The National Bureau of Standards¹ was established by an act of Congress on March 3, 1901. The Bureau's overall goal is to strengthen and advance the nation's science and technology and facilitate their effective application for public benefit. To this end, the Bureau conducts research and provides: (1) a basis for the nation's physical measurement system, (2) scientific and technological services for industry and government, (3) a technical basis for equity in trade, and (4) technical services to promote public safety. The Bureau's technical work is performed by the National Measurement Laboratory, the National Engineering Laboratory, the Institute for Computer Sciences and Technology, and the Institute for Materials Science and Engineering.

The National Measurement Laboratory

Provides the national system of physical and chemical measurement; coordinates the system with measurement systems of other nations and furnishes essential services leading to accurate and uniform physical and chemical measurement throughout the Nation's scientific community, industry, and commerce; provides advisory and research services to other Government agencies; conducts physical and chemical research; develops, produces, and distributes Standard Reference Materials; and provides calibration services. The Laboratory consists of the following centers:

- Basic Standards²
- Radiation Research
- Chemical Physics
- Analytical Chemistry

The National Engineering Laboratory

Provides technology and technical services to the public and private sectors to address national needs and to solve national problems; conducts research in engineering and applied science in support of these efforts; builds and maintains competence in the necessary disciplines required to carry out this research and technical service; develops engineering data and measurement capabilities; provides engineering measurement traceability services; develops test methods and proposes engineering standards and code changes; develops and proposes new engineering practices; and develops and improves mechanisms to transfer results of its research to the ultimate user. The Laboratory consists of the following centers:

- Applied Mathematics
- Electronics and Electrical Engineering²
- Manufacturing Engineering
- Building Technology
- Fire Research
- Chemical Engineering²

The Institute for Computer Sciences and Technology

Conducts research and provides scientific and technical services to aid Federal agencies in the selection, acquisition, application, and use of computer technology to improve effectiveness and economy in Government operations in accordance with Public Law 89-306 (40 U.S.C. 759), relevant Executive Orders, and other directives; carries out this mission by managing the Federal Information Processing Standards Program, developing Federal ADP standards guidelines, and managing Federal participation in ADP voluntary standardization activities; provides scientific and technological advisory services and assistance to Federal agencies; and provides the technical foundation for computer-related policies of the Federal Government. The Institute consists of the following centers:

- Programming Science and Technology
- Computer Systems Engineering

The Institute for Materials Science and Engineering

Conducts research and provides measurements, data, standards, reference materials, quantitative understanding and other technical information fundamental to the processing, structure, properties and performance of materials; addresses the scientific basis for new advanced materials technologies; plans research around cross-country scientific themes such as nondestructive evaluation and phase diagram development; oversees Bureau-wide technical programs in nuclear reactor radiation research and nondestructive evaluation; and broadly disseminates generic technical information resulting from its programs. The Institute consists of the following Divisions:

- Ceramics
- Fracture and Deformation³
- Polymers
- Metallurgy
- Reactor Radiation

Headquarters and Laboratories at Gaithersburg, MD, unless otherwise noted; mailing address Gaithersburg, MD 20899.

²Some divisions within the center are located at Boulder, CO 80303.

³Located at Boulder, CO, with some elements at Gaithersburg, MD.

A PRECISION PROGRAMMABLE STEP GENERATOR
FOR USE IN AUTOMATED TEST SYSTEMS

H. K. Schoenwetter, D. R. Flach, T. M. Souders, and B. A. Bell

ABSTRACT

A precision voltage step generator has been designed for use in automated systems to test the dynamic response of waveform recorders and other instruments. The programmable pulse parameters include transition polarity, pulse length, and repetition rate. The initial and final levels of voltage steps are each programmable within the range of ± 1 V for a $50\ \Omega$ termination and within ± 5 V for a high impedance load. Voltage steps within these ranges settle to within $\pm 0.02\%$ of full scale range (FSR) in less than 22 and 26 ns, respectively, for small load capacitance. The corresponding transition durations are approximately 6 and 7 ns.

1. INTRODUCTION

The NBS Step Generator was designed for use in automated test systems to characterize the transient response of waveform recorders, oscilloscopes, and other instruments.¹ In particular, the system was intended for testing waveform recorders and digitizing oscilloscopes with resolutions of 8 to 10 bits and bandwidths up to 50 MHz. The step generator system has been used to test a wide range of high performance waveform recorders. Tests were made on these units to determine: static errors, including offset, gain, linearity, and noise; transfer functions, including step response, impulse response, and frequency response; and transient errors, including dynamic linearity, settling time, transition duration, and transient thermal errors. Several of these test methods are described in a previous paper [1]², which is reproduced in Appendix A.

The step generator was designed to output programmable voltage pulses, with one well-defined transition per period, the beginning and terminating levels of which are designated V_1 and V_2 . (The transition from V_2 to V_1 is less well characterized, and is not relied upon for most measurements.) Either single shot or repetitive pulses can be generated, with the repetition rate and duty cycle programmable over many orders of magnitude. The initial and final levels defining the steps are each programmable within the range of ± 1 V for a $50\ \Omega$ termination and within ± 5 V for a high impedance load. Voltage steps within these ranges settle smoothly, with no overshoot, to within 0.1% of full scale range in less than 15 and 19 ns, respectively, for small load capacitance. The corresponding 10-90 percent transition durations are approximately 6 and 7 ns. The voltage step waveform has been characterized by independent means, and has been shown to approximate an

¹ NBS received the IR-100 Award for this system, which was selected by the Research and Development Magazine as one of the 100 most significant new products of 1986.

² Numbers in brackets refer to the literature references listed on p. 53 of this report.

exponential response. At high values of output capacitance, the more slowly rising waveform becomes sufficiently close to an exponential that it can be used for dynamic measurements of linearity errors. Since the information yielded from these measurements is important for characterizing a waveform recorder, these tests are routinely performed using two capacitance fixtures (small modules) supplied with the system.

2. THEORY OF OPERATION

2.1 Step Generator Requirements

A step generator (SG) design was sought for use in automatic test systems to characterize waveform recorders with resolutions up to 10 bits and bandwidths up to 50 MHz (rise time of 7 ns for a 6 dB/octave response roll-off). Commercial pulse generators are not accurate enough for these tests, and laboratory step generator designs lack the overall test capability required, including wide-range programmability of the pulse parameters. An earlier NBS design had an accuracy that approached the required performance [3,7], as described in the next section. The minimum SG requirements for comprehensive and accurate testing of these waveform recorders follows.

- (1) The initial level, V_1 , and the final level, V_2 , of voltage transitions should be independently adjustable, and each should have a range of at least ± 5 V for high impedance loads. The corresponding range for 50 Ω loads should be ± 1 V. These levels should be accurately related to measurable dc values for accurate calibration.
- (2) The transition duration (10-90% rise time, T_R) of the voltage steps should be less than 7 ns.
- (3) The voltage step should settle to within $\pm 0.1\%$ and $\pm 0.02\%$ of V_2 in less than 22 ns and 27 ns, respectively, measured from the 10% amplitude point.
- (4) The output impedance of the SG should be essentially resistive for frequencies ranging from dc to several times the upper cutoff (-3 dB) frequency of the test instrument. A passive output circuit is preferred.
- (5) The SG output circuit should be packaged for direct connection to the test device, to avoid losses (and pulse distortion) from a connecting cable.
- (6) The pulse width and pulse repetition rate should be independently selectable, with pulse widths ranging from 50 ns to 5 ms, and repetition rates up to 5 MHz. After settling to level V_2 with $\pm 0.02\%$ accuracy, the voltage must remain within these error bounds for all pulse widths.
- (7) All pulse parameters should be programmable, so that the SG may be used in automatic test systems.

A practical level of accuracy for a settled voltage step is $\sim 1/2$ LSB of the waveform recorder under test. Thus, in item 1, if the static accuracy of V_2 is $\pm 0.03\%$, the settling error (item 3) should be no more than $\pm 0.02\%$ for a 10-bit recorder. For an 8-bit recorder, the allowable settling error could be as large as $\pm 0.17\%$, etc. The accuracy of V_1 should be at least $\pm 2\%$.

The rise and settling times given in (2) and (3) are minimum requirements for the application. Smaller values would simplify the error analysis of the test recorders.

Item 4 is desired so that overshoot and ringing in the voltage step are minimal if the input circuit of the test instrument has significant parasitic reactances (lead inductance and shunt capacitance, etc.)

Item 5 is very important, since a terminated connecting cable greatly increases the settling time (ST). When an unterminated cable is used, cable capacitance or voltage reflections may increase the ST. The effects of a connecting cable on ST are discussed in [2].

In item 6, pulse widths of several milliseconds are desirable for measuring thermal transients in the test instruments.

2.2 Design Approaches

2.2.1 Prior Techniques

In previous years, tunnel diodes and mercury relays have been employed in SGs to yield rise times as low as 20 ps and 39 ps, respectively [3]. However, these SGs had poor settling characteristics, i.e., the uncertainty of the voltage after transitions was 1 to 2 percent, or larger [4, 5].

In an effort to obtain step-like waveforms of known amplitude and flatness, a number of SGs or waveform standards have been developed at NBS, using various techniques. For example, reference 6 describes the development of a solid-state waveshaping filter that yields a 1/4 V step with a transition duration of 400 ps, when the filter is excited by a tunnel diode SG. The output waveform of the filter has a smooth transition with negligible aberrations; however, ST information is not available.

The reference flat pulse generator³ (RFPG) described in [3] and [7] has the following important characteristics: (1) the initial and final voltage levels of the transitions are calibrated from dc measurement; (2) the transition duration of the voltage steps is very small; and (3) the output voltage is flat after settling. This SG employs very fast precision Schottky diode switching circuits to obtain an output step of ± 0.50 V to 0.00 V.

The basic RFPG circuit is shown functionally in figure 2.1. Current I_1 flows through diode D2 and the 25 Ω parallel resistance of R_g and load resistance R_L ; thus, $V_O(t) = 0.5$ V. When the control pulse is applied, switch S changes from position 1 to position 2. Diode D1 conducts 10 mA for a nodal current balance and D2 is reverse biased and becomes nonconducting. Therefore, $V_O(t)$ rapidly approaches 0 V. In practice, the current switching by S is performed by an NPN emitter-coupled differential switch pair, and I_1 and I_2 are current sources employing PNP and NPN transistors, respectively.

³ These papers also briefly describe or reference other pulse generators or waveform standards that have been developed for testing high-speed instruments.

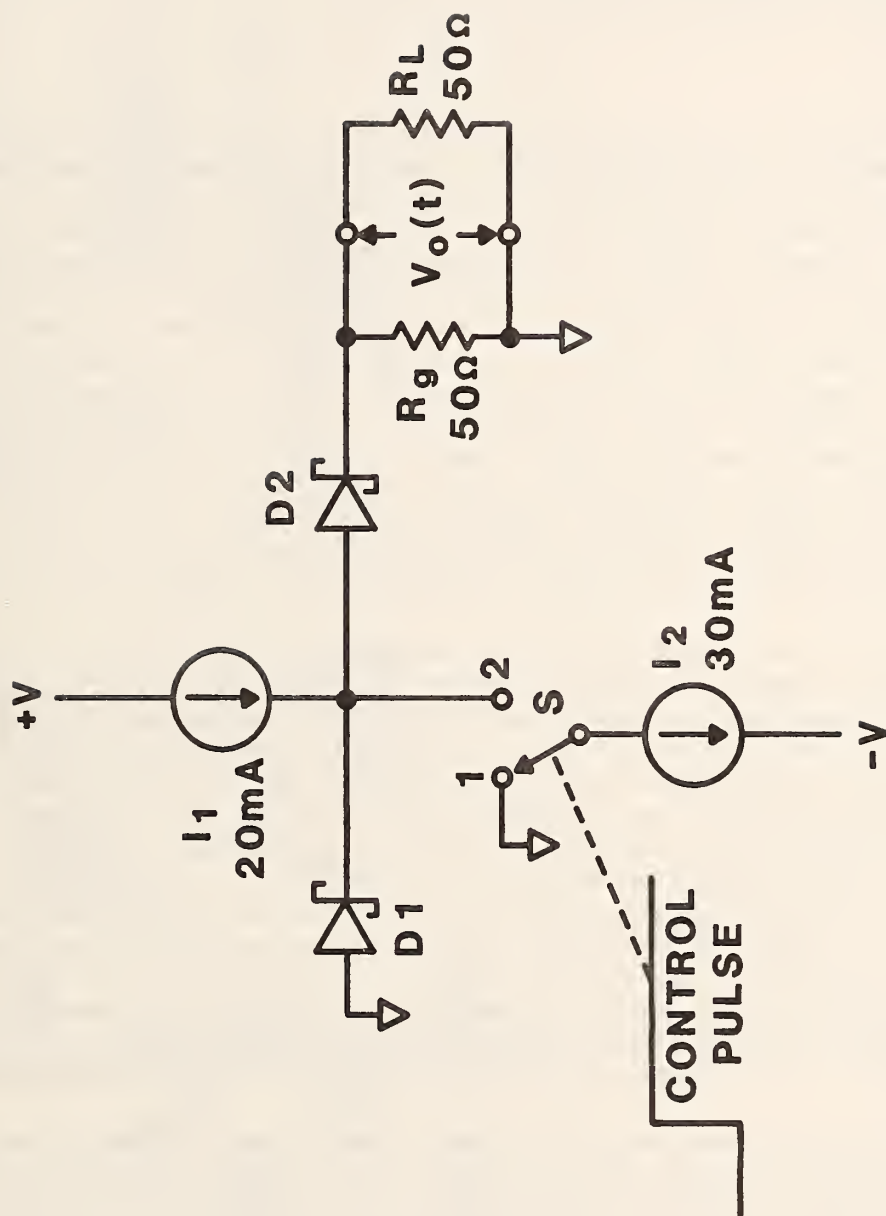

Fig. 2.1 Functional diagram of the NBS reference flat pulse generator (RFPG).

The baseline of the output step differs from 0 V by less than 10 μ V, and the top line equals $0.5 \text{ V} \pm 0.1\%$, assuming $R_L = R_g$.

The measured transition duration of this generator is 600 ps, and the measured ST to $\pm 0.2\%$ accuracy is approximately 8 ns. ST measurements to better than 0.2% were not available for this instrument. However, the RFPG was not specifically designed for settling accuracies better than 1%. The RFPG has other limitations which reduce its suitability for the applications considered here. These include inadequate step size, and the inability to select other initial and final step voltages.

2.2.2 Present Design

Figure 2.2 is a functional diagram of the SG that was designed to meet the preceding specifications [8]. Two output ranges are provided: a $\pm 5 \text{ V}$ range from output H, intended for high-impedance loads, and a $\pm 1 \text{ V}$ range from output L for 50Ω loads. Operation is as follows: the voltage-to-current converter linearly converts programmable voltage V_B to current I over the range of $\pm 80 \text{ mA}$. When the TTL input is HIGH, current I is steered to output 2 of switch S. Output voltage V_H is determined by the programmable voltage V_A and the ratio $(R_2 + R_3)/(R_1 + R_2 + R_3)$ formed by the resistive voltage divider. Hence, $V_H = V_A/2$. When the TTL input is LOW, current I is steered to output 1 of S, changing V_H by IR_p , where R_p is the parallel resistance of R_1 and $(R_2 + R_3)$. Thus, $V_H = V_A/2 + IR_p$. Resistance R_p , equal to 125Ω , is also the source impedance for V_H . The low-level output V_L is equal to $V_H/5$. When output L is used, the 50Ω terminating resistor R_3 shown in figure 2.2 is actually the input impedance of the test device; otherwise a 50Ω coaxial termination is used.

Switch S operates within a few nanoseconds after the TTL input changes state. Also, when it switches current I from terminal 1 to terminal 2, all active elements are isolated from terminal 1. Consequently, the transition from $(V_A/2 + IR_p)$ to $V_A/2$, is an exponential waveform determined by R_p and the total capacitance between terminal 1 and ground. Since the transition to $V_A/2$ involves only passive elements, it can be much more accurately characterized than the reverse transition, which involves active elements. Therefore, the transition to $V_A/2$ is recommended for waveform recorder testing. The initial and final levels of this transition have been designated V_1 and V_2 . Output voltage $V_L(t)$ has a smaller settling time than $V_H(t)$, but has essentially the same waveshape. The pulsewidth and repetition rate are determined by the timing circuit, which is under computer control, as are programmable voltage supplies A and B, via the IEEE-488 bus. In practice, the timing circuit is a programmable pulse generator with TTL-type output pulses.

Since rapid load current changes cause output voltage transients in most voltage supplies, dummy load R_4 - R_5 and complementary switching circuits in current switch S and the voltage-to-current converter are employed to maintain constant load currents for voltage supplies A and B. Also, terminal 3, placed physically close to R_1 , is carefully bypassed so that the impedance to ground is essentially zero for the frequency range of interest. In order to enhance the effective accuracies of V_H and V_L , corrections to the resistance ratios and values of V_A can be stored in a computer for later application to test data. Since the relative heat dissipation in R_1 and $(R_2 + R_3)$ varies with changes in V_A , I , and pulse duty cycle, resistors R_1 and R_2 (metal film) were chosen to have small temperature coefficients.

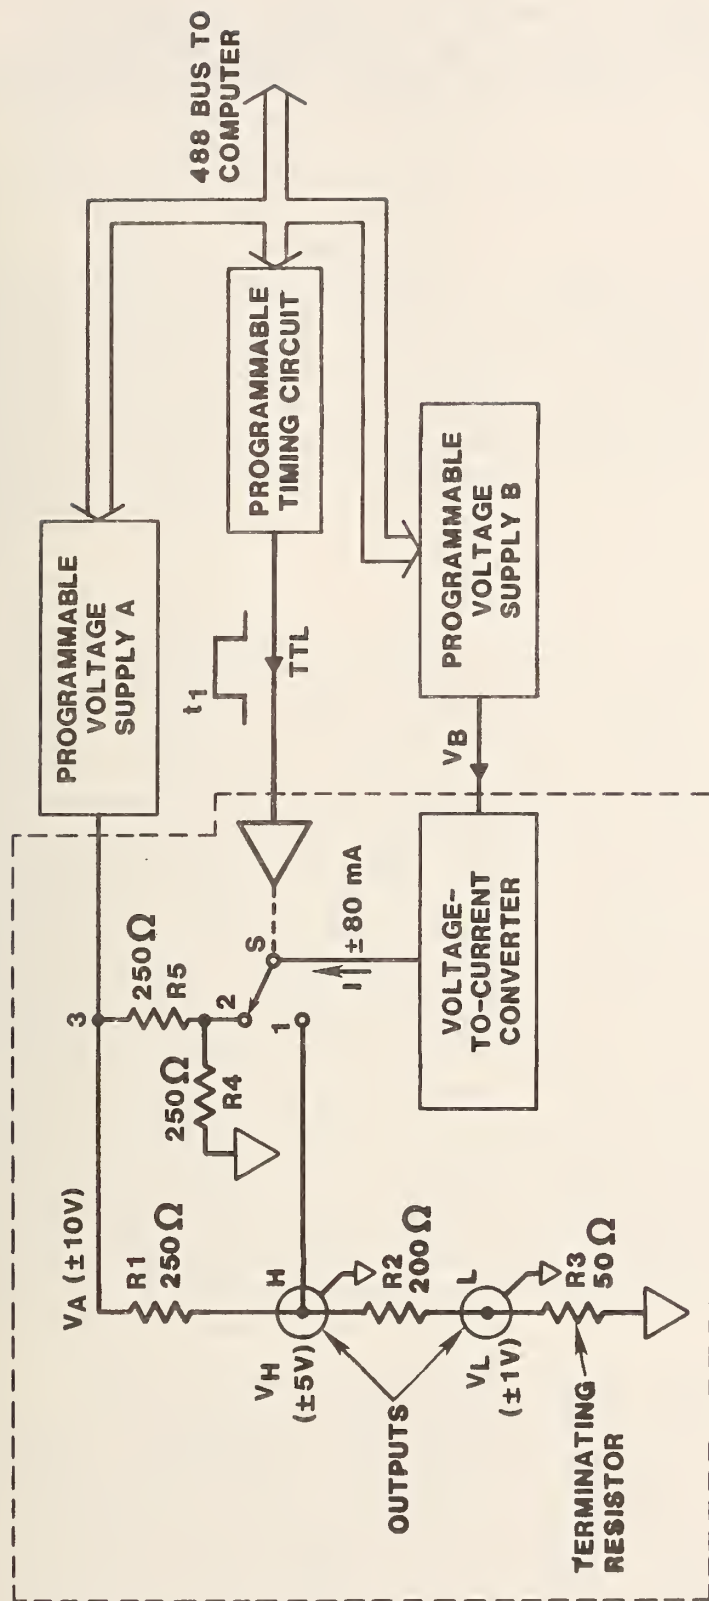

Fig. 2.2 Precision step generator. The pulse level following a voltage step transition is determined by V_A . Amplitude and polarity of the transition are determined by current I , which is a linear function of V_B . Voltage ranges are ± 5 and ± 1 V from outputs H and L, respectively. Pulse width and repetition rate are determined by the TTL input from the timing circuit.

