U.S. DEPARTMENT OF COMMERCE National Bureau of Standards

## THE NATIONAL BUREAU OF STANDARDS

The National Bureau of Standards ${ }^{1}$ provides measurement and technical information services essential to the efficiency and effectiveness of the work of the Nation's scientists and engineers. The Bureau serves also as a focal point in the Federal Government for assuring maximum application of the physical and engineering sciences to the advancement of technology in industry and commerce. To accomplish this mission, the Bureau is organized into three institutes covering broad program areas of research and services:
THE INSTITUTE FOR BASIC STANDARDS . . . provides the central basis within the United States for a complete and consistent system of physical measurements, coordinates that system with the measurement systems of other nations, and furnishes essential services leading to accurate and uniform physical measurements throughout the Nation's scientific community, industry, and commerce. This Institute comprises a series of divisions, each serving a classical subject matter area:
-Applied Mathematics-Electricity-Metrology-Mechanics-Heat-Atomic Physics-Physical Chemistry-Radiation Physics-Laboratory Astrophysics ${ }^{2}$-Radio Standards Laboratory, ${ }^{2}$ which includes Radio Standards Physics and Radio Standards Engineering-Office of Standard Reference Data.

THE INSTITUTE FOR MATERIALS RESEARCH . . . conducts materials research and provides associated materials services including mainly reference materials and data on the properties of materials. Beyond its direct interest to the Nation's scientists and engineers, this Institute yields services which are essential to the advancement of technology in industry and commerce. This Institute is organized primarily by technical fields:
-Analytical Chemistry-Metallurgy-Reactor Radiations-Polymers-Inorganic Materials-Cryogenics ${ }^{2}$-Materials Evaluation Laboratory-Office of Standard Reference Materials.

THE INSTITUTE FOR APPLIED TECHNOLOGY . . . provides technical services to promote the use of available technology and to facilitate technological innovation in industry and government. The principal elements of this Institute are:
-Building Research-Electronic Instrumentation-Textile and Apparel Technology CenterTechnical Analysis-Center for Computer Sciences and Technology-Office of Weights and Meas-ures-Office of Engineering Standards Services-Office of Invention and Innovation-Clearinghouse for Federal Scientific and Technical Information. ${ }^{3}$
${ }^{1}$ Headquarters and Laboratories at Gaithersburg, Maryland, unless otherwise noted; mailing address Washington, D. C., 20234.

2 Located at Boulder, Colorado, 80302.

## Preface

This note describes and evaluates an attempt to analyze the picto-
rial structure of Chinese characters. The approach underlying this
analysis is borrowed from the field of linguistics. The collection of objects under study is the set of all well-formed Chinese characters;
that is, the set of all character-like structures which an informant accepts as actually occurring or possibly occurring. The set of these well-formed Chinese characters is considered to be a language. The corpus on which the grammar is based is Mathews' (3) (see Bibliography, page 118) minus a handful of entries which are deliberately excluded.l/ The task of analyzing this language is taken to be that of constructing a grammar to account for the pictorial structure of characters by generating objects which correspond to characters. These

1/ More precisely, our corpus consists of hand-written copies of the characters in Mathews'. See Appendix A for a listing and classification of the excluded entries.
objects are well-formed at a high (syntactic) level of structure only, and are properly viewed as requiring further processing by an output transducer which is yet to be constructed. This transducer will
contain rules for size and shape variation in character sub-parts and rules for precise spatial placement of character sub-parts.

The grammar l/ displayed in this note is a mixture of various formalisms which in turn are inspired by formalisms used in the fields of linguistics and computation. Although it is a mixture, the central property of the grammar is its capability of imposing a kind of phrase structure on its output characters.2/

1/ The grammar, GCC-3 (Grammar for Component Combination, number three),
is a refinement and extension of the concepts developed in two previously
constructed grammars: GCC-1, in Rankin, Sillars, and Hsu (5) and GCC-2, in Rankin (4).

2/ See Chomsky (2), Chapter 4 for a discussion of phrase structure grammars for natural languages.

Phrase structure grammars are well-suited for describing natural
languages or sub-languages whose sentences show an internal structure
in terms of hierarchical combinations of smaller units (e.g, words or morphemes) into larger units (e.g., phrases and ultimately sentences).

Phrase structure grammars are also well-suited for describing such
artificial languages as some of the logical calculi and some of the programming languages.

It is now suggested that modified phrase structure grammars can
well describe languages other than the one-dimensional languages just
mentioned. In particular, modified phrase structure gramars are well-
suited for describing the two-dimensional language of Chinese characters

The following discussion will be in three parts. First, there is
a section dealing with the description of the various phenomena and
processes in the language of Chinese characters. Second, there is a
section in which the grammar constructed to account for this language
is characterized and discussed. Finally, there is a section dealing with the evaluation of this grammar in terms of criteria originally proposed for evaluating grammars for natural languages.

#### Abstract

A linguistic analysis of one aspect of the structure of Chinese characters is presented. The analysis is an extension into two dimensions of a general approach to one-dimensional language study. Results of the analysis are in the form of a threelevel generative grammar. The first level formalizes restrictions governing the general complexity of wellformed Chinese characters; the second level formalizes co-occurrence constraints among character components and the particular spatial arrangement of these components in classes of characters; the third level constitutes a procedure for selecting actual components from a lexicon. Finally an evaluation of the grammar is presented, in terms of criteria used in evaluating natural language grammars.

Key-Words

Chinese characters grammar
generative grammar component combination
phrase structure grammar linguistics
frame embedding two-dimensional languages

This discussion of the language is based on two fundamental notions:
component and frame. Chinese characters may be viewed as occupying a
hypothetical square;1/ they may also be viewed as being composed of re-
curring sub-parts - here called components. The segmentation of char-
acters into components segments the square in a variety of ways. These segmentations of the square are here called frames. Frames can thus be viewed as abstract representations of classes of characters.

With the notion of component and frame now introduced, the notion
of positioning of components with respect to frames can be discussed.

