MATERIALS FOR PLACEBO V

WILLIAM C. WATT

THE NATIONAL BUREAU OF STANDARDS

The National Bureau of Standards is a principal focal point in the Federal Government for assuring maximum application of the physical and engineering sciences to the advancement of technology in industry and commerce. Its responsibilities include development and maintenance of the national standards of measurement, and the provisions of means for making measurements consistent with those standards; determination of physical constants and properties of materials; development of methods for testing materials, mechanisms, and structures, and making such tests as may be necessary, particularly for government agencies; cooperation in the establishment of standard practices for incorporation in codes and specifications; advisory service to government agencies on scientific and technical problems; invention and development of devices to serve special needs of the Government; assistance to industry, business, and consumers in the development and acceptance of commercial standards and simplified trade practice recommendations; administration of programs in cooperation with United States business groups and standards organizations for the development of international standards of practice; and maintenance of a clearinghouse for the collection and dissemination of scientific, technical, and engineering information. The scope of the Bureau's activities is suggested in the following listing of its three Institutes and their organizational units.

Institute for Basic Standards. Applied Mathematics. Electricity. Metrology. Mechanics. Heat. Atomic Physics. Physical Chemistry. Laboratory Astrophysics.* Radiation Physics. Radio Standards Laboratory:* Radio Standards Physics; Radio Standards Engineering. Office of Standard Reference Data.

Institute for Materials Research. Analytical Chemistry. Polymers. Metallurgy. Inorganic Materials. Reactor Radiations. Cryogenics.* Materials Evaluation Laboratory. Office of Standard Reference Materials.

Institute for Applied Technology. Building Research. Information Technology. Performance Test Development. Electronic Instrumentation. Textile and Apparel Technology Center. Technical Analysis. Office of Weights and Measures. Office of Engineering Standards. Office of Invention and Innovation. Office of Technical Resources. Clearinghouse for Federal Scientific and Technical Information.**

*Located at Boulder, Colorado, 80301.

**Located at 5285 Port Royal Road, Springfield, Virginia, 22171.

NATIONAL BUREAU OF STANDARDS

Technical Note 281

ISSUED JANUARY 17, 1966

MATERIALS FOR PLACEBO V

William C. Watt

NBS Technical Notes are designed to supplement the Bureau's regular publications program. They provide a means for making available scientific data that are of transient or limited interest. Technical Notes may be listed or referred to in the open literature.

Materials for PLACEBO V

William C. Watt

This paper presents materials which make the microgrammar PLACEBO V accessible to inspection. In the form given here, the microgrammar may be used in company with the requisite computer programs for producing or analyzing English sentences of a certain biological dialect, as part of a 'Question/Answer' device.

PLACEBO V includes its predecessor, PLACEBO IV, in the sense that every sentence generated by the earlier microgrammar is generated in the same way by the later one. This and other kinds of 'inclusion' are considered, and related to practical problems of microgrammar-design.

0. Introduction.

This paper consists almost entirely of materials on PLACEBO V, a microgrammar of about 2,100 context-free rules.¹ These materials comprise a listing of the rules of the microgrammar and a selection of sentences produced from those rules by a computer 'service program.' In addition, since perhaps the most interesting facet of PLACEBO V (if it has any at all) is that it 'radically includes' its predecessor, PLACEBO IV², I will briefly discuss properties of inclusion, and will also list the two microgrammars side-by-side for ease of comparison.

Considered as a computer-algorithm only, PLACEBO V is shown here in a form which may be examined independently of any other papers on its natural-language aspects or its proposed functions. Taken as a natural-language microgrammar, however, and as a functioning part of the "ITSELF" artificial-intelligence system (reference below), it is presented less autonomously: a clearer understanding of the properties of PLACEBO V, and of the points discussed, may be gained from consulting

¹ The research on which this paper is based has been supported by the National Institutes of Health under Agreement NB-05613-01.

In the format used (and explained) below, these 2,107 context-free rules are compressed into 1,090 'amalgam' rules.