The circuits shown in the dotted outline comprise the output circuit of the SG, and are contained in a small package ("test head") which may be connected directly to the instrument under test. The programmable voltage supplies and timing circuit are contained in a separate support package, which is designated the control unit.

3. GENERAL DESCRIPTION OF SYSTEM

The NBS Step Generator (SG) is designed to output programmable voltage pulses, with one well-defined transition per period, the beginning and terminating levels of which are designated V_1 and V_2 . The SG consists of the output circuit and the control unit, which were described briefly in section 2.2.2. As mentioned previously, the system also includes two capacitance modules for dynamic linearity measurements.

Figure 3.1 shows the SG in an automated test system. Overall control is provided via the IEEE-488 bus, for which an internal interface (not shown) has been provided. The waveform recorder under test is also interfaced to the controller via this bus. The output circuit of the step generator is a small test head which connects directly to the input terminal of the waveform recorder under test. The control unit provides the power, precision dc voltage levels (V_A , V_B), polarity selection pulses, and timing pulses necessary to control the parameters of the voltage steps generated in the output circuit.

3.1 Output Circuit

The step generator output circuit, shown in figure 3.2 is packaged in a small, lightweight container that is separate from the voltage supplies and timing circuit. Output connectors H and L are male BNC connectors which permit direct connection to a waveform recorder, or other measuring device, without the use of a coaxial cable. The step generator actually consists of two, essentially complementary, voltage step generators—one for each polarity of transition. A simplified schematic diagram of the circuit used for producing positive voltage steps is shown in figure 3.3. Transistors Q1 and Q2 perform the function of switch S in figure 3.2, switching current I to terminal 1 or I' to terminal 2. Collector currents I and I' are proportional to the common base current gains of Q1 and Q2, and typically differ by less than two percent. The magnitude of I is approximately $(|V_B| - 8.3)/125$. (Example: for a 6V step at connector H, $I = 48$ mA and $|V_B| = 14.3$ V). Schottky TTL buffers U1 and U2 provide the drive currents for Q3 and Q4, which alternately bias Q1 and Q2 off. Operation is as follows: prior to the TTL input pulse, the outputs of U1 and U2 are LOW and HIGH, respectively, so that Q3 is biased off and Q4 is conducting. Therefore, Q2 is biased off and Q1 conducts current I to terminal H, yielding an output voltage $V_H = V_A/2 + IR_p$. Upon application of the TTL pulse at time T_1 , the outputs of U1 and U2 switch to HIGH and LOW levels, respectively, switching Q3 on and Q4 off. This action switches Q1 off and Q2 on. Consequently, voltage V_H switches to level $V_A/2$.

Except for some modification of the TTL buffer circuits and the biasing of the lower pair of transistors, the circuit for producing negative voltage steps is essentially the complement of the circuit shown in figure 3.3. A latching DPDT relay is employed to connect Q1 or its complementary counterpart to connector H or to ground. A second DPDT relay is used to apply ± 5 V to Q3, Q4, U1, U2, or their counterparts. Thus, programming the SG includes pulsing the appropriate relay windings to select the voltage step polarity. Diodes D1 and D2 protect Q1 and Q2 when these transistors are disabled.

Fig. 3.1 Automated test system. The step generator consists of the control unit and the output circuit. All functions shown in the control unit are programmable via the IEEE-488 bus, except for the fixed power supplies.

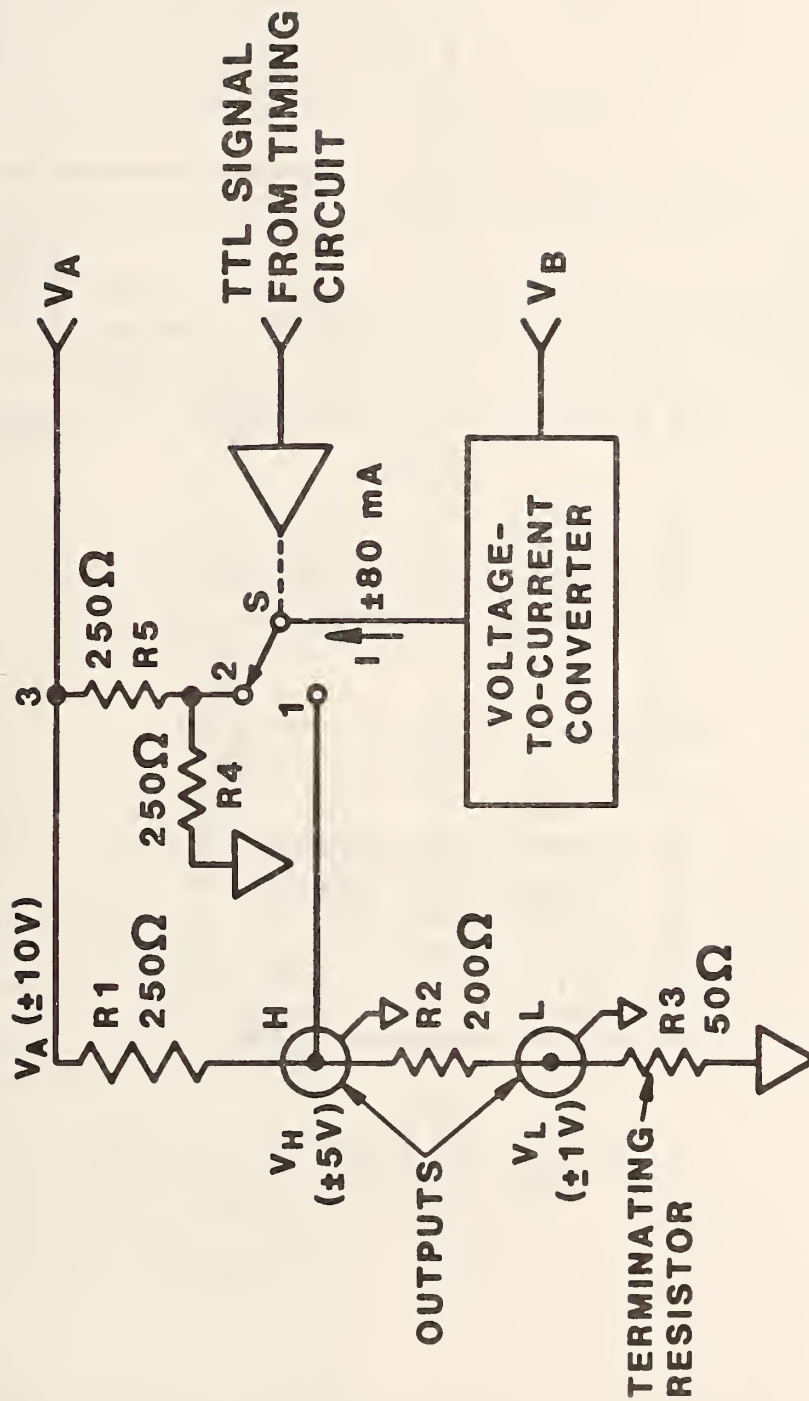

Fig. 3.2 Functional diagram of the step generator output circuit.

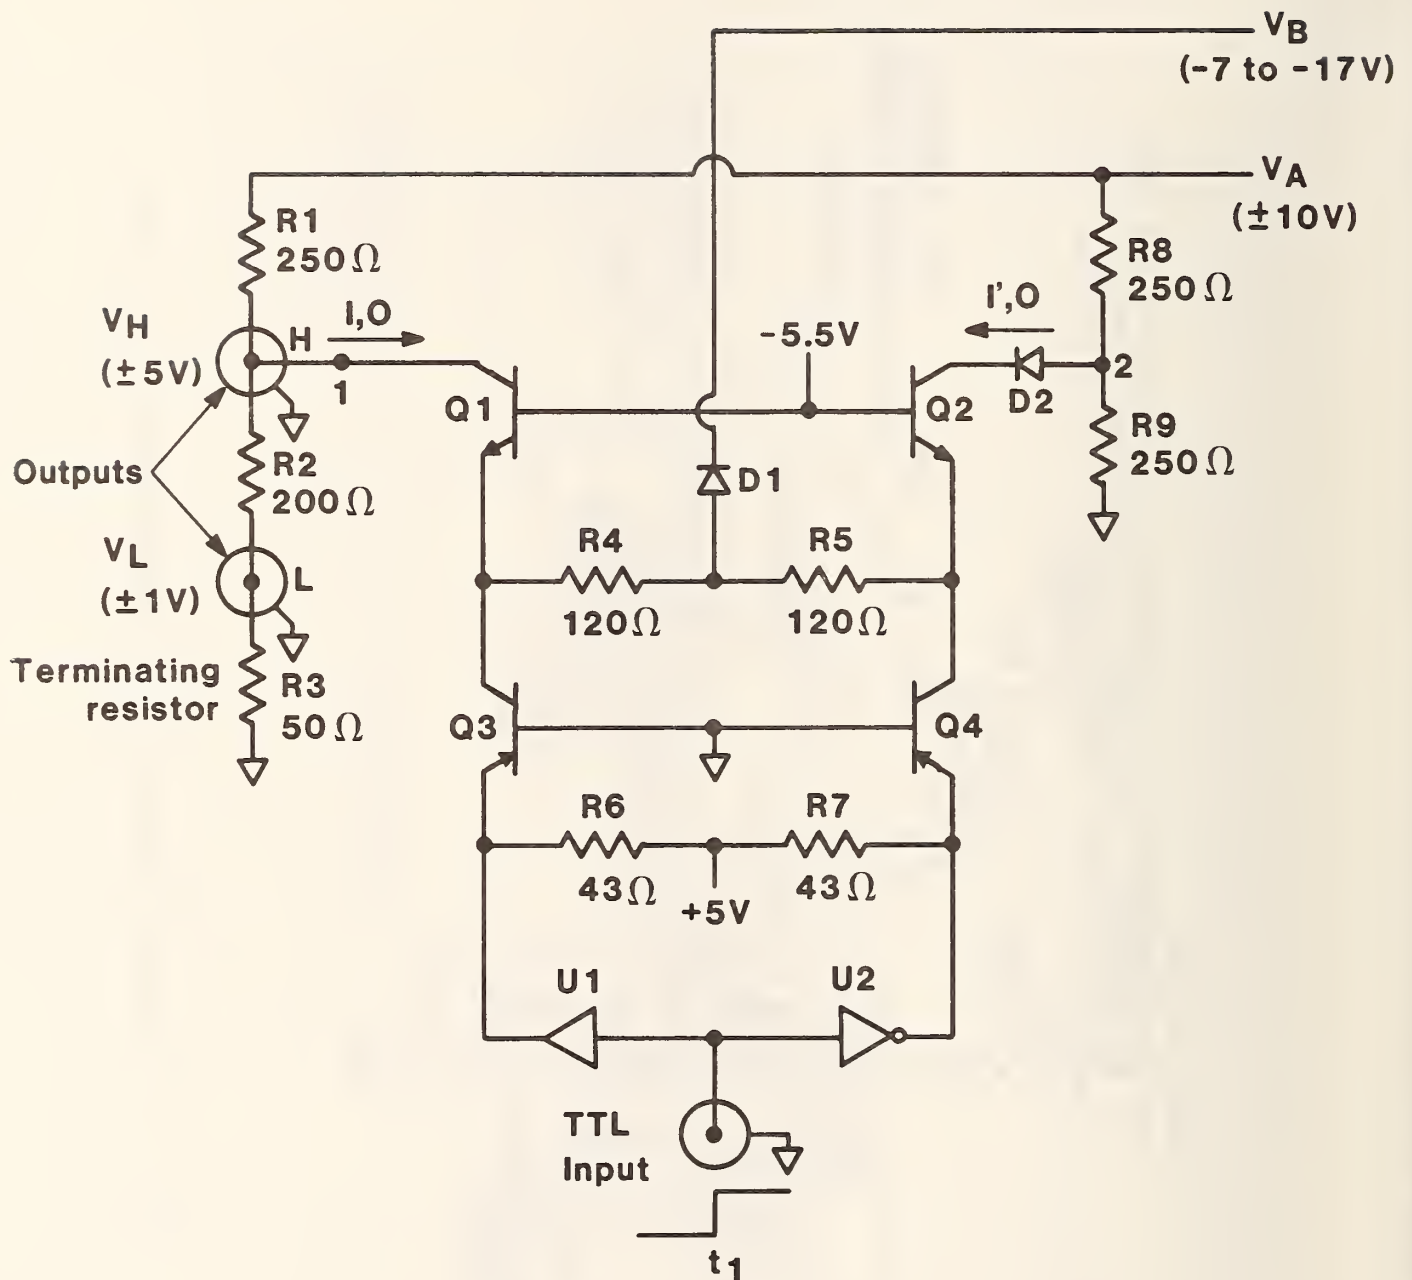

Fig. 3.3 Simplified diagram of the output circuit for producing positive voltage steps. Transistors Q1 and Q2 perform the function of switch S in figure 2.2.

A detailed diagram of the complete output circuit is shown in figure 3.4. The circuits for producing negative and positive voltage steps are shown on the left and right sides of the drawing, respectively. The functions of some of the components/circuits not shown in figure 3.3 are given below:

- (1) Clipping diodes CR4-CR9 and CR15-CR20 are used to keep transistor pairs Q3, Q4, and Q7, Q8 out of saturation, respectively. Preventing saturation permits pulse repetition rates up to 10 MHz.
- (2) Diodes CR2, CR3, and CR13, CR14 minimize switching transients, capacitively coupled to the collector circuits of Q1 and Q5, respectively.
- (3) R40 and R41 are selected for minimum settling time for negative and positive transitions, respectively.
- (4) Capacitors C30-C41 were added to minimize the effect of capacitive loading of voltage supply V_A , when large capacitors are connected across output H for dynamic linearity tests (discussed later).

The numbered leads, ranging from 1 to 18, refer to umbilical connector pin numbers.

Figure 3.5 is a photograph showing connector L (± 1 V range) of the output circuit connected to an oscilloscope. Since the oscilloscope has a high input impedance, a 50 ohm coaxial termination is required. The output circuit test head dimensions are approximately 7.6 x 7.6 x 3.8 cm, excluding connectors, and its weight is approximately 200 g.

3.2 Control Unit

3.2.1 General Description

Figure 3.6 shows a complete block diagram of the control unit. Overall control is provided via the IEEE-488 bus for which an internal listener interface has been provided. This bus interface, in turn, drives a system bus to distribute data for controlling the operating parameters of the step generator output circuit (test head). These parameters are: the pulse repetition rate, pulse length, voltage step polarity, and the initial and final voltage levels (V_1 , V_2 , respectively) of the step. The ranges of the pulse parameters are as follows:

- . Pulse repetition rate: 153 Hz to 5 MHz
- . Pulse length: 20 ns to ~ 6 ms
- . Duty cycle: approximately 5% to 95%
- . V_1 , V_2 : ± 5 V
- . Polarity of transition: either + or -

Fig. 3.4

Fig. 3.5 Photograph showing the step generator output circuit connected to an oscilloscope.

Fig. 3.6 Complete block diagram of the control unit.

The most critical of these parameters is V_2 , which is equal to $V_A/2$. For a given (selected) value of V_2 , V_A should be invariant over the complete ranges of the other parameters. Also, the resolutions in the selection of V_2 and V_1 are determined by the resolutions of V_A and V_B (0.024% for V_A and 0.09% for V_B). The details of the circuits that determine the pulse parameters is given in later sections. A photograph of the control unit is shown in figure 3.7.

3.2.2 Backplane Wiring

The backplane wiring and connectors for the plug-in circuit boards are shown in figure 3.8. The circuit boards and 108-pin mating connectors are numbered according to their position in the card cage (see figure 3.9). As mentioned previously, the IEEE-488 bus is connected to J8 (rear panel) of the control unit. Eight-conductor and eighteen-conductor flat cables are used to connect J8 to the connector (#3) for the IEEE-488 interface board. These pin connections are outlined by dashed lines.

It is seen that control signals from the interface board are sent only to the Timing, DAC/OA, and Output boards (boards 5, 7, and 9, respectively). The pin numbers (A6, B6, C12, etc.) to which wires are connected are used to designate the signal lines on the schematic drawings for these four boards. The regulated voltage supplies required for powering the step generator control unit and output circuit are mounted on boards 11, 15, 19, and 23. Also, the frequency synthesizer board (FREQ. SYN.) is not employed in the present application.

3.2.3 IEEE-488 Interface

A schematic diagram of the IEEE-488 interface circuit board is shown in figure 3.10. These circuits represent a hardware (chip level) implementation of an IEEE-488 interface having the following functions: acceptor handshake function, device clear function, and listener function, extended to honor secondary addresses [9]. The following sections provide a detailed description of the design of this particular implementation.

The components of the IEEE-488 bus are the data bus, the transfer bus, and the management bus. Transceiver ICs U01 and U02 interface with the data bus (signals DI01-DI08), and transceiver ICs U03 and U04 interface with the transfer and management buses.⁴ The transfer bus handles handshake duties and includes the three signal lines DAV (data valid), NDAC (data not accepted), and NRFD (not ready for data). Of the five signal lines in the management bus, only the ATN (attention) and IFC (interface clear) lines are used in this application.

3.2.3.1 Purpose of Interface

Three circuit boards in the control unit are used to control the pulse parameters of the SG, and a certain amount of information must be stored on these boards to quantify these parameters. Shown in the following table are the bits of information used to quantify each parameter, the number of memory chips (ICs) used to store this information, and the circuit board location.

⁴ These interface buffers have inverters in the input/output lines from/to the IEEE-488 bus.

<u>Parameter</u>	<u>Number of Bits</u>	<u>Number of Chips</u>	<u>Circuit Board</u>
(1) Polarity of transition	1	1	Output
(2) Level V_1 of step	12	3	DAC/OA
(3) Level V_2 of step	12	3	DAC/OA
(4) Pulse repetition period	16	4	Timing
(5) Pulse length	16	4	Timing
(6) Pulse length, using delay line	4	1	Timing
(7) Selection between (5) & (6)	1	1	Timing
(8) External/Internal clock choice	1	same chip as for (7)	Timing

The values chosen for each of these parameters can be those entered via the user definable keys (see section 6, OPERATING INSTRUCTIONS), or values chosen by a computer program. In either case, the purpose of the interface board is to see to it that the data required to quantify the voltage step parameters are directed to the correct boards, and are accompanied by chip address codes so that each memory chip receives the intended data word.

The chip address decoder located on each board distributes the data words to the correct memory chips on that board, based on the chip address codes received from the interface board.

3.2.3.2 Controller/Interface Operation

A cursory description of the procedure followed by the controller and the interface circuits to perform the required interface functions is given below. Except for DAV signals, the detailed handshake activity will be omitted. A more detailed description of the circuits outlined by dotted lines in figure 3.10 is given in later sections. This procedure is for sending data words to the DAC/OA circuit board from the controller.

<u>Controller Action</u>	<u>Interface Response</u>
(1) ATN line set low. ⁵	Address decoders U17, U18, and U19 are partly enabled. With DAV signals, (action 2) address decoders U17, U18, and U19 are fully enabled.
(2) Primary address put on lines DI01(LSB) - DI08 (1st data byte). DAV signal sent, i.e., DAV line set low, then high.	This address is compared with primary listen address stored in interface address decoder. If addresses are equal, primary address flag is "set" in interface address flipflop U22.
(3) Secondary address sent (2nd data byte). DAV signal sent.	This address is compared with secondary listen address stored in interface address decoder. If addresses are equal, secondary address flag is set in U22, and output 2Q high enables U15A and U15B.

⁵ Note: 1=low state (<0.8V), 0=high state (>2.0V), per the IEEE-488 standard [10]. "Low" and "high" in this discussion also refer to TTL level negative true logic levels.