The following position classes are necessary in a description of

Chinese character component combination: NORTH, SOUTH, WEST, EAST,
 as follows:

1/ This is, in fact, a part of the traditional native Chinese view of Chinese characters.

the component $才$ is a WEST and the component $\theta$ is an EAST． The character $\frac{1}{3 x}$ is segmented as follows： | $\sqrt{3}$ |
| :---: |
| ，and is re－ | presented by the frame

 ；the component $\longmapsto$ is a NORTH and the component 豕 is a SOUTH．The character 木 is segmented as follows：$\square$ ，and is represented by the frame $\square$ ；the component $\square$ is a BORDER and the component 大 is an INTERIOR。 （BORDERS may occupy two，three，or four sides of the square．Other examples are $\dot{z}$ ，and $\square$ ．）Thus，a frame for any two－component character consists of two sub－frames of equal area．

The only such frames are
 －The single－component character $\nrightarrow$ is represented by the frame
 and the component $\biguplus$ is a FREE．

Based on the discussion so far，in particular the notions of
frame and position class，we can represent the above four characters as：

abbreviations for the position class names．In fact，the grammar
provides further information for $W, E, N$ ，and $S$ in the form of sub－
scripts on these symbols and these will be discussed just below．

There are，to be sure，characters of greater complexity than
those mentioned above．For example，there is the character 攸， whose frame can be viewed as being derived from simple frames by means of a process of frame－embedding．後 is represented by the frame，which is derived by means of the embedding of

in
the EAS＇part of
 －Note that here embedding results in two sub－frames of equal area，the sum of their areas being equal to the area of the sub－frame not embedded in．Frames for other complex char－ acters are derived by means of similar embeddings．1／

A final word on positioning．Most components occur in many but not all positions．Only a few occur in only one position．As was seen above；the component $才$ is a WEST and an INTERIOR；it is 1／Actually，any frame except $F$ is derived via frame－embedding． See page ll，ff．
also an EAST，a NORTH，a SOUTH，and a FREE．The component a WEST and an EAST，and nothing else．The component $\dot{j}$ is a BORDER on 1 y ．

The broad outline of the phrase structure of Chinese characters arises out of this classification of components into position classes．

However，if a grammar were constructed to represent this and only this classification，it would be inadequate because it would generate a great deal of unacceptable output．Further inspection of the co－ occurrence properties of components has prompted us to sub－classify each position class according to the dimensions of strength and adjunctiveness．

Before discussing these two co－occurrence properties，we will
have to introduce the concept of＂in construction with＂．Two components
are in construction with each other if they occur in sub－frames of equal area．For example，in 庙，不 and $G$ are in con－ struction with each other．The frame for 大日，which is $\square$ ， contains two sub－frames of equal area，one in which $\$$ occurs and
one in which
complex character sub－part if it occupies a sub－frame whose area is
equal to the sum of the areas of the sub－frames occupied by the com－ ponents in that complex sub－part．For example，後 has the frame

area is equal to the sum of the areas of the sub－frames occupied by幺 and 久 ，namely，the shaded sub－frames：

We are now ready to introduce the concept of strength which was
mentioned just above．A component is strong in a particular position
if it can be in construction with many single components and with many
complex character sub－parts while in that particular position．It is
perhaps the case that many of the strong components in our lexicon are so limited in terms of the number of components with which they can
occur that they do not fit this definition，under any reasonable inter－
pretation of the term＂many＂（even though the notion＂can be in
construction with＂is not intended to be corpus restricted）．There
seems，in fact，to be a scale of strength，only the outlines of which are understood currently．I／At the present time we therefore consider a component to be either strong or not strong with respect to a partic－ ular position．For example，$\ddagger$ is strong in WEST because it can be in construction with $\theta$（in 有日），$L$（in 木L ）and with many other single components；and with $\begin{aligned} & \text { 口（in 木吉 ），可 }\end{aligned}$ （in 有同 ），and with many other complex character sub－parts．Simi－ larly，$\ldots$ is a strong SOUTH，$\|$ is a strong EAST，and $+\boldsymbol{t}$ is a strong NORTH．All BORDERS are strong．INTERIORS（since no INTERIOR can occur with many BORDERS）and FREES（since strength is a property of components in construction）are not strong．It is typical that a component which may occur in several positions is strong in one or more positions and not strong in others．A good example is $\square$ ．It is strong in SOUTH and not strong in EAST，WEST，and NORTH．

1／See page 55 for a discussion of this problem．Much more informant work is needed before this limitation can be corrected．

A property of certain strong components is adjunctiveness.1/

A strong component is either an adjunct or it is not regardless of position. That is, an adjunct is an adjunct wherever it occurs. An adjunct is a strong component which cannot occur in FREE. Examples of adjuncts are 1 and $;$ in WEST, $\sqrt{j}$ in EAST,
$\cdots$ and $川$ and $\longmapsto$ in SOUTH and $\longmapsto$ in $\longmapsto$ artH. Adjuncts
have the further property that they may never be in construction with
adjuncts. Thus the structure $\frac{1}{10}$ is not an acceptable character since both 111 and 1 are adjuncts. In fact, it was in order to avoid generating such unacceptable structures that the dimension of adjunctiveness was established.

1/ Rankin (4) recognized both strong and non-strong adjuncts (p.32) Further informant work has prompted us to reassign non-strong adjuncts either to the class of strong adjuncts or to the class of FREE
components. This solution, incidentally, seems to be not entirely satisfactory.

Since they must be strong components, adjuncts occur only in WEST,

EAST, NORTH, SOUTH, and BORDER. Among the strong components in each of these position classes, some are adjuncts and some are non-adjuncts.

Based on the discussion so far, we can give the grammar's full
representation of the four sample characters given on pages 2 and 3. For
朴, there is $I$, and for $\nrightarrow$, there is $F$. $W_{\text {sf }}$ determines a WEST component which is strong (by subscript s) and non-adjunctive (by subscript $f$ indicating that the component can occur
in FREE.) E determines any EAST component by lack of subscript, for any EAST can be in construction with a strong non-adjunctive WEST. $\mathrm{N}_{\mathrm{S} \overline{\mathrm{E}}}$ determines a strong (by s) adjunctive (by $\overline{\mathrm{f}}$ ) NORTH. $\mathrm{S}_{\mathrm{f}}$ determines a non-adjunctive (by f) strong or non-strong (by lack of s) SOUTH.
(Note how the constraints on the occurrence of strong components and adjuncts are governed by these subscripts.) B, I, and F are subscript-
less in the grammar, $B$ always being strong, $I$ and $F$ being insensitive to the strength dimension, but both $I$ and $F$ being non-adjunctive.
acters is that of component repetition．We here recognize four 1／ types of repetition；horizontal continuous，as in 貝貝 ；vertical， as in 女 ；triangular，as in $\square \square$ ；and horizontal discontin－ nous，as in $火 火$ ．With the exception of the horizontal discontin－ uous cases，all $2 /$ instances of repetition function in the grammar as non－ strong，non－adjuncts in WEST，EAST，NORTH，SOUTH，INTERIOR，and FREE．The horizontal discontinuous cases function as strong adjuncts

1／For a treatment of repetition which recognizes the existence of more than four types and which is non－generative in nature see Rankin（4）． In a generative treatment，such as we are presenting here，we feel that only these four should be recognized．

2／There are a few exceptions in this observation．Some structures， like $t+$ and $\square \square$ ，could be generated by repetition rules，but are not，because they are strong components and it is desirable that strong components be listed in the lexicon as single components．This in－ clusion of complex structures in the lexicon is one of the limitations in the current treatment．
in BORDER and do not occur in any other class．

These instances of repetition are represented in the grammar as follows：貝㞣 as C（horizontal continuous），女 as $\nabla$（vertical），$\square \square$ as $T$（triangular），and $火 火$ as
（horizontal discontinuous）．

## B．DETAILS

What follows now is a rather more detailed account of some of the phenomena and processes that have just been introduced．

The process of frame－embedding has been mentioned briefly．In this detailed treatment，we will use the notions of host－frames， occupant－frames，and product－frames．

Further，we will highlight the process of frame－embedding by ignoring all marks which in the grammar may occur in frames or sub－ frames－except for the mark H（for＂host＂），which is the recursive element in the grammar that activates the process of frame－embedding． We will refer to the sub－frame containing $H$ as the＂H sub－frame＂．

We will use the formula：

```
Occupant-frame + Host-frame }->\mathrm{ Product-frame
```

which is read "Embed the occupant-frame in the host-frame to produce the product-frame". The host-frame always has $H$ in one of its subframes (or in its only sub-frame in $H$ ). This one sub-frame may be thought of as the hypothetical square or size and shape transformations of it. The occupant frame (always of the form:

sub-frames. The product-frame of any embedding will have $H$ in one of
its sub-frames if the occupant-frame that produced it has an $H$ sub-
frame. The product-frame of the first embedding is always identical to the occupant-frame of the first embedding.

