INDUSTRIAL SPONSORS OF THE BONE CHAR RESEARCH PROJECT, INC.

The preparation of this volume was conducted as part of a program of research under the cooperative sponsorship of the National Bureau of Standards and the Bone Char Research Project, Inc., a research associateship established at this Bureau in 1939. The current industrial sponsors are listed below.

Acadia-Atlantic Sugar Refineries, Ltd., Halifax, Nova Scotia
American Agricultural Chemical Company, Detroit, Mich.
American Sugar Refining Company, New York, N. Y.
Atlantic Sugar Refineries, Ltd., Saint John, New Brunswick
Baugh & Sons Company, Philadelphia, Pa.
British Charcoals & Macdonalds, Ltd., Glasgow, Scotland
British Columbia Sugar Refining Company, Ltd., Vancouver, British Columbia
California & Hawaiian Sugar Refining Corp., Ltd., San Francisco, Calif.
Canada & Dominion Sugar Company, Ltd., Montreal, Quebec
Colonial Sugar Refining Company, Ltd., Sydney, Australia
Colonial Sugars Company, Gramercy, La.
Companhia Uniào dos Refinadores, São Paulo, Brazil
Consolidated Chemical Industries, Inc., New York, N. Y.
Godchaux Sugars, Inc., New Orleans, La.
Henderson Sugar Refinery, Inc., New Orleans, La.
Hershey Corporation, Central Hershey, Cuba
Hulett's South African Refineries, Ltd., Durban, South Africa
Imperial Sugar Company, Sugar Land, Tex.
National Sugar Refining Company, New York, N. Y.
Refined Syrups & Sugars, Inc., Yonkers, N. Y.
Revere Sugar Refinery, Charlestown, Mass.
Savannah Sugar Refining Corp., Savannah, Ga.
St. Lawrence Sugar Refineries, Ltd., Montreal, Quebec
Tate & Lyle, Ltd., London, England
Tirlemont Refinery, Tirlemont, Belgium
Wed. P. Smits & Zoon, Utrecht, Holland
Westburn Sugar Refineries, Ltd., Greenock, Scotland

FOREWORD

Annotated bibliographies of special topics in science have as their primary purpose the assembly of a scattered literature. From such surveys the research worker may gain a perspective of his field not otherwise possible because of the press of specific problems. In the training of new personnel, the availability of comprehensive reference material by subject is invaluable as the essential starting point to active investigation. It provides background, and it reveals areas where strengthening of knowledge is needed. The present volume furnishes information on these sources in a specific field of science.

The scientific literature in Circular 566, Bibliography of Solid Adsorbents 1943 to 1953, covers a significant period in science and technology. In the highly specialized field of investigation here concerned, that of commercial solid adsorbents, progress has been as exceptional as in other technical fields. Approximately twice as many publications appear in this volume for the period 1943–53 as in Bibliography of Solid Adsorbents 1900 to 1942.

It is gratifying to note that the joint sponsorship of the Bone Char Research Project, Inc. and the National Bureau of Standards has continued without a break since 1939. During this period the industrial sponsors have increased in number and now represent industry in other countries, as well as the United States. The program of fundamental research envisioned at the outset of this project has been maintained. The Cane Sugar Refining Industry and the Bone Char Manufacturers have shown exceptional foresight in maintaining a continuity of effort that can only result in mutual benefits.

The Research Associate Plan of the National Bureau of Standards makes it possible for an industry to cooperate in the prosecution of a fundamental research program. Research Associate projects are required not only to be of value to all groups concerned in a particular field and to the Federal Government, but must also be important from the standpoint of the Nation's sum total of technological knowledge. The publication of Circular 566 is a good example of such cooperation. Those responsible for this volume have rendered a valuable service in the field of adsorption in particular and to science and industry in general.

Allen V. Astin, *Director*.

June 15, 1955.

PREFACE

The decade since the publication of the Bibliography of Solid Adsorbents 1900 to 1942[2] has seen remarkable progress in both basic theory and the applications. The accomplishments of the latter often exhibit spectacular successes. Essentially, the industrial use of an adsorbent involves a relatively simple unit operation and relatively simple equipment, a situation having obvious advantages. The advances in basic theory may appear meager when viewed alongside the striking exhibition made by a successful technical process, but so powerful is the contribution of basic theory that its guiding influence is felt over the complete range of activities in industry, as well as in research.