- | | |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>(4) "Selected Device Clear" command sent.</p> <p>(5) ATN line set high.</p> <p>(6) 3rd data byte sent. 1st 3 bits contain board address information. DAV signal sent.</p> <p>(7) 4th data byte sent (first 4-bit data word for DAC/OA board). DAV signal sent.</p> <p>(8) 5th data byte sent (second 4-bit data word for DAC/OA board).</p> | <p>Signal sent via U15A and U26 clears chip address counter U23 to zero. (Code output from U23 is $(0000)_2$).</p> <p><u>U15C</u> is enabled via U15B which allows DAV signal to clock the chip address counter U23 (see action 7).</p> <p>1st 3 bits of data byte are applied to board address register U24. Code applied to register is assumed to be $(000)_2$.</p> <p>Positive DAV pulse is sent via U15C to U16B and U28A. Leading edge of pulse latches board address into U24; trailing edge increases count in U23 by one. Board address decoder then activates line 15 of U06-U09 when strobed by the outputs from U23.</p> <p>4-bit data word from board data bus lines A6, B6, A5, B5 is latched into chip U1 of DAC/OA board (see figure 3.11) by its chip address decoder U7, since code output of U23 of interface board is $(0001)_2$. Data latch signal from U10 is timed with leading edge of DAV pulse. Leading edge of DAV pulse cannot affect U24 as before since $(0001)_2$ code from U23 disables U16B. Therefore, the board address does not change. U16C is enabled, however, allowing DAV to latch board address into U10, thus activating data latch signal to the DAC/OA board. Trailing edge of DAV increases count in U23 to $(0010)_2$.</p> <p>4-bit data word is latched into chip U2 of DAC/OA board by its chip address decoder U7; latch signal timed with leading edge of next DAV pulse as before.</p> |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

The above procedure continues until no more data words are to be sent to the DAC/OA board. Then, the unaddressing sequence follows steps (a) through (e) below.

- | <u>Controller Action</u> | <u>Interface Response</u> |
|--------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------|
| <p>(a) ATN line set low.</p> <p>(b) Unlisten command issued, i.e., $(00111111)_2$ sent.</p> | <p>With step (c), address decoders U17, U18, and U19 are enabled.</p> |

- | | |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| (c) DAV line set low. | Inputs 1 and 13 of U22 are set low clearing interface address flipflop of address flag information. 2Q output of U22 set low. |
| (d) DAV line set high. | Inputs 1 and 13 of U22 are reset high. |
| (e) ATN line set high. | $\overline{\text{NRFD}}$ and $\overline{\text{NDAC}}$ are set low via U14A and U27. (See next section 3.2.3.3 for details). |

The overall procedure starting with step (1), and ending with step (e), is now repeated for sending data words to the timing and output circuit boards, with the board address changing to $(001)_2$, and then $(010)_2$ in step 6.

3.2.3.3 Listen Handshake Circuits

These circuits are outlined by dotted lines shown in figure 3.10. The handshake circuits send combinations of $\overline{\text{NRFD}}$ and $\overline{\text{NDAC}}$ to U04, in response to the ATN and DAV signals sent by the controller. The handshake process is fully described in Appendix B of [10].

A handshake sequence is executed by the controller and the interface over the transfer bus each time a byte is transferred over the data bus. Since NRFD and NDAC on the IEEE-488 bus each have two states, the two quantities taken together have a total of four different states (11, 10, 01, 00).

The 1,1 state indicates that the interface is not ready for data ($\text{NRFD}=1$) and has not accepted data ($\text{NDAC}=1$). In this state, communication is temporarily held up on the bus. This state can arise, e.g., if ATN is high and the primary and secondary address flags have not been "set" in the interface address flipflop.

The 0,1 state indicates that the interface is ready for data ($\text{NRFD}=0$) and is not accepting data ($\text{NDAC}=1$). Thus, the interface is prepared to receive messages.

The 1,0 state indicates that the interface is not ready for data ($\text{NRFD}=1$) because it is in the process of accepting data ($\text{NDAC}=0$).

The 0,0 state is an error condition.

Between receiving messages from the controller, the $\overline{\text{NRFD}}$ and $\overline{\text{NDAC}}$ lines of the listen handshake circuits are high so that NRFD and NDAC on the IEEE-488 bus are low and in the 1,1 state. After the controller sets the ATN line low, the normal handshake sequence is as follows: data is put on the data bus when the state is (0,1) indicating that the interface is ready for data. After allowing time for the data to settle, DAV (data valid) is set low by the controller. After DAV is set low, the handshake circuits set NRFD low, followed by NDAC being set high (state 1,0). The latter step tells the controller that the interface has received the data (or address) byte. Following the (1, 0) state, a certain minimum time, T_D , is required for the controller to return DAV to the high state. The circuits in the interface board will function properly with a wide range of T_D values. After DAV is

set high, the NRFD/NDAC state is returned to (0, 1), ready for another handshake cycle. After the message has been received, the controller then sets the ATN line high, and the following inputs are applied to the handshake circuits: (1) the output from U15B is low, (2) the DAV line is high, (3) the ATN and ATN lines are high and low, respectively. Consequently, NRFD and NDAC are set low via U14A, U27, and U14C, U14D.

3.2.3.4 Interface Address Decoder

These circuits are used to decode primary and secondary listen addresses on the data bus, the "Selected Device Clear" command, and the unlisten command. The manner in which the address decoder decodes these addresses and commands will be discussed. Handshake responses will be omitted for the sake of brevity.

Primary Listen and Secondary Addresses

After setting the ATN line low, the controller puts the primary address (00101000)₂ on the data bus and sets the DAV line low. To recognize this primary listen address the three inputs to OR gate U12A must all go low, thus providing a rising edge to the LCK clock input of dual J-K flipflop U22. ATN low and DAV low enable U17, U18, and U19 (3 line to 8 line decoders). Since bit 7 on the data bus is 0, pin 10 of U01 is low, and pin 15 of U17 and pin 13 of U12A are low. Also, since bit 6 is 1, pin 6 of U01 is high and pin 2 of U12A is low. Finally, the first five bits also agree with address 8 set by switch S1. Therefore, output 6 (U21) of comparator pair U20, U21 will be high and pin 1 of U12A low. With all inputs of U12A set low, pin 3 of U22 goes high and 1Q is set low, as is pin 8 of U13A. Thus, the primary address has been "captured" off the IEEE-488 bus, and the primary address flag "set".

With ATN still low, the controller puts the secondary address (01101100)₂ on the bus and sets DAV low. U17, U18, and U19 are again enabled. It can be shown that inputs 9, 10, and 11 of U12B are now low, causing input 9 of U13A to go low. Since pin 8 was previously set low, the positive-going output of U13A is applied to pin 11 of U22, setting 2Q high. Therefore, the secondary address is now captured and the secondary address flag set. It is seen that output 2Q has also set input 9 of U15A and input 1 of U15B high, thus enabling these gates. These conditions are necessary for the operation of the remaining circuits. Also, if U15B were not enabled, the handshake circuits would set the NRFD, NDAC state to (0,0), an error condition as previously mentioned.

Selected Device Clear (SDC) Command

This IEEE-488 bus command clears the chip address counter U23 to zero. The controller keeps ATN low and issues the SDC command, (00000100)₂. When DAV is set low by the controller, U17, U18, and U19 are enabled, and the outputs from U01 and U02 cause all inputs of U11B to go low. Output 12 of U11B goes high, and since U15A was previously enabled, a clear signal is applied to U23, setting outputs QA, QB, QC, and QD of the counter to low (output code of (0000)₂). These lows are applied to pins 2, 3, 11, and 12 of U13C and U13D, producing a high at pin 6 of U16A and pin 2 of U16B, enabling the latter. Note that after the first count has been given to U23, U16B is then disabled and U16C is enabled. (See steps 6, 7, and 8 of section 3.2.3.2).

Unlisten Command

When no more data bytes are to be sent, which is determined by the controller, the ATN line is set low and the unaddressing sequence begins. (See step (a)-(e) of section 3.2.3.2). With ATN set low, the controller issues the unlisten command $(00111111)_2$. The controller also sets DAV low, enabling U17, U18, and U19. The above code sets lines 3, 6, 10, and 14 of U02 and lines 3 and 6 of U01 high. Line 10 of U01 is set low. It can be seen that these inputs to U17, U18, and U19 cause lows on the inputs of U12C and, therefore, a low at input 1 (1 CLR) and input 13 (2 CLR) of U22. This signal clears flipflop U22 of address flags. When DAV goes high, inputs 1 and 13 of U22 are set high. The controller may then proceed to issue an untalk command $(10111111)_2$, to which only the handshake circuits respond. The controller sets ATN high, ending the command sequence.

3.2.3.5 Code Converter

IC U05 is a 4-bit binary full adder which is used to translate ASCII characters to hexadecimal digits. Lines 3, 6, 10, and 14 of U02 and line 3 of U01 are connected to the adder, as shown in Fig. 3.10. If the incoming data is an ASCII "0" to "9", the adder takes no action. If the incoming data is an ASCII "A" to "F" (the signal applied to B1 and B4 is high), a 9 is added to the first 4 bits to obtain a sequence of numbers in the range of 0 to 15. This allows entry of the hex digits, A to F, from the controller keyboard or in a program mode. The data output lines of U05 are connected by backplane wiring to the three control unit circuit boards mentioned previously. The inactive boards cannot access this data, however, because the chip address lines are held high and the chip address decoder receives no latch signals.

3.2.3.6 Board Address Decoder

This circuit employs ICs U06-U10. The three lines of the board address register U24 are connected to the inputs of U06 through U10, which are three line to eight line decoders. For example, if the register output is $(000)_2$, output Y_0 (pin 15) of the five chips is active. If the register output is $(001)_2$, output Y_1 (pin 14) of the five chips, is active, etc. Outputs Y_3 through Y_7 are not used. Outputs Y_0 are connected to the DAC/OA board, outputs Y_1 to the timing board, and outputs Y_2 to the output board. Outputs which are inactive at any time are held high.

Outputs QA, QB, QC, and QD of chip address counter U23 are applied to pin 4 (G2A) of U06, U07, U08, and U09, respectively, and are used to latch the active output lines of U06-U09. These lines are connected to the chip address decoder located on the activated board. The decoder determines which chip is to receive the data sent to the board. Each chip address is latched into the decoder by a data latch signal received from the active output line of U10. The latch signal occurs when DAV is passed through U16C and U28C to pin 4 (G2A) of U10.

Succeeding data bytes are handled by the interface in the same way, with the chip address counter advancing one count with each DAV pulse. Thus, the counter and ICs U06-U09 serve as a chip address encoder. When all chips have received data for the selected board, the chip address counter is reset to zero as before by the SDC command, and the process just outlined is repeated for the next board, etc.

3.2.4 DAC/OA Board

The DAC/OA board contains the circuits necessary to generate voltage V_A and V_B (see figure 3.11). If V_1 and V_2 are the initial and final voltage levels of the desired voltage step, respectively, then

$$V_A = 2 * V_2,$$

and

$$V_B = \text{sign}(V_2 - V_1) * (|V_2 - V_1| + 8.3),$$

where $*$ indicates multiplication, the sign function is -1 if $V_2 > V_1$, and is $+1$ if $V_2 < V_1$. In order to have approximately 10% overrange capability for V_2 and V_1 , the ranges for V_A and V_B are set at ± 11 V and ± 20 V, respectively.

Voltages V_A and V_B are generated by a pair of D/A converters (DACs) with output amplifiers (OAs). Since the DACs for both supplies have an output range of ± 10 V, the nominal amplifier gains for the V_A and V_B supplies are set at 1.1 and 2.0 respectively. Therefore, these ratios are used for R_2/R_1 and R_4/R_3 , respectively, in amplifiers U_A and U_B .

If V'_A and V'_B are the output voltages from DAC A and DAC B, respectively, then

$$\begin{aligned} V'_A &= -0.909091 * V_A, \\ \text{and} \\ V'_B &= -(1/2) * V_B. \end{aligned}$$

The networks in the output circuits of amplifiers U_A and U_B , including C_1 and C_2 , are recommended by the manufacturer to improve the load transient response.

Complementary offset binary coding is used for both DACs. Registers U_1 , U_2 , and U_3 provide the input code for DAC A and registers U_4 , U_5 , and U_6 provide the input code for DAC B.

The inputs to the chip address decoder (U_7) are obtained from outputs Y_0 of U_6 - U_9 of the board address decoder shown in figure 3.10. As the input code changes one bit at a time from $(0001)_2$ to $(0110)_2$, 4-bit data words from the board data bus are sequentially loaded into registers U_1 through U_6 . The data latch signal on line C_8 and on G_1 and G_2 of U_7 is the gated DAV pulse from the IEEE-488 interface board. Since the selected output line of U_7 goes low when G_1 and G_2 go low, the flipflops in the selected register are triggered on the leading (negative going) edge of DAV. The complete process by which the address code and the data words are obtained (for registers U_1 - U_6) is explained in section 3.2.3.

The board address $(0000)_2$ and the six 4-bit data words, needed to establish V'_A and V'_B , are contained in a 7-digit hexadecimal word string, which may be entered via the keyboard or a computer program. The make-up of the DAC/OA board word string is discussed further in section 4., DRIVER SOFTWARE.

3.2.5 Timing Board

The circuits on the timing board (see figure 3.12) control the pulse repetition period and the pulse length of the voltage steps as well as the internal/external clock choice. The inputs to the chip address decoder U11 are obtained from outputs Y1 of U06-U09 of the board address decoder shown in figure 3.10. As the input code changes one bit at a time from $(1001)_2$ to $(1010)_2$, 4-bit data words from the board data bus are sequentially loaded into registers U1 through U10. The latching signal on line C14 and G1 and G2 is the gated DAV pulse from the IEEE-488 interface board, and appears on the selected output line of U11. The data word is latched into the selected register by the leading edge of this pulse after it is inverted by one of the U18 or U19 inverters.

The data words (codes) that have been latched into registers U3-U10 are preset into counters U21-U28 once each output pulse repetition period. Timing of the presetting occurs with the first negative transition of the clock signal after the load input (pin 9) of the counters is set low.

The pulse repetition period of the step generator is determined by the code value preset into counters U21 through U24, and equals the complement of this code times the (10 MHz) clock period. When these counters receive a full count, the code values in registers U3-U6 are preset into these counters. The code values in registers U7-U10 are also preset into counters U25 through U28 at the same time. These latter ICs are used to control the pulse length, which is discussed next.

Outputs 3 and 6 of U1 are applied to U12 to select either the internal clock (U16) pulses or the external clock pulses from line A17. Outputs 11 and 14 of U1 are applied to U13 to select the means of controlling the pulse length. The function table for U13 is shown below:

	<u>B</u>	<u>A</u>	<u>1C₀</u>	<u>1C₁</u>	<u>1C₂</u>	<u>1C₃</u>	<u>1Y</u>
1.	L	H	x	L	x	x	L
2.	H	L	x	x	H	x	H
3.	L	L	L	x	x	x	L
4.	L	L	H	x	x	x	H
5.	H	H	x	x	x	L	L
6.	H	H	x	x	x	H	H

Thus, when inputs A and B are both low the output waveform (at 1Y) is determined by the input pulse to $1C_0$. The length of this pulse is determined by the binary code preset into counters U25 through U28, and is equal to the complement of this code times the (10 MHz) clock period. Pulse lengths ranging from 100 ns to ~6 ms may be selected (see section 4.1.1.2).

This same pulse is applied to U20 and delay line U15, and appears at the output of U29 and input $1C_3$ of U13. However, this pulse is terminated by the delayed pulse through U15. Therefore, the length of the pulse at $1C_3$ equals the delay of U15, which is programmed via U2. This method provides for pulse lengths in the range of 15 to 165 ns (see section 4.1.1.2). The pulse at $1C_3$ appears at output 1Y of U13 when inputs A and B are both high. Output pin 1Y

is connected via A20 and C29 to pin 2 of U3 on the Output Board (see figure 3.13). The function table also shows that steady-state values are produced at 1Y for HL and LH combinations of A and B, respectively. Therefore, dc levels of either V1 or V2, as well as transitions between these levels, can be selected for the step generator output by programming the states of the A and B inputs to U13.

The complete process by which the chip address code and the data words are obtained (for the registers U1-U10) is explained in section 3.2.3.

The board address $(001)_2$, pulse length and repetition period, internal/external clock choice, and other quantities are selected by an 11 digit hexadecimal word string, which may be entered via the keyboard or a computer program. The composition of the timing board word string is described in section 4., DRIVER SOFTWARE.

3.2.6 Output Board

The circuits for selecting the polarity of voltage steps, under program control, are located on the output board and shown in figure 3.13. Also shown are circuits for receiving an external TTL compatible clock signal, and for outputting TTL timing signals.

External clock pulses, input at J4, are applied to U4 using a coaxial cable, and the output of U4 is applied to C30 and routed to A17 of the timing board. The TTL timing signal received from the timing board is wired to have both an undelayed output and an output with 150 ns delay, obtained by using delay line U5. These outputs are available at J6 and J5, respectively.

A TTL level pulse of at least 1.5 ms duration is required from Q1 to set the relays in the step generator output circuit for negative steps. A similar pulse is required at the output of Q2 to set the relays for positive steps. The corresponding logic states for the signal lines leading to Q1 and Q2 are as follows:

	U6 Input (pin no.)				U2				Transistors	
	9	5	3	1	4Q	3Q	2Q	1Q	Q2	Q1
(1)	x	x	L	H	x	x	H	L	L	H
(2)	x	x	H	L	x	x	L	H	H	L
(3)	x	x	L	L	x	x	H	H	L	L

States (1) and (2) must be latched into U2 and held for at least 1.5 ms to operate the relays. The logic levels for the U6 inputs may be changed after the signals are latched into U2. Thus, three different input words are required from the board data bus: $(xx01)_2$, $(xx10)_2$, and $(xx00)_2$.

Operation of these relay driver circuits can be described with an example. Assume that state (3) exists initially and that a negative transition is desired. The procedural steps described in 3.2.3.2 are followed, except that the board address is $(010)_2$ and the board address decoder activates lines 13 (Y_2) of U06-U10 on the IEEE-488 interface board. Also, from the fourth data byte (step 7), the 4-bit data word sent to the input of U6 is $(xx01)_2$. The second DAV signal, applied to U6 via U1, latches the data word into U2 and the Q1 output goes high. The controller now issues

the unaddressing sequence (steps (a)-(e)) of section 3.2.3.2. When the sequence is complete, the controller repeats the above procedure, except that this time the data word applied to U6 is $(xx00)_2$. This sets the output of Q1 to the low state. The time consumed between corresponding points in the two commands is approximately 5 ms, and determines the relay latching pulse length. The procedure is the same for a positive transition, except that the first data word applied to U6 is $(0010)_2$ for activating Q2. Transistors Q3 and Q4 are not used in this application.

3.2.7 Fixed Power Supplies

Several fixed, regulated power supply voltages are required for powering the circuits boards described in the previous sections (see figure 3.9). The + 5 V and - 5 V power supplies (1.5 A each), required for the step generator test head, are mounted on board 15. The ± 15 V supply (one module), required for the test head, is mounted on board 11. Also mounted on the latter board is the ± 15 V supply (one module), required for operating the DACs on board 7. All 15 V supplies have a 200 mA capacity. The + 26 V and - 26 V supplies (300 mA each), mounted on board 19, are required to operate the output amplifiers (U_A , U_B) on board 7. In addition to the board-mounted supplies, a 3 A, 5 V logic supply is mounted on the rear panel of the control unit.

4. DRIVER SOFTWARE

4.1 VSG Driver Program⁶

The VSG driver program is listed in Appendix B. The numeric and string variables and the line labels used in this program are all defined there. Also given are flow charts for each of the user definable keys and for GOSUB 2500, the main routine used to calculate codes needed for the DACs (see figure 3.11).

The VSG driver program facilitates operating the step generator system by the user-definable keys of the computer (controller/processor). (see section 6. OPERATING INSTRUCTIONS). The program generates the necessary board string variables from the pulse parameter values entered on the keyboard. Each string variable identifies the circuit board that controls the parameter (or parameters) being quantified by the keyboard entries, and the data words to be sent to specific registers on the board. In addition to computing data words from the parameter values, the program also flags unacceptable (illegal) parameter values, such as $V_1 = V_2$ or pulse length > pulse period.

4.1.1 Coding to the Storage Registers

The IEEE-488 bus interface board has an adder circuit in the data lines to the registers in the control unit. Allowable ASCII symbols that can be set are 0-9, A, B, C, D, E and F. When letters A-F are sent, bit 5 of the ASCII character enables the adder and adds 9 to bits 1 to 4 (bit 1 = LSB) to obtain a hexadecimal code. This allows use of characters A-F from the keyboard or in a programmable mode. In the explanations of the string variable for each board, the use of 0-9 and A-F refer to ASCII inputs from the computer to the IEEE-488 interface.

Note: to ensure reliable loading of data into storage registers, the internal/external clock is turned off while loading data (see the timing board functions in section 4.1.1.2).

4.1.1.1 DAC/OA Board String Variable DAC \$

Position Code	1 0	2 LSHD	3 +1	4 MSHD	5 LSHD	6 +1	7 MSHD	Each position 4 bits wide
------------------	--------	-----------	---------	-----------	-----------	---------	-----------	------------------------------

Bit location in
each position:

Position Number			
LSB	+1	+2	MSB

⁶ The notation, voltage step generator (VSG), is used interchangeably with numeric variable Vsg (in Appendix B), and step generator (SG).