² For a detailed presentation of the earlier microgrammar, see PLACEBO IV: Rules, Concordance, Sample Computer Generation, NBS Technical Note 255; Washington: 1965. PLACEBO IV contains 1,167 context-free rules, formatted as 676 'amalgam' rules.

three other papers. These are "Analysis, Synthesis, and Description of Biological Images"³, A Prerequisite to the Utility of Microgrammars,⁴ and General Properties of Microgrammars.⁵ In addition, the aforementioned piece on PLACEBO IV may be consulted for a discursive presentation of the manner of producing sentences from the rules of microgrammars like PLACEBO IV and V.⁶

PLACEBO V is one of a sequence of microgrammars of which the last will be a working component of the "ITSELF" system, as described in Lipkin, Watt, and Kirsch op.cit. (There will probably be no more than three further microgrammars in this series: perhaps fewer.) Briefly, the "ITSELF" system will enable neuropathologists to use a computer as an ally in the analysis of pictures of brain-tissue, and of sets of such pictures. The final PLACEBO will allow its users to describe such pictures (or 'sections') in English sentences, to query the computer in English and to issue instructions in English for picture-processing. The computer, in turn, will respond in English. As the "micro-" prefix indicates, the final PLACEBO will be able to analyze only a very small set of English sentences---though this set is infinitely large---; so that in a way only a semblance of speaking English is offered the neuropathologist. If the user is to derive any real benefit, then,

3 Lewis E. Lipkin, William C. Watt, and Russell A. Kirsch, Annals of the New York Academy of Sciences (to appear).

4 William C. Watt, NBS Technical Note 258; Washington: 1965.

5 William C. Watt (forthcoming).

6 In informal use no harm is done by synonymizing "production" and "generation," but more formally speaking the two should be kept distinct. Roughly, it may be said that a generative grammar (like PLACEBO V) generates sentences, if the grammar is well-formed, without any processing taking place: "generating" is something like the "equalling" done by the formula "2+2=4." A grammar produces sentences when the rules are actually used (by a human or a computer) to determine real sentences---i.e. to write them down in some way. (The analog is "He added 2 and 2 and got 4"). A grammar may "generate" an infinite number of sentences (as both PLACEBO IV and V do); but the number of sentences it "produces" is always finite.

from being allowed to 'speak English', the set of sentences available to him must be chosen with some care: it must be such a set as he will not be constantly overstepping in his efforts to say what he wants. A set of sentences which is adequate in this way I have elsewhere⁷ called a "habitable" microgrammar. Of course there is no reason to expect that it will be possible to build a microgrammar which is completely habitable: my goal is only to approach this ideal as closely as possible: to achieve maximum practicable habitability.

PLACEBO V is nowhere near reaching even this more modest goal, but it wasn't expected to be. This microgrammar was developed with a more immediate objective in mind: that of creating a "core" grammar of sufficient syntactical and lexical variety (and consistency among sets of variants) so that needed additions could be made with some facility and with little perturbation of the rules so far integrated. The procedures for deriving such a "core" microgrammar are at present best described as ad hoc; but PLACEBO V is indeed proving easy to expand, and so the procedures can be said to have worked. Unless, of course, the "core" was arrived at serendipitously and/or unless any moderately large microgrammar constitutes such a "core;" but neither of these suppositions is very plausible.

From this point on the process of developing microgrammars of the PLACEBO series will be quite different. PLACEBO IV and V have been brought this far by adding assumedly general-purpose structures (containing neuropathological lexicon) which are anticipated to be useful and/or to lend the microgrammar 'extrapolative symmetry'⁷. But henceforward only structures specifically produced by neuropathologists will be added (together with their obvious extrapolations). As of this writing the microgrammar is slowly expanding while being constantly checked, against neuropathological discourse, for habitability.

⁷ See the Prerequisites paper.

In the meantime, it may be remarked that in an admittedly un-rigorous experimental situation, about one-third of the sentences volunteered by one neuropathologist were found to be already generated by PLACEBO V. For various reasons---including lack of a mechanical parser to check the validity of these 'findings'---I do not attach very much importance to this result, though I insist on being heartened by it.

This paper is divided into three main sections. Section 1 opens with a key to the format in which these microgrammars are written, and then proceeds to a full listing of the rules of PLACEBO V, with the PLACEBO IV rules en face.

Section 2 discusses grammatical 'inclusion,' and exposes some disadvantages of requiring PLACEBO V to include its predecessor.

Section 3 lists a number of sentences machine-generated from the PLACEBO V rules.

NBS Technical Report 8934, Concordance to the Rules of PLACEBO V, provides a supplement to these materials which should be of particular value to anyone adapting the microgrammar to some use of his own.

1. The Rules of PLACEBO V, with those of PLACEBO IV en face.

1.1. Prefatory Note.

What follows is a complete listing of the rules of the two microgrammars PLACEBO V and PLACEBO IV. The rules for each are given in alphanumeric order⁸, except that the initiating grammatical category 'S' is listed first. Most of the categories, as will be evident, have names which are of mnemonic value to people working with the microgrammars; these mnemonics are not entirely consistent, however, and contribute nothing to the algorithmic functioning of the microgrammars.