Sample Single Embeddings:

Occupant-frame + Host-frame $\rightarrow$ Product-frame

In general, $H$ may occur in any sub-frame except the border sub-
frame, since border is not a possible transformation of the hypothetical
square. (For purposes of this discussion, "border" sub-frames can be
filled by components from both the BORDER position class and the
horizontal discontinuous repetition class.) Thus there are no complex
borders.l/

If a product-frame contains an $H$ sub-frame, that product-frame is
then redefined as a host-frame. This redefinition is shown in the
following example.

1/ Actually there are some BORDERS which appear to be complex.

Examples are 血 and 屈 . Complexity in BORDER is extremely rare and we circumvent the problem by listing such instances as the two above as single components in the lexicon. Further, all instances of horizontal discontinuous repetition appear to subdivide the border sub-frame. However, they do conform to our general definition of

BORDER in that they occupy two sides of the hypothetical square (see page 3).

Occupant-frame + Host-frame $\rightarrow$ Product-frame
lst embedding:

2nd embedding:

Note that in the first embedding one of the sub-frames of the
occupant-frame contains $H$. It is this occurrence of $H$ that both allows the second embedding to take pl ace and also marks the pl ace where the second is to take place. If there were no $H$ sub-frame in the occupantframe, no second embedding could take place.

Further, no occupant-frame in the gramar may contain more than
one H sub-frame. This restriction imposes a "blocking" of embedding.

Once an occupant-frame has been embedded in a host-frame in any
embedding, the sub-frame which is equal in area to the $H$ sub-frame is
permanently blocked from embedding. Another way of saying this is that
the grammar does not allow any host-frame to contain more than one $H$.

In the following sample products the shaded sub-frames are blocked
from embedding:

There are further constraints on the process of frame-embedding.

First, there is an upper limit of four embeddings in the generation of any character--giving rise to a maximum of five sub-frames per frame.

Second, there may be only two BORDERS in the generation of a frame for any character. (With respect to this constraint, cases of horizontal discontinuous repetition are treated as BORDERS). Finally, there is a limit of four sub-frames per frame if any sub-frame is occupied by a case of horizontal continuous, vertical, or triangular repetition. This is so because these cases of repetition are in a sense multi-componential. In contrast, cases of horizontal discontinuous repetition function as a single-component BORDERS.

Blocking of embedding is closely related to the functioning of strong components in the following sense. A strong component must occur in every blocked sub-frame of a frame. Further, a terminal frame contains within it two sub-frames of equal area (shaded in the following examples:
 and
 ). A strong component must occur in at least one of these two sub-frames of equal area. It follows that an output character contains at most one non-strong component.
component may occur with one exception．There are no cases of adjuncts
being in construction with adjuncts．So，not both of the sub－frames
of equal area may be occupied by adjuncts．That is，for example，not
both shaded sub－frames in any one of the following frames may be occupied by adjuncts：

that in any output character there must be at least one non－adjunct．

Finally，not both sub－frames of equal area in any frame may be occupied by the same component．If it were otherwise，such output characters as 因 would be ambiguous（or derivable in more than one way）．One derivation of 目是 would be an EAST plus a WEST with Eilling both positions；the other derivation would be the correct one：that 目目 is a case of horizontal continuous repetition． II．THE GRAMMAR

A．INTRODUCTORY

The grammar is set up to generate output characters in three
stages．The gramar also imposes a hierarchical classification on the
set of all output characters, and this can best be seen by first
discussing the three stages of the generative process.

Stage one is a string of symbols generated by a finite state
diagram. This string controls the number and type of embeddings in the output character. I/ Stage two is a two-dimensional constituent array (generated via the process of frame embedding) which determines the two-dimensional phrase structure of the output character and governs the positioning, strength, and adjunctiveness constraints on the components to be selected. Stage 3 is the output character itself: a frame filled with components selected (via a lexical look-up procedure)
from the lexicon.

The hierarchical classification is as follows. Any stage 1
string determines a number of constituent arrays and any stage 2 frame
determines a number of output characters. Thus, the set of all strings

1/ The various constraints and phenomena discussed here in terms of the grammar have already, of course, been discussed in Section I, to which the reader is now referred.
permitted by the finite state diagram ultimately determines the set of all output characters. The hierarchy referred to can be depicted as a tree structure, as follows: State Diagram

String:

Constituent array:

Output character:

The path from KM to
 to the output character the derivation of this output character in terms of how the grammar generates it. The dashed line-----between nodes in the tree indicates that in general there are many (though finitely many) other nodes at the same stage dominated by the same node of the previous stage. 1/

1/ Or in the case of Stage 1 , other nodes dominated or generated by the state diagram.

## B. DETAILS

## To produce Stage 1:

Stage 1 is an output string from a finite state diagram, which
consists of a number of states with input and output transitions. One state is distinguished by having only output transitions, and this is the initial state. One state is distinguished by having only input transitions, and this is the final state. Along the transition arrows there are either one or two output symbols (K, G, H, H', M, M'). I/

1/ These symbols are explained on pages 21 and 22.
from the initial state to the final state (perhaps through intermediate
states) is begun. At each transition from state to state one output
symbol is produced. If there is only one symbol along the transition
arrow, that symbol is necessarily chosen. If there are two symbols along the transition arrow, one is chosen at random. The next transition causes a symbol to be produced to the right of the last-produced symbol, and so on. As the final state is entered, the last (rightmost) symbol is produced, and the process terminates, producing the string which is Stage $1: x_{1} x_{2} \ldots x_{n-1} x_{n} \cdot 1 /$

1/ Since $n$ cannot exceed 5, it might seem inappropriate to set up the
general case for this and all the other stages and processes in the
grammar. However, by so doing, we have achieved ease of manipulation and generality for such future applications as the study of frame-
embedding as an isolated process.