LSHD = least significant hex digit; + 1 = second hex digit
MSHD = most significant hex digit
LSB = least significant bit; + 1 = second bit; + 2 = third bit
MSB = most significant bit

Position 1: Board address. Set to "0" for DAC/OA board address.

Positions 2-4: Hex code for DAC A. Coding is complementary offset binary and output voltage range of DAC A is +/- 10 volts.

Positions 5-7: Hex code for DAC B. Coding is complementary offset binary and output voltage of DAC B is +/- 10 volts.

Note: See restrictions in section 3.2.4 regarding allowable voltages when positive or negative transitions are used.

4.1.1.2 Timing Board String Variable Time \$

1	2	3	4	5	6	7	8	9	10	11
1	Func	Delay	LSHD	+1	+2	MSHD	LSHD	+1	+2	MSHD

POSITION

FUNCTION

1 Board address
2 Selects timing board functions
3 Program pulse length using delay line
4-7 Sets the voltage-step generator drive frequency
8-11 Sets the pulse length

Position 1: Set to "1", the timing board address
Position 2: Selects timing board functions

Code

"0" Numeric variables C1=0, C2=0; internal clock, VSG drive frequency, and pulse length set by programmable counters.
"1" Numeric variables C1=1, C2=0; external clock, VSG drive frequency, and pulse length set by programmable counters.
"2" Numeric variables C1=2, C2=0; turn internal/external clock off.
"5" Numeric variables C1=1, C2=4; initial level output, the internal/external clock is turned off.
"9" Numeric variables C1=1, C2=8; final level output, the internal/external clock is turned off.
"C" Numeric variables C1=0, C2=12; pulse length set with delay line using internal clock. This must be set before using Key 5.
"D" Numeric variables C1=1, C2=12; pulse length set with delay line using external clock. This must be set before using Key 5.

Position 3: Program pulse length using delay line. This is used after "C" or "D" set in position 2. The coding is in one hex digit, "0" = smallest step size of 15 ns (the initial delay), then in 10 ns steps to 165 ns for "F". Minimum step size that propagates thru the system is about 35 ns, a "2". Note: pulse length must be set to a value greater than one multiplied by (internal or external clock periods).

Positions 4-7: Divide the internal/external clock frequency by an integer from 2 to 65,535 to obtain the VSG drive frequency. Coding for each digit is in hexadecimal.

Positions 8-11: Set the pulse length in clock periods (internal or external) multiplied by an integer from 1 to 65,534. Coding for each digit is in hexadecimal. Note: when setting up the VSG drive frequency, the pulse length must be less than the period of the VSG drive frequency.

4.1.1.3 Output Board String Variable "XX"

Position:
Code

1	2
2	C

Each position
4 bits wide

Position 1: Board address. Set to a "2" for output board address.

Position 2: Transition code (polarity of step change).

Code

"0" Normal and initialization setting.
 "2" Positive transition; should be set to "2" for about 5 ms, then set back to "0".
 "1" Negative transition; should be set to "1" for about 5 ms, then set back to "0".

4.2 Computer/IEEE-488 Interface Code

Decimal 7 is a selection code used by the HP9000 series 200 computer to address the accessory slot in the computer where the IEEE-488(GP1B) interface is installed. This interface select code is not sent out on the IEEE-488 bus. The following two examples illustrate the use of this code.

Example 1: Selected Device Clear

CLEAR 70812 = Selected device clear,

where 08 is the primary listen address set by S1 on the interface board (figure 3.10) and 12 is the secondary address. After the primary and secondary address are set in the address register, the selected device clear command is executed.

Example 2: Output data

OUTPUT 70812; AXX ... XX,

where

A = board address (0, 1 or 2)

XX ... XX = ASCII data to storage registers.

The storage register for the board address is IC U24 on the IEEE-488 interface board.

5. SPECIFICATIONS

The performance specifications of the NBS Step Generator system are given below in Table 1. Static, step, and exponential waveform errors are given in terms of either the 10 V full scale range (FSR) or the 2 V FSR. The polarity selected by the operator corresponds to the transition between V_1 and V_2 , the initial and final values of a step, respectively. Settling times to within $\pm 0.1\%$ of FSR and within $\pm 0.02\%$ of FSR are listed under "Step Limitations". Self-heating effects on the V_2 level are listed under "Duty Cycle Dependence".

Table 1
Typical Performance Specifications

Static Errors	Level V_2	Level V_1	
Offset (software corrected)	0.01	1.0	% FSR
Gain (software corrected)	0.01	1.0	% FSR
Linearity (Max.)	0.008	0.5	
Quantization uncertainty	0.012	0.024	% FSR
Noise (40 MHz BW)	<500	<500	μV p-p
<hr/>			
Step Limitations	± 5 V Range	± 1 V Range	
Transition Duration	7	6	ns
Settling Time			
0.1%	19	15	ns
0.02%	26	22	ns
Equivalent Bandwidth	50	58	MHz
Droop/Flatness/Aberrations			
After Settling	<0.02	<0.02	% FSR
<hr/>			
Exponential Waveform Errors	0.55 μs	27.5 μs	
<hr/>			
Deviation From Ideal Waveform			
Max.	0.05*	0.02**	% FSR
rms	0.01*	0.01**	% FSR

*Not including 1st 10% of waveform. **Not including 1st 5% of waveform.

Duty Cycle Dependence

V_2 Level Change With Duty Cycle (5-95%)		
0=100 ms	<0.02	% FSR
Max. Final Change (30 s)	<0.05	% FSR

Ranges of Other Pulse Parameters:

- . Pulse Repetition Rate - 153 Hz to 3.3 MHz; to 5 MHz with external clock
- . Pulse Length - 20 ns to ~ 6 ms
- . Duty Cycle - approximately 5% to 95%

6. OPERATING INSTRUCTIONS

Drawings of the front and rear panels of the NBS Step Generator control unit are shown in Figs. 6.1 and 6.2. The control unit should first be checked out for correct operation before connecting the umbilical cable of the test head to the front panel. The functions and voltages for connector J7 pins are listed in Table 2. The signals on pins 1-5 are generated under computer control. After correct operation of the control unit has been verified, connect the test head umbilical to connector J7. Connector J2 (± 1 V range) of the test head must be terminated in a $50\ \Omega$ impedance, either a coaxial termination or the input impedance of the instrument under test. Connector J3 which accepts the timing signal, may be connected to either J5 or J6.

The primary address of the control unit has been set to 8. If the address must be changed, the address switch is located on the IEEE-488 Interface Board (#3). To gain access, the front panel must first be removed, and the board pulled from the chassis (see installation instructions sent with instrument). Addresses 1-31 may be set with the address switch. The switch is coded in binary negative true logic, where the MSB is position 1 and the LSB is position 5. The secondary address of the control unit is 12, and is hard-wired into the interface board.

The software for operating the control unit was written in BASIC 3.0 language for use with HP 9000 series 200 computers. The accompanying driver software permits simple selection and entry of all programmable functions. The basic features with user definable key numbers include:

Key 0 Initiation routine. The step generator must be initialized before using the remainder of the driver software. The initialization parameters (for the 10 MHz internal clock) are:

- repetition rate is 50 kHz
- pulse length is $5.0\ \mu\text{s}$ (50 clock periods)
- transition is positive
- initial level is -1 V
- final level is $+1$ V
- internal clock is selected
- programmable frequency and pulse length mode selected
- clock is enabled

- Key 1 Reserved for future use.
- Key 2 Sets the polarity of the transition, and the final and initial voltage levels for the ± 5 V range.
- Key 3 Sets the repetition rate of the output step pulse train with a range of 153 Hz to 5.0 MHz using the internal clock. The software calculates the closest allowed frequency to the one selected, based on the requirement that the clock frequency be an integral multiple of the selected frequency.
- Key 4 Sets the pulse length (duration of the final level) in increments of 100 ns when using the internal clock, otherwise in increments of the external clock period.
- Key 5 Sets the pulse length using a programmable delay line to obtain pulses shorter than those obtainable with key 4. This function will have been previously set with keys 7 or 8. The pulse length is set in 10 ns increments from 20 ns to 160 ns. When using this key, the pulse length set by key 4 must be set to 200 ns or greater.
- Key 6 Sets the pulse length and frequency by an integer procedure. The pulse length is set by entering the desired number of clock periods of the internal or external clock. The period of repetition is similarly set by entering an integer multiplier (2-65,535) of the clock period. Pulse lengths greater than the period of repetition should not be entered.
- Key 7 Displays on the screen the timing board functions and codes needed to obtain these functions. Variables C₁ and C₂ are entered to obtain the functions.
- Key 8 Permits entering C₁ and C₂ without displaying the timing board functions.
- Key 9 Reserved for future use.
- Key 10 Status. Gives the repetition rate, pulse length, transition polarity, voltage levels, and clock selected (internal or external).
- Key 11 Change the transition. The initial and final voltage levels are interchanged.
- Key 12 Enables/disables clock.
- Key 13 Change the final voltage level.
- Key 14 Change the initial voltage level.
- Keys 15-20 Reserved for future use.

Fig. 6.1 Front panel connectors. Connector J4 permits external synchronization of the TTL timing signals output by J5 and J6. The signal from J5 is delayed 150 ns relative to that from J6. The umbilical cable to the step generator output circuit is connected to J7. DS1 is an LED for power ON/OFF indication.

Fig. 6.2 Rear panel connectors and power switch (SI). J9 is the power line connector (120 V) with an integral 3A fuse. The IEEE-488 bus to the controller is connected to J8.

Table 2

Functions and Voltages for Connector J7 Pins
 Values Given for V_A and V_B are Outside Limits
 (See Note at Bottom of Table)

<u>Pin No.</u>	<u>Function/Voltage</u>
1 & 2	V_A/\pm 11 V
3	V_B/\pm 20 V
4	Neg. Pol. Relay Drive/TTL. Pulses approx. 5 ms wide
5	Pos. Pol. Relay Drive/TTL. Pulses approx. 5 ms wide.
6 & 7	N. C.
8 & 9	Supply/ + 5 V \pm 0.2 V
10	Supply/ - 5 V \pm 0.2 V
11 & 12	N. C.
13 & 14	V_A Return/0 V
15	V_B Return/0 V
16	Relay Returns/0 V
17	Supply/ + 15 V \pm 0.3 V
18	Supply/ - 15 V \pm 0.3 V
19	\pm 15 V Return/0 V
20 & 21	+ 5 V Return/0 V
22	- 5 V Return/0 V
23 & 24	N. C.

Note: Under program control, $V_A = 2 * V_2$ and
 $V_B = \text{sign}(V_2 - V_1) * (|V_2 - V_1| + 8.3)$, where
 * indicates multiplication, the sign function is
 -1 if $V_2 > V_1$, and is + 1 if
 $V_2 < V_1$. $V_2 = V_1$ is a disallowed condition.

7. TESTING

7.1 Static Testing

The static errors of the NBS Step Generator system have been measured over the full range at the step generator's output terminals using a precision DVM. Offset and gain errors are corrected in the system software using data from periodic calibration. The measured maximum independently based linearity error at the V_2 level is 0.008 percent of full-scale range. Figure 7.1 is a typical linearity error plot of V_2 .

The noise at the generator's output has also been measured at the ± 5 V output terminal, with the peak-to-peak value found to be less than 500 μ V in a 40 MHz bandwidth.

A complete list of the static errors for both of the V_2 and V_1 levels of voltage steps is given in Table 1 of section 5. SPECIFICATIONS. Also shown in that table is the quantization uncertainty. This uncertainty is caused by the lack of resolution in the programmable power supplies (V_A , V_B), from which V_2 and V_1 are derived.

If the device under test (DUT) has a 50 Ω input impedance, connector J2 (± 1 V range) should be connected to the DUT input without using a coaxial termination (see section 3.1). Voltage uncertainty, caused by DUT input impedance uncertainty, can be removed by static measurements of V_2 and V_1 . Static measurements can be made at the DUT input with a DVM by placing a BNC T-connector between J2 and the DUT input.

7.2 Measurement of Voltage Step Characteristics

A sampling voltage tracker (SVT), peak detector circuits, and a sampling oscilloscope were used to characterize the output waveforms of the step generator. The SVT and peak detector were used for settling time (ST) measurements, and the SVT and sampling oscilloscope were used for transition duration measurements. The sampling voltage tracker has been used previously for similar measurements [2], [8], [11], [12], and [13].

The basic SVT consists of a high-speed sampling comparator and a voltage integrator in a feedback loop, and can be represented by figure 7.2. The strobe pulses, 5 to 10 ns wide, cause the input waveform $f(t)$ to be sampled (compared with the output voltage V_D of the integrator) at instants in time coinciding with the trailing edges of these pulses. Assume that the period of $f(t)$ is T and that the value $f(t_1)$ is to be measured. Then, the strobe pulses must be timed to sample $f(t)$ at times t_1 , $t_1 + T$, $t_1 + 2T \dots$. The result of these comparisons is to drive V_D positive or negative until it nearly equals the value of $f(t)$ at the instants of comparison. If some other value of $f(t)$, say $f(t_2)$, is to be measured, $f(t)$ must be sampled at times t_2 , $t_2 + T$, $t_2 + 2T, \dots$, etc.

The SVT was employed in the automatic measuring system shown in figure 7.3 with the delay generator programmed to have delay steps (increments) of 0.5 ns. The maximum allowable voltage range for the comparator in the SVT is

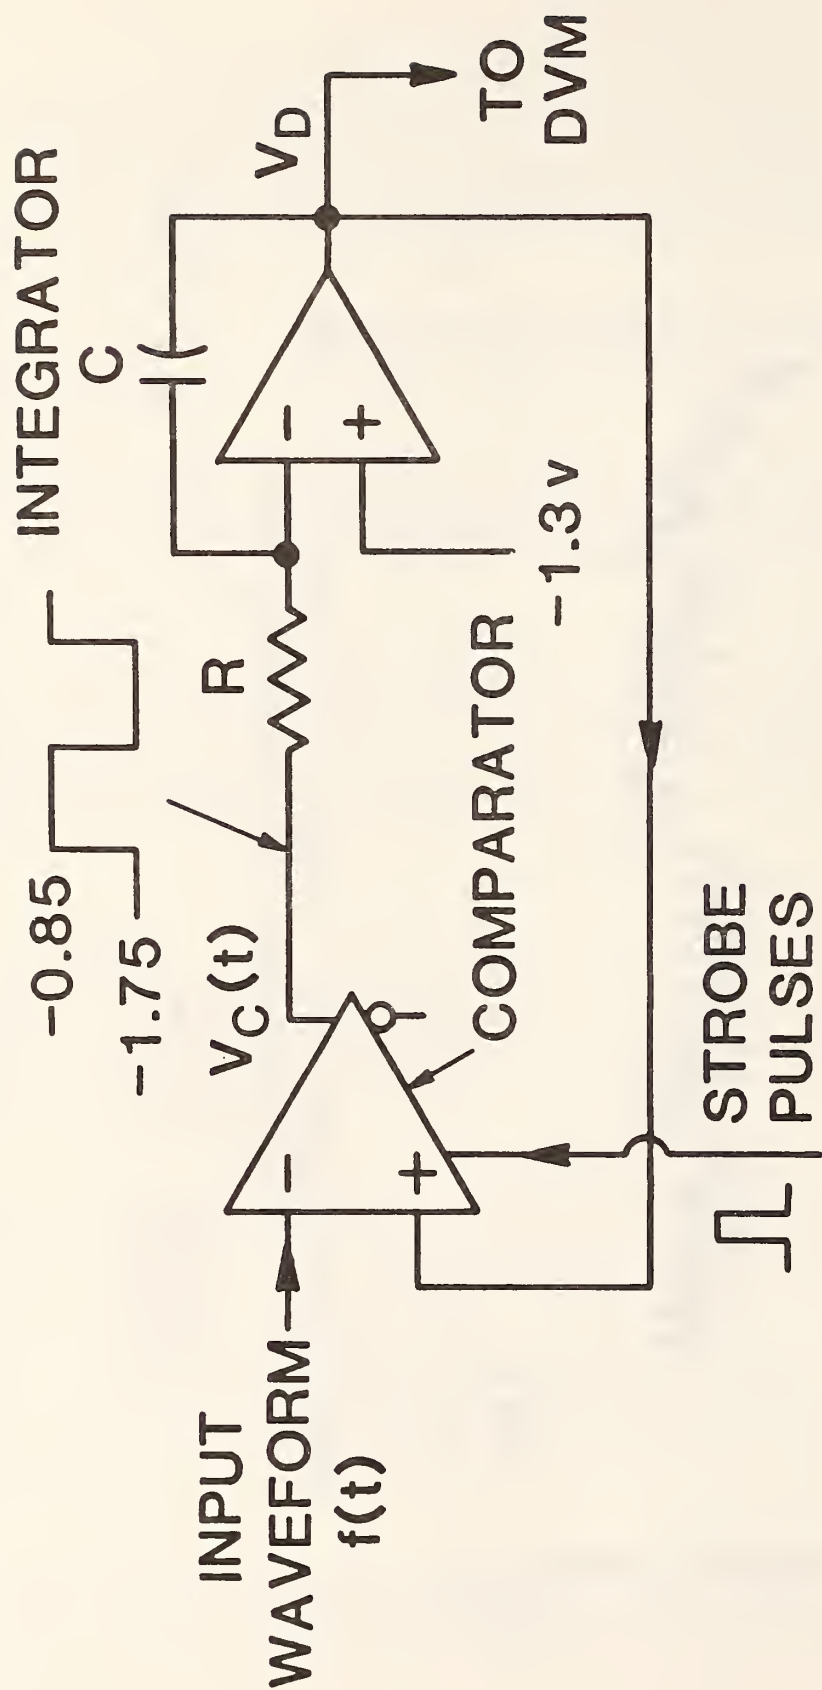

Fig. 7.2 Basic sampling voltage tracker (SVT). Input waveform $f(t)$ is sampled (compared with voltage V_D) at instants in time coinciding with the trailing edge of strobe pulses.

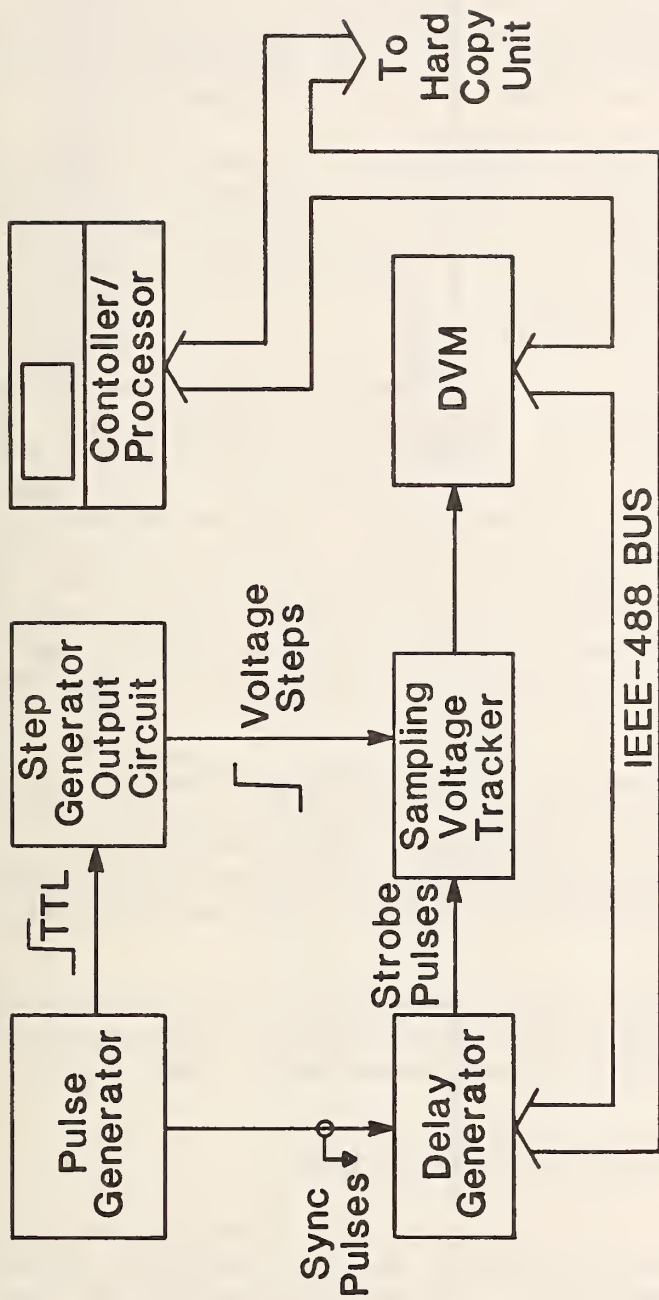

Fig. 7.3 Automatic voltage tracker system used to measure transition characteristics of voltage steps from the step generator.

