ⁰ 0
B		03 ¹ 1-01 ^{1e} 0
C		03 ¹ 1-01 ^{1f} 0
D		02 ⁰ 2-00 ⁰ 1
E		04 ² 1-02 ^{2e} 0
F		04 ² 1-02 ^{2f} 0
G		04 ⁰ 1-02 ⁰ 0
H		03 ¹ 2-01 ^{1e} 1
I		03 ¹ 2-01 ^{1f} 1
X		02 ² 1-00 ⁰ 0
P	$^{16}\text{O}^{12}\text{C}^{34}\text{S}$	02 ⁰ 1-00 ⁰ 0
Q		03 ¹ 1-01 ^{1e} 0
R		03 ¹ 1-01 ^{1f} 0
T	$^{16}\text{O}^{13}\text{C}^{32}\text{S}$	02 ⁰ 1-00 ⁰ 0
U		03 ¹ 1-01 ^{1e} 0
V		03 ¹ 1-01 ^{1f} 0

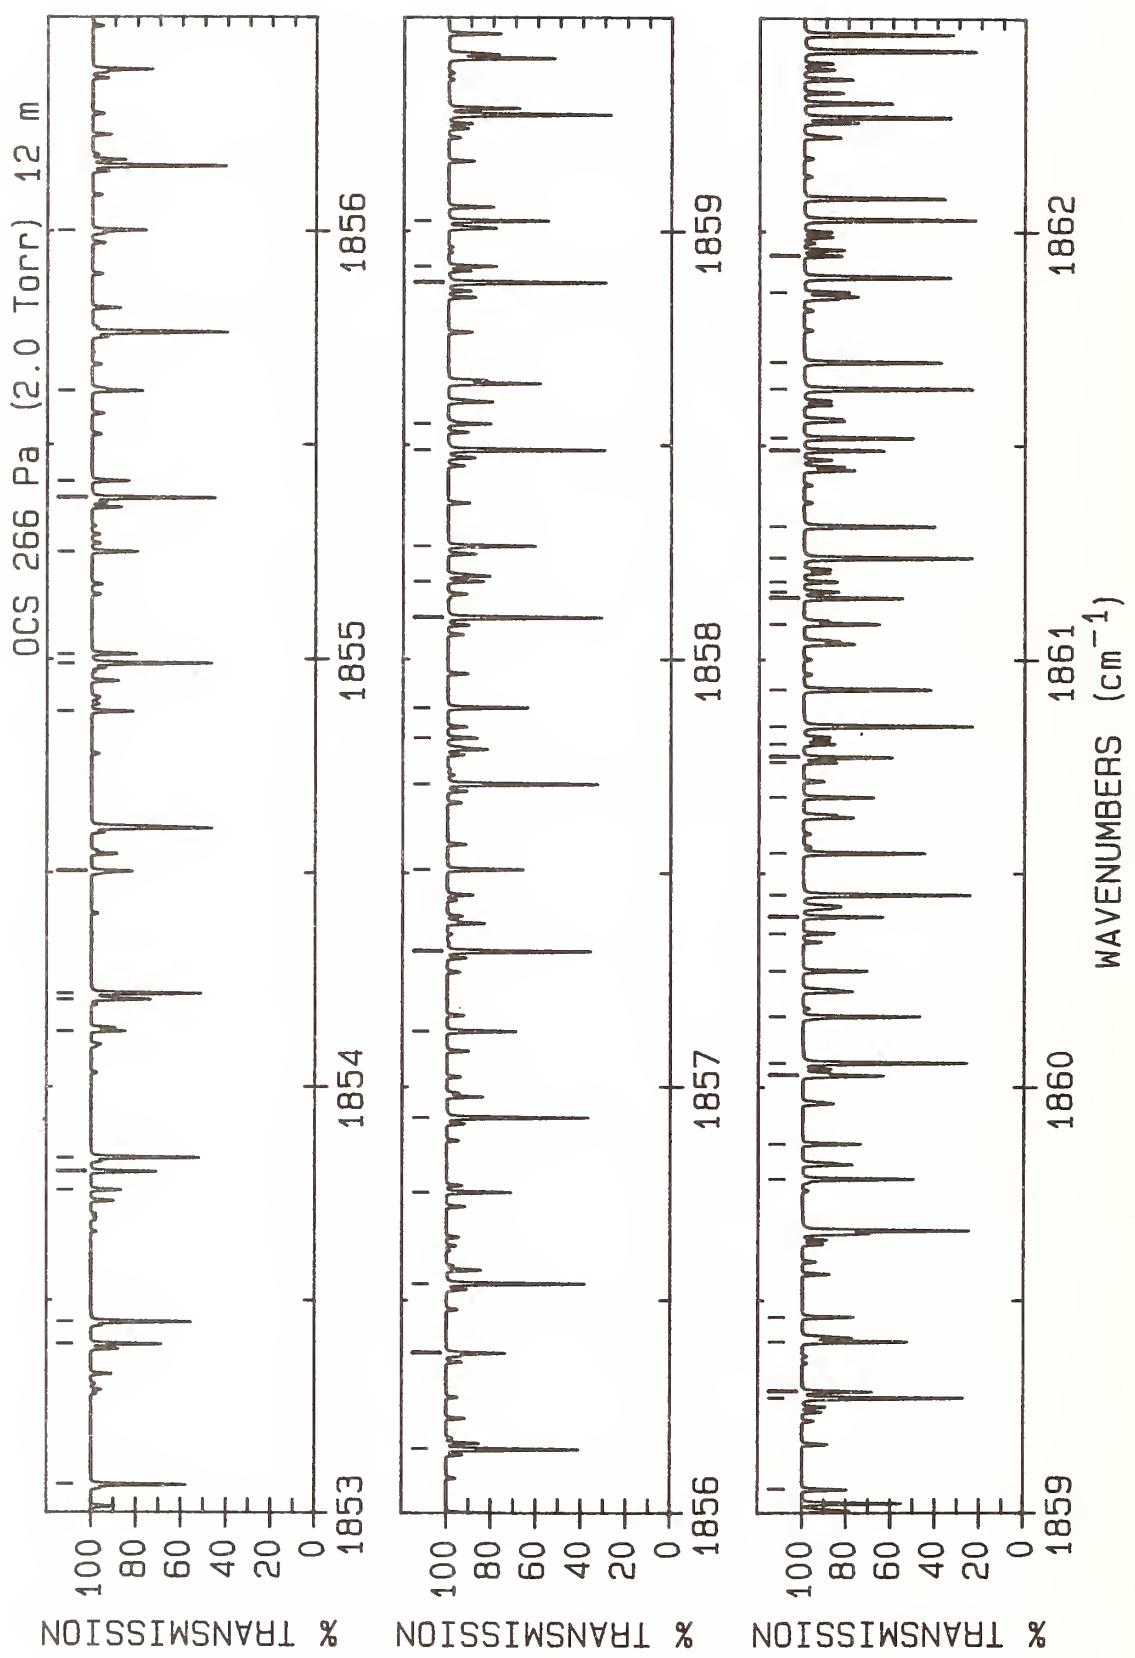

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.003 cm^{-1} , a temperature of 296 K , and a transition moment of 0.022 debye . No Herman-Wallis constant was included in the intensity calculation.

U		11^10-01^1e0
V		11^10-01^1f0

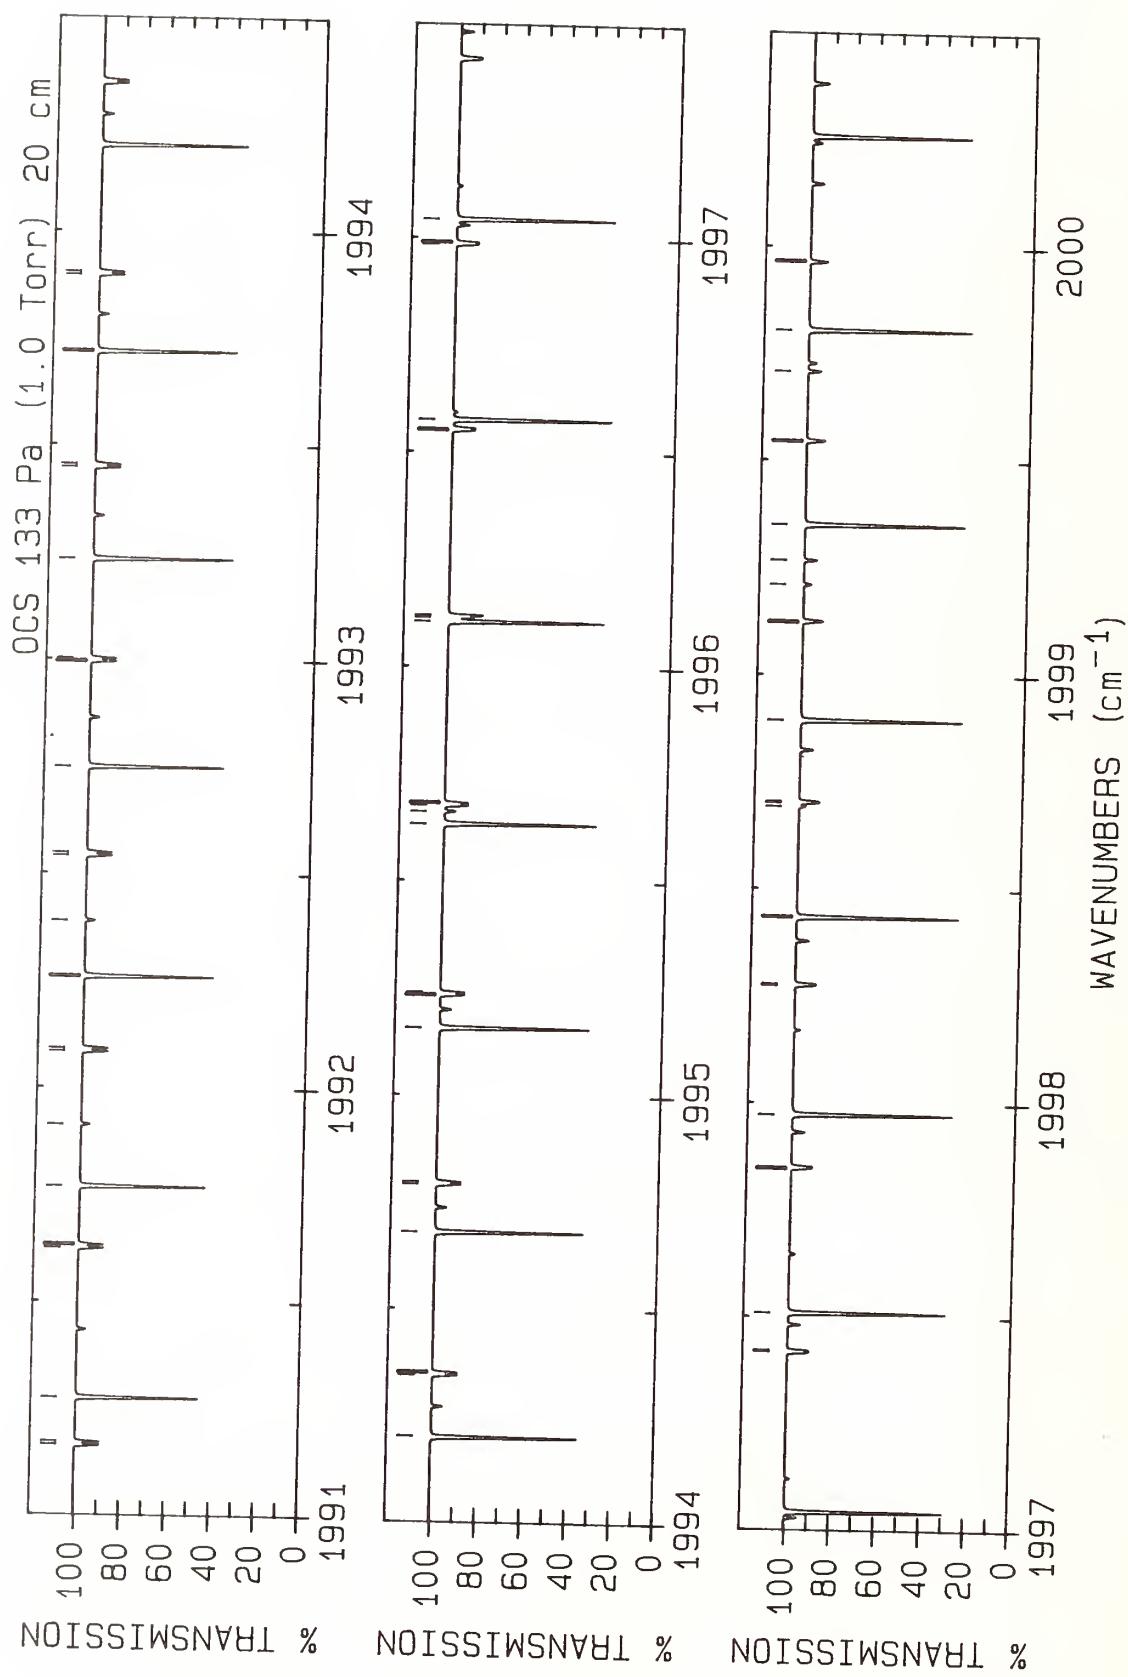

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.003 cm^{-1} , a temperature of 296 K , and transition moments of 0.345 debye for $\Delta v_1=1$ transitions, 0.024 debye for the W band, and 0.017 debye for the Y and Z bands. No Herman-Wallis constant was included in the intensity calculation.

X		12 ⁰ 0-01 ¹ 0
Y		12 ² 0-01 ^{1e} 0
Z		12 ² 0-01 ^{1f} 0
L	¹⁶ O ¹² C ³³ S	11 ¹ 0-00 ⁰ 0
P	¹⁶ O ¹² C ³⁴ S	00 ⁰ 3-00 ⁰ 0
Q		11 ¹ 0-00 ⁰ 0
T	¹⁶ O ¹³ C ³² S	00 ⁰ 3-00 ⁰ 0
U		11 ¹ 0-00 ⁰ 0

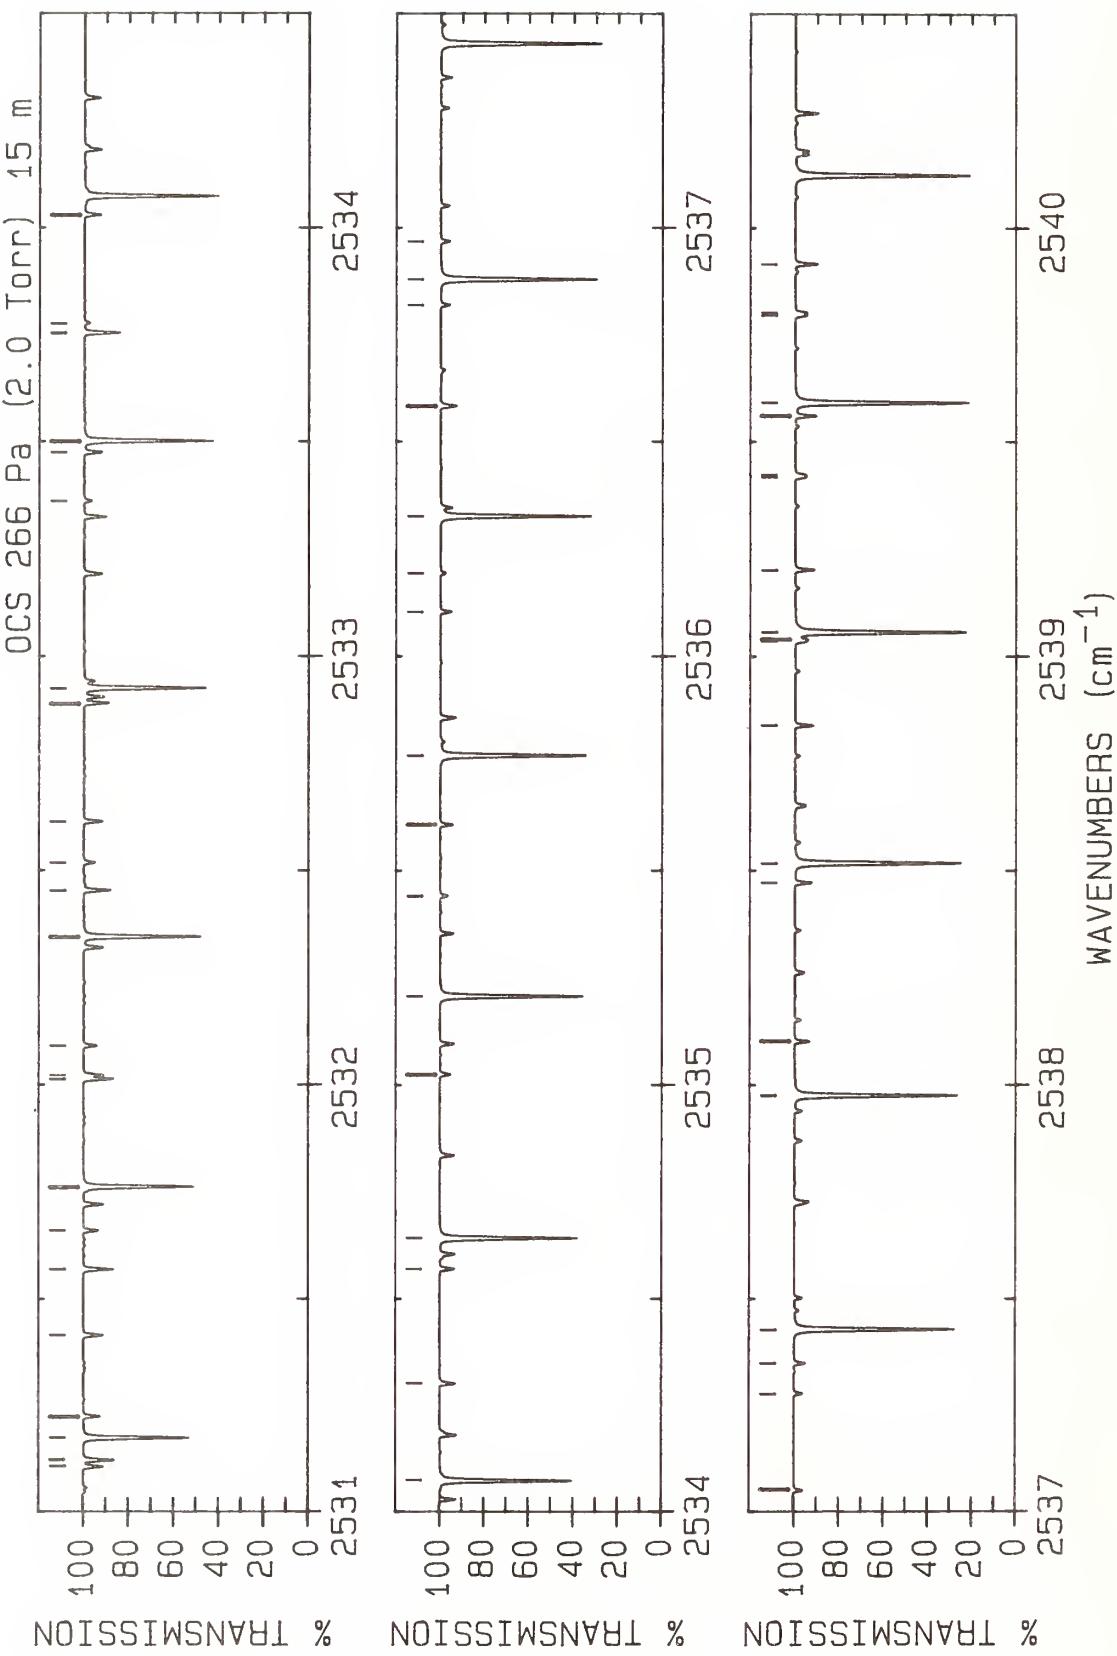

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.003 cm⁻¹, a temperature of 296 K. Except for the B and C bands for which the transition moment used was 0.00284 debye, the transition moment used for the $\Delta v_3=3$ transitions was 0.00367 debye and that used for the $\Delta v_1=1$, $\Delta v_2=1$ transitions was 0.00257 debye. No Herman-Wallis constant was included in the intensity calculation for the $\Delta v_3=3$ bands but the Herman-Wallis correction of $C_1=0.00463$ was used for the $\Delta v_1=1$, $\Delta v_2=1$ bands as recommended by Dang-Nhu and Guelachvili [5.104].