The PLACEBO grammars are in what is known generally as the 'Simple (or Context-Free) Phrase Structure' model, but they are written in an unusual format.

The symbol " $=$ " is identical to the more traditional " \rightarrow ", and is to be interpreted as "is instantiated as."

The function of " $,$ " may be exemplified by the rule " $S = \text{DIR}, \text{STTT}$ "; this rule is equivalent to the two 'normal' rules " $S = \text{DIR}$
 $= \text{STTT}$ ". Thus,

" $,$ " may be read as "or."

The symbol " $+$ " is to be interpreted as "concatenated with to the Right."

In sum, then, the PLACEBO V (and also PLACEBO IV) rule

$$\text{AJC} = \text{AJCA}, \text{AJCB}, \text{AJCC} + \text{AJFIXE}, \text{AJCD} + \text{AJFIXE}$$

is equivalent to the rules:

$$\begin{aligned} \text{AJC} &= \text{AJCA} \\ &= \text{AJCB} \\ &= \text{AJCC} + \text{AJFIXE} \\ &= \text{AJCD} + \text{AJFIXE} \end{aligned}$$

Two other conventions must be explained. The symbol " $*$ " flanks all terminals, as in the rule " $\text{ABT} = * \text{ABOUT} *$ ". All symbols on the left

⁸ Letters are in order A...Z, numerals are in order 0...9, letters precede numerals, '12' follows '11' but also follows '112'.

of " = " having terminal (starred) symbols on the right, are instantiated only as terminals: such terminal-instantiators I will elsewhere refer to as 'penterminal' symbols. Note that the penterminal symbol "X" has the instance "* *"--that is, its instance is a space. Use of the "X" penterminal constitutes a kind of 'overt deletion', in the production of strings; its function is more fully explained in the General Properties paper.

Note lastly that a "terminal" consists only and entirely of what appears between asterisks.⁹ For example, the terminal quoted above is not "about", but " about", with preceding space. Spaces must be introduced in this way, given the 'service programs' cited below, whenever in the production of strings it is desirable to separate terminal symbols, e.g. words. This preceding space is omitted when the terminal is a suffix, for example---e.g. AJFIXING = *ING*---and in general whenever a terminal may be directly preceded by another terminal. If a terminal (e.g. *REGULAR*) may be preceded either by another printed terminal (e.g. * IR*) or by space (as when "regular" is not negated), then this space is introduced by means of a "Z" penterminal, whose only instance is "* *".

In the form presented here, both microgrammars have been 'weighted' for production purposes. That is, to prevent the frequent occurrence of very long strings with low readability, certain rules have been weighted with several "X" penterminals, in order that the 'generating' program, in making its random choices, will have a statistical probability of choosing to delete certain symbols rather than entering their further instances and thus entering a recursive loop. If used

⁹ Actually this is quite false, except in an informal context (such as this one) where the term "terminal symbol" refers to symbols appearing in produced strings and strings to be parsed. Strictly speaking, of course, the terminal symbols include their flanking asterisks: for otherwise such a rule as "L = *L*" would introduce into the grammar a no-exit recursive loop. More exactly, then, the PLACEBO service-programs print out PLACEBO terminals less their asterisks.

as they are for parsing purposes, these microgrammars will be faulty instruments, for wherever one of these 'favored' deletions is analyzed as present in the input string, the parsing program will be at pains to point out that the deletion (=terminal space) could have resulted from, first, the first 'X' of the rule in question; from, secondly, the second 'X' of that rule; and so on. To be spared such tiresome news, one must remove all but one 'X' from each rule in which more than one 'X' occurs.

For ease of comparison, I have insured that each rule in PLACEBO V which expands a rule in PLACEBO IV, will be found on the page facing the page on which that PLACEBO IV counterpart appears. No other significance is to be attached to the varying number of rules displayed on the PLACEBO IV pages.

2. Inclusion Properties Between Context-Free Grammars: Sketch.¹⁰

Noam Chomsky has defined 'equivalence' properties as these may obtain for a pair of grammars. Informally, two grammars "...will be called weakly equivalent if they generate the same language; they will be called strongly equivalent if they generate the same set of structural descriptions."¹¹ These notions of equivalence have inspired my present interest in notions of inclusion between two grammars. In this paper, except where noted otherwise, I will state inclusion properties only for Context-Free Grammars (CFG), as defined by Chomsky¹², for only such grammars are my concern here. Moreover, I will present these properties in a rather informal style. At a later time I expect to treat of inclusion properties more broadly and more formally.