± 3 V. The TTL pulses applied to the output circuit are delayed 150 ns to approximately match the minimum delay of the delay generator. Figure 7.4 is a plot of a -3 to +3 V transition of the step generator, when loaded with 30 pF capacitance, a typical input capacitance for waveform recorders. Based on tabulated DVM readings, the transition duration (10-90 percent rise time) was 11 ns and the STs to within ± 0.1 and ± 0.02 percent of FSR were 35 and 39 ns, respectively. When the load capacitance was decreased to 6 pF, the input capacitance of the measuring system, the corresponding STs decreased to 19 and 26 ns. The transition duration decreased to 7 ns. ST measurements, using a peak detector, agreed with the above values to within ± 10 percent.

The peak detector used for negative transitions is shown in figure 7.5. Battery and diode polarities are reversed for positive transitions. The voltage step (applied to the female BNC connector) is adjusted so that the diode conducts during approximately the last 1 percent of the voltage transition. This permits the latter part of a transition to be examined, using a sensitive range of the oscilloscope.

The Schottky diode shown in figure 7.5 has minimum forward conductances of 1 mA and 75 mA at forward voltages of 400 mV and 1 V, respectively. Its shunt capacitance is less than 1 pF. The sensitivity of the detector is calibrated by observing the change in oscilloscope deflection of the upper trace of figure 7.6 caused by a known change in V_A . Since the detector is calibrated using a change in dc voltage, it can also be used to measure very slowly charging voltages such as thermal drift (see section 7.4). The self-heating change of the diode with 0 to 100% duty cycle change causes a computed change in the detector output of 0.05 mV. With a 2 mV/cm scope deflection sensitivity, this corresponds to 0.02 cm deflection change, which is negligible.

Figure 7.6 shows a ST measurement of a 2 V transition from connector L, using a peak detector with negligible input capacitance (~ 3 pF) and a calibrated sensitivity of 0.25 percent of FSR/cm. The sweep speed was 10 ns/cm. Since the minimum battery voltage is 1.4 V and the diode forward drop is ~ 0.3 V, the ST of the 2V output was obtained using approximately a 0.3 to +1.7 V transition.

Deviations from flatness (droop, aberrations, etc.) can be measured to within approximately $\pm 0.01\%$ of FSR, using a peak detector. This quantity, along with other voltage step limitations are summarized in Table 1 of section 5. SPECIFICATIONS.

7.3 Exponential Waveform Errors

Exponential waveforms having transition durations (risetimes) of 0.55 μ s and 27.5 μ s are available for dynamic linearity testing of waveform recorders, using external capacitors. The deviation of these waveforms from the true exponential response has been determined using the sampling voltage tracker to measure the waveforms, and then fitting the data to an ideal model of the form $Y = A_0 - A_1 e^{-BT}$ using a nonlinear least-squares curve fitting routine. The maximum values of the residuals of the curve fitting are given in Table 1 of section 5.

Fig. 7.4 Plot generated by the system shown in figure 7.3 of a -3 to $+3$ V transition of the step generator, when loaded with 30 pF capacitance.

Fig. 7.5 Peak detector using small H_g hearing aid batteries, ~ 1.4 V each. Reverse bias on the diode is determined by the number of batteries employed. Shunt capacitance of the diode is less than 1 pF. The terminating resistance is typically less than $180\ \Omega$.

Fig. 7.6 Upper trace shows peak detector response to a +2 V transition of V_L (lower trace). Sweep speed is 10 ns/cm and detector sensitivity is 0.25 percent of 2 V FSR/cm. The initial narrow pulse in detector output is caused by shunt capacitance of the detector diode (see Fig. 7.5). The waveform following this pulse accurately represents the transition of V_L .

The software used to compute these residuals employs an algorithm based on a Gauss-Newton approach [14].

A few practical difficulties are encountered in using the capacitor modules. With the 0.55 μ s unit, ringing was significant for approximately the first 50 ns of the transition. With the 27.5 μ s unit, some slumping of V_A was encountered during a transition. This effect was minimized by using additional filter capacitance in the output circuit of the step generator (see section 3.1).

7.4 Duty Cycle Dependence

In many high speed circuits, transient thermal imbalances often arise, causing effects such as droop, or "thermal tails", and duty cycle dependence. These effects have been measured for the step generator, using peak detector circuits to discriminate very small changes in the step level following switching. For these measurements, pulse repetition rates ranging from 1 kHz to less than 10 Hz were employed. Changes of less than 0.02 percent in the first 100 ms were noted in the final level when changing the duty cycle between five and ninety five percent, for 10 V steps. The changes increased to a maximum of less than 0.05 percent, after about 30s. For the latter measurement, a single shot step and a scope with a free-running sweep were used (see section 7.2 for detector characteristics).

8. CONCLUSIONS

A precision programmable step generator system, designed for use in automated test systems, has been described. The step generator is intended for testing waveform recorders and digitizing oscilloscopes with resolutions of 8 to 10 bits and bandwidths up to 50 MHz. Fast, accurate settling, together with the programmability of step levels, duty cycles, and repetition rates provides the means for testing the dynamic and thermal characteristics of waveform recorders and digitizing scopes. These characteristics include step response, impulse response, and frequency response; transient characteristics, including dynamic linearity, settling time, transition duration, and transient thermal errors, can also be tested. All voltage levels in the system are also programmable. These levels can be used for static measurements to determine the offset, gain, linearity, and noise of the waveform recorder or digitizing scope under test.

9. ACKNOWLEDGEMENTS

The authors are grateful to P. S. Hetrick for AVT software and calibration assistance, to M. E. Parker for packaging and technician help, and to R. H. Palm for preparation of SG drawings and technician help. They would also like to thank Ms. Y. Dube, Mrs. M. E. Sullivan, and Mrs. B. Meiselman for their help in preparing this report.

Test methods for characterizing the transient response of waveform recorders are presented, together with typical test results. The methods, based on the use of a precision, programmable step generator developed at NBS, are suitable for recorders having up to 10 bits of resolution and 100 MHz bandwidth.

Introduction

Waveform recorders are subject to a number of types of errors which can limit their ability to accurately characterize transient signals [1, 2, 3, 4]. Principle among these are dynamic linearity errors, impulse response and settling time limitations, transient thermal errors, and time base jitter. An automated measurement system based on a precision programmable step generator has been developed for characterizing such errors in waveform recorders having up to 10-bits of resolution, and bandwidths on the order of 100 MHz.

The test system is designed to output programmable voltage pulses, with one well-defined transition per period, the beginning and terminating levels of which are designated V_1 and V_2 . (The transition from V_2 to V_1 is less well characterized, and is not relied upon for most measurements.) Either single shot or repetitive pulses can be generated, with the repetition rate and duty cycle program-mable over many orders of magnitude. The initial and final levels defining the steps are each programmable within the range of ± 1 V for a $50\ \Omega$ termination and within ± 5 V for a high impedance load. Voltage steps within these ranges settle smoothly, with no overshoot, to within 0.1% of full scale range in less than 15 and 19 ns, respectively, for small load capacitance. The corresponding 10-90 percent transition durations are approximately 6 ns and 7 ns. The voltage step waveform has been characterized by independent means, and has been shown to approximate a simple exponential response. At high values of output capacitance, the more slowly rising waveform becomes sufficiently close to an ideal exponential that it can be used for dynamic measurements of linearity errors.

System Description

A block diagram of the complete test system is given in figure 1. Overall control is provided via the IEEE 488 bus, for which an internal listener interface has been provided. The waveform recorder under test is also interfaced to the controller via this bus. To minimize load capacitance, the output circuit of the step generator has been designed as a small hand-sized package which connects directly to the input terminals in the same fashion as many sampling heads for sampling oscilloscopes. The generator's power and control signals are provided by a separate support package via a flexible umbilical cable.

A functional diagram of the output circuit of the step generator is shown in figure 2. A more detailed

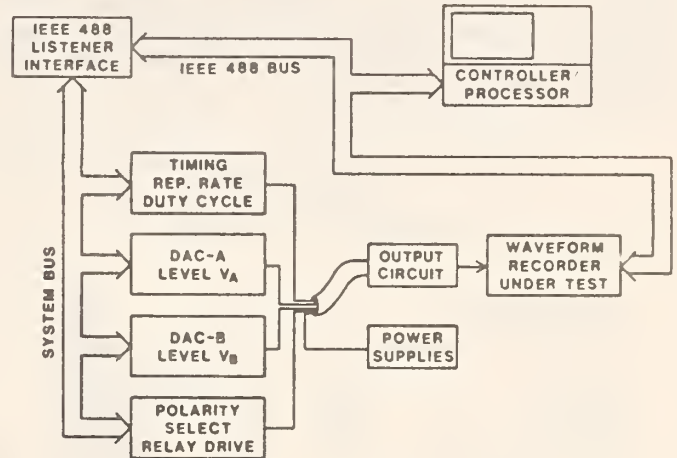

Fig. 1. Block diagram of test system.

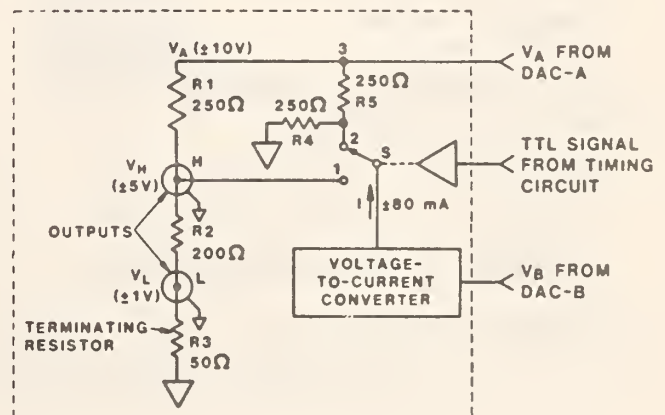

Fig. 2. Simplified diagram of step generator output circuit.

description can be found in reference [5]. Two output ranges are provided: a ± 5 V range from output H, intended for high impedance loads, and a ± 1 V range from output L for $50\ \Omega$ loads. When output L is used, the $50\ \Omega$ terminating resistor shown in the figure is actually the input impedance of the test device; otherwise, a $50\ \Omega$ coaxial termination is used. The precision step is generated by switching the current source from position 1 to 2. After switching, all active elements are isolated from terminal 1. Consequently, the transition is essentially an exponential waveform determined by the $125\ \Omega$ output resistance and the total capacitance between terminal H and ground.

As was previously mentioned, highly accurate exponential waveforms are produced by the generator at higher levels of output capacitance. These waveforms are readily obtained by shunting output terminal H

with high quality capacitors contained in small in-line enclosures which can be connected directly to the output terminal H.

Dynamic Linearity Testing

Exponential waveforms having transition durations of 0.55 μ s or longer are available for dynamic linearity testing using external capacitors. The deviation of these waveforms from the true exponential response has been determined using a sampling voltage tracker [6] to measure the waveforms, and then fitting an ideal model of the form $Y = A_1 - A_2 e^{Bt}$ to the data using a nonlinear least-squares curve fitting routine. The errors in these waveforms, as indicated by the residuals of the curve fitting process, are less than 0.05% as shown in Table 1.

TABLE 1

Performance Specifications

Static Errors	V ₂	V ₁	
Offset	0.01	1.0	% FSR
Gain	0.01	1.0	% FSR
Linearity (Max)	0.02	0.5	% FSR
Noise (40 MHz BW)	<500	<500	μ V p-p
<hr/>			
Step Limitations	± 5 V	± 1 V	
Transition Duration	7	6	ns
Settling Time			
0.1%	19	15	ns
0.02%	26	22	ns
Equivalent Bandwidth	50	58	MHz
Droop/Abberations			
After Settling	<0.02	<0.02	% FRS
<hr/>			
Exponential Waveforms	0.55 μ s	27.5 μ s	
Deviation From Ideal Waveform (Max)	0.05	0.01	% FSR
rms	0.01	0.006	% FSR

Duty Cycle Dependence

V₂ Level Change With Duty Cycle (5%-95%)

0-100 ms	<0.02	% FSR
Max. Final Change (30 s)	<0.05	% FSR

Dynamic linearity measurements are made in the same way by digitizing the exponential waveforms with the recorder under test. Once the waveform has been recorded, the linearity errors are computed from the residuals of the curvefit.

Results of two dynamic linearity tests, one performed on a 10-bit, 60 MHz (sampling rate) recorder and the other on an 8-bit, 200 MHz unit, are presented in figures 3 and 4. The first shows the linearity errors (residuals) of the recorder tested with a waveform having a 27.5 μ s transition duration. The maximum and rms errors are 1.5 and 0.42 least significant bits (LSB), respectively. Figure 4 shows the errors with an exponential input having a 0.55 μ s transition

duration. For this instrument, the maximum and rms errors are 1.3 and 0.46 LSB. In both cases, the ideal maximum and rms error limits are 0.5 and 0.29 LSB, respectively.

Dynamic linearity measurements of this type include errors resulting from ideal quantization uncertainty and time base jitter, as well as differential and integral linearity errors.

Fig. 3. Dynamic linearity errors of 10-bit, 60 MHz recorder with exponential input signal having 27.5 μ s transition duration.

Fig. 4. Dynamic linearity errors of 8-bit, 200 MHz recorder with exponential input signal having 0.55 μ s transition duration.

Step Response Measurements

Measurements of step, impulse, and frequency response, as well as transition duration and settling time can, in principle, all be made directly using the step generator, simply by recording the response to a step, and calculating the desired parameters from the recorded data. In practice, however, two points must be taken into consideration. First, the sampling rate of the test recorder limits the effective bandwidth of the measurement. Because of aliasing errors which result when using a wideband input step, this limitation makes it impossible to characterize the

Fig. 5. Step response of 10-bit, 60 MHz recorder, measured using equivalent time method (0.98 ns / sample).

frequency response with reasonable accuracy. The second point is that the input step itself has finite equivalent bandwidth (see Table 1), and for very fast recorders, its frequency response may not be flat enough to ignore.

The sampling rate limitation can often be overcome by extracting equivalent time sampling data from a single record, provided that the repetition rate of the input step is selected appropriately, as follows. Set the ratio of the sample rate, f_s , to the step repetition rate f_r , so that $(N-1) < (f_s/f_r) < N$, where N is some integer, thus not allowing f_s and f_r to be phaselocked.

With the step generator, this is accomplished using an external, programmable frequency synthesized source. If, under these conditions, every N th sample is taken from the record of length M , then the resulting M/N data points will represent equivalent time samples of the original waveform. The exact repetition rate needed to obtain one complete period sampled in equivalent time can be calculated, given a choice of N , from

$$f_r = (f_s / N) (N/M + 1).$$

Note that N/M is the reciprocal of the number of samples that will be in the final record, so that this ratio determines the number of equivalent time samples in one period of the input step. It can be seen from this relationship that the measurement bandwidth is directly proportional to the record length. The interval between the equivalent time samples is given by

$$\Delta t = N(1/f_s - 1/Nf_r).$$

Problems imposed by the limited bandwidth of the step generator can be overcome to some extent, by mathematically deconvolving its response from the recorded response of the waveform recorder under test [7]. The ability to accurately measure the input step using independent, equivalent time techniques makes it possible to at least double the effective bandwidth of measurements made with the step generator. In a future paper, the application and results of deconvolution techniques will be presented.

Some typical test results are given in figures 5-8 for a 10-bit, 60 MHz recorder. These plots give, in order, recorded step response, impulse response, frequency response (showing the computed 3 dB point at

Fig. 6. Impulse response calculated from step response data of figure 5.

Fig. 7. Frequency response calculated from impulse response data of figure 6. The bandwidth (3 dB point) thus measured is 17 MHz vs. 15 MHz claimed by the manufacturer.

17 MHz), and settling with apparent undershoot of approximately 8 LSBs. Equivalent time sampling was used for all measurements except settling time, with an equivalent sampling interval of 0.98 ns.

To illustrate the utility of such data in predicting the response of a particular waveform recorder when digitizing real-world signals, figure 9 presents an example in which a double exponential waveform is considered. The figure shows an ideal waveform (0.125/10 μ s rise/fall time) together with the response error predicted by convolving it with the measured impulse response. Distortion, causing error in the peak value on the order of 7 LSBs, is plotted in figure 9-b. To arrive at an overall estimate of the errors which would likely occur when digitizing such a candidate waveform, the dynamic linearity errors, as presented in figure 3, should also be included.

Testing of Transient Thermal Response

It is common practice to calibrate waveform recorders using static measurement methods. These data are used, if deemed necessary, to correct the actual data obtained when transient waveforms are recorded. In fact, such a process is used in the self calibration

Fig. 8. Expanded view of step response of 10-bit, 60 MHz recorder, showing 8 LSB undershoot and settling time of approximately 6 μ s to 1 LSB.

Fig. 9. Ideal double exponential input waveform with 0.125/10 μ s rise/fall time (a), and predicted response error (b).

Fig. 10. Transient thermal response of 10-bit, 20 MHz recorder.

routines of several commercial recorders. Unfortunately, even for very slow events, the waveform recorder will likely respond differently to transient signal levels than to dc levels, primarily because of internal transient thermal imbalances which can have rather long time constants. Because these effects are related to signal power, they are nonlinear and thus cannot be represented simply by a transfer function. The magnitude of these effects are easily measured with the step generator however, by first recording one half cycle of a low frequency square wave, and then subtracting from it the record of a dc signal having the same value as the recorded level of the square wave. If transient thermal errors are present, they will appear in the resulting difference between the two records. Figure 10 shows the results of such a test in which a 500 Hz square wave of nearly full scale amplitude has been used. The recording of the upper level of the square wave has been subtracted from a recording of the equivalent dc level. Note the initial overshoot of about 30 μ s duration, followed by the long, slowly decaying tail. The peak errors are 12 LSBs.

Conclusions

The step response test system that has been described is capable of accurately measuring many error parameters that are important in assessing the overall transient response of waveform recorders. Fast, accurate settling, together with the programmability of step levels, duty cycles, and repetition rates provides the means needed to measure and separate both linear and nonlinear effects, and to provide information relevant to both the time and frequency domains.

Additional work under way in this area includes the development of a faster generator test head, with a goal of a 2 ns transition duration and settling to 0.1% in 8 ns. This capability would permit the measurement of 10-bit recorders having bandwidths as high as 350 MHz.

APPENDIX B

Appendix B contains the documentation for the VSG driver program. This program is written in the Hewlett-Packard BASIC 3.0 language. Pages 60 through 68 contain the program listing. A brief description of each numeric variable is given in pages 69 to 71, and a brief description of each string variable is given on pages 71 and 72. The line labels used in the program are listed on pages 72 through 74, with a short description of the function performed when that section of the program is executed. If a line label is executed when a softkey is pressed, this is indicated by the key number in brackets below the line label. Pages 75 through 87 contain flow charts for each of the defined softkeys and for GOSUB 2500, the main routine used to calculate digital code for the DACs on the DAC/OA board.

NUMERIC VARIABLES

C1	Control character for entering timing card functions. Contains the two least significant bits.
C2	Control character for entering timing card functions. Contains the two most significant bits.
C3=C1+C2	Hex control character for entering timing card functions.
Ck1ctrl	Decimal value of the second character of Time\$, contains the clock on/clock off control bit.
Ck2ctrl	Clock control bit in Ck1ctrl is complemented, new decimal value.
Ctrl	Selects computation for DAC A or DAC B; 1= DAC A; 2= DAC B.
D	In Status routine: Length of pulse when set by delay line $= (D+1) \times 10$ nanoseconds. D is the decimal value of the hex character programmed into position 3 of Time\$ to set the pulse length.
Delay_line	Length of pulse when using programmable delay line, entered by operator, range 1-16, corresponds to a range of 10-160 nanoseconds.
Exchange1	Used, with Exchange2, to interchange the initial and final voltage levels in the change transition routine.
Exchange2	Used, with Exchange1, to interchange the initial and final voltage levels in the change transition routine.
Final_v1	The value of the final voltage (Level V2 in instructions). In Trvls:, it is an entry variable.
Flag	Used in the Ch_f_v1: (Change final voltage level only) and Ch_i_v1: (Change initial voltage level only) routines Flag= 0 calculate new voltage level, Flag=1 illegal voltage level entry, reenter a new voltage level.
Freq_int	A positive integer greater than one. The internal/external clock frequency is divided by Freq_int to obtain the Vsg drive frequency. This is positions 4-7 of Time\$.
Freq_int2	$= 65536 - \text{Freq_int}$. Put in format for loading registers in support unit.
Init_v1	The value of the initial voltage level (Level V1 in the instructions). In Trvls:, it is an entry variable.
Lsb_s	This is the value in least significant bits of the variable Vdac+10. The entry variable Vdac in routine Code: is converted to a positive offset voltage by adding 10 to it, then digitizing it to the nearest 12 bit LSB. Lsb_s is

then converted to the complementary offset code that is sent to the DAC registers.