ATLAS OF OCS ABSORPTION LINES FROM 2693 cm^{-1} TO 2763 cm^{-1}

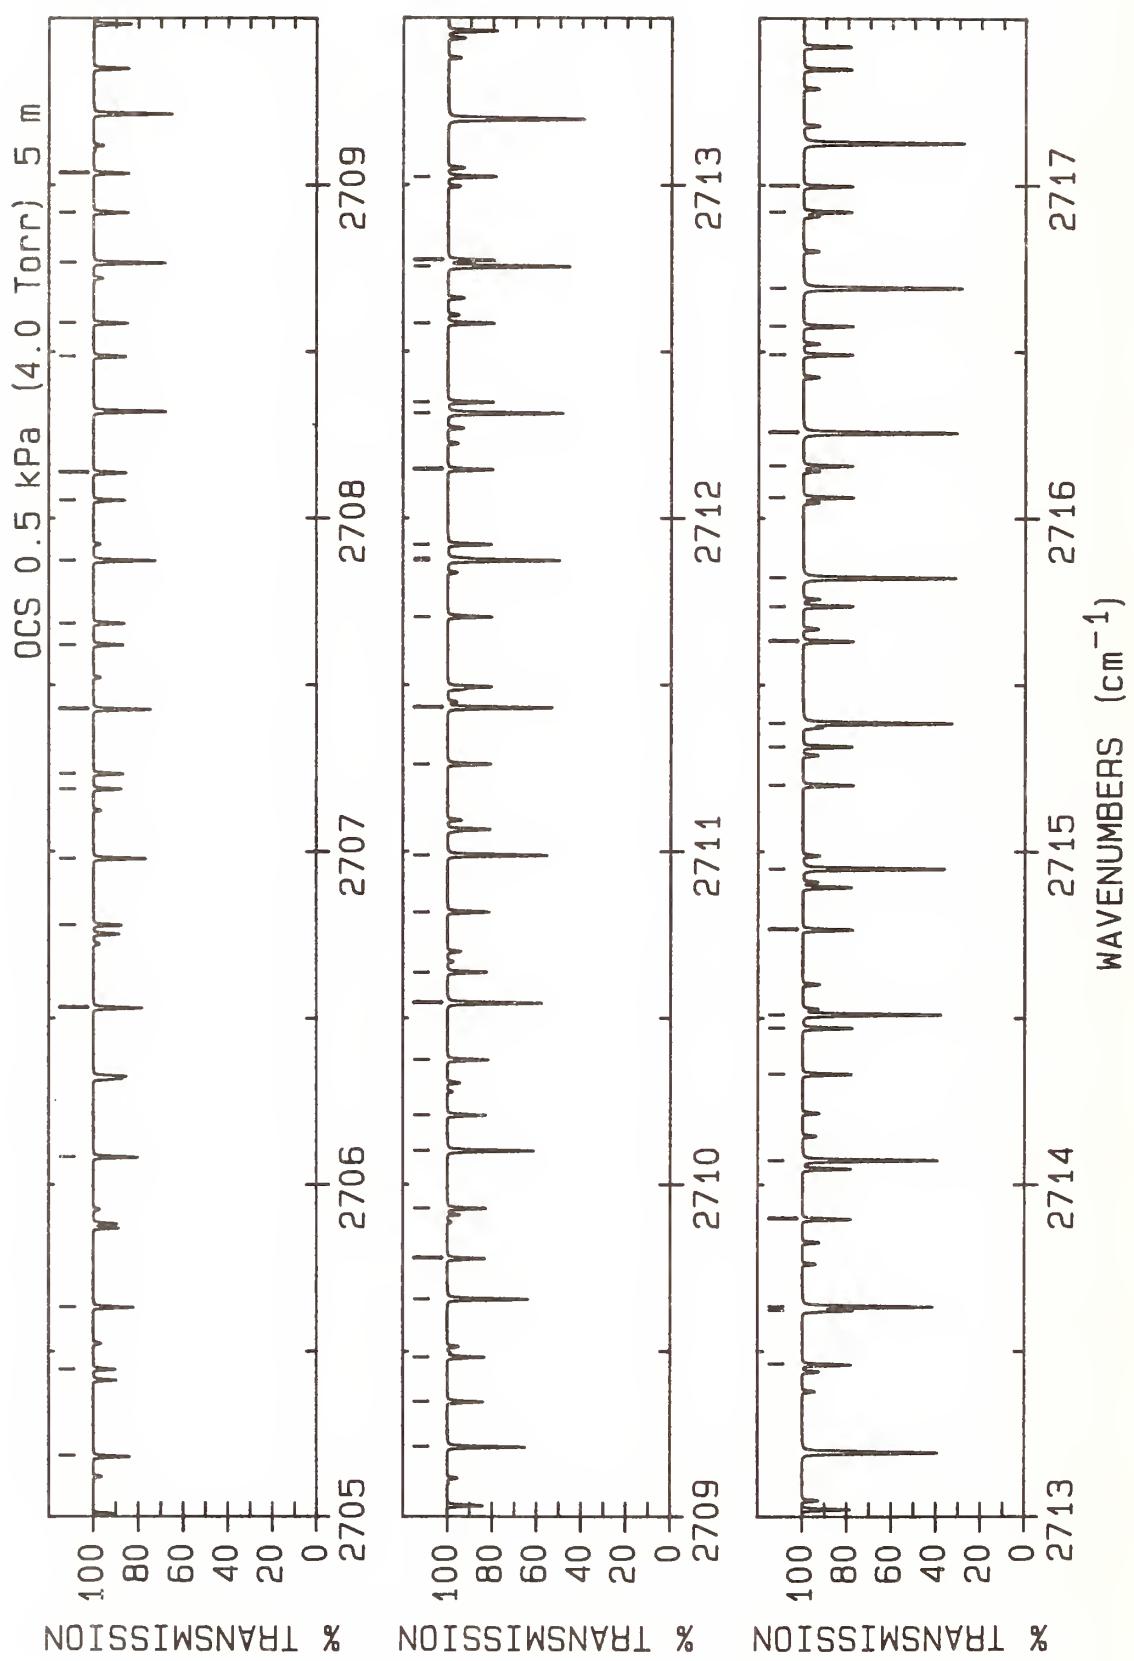

key:

Band	Isotopomer	Vibrational Transition
A	$^{16}\text{O}^{12}\text{C}^{32}\text{S}$	02^02-00^00
B		$03^12-01^1\text{e}0$
C		$03^12-01^1\text{f}0$
D		02^03-00^01
P	$^{16}\text{O}^{12}\text{C}^{34}\text{S}$	02^02-00^00

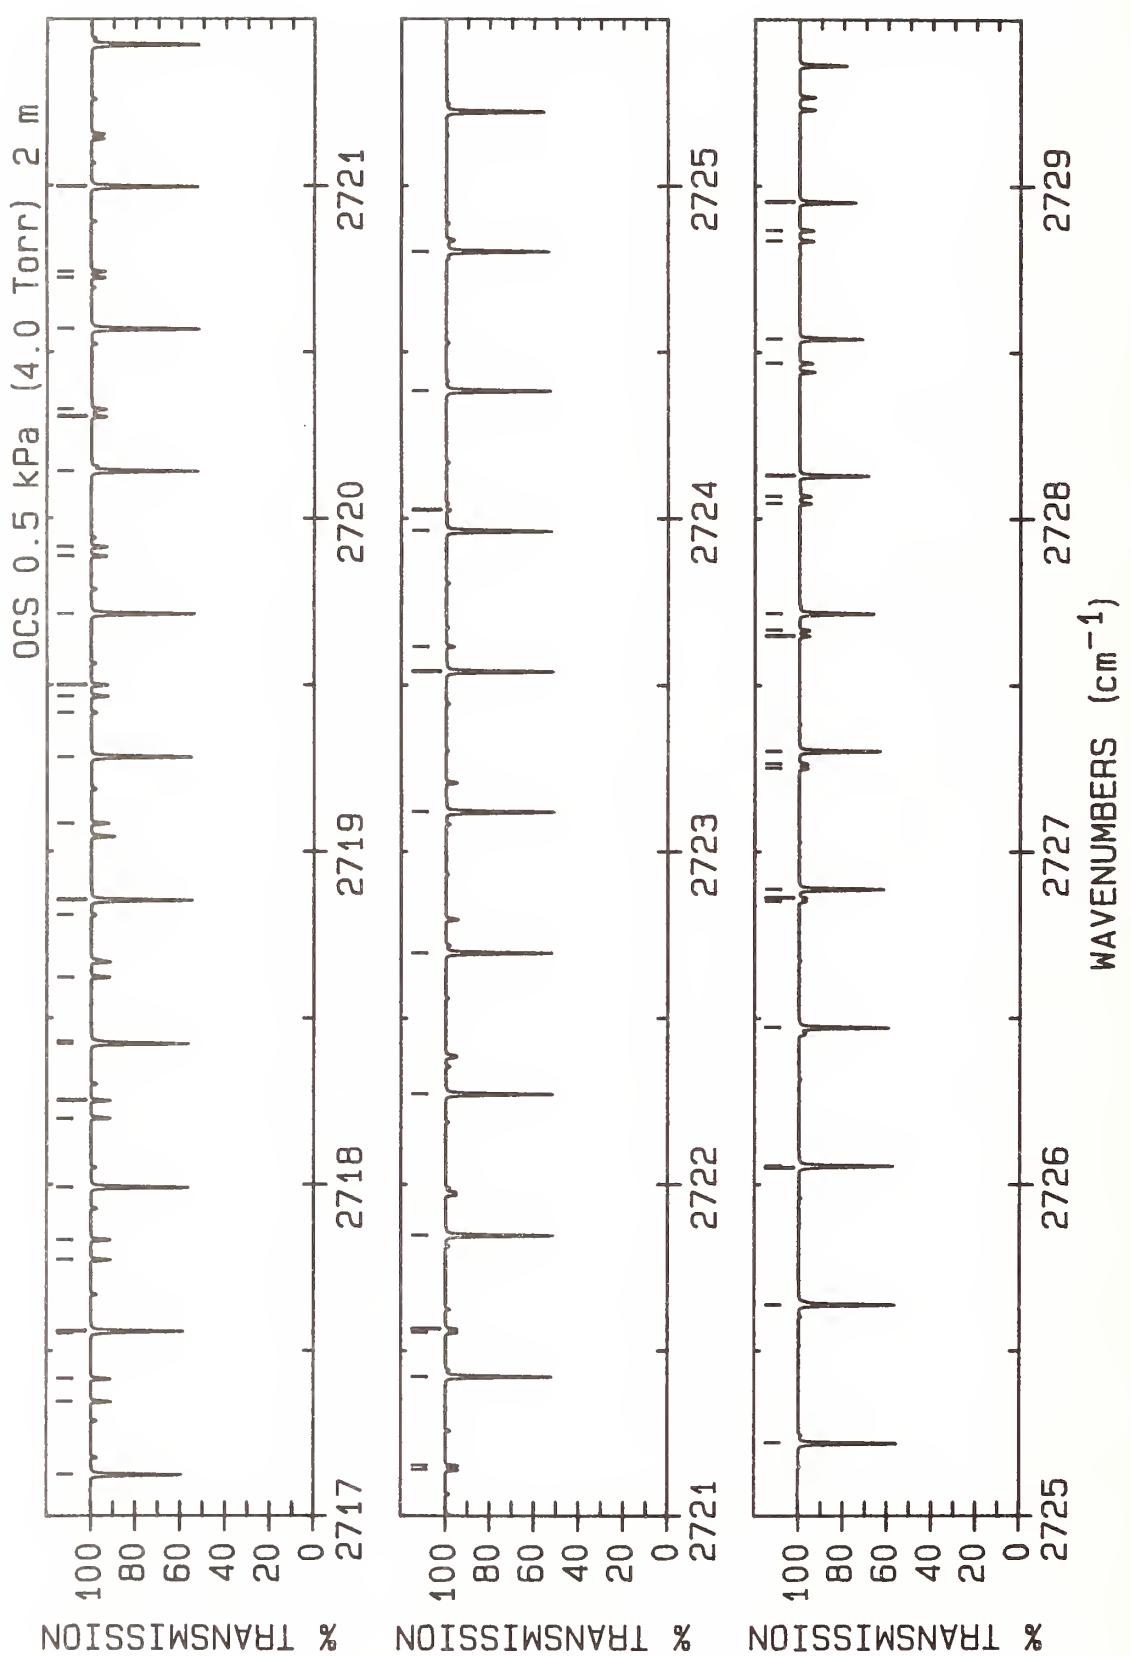

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.003 cm^{-1} , a temperature of 296 K , and a transition moment of 0.004 debye for the A, D, and P bands and 0.0039 debye for the B and C bands. No Herman-Wallis constant was included in the intensity calculation.

R		11 ¹ 0-01 ^{1f} 0
T	¹⁶ O ¹³ C ³² S	10 ⁰ 1-00 ⁰ 0

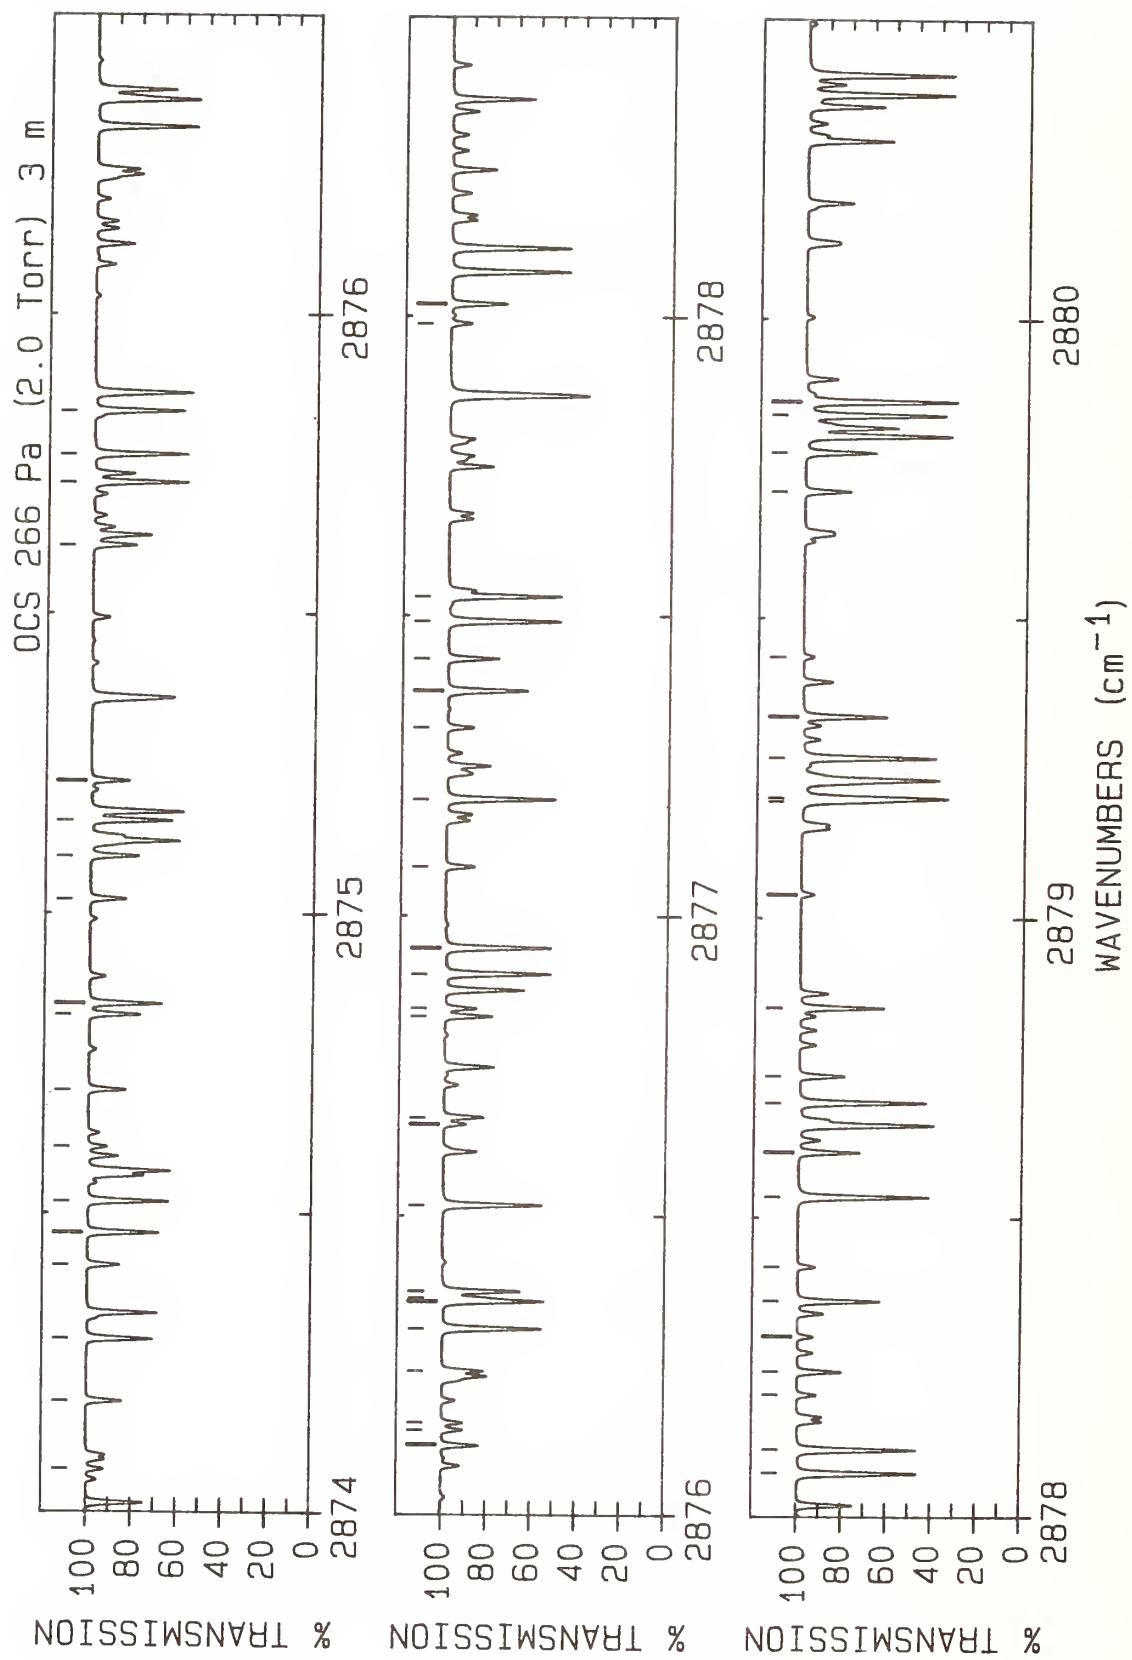

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.003 cm⁻¹ and a temperature of 296 K. The $\Delta v_1=1, \Delta v_3=1$ transitions (except for the D band) were calculated with assumed transition moments of 0.034 debye, the W band was calculated for a transition moment of 0.0036 debye, and the Y and Z bands were calculated with assumed transition moments of 0.0025 debye. No Herman-Wallis constant was included in the intensity calculation except for the D and X bands which are in resonance. For the D band a transition moment of 0.031 debye was used with a Herman-Wallis constant of $a_3 = -0.00034$. For the X band the transition moment was 0.0146 debye and the Herman-Wallis constant was $a_3 = 0.00105$.