Sample output strings of the form $x_{1} x_{2} \cdots x_{n-1} x_{n}$, generated
by the state diagram, are: $\mathrm{KM}^{\prime}$ (by taking the topmost path through the diagram), G (by taking the bottom-most path through the diagram), KHM and KHHM (by taking two of the middle paths through the diagram).

The nature of any string generated by the state diagram determines the size and complexity of the final output character. For example no string may exceed length five, and this restriction guarantees that no output character shall have more than five components. Each symbol in the string represents a set of frames (see the correspondence table on pages 23 and 24). The frames of each set have certain properties in common, related to the embedding process, and to the border-non-border distinction. Border here includes not only the position class BORDER but also the discontinuous repetition cases, which are represented by the same frame configuration as the BORDER position class and which function in the grammar subject to the same restrictions. $K=\left\{\begin{array}{l}\mathrm{H} \\ \hline\end{array}\right.$ is the one frame which is a host only. That is, it
is the initial step with respect to frame embedding.
$G=\{\boxed{F}\}$ is the one case of non-embedding. It is neither a host nor an occupant.

are the sets of frames which function as both hosts and occupants.

They are the intermediate steps with respect to frame embedding. They
are distinct sets in that $H$ is non-border and $H^{\prime}$ is border.

are the sets of frames which function as occupants only. They are the
terminal steps with respect to frame embedding. They are distinct in
that $M$ is non-border and $M^{\prime}$ is border.

Finally, the state diagram (by distinguishing $H$ from $H^{\prime}$ and $M$ from M' and by prohibiting certain transitions) guarantees that no output string may contain more than two instances of "symbol-prime". Thus it guarantees that no output character may contain more than two borders.

## To produce Stage 2:

And now, before discussing the process that generates Stage 2,
we will display the output symbol-to-frame correspondence table referred to above. Each output symbol of the state diagram corresponds to a set of frames. These output symbols appear as column headings. The filled frames are listed underneath.

Table of Correspondences Between Output Symbols from Stage 1 and Frames:

| $N_{s}$ |
| :--- |
| $H$ |

| $N_{s I}$ |
| :--- |
| $S_{f}$ |

| $N_{\text {sf }}$ |
| :--- |
| $S$ |

T

There are two steps in the process that generates a Stage 2
constituent array from Stage $l$ string. First, a sequence of frames
is created. Second, if there is more than one frame in the sequence,
these frames are compiled into a constituent array.

First, each symbol in any string of Stage 1 corresponds to a
column in the table of correspondences. To obtain the sequence of
frames, select at random one frame from each column indicated by the

Stage 1 string. Thus a sequence of frames is created: $E_{1} \ldots E_{n}$. The
frames of the sequence $E_{1} \ldots E_{n}$ consist of sub-frames which contain
either or both of two types of marks: (1) the mark H (for Host) which
sets up the process of frame embedding and (2) the marks called con-
stituents which will later be used in the process of component select-
ion. At this stage in the process, since we are concerned with frameembedding, only the frame configurations and the mark $H$ will be relevant to our discussion.

Second, when there is more than one frame in the sequence, the process of frame-embedding is initiated so as to compile the sequence of frames into a constituent array.

To produce the constituent array, apply the frame-embedding formula:

$$
\text { Occupant-frame + Host-frame } \rightarrow \text { Product-frame }
$$

to the sequence of frames:

$$
\mathrm{E}_{1} \mathrm{E}_{2} \ldots \mathrm{E}_{\mathrm{n}} \quad 1 \leq \mathrm{n} \leq 5
$$

The frame-embedding process may be viewed as a recursive process
initiated by $E_{1}$ which is the hypothetical square, or host-frame of the first embedding. Hence we will set $\mathrm{E}_{1}=\mathrm{H}_{1} ; \mathrm{H}_{1}$ for the first host-frame. The subsequence $E_{2} \ldots E_{n}$ is the set of occupant-frames which are called upon during the embedding process, one occupant-frame necessary for each embedding. Note that where there is only one frame
in the sequence, it is not possible to define either host or occupant
frames.

Embed occupant-frame $\mathrm{E}_{2}$ in host-frame $\mathrm{H}_{1}$ to obtain productframe $\mathrm{H}_{2}$. Redefine $\mathrm{H}_{2}$ as the host-frame of the second embedding. Embed $\mathrm{E}_{3}$ in $\mathrm{H}_{2}$ to obtain product-frame $\mathrm{H}_{3}$. Continuing in this way, embed occupant-frame $E_{i}$ in host-frame $H_{i-1}$ to obtain frame $H_{i}$, etc., until $\mathrm{E}_{\mathrm{n}}$ is embedded in $\mathrm{H}_{\mathrm{n}-1}$ to obtain the final product-frame $\mathrm{H}_{\mathrm{n}}$, which is defined to be the constituent array.

A distinction should be made between $H$ and $H_{i}, i=1,2, \ldots, n$. $H_{i}$ is a well-formed frame with an $H$ in one sub-frame. $H$ is a mark which indicates the precise location of embedding. $H_{1}=E_{1}$ is the hypothetical square with an H inside, $H \quad$. Size and shape transformations of this hypothetical square are created automatically as we go through the recursive process. In other words, the sub-frame containing an $H$, of a product-frame $H_{i}$, is considered to be the transformed hypothetical square.
$H$, which is present in one sub-frame of each $E_{i}$ except $E_{n}$ and each
$H_{i}$ except $H_{n}$ (constituent array), acts as the indicator of the subframe in which the next embedding is to occur. In this way $H$ is the activator of the frame-embedding process. When an $H$ fails to appear in a product-frame after an embedding has taken place, that product-frame cannot be redefined as a host-frame, and the process stops. That final product-frame where $H$ fails to appear is, of course, $H_{n}$, the constituent array.

This discussion of the recursive process of embedding occupant-
frame is host-frame to produce product-frame and redefining productframe of the previous embedding as host-frame and embedding again, until the constituent array $\left(H_{n}\right)$ is obtained may be expressed in compact form as the following sequence of formulas where + is the embedding operation:

$$
\begin{aligned}
& \mathrm{E}_{2}+\mathrm{H}_{1} \rightarrow \mathrm{H}_{2} \\
& \mathrm{E}_{.3}+\mathrm{H}_{.2} \rightarrow \mathrm{H}_{.3} \\
& \begin{array}{l}
\cdot \\
\dot{E}_{i}+\dot{H}_{i-1} \rightarrow \dot{H}_{i} \\
\cdot \\
\dot{E}_{n}+\dot{H}_{n-1} \dot{C}_{n}
\end{array} \\
& 1 \leq n \leq 5
\end{aligned}
$$

For each occupant-frame + host-frame embedding a product-frame is
produced. This product-frame is then the host-frame of the next
formula in the sequence. The recursive nature of the embedding process
is evidenced by the generation of a sequence of formulas in which there
is a successive production of product-frames and redefinition as host-
frames. The sequence ends with the production of the final product-
frame $H_{n}$, the constituent array.