New_fvl	Used in Ch_f_vl: to enter a new final voltage level. If New_fvl is a valid voltage, then Final_vl is the new final voltage level.
New_ivl	Used in Ch_i_vl: to enter a new initial voltage level. If New_ivl is a valid voltage level, then Init_vl is the new initial voltage level.
Plength	Used in Pulse_length: to enter a new value of pulse length in nanoseconds. Entered in increments of 100 nanoseconds.
Pos	Decimal value of Ck\$, the hex digit in position 2 of Time\$. Bit 2 of Ck\$ contains the clock control bit.
Pos1	Decimal value of Pos with the clock control bit complemented to turn the clock on if off, or off if on.
Pulse_int	A positive integer less than Freq_int. The pulse length (duration of final voltage level) is equal to clock period*Pulse_int. This is in positions 8-11 of Time\$. Note: Pulse_int entered from keyboard has one subtracted from it, therefore Pulse_int used in program will be one less than the keyboard entry.
Pulse_int2	=65536-Pulse_int. Put in a format to load registers in the support unit.
Raw_lsbs	Undigitized value of Lsb_s. Not used in this program.
Tr	Sets the transition. Tr=1 is positive transition (initial level to final level), Tr=2 is negative transition (final level to initial level).
Vdac	Voltage used for DAC A and B code calculations.
Vdac3	=Vdac+10. Forces voltage to be a positive number from 0 to 20 to facilitate conversion to LSB's and code calculations.
Vsg	IEEE-488 identification of the the voltage-step generator support unit. Initially set to 70812 in line 110.
Vsgfreq1	User entered Vsg drive frequency in Vsgfreq: routine. Converted to Freq_int by the relationship $\text{Freq_int} = \text{INT}(10,000,000/(\text{Vsgfreq}) + 0.4999999)$ based on the internal 10 MHz clock.
Xdacb	The output voltage, when multiplied by -0.5, needed from DAC B to produce the programmed output levels.
Xdacb1	=-0.5*Xdacb. Save if needed for later use.
Ydaca	The output voltage, when multiplied by -1, needed from DAC A to produce the programmed output levels.

Ydacal $=(-1)*Ydaca$. Save if needed for later use.

STRING VARIABLES

Bindac_a\$ Set equal to X\$, this is the code sent to the registers for DAC A.

Bindac_b\$ Set equal to X\$, this is the code sent to the registers for DAC B.

Ck\$ Hex character in position 2 of Time\$. Contains the clock control bit in position 2.

Ck1\$ Hex character in position 2 of Time\$. Used in Ckon_off: routine. Contains the clock control bit in position 2.

Ck2\$ String of Ck1ctrl in binary. Bit 15 contains the clock control bit.

Ck3\$ ="1"&Ck2[4]. Used to turn the clock off in line 1580. Saved for future use.

Ck_on\$ Saved to turn the clock back-on, after use of Ck3\$ to turn clock off.

Clear_crt\$ =CHR\$(255)&CHR\$(75). Use, with OUTPUT 2 statement, to clear CRT screen.

Dac\$ Contains the DAC coding to the support unit storage registers. Format is "0AAABBB".
"0"=Board Address.
"AAA"=coding DAC A
"BBB"=coding DAC B

F\$ Hex code for dividing the clock frequency by Freq_int. Used in Vsgfreq: routine. This is a four digit code inserted into Time\$ in positions 4-7.

Hex1\$ Hex string obtained from Lsb_s. The first three digits contain the coding for the 12 bit DAC's.

P\$ Hex code for dividing the clock frequency by Pulse_int. Equivalent to multiplying the clock frequency by Pulse_int to find the pulse length. This is a four digit code inserted into positions 8-11 of Time\$.

Time\$ Contains the coding to the timing card storage registers. Format="1GLFFFFPPP"
"1"=Board Address
"G"=Function Select Code
"L"=Programmable delay line coding
"FFFF"=Divide the clock frequency by a four digit hex number to set the Vsg drive frequency.
"PPPP"=Divide the clock frequency by a four digit hex

number to set the duration of the final voltage level.
(Pulse Length).

Tr\$ ="POSITIVENEGATIVE". Substring of used in Status: routine
to indicate positive or negative transition.

V\$ Set equal to X\$ in lines 3157 and 3210. Intermediate
storage of the coding to DAC's A and B.

X\$ =Hex1\$[2]. After reversal of digits, contains the hex code
sent to the storage registers for DAC's A and B.

Xx\$ Digit two of Time\$ when used in Card: routine.

Xx1\$ Programmable delay line code of one hex digit inserted
into position three of Time\$.

LINE LABELS

Bindaca: Assemble the code for DAC A into Dac\$. Ctrl=1 is used to
access this routine.
Return at line 3230.

Bindacb: Assemble the code for DAC B into Dac\$. Ctrl=2 is used to
access this routine.
Return at 3180.

C1c2:
[Key 81] Enter C1 and C2 without displaying the timing card menu.
Entry variables are C1 and C2, routine can be entered at line 675
if these are set.
Return at line 700

Card:
[Key 71] Display the functions available on the timing card. Variables
C1 and C2 are entered to implement these functions. Can be
entered at line 675 if C1 and C2 are set [no display].
Return at line 700.

Ch1_f_vl: Check positive transition, final voltage level, error
statement. Lies within Ch_f_vl: routine.

Ch1_i_vl: Check positive transition, initial voltage level, error
statement. Lies within Ch_i_vl: routine.

Ch2_f_vl: Check negative transition, final voltage level,error
statement. Lies within Ch_f_vl routine.

Ch2_i_vl: Check negative transition, initial voltage level, error
statement. Lies within Ch_i_vl routine.

Ch_f_vl:
[Key 131] Change the final voltage level without changing transition
or initial voltage level. Entry variable is New_fvl, when
determined to be valid, Final_vl is set equal to New_fvl.
Can be entered at line 7030 if New_fvl is set.
Return at 7070.

Ch_i_vl: Change the initial voltage level without changing the transition or the final voltage level. Entry variable is New_ivl, when determined to be valid, Init_vl is set equal to New_ivl. Can be entered at line 7530 if New_ivl is set. Return at 7070.

[Key 14]

Changetr: Transition is changed, initial and final voltage levels are interchanged, and the new transition and voltage levels are output. Return at 8120.

[Key 11]

Ck_off: Before entering any new data to the storage registers, the clock is turned off to ensure reliable loading of the storage registers. The clock off routine turns the clock off without changing any other settings. The string Ck_on\$ is used for turning the clock back on. Return at 1600.

Ckon_off: Cycle the clock on/off or off/on. The clock control bit in Time\$ is also changed to reflect the clock on/off status. Return at 770.

[KEY 12]

code: Calculations to obtain the complementary offset binary code code to load the DAC registers using Dac\$. Return at 3140.

Dac_va: DAC A calculations for the voltage necessary to output the programmed initial and final voltage levels. Return at 3140.

Dac_vb: DAC B calculations for the voltage necessary to out put the programmed initial and final voltage levels. Return at line 2870.

Dacv_s: Compute and output the voltages and binary codes for DAC's A and B to obtain the programmed initial and final voltage levels using Dac\$. Return at line 2640.

Delayline: Set the pulse length with the programmable delay line. Entry variable is Delay_line. Can be entered at line 6030 if Delay_line is set. Return at line 6070.

[Key 5]

Final_vlrg: Check the value of Final_vl to determine if a valid voltage. Lies within Trvls: routine.

Init: Set up the Voltage-step generator parameters. After executing a RUN statement, Init: must be executed. Parameters set include Tr, Dac\$, Time\$, Bindac_a\$, Bindac_b\$, Init_vl, Final_vl, Freq Int, Pulse_int and Vsg. Return at line 250.

[Key 0]

Init_vlrg: Check the value of Init_vl to determine if a valid voltage. Lies within Trvls: routine.

Integer: Enter the pulse length and Vsg drive frequency using positive integers. Freq_int and Pulse_int are the entry variables. One is subtracted from Pulse_int entry so new Pulse_int is one less then the value entered. Can be entered at line 5540 if Freq_int and Pulse_int are set. Return at line 5610.

[Key 6]

Loop: After RUN is executed, program remains at line 90 using a GOTO Loop statement. After a key is pressed, when execution of the subroutine associated with that key is completed, the program returns to Loop:.

Neg_tr: Sets the negative transition. Return at line 530.

Pos_tr: Sets the positive transition. Return at line 510.

Pulse_length: Set the pulse length based on the 10 MHz internal clock. [Key 4] Pulse length is entered in units of 100 nanoseconds. Return at line 5250.

Pulse_q3: Not used. Produces a pulse at transistor Q3 output. Return at line 550.

Pulse_q4: Not used. Produces a pulse at transistor Q4 output. Return at 570.

Start: Line 2. Not used, going to Start: equivalent to a RUN statement. Program remains in a loop at Loop:.

Status: Prints on CRT the current Voltage-step generator parameters. [Key 10] Return at line 6880.

Trvls: Set a new transition, new final voltage level, and a [Key 2] new initial voltage level. Entry variables are Tr, Final_vl and Init_vl. Can be entered at line 2060 if these three variables are already set. Return at line 2640.

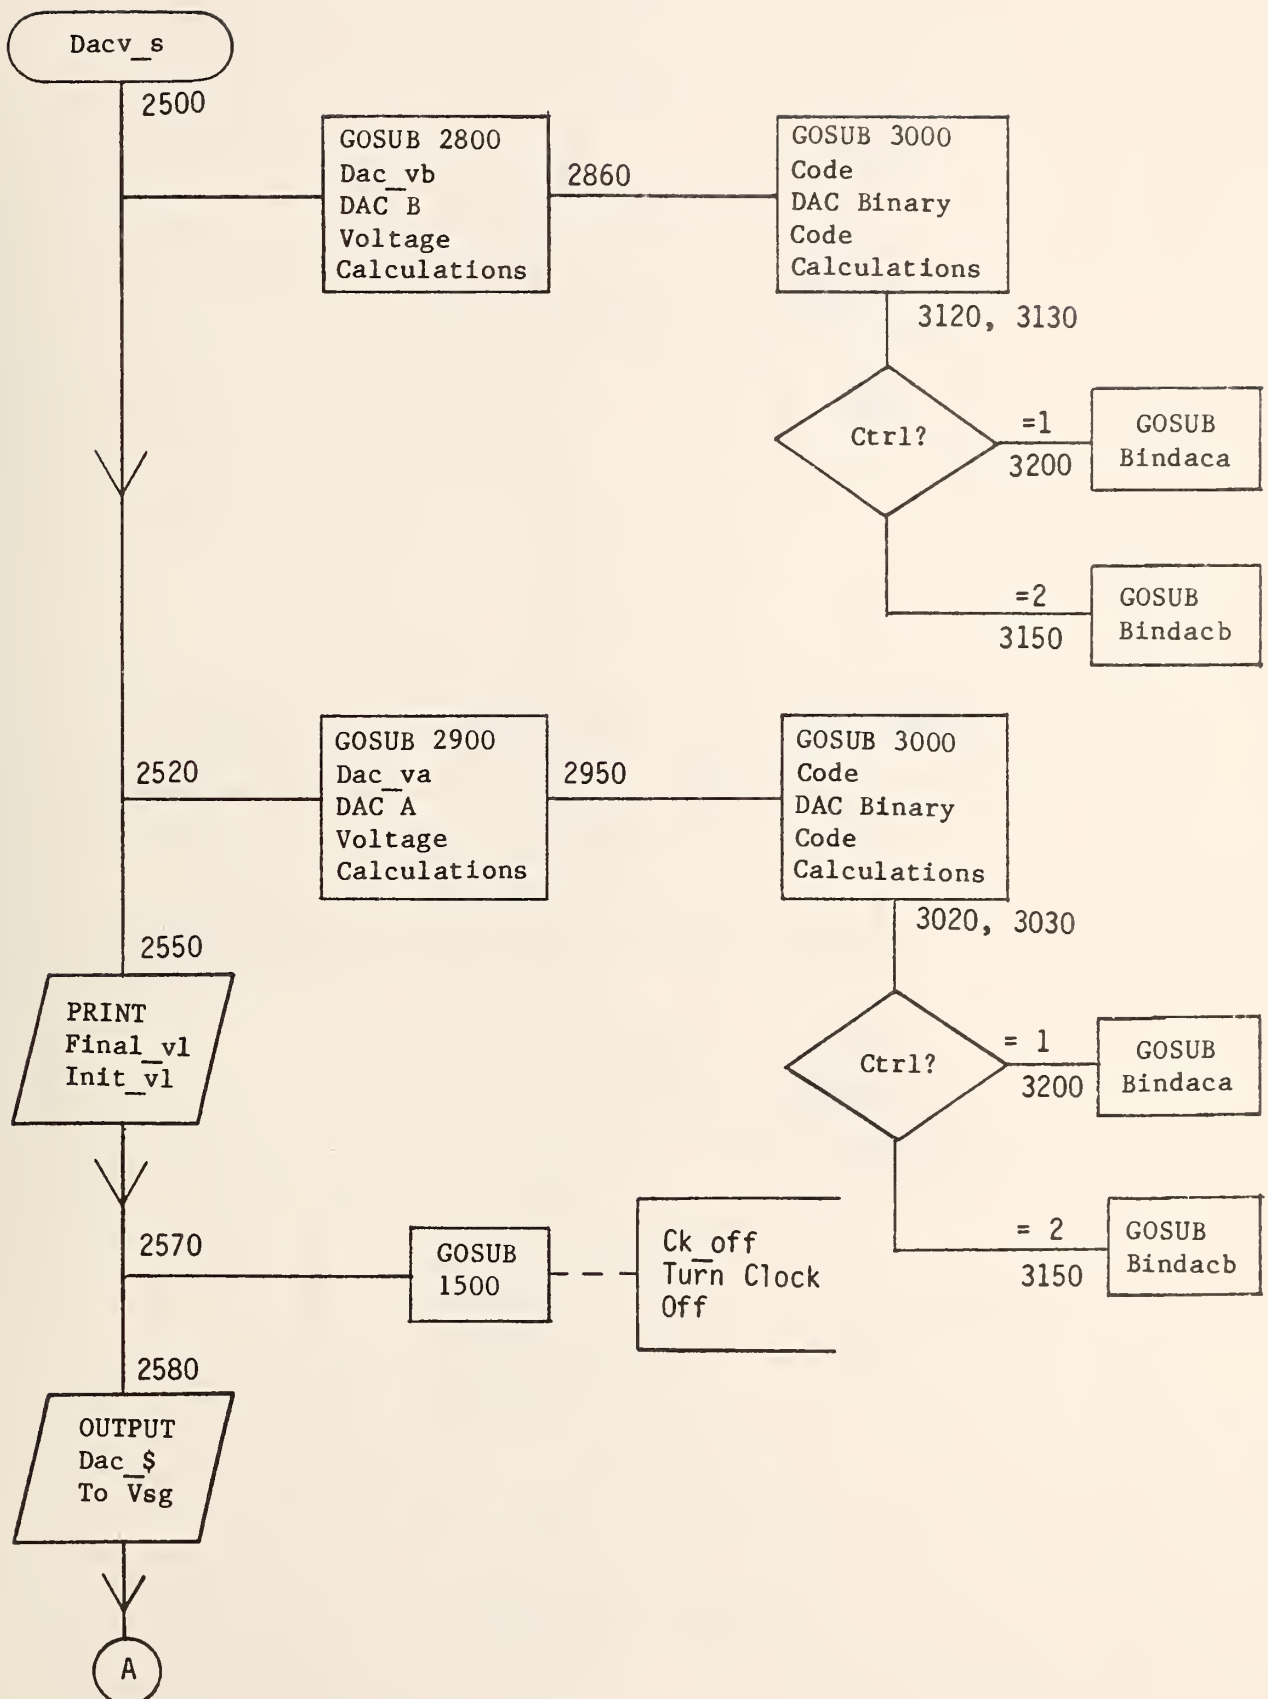

User: A user defined subroutine. [Key 9] Return at line 12165.

Vsgfreq: Enter the Voltage-step generator drive frequency based [Key 3] on the 10 MHz internal clock. Entry variable is Vsgfreq1. Can be entered at line 4040 if Vsgfreq1 is already set. Return at line 4300.

FLOW CHARTS

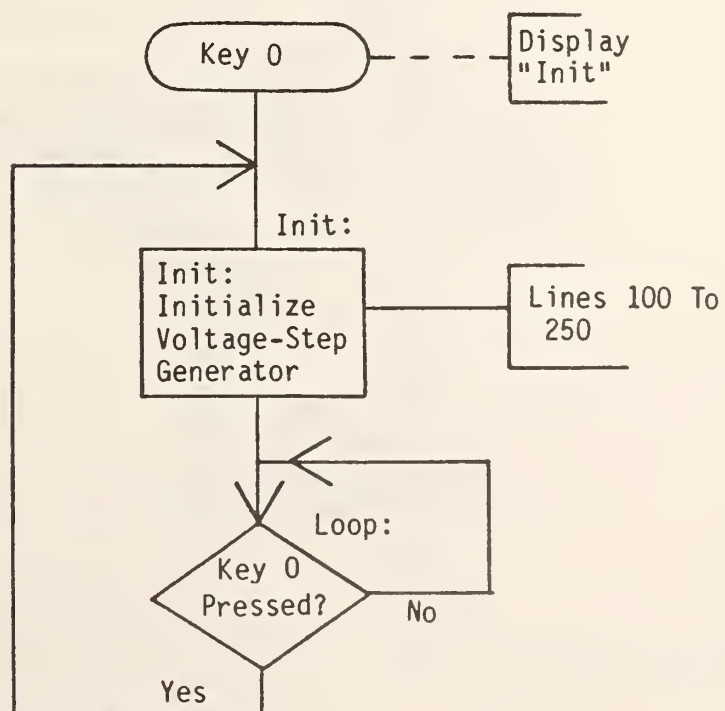

Flow charts are given for each of the defined keys and GOSUB 2500, the main routine used to calculate codes needed for the DAC's. After a RUN statement is executed , the program remains in a loop at line 80 "Loop:", and all operations are from the Softkeys.