As articles of commerce, the variety and number of solid adsorbents have increased markedly in the last decade. In the early stages of development, the commercial adsorbent was a by-product, and men with great faith in their product set forth to find applications in established processes of industry. Progress was slow and steady while a generation of chemical engineers was being trained in the fundamentals and possibilities of the adsorption process. A commercial adsorbent became a success when with its use it was possible to do what would otherwise be impractical or uneconomical with some other unit process. In many cases the process has made a success of the adsorbent, but frequently the reverse has been true.

Twice as many publications are cited for the decade covered by this volume as for the previous four decades. There are many reasons that have contributed to this tremendous growth. One of the most important developments has been in the refining of petroleum and the synthesis of various chemicals from petroleum products. Although the first applications of silica and alumina gels were as desiccants, and it was in this capacity that they were used in large tonnages during World War II, the development of catalytic cracking and reforming of hydrocarbons has entailed tremendous quantities of these materials. Scores of publications have been concerned with the many problems involved. A second development has been the ion-exchange synthetic resins, which now are the subject of a significant part of the adsorbent literature. With their aid the removal of inorganic constituents by adsorption was given a selectivity that had immediate applications. A third development has been the growth of chromatography, a subject that has richly endowed the chemist with many and varied techniques having a potential selectivity not hitherto possible. This tool has proved to be very productive in many fields of investigation and is being used by the analyst and the chemical engineer with skill and ingenuity.

No claim for completeness is made in the compilation of this volume. The opportunity has been taken to include references that were omitted in Bibliography of Solid Adsorbents 1900 to 1942. Thanks are due to readers who have kindly called attention to some unintentional omissions. Many references to publications both before and after 1943 have been added from the fields of heterogeneous catalysis and surface reactions on textile materials. However, the coverage in both volumes is still restricted to heterogeneous phenomena at solid-liquid and solid-gas interfaces. As before, the patent literature is not covered. Notwithstanding repeated checking of the subject matter, some omissions are probably present among the 13,763 references contained in this volume. It would be appreciated if the reader would call attention to these.

The sources of the literature references and the abstracts have been many. Published books tabulated on pages 1361 to 1363 have been explored for pertinent references. The abstract given with each entry was prepared from one or more of the following sources: (1) The original publication, (2) Chemical Abstracts, (3) British Chemical Abstracts, (4) Chemisches Zentralblatt. The Chemical Abstract reference is given with each journal reference because of the universal availability of these abstracts. An acknowledgment is herewith made of the general permission granted to use individual abstracts. Periodical abbreviations conform with those used in Chemical Abstracts. These were tabulated in an appendix of Bibliography of Solid Adsorbents 1900 to 1942. A list published by the American Chemical Society in 1951 is available under the title "List of Periodicals Abstracted by Chemical Abstracts."

The author takes this occasion to express his sincere appreciation to the many assistants who have lent a helping hand in the preparation of this work. The aid from those with nontechnical training has been invaluable because of the care and pride they have taken in their work. The author is indebted to his colleagues of the Bone Char Research Project, Inc., for their able assistance in the tedious task of proofreading.

VICTOR R. DEITZ.

CONTENTS

Chapter I. ADSORPTION OF GASES AND VAPORS ON SOLID ADSORBENTS

Adsorbents are used in industry for their effects on particular gases, liquids, or solutions. It would have been useful to assemble the literature from this point of view and group the publications on particular systems with the various adsorbents. However, it is not practical to do this in any detail for several reasons. The variations among the same species of adsorbent have been many and the particular systems in which the adsorbents have been used have been too numerous for a convenient classification. Instead, the grouping of the literature has been based on the type of adsorbent and some general aspect of the gas or solution phases. Carbon adsorbents, metal surfaces, inorganic crystals, silica gel, and so forth are examples of adsorbent types; the complete arrangement may be seen by a perusal of the Contents.

During the period 1943–53 there was a notable increase in the number of investigations reported for the adsorption of hydrogen and other gases on metals. About one-third of the papers covered in Chapter I are on this subject. With interest mounting in the fields of high-temperature corrosion-resistant alloys, metal catalysts, and the electrical properties of the solid state, it is probable that the literature covering this field will continue to grow at a rapid rate.

The most significant development in adsorption at the gas-solid interface during the past decade has been the application of the Brunauer-Emmett-Teller [2] model of physical adsorption to the estimation of the surface area of solids. This method was introduced in 1938 and, together with the constructive criticism which followed, it constitutes one of the milestones in the understanding of adsorption phenomena.