An example of the generation of a constituent array from an output
string is now given:

The string KHM gives the sequence of frames $E_{1}, E_{2}, E_{3}$, and
these frames then enter into the embedding process:

$$
\begin{aligned}
& \text { Occupant-frame }+ \text { Host-frame } \rightarrow \text { Product-frame } \\
& \qquad \mathrm{E}_{\mathrm{i}}+\mathrm{H}_{\mathrm{i}-1} \rightarrow \mathrm{H}_{\mathrm{i}}
\end{aligned}
$$

The process is repeated in this case until $E_{3}$ is embedded in $H_{2}$ to
produce $\mathrm{H}_{3}$, the constituent array.

To produce Stage 3:

We will now describe the process which generates an output char-
acter from a Stage 2 constituent array. The process selects a component
in the lexicon for each constituent which occurs in the constituent
array of Stage 2. The constituents are handled in order according to the size of the sub-frames that they occupy - from largest to smallest.

For constituent arrays having two sub-frames of equal size a diagonal order, from top-left to bottom right is followed. 1/ Specifically, the

I/ Actually, this corresponds to the traditional stroke order. A person trained in traditional calligraphy writes most Chinese characters start-
ing at top-left of the hypothetical square, and finishing at bottom-right.
"north" sub-frame precedes the "south" sub-frame; "west" precedes "east";
and "border" precedes "interior."

These constituents are of the form $\Sigma$, where $\Sigma$ is a symbol cor$\alpha$
responding to one of the position classes, or to one of the repetition classes, and $x$ is a subscript which gives information on strength and adjunctiveness. The combination of $\Sigma_{\alpha}$ 's allowed guarantees that each output character has at least one non-adjunct, and at most one non-strong component (see pages 15 and 16).

For instance, for the Stage 2 constituent array | $W_{s f}$ | $N_{s f}$ |
| :--- | :--- |
|  | S | , the constituents are (in order) $W_{s}, N_{s f}$, and $S$. In the case of $W_{s}$, we have $\sum$ as $W$ and $\alpha$ is the single subscript $s$. For $N_{s f}$ we have $\sum$ as $N$ and $\alpha$ is the double subscript sf. Finally, $S$ is an example of $\Sigma$ with $\alpha$ as the null subscript.

Next it will be necessary to describe the lexicon, an essential tool used in the creation of stage 3 .

The lexicon is a table with components $1 /$ down the side for each
row, symbols across the top for column headings, and tallies at certain row-column intersection points signifying that the components may occur
in the positions signified by column headings $W, E, N, S, B, I$, or $F, \underline{2 /}$ or may undergo the repetition processes signified by $\nabla, C, T$ or $D$. 3/

1/ Each of the components has a unique number associated with it. These numbers are not a part of the formal apparatus of the grammar. We are including them for the purpose of making lexical look-up easier for those readers familiar with Chinese characters. The component numbers are of the following form: S.T.N, where $S$ is the number of strokes in the component $(S=1-19), T=1-8$ characterizes the types of the last stroke (last in the sense of traditional stroke order) of the component: 1 for horizontal, 2 for vertical, 3 for dot, 4 for \-like, 5 for / -like, 6 for / -like, 7 for hooked, and 8 for multi-directional. $N$ is the number of the component in the sub-list.

2/ These column headings are abbreviations of the position classes discussed in Section $I$. $W=W E S T, E=E A S T, N=N O R T H, S=S O U T H, B=B O R D E R$, $I=I N T E R I O R$, and $F=F R E E$.

3/ These column headings are abbreviations of the repetition processes discussed in Section $I$. V=Vertical repetition, C=horizontal Continuous repetition, $T=$ Triangular repetition, and $D=h o r i z o n t a l$ Discontinuous repetition.

Sample Lexicon：
（The superscripts on some of the talies are to be ignored．Their significance will be explained on page 74．）

|  |  | W | E | N | S | B | I | F | V | C | T | D |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 3.2 .11 | Y | 8 |  |  |  |  |  |  |  |  |  |  |
| 3.3 .3 | 乡 | $\stackrel{-}{8}$ | $\bar{s}$ | $\bar{s}$ | $\bar{s}$ |  |  | x |  | x |  | x |
| 4.4 .4 | 文 |  | 8 | $s^{5}$ | $s^{5}$ | $x^{5}$ |  | $x$ |  |  |  |  |
| 6.3 .13 | 京 | $8^{5}$ |  |  | 8 |  | $x$ | $x$ |  |  |  | x |
| 6.8 .3 | $\frac{4}{儿}$ | $\bar{s}$ | $\bar{s}$ |  |  |  | $x$ | x |  | x |  |  |
| 7.1 .5 | 言 | $s$ | $s$ |  | 8 |  | x | x |  | x |  |  |
| 7.3 .3 | 貝 | 8 | $s$ |  | $s$ |  | x | x |  | x | $x$ |  |

In general，the lexicon will be used in the following way．For
any constituent $\Sigma_{\alpha}$ ，we examine the column specified by $\Sigma$ ，where $\Sigma$ is
any one of the eleven column headings，to determine the set of rows
which have tallies corresponding to the subscript $\alpha$ ．

If $\alpha$ is $f$ or includes either $f$ or $\bar{f}$（such as in $S_{f}$ or $N_{s f} \bar{f}$ ），
we must further determine the subset of these rows which also have
tallies in column F．Note that the column $F$ has two functions．First，

It is one of the columns denoted by $\Sigma$ ．Second（as in this part of the
discussion), it is a column to be searched for adjunctiveness information in conjunction with the search in column $\Sigma$.

The following chart summarizes the types of subscripts which may occur in each constituent mark, and the types of tallies which match the subscripts.

| Subscripts* | Tallies activated by $\alpha$ in: |  | Explanation |
| :---: | :---: | :---: | :---: |
|  | Column $\Sigma$ | Column F |  |
| $\varnothing$ | 8, E, x |  | The null subscript specifies a row which has any tally in the $\Sigma$ column. |
| 8 | s |  | The subscript specifies a row which has an $s$ tally in $\Sigma$. |
| f | s, $\overline{8}$ | x | The f subscript specifies a row which has both an $x$ tally in column $F$, and either an tally or an $\bar{s}$ tally in column $\Sigma$. |
| $\overline{\mathbf{s} f}$ | $\overline{5}$ | x | The $\overline{s i}$ subscript specifies a row which has both an $\bar{s}$ tally in column $\Sigma$, and an $x$ tally in column $F$. |
| sf | s | x | The sf subscript specifies a row which has both an s tally in column $\Sigma$, and an $x$ tally in column $F$. |
| sf | s | $\bar{x}$ | The sf subscript specifies a row which has both an stally in column $\Sigma$, and no $x$ tally in column $F$. |

* Note that $\overline{\mathrm{EF}}$ does not occur. See page 8 footnote.

For each of the first two cases ( $\varnothing$ and s) a set of rows is
determined by searching column $\Sigma$. For each of the last four cases ( $f, \overline{s f}, s f$, and $s \bar{f})$ a set of rows is determined by searching column $\Sigma$, and further, a subset of this set is determined by searching column $F$.