As in PLACEBO IV and V, I will use the symbol "=" in place of the 'Chomsky Arrow', a "...finite, two-place, irreflexive and asymmetric relation defined on certain strings..."¹³; this symbol may be read, as Chomsky suggests, as "is rewritten as" or, equivalently, as "is instantiated as". I will use the symbol "+" in place of the concatenation symbol "∧"; "+", then, is "...an associative and non-commutative ...operation on strings..."¹³ (I have adopted these two notational conventions only for reasons of typing convenience.)

I will generally define inclusion relations between CFG as obtaining on an abstractive plane above that of the terminal or non-terminal symbols used by the individual grammars: that is, one grammar

10 B.K.Rankin III, R.A.Kirsch, and R.W.Hsu must receive some credit for whatever accuracies may be found in this section.

11 Noam Chomsky, "Introduction to the Formal Analysis of Natural Languages," in: Handbook of Mathematical Psychology, edited by R.L. Luce, R.R.Bush, and E.Galanter; Volume II, pp.269-321. The quoted passage is on p.297.

12 Ibid., pp.292ff. CFG are often called "simple phrase-structure" grammars.

13 Chomsky, loc.cit.

may in my usage include another (in one or another way) even though the including and included grammars share no symbols. From this point of view, structurally-isomorphic grammars or languages are identical: they are simply "realphabetizations" each of the other. A grammar (or grammar sub-part) 'X' will be said to be a "realphabetization" of another grammar (or subpart) 'Y' if an isomorphism can be stated for 'X' and 'Y' such that every rule in 'X' is matched by a rule in 'Y', and vice-versa, where one rule "matches" another if there is a one-to-one mapping, symbol for symbol and connective for connective, of the one onto the other; and where no symbols or connectives not identical in 'A' are identical in 'B', and vice-versa. Here, a "symbol" is a symbol of the terminal or nonterminal vocabulary; a "connective" is "=" or "+".

Hereafter when I speak of a grammar 'B' being included in some grammar 'A' in some way, I will mean "'B' is included or some realphabetization of 'B' is included" unless otherwise specified.

2.1. Strong Inclusion.

A grammar 'B' will be said to be strongly included in a grammar 'A' if the set of rules comprising 'B' is a proper subset of the set of rules comprising 'A'.

In the exemplificatory grammars which follow (where symbols from the terminal vocabulary are given in lower-case), both 'B' and 'C' are strongly-included in 'A':

'A'	'B'	'C'
Q = R	Q = R	L = M
R = S	R = S	M = N
R = T	S = u	N = p
S = u		
T = v		

Note that it is only for convenience, in these grammars, that I mark symbols of the terminal vocabulary in any way; for any instance-symbol which never occurs as an instantiator (i.e. on the left side of "=") is a terminal symbol. Thus, grammar 'D' is also strongly included in 'A':

$$\begin{array}{c} \hline 'D' \\ \hline Q = R \\ R = S \\ \hline \end{array}$$

2.2. Weak Inclusion.

A grammar 'B' will be said to be weakly included in some grammar 'A' if the set of strings generated by 'B' is a proper subset of the set of strings generated by 'A'

In the above examples, 'B', 'C', and 'D' are all weakly included in 'A'.

2.3. Relations between Strong and Weak Inclusion.

'B' may be strongly included in 'A' but yet not weakly included; 'B' may be weakly included in 'A' but not strongly included. Thus, strong and weak inclusion are independent of each other.

$$\begin{array}{cc} \hline 'A' & 'B' \\ \hline Q = R + R & R = s \\ R = s & \\ \hline \end{array}$$

The rules of grammar 'B' are a proper subset of the rules of grammar 'A'; however grammar 'A' generates only the string "ss", while 'B' generates only the string "s". So 'B', while strongly included in 'A', is not weakly included.

'A'	'B'
$Q = R + s$	$Q = R + W$
$Q = t$	$R = u$
$R = u + v$	$W = v + s$

Grammar 'A' generates the two strings "uvs" and "t"; grammar 'B' generates the string "uvs". However, it is not true that the set of rules comprising 'B' is a proper subset of the rules comprising 'A'; thus 'B', though weakly included, is not strongly included in 'A'.

There are one or two peculiar relations between strong and weak inclusion which, even in this rather narrow treatment, deserve mention. One relation is this: there are context-free languages which necessarily have non-context-free languages as proper subsets: thus there are cases of two grammars 'A' and 'B' where 'B' is necessarily weakly included in 'A' but cannot be strongly included (where we insist that both be CFG). For, as Chomsky has pointed out,¹⁴ the language consisting of all and only the strings $(a^n b^n a^m)$ is context-free; while the language $(a^n b^n a^m / n=m)$ is not context free.¹⁵ But the latter (generated by 'B') is a proper subset of the former (generated by 'A'), and in fact there is no CFG 'A' which does not generate the language 'B'. Then 'B' must be weakly-included in 'A', but cannot be strongly-included in 'A'.