ATLAS OF OCS ABSORPTION LINES FROM 3065 cm^{-1} to 3120 cm^{-1}

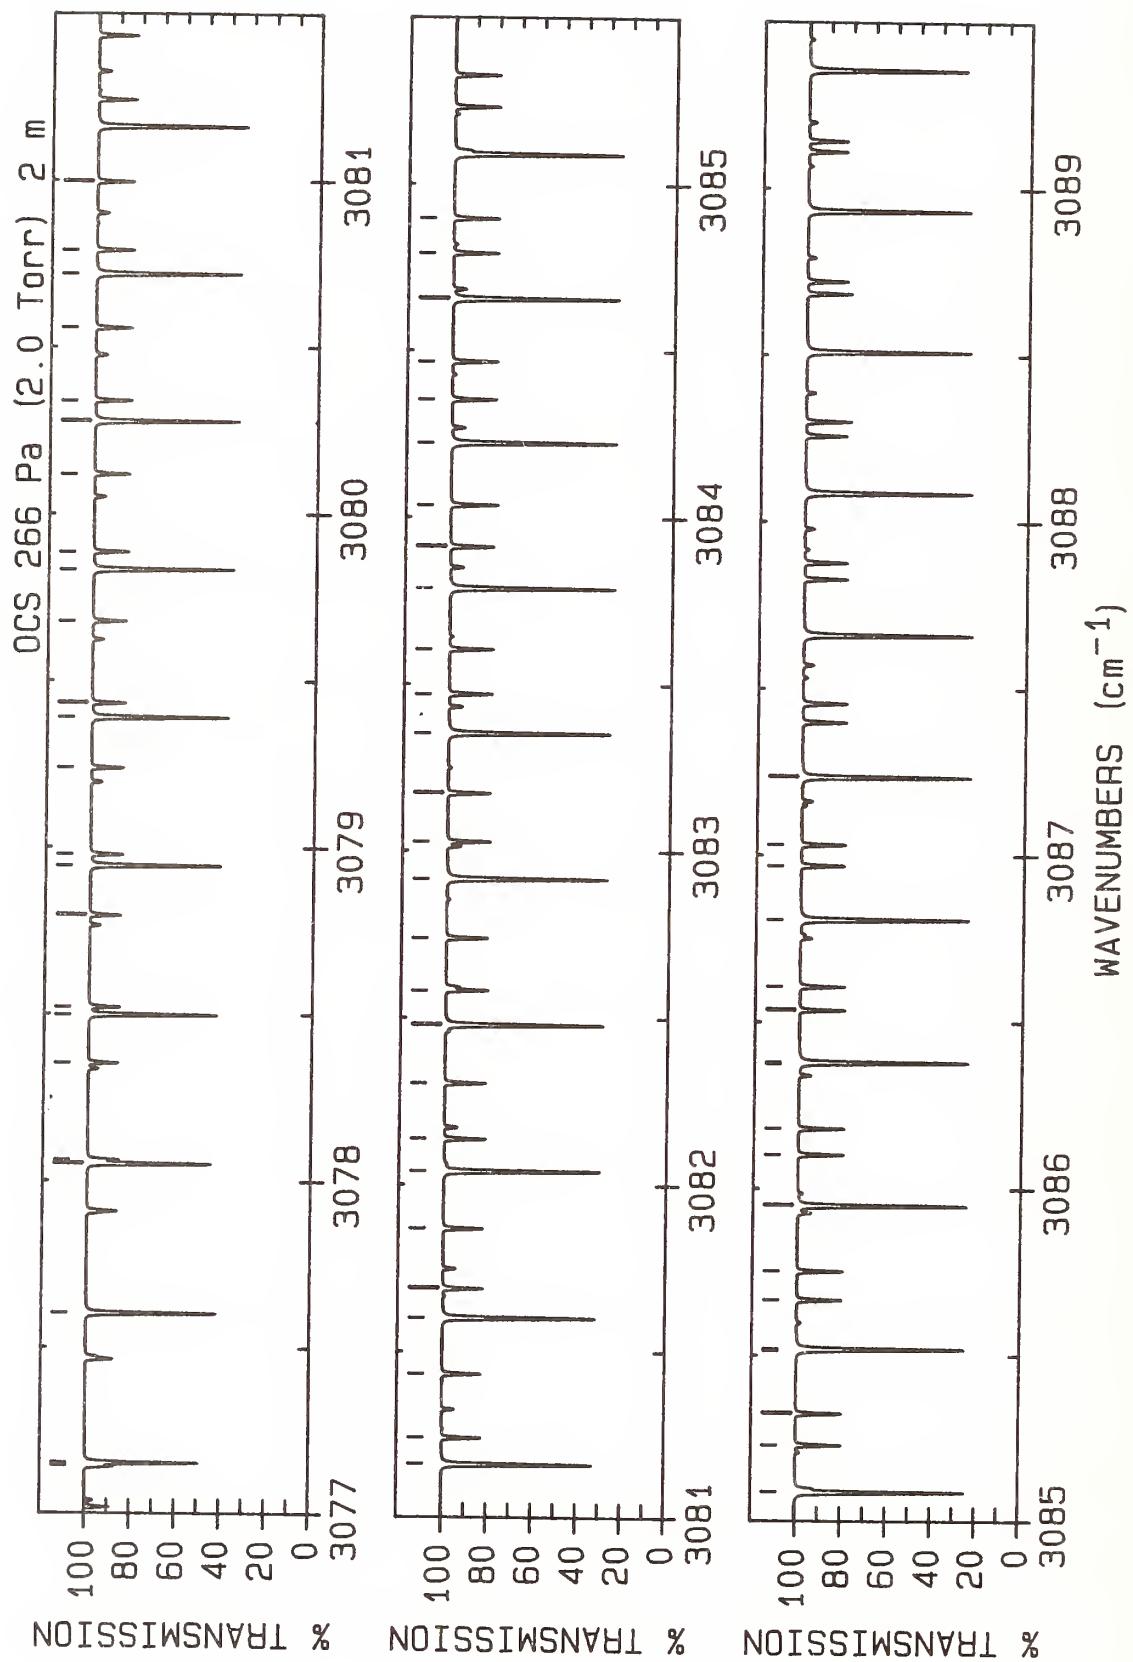

key:

Band	Isotopomer	Vibrational Transition
A	$^{16}\text{O}^{12}\text{C}^{32}\text{S}$	12^00-00^00
B		$13^10-01^{1e}0$
C		$13^10-01^{1f}0$
D		12^01-00^01
P	$^{16}\text{O}^{12}\text{C}^{34}\text{S}$	12^00-00^00

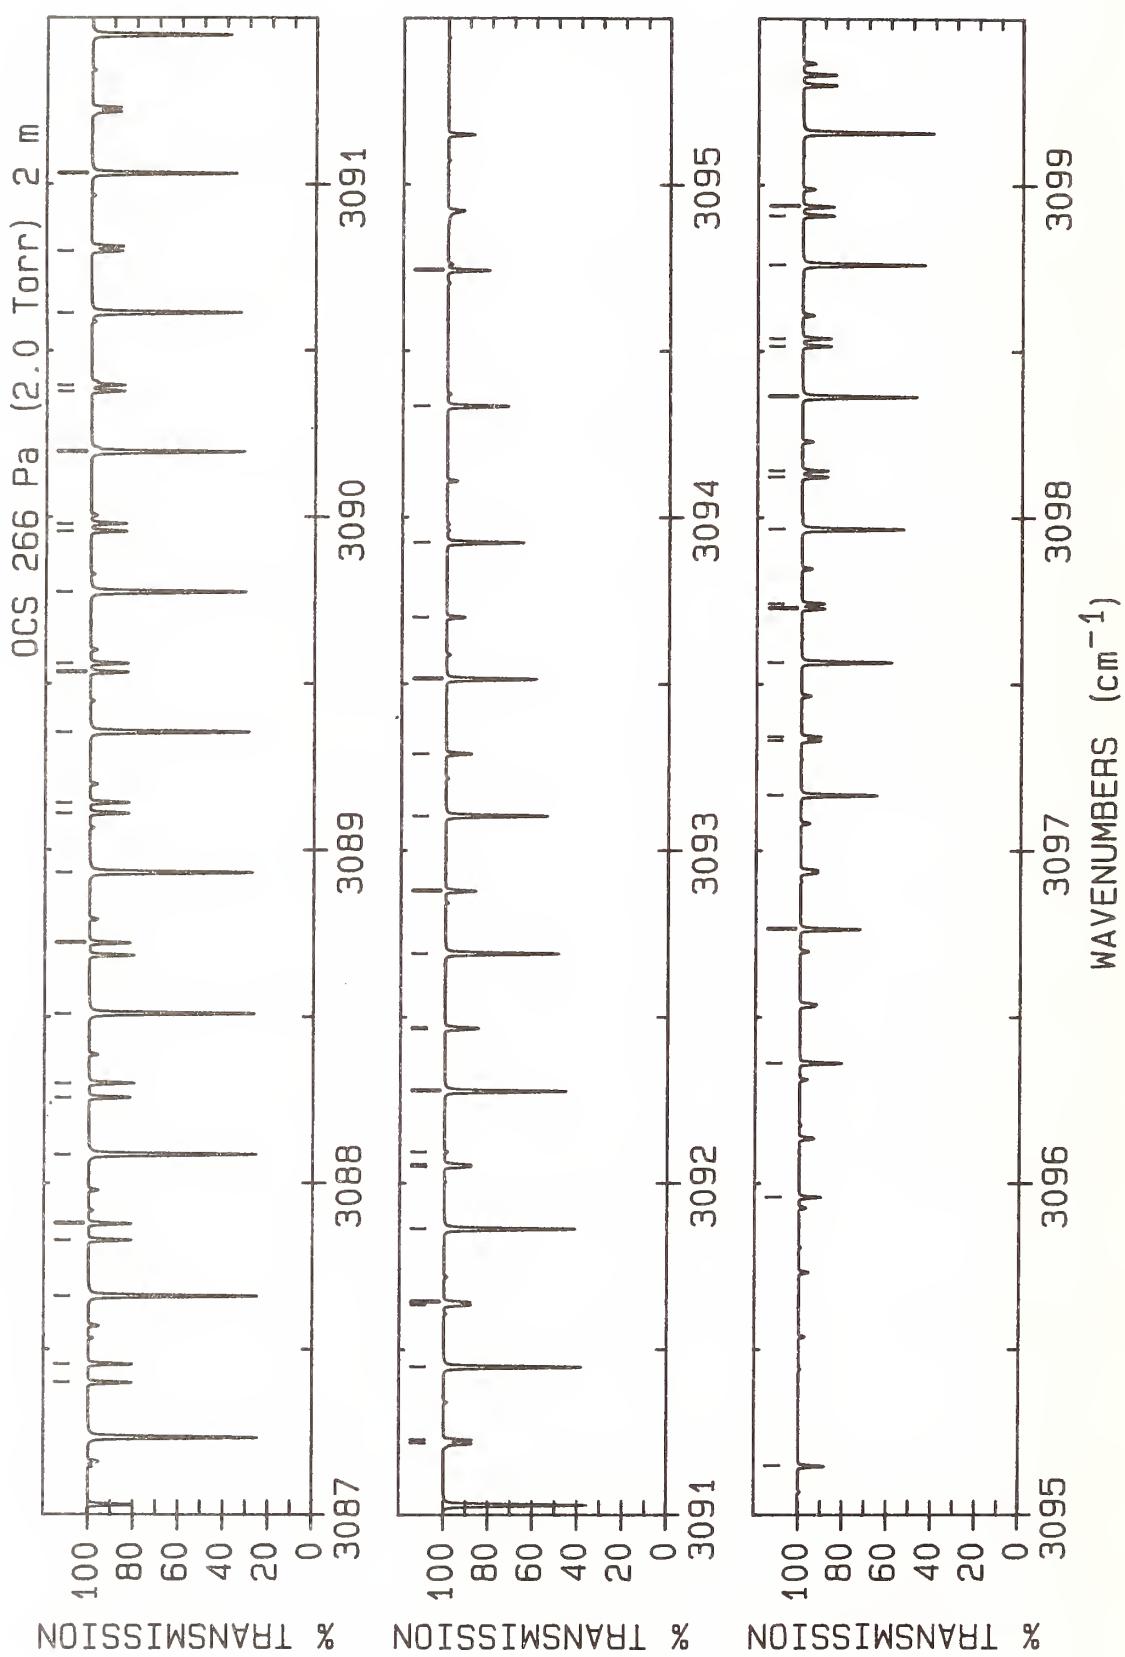

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.003 cm^{-1} , a temperature of 296 K , and a transition moment of 0.008 debye . No Herman-Wallis constant was included in the intensity calculation. Since no heterodyne measurements are available for this region, all uncertainties have been increased by 0.0002 cm^{-1} .

Energy Levels for N₂O

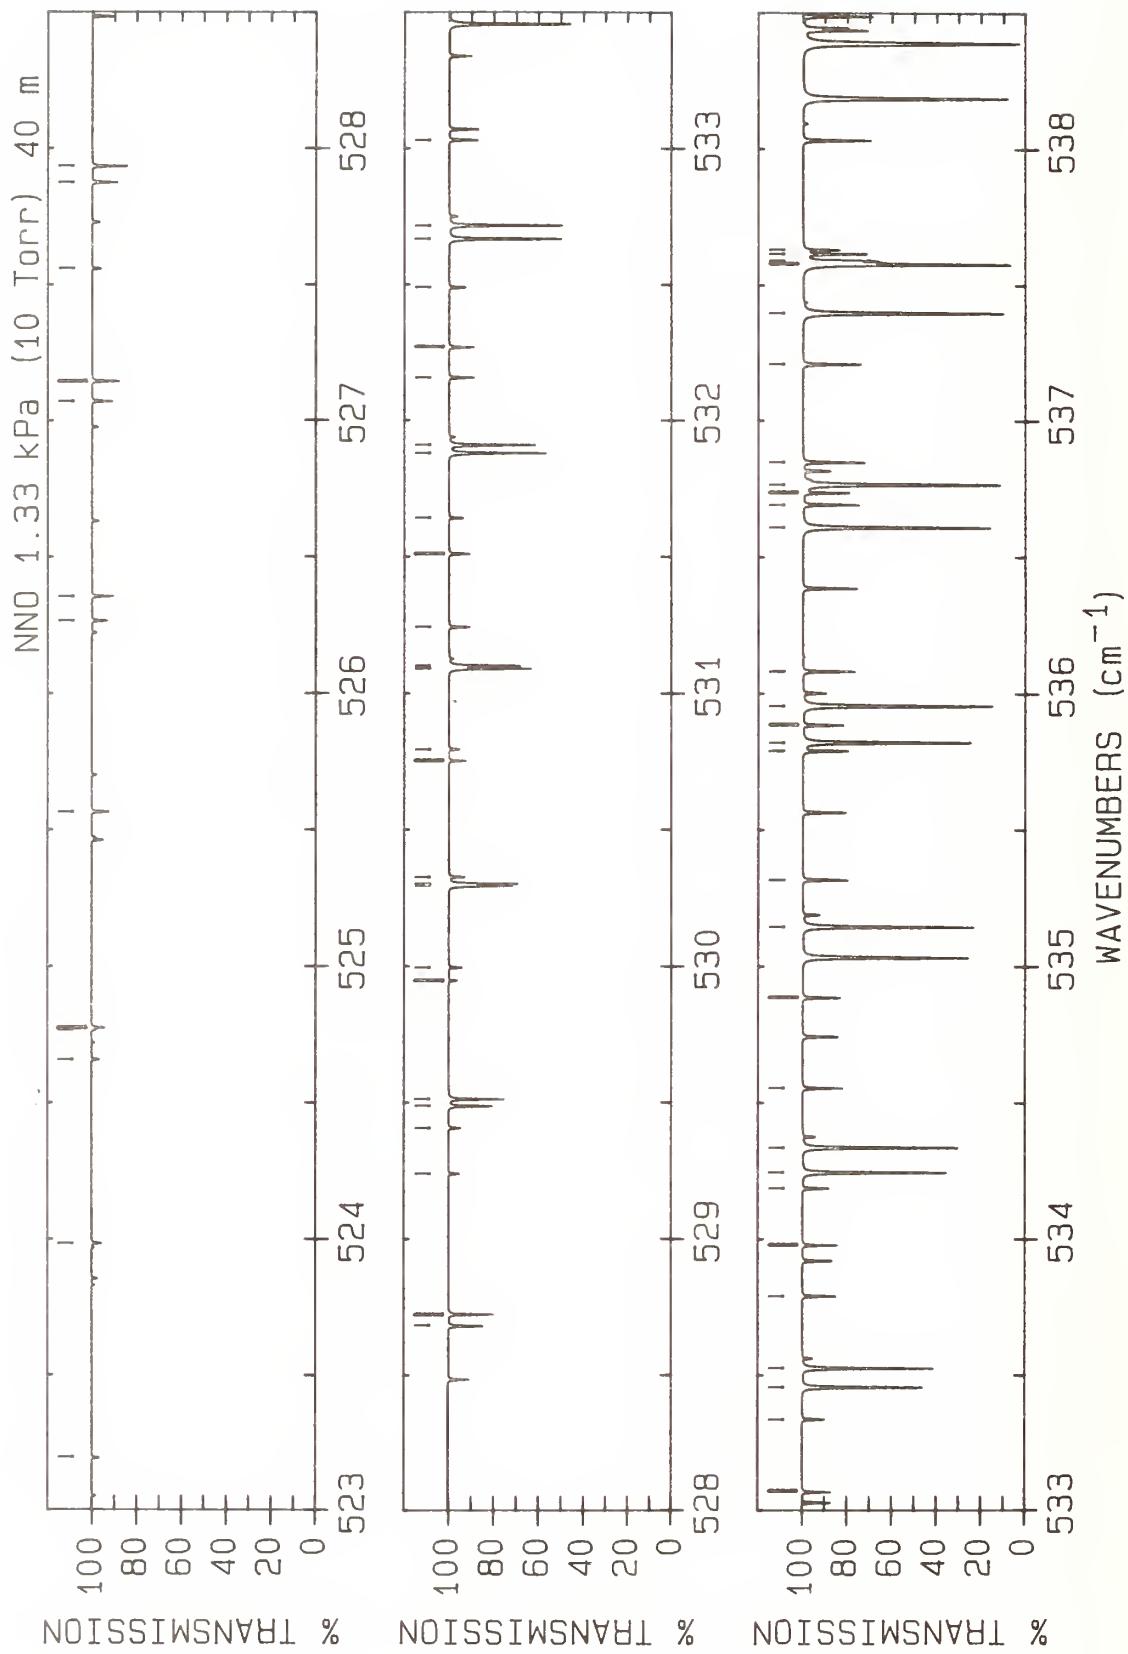

ATLAS OF N₂O ABSORPTION LINES FROM 523 cm⁻¹ TO 659 cm⁻¹

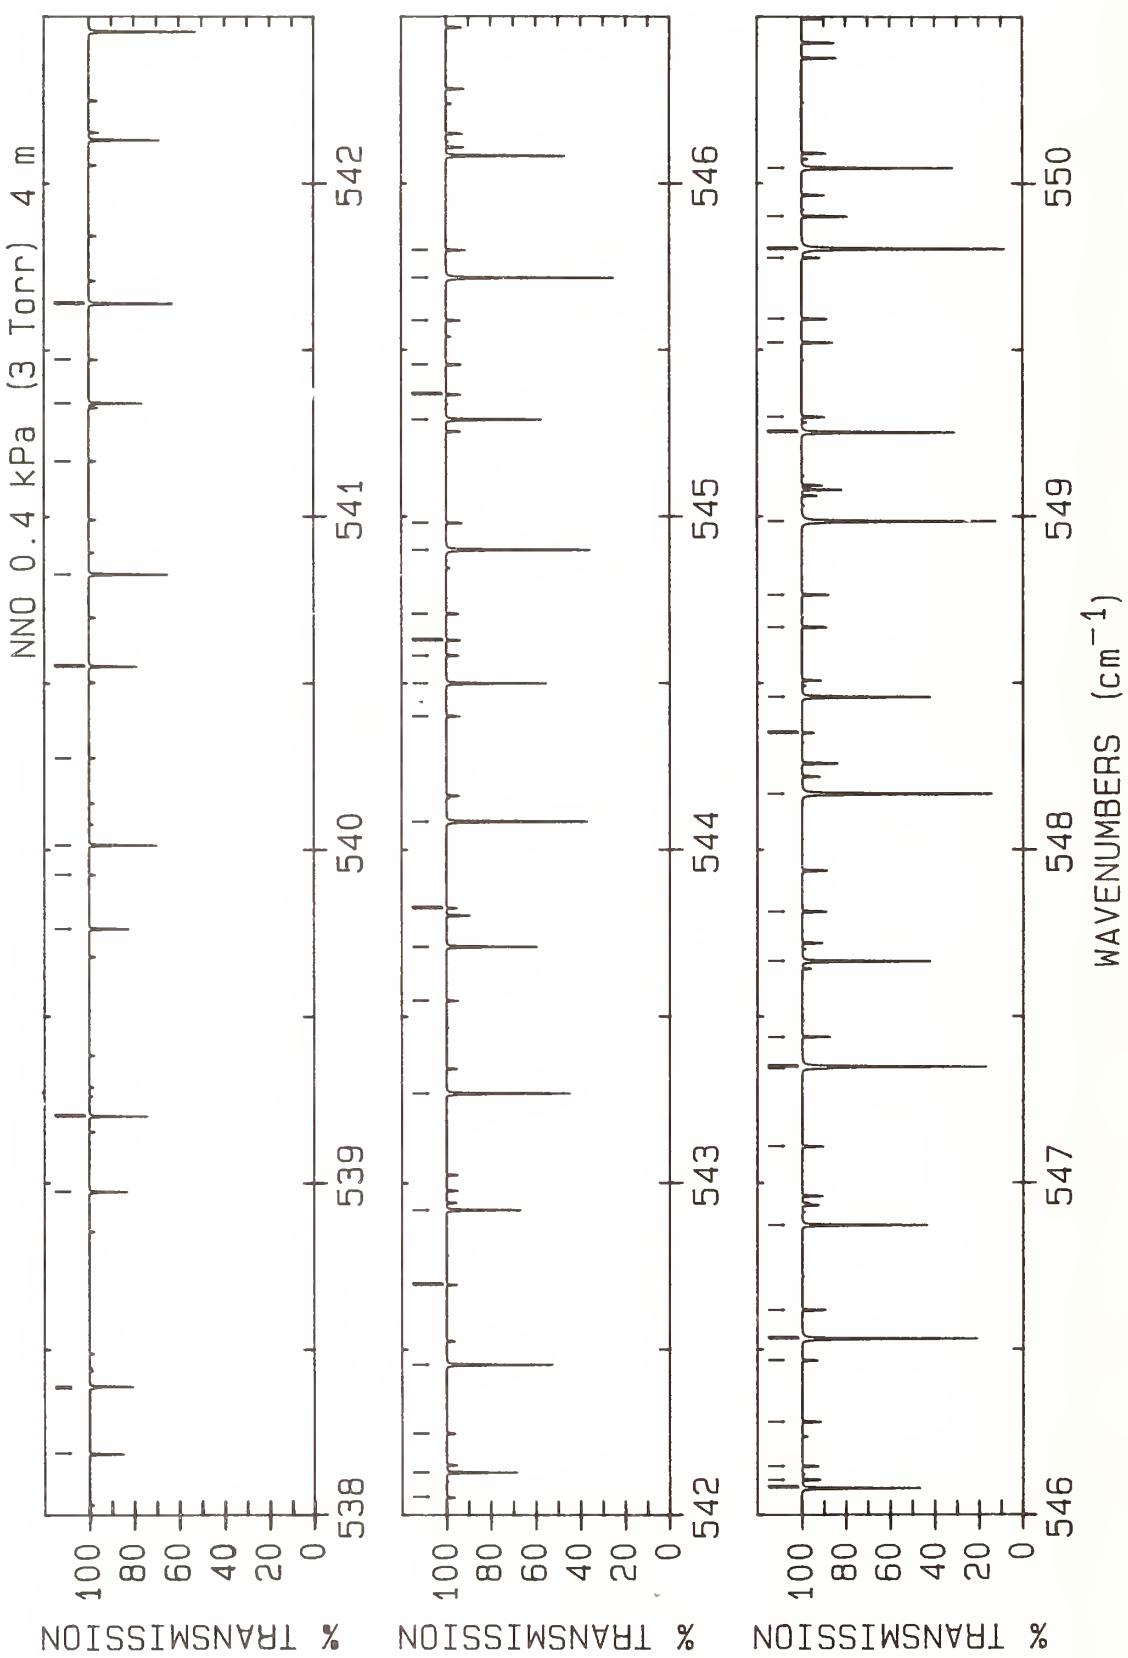

key:

Band	Isotopomer	Vibrational Transition
A	¹⁴ N ¹⁴ N ¹⁶ O	01 ¹ 0-00 ⁰ 0
B		02 ² 0-01 ^{1e} 0
C		02 ² 0-01 ^{1f} 0
D		01 ¹ 1-00 ⁰ 1
E		03 ³ 0-02 ^{2e} 0
F		03 ³ 0-02 ^{2f} 0
G		03 ¹ 0-02 ⁰ 0
H		02 ⁰ 0-01 ¹ 0
I		03 ¹ 0-02 ^{2e} 0
J		03 ¹ 0-02 ^{2f} 0
P	¹⁴ N ¹⁵ N ¹⁶ O	01 ¹ 0-00 ⁰ 0
R	¹⁵ N ¹⁴ N ¹⁶ O	01 ¹ 0-00 ⁰ 0
T	¹⁴ N ¹⁴ N ¹⁸ O	01 ¹ 0-00 ⁰ 0

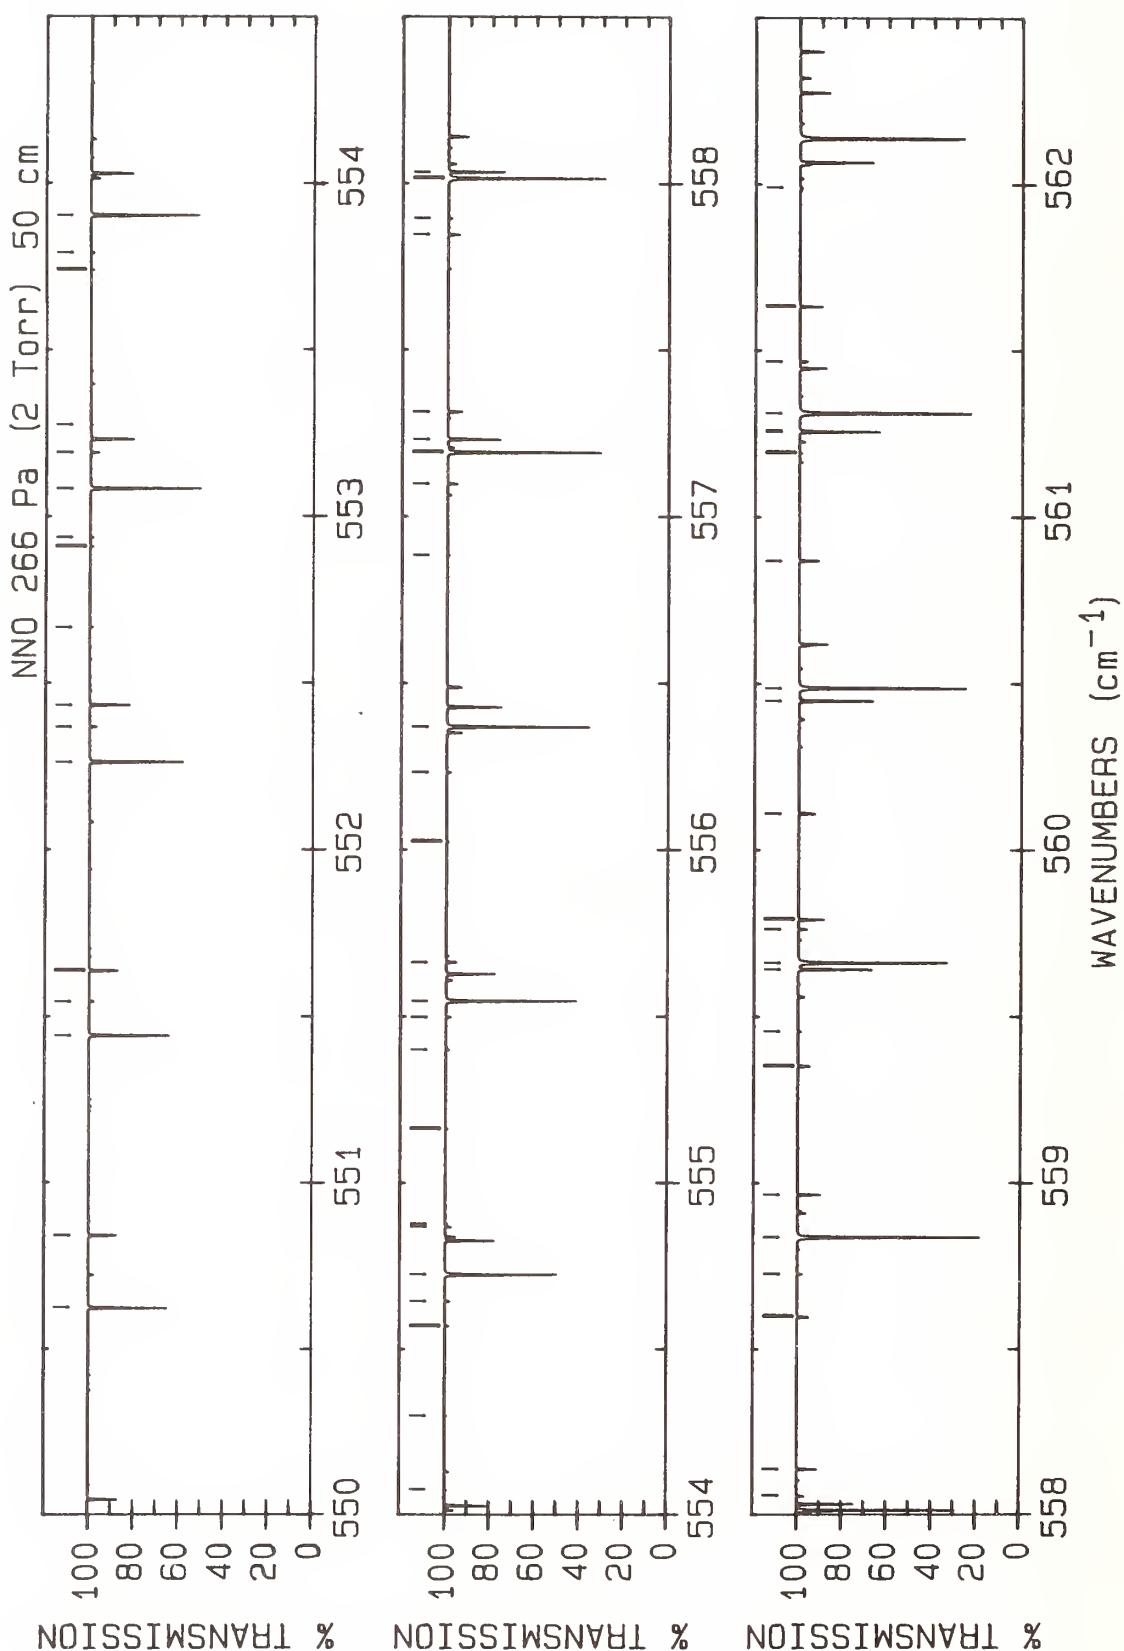

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.002 cm⁻¹ and a transition moment of 0.0692 debye at a temperature of 296 K. A Herman-Wallis constant of $a_1 = 0.0016$ is included in the intensity calculation for the lines of all the bands.

ATLAS OF N₂O ABSORPTION LINES FROM 880 cm⁻¹ to 1087 cm⁻¹

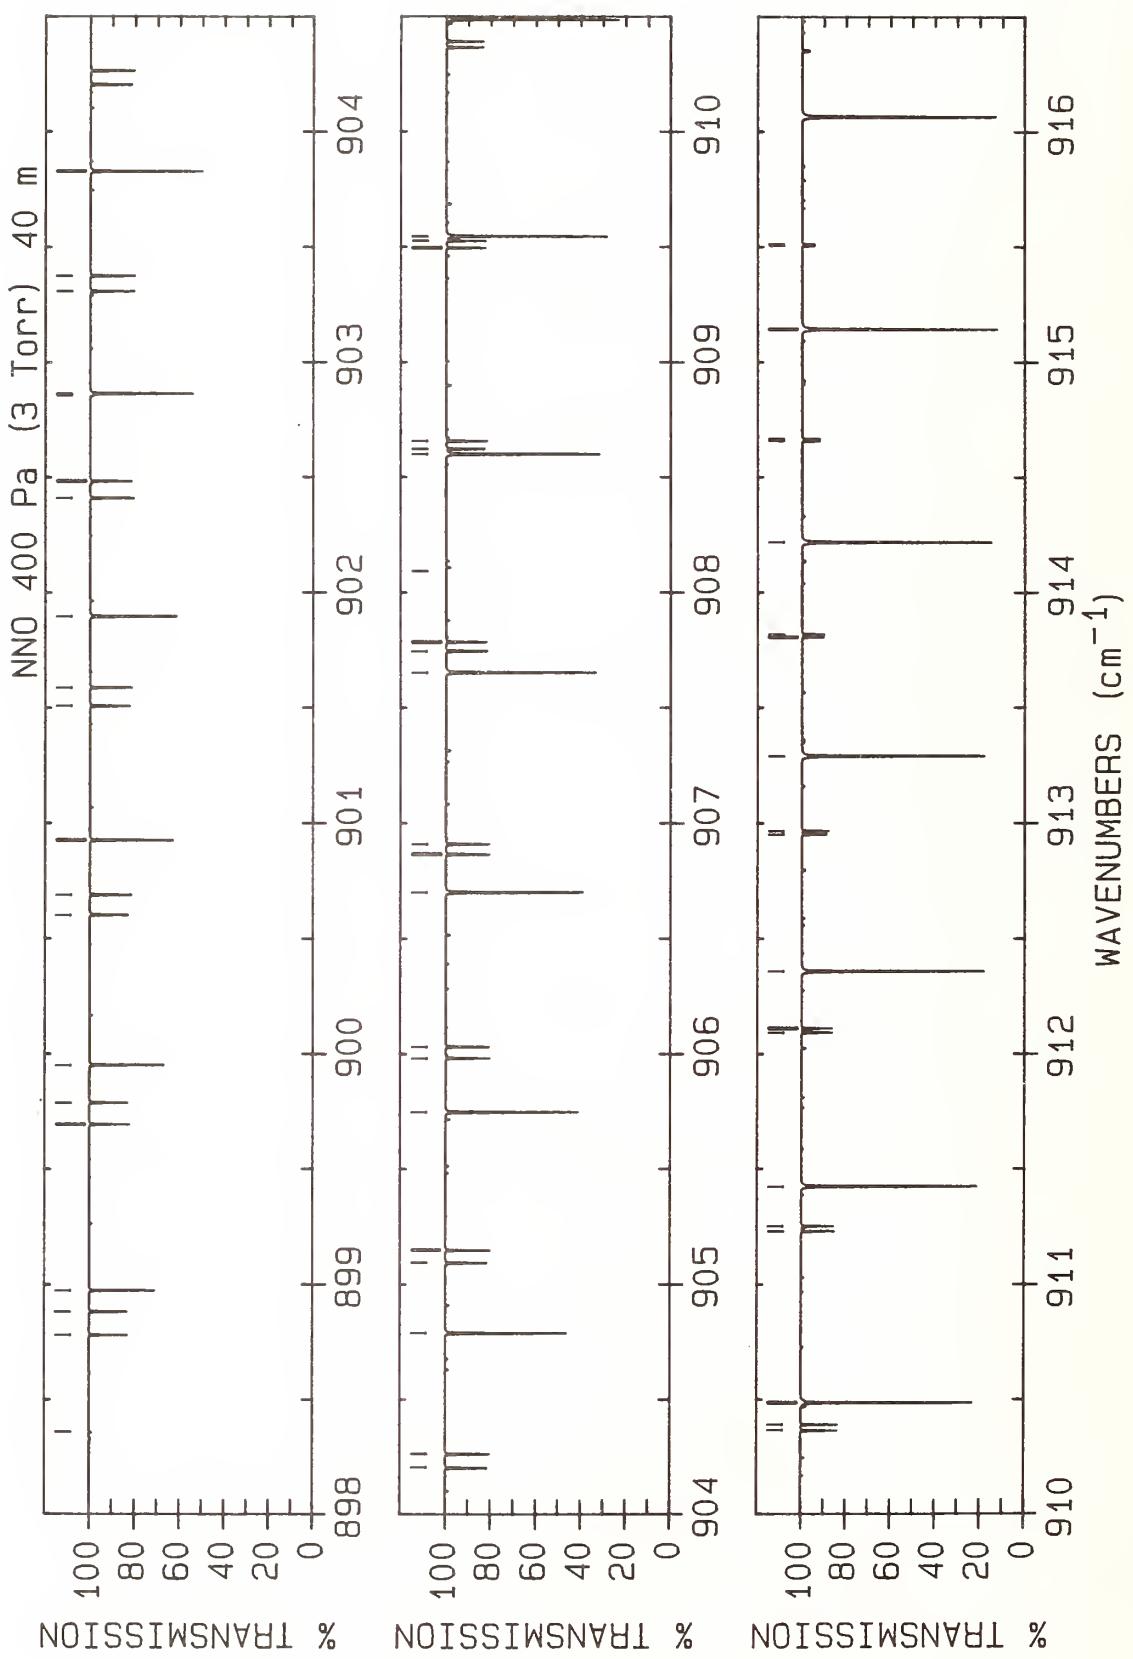

key:

Band	Isotopomer	Vibrational Transition
A	¹⁴ N ¹⁴ N ¹⁶ O	10 ⁰ 0-00 ⁰ 1
B		11 ¹ 0-01 ^{1e} 1
C		11 ¹ 0-01 ^{1f} 1
D		12 ⁰ 0-02 ⁰ 1
E		12 ² 0-02 ^{2e} 1
F		12 ² 0-02 ^{2f} 1
G		10 ⁰ 1-00 ⁰ 2
M		10 ⁰ 0-02 ⁰ 0
N		11 ¹ 0-03 ^{1e} 0
O		11 ¹ 0-03 ^{1f} 0
P	¹⁴ N ¹⁵ N ¹⁶ O	10 ⁰ 0-00 ⁰ 1
R	¹⁵ N ¹⁴ N ¹⁶ O	10 ⁰ 0-00 ⁰ 1
T	¹⁴ N ¹⁴ N ¹⁸ O	10 ⁰ 0-00 ⁰ 1

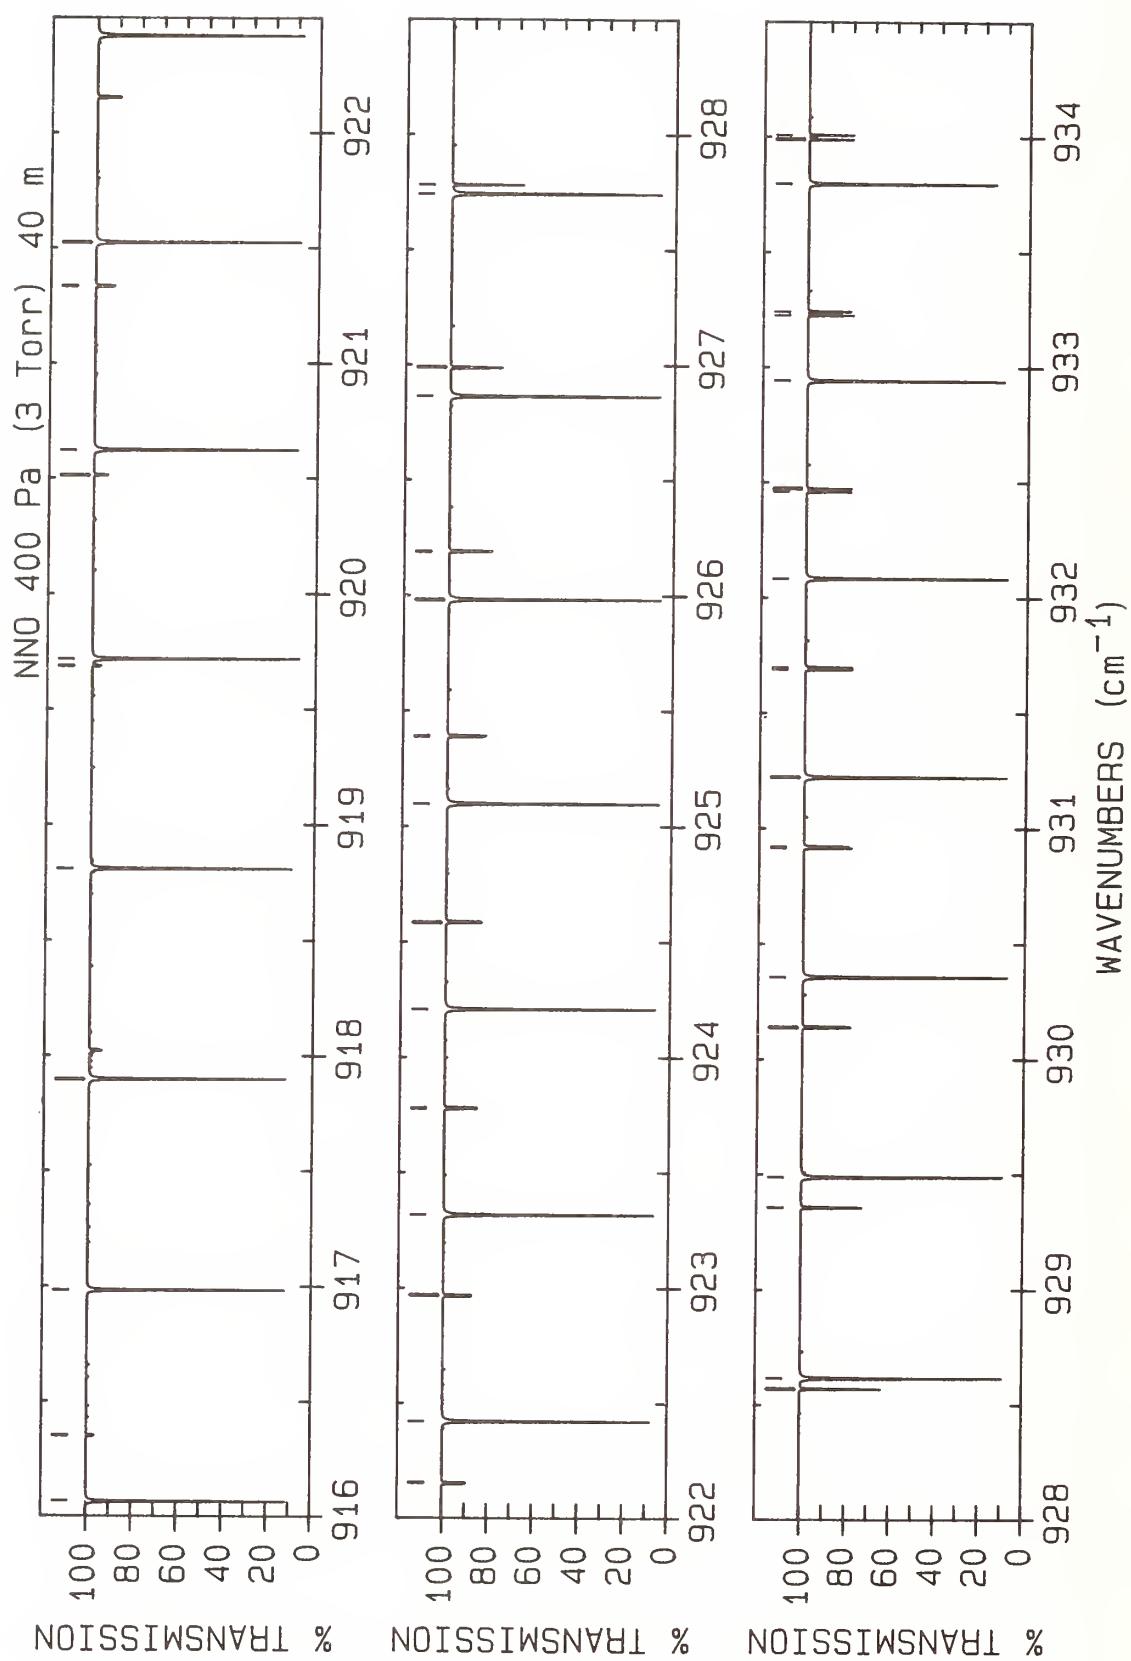

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.002 cm⁻¹, a temperature of 296 K, and a transition moment of either 0.056 debye (for the $\Delta v_1=1$ and $\Delta v_3=1$ transitions) or 0.018 debye (for the $\Delta v_1=1$ and $\Delta v_2=2$ transitions). No Herman-Wallis constants were used in the calculations.