The need to identify adsorption sites with more exactness has influenced many investigators to select inorganic crystals and metals for the surfaces to be studied. This has been done with a high degree of success in recent investigations on tungsten of J. A. Becker and C. D. Hartman.[3] One may indeed look forward with anticipation to the results of more investigations of this type for real progress in understanding the properties at solid-gas and solid-solution interfaces.

The voids within the real solid contribute in varying degrees to the adsorption process. The voids may range from simple faults and breaks within an otherwise perfect crystal to the elaborate porosity ascribed to commercial adsorbents and catalysts. Methods have now been published for the evaluation of the size distribution (assumed to be cylindrical pores) and the total volume of the voids. These techniques have greatly aided in elucidating the macro-scale physical structure of solid adsorbents. There is, also, an increasing literature concerned with the important role that this internal structure plays on surface reactions in the solid phase.

The similarity of some of the problems in solid state physics with those in surface adsorption and catalysis should be better appreciated. An increasing number of publications treat systems of overlapping interest, and significant progress can be expected in the future.

The well-established but poorly-defined carbon adsorbents continue to excite further research, although the number of these publications in 1943–53 constitute only 20 percent of Chapter I. More than half of these were concerned with the reaction of carbonaceous residues with oxygen. The chemisorption of oxygen on these adsorbents constitutes an old but as yet little-understood system. Section 5, "Reactions of Oxygen and Carbons," includes not only the subject of the adsorption of oxygen, but also the publications which have dealt with the initial reactions leading to partial or complete oxidation of the solid state.

The Subject Index provides an extensive cross index of subject headings not listed in the Contents. It is a useful aspect of the Bibliography and serves to subdivide further the material covered. A subject that might properly be placed in more than one chapter has been entered but once and may be located by means of the Subject Index. The entries in the latter have been made according to the particular adsorbent and under these are tabulated the various adsorbates that have been investigated.

I-1. Inorganic Gases on Carbon Adsorbents

1. PETERS, KURT. **Adsorption and desorption.** *Reichsamt Wirtschaftsaubau, Prüf-Nr.* **43**, (PB 52003), 113-20 (1940).—*C.A.* **41**, 6105f.

The theoretical and practical aspects of adsorption and desorption as a means of sepn. and purification of gases was reviewed. The sepn. and purification of Kr, Xe, and A, using activated charcoal, was described. Through adsorption and fractional desorption, the m.p. of the purified Kr was found to be −157°C as compared with a previously reported value of −169°C, purified Xe m. −112°C as compared with −140°C previously reported.

2. WICKE, E. **Fundamentals concerning the sorption separation process.** *Reichsamt Wirtschaftsaubau, Prüf-Nr.* **43**, (PB 52003), 103-12 (1940).—*C.A.* **41**, 6105h.

Mixed adsorption over silica gel and over activated charcoal was described. The data showed highly specific adsorption of oxygenated compds. such as esters and ethers on silica gel in the presence of *n*-pentane and related hydrocarbons. A general discussion was included of chromatographic analysis, diffusion analysis, and continuous sepn. processes for gases and liquids from room temp. at 150°C.

3. GERLING, E. K. AND ERMOLIN, G. M. **A method for the separation of helium from neon.** *Compt. rend. acad. sci. (U.S.S.R.)* **32**, 641-3 (1941) (in English).—*C.A.* **37**, 2522^8.

Charcoal adsorbed Ne at −225°C and to find out whether this could be used to separate Ne from He, adsorption of each was studied. At −195.7°C, 3% Ne was adsorbed by He charcoal, at −207°C, 47.1%, at −215°C, 70.6%, at −224.7°C, 95.7%, and at −225°C, 99.7%, pressures varying from 1.15×10^{-3} to 2×10^{-6} mm Hg. At −224.8°C, 3.8% He was adsorbed by charcoal and 6 determinations from −224.8° to −229.4°C at various pressures gave an average adsorption of 5.1%. It was possible to make a separation of the two gases.

4. ALEKSEEVSKII, E. V. AND LIKHAVEV, N. A. **Effect of certain chemical and physical factors on the activity of charcoal. Activation by chlorination.** *J. Gen. Chem. (U.S.S.R.)* **12**, 306-19 (in English, 319-20) (1942).—*C.A.* **37**, 2913^5.