A second peculiarity may be exemplified by these same 'A' and 'B' grammars. Of course, for some subsets of 'B' there can be devised CFG; let us select one of these languages and call it 'B α '. But all of the strings generated by 'B α ' are also generated by any CFG 'A'. Then there can be no CFG which unambiguously strongly includes any CFG for the language 'B α ' and the language 'A'.

2.4. Thorough Inclusion.

A slightly more useful notion of inclusion is provided by what I

¹⁴ Op.cit., p.380.

¹⁵ Ibid., p.367.

will call "thorough inclusion."

A grammar 'B' will be said to be thoroughly-included in some grammar 'A' if the set of sentences (\neq 'set of strings') generated by 'B' is a proper subset of the set of sentences generated by 'A'.

My distinction between string and sentence appears to be close to the distinction between "sentence" and "sentoid" made recently by Katz and Postal.¹⁶ A string is a sequence of terminal symbols regardless of what description it receives; while a sentence is such a string with a unique structural description associated with (= imposed on) it. Thus a sentence is syntactically univocal -- displays no constructional homonymity -- while a string may be ambiguous, with respect to a particular grammar which generates it, in that the same grammar may also generate another string, isomorphic with the first, with a different (non-identical) set of rules.

I would add only one additional note to this presentation. One may also consider cases where grammars, in generating strings, impose on them no structural description (sd) at all. Such cases of what we might call "constructional anonymity" have little interest on their own account, though they may involve pragmatic considerations of greater weight. A constructionally-anonymous string may have an ancillary property of "pseudoambiguity": when the string is given (as it generally is) as just a sequence of terminal symbols, without intervening concatenation symbols, it may not be possible even to partition the string into its proper terminals, if e.g. "d", "e", and "de" are, all three, possible terminal symbols. Pseudoambiguity can be circumvented easily enough in exemplificatory grammars, but it can pose a real problem to programs for recognizing written English, where the presented terminal strings contain only spaces (rather than concatenative symbols) between words.

¹⁶ J.J.Katz and P.M.Postal, An Integrated Theory of Linguistic Descriptions (=Research Monograph #26), The M.I.T. Press, Cambridge, Mass., 1964; xi, 178 pp. See also J.F.Staal's review: Foundations of Language 1.133-154 (1965).

2.5. Relations among Thorough, Strong, and Weak Inclusions.

It is clear that 'B' can be both strongly and weakly included in 'A' without being thoroughly included.

'A'	'B'
$R = S+S$ $= D+c$ $S = a+b+c$ $D = a+b$	$S = a+b+c$

'A' generates the strings "abc" and "abcabc"; 'B' generates "abc". The rule in 'B' is included among those of 'A'. Yet 'B' and 'A' generate their common string "abc" in quite different ways: so 'B', while both strongly and weakly, is yet not thoroughly included in 'A'.

On the other hand, if 'B' is thoroughly included in 'A', then its sentences are included; then its strings are included: so then 'B' is also weakly included in 'A'. But if 'B' imposes on this set of strings the same set of sd as is imposed by 'A', it must do so by the same set of rules: so 'B' must be strongly, as well as weakly, included in 'A', if thoroughly included. Note especially that it is definitely not enough for each sentence in 'B' to be individually isomorphic to some sentence in 'A': the two sets must be isomorphic. I will not bother to here, but it is quite easy to devise two grammars 'A' and 'B' such that each one of the sentences of 'B' is matched isomorphically by a sentence in 'A', but where the sets of sentences of the two grammars, due to failure to preserve realphabetizational symbol-identity, are not isomorphic.

2.6. Comment on Thorough Inclusion.

From the informal definitions given above, it is plain that it would be relatively easy to devise a grammar for a large subset of all

e.g. French sentences, which would be thoroughly included in some grammar for a large subset of the set of all English sentences. In fact, since PLACEBO IV is thoroughly included in PLACEBO V, it is possible to "reterminalize" PLACEBO IV so that all lexical items are French ones---the resulting generations are largely gibberish, to be sure---where the product of such an operation is thoroughly included in PLACEBO V. More seriously, both "French PLACEBO IV" and the English PLACEBO V could be altered here and there, perhaps exclusively at the pentterminal level, so that the French microgrammar generated well-formed French sentences, PLACEBO V generated only well-formed English sentences, and PLACEBO V still thoroughly included PLACEBO IV. Or, if this could not quite be done, two other large microgrammars might be constructed so as to be related in this way. The relation "thorough inclusion", then, may apply to some useful cross-language limited natural-language systems, such as workers in Mechanical Translation may come to be interested in.