ATLAS OF N₂O ABSORPTION LINES FROM 1105 cm⁻¹ to 1230 cm⁻¹

key:

Band	Isotopomer	Vibrational Transition
a	¹⁴ N ¹⁴ N ¹⁶ O	02 ⁰ 0-00 ⁰ 0
x		02 ^{2e} 0-00 ⁰ 0
b		03 ¹ 0-01 ^{1e} 0
c		03 ¹ 0-01 ^{1f} 0
d		02 ⁰ 1-00 ⁰ 1
e		04 ² 0-02 ^{2e} 0
f		04 ² 0-02 ^{2f} 0
g		04 ⁰ 0-02 ⁰ 0
p	¹⁴ N ¹⁵ N ¹⁶ O	02 ⁰ 0-00 ⁰ 0
r	¹⁵ N ¹⁴ N ¹⁶ O	02 ⁰ 0-00 ⁰ 0
t	¹⁴ N ¹⁴ N ¹⁸ O	02 ⁰ 0-00 ⁰ 0
v	¹⁴ N ¹⁴ N ¹⁷ O	02 ⁰ 0-00 ⁰ 0

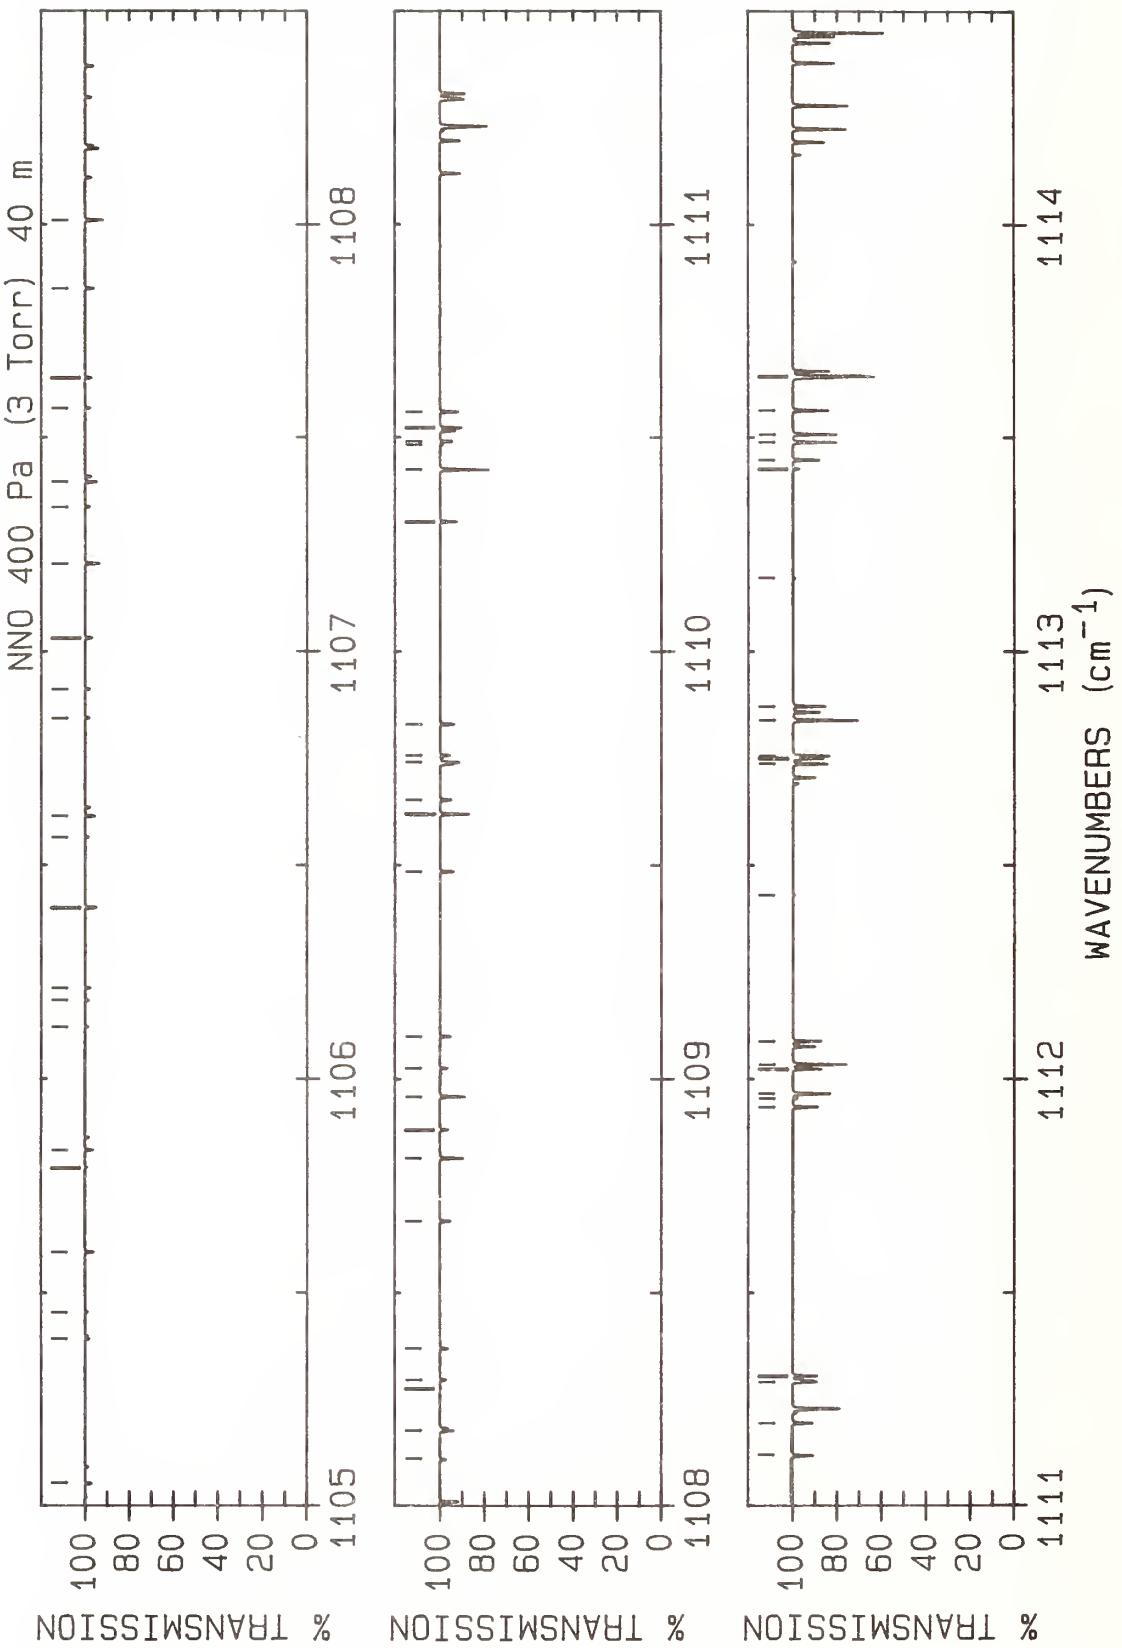

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.002 cm⁻¹ and a temperature of 296 K. For the a band a transition moment of 0.0247 debye was used and the Herman-Wallis constants given by Toth [5.218] were used in the intensity calculation. For the b and c bands the transition moment used was 0.024 debye and the same H.-W. constants were used as for band a. The g, e, and f bands used no H.-W. constants and the same transition moment as band b and c. Band d used the same transition moment as band a but used H.-W. constants $a_1 = 0.627 \times 10^{-2}$ and $a_2 = 0.185 \times 10^{-3}$. Band x derives its intensity from the l -type resonance effect on band a, but the calculated intensity was raised by using a transition moment for a of 0.03 debye (for the x intensity calculation only). Of the different isotopes, only band r was given the same intensity constants as band a although all were given the same H.-W. constants as band a. Band p used a transition moment of 0.0175 debye; band t used a transition moment of 0.035 debye; and band v used a transition moment of 0.029 debye.

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.002 cm⁻¹ and a transition moment of 0.1326 debye at a temperature of 296 K. The transition moments and Herman-Wallis constants used in the calculations were taken from Toth [5.218] after making allowance for the vibrational factors of 2, etc. included in Toth's transition moments, see Chapter III. Hot bands not covered by Toth's data were given the same transition moments and Herman-Wallis constants as the ground state transitions. The same intensity constants were used for band V as for band A.

ATLAS OF N₂O ABSORPTION LINES FROM 1820 cm⁻¹ to 1925 cm⁻¹

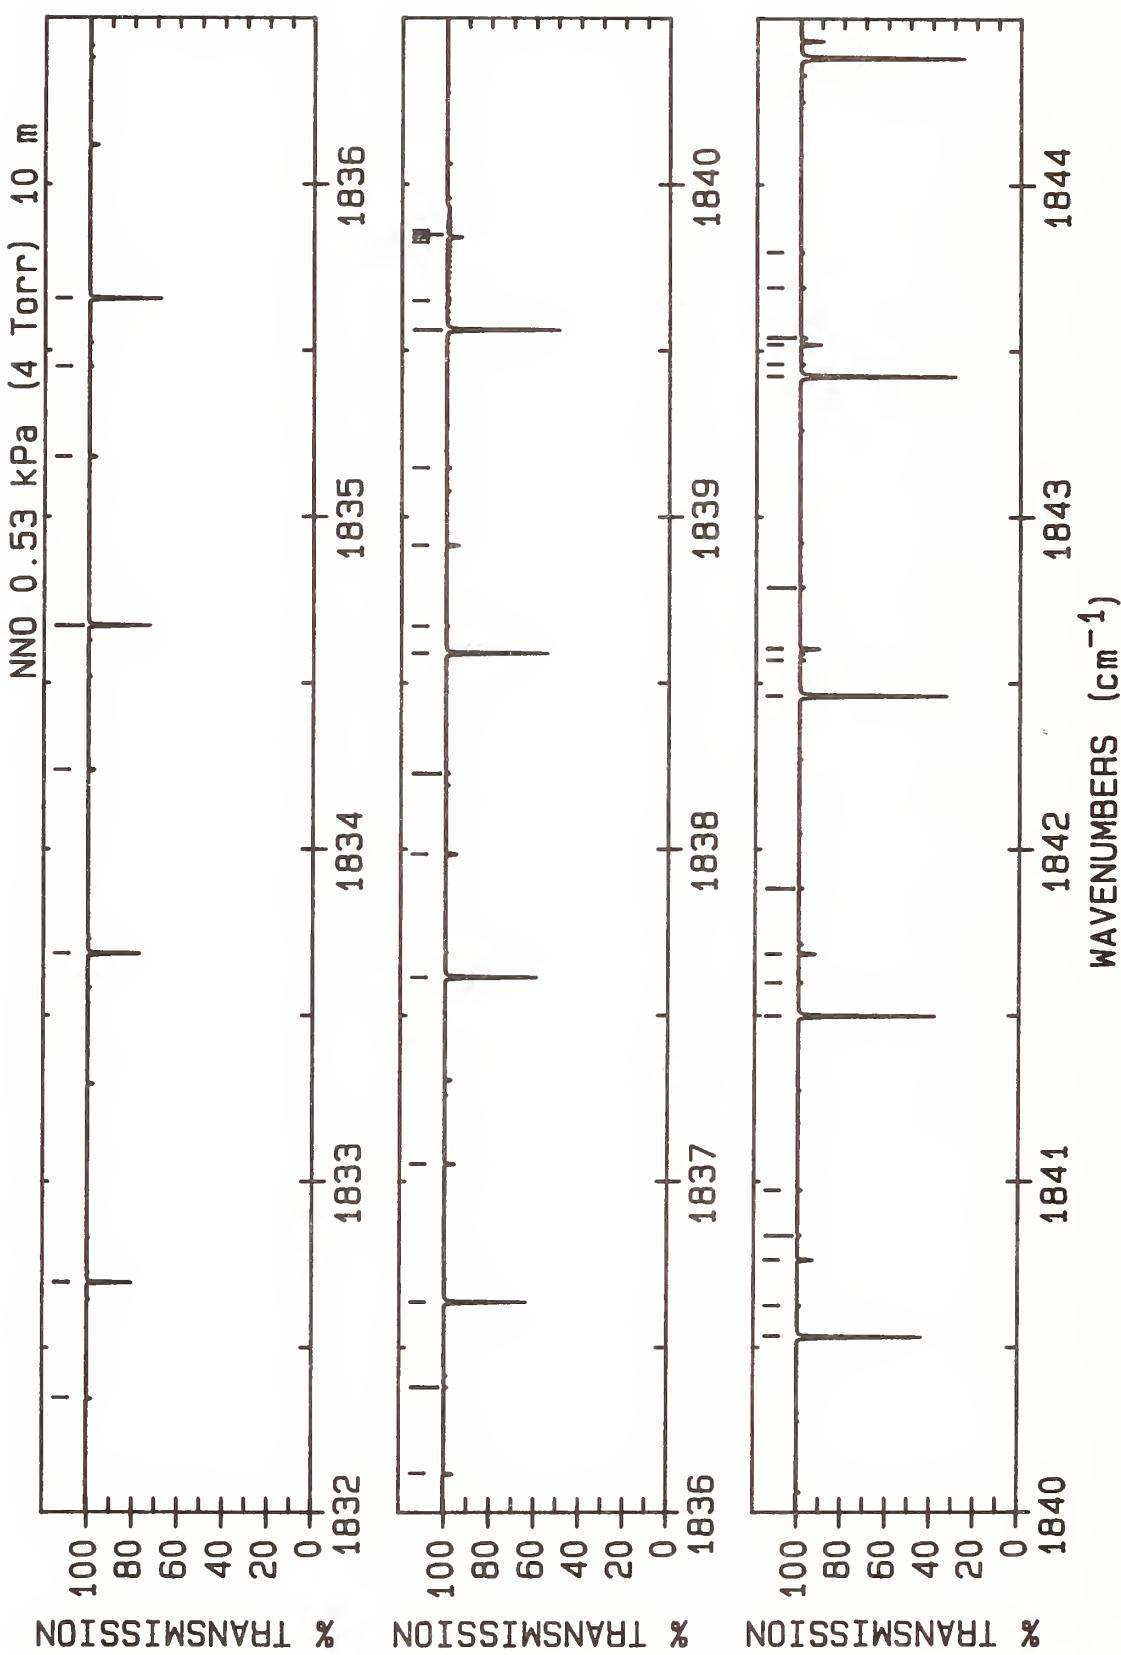

key:

Band	Isotopomer	Vibrational Transition
A	¹⁴ N ¹⁴ N ¹⁶ O	01 ¹ 1-00 ⁰ 0
B		02 ² 1-01 ^{1e} 0
C		02 ² 1-01 ^{1f} 0
D		01 ¹ 2-00 ⁰ 1
E		03 ³ 1-02 ^{2e} 0
F		03 ³ 1-02 ^{2f} 0
G		03 ¹ 1-02 ⁰ 0
H		02 ⁰ 1-01 ¹ 0
I		03 ¹ 1-02 ^{2e} 0
J		03 ¹ 1-02 ^{2f} 0
P	¹⁴ N ¹⁵ N ¹⁶ O	01 ¹ 1-00 ⁰ 0
R	¹⁵ N ¹⁴ N ¹⁶ O	01 ¹ 1-00 ⁰ 0
T	¹⁴ N ¹⁴ N ¹⁸ O	01 ¹ 1-00 ⁰ 0