At this point, a single row is randomly selected from the set or subset
thus determined, and the component (if the symbol of the constituent
is $W, E, N, S, B, I, F$ ) or repetition of the component (if the symbol
of the constituent is $V, C, T$, or $D$ ) on that row replaces the constituent
being processed. This restriction prevents the class of ambiguous derivations mentioned on page 16.

The lexical search procedure can be summarized in the following
way:

Output character

An example of the generation of an output character from a
constituent array is now given.

The stage 2 constituent array, |  | $\mathrm{W}_{\mathbf{s}}$ |
| :---: | :---: |
|  |  |
|  | $\mathrm{S}_{\mathbf{s}}$ | , is processed to generate an output character in the following fashion.

First, the constituents are ordered according to the decreasing size of the sub-frames that they fill. Since there are two terminal sub-frames of equal size, the order of these last two is determined by the diagonal line procedure.

Then, the sets or subsets of rows which have tallies corresponding to each constituent are determined. In other words, column W will be searched for the set of rows which have tallies corresponding to subscript s. Column $N$ will be searched for the set of rows which have tallies corresponding to subscript $\bar{\Omega}$, and further, we determine the subset of this set of rows having $x$ tallies in column $F$. Finally column $S$ will be searched for the set of rows which have tallies corresponding to subscript $s$. To illustrate what is taking place at this point, the tallies corresponding to $W_{s}$ will be circled once in
the sample lexicon，the tallies corresponding to $N_{s f}$ will be circled twice，and the tallies corresponding to $S_{s}$ will be circled three times．

|  |  | W | E | N | S | B | I | F | V | C | T | D |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 3.2 .11 | Y | （3） |  |  |  |  |  |  |  |  |  |  |
| 3.3 .3 | 4 | $\overline{8}$ | $\overline{8}$ | 8 | $\overline{8}$ |  |  | x |  | x |  | $x$ |
| 4．4．4 | 文 |  | 8 | $s^{5}$ | （5） | $x^{5}$ |  | x |  |  |  |  |
| 6.3 .13 | 圱 | （5） |  |  | （s） |  | x | $x$ |  |  |  | x |
| 6.8 .3 | 去 | $\bar{s}$ | $\bar{s}$ |  |  |  | x | $x$ |  | $x$ |  |  |
| 7.1 .5 | $\frac{1}{\bar{\square}}$ | （s） | $\overline{8}$ |  | （s） | ； | x | x |  | $x$ |  |  |
| 7．3．3 | 目 | s | $\bar{s}$ |  | （8） |  | x | x |  | $x$ | x |  |

Then one of the rows in each set or subset is picked at random，
with the constraint that the row selected for $\mathrm{N}_{\mathrm{sf}}$ may not be the same
as the row selected for $S_{S}$ ，since they are in construction with each other．Again，one，two and three circles will be used to illustrate

|  |  | W | E | N | S | B | I | F | V | C | T | D |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 3.2 .11 | 1／1 | （8） |  |  |  |  |  |  |  |  |  |  |
| 3．3．3 | $\Sigma$ | $\bar{s}$ | $\overline{8}$ | （3） | $\overline{8}$ |  |  | x |  | X |  | x |
| 4.4 .4 | 文 |  | 8 | $8^{5}$ |  | $x^{5}$ |  | x |  |  |  |  |
| 6.3 .13 | 分 | $8^{5}$ |  |  | 8 |  | x | x |  |  |  | x |
| 6.8 .3 | $\frac{4}{\sim}$ | $\overline{8}$ | $\overline{8}$ |  |  |  | x | x |  | x |  |  |
| 7.1 .5 | 玄 | 8 | $\overline{\mathbf{s}}$ |  | 8 |  | X | x |  | x |  |  |
| 7．3．3 | 日 | 8 | $\overline{8}$ |  | 8 |  | X | x |  | X | X |  |

Finally，the component which occurs on the row of the tally
just selected replaces $\Sigma_{\alpha}$ 。

This example can also be represented in the following way:

Sample Derivation from Total Grammar:

## A. GENERAL REMARKS

How are grammars for component combination to be evaluated? There
are two criteria which are used here: completeness and tightness.

These criteria are well-known in the literature of natural language
study. Tightness and completeness taken together in fact constitute
the transformationists" "minimal requirements" on natural language
grammars - that they should generate all and only the grammatical
sentences of the languages under study. 1/

There are, of course, other conditions that might be put on a
successful grammar of component combination - conditions having to do
with simplicity, with the choice of a grammar model, with relative
correctness of structural descriptions assigned by the grammar to
output objects, with integratability of the grammar with other
grammatical processes necessary in the total description of Chinese

1/ See, for example, Bach (1), page 5.
characters, with possible applicability of the grammar or grammar model
to other two-dimensional 1 anguages, and so on. In this note, however, we will be concerned only with completeness and tightness.

GCC-3 constitutes an attempt to construct a simple grammar which is balanced between completeness and tightness. It seems to be nearly as simple as possible in terms of the size of the lexicon of components and the number and complexity of gramar rules. It is neither 100 per cent tight nor 100 per cent complete, but it would seem that any adjustment to make it tighter would result in less simplicity and/or completeness, and that any adjustment to make it more complete would also result in less simplicity and/or tightness.

## 1. Completeness

A complete gramar for the language of Chinese characters is one which generates all of the well-formed characters in the language. This is an extremely difficult condition to satisfy, if only because it is so difficult to determine in many cases exactly what is and what
is not in the language. I/ The problem here is probably no worse than the problem in natural language study of deciding for border-1ine strings whether or not they are grammatical sentences of the language under study.

A less demanding condition is that a successful grammar generate
all the well-formed characters in some target corpus.

Such a grammar will be called "corpus-complete", and a grammar
that is complete with respect to the language will be called "language-
complete." Only corpus-completeness will be used in evaluating GCC-3.

The grammar might then be tested against other corpora for corpus-
completeness. In this way, the language-complete gramar would be
approximated by the grammar which is corpus-complete for several corpora, but it would never be known whether the grammar actually attains language-completeness.

1/ Decisions on what is and what is not in the language are currently
based on judgments given by the informant.

## 2.

## Tightness

A tight gramar for the language of Chinese characters is one which generates only well-formed Chinese characters. Tight grammars are easy to come by. A trivial example would be a "grammar" which lists some small number of actually-occurring characters.

In a way analogous to the completeness situation, we may speak of corpus-tightness and language-tightness. If a GCC is language-tight, then it generates only those characters in the target corpus. It turns out that any serious GCC, i.e., one which attempts to reveal the internal structure of the characters (and does not simply list characters), is almost bound not to be corpus-tight. This is an empirical observation, and an analogous observation probably holds for any serious attempt at grammar construction for natural language corpora. Only language-tightness is used in this evaluation.

Lack of completeness implies insufficient output, or under-generation. Lack of tightness implies too much output, or over-generation. We have discussed over-generation of output characters so far, but
there is another type of over-generation, and that is the over-generation of derivations per character.