2.7. Radical Inclusion.

We will say that a grammar 'B' is radically included in some grammar 'A' if 'B' is thoroughly included in 'A' and sentences structurally isomorphic in 'A' and 'B' are formally identical.

That is, the sentences in the two grammars which have identical analyses and which are manifested as equivalent strings (identical except for realphabetization), are identical in form (are not realphabetizations).

This last is a slightly more trenchant notion than those preceding: for example, PLACEBO IV is radically included in PLACEBO V.¹⁷ This is also a somewhat more practical notion, in that in practice -- technical "undecideability" aside -- it should be easier to determine whether two grammars are related by radical inclusion than to determine whether they are related merely by thorough inclusion. The generation by 'B' of one string not identical in form to some string generated by 'A', suffices to rule out the radical inclusion of 'B' in 'A'.

Since radical inclusion subsumes and presupposes thorough inclu-

¹⁷ Checked manually.

sion, all remarks made above about the relations between thorough inclusion on the one hand, and weak and strong inclusions on the other, apply mutatis mutandis for radical inclusion.

Note, lastly, that the radical inclusion of 'B' in 'A' can never disambiguate 'B'; for inclusion can only preserve, compound, or create ambiguity: never reduce it.

2.8. Manubrial Inclusion.

We will say that a grammar 'B' is manubrially included in some grammar 'A' if 'B' is radically included and every pair of structurally-isomorphic symbols from 'A' and 'B', contains only symbols identical in form.

Manubrial inclusion is of course the notion of least linguistic interest, since from the point of view of Language the formal identity of nonterminal symbols is of no consequence whatever, except perhaps in some peripheral way (e.g. if the symbol-names are themselves to be analyzed). But on the other hand manubrial inclusion is by far the most practical notion advanced in these pages, since it is much the easiest to test for; no elaborate algorithm need be pursued to ferret out every possibility of realphabetization. For example, it is known that PLACEBO IV is radically included in PLACEBO V only because IV is manubrially included in V.

Since all linguistic interest resides in radical inclusion, rather than in manubrial inclusion, all of the following remarks on the particulars of IV's inclusion in V, will deal with radical inclusion only.

2.9. PLACEBO IV's Radical Inclusion within PLACEBO V.

Now, after much ado about setting the scene, we consider the effects of insisting that PLACEBO IV be radically included in PLACEBO V.

2.9.1. Why Bother?

It must be obvious, with no further discussion, that it would be far easier to "base" PLACEBO V on IV in some relaxed way than to build it so as to radically include IV. For the more rigorous demand is

tantamount to requiring that the microgrammarians never bury his mistakes ---or even, as architects do, cover them with ivy. Every misguided or shortsighted decision made earlier, will be preserved; and will in many cases be exposed more glaringly and be more troublesome. In which case, it is reasonable to ask why anyone should take the trouble.

The answer is that a very real practical benefit can ensue. For the writing of large microgrammars, where "large" equals 1,000 rules and up, is a tedious and rather time-consuming affair; to build a 5,000-8,000 rule microgrammar may take one or two years. If this microgrammar is being constructed for some use or other -- say for an artificial intelligence system -- then the microgrammar will be but one of several components, ideally all being developed concurrently toward the common end. Yet if any of those components must be made to "serve" or "be served by" the microgrammar, such a component cannot be started till the microgrammar is completed, unless some thought is given to concurrent development. Clearly this microgrammar-bound component will be worthless if it is developed for a microgrammar-fragment which is superseded as the microgrammar is expanded: either wholly superseded or superseded only partially but in a haphazard manner. For concurrent development of mutually-dependent components, all of the matched parts must be incorporated into matched wholes; each microgrammar must be radically included in the next one. Or close to it, at least: the exceptions to the preservation of radical inclusion must be few enough to be conveniently kept track of.

In the aforementioned ITSELF artificial-intelligence system the last PLACEBO will be tied to at least one other component, in all probability: this is the algorithm which translates PLACEBO-analyzed sentences into machine-instructions and the like. Another PLACEBO-bound component will be the "iconic microgrammar" discussed briefly in Lipkin, Watt, and Kirsch, op.cit. It is imperative that such components be begun relatively early-on: imperative, then, that there can be built partial components for PLACEBO IV which can be incorporated into larger partial components (or be of service unchanged) for PLACEBO V, e.g.