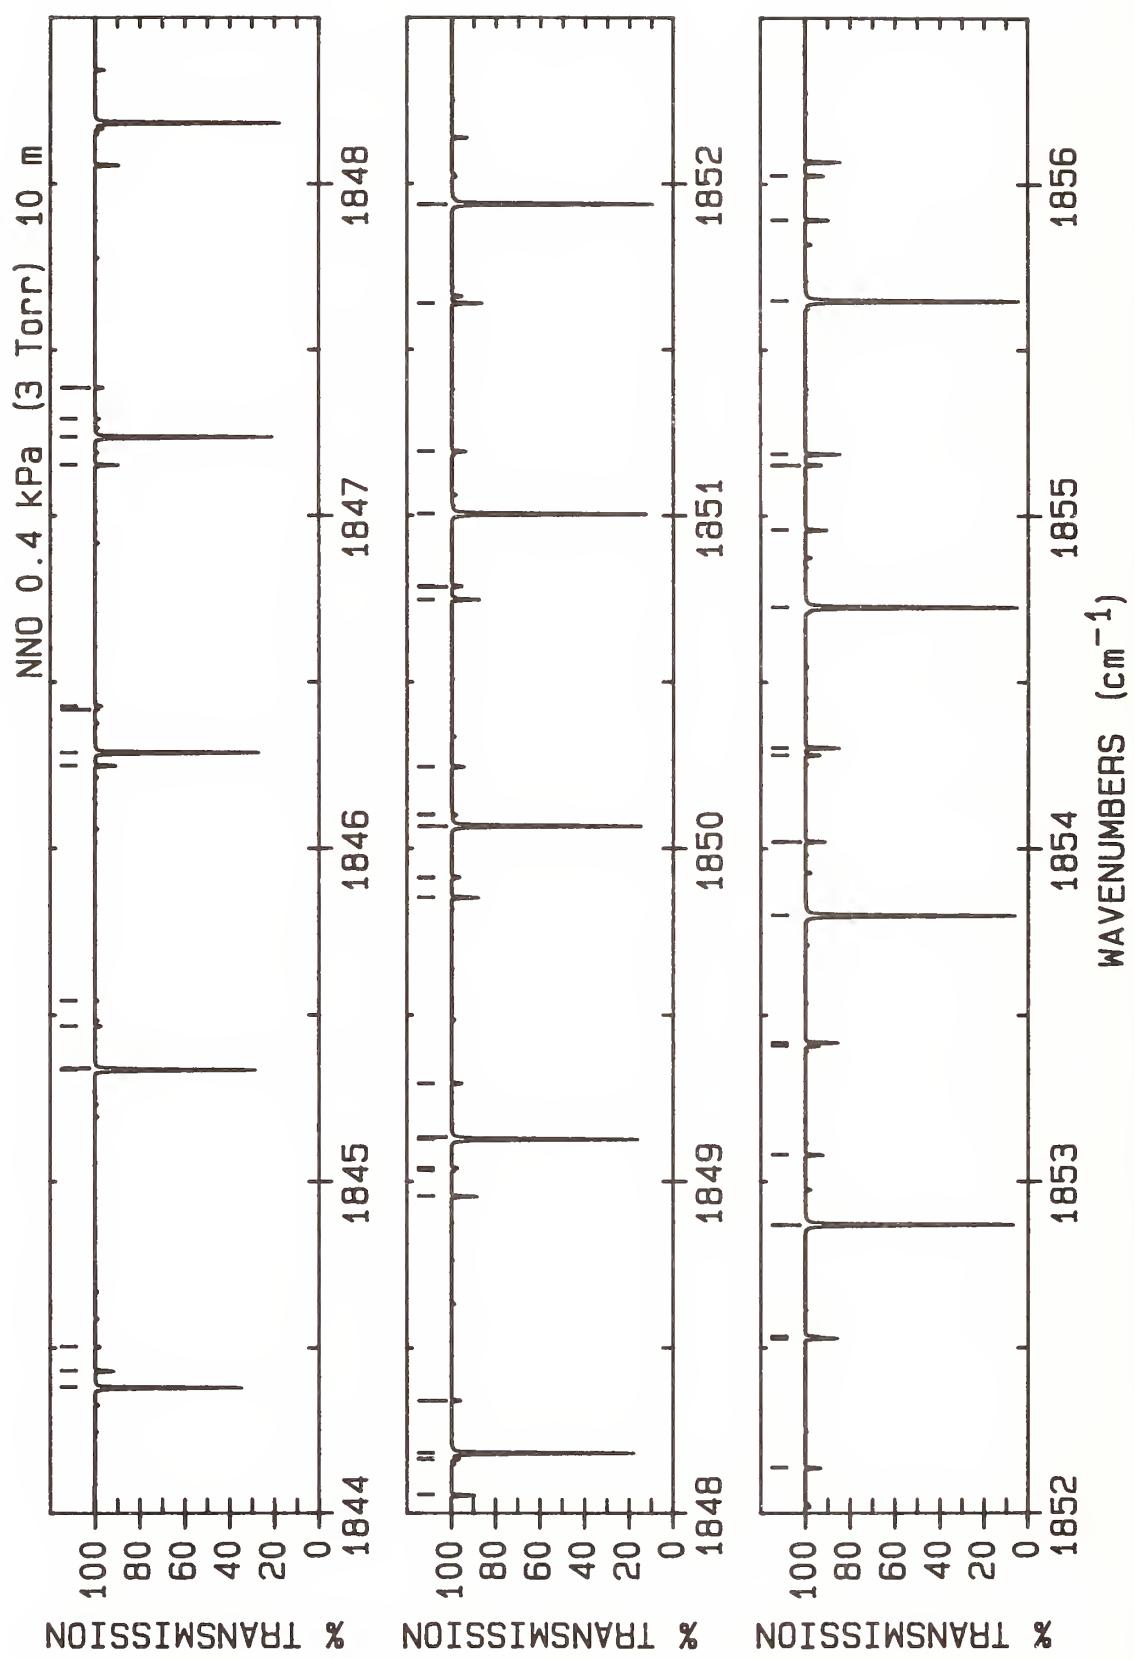

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.002 cm⁻¹ and a transition moment of 0.00548 debye at a temperature of 296 K. For the H band a transition moment of 0.00406 debye was used. A Herman-Wallis constant of $\xi_1 = -0.0107$ is included in the intensity calculation for the lines of all bands.

V	¹⁴ N ¹⁴ N ¹⁷ O	10 ⁰ 0-00 ⁰ 0

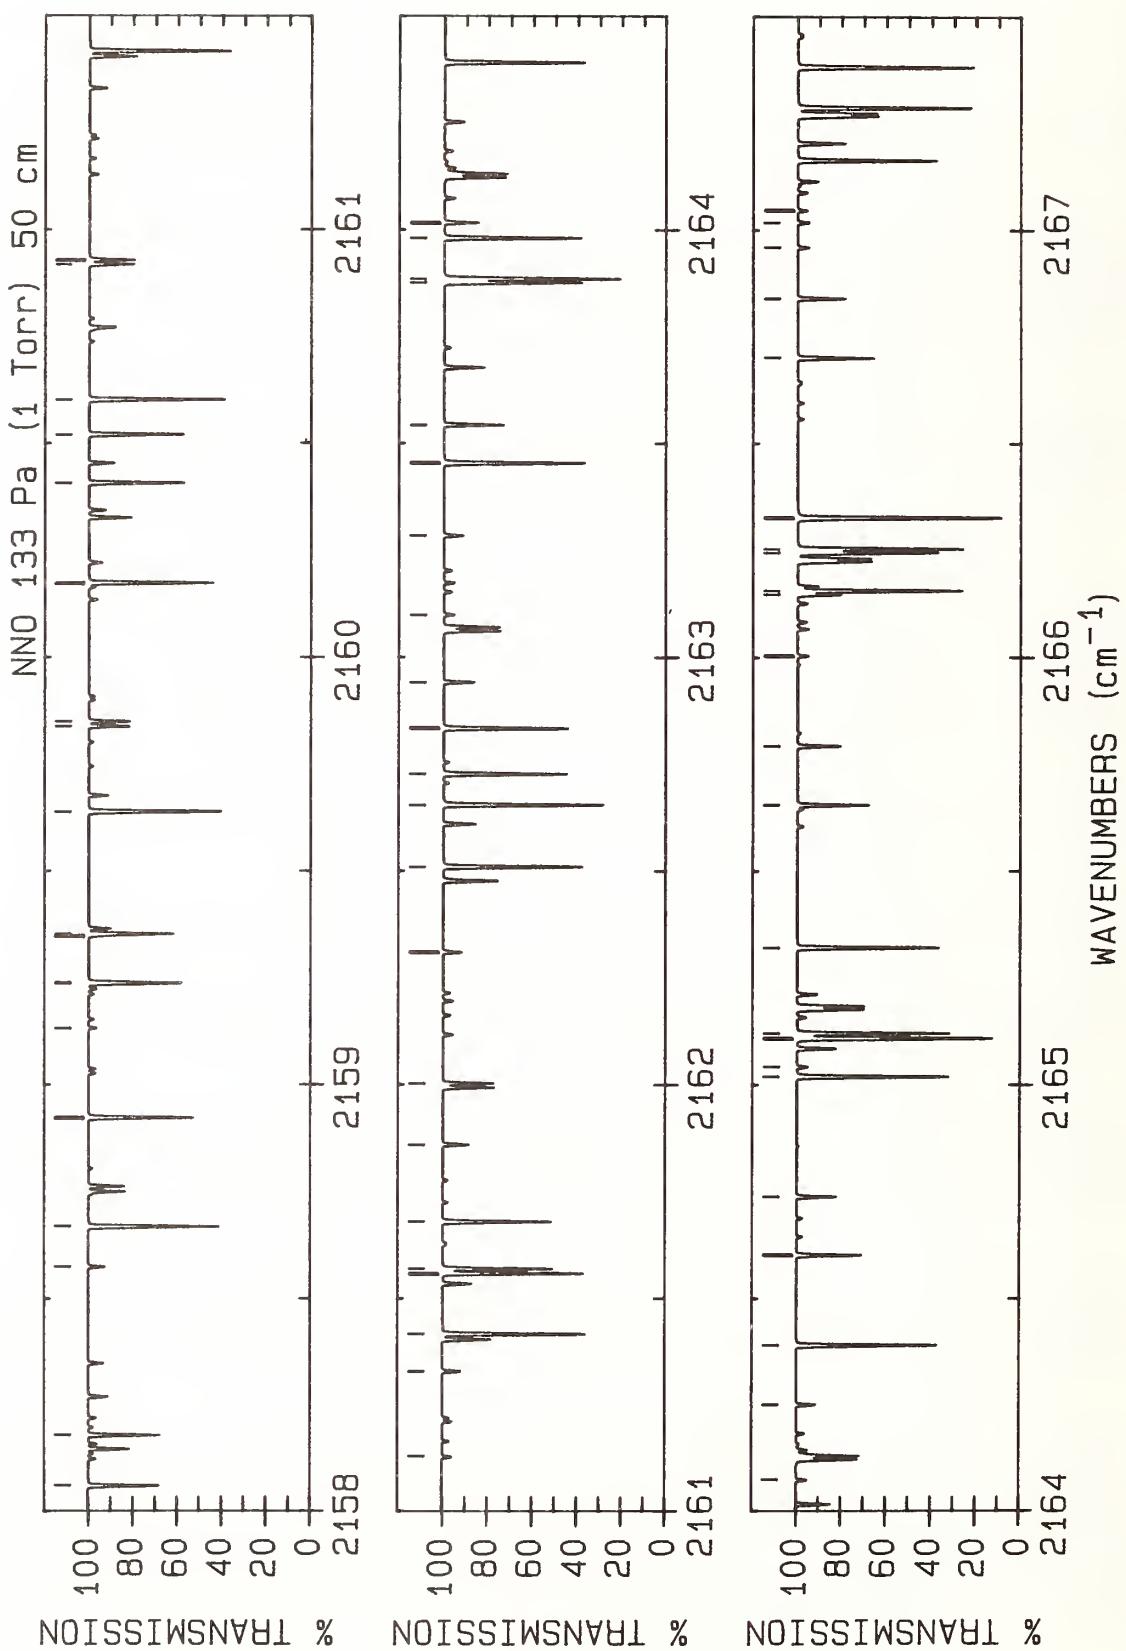

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.002 cm⁻¹ and a transition moment of 0.244 debye at a temperature of 296 K. The Herman-Wallis constants used in the calculations were $C_1 = -0.00012$ and $C_2 = -0.0000098$ as given by Boissy *et al.* [5.187].

ATLAS OF N₂O ABSORPTION LINES FROM 2400 cm⁻¹ to 2520 cm⁻¹

key:

Band	Isotopomer	Vibrational Transition
a	¹⁴ N ¹⁴ N ¹⁶ O	02 ⁰ 1-00 ⁰ 0
x		02 ^{2e} 1-00 ⁰ 0
b		03 ¹ 1-01 ^{1e} 0
c		03 ¹ 1-01 ^{1f} 0
d		02 ⁰ 2-00 ⁰ 1
e		04 ² 1-02 ^{2e} 0
f		04 ² 1-02 ^{2f} 0
g		04 ⁰ 1-02 ⁰ 0
p	¹⁴ N ¹⁵ N ¹⁶ O	02 ⁰ 1-00 ⁰ 0
r	¹⁵ N ¹⁴ N ¹⁶ O	02 ⁰ 1-00 ⁰ 0
t	¹⁴ N ¹⁴ N ¹⁸ O	02 ⁰ 1-00 ⁰ 0
v	¹⁴ N ¹⁴ N ¹⁷ O	02 ⁰ 1-00 ⁰ 0

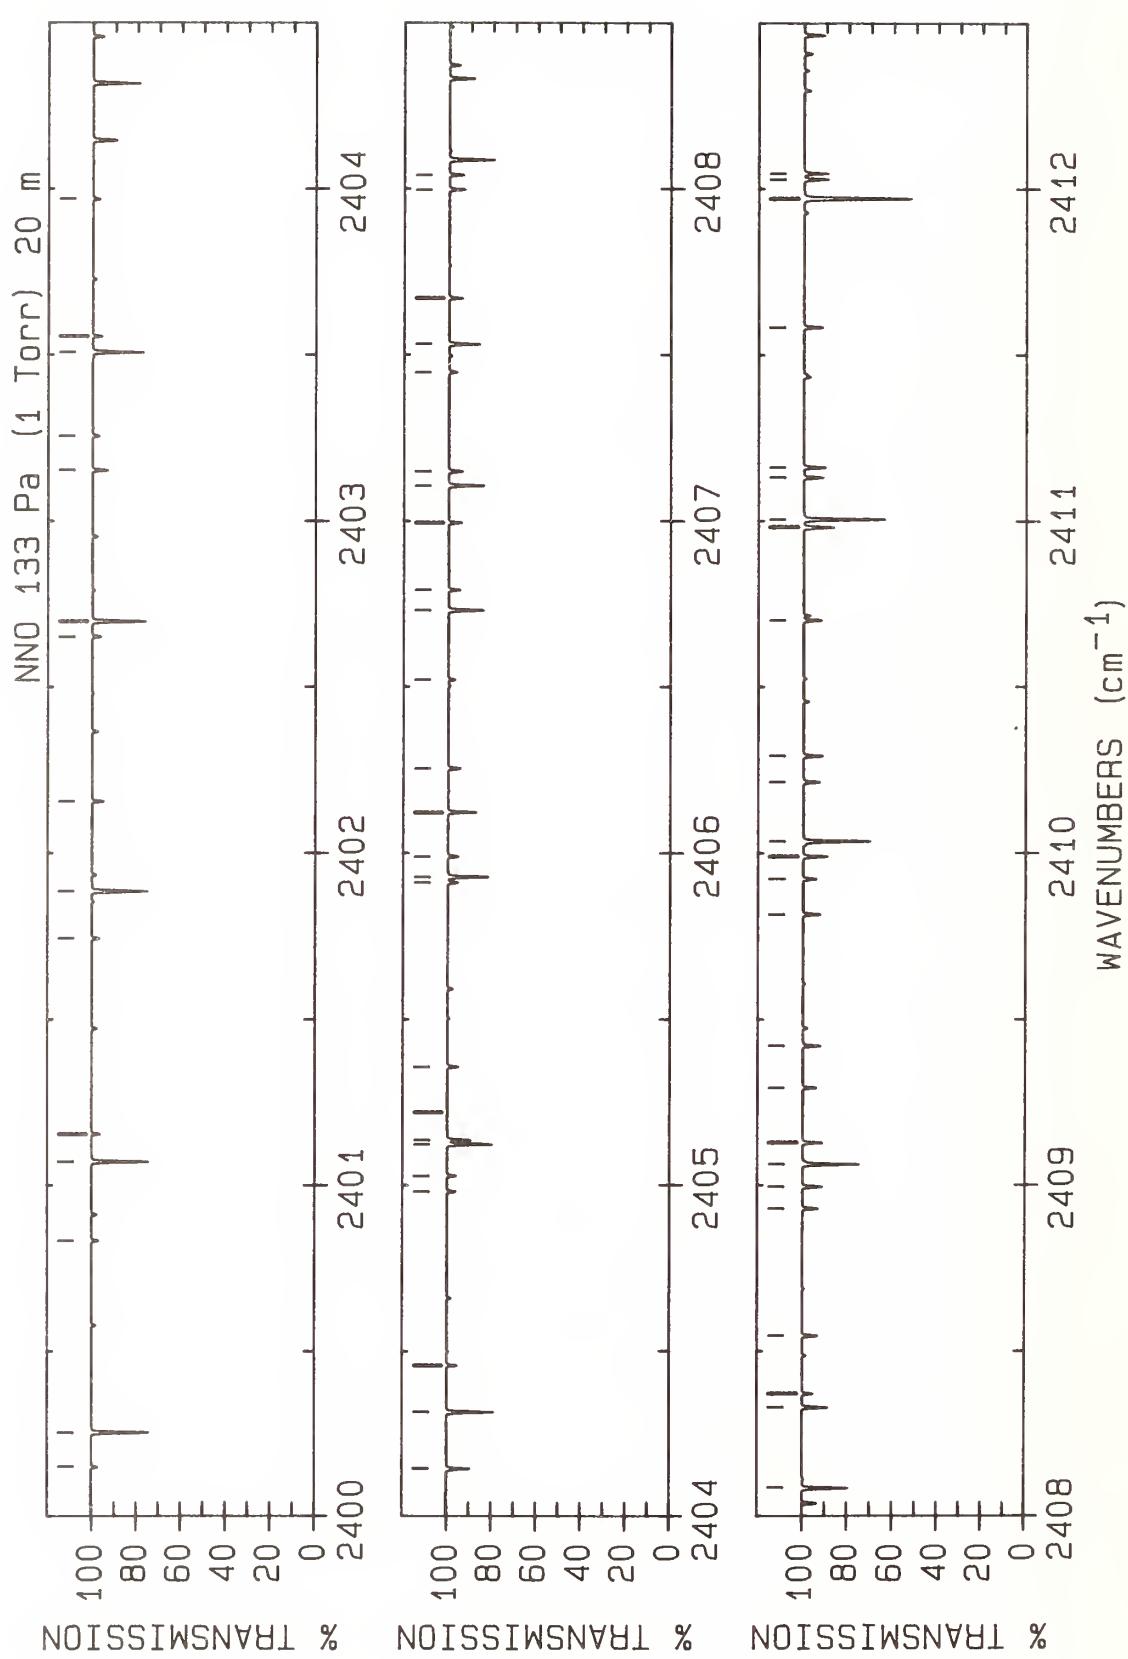

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.002 cm⁻¹ and a temperature of 296 K. For all bands, except the x band, the Herman-Wallis constant $\xi_2=0.3\times10^{-4}$ was used. For the a band a transition moment of 0.017 debye was used, for the b and c bands 0.0155 debye, for the d band 0.024 debye, for the e, f, and g bands 0.014 debye, for the p band 0.013, for r 0.021, for t 0.030, and for v 0.023 debye. In the case of the x band a Herman-Wallis constant of $C_2=0.0007$ was used along with the intensity given by the normal l -type doubling intensity borrowed from the a band.

ATLAS OF N₂O ABSORPTION LINES FROM 2450 cm⁻¹ to 2607 cm⁻¹

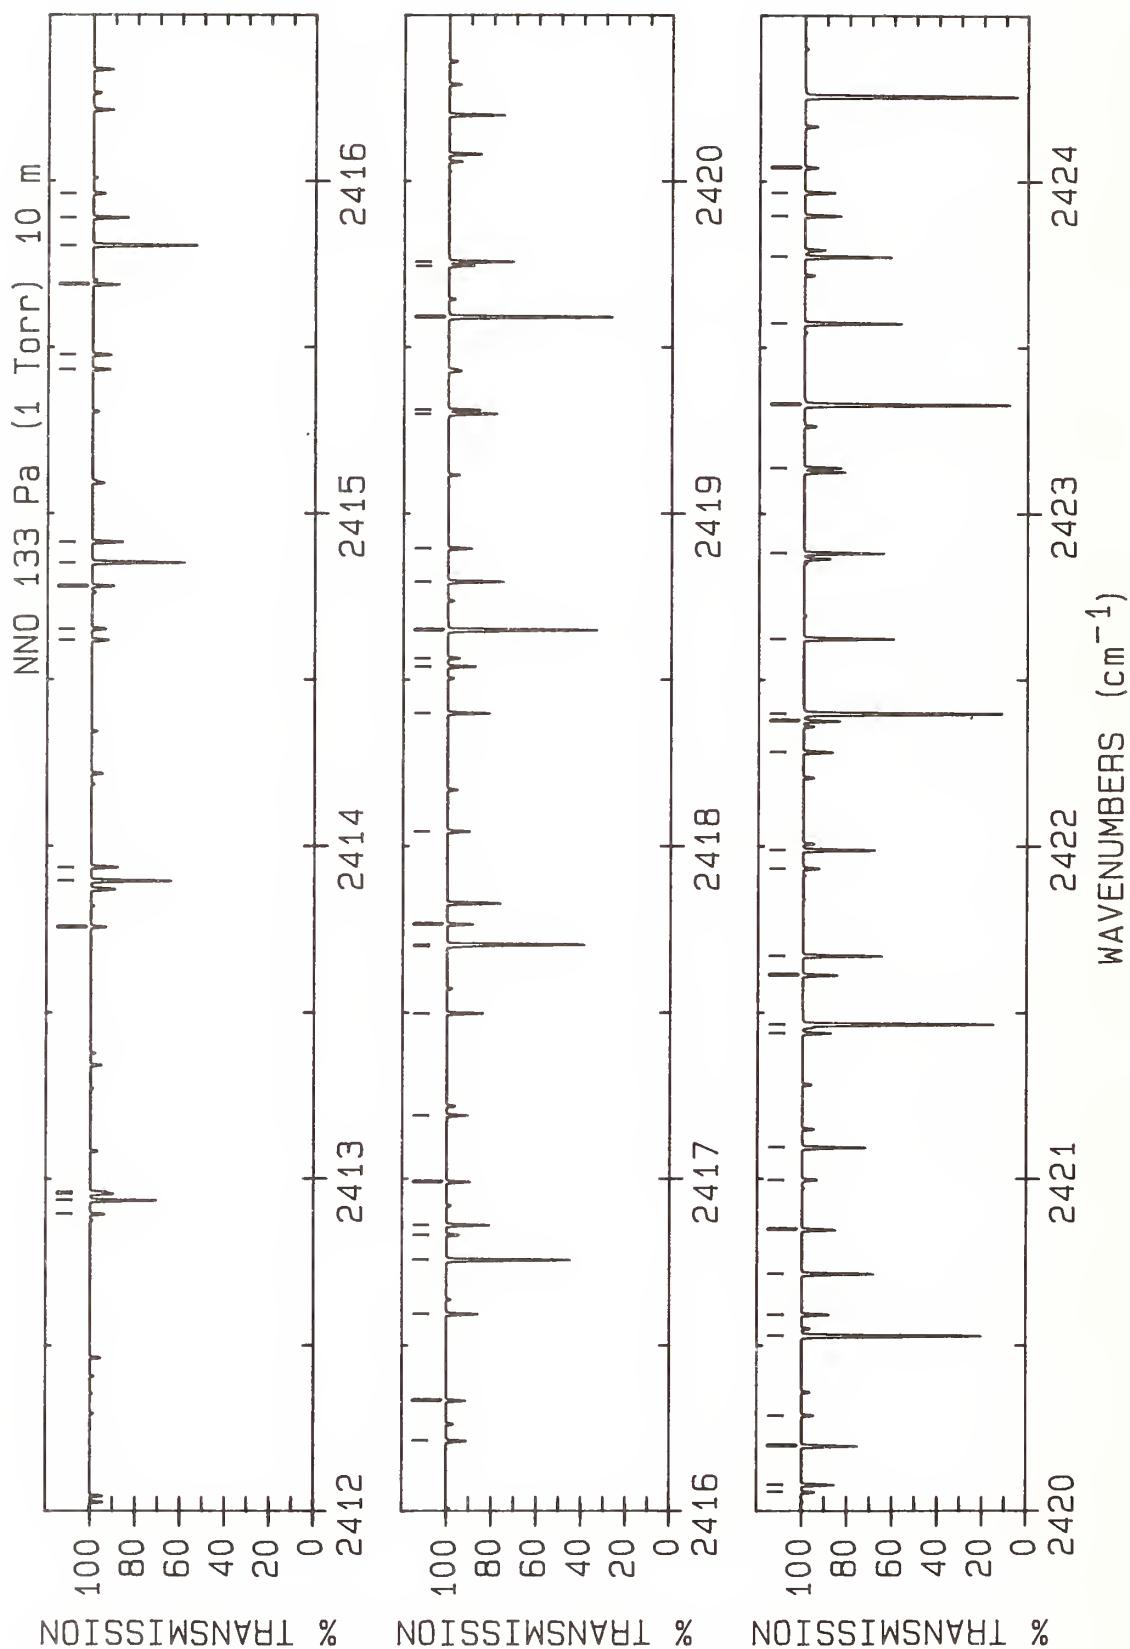

key:

T	¹⁴ N ¹⁴ N ¹⁸ O	00 ⁰ 2-00 ⁰ 0
V	¹⁴ N ¹⁴ N ¹⁷ O	00 ⁰ 2-00 ⁰ 0

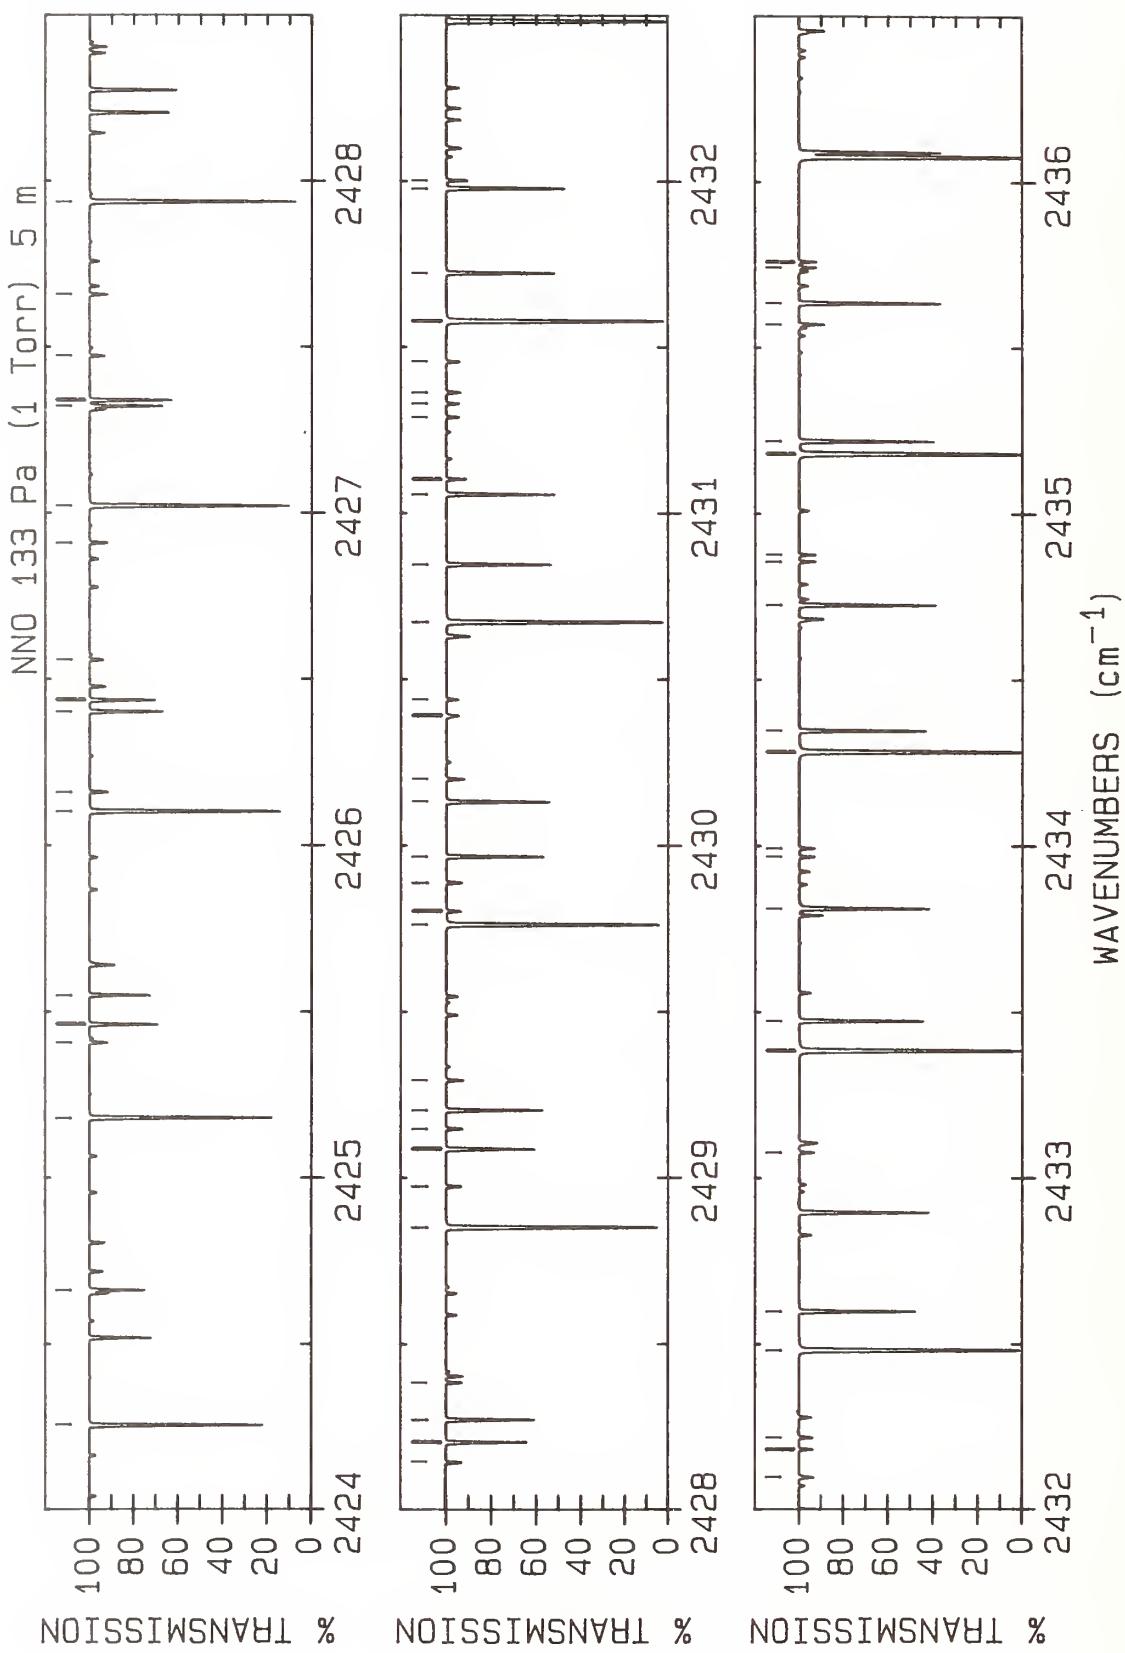

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.002 cm⁻¹ and a transition moment of about 0.037 debye at a temperature of 296 K. No Herman-Wallis constants were used in the calculations. For the T and V bands respectively, transition moments of 0.042 and 0.0395 debye were used.

ATLAS OF N₂O ABSORPTION LINES FROM 2725 cm⁻¹ TO 2842 cm⁻¹

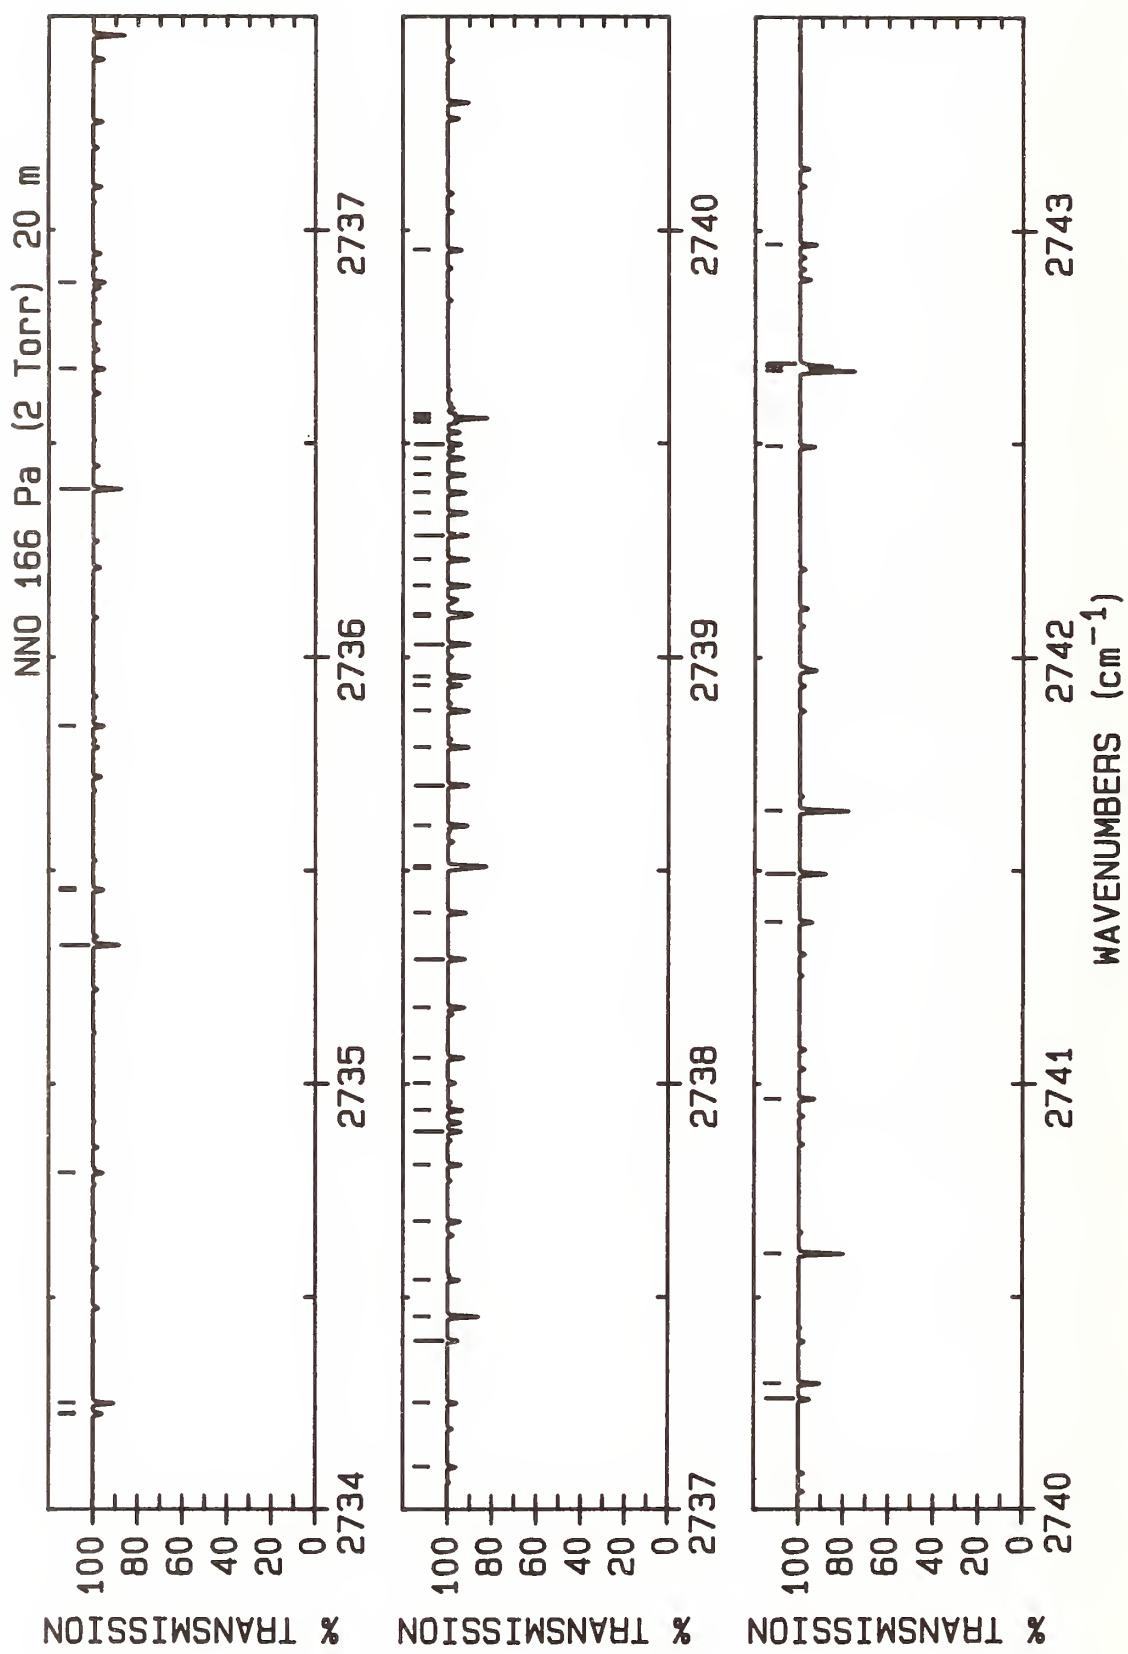

key:

Band	Isotopomer	Vibrational Transition
A	¹⁴ N ¹⁴ N ¹⁶ O	11 ¹ 0-00 ⁰ 0
B		12 ² 0-01 ^{1e} 0
C		12 ² 0-01 ^{1f} 0
D		11 ¹ 1-00 ⁰ 1
E		13 ³ 0-02 ^{2e} 0
F		13 ³ 0-02 ^{2f} 0
G		13 ¹ 0-02 ⁰ 0
H		12 ⁰ 0-01 ¹ 0
I		13 ¹ 0-02 ^{2e} 0
J		13 ¹ 0-02 ^{2f} 0
P	¹⁴ N ¹⁵ N ¹⁶ O	11 ¹ 0-00 ⁰ 0
R	¹⁵ N ¹⁴ N ¹⁶ O	11 ¹ 0-00 ⁰ 0
T	¹⁴ N ¹⁴ N ¹⁸ O	11 ¹ 0-00 ⁰ 0

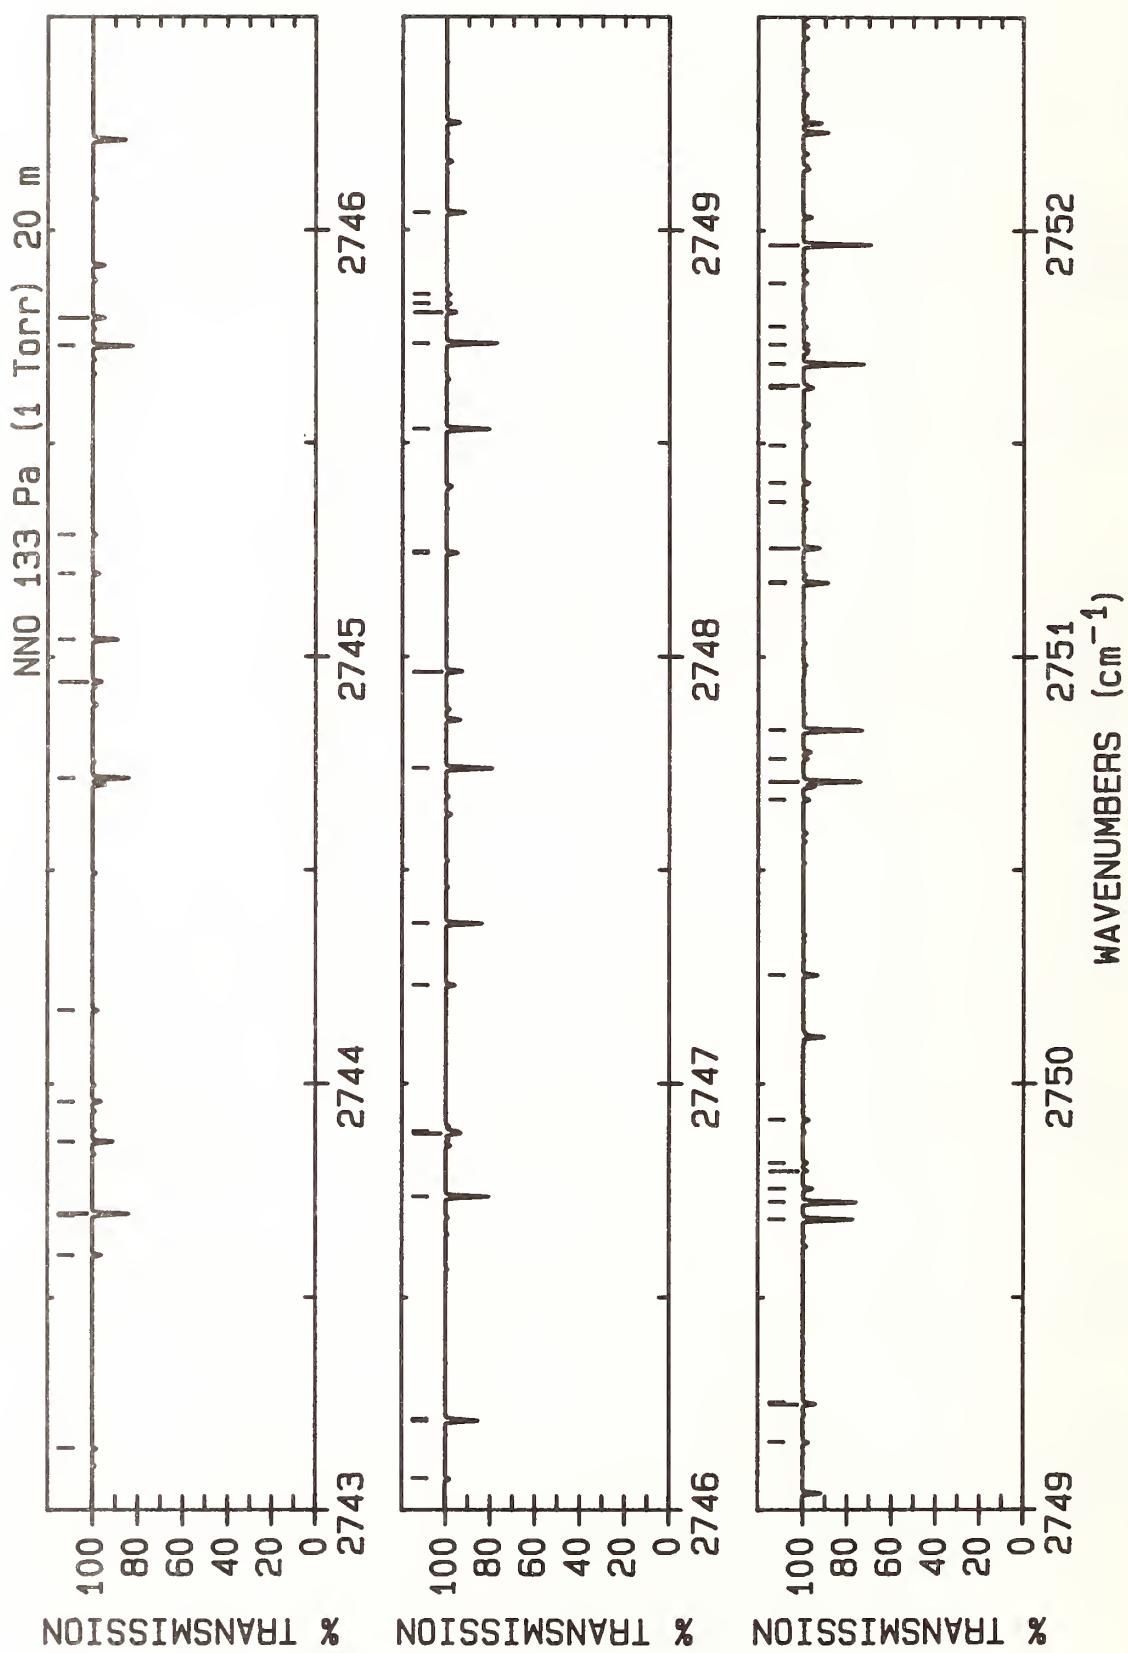

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.002 cm⁻¹ and a transition moment of 0.0086 debye at a temperature of 296 K. No Herman-Wallis constants were included in the intensity calculations.