GOSUB 2500 or Dacs_s

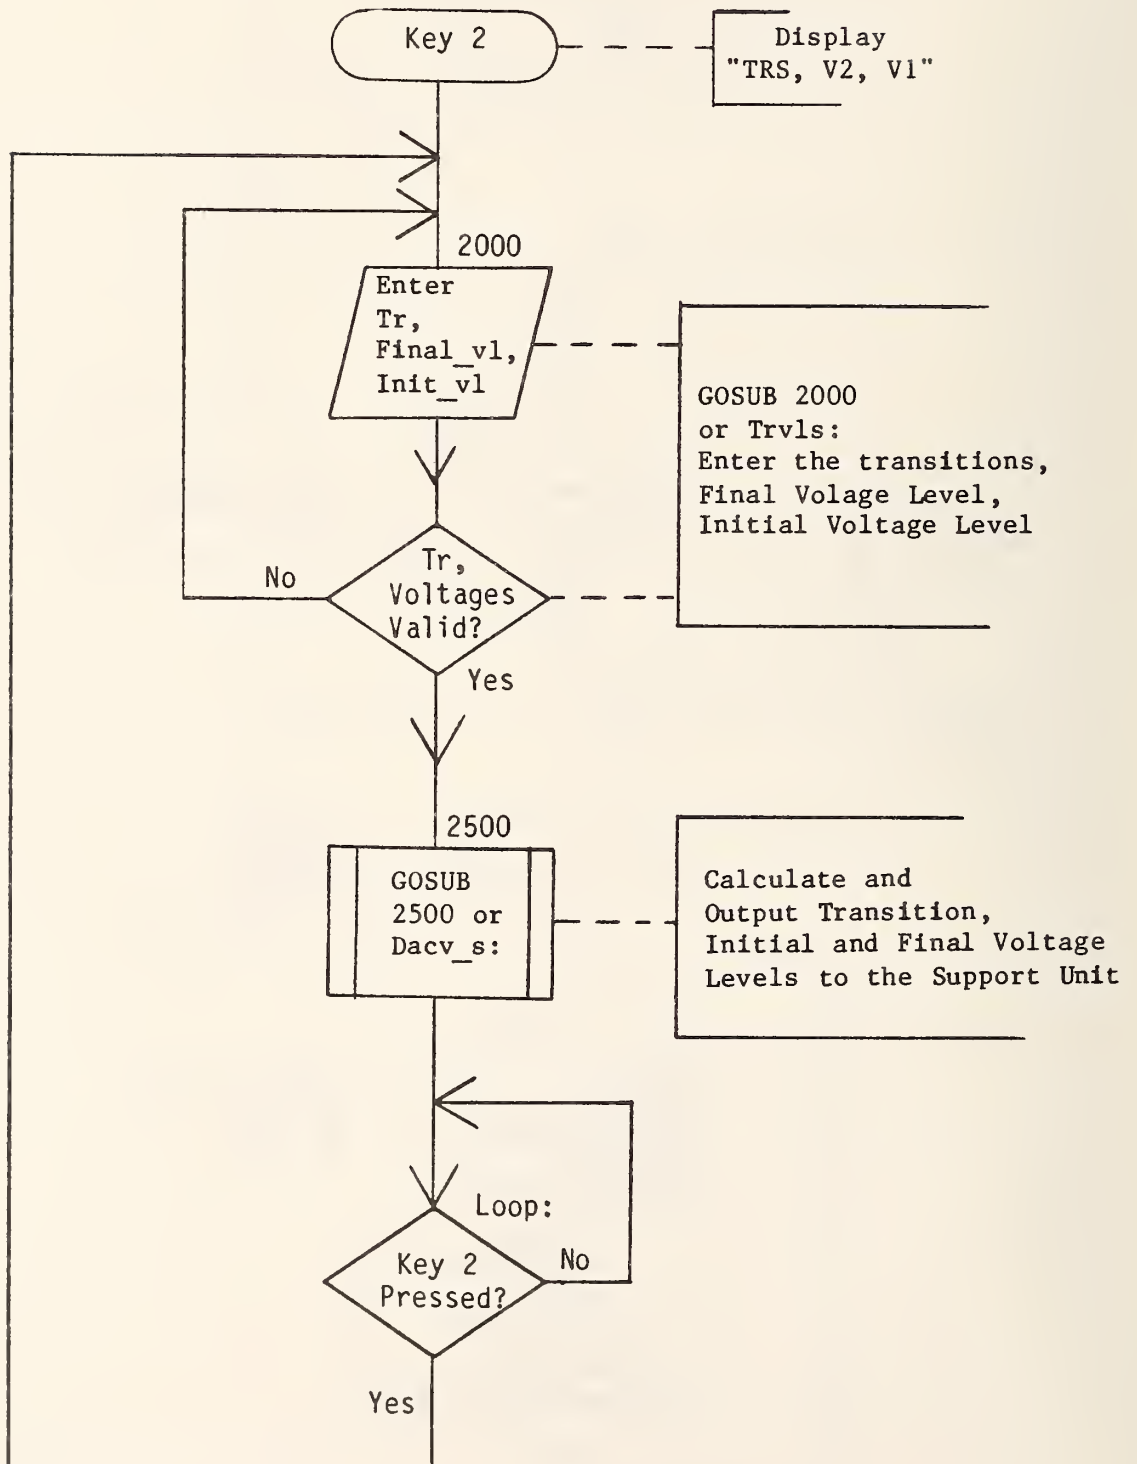

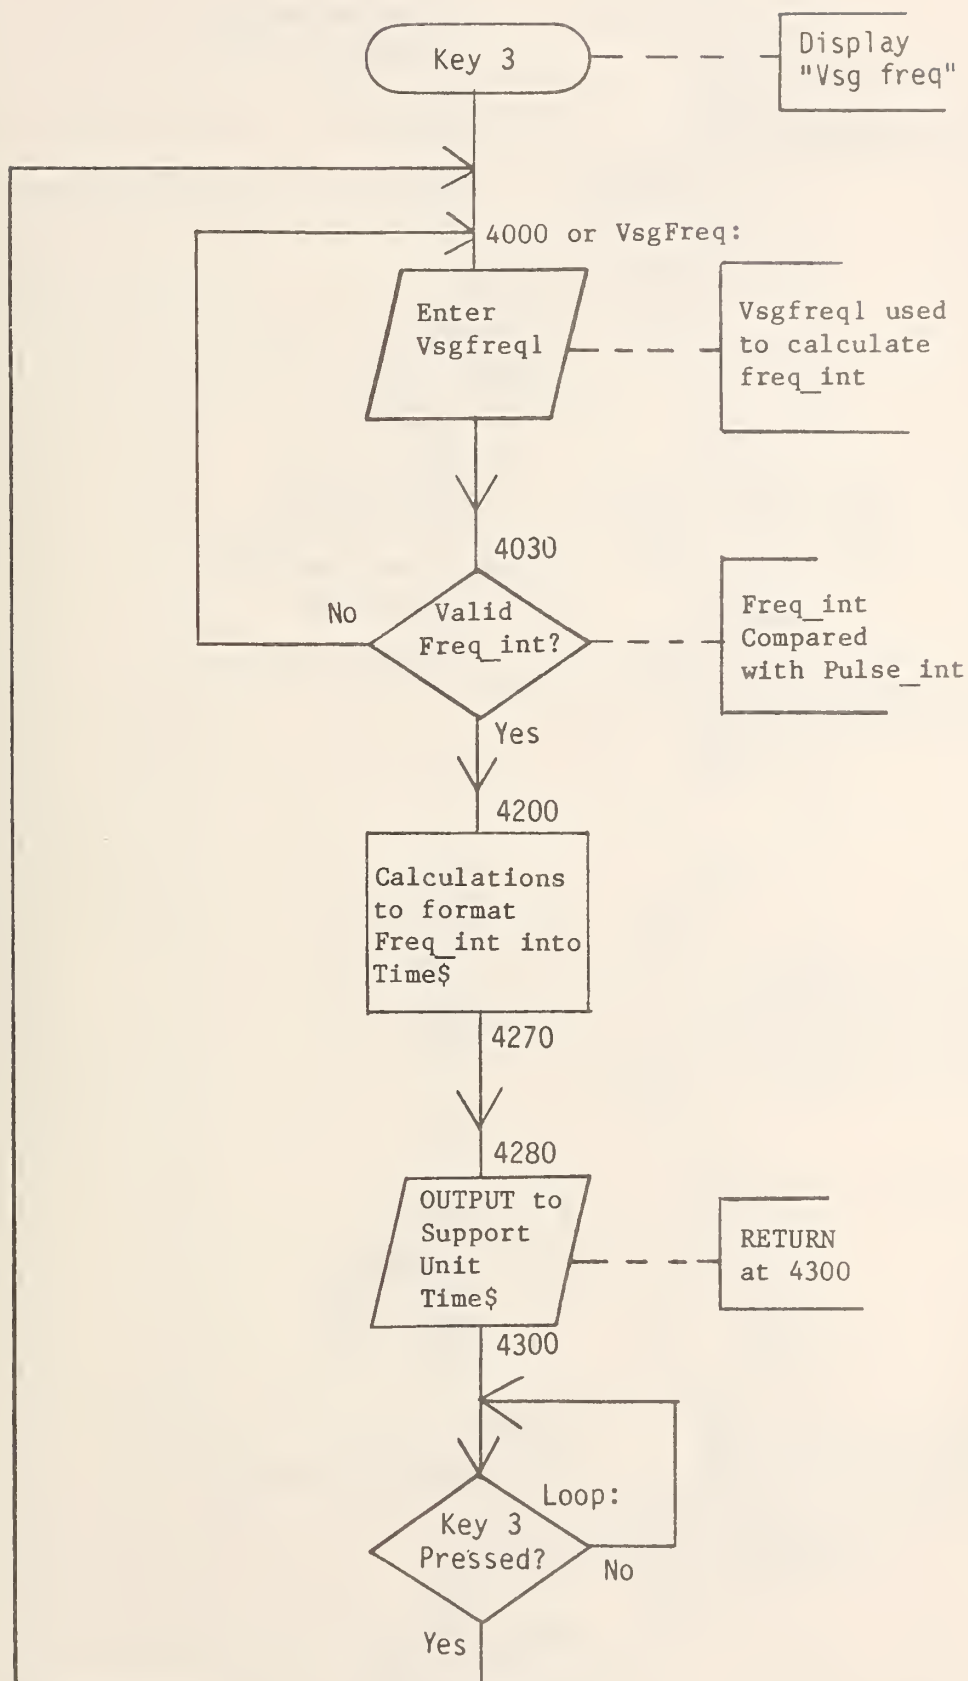

Key 0 GOSUB Init

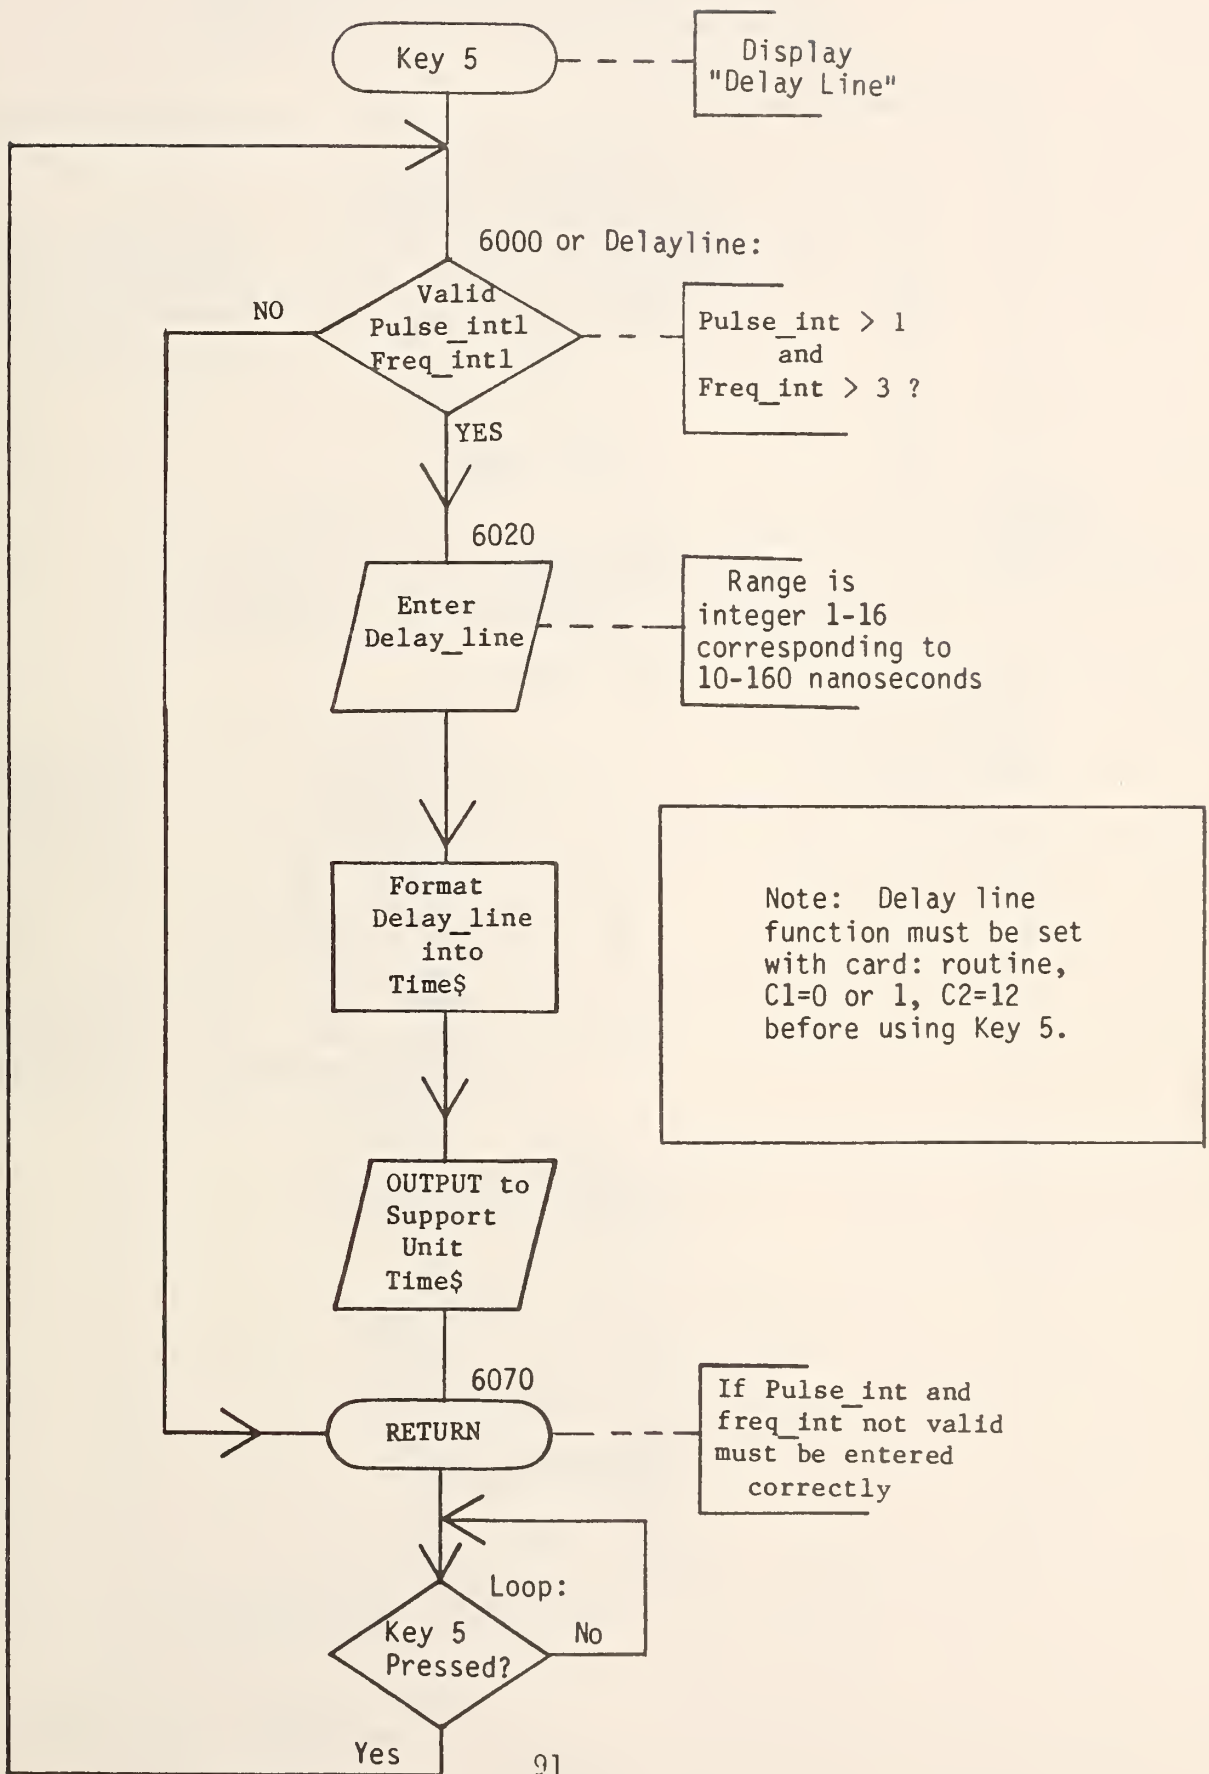

Key 2 Enter Polarity of transition,
Final and Initial Voltage Levels

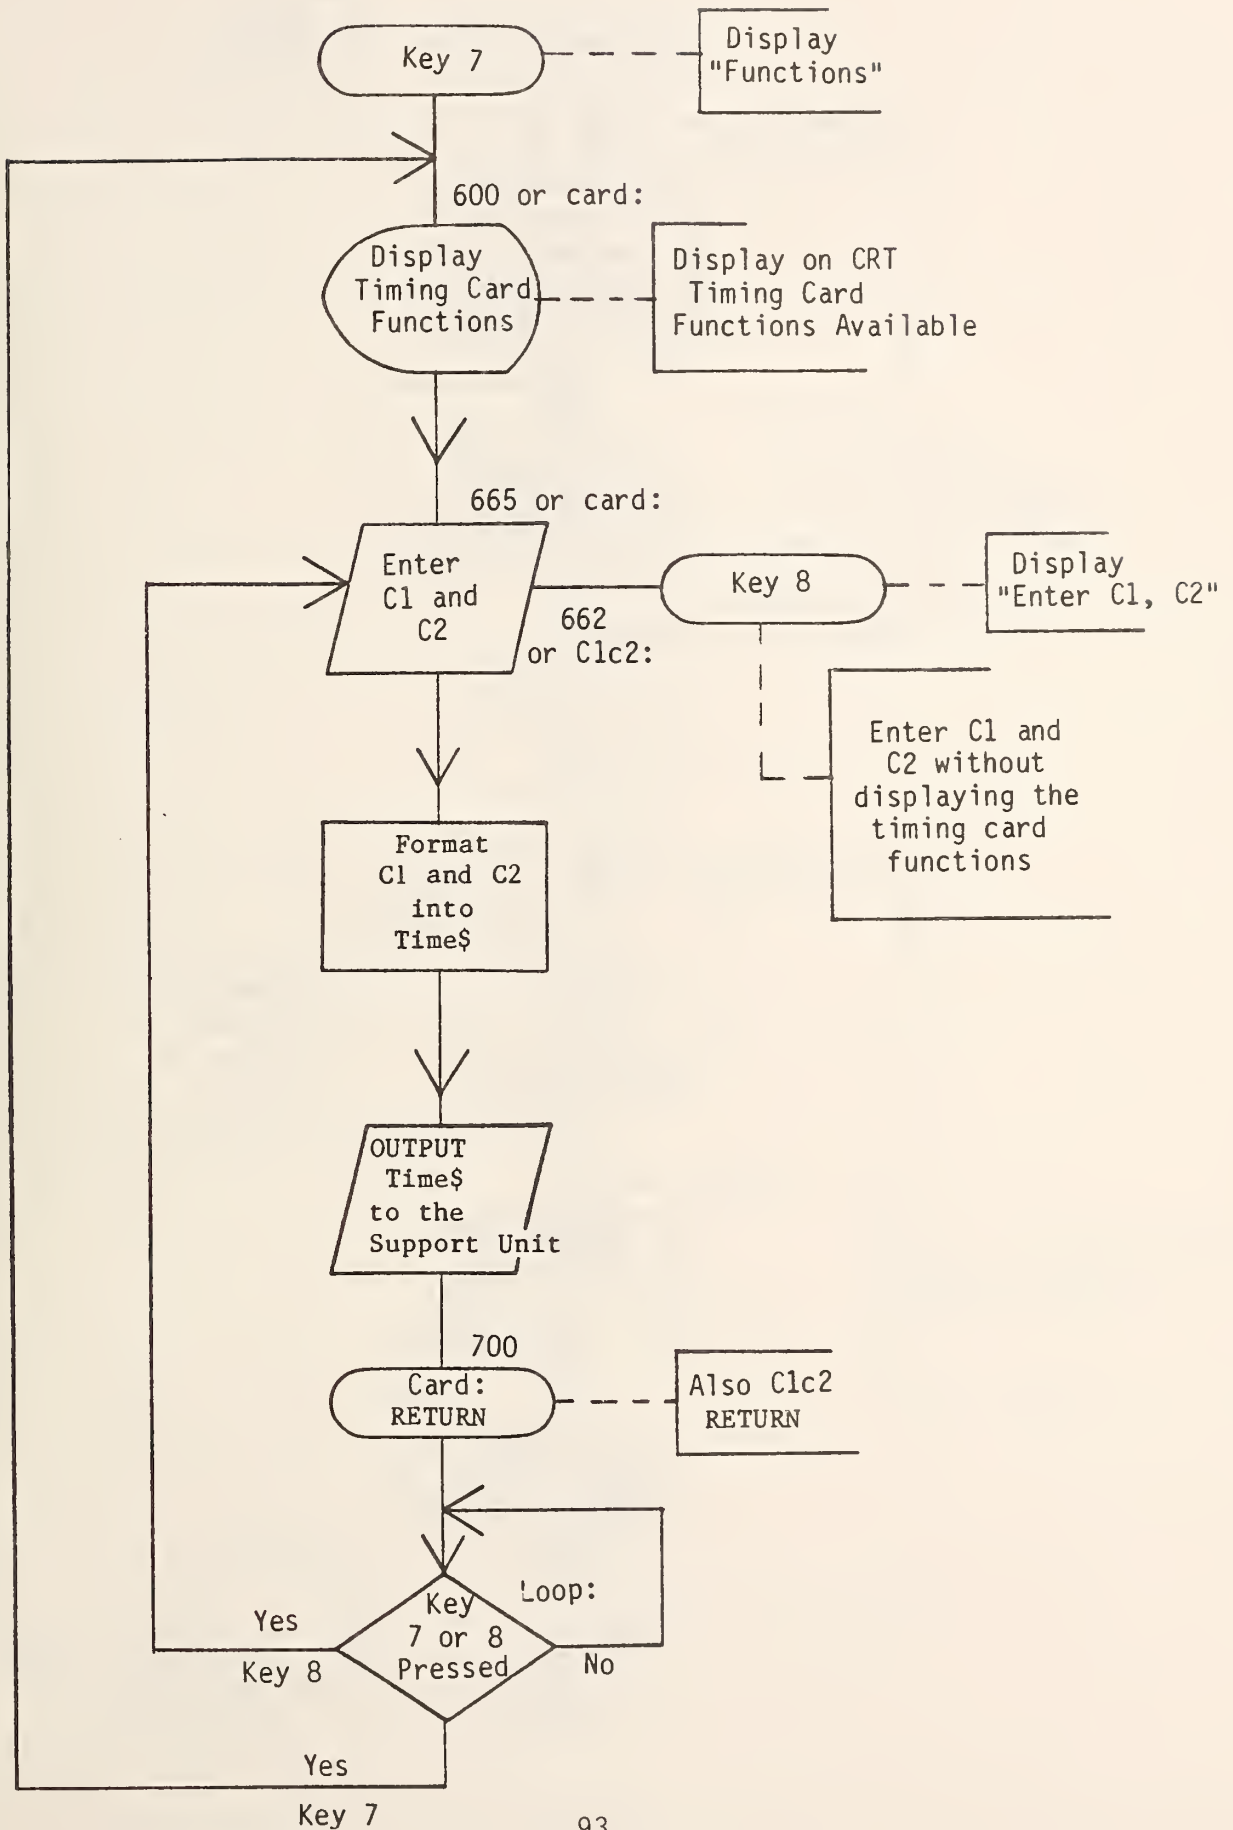

Key 5 GOSUB Delayline

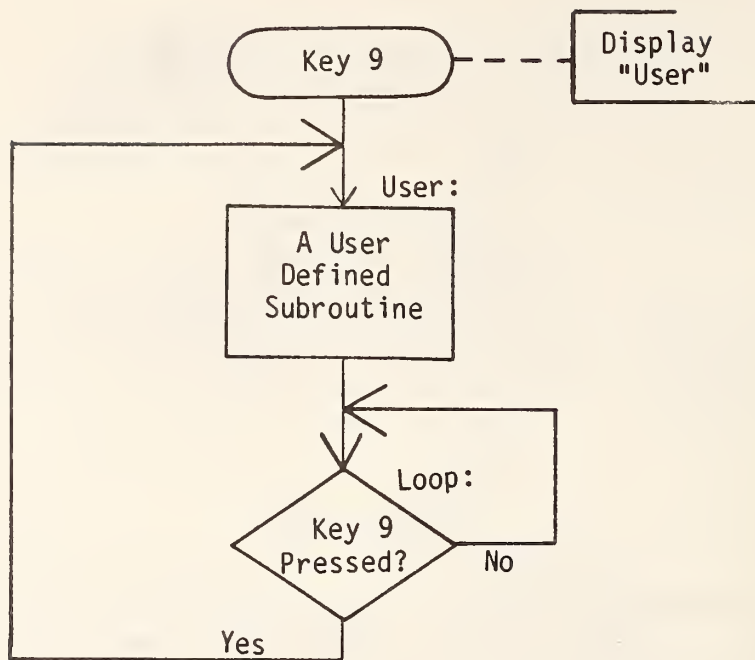

Key 6 Gosub Integer

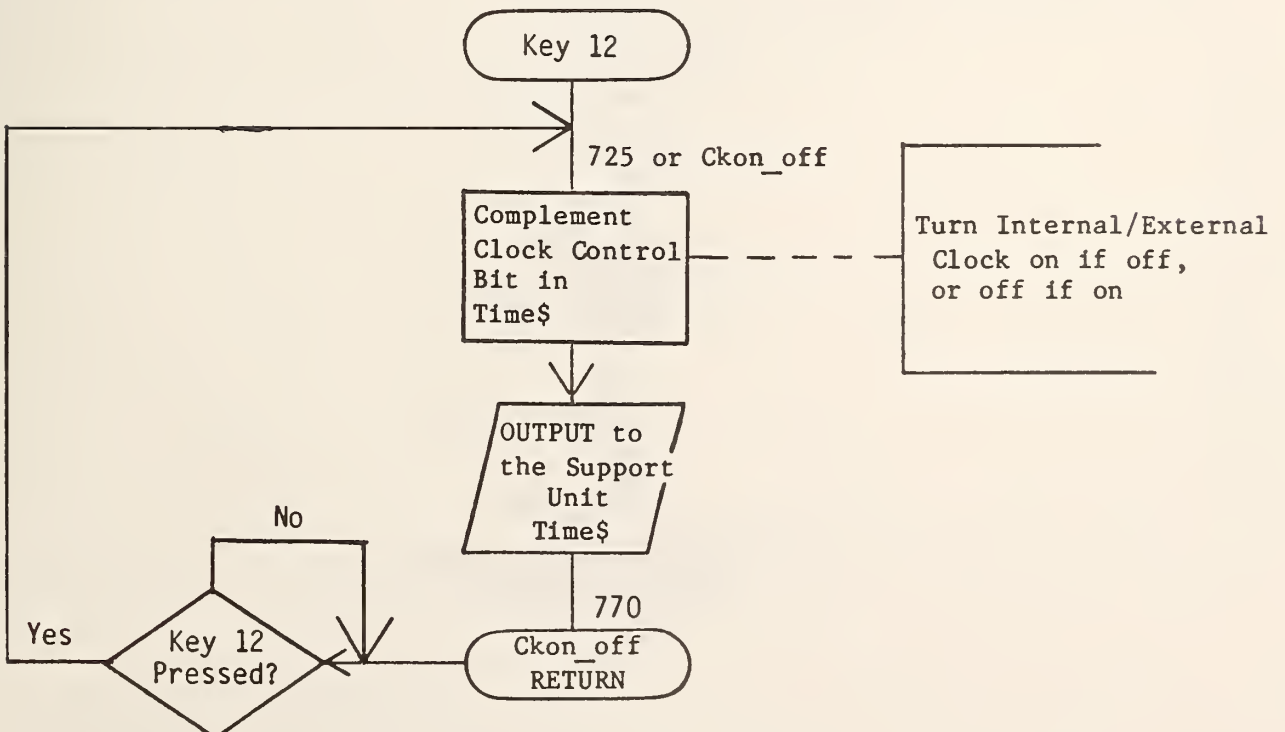

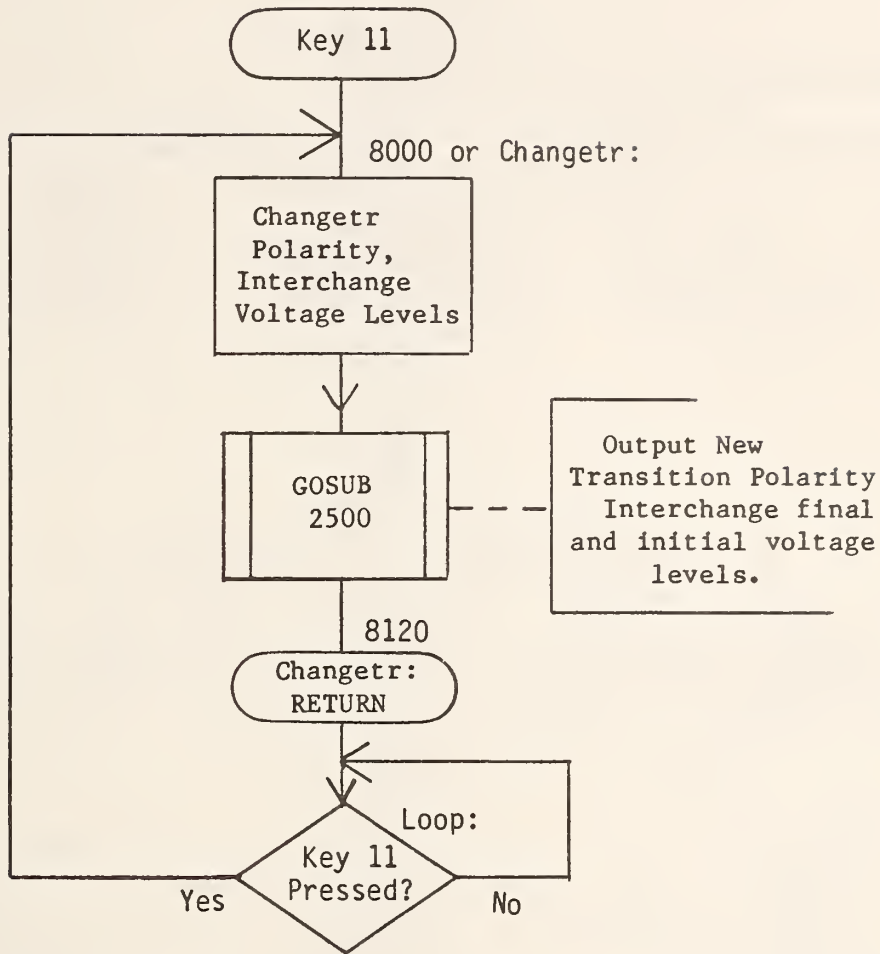

Key 7 GOSUB card
Key 8 GOSUB Clc2

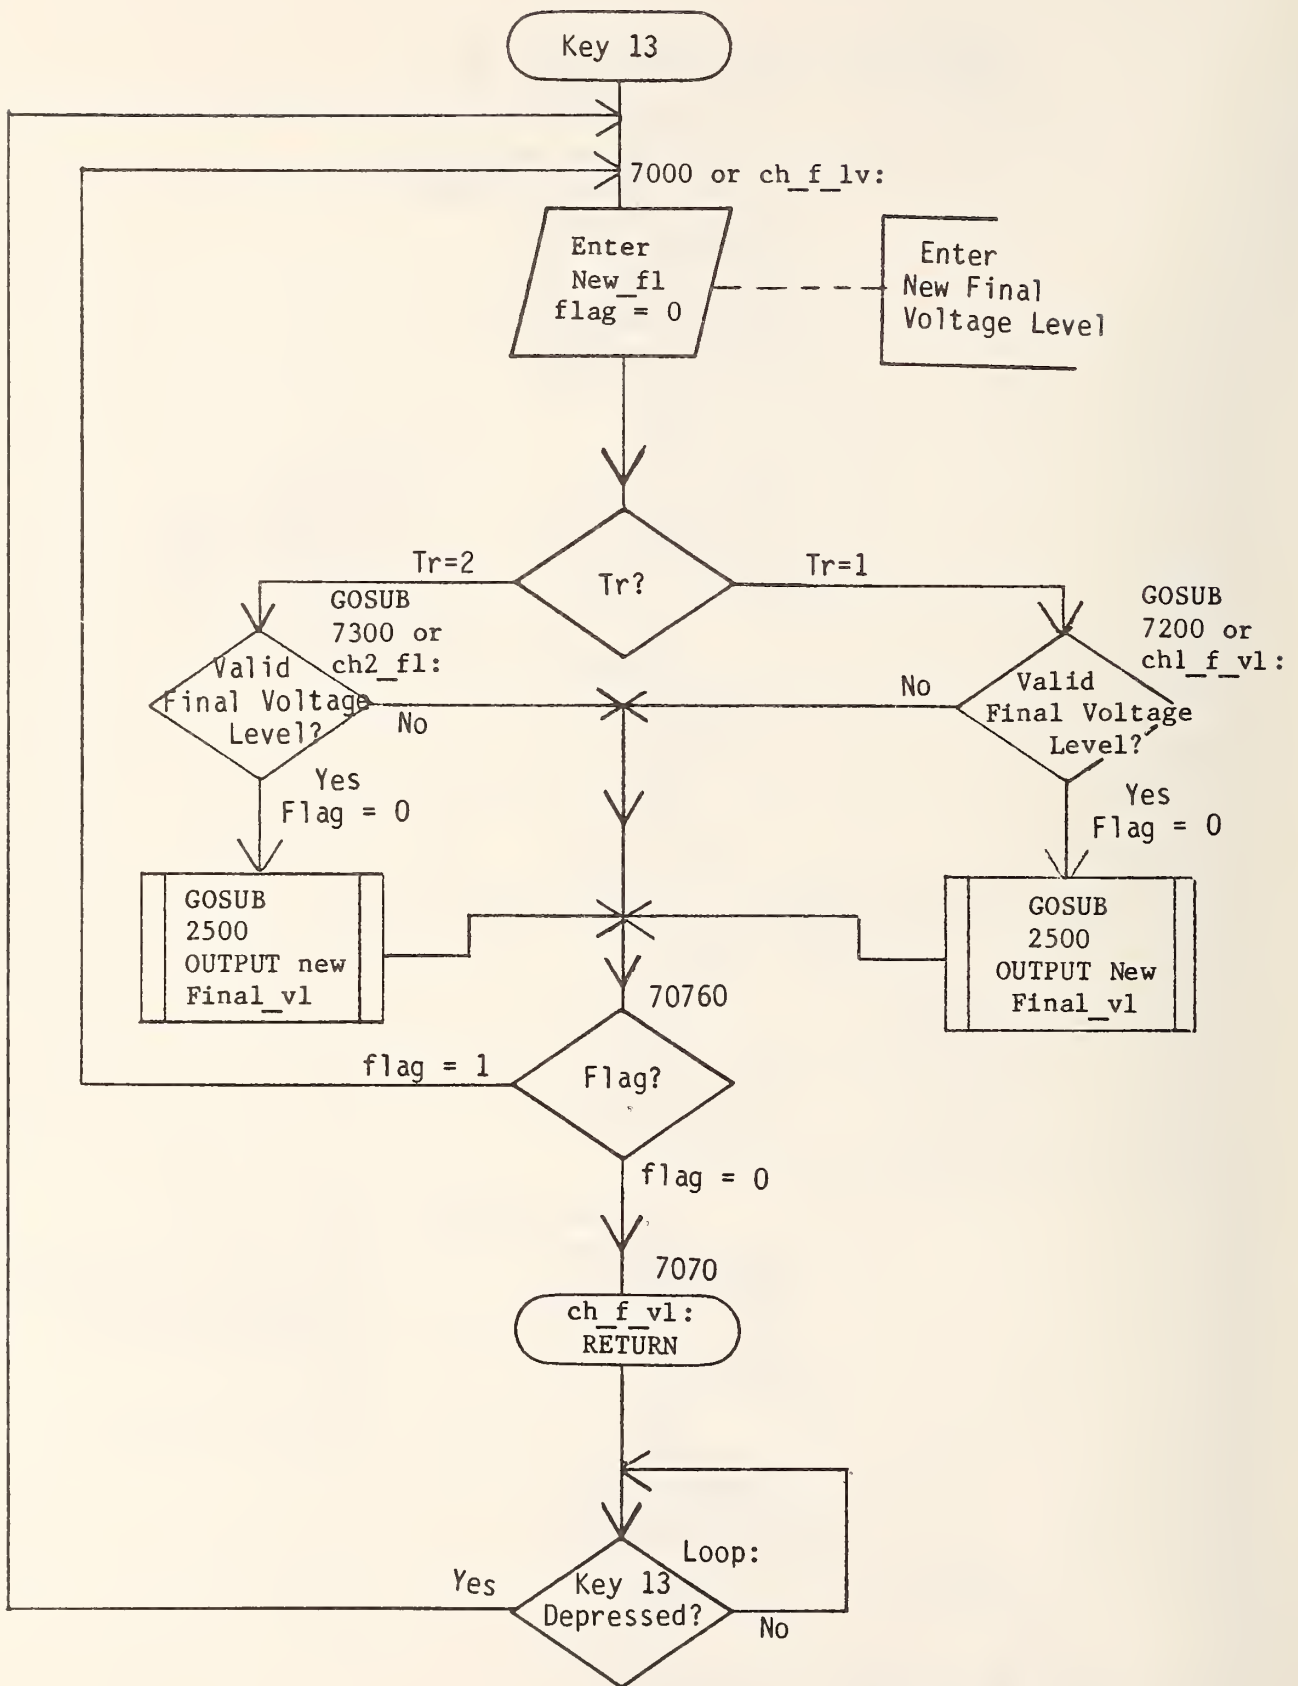

Key 9 GOSUB User
Key 10 GOSUB Status

Key 11 GOSUB Changetr
Key 12 GOSUB Ckon_off

9. SPONSORING ORGANIZATION NAME AND COMPLETE ADDRESS <i>(Street, City, State, ZIP)</i> Same as item 6.			
10. SUPPLEMENTARY NOTES <input type="checkbox"/> Document describes a computer program; SF-185, FIPS Software Summary, is attached.			
11. ABSTRACT <i>(A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here)</i> <p>A precision voltage step generator has been designed for use in automated systems to test the dynamic response of waveform recorders and other instruments. The programmable pulse parameters include transition polarity, pulse length, and repetition rate. The initial and final levels of voltage steps are each programmable within the range of ± 1 V for a 50 Ω termination and within ± 5 V for a high impedance load. Voltage steps within these ranges settle to within $\pm 0.02\%$ of full scale range (FSR) in less than 22 and 26 ns, respectively, for small load capacitance. The corresponding transition durations are approximately 6 and 7 ns.</p>			
12. KEY WORDS <i>(Six to twelve entries; alphabetical order; capitalize only proper names; and separate key words by semicolons)</i> automated test systems; programmable step generator; pulse generator; rise time; settling time; transition duration; waveform recorder testing

NBS *Technical Publications*

Periodical

Journal of Research—The Journal of Research of the National Bureau of Standards reports NBS research and development in those disciplines of the physical and engineering sciences in which the Bureau is active. These include physics, chemistry, engineering, mathematics, and computer sciences. Papers cover a broad range of subjects, with major emphasis on measurement methodology and the basic technology underlying standardization. Also included from time to time are survey articles on topics closely related to the Bureau's technical and scientific programs. Issued six times a year.

Nonperiodicals

Monographs—Major contributions to the technical literature on various subjects related to the Bureau's scientific and technical activities.

Handbooks—Recommended codes of engineering and industrial practice (including safety codes) developed in cooperation with interested industries, professional organizations, and regulatory bodies.

Special Publications—Include proceedings of conferences sponsored by NBS, NBS annual reports, and other special publications appropriate to this grouping such as wall charts, pocket cards, and bibliographies.

Applied Mathematics Series—Mathematical tables, manuals, and studies of special interest to physicists, engineers, chemists, biologists, mathematicians, computer programmers, and others engaged in scientific and technical work.