Charcoals from a wide variety of plant sources were treated with Cl_2 at 750°C and 950°C; the sorption of gaseous and dissolved materials (benzene vapor, I_2 solns., solns. of salicylic acid, solns. of H_2O_2, chloropicrin, and Cl_2) on these charcoals were studied. Charcoals activated by Cl_2 may be superior to commercial charcoals. A considerable part of Cl_2 which accumulated during chlorination, could not be washed out by boiling water or alkalies, nor removed by heating in vacuo nor by electrodialysis.

5. IMADA, FUMIO. **Studies on carbon. II. Sorption isotherm of charcoal and the mechanism of its activation.** *Technol. Repts. Kyushu Imp. Univ.* **18**, 53-7 (1943).—*C.A.* **43**, 5572a.

Charcoals prepd. from various trees (yield 24-35%) showed adsorption of 9.8-18.7 cc/g of Cl_2 (satd. at 18°C). Current theories of sorption to explain the activation were reviewed.

6. IMADA, FUMIO. **Studies on carbon. VI. Chlorination.** *Technol. Repts. Kyushu Imp. Univ.* **18**, 72-5 (1943).—*C.A.* **43**, 5572d.

The most active charcoal (after wetting with steam) consumed under similar conditions more Cl_2 (163 cc/g at 20°C) than other materials such as another active charcoal (92 cc/g), and graphite (21 cc/g).

7. IMADA, FUMIO. **Studies on carbon. IX. Evaluation of the results.** *Technol. Repts. Kyushu Imp. Univ.* **18**, 88-93 (1943).—*C.A.* **43**, 5572f.

The observed values showed in part the monomol. adsorption of Langmuir.

8. GLUECKAUF, E. **Simple analysis of the He content of air.** *Trans. Faraday Soc.* **40**, 436-9 (1944).—*C.A.* **39**, 2038^2.

The procedure was based on the adsorption in 3 gas-adsorption charcoal tubes which had been previously outgassed in vacuo at 400°C for 20 min., and then immersed in liquid N_2. Known mixts. of He and air were used to det. the loss of He during this purification process. Air was found to contain normally 5.24 ±0.03 p.p.m. of He.

9. NIKITIN, B. A. AND IOFFE, E. M. **Adsorption of radon on charcoal under dynamic conditions.** *Bul. acad. sci. U.R.S.S., Classe sci. chim.* **1944**, 210-15 (English summary).—*C.A.* **39**, 1583^9.

In adsorption of small quantities of Rn in a stream of air, the max. on the charcoal cannot exceed the product of Henry-law distribution coeff. and the Rn concn. in the air stream. For high grades of charcoal this distribution coeff. may attain the value of 500-1500. Rn, first adsorbed on the surface layers, completely distributed itself within the depth of 5 cm in the course of a few hrs. Foreign materials adsorbed previously, sharply reduced the adsorption of Rn.

10. GLEYSTEEN, LELAND F. AND DEITZ, VICTOR R. **Hysteresis in the physical adsorption of nitrogen on bone char and other adsorbents.** *J. Research Natl. Bur. Standards* **35**, 285-307 (1945) (Research Paper 1647).—*C.A.* **40**, 1375^7.

Adsorption of N_2 at 77°K on bone char, activated charcoal, silica gel, and coconut-shell charcoal showed closed hysteresis loops. Hysteresis became less pronounced in the order of adsorbents given. On coconut-shell charcoal, it occurred only if desorption was begun very close to the satn. pressure, in the region where the Langmuir adsorption equation was no longer obeyed. An interpretation, in terms of the theory of multimol. layer adsorption, postulated the formation of mol. clusters on the surface which remained independent of one another until a certain pressure was reached, when they joined together in some fashion. Desorption occurred from this more stable modified layer. The desorption isotherm remained above the adsorption isotherm until the pressure was so low that the clusters were not stable.

11. MARTIN, FRANCISCO MORENO. **Quantitative separation of gaseous silicon fluoride and carbon dioxide by activated carbon.** *Anales fis. y quim. (Madrid)* **41**, 1303-16 (1945).—*C.A.* **41**, 4404i.