An output object from any grammar is said to be ambiguous if the
grammar can generate it in more than one way, i.e., provides more than one derivation of it. The problem of whether or not there are ambiguous
characters, or what would be meant by "ambiguous character" have by no
means been solved. However, it seems that every character in the
language is uniquely segmentable into components by the informant, and
therefore our current position is that there are no ambiguous characters
in the language of Chinese characters. Consequently, a grammar that
generates any character is more than one way "over-generates".
B. EVALUATION OF GCC-3

1. Completeness

GCC-3 appears capable of accounting for $94 \%$ of the acceptable
characters in Mathews＇．1／The characters that GCC－3 cannot account
for fall into seven known small classes．2／The grammar could be
adjusted so as to account for these classes，but only with a great loss
in tightness and／or simplicity．

First，there are those characters which contain more than five
components．Since the state diagram in the grammars sets a maximum of
five components per character，such characters cannot be accounted for．

Examples are：揭（ 才 ，十九，田，人 ，，and

（111）．

1／To arrive at an indication of how complete GCC－3 is，we conducted the following test．We selected（via a random number table） 200
characters from Mathews＇．We then attempted to generate each character
from GCC－3．We found that GCC－3 could generate 188 of the 200－－some
in more than one way．（See the discussion of ambiguity on pages 56－62）．

2／With the exclusion of possible clerical errors．

Second，there are those characters which are（or which contain sub－

parts which are）complex in both NORTH and SOUTH（represented by the frame | $H$ |
| :---: |
| $H$ | ，or in both EAST and WEST（represented by the frame

 with $\frac{\grave{2}}{\text { 白 }}$ ）and 声番（ 殸 in construction with 香 ）。
 and高品（

Third，there are those characters which contain weak components
in strong positions：either a weak component in construction with a
weak component or a weak component in construction with a complex
character sub－part．Examples of characters having a weak component in

男 are in construction but both weak，and 生男，where 生
and are in construction but are both weak．Examples of char－ acters in which there is a weak component in construction with a complex character sub－part are：止充，where $\sqrt{\boldsymbol{y}}$ is weak，but in construe－ tion with 充，and 虔号，where $\frac{\pi}{\jmath}$ is weak but in construction
with

Fourth，there are those characters which contain more than two

BORDERS．Since the state diagram prohibits any output character
from having more than two BORDERS，such characters cannot be accounted for by the grammar．Examples are $\dot{\text { 遍，which contain the three }}$ BORDERS $\dot{z}$ ，$\dot{户}$ ，and $\square$ ，and $\dot{\boldsymbol{j} ⿹ 勹 巳}$ ，in which there are the three BORDERS $\dot{2}, ~ J$ ，and $L$ ．

Fifth，there are those characters in which there is a BORDER in
construction with a non－FREE component．Since in the grammar，the set of INTERIORS（those components which are in construction with BORDERS）form a proper subset of the set of FREES，BORDER plus non－ FREE structures cannot be accounted for by the grammar．The only known examples are 行，in which the INTERIOR ；（in con－ struction with BORDER $/$（ $)$ is an adjunct，and 土⿹勹冫 ，in which the INTERIOR（in construction with BORDER $ク$ ）is an adjunct．

Sixth，there are those characters which contain the form－
(This form is not to be confused with , a component in the
lexicon, and for structural reasons cannot be considered simply a
shortened variant of —.) There are doubts as to whether this
form should be considered a component. If it were, it would seriously
affect the tightness of the grammar. Therefore, all that can be said
is that there are characters which contain it and cannot be accounted
for by the grammar because the grammar does not list it as a component.
 and

Seventh, there are a few characters, which if segmented into
components, would yield extremely irregular frames. I/ Examples are:
分分 , whose frame would be something like $\square \square$, and

1/ These constitute a type of component superimposition. Component superimposition is discussed in Rankin (4). However, the type of superimposition discussed there does not include these characters.

䂆》 ，whose frame would be something like only frames in the frammar are
 and or results of combining these，characters segmentable into
frames like those above are not accountable for by the grammar．

There are two final observations．First，some characters which
cannot be accounted for by the grammar fall into more than one of the classes discussed above．Second，some characters which appear to fall into one of the above classes are actually accounted for by the grammar． This is so，because there is always the option of listing as a single component those complex sub－parts which give trouble．For example， the complex sub－part ${ }^{\text {ap }}$ is listed as a component，even though it might fall into class seven above，and the complex sub－part 力口 is listed as a component even though it might be segmented into
plus $\square$ ，which segmentation would cause characters containing ग口 to fall into class three above．Generally，decisions on seg－ mentation are motivated by three considerations：（1）a structure is segmented into two components if the two components either must not
ponents if the segmentation generally corresponds to one of the three recognized frame types: $\square$, and $\square$; (3) a
structure is segmented into two components if each sub-structure can
occur in different environments. 1/

## 2. Tightness

A. Over-generation of output characters

Rather than sampling random output with a view to assigning a tightness percentage, we feel it is more to the point ot sub-classify the unacceptable output on linguistic grounds. The reason is that potentially there exist infinitely many grammars equivalent to GCC-3 in the sense that they all generate the same language, all having different tightness percentages associated with them. For example, we could construct a GCC-4 from GCC-3 by substituting the following set of trans-

1/ For a previous and more detailed discussion of segmentation, see Rankin (4), chapter 4.
itions for the bottom-most transition which produces the single
symbol G.

Then there would be added to GCC-3 rules by which Gl would
ultimately determine the subclass of the current FREE class which contain, e.g., fewer than five strokes: G2, G3, and G4 would respectively determine subclasses containing 5-to-10 strokes, 11-to-15 strokes, and more than 15 strokes. GCC -4 would generate precisely the same language as that generated by GCC-3, but random output from GCC-4 would contain a higher percentage of acceptable characters than random output from GCC-3. This is so because GCC-4 has a higher probability of generating single-component characters, and all of these are by definition acceptable.

There are three classes of unacceptable output. The first class of unacceptable output contains characters of excessive size. Here,
there are three sub-classes. First there is a sub-class which contains
characters of excessive overall size. Examples are (1) 1/ and (2).

The problem with these output characters is that the frame for each has
the maximum number of sub-frames, and each sub-frame is occupied by a
component which is itself very large. Second, there is a sub-class
containing characters which are excessively horizontal. Examples are
(3) and (4). The problem here is that the frames for these characters
are of the maximum horizontality allowed by the grammar, and the sub-
frames are filled with "very horizontal" components. Then, there is a corresponding excessively vertical sub-class. Examples are (5) and (6).

The frames for these characters are of the maximum verticality allowed
by the grammar, and the sub-frames are filled with "very vertical"
components.

1/ This output character and the following five (where there are
numbers in parentheses) are found in Appendix D.