2.9.2. The Risk of Ambiguity.

The primary risk run in radically including one microgrammar in another, is of course that in the process of so doing unwanted ambiguities may creep in. This danger is widely recognized among computational linguists, to such an extent in fact that it has been suggested that radical inclusion is in the main an impractical goal. Yet I think it unlikely that any microgrammar and its generated language will be such that a desired including language will demand a microgrammar which, if it is to include the smaller algorithm, must necessarily be ambiguous. So that the problem is not formal but pragmatic: and insuring against spurious ambiguity merely entails extensive watchfulness.

However, a successful attempt to avoid unwanted ambiguities may have a secondary effect: the including microgrammar may have to go to such lengths to avoid some ambiguities that its list of rules is artificially increased, and greatly so. We might justly call this phenomenon one of "inflation"; and assuredly PLACEBO V is "inflated" in this sense.

Let us pass to an example.

On page 36, above, the following rule may be found:

Q1RELP = EE1POS + SB1 + RELOB1.

On the facing page 37, we find the PLACEBO V expansion of this rule:

Q1RELP = EE1POS + SB1 + RELOB1 , EE1POS + SB1 + DQ + RELOB1 ,
EE1POS + INDEF1Q + XDQ + RELOB1 , ETHP1 + WHCL1XB.

The first segment of the PL/V rule simply preserves the whole of the corresponding PL/IV rule. The second segment preserves the same PL/IV rule, but adds a new element: "DQ". The third segment preserves some of the PL/IV rule, but adds an element "XDQ", while substituting "INDEF1Q" for "SB1". The fourth segment is wholly new.

The symbol "EE1POS" instantiates immediately as "is"; "SB1" will eventually instantiate as a noun or as a pronoun: "this", "that", or "this/that/the (±ADJECTIVE) thing". "RELOB1" instantiates eventually as one of a large set of RELative OBjects, e.g. "next to the _____".

"DQ" will instantiate as one of the adverbs that can occur (in this position) in a question. But "XDQ" instantiates either as "DQ" or as "X"; and "X", the "overt deletion pentterminal", in effect deletes this node entirely, so that entering the "XDQ" node is equivalent to being presented with a choice between continuing into "DQ" or halting. Any rule "A=B+XDQ+C", then, is equivalent in effect to the two rules "A=B+C" and "A=B+DQ+C". This "X-rule" method of compressing two rules into one, where the two rules differ only in that one includes an extra symbol, has been used in part of the "Q1RELP" rule cited above, i.e. in the instance "EE1POS+INDEF1Q+XDQ+RELOB1". Thus the symbol "XDQ" has been brought into being, to serve wherever either the presence or absence of "DQ" is allowable. Yet "XDQ" cannot be used throughout the "Q1RELP" rule for this purpose. The absence of "DQ" has already been taken care of in the string brought (forcibly) over from PLACEBO IV -- "EE1POS+SB1+RELOB1". If now the next string in this (PL/V) rule were given as "EE1POS+SB1+XDQ+RELOB1" -- which seems reasonable enough in light of the previously-cited use of "XDQ" -- then all of the "EE1POS+SB1+...+RELOB1" eventual strings (i.e. omitting any "DQ") would have two derivations: one from the "X" choice offered by "XDQ"; one from the absence of any "DQ"-instantiating symbol in the three-symbol string. Since such an ambiguity is intolerable, the "Q1RELP" rule must be given as cited, with two instanced strings included where one "XDQ"-containing instanced string would, if PLACEBO IV had not intruded, have done as well. It is just such considerations as this which "inflate" an including microgrammar.

It is not always so easy to forestall ambiguities of the kind just discussed; in the final analysis they are best guarded against by constant recourse to mechanical parsing of submitted sentences: the ambiguities thus diagnosed can be struck out as discovered. I do not yet have a practical mechanical parser for the PLACEBO microgrammars, so it would be foolish of me to claim that PLACEBO V has no unwanted ambiguities built into it.

2.10. A Practical Alternative to Radical Inclusion.

In view of the disadvantages of radical inclusion strictly construed, an alternative proposal might be welcome: a proposed method of letting work on microgrammar-bound programs proceed concurrently, with its future usefulness guaranteed, while freeing the microgrammarians from the constraints of radical inclusion. From what has been said above, it is clear that this "guarantee" and this "freedom" can only be relative; a compromise with radical inclusion, then, will be acceptable only to the extent that the microgrammarians' coworkers show themselves willing to redo some portion of their work. "Partial radical inclusion" -- the informal property being discussed here -- must be part of a 'social contract'; I see no hope at present of defining it very exactly, or of predicting the scope of coworkers' tolerance.