A mixt. of CO_2 and SiF_4 when passed through a granular activated charcoal was sepd. into its components. SiF_4 remained and CO_2 passed through. When SiF_4 was adsorbed, it displaced the CO_2 from the charcoal. This caused a small loss in wt, which prevented exact, gravimetric detn. of SiF_4. The SiF_4 value must be corrected by 2%. HCl dislodged the SiF_4 adsorbed on the charcoal.

12. ANDERSON, ROBERT B. **Improved adsorption vessel.** *Ind. Eng. Chem., Anal. Ed.* **18**, 156 (1946).—*C.A.* **40**, 1702^7.

An adsorption vessel consisted of an adsorbent chamber and special 4-way stopcock. This was light enough to be weighed on an analytical balance.

13. COURTY, CLEMENT AND ROUGEOT, LOUIS. **Oxidation of ammonia fixed on activated charcoal.** *Compt. rend.* **223**, 624-5 (1946).—*C.A.* **41**, 1945b.

NH_3 was adsorbed by activated charcoal which was then exposed to the air. All odor of NH_3 disappeared at the end of 3 hrs. From then on it increased in wt even in an atm. free of moisture and CO_2. After 8 hrs, wash water from the satd. charcoal clearly showed the reducing properties of hydroxylamine. After several days' exposure of the charcoal to pure dry air, the wash water no longer had the properties of hydroxylamine but had those of NH_4NO_2. These oxidation reactions were accelerated by moistening the charcoal after it had been satd. with NH_3.

14. DESORBO, WARREN; MILTON, ROBERT M., AND ANDREWS, DONALD H. **New cryogenic methods of using liquid hydrogen.** *Chem. Rev.* **39**, 403-17 (1946).—*C.A.* **41**, 1133d.

The liquefier was of the Ahlberg type, operating from ordinary tank H_2 purified by passing over charcoal at 90°K. It produced about 1.5 liter of liquid H_2 in 45 min. from 3 standard tanks in which the pressure dropped from 2000 to 1000 lb/in^2.

15. GREGG, S. J. **An electrical sorption balance.** *J. Chem. Soc.* **1946**, 561-2.—*C.A.* **40**, 6302^3.

Construction of a balance suitable for adsorption measurements was described. A glass beam and sample supports, with steel needle and glass-cup bearings, were enclosed in a glass-tube vessel which could be evacuated. The construction permitted out-gassing the sample. The sensitivity was 0.3 mg, independent of the total load, which may be 10-20 g. Balance was obtained by adjusting the current through two solenoids.

16. KEĬER, N. P. AND ROGINSKIĬ, S. Z. **Chemisorption of gases on activated charcoal and the abundance of surfaces with exponential distribution functions.** *Compt. rend. acad. sci. U.R.S.S.* **52**, 781-3 (1946).—*C.A.* **41**, 1523*i*.

Expts. were made on the kinetics of activated adsorption on a sugar charcoal at const. pressure. Adsorption isotherms of H_2 and O_2 followed the equation $q=a\ t^{1/n}$, where q was the quantity of adsorbed gas and t the time. The temp. coeff. of the adsorption was observed.

17. LINDEBOOM , J. **The adsorption of a few gases and of their binary mixtures by carbon, in relation to the regeneration of neon tubes.** *Rec. trav. chim.* **65**, 877-90 (1946) (in French) *C.A.* **41**, 3676h.

The adsorption isotherms were measured of pure N_2, H_2, and Ne and of the mixts. N_2-H_2 at 20°C and 760 mm by 15 g active charcoal, Ne-H_2 at -79°C and 760 mm by 15 g charcoal and Ne-H_2 at -192°C by 1 g charcoal at 760, 50 and 10 mm. The data were given in tables and graphs compared with the straight line and hyperbola calcd. from Henry's law. H_2 was adsorbed more strongly than Ne although its b.p. was lower, whereas for N_2-H_2 mixts. the reverse was true. No satisfactory interpretation of the elimination of H_2 from Ne-H_2 mixts. (used by Claude to purify Ne) could be made. Subjecting the charcoal used for the purification of Ne-H_2 mixts. to vacuum of 10 mm, increased considerably the yield of Ne without increasing the proportion of H_2 appreciably.

18. ANDERSON, ROBERT B. AND EMMETT, P. H. **Surface complexes on charcoal. Gas evolution as a function of vapor adsorption and of high-temperature evacuation.** *J. Phys. & Colloid Chem.* **51**, 1308-29 (1947).—*C.A.* **42**, 1410c.