The second class of unacceptable output contains characters in
which there are co－occurrence problems．That is，it is not the case
that，say，every WEST can occur with every EAST（even given the strength
and adjunctiveness constraints），and so on for other pairs of classes．

The one pair of classes which gives rise to the greatest number of co－ occurrence problems is the BORDER－INTERIOR pair，but there are co－ occurrence problems for every pair．Examples are 木个，丘，and过 ，in which $才$ and $\leftarrow, ~ 上$ and $\div$ ，and $\dot{\xi}$ and $L$ ，respectively simply should not co－occur． Finally，there is a class of unacceptable output characters which contains certain components in strong positions，these components being only moderately strong．There seems，in fact，to be a scale of strength，Among WESTS，for example，the scale ranges from，say （very strong）through 我（moderately strong）to 事（weak）． Currently in the grammar，the class of strong components includes very strong and moderately strong components．This blurring of the scale of strength gives rise to such unacceptable output characters as 我斗
and 等 ，where it and 寺 are only moderately strong （ 我 and 几 being weak）。

B．Over－generation of Derivations

There are three types of ambiguous characters．Actually，ambiguity
is not apparent at the output character level，but only at the post－
transducer level．This is because our current output characters contain
parts of their deriviations－their frames．For example，at the output character level，the following are distinct：

However，at the post－transducer level both would be realized as 吽斬，
which is for that reason ambiguous．In this treatment，we will have to
discuss ambiguity as if we already had the output transducer referred
to on page iv and we will use the term＂character＂to mean＂post－
transducer character．＂

First，some characters which are（or contain）horizontal arrays
of three or more components are ambiguous with respect to the grouping
of components．For example，慚 has two derivations，one of which imposes a if plus 車斤 grouping，the other of which imposes a

悔 plus $f$ grouping．Then some of the characters which are （or contain）vertical arrays of three or more components are ambiguous． The sub－part $\underset{\frac{\grave{n}}{\text { 子 }}}{\text { 子 }}$ of the character 惊 has two derivations，one of which imposes a $\frac{1}{\square}$ plus $\frac{Z}{}$ grouping，the other of which imposes a 1 plus $\frac{\square}{子}$ grouping．

This type of ambiguity is introduced in the first step of the process that generates Stage 2，that is，in the selection of frames from the table of correspondence．It is possible for two distinct sequences of frames（which are generated by the same output string） ultimately to determine the same character．This is shown in the following two derivations of 慚 ．In these，and the derivations to follow，the single arrow $\rightarrow$ is used for＂directly determine＂and the double arrow $\Rightarrow$ for＂ultimately determine＂．

Two derivations of 慚：

慚

$\sqrt{y}$

$\sqrt{V}$

Second，there are those characters which are themselves（or
which contain components which are）further segmentable into components．

For example，冗 is listed in the lexicon as a single component－ because of its frequency of occurrence（specifically，it is a strong EAST）．It is also the case that 凤 can be generated by the grammar as $几$ in construction with 又 This type of ambiguity is introduced at Stage 1 ，where it is possible for two distinct output strings from the state diagram ulti－ mately to determine the same character．

Two derivations of 几:

Finally，some characters are（or contain sub－parts which are）

analyzable in more than one way－but into the same frame．An example is 并 which is analyzable as either | $H$ |
| :---: |
| $H$ |
| $\pi$ | or并 in isolation is ambiguous，and any character which contains并 as a sub－part is ambiguous．

This type of ambiguity is introduced（as in the first type dis－ cussed here）in the frame selection process．However，unlike the first type，these characters have identical frames at the output character level．

The research summarized in this note was supported by Rome Air

Development Center under RADC contract number (30-602)-66-4042. We are grateful for this support.

We wish to thank the following people for reading earlier versions of this note and for making valuable suggestions: Dr. Stephen J.

Tauber, Mr. H. H. Ku, and Mr. David Rosenblatt of the National Bureau
of Standards; Mr. W. C. Watt of Technical Operations Research; and

Professor E. I. Burkart of American University.

Finally, we are indebted to Delores Allnutt of the National Bureau of Standards for typing the final version.

## APPENDIX A

Classes of Mathews' entries which are deliberately excluded from the
corpus (Mathews' sometimes lists several semantically related entries
under one number. The number in parentheses indicates which of these
entries is referred to.)

The following classification of excluded Mathews' entries arises
out of a first approximation to a filtering process aimed at excluding entries which are not totally well-formed. We selected these particular
ones in the following way. First, Mathews' lists all of these characters as secondary or tertiary variants. Second, the informant considers most of them to be less than acceptable. Third, they do not fit well into the current grammatical framework. This is by no means a definitive listing or classification.

1．＂Radicals＂which are cited in Mathews＇as separate entries
but which do not occur in isolation in everyday usage．I／

1. Variation Processes and List

Component variation has been extensively studied, but a final
statement on this phenomenon is not ready for presentation. What
follows is a statement of four general processes and a list of rather
more ad hoc variations. Component variation belongs properly in the rules of the output transducer, which has not been constructed, and
is presented here mostly as an aid to human generation of output characters.

Further, some of the general variation processes may not be
precisely stated here, and there are indications that some of the
instances of ad hoc variation should be grouped together into general
processes.

Variation Process 1, (BORDER)

For certain components whose base forms I/ have $L$ or $L$

1/ A base form is that form of a component which can occur in isolation, those which belong to FREE.
in their＂eastern＂portions，this process causes the BORDER variant to assume a shape wherein $\square$ becomes $\square$ and $L$ becomes
 Variation Process 2，（WEST）

For certain components which have－in their＂south central＂ portions，this process causes the WEST variant to assume a shape where－ in－becomes／Examples：4．1．7：止 $\rightarrow$ 止，and 8．1．3：毛 $\rightarrow \widehat{\text { 老 }}$ 。 Variation Process 3，（WEST）

For certain components which contain $小$ or a $丸$－like structure，this process causes the WEST variant to assume a shape wherein becomes $\backslash$ Examples：4．4．21：木 $\rightarrow$ 大 and 7．4．6：束 $\rightarrow$ 束 。

Variation Process 4，（BORDER）

For certain components which have or（in their＂south－ eastern＂portions，this process causes the BORDER variant to assume a shape wherein $\backslash$ or $\backslash$ become $\quad$ Examples：5．4．5：后

$$
\text { 瓜 } \rightarrow \text { 瓜, and 5.4.8: 永 } \rightarrow \text { 永。 }
$$

The Lexicon

The lexicon is described on pages 34 through 39. There is, however, one extra-grammatical type of information included in the lexicon which must now be explained. There are superscripts (1-5) on some of the tallies, l/ the significance of these superscripts is that the component on the row of this tally, when it occurs in the position class specified by the column heading of the tally, undergoes a shape variation. Superscripts $1-4$ refer to variation processes $1-4$ described in Appendix B; superscript 5 refers to the ad-hoc list of variants in Appendix B. The ad-hoc list follows the order of appearance of components in the lexicon.

1/ In two cases the component itself is superscripted. There are cases where there is more or less free variation among the component variants.