If the e or f designation is not specified (for $l \neq 0$), then the transition is to either level, depending on the selection rules and the change in the rotational quantum number, J . Spectra are given for a slitwidth of 0.002 cm⁻¹, a temperature of 296 K, and a transition moment of 0.27 debye. No Herman-Wallis constant was included in the intensity calculation.

ATLAS OF NO ABSORPTION LINES FROM 1741 cm⁻¹ to 1940 cm⁻¹

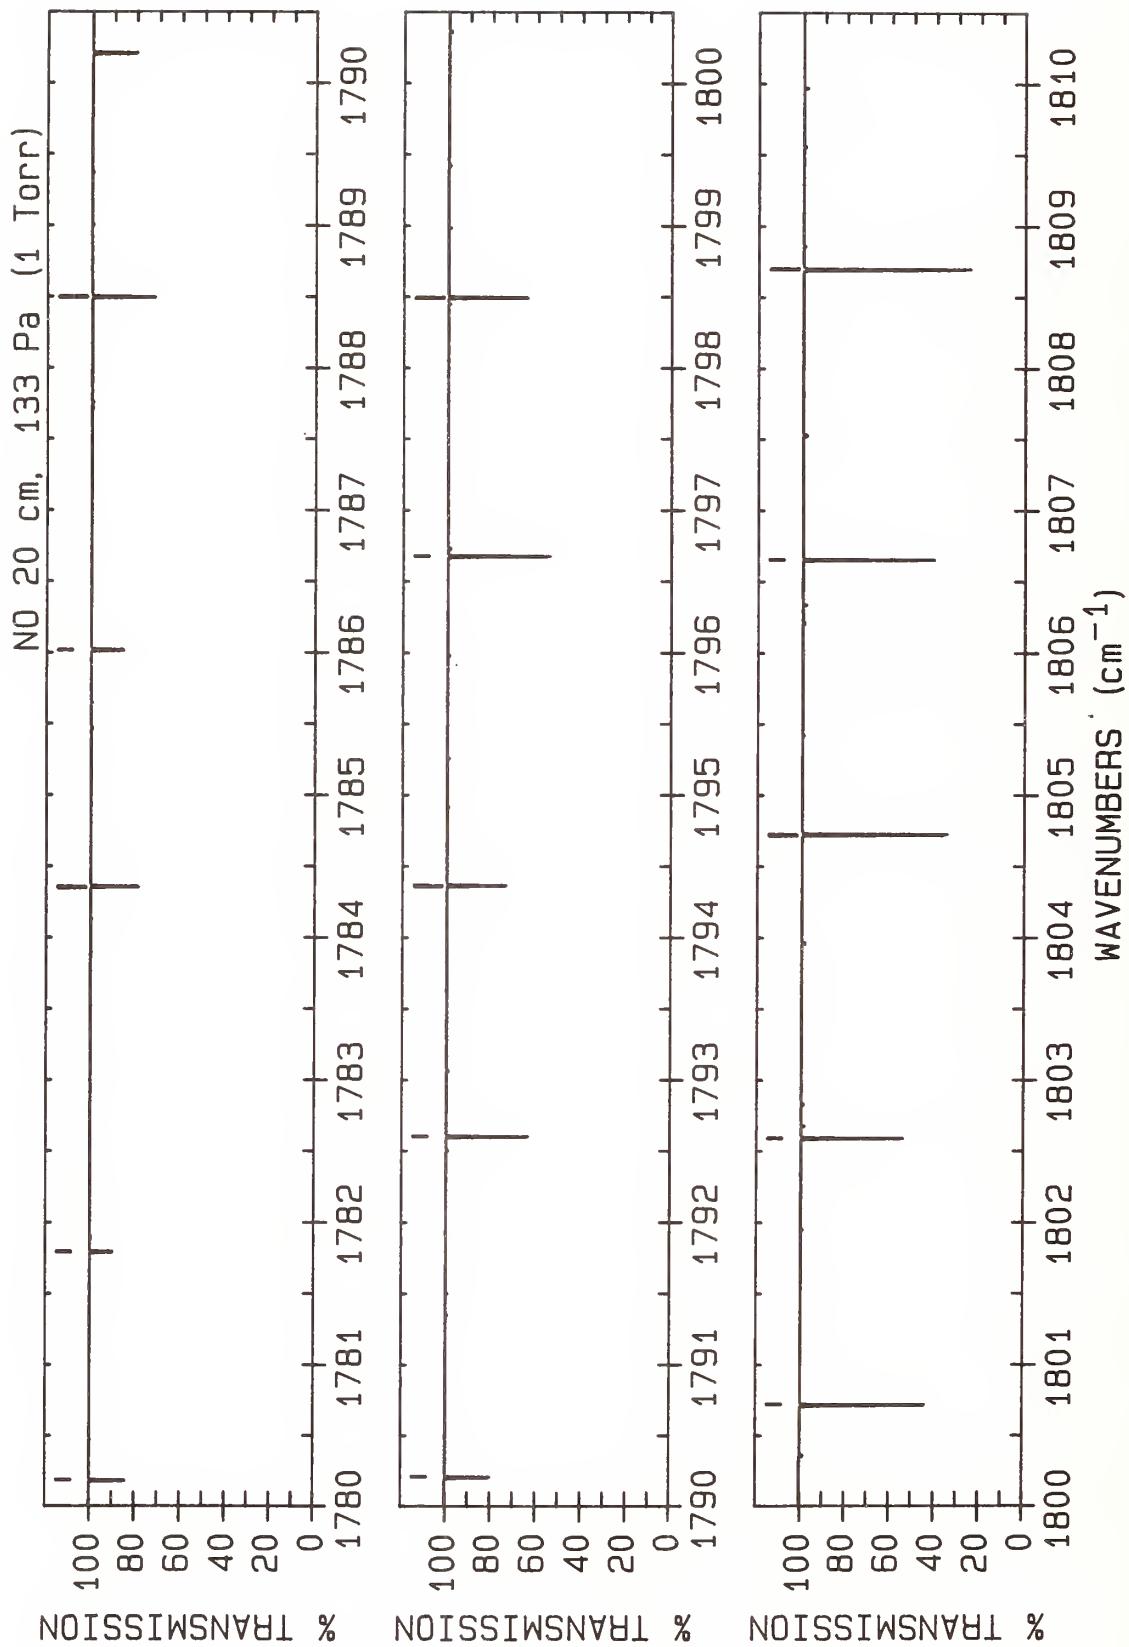

key:

Band	Isotopomer	Transition
A	¹⁴ N ¹⁶ O	$^2\Pi_{1/2} - ^2\Pi_{1/2}(e)$
B	¹⁴ N ¹⁶ O	$^2\Pi_{1/2} - ^2\Pi_{1/2}(f)$
C	¹⁴ N ¹⁶ O	$^2\Pi_{3/2} - ^2\Pi_{3/2}(e)$
D	¹⁴ N ¹⁶ O	$^2\Pi_{3/2} - ^2\Pi_{3/2}(f)$

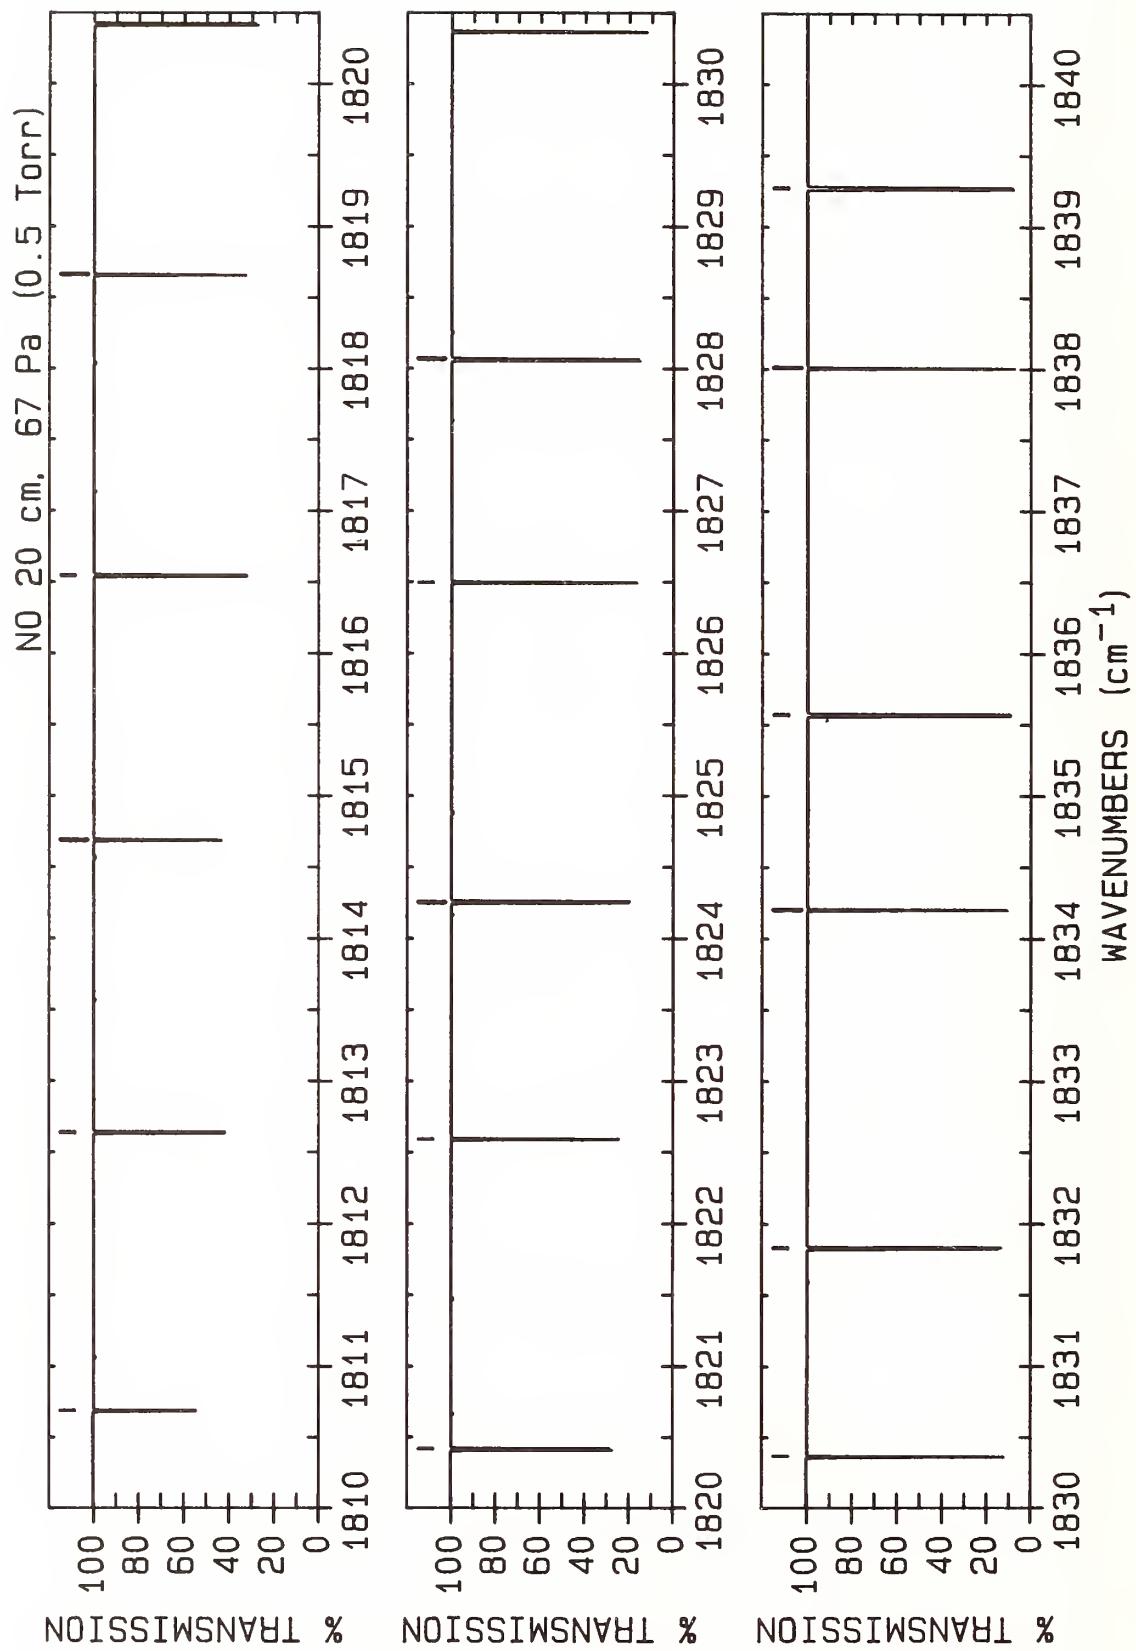

The e or f designation only refers to the lower level. The transition is to the appropriate upper level, depending on the selection rules and the change in the rotational quantum number. Spectra are given for a slitwidth of 0.003 cm⁻¹ and a transition moment of 0.00412 debye at a temperature of 296 K.

APPENDIX

Useful Equations and Formulas

Conversion factors

dipole moment or transition moment:

$$1 \text{ debye} = 3.335 \times 10^{-30} \text{ coulomb meter}$$

wavenumber:

$$1 \text{ cm}^{-1} = 29\,979.2458 \text{ MHz}$$

pressure:

$$1 \text{ atm} = 101\,325 \text{ Pa (pascal)}$$

$$1 \text{ torr} = 133.322 \text{ Pa}$$

absorption intensity:

$$1 \text{ cm}^{-2} \text{ atm}^{-1} \text{ at } 296 \text{ K} = 4.033 \times 10^{-20} \text{ cm / molecule}$$

Useful equations

Boltzmann factor:

$$N_i = N_j \exp(-1.439 E_{ij}/T),$$

where N_i is the population of the i 'th level and N_j is the population of the j 'th level with energy difference in cm^{-1} of E_{ij} at a temperature of T kelvin.

Doppler half-width at half intensity, γ_D :

$$\gamma_D = 3.581 \times 10^{-7} \nu (T/M)^{1/2},$$

where ν is the frequency in the same units as γ_D , T is the temperature in kelvin, and M is the mass of the molecule in atomic mass units.

Peak intensity of a Doppler shaped line:

$$\% \text{ transmission} = 100 \exp(-1.1494 \times 10^{14} S l p / \gamma_D),$$

where S is the intensity given in the tables, l is the pathlength in cm, and p is the pressure in Pa.

Peak intensity of a Lorentzian line:

$$\% \text{ transmission} = 100 \exp(-0.7789 \times 10^{14} S l p / \gamma_L),$$

where S is the intensity given in the tables, γ_L is the Lorentzian half-width at half height, l is the pathlength in cm, and p is the pressure in Pa.

10. SUPPLEMENTARY NOTES		
11. ABSTRACT (A 200-WORD OR LESS FACTUAL SUMMARY OF MOST SIGNIFICANT INFORMATION. IF DOCUMENT INCLUDES A SIGNIFICANT BIBLIOGRAPHY OR LITERATURE SURVEY, MENTION IT HERE.) This new calibration atlas is based on frequency rather than wavelength calibration techniques for absolute references. Since a limited number of absolute frequency measurements is possible, additional data from alternate methodology is used for difference frequency measurements within each band investigated by frequency measurement techniques. Data from these complementary techniques includes the best Fourier transform measurements available. Included in the text portion of the atlas are a description of the heterodyne frequency measurement techniques, details of the analysis including the Hamiltonians and least-squares-fitting and calculation procedures. Also included here are other relevant considerations such as intensities and lineshape parameters. A 350 entry bibliography which contains all data sources used and a subsequent section on errors conclude the text portion.		
12. KEY WORDS (6 TO 12 ENTRIES; ALPHABETICAL ORDER; CAPITALIZE ONLY PROPER NAMES; AND SEPARATE KEY WORDS BY SEMICOLONS) calibration atlas; carbonyl sulfide; carbon monoxide; carbon disulfide; IR frequency calibrations; IR wavenumber calibrations; nitric oxide; nitrous oxide; wavenumber tables

NIST Technical Publications

Periodical

Journal of Research of the National Institute of Standards and Technology—Reports NIST research and development in those disciplines of the physical and engineering sciences in which the Institute is active. These include physics, chemistry, engineering, mathematics, and computer sciences.

Papers cover a broad range of subjects, with major emphasis on measurement methodology and the basic technology underlying standardization. Also included from time to time are survey articles on topics closely related to the Institute's technical and scientific programs. Issued six times a year.

Nonperiodicals

Monographs—Major contributions to the technical literature on various subjects related to the Institute's scientific and technical activities.

Handbooks—Recommended codes of engineering and industrial practice (including safety codes) developed in cooperation with interested industries, professional organizations, and regulatory bodies.

Special Publications—Include proceedings of conferences sponsored by NIST, NIST annual reports, and other special publications appropriate to this grouping such as wall charts, pocket cards, and bibliographies.

Applied Mathematics Series—Mathematical tables, manuals, and studies of special interest to physicists, engineers, chemists, biologists, mathematicians, computer programmers, and others engaged in scientific and technical work.

National Standard Reference Data Series—Provides quantitative data on the physical and chemical properties of materials, compiled from the world's literature and critically evaluated. Developed under a worldwide program coordinated by NIST under the authority of the National Standard Data Act (Public Law 90-396). NOTE: The Journal of Physical and Chemical Reference Data (JPCRD) is published bimonthly for NIST by the American Chemical Society (ACS) and the American Institute of Physics (AIP). Subscriptions, reprints, and supplements are available from ACS, 1155 Sixteenth St., NW, Washington, DC 20056.

Building Science Series—Disseminates technical information developed at the Institute on building materials, components, systems, and whole structures. The series presents research results, test methods, and performance criteria related to the structural and environmental functions and the durability and safety characteristics of building elements and systems.

Technical Notes—Studies or reports which are complete in themselves but restrictive in their treatment of a subject. Analogous to monographs but not so comprehensive in scope or definitive in treatment of the subject area. Often serve as a vehicle for final reports of work performed at NIST under the sponsorship of other government agencies.

Voluntary Product Standards—Developed under procedures published by the Department of Commerce in Part 10, Title 15, of the Code of Federal Regulations. The standards establish nationally recognized requirements for products, and provide all concerned interests with a basis for common understanding of the characteristics of the products. NIST administers this program as a supplement to the activities of the private sector standardizing organizations.

Consumer Information Series—Practical information, based on NIST research and experience, covering areas of interest to the consumer. Easily understandable language and illustrations provide useful background knowledge for shopping in today's technological marketplace.

Order the above NIST publications from: Superintendent of Documents, Government Printing Office, Washington, DC 20402.

Order the following NIST publications—FIPS and NISTIRs—from the National Technical Information Service, Springfield, VA 22161.

Federal Information Processing Standards Publications (FIPS PUB)—Publications in this series collectively constitute the Federal Information Processing Standards Register. The Register serves as the official source of information in the Federal Government regarding standards issued by NIST pursuant to the Federal Property and Administrative Services Act of 1949 as amended, Public Law 89-306 (79 Stat. 1127), and as implemented by Executive Order 11717 (38 FR 12315, dated May 11, 1973) and Part 6 of Title 15 CFR (Code of Federal Regulations).

NIST Interagency Reports (NISTIR)—A special series of interim or final reports on work performed by NIST for outside sponsors (both government and non-government). In general, initial distribution is handled by the sponsor; public distribution is by the National Technical Information Service, Springfield, VA 22161, in paper copy or microfiche form.