The gases evolved on evacuating charcoals for gas masks to 1200°C were collected at 300°C intervals and analyzed for CO, CO_2, H_2, H_2O, and CH_4. The O-contg. gases were formed by the decompn. of surface complexes and by the reduction of the inorg. oxides present as ash. The CO and CO_2 evolution reached a max. at about 600°C for charcoals prepd. by the $ZnCl_2$ process, and at 900 to 1200°C for those prepd. from coal. The total O-contg. gases evolved were always equiv. to less than 50% of the charcoal surface. Extg. charcoals with HF and re-exposing them to air resulted in about a twenty-fold increase in the amt. of CO evolved on heating the samples to 600°C. H_2 evolution in the temp. range 600 to 1200°C amounted to 25 to 147 cc. for the various charcoals. Activation of the charcoals by steam was shown to form very little O-complex. NH_3 at 750° to 900°C formed a N-complex on the charcoals that was more stable than the O-complexes.

19. DUBININ, M. M. AND RADUSHKEVICH, L. V. **The equation of the characteristic curve of activated charcoal.** *Doklady Akad. Nauk S.S.S.R.* **55**, 327-9 (1947) Chem. Zentr. 1947, 1, 875.—*C.A.* **43**, 3686g.

The relation between the vol. of the liquid adsorbate (W) and the adsorption potential (ϵ) was studied, and the following equation derived $\epsilon^2 = a^2 \ln W_0/W$, in which W_0 = the vol. of the liquid adsorbate at $\epsilon = 0$. The factor a varied with the nature of the adsorbed vapor, but W_0 was independent, since only the structure of the adsorbent detd. the vol. of the adsorbate. The relation between W and ϵ was applied to the adsorption of CO_2 and alcohol on wood charcoal.

20. HARRIS, G. M. AND TICKNER, A. W. **Reaction of hydrogen atoms with solid carbon.** *Nature* **160**, 871 (1947).—*C.A.* **42**, 3638c.

Thin-soot deposits on glass completely disappeared in an atm. of 20% at. H at 0.4 mm pressure. A typical reaction product contained CH_4, a small amt. of C_2 to C_5 fraction, and no nonvolatile substance.

21. Holmes, James and Emmett, P. H. **Alteration of the size and distribution of pores in charcoals.** *J. Phys. & Colloid Chem.* **51**, 1276-1307 (1947).—*C.A.* **42**, 1102e.

Pore size and surface-area alterations produced in 4 gas-mask charcoals by various combinations of steaming, hydrogenation, oxidizing, sintering, or impregnating with NiO, CuO, Mo_2O_3, Na_2CO_3, Fe_2O_3, or Cr_2O_3 were studied. Adsorption isotherms for N_2 at −195°C were used to judge the changes in pore-size distribution and surface area. The samples included two charcoals made by the $ZnCl_2$ process, one steam-activated coconut shell charcoal and one made from coal by a combination of calcination and steam activation. Suitable combinations of the treating process seem capable of increasing the relative proportion of any particular size of pore that was desired in the charcoals.

22. Holmes, James and Emmett, P. H. **Investigation of low-temperature nitrogen adsorption at high relative pressures.** *J. Phys. & Colloid Chem.* **51**, 1262-76 (1947).—*C.A.* **42**, 1101a.

N_2 adsorption isotherms were detd. at −195°C at relative pressures as high as 0.9995 on porous glass, several charcoals, carbon blacks, and glass microspheres. The porous glass and some of the charcoals showed no increase in adsorption above a relative pressure of about 0.95. Other charcoals and all of the nonporous finely divided solids showed a considerable increase in adsorption above 0.95.

23. Imada, Fusao. **Carbons. XVII. Experiments on the active carbon in dry air-cells. The sorption of hydrogen.** *Kogaku Iho, Kyushu Univ.* (Technol. Rept., Kyushu Univ.) **19**, 243-6 (1947).—*C.A.* **47**, 5819i.

To det. the role of H ion in the electromotive reaction of the dry air-cell, the sorption of H_2 on active carbon was investigated. Active carbon treated with 1.17% Fe adsorbed 6 times as much H_2 as untreated material.

24. Keĭer, N. P. and Roginskiĭ, S. Z. **A differential isotopic method for the investigation of activated surfaces.** *Doklady Akad. Nauk S.S.S.R.* **57**, 157-9 (1947).—*C.A.* **44**, 8194g.