National Standard Reference Data Series—Provides quantitative data on the physical and chemical properties of materials, compiled from the world's literature and critically evaluated. Developed under a worldwide program coordinated by NBS under the authority of the National Standard Data Act (Public Law 90-396).

NOTE: The Journal of Physical and Chemical Reference Data (JPCRD) is published quarterly for NBS by the American Chemical Society (ACS) and the American Institute of Physics (AIP). Subscriptions, reprints, and supplements are available from ACS, 1155 Sixteenth St., NW, Washington, DC 20056.

Building Science Series—Disseminates technical information developed at the Bureau on building materials, components, systems, and whole structures. The series presents research results, test methods, and performance criteria related to the structural and environmental functions and the durability and safety characteristics of building elements and systems.

Technical Notes—Studies or reports which are complete in themselves but restrictive in their treatment of a subject. Analogous to monographs but not so comprehensive in scope or definitive in treatment of the subject area. Often serve as a vehicle for final reports of work performed at NBS under the sponsorship of other government agencies.

Voluntary Product Standards—Developed under procedures published by the Department of Commerce in Part 10, Title 15, of the Code of Federal Regulations. The standards establish nationally recognized requirements for products, and provide all concerned interests with a basis for common understanding of the characteristics of the products. NBS administers this program as a supplement to the activities of the private sector standardizing organizations.

Consumer Information Series—Practical information, based on NBS research and experience, covering areas of interest to the consumer. Easily understandable language and illustrations provide useful background knowledge for shopping in today's technological marketplace.

Order the above NBS publications from: Superintendent of Documents, Government Printing Office, Washington, DC 20402.

Order the following NBS publications—FIPS and NBSIR's—from the National Technical Information Service, Springfield, VA 22161.

Federal Information Processing Standards Publications (FIPS PUB)—Publications in this series collectively constitute the Federal Information Processing Standards Register. The Register serves as the official source of information in the Federal Government regarding standards issued by NBS pursuant to the Federal Property and Administrative Services Act of 1949 as amended, Public Law 89-306 (79 Stat. 1127), and as implemented by Executive Order 11717 (38 FR 12315, dated May 11, 1973) and Part 6 of Title 15 CFR (Code of Federal Regulations).

NBS Interagency Reports (NBSIR)—A special series of interim or final reports on work performed by NBS for outside sponsors (both government and non-government). In general, initial distribution is handled by the sponsor; public distribution is by the National Technical Information Service, Springfield, VA 22161, in paper copy or microfiche form.