In any case, PLACEBO V will only be partially radically-included in PLACEBO VI (now a-building); we will see whether anything can be learned from this experience; and if learned, communicated.

3. Sentences from Random Production.

A microgrammar may or may not have "closure" with respect to some natural language, e.g. English. A microgrammar which is completely closed in this sense generates only sentences of e.g. English, all with their correct structural descriptions. Now, it has been said many times¹⁸ that English is beyond the strong generative capacity of the Context-Free model: but obviously there are subsets of English which are within CF strong generative capacity;¹⁹ and there are even larger subsets of English which are clearly within CF weak generative capacity. Thus there may be built CF microgrammars which are closed with respect to English. If in this regard we distinguish between "strong" and "weak" closure -- the meaning of which terms is obvious in the present context -- then we may say that there may be built microgrammars which are both weakly and strongly closed.

¹⁸ See e.g. Chomsky, op.cit., pp.297 ff.

¹⁹ Ibid.

PLACEBO V generates many terminal strings whose assigned structural descriptions would rightly be labeled inadequate with respect to any acceptable full-scale grammar of English. (Prenominal adjectival strings are an example of such inadequacy)²⁰. Thus, this microgrammar plainly falls short of strong closure. The case for weak closure is often harder to make out, for here we run afoul of the question of grammaticality: what terminal (printed) strings are so grossly malformed that no assigned structural description can make them into English sentences? Generally, PLACEBO V is much closer to achieving weak closure than to achieving strong closure -- this is hardly surprising -- ; but there are many "borderline" strings generated by this microgrammar, and some which to me seem to overstep the border into ungrammaticality. Such a string as:

"Are there always any neurons near the astrocyte?" seems clearly beyond the pale, due to the requirement in English that strongly-positive questions (e.g. any question containing "always") employ "some" instead of "any".²¹ Yet it is far easier to let PL/V generate a large set of questions containing "always", nearly all of which are well-formed, than to make it generate all of that set less the few which are malformed. So that PLACEBO V has been left somewhat short of complete weak closure.²²

20 Chomsky takes up the similar problem of coordinated predicate adjectives on pp. 298-9, op.cit.

The question of whether the artificial-intelligence deictic situation can compensate for lack of strong closure, will be taken up in a later paper.

21 Of course this is far from a complete description of the named effect.

22 It is my hope -- it may be a vain one -- that the sentences actually submitted to any artificial intelligence device using PLACEBO V will be largely such as to receive correct structural descriptions, perhaps in a less-than-global meaning of "correct". (That is, they may be acceptable in the limited context though still not exactly the sd one would want a "quasi-complete" grammar to assign.) For example, prenominal adjectival strings containing only two adjectives are more correctly analyzed than are such strings containing three or more adjectives. It may be possible, moreover, to construct a limited context-sensitive device to peruse context-free analyses and improve them where needed.

Generative closure is most easily gaged by examining the results of computer-production from the rules of the microgrammar. A "random generation" routine (more properly, "random production") for producing sentences from grammatical rules has been amply described by Yngve²³; and a particular such routine, as applied to PLACEBO IV, has also been described.²⁴ That same routine, as adapted for larger microgrammars by R. W. Hsu²⁵, has been used to produce the sentences from PLACEBO V which follow on the next few pages, each with its accompanying "trace" of generation. These "traces" show how the sentence in view is generated from the rules of PLACEBO V -- i.e. how the computer produced the sentence --; working through four or five of these "traces", for anyone who has the patience, is the easiest way to become familiar with the microgrammar. Full instructions for reading these "traces" are offered in the PLACEBO IV paper; here let it suffice to point out that every symbol preceding the symbol "/" is penterminal, and is matched by a terminal symbol (without flanking asterisks) in the string itself; each symbol is preceded by "/" or by the symbol which instantiates it, if any.

23 Yngve described "random generation" in "The Depth Hypothesis", Proceedings of the Twelfth Symposium in Applied Mathematics, ed. Roman Jakobson, Providence: 1961; and in "Random Generation of English Sentences", 1961 International Conference on Machine Translation of Languages and Applied Language Analysis, Volume I; London: 1962; and again in "Final Report to the National Science Foundation", Massachusetts Institute of Technology Research Laboratory of Electronics, Cambridge: 1965.

24 Computer Programs for Processing Phrase Structure Grammars, by Donald Cohen, Walter Sillars, Richard B. Thomas, National Bureau of Standards Technical Report 8161; 1964; and also in the previously-referenced paper on PLACEBO IV.

25 To be reported on in a future publication.