All adsorbed gases were removed from activated sugar charcoal by long heating at 1100°C and protected during subsequent cooling. H_2 and D_2 at the temp. of liquid air were adsorbed and desorption was accomplished by slowly raising the temp. The compn. of the evolved gases was deted. by measuring the change in the resistance of a Wollaston filament through which a const. current flowed. The gas adsorbed last was evolved first; then, a mixt. of H_2 and D_2 was evolved; then, the gas adsorbed first was evolved. The results indicated that the phenomenon was one of "energetic inhomogeneity" of the surface (different adsorption areas) rather than one involving spaces of varying accessibility. The adsorption isotherm obtained was similar to that of Freundlich.

25. Keĭer, N. P. and Roginskiĭ, S. Z. **Investigation of the nonhomogeneity of the surface of active carbon by the activated adsorption of hydrogen and of oxygen.** *Bull. acad. sci. U.R.S.S., Classe sci. chim.* **1947**, 571-83 (in Russian).—*C.A.* **42**, 3638*d*.

Rates of adsorption on sugar charcoal were detd. in a vol. of 240 cc; the pressure was allowed to drop by not more than 5-7% of the initial pressure. The charcoal was evacuated with gradual heating up to 1000-1100°C, kept at that temp. 1 hr, then for 2 hrs at 900°C. Reproducibility of the rate measurements was shown by the coincidence of two curves for O_2 at $p_0 = 6.23$ mm Hg, 204°C, in 2 expts. sepd. by 17 intervening consecutive adsorptions of O_2, H_2, CO, and CO_2. The kinetic equation was $q = At^{1/n}$ where $1/n = aRT$ and $A = f(p_0)$. The exptl. plots of log q against log t for O_2 at $p_0 = 6.23$ mm Hg, temp. 0°, 100° and 204°C, were actually linear, with $1/n = 0.327$ to 0.343, 0.447, and 0.510 to 0.570 at 0°, 100°, and 204°C, resp. The equation held equally well for the adsorption of H_2, with $1/n = 0.29$, 0.44, and 0.53 at 280°, 426°, and 540°C, resp. The activation energies E of adsorption of H_2 as a function of q, check satisfactorily with the values obtained by Arrhenius' equation.

26. Loebenstein, W. V. and Deitz, V. R. **The magnitude of the experimental error in the adsorption of nitrogen at 78°K on various surfaces.** *J. Chem Phys.* **15**, 687-8 (1947).—*C.A.* **41**, 7200d.

Large samples were required to det. a small B.E.T. surface. The exptl. error due to the use of adsorption tubes of various sizes was studied. For samples of cement, cotton, bone char, glass spheres, activated coconut shell charcoal, and TiO_2, weighing 0.7 to 31 g, and with B.E.T. surface areas of 0.7 to 1720 m^2/g, the error was 0.12 to 10.4%. In a general way, the error increased as the surface area decreased.

27. Strickland-Constable, R. F. **Interaction of carbon filaments at high temperatures with nitrous oxide, carbon dioxide, and water vapor.** *Trans. Faraday Soc.* **43**, 769-78 (1947).—*C.A.* **42**, 5316h.

The reactions were detd. at temps. of 900°-2000°C and at pressures of less than 1 mm. All were of the first order above 1200°C but tended to fractional order below this. The rates of reaction of all three gases rose from 900° to 1200°C and then remained approx. const. up to 2000°C, except in the case of N_2O, whose rate increased again above 1600°C. The rates of reaction depended to a certain extent on the immediate past history of the filament, especially from 1200° to 1600°C. Heating the filament at a high temp. reduced the rate of reaction at low temps. Reactions at low temps. increased the rate of subsequent reactions at higher temps. In the reactions N_2O and H_2O the principal O-contg. product was CO; very little CO_2 was formed. The primary product of the reaction of O_2 with C above 1000°C was principally CO and not CO_2.

28. Andreev, E. A. and Kavtaradze, N. N. **Catalytic oxidation of phosphine in adsorbed layers.** *Doklady Akad. Nauk S.S.S.R.* **60**, 1193-5 (1948).—*C.A.* **43**, 6898a.

The catalytic oxidation on dry charcoal in the presence of Cu salts involves as a 1st step the activated adsorption of PH_3 onto the supported Cu salt with an activation energy of about 2 kcal. The activation energy for the reaction of O with the adsorbed PH_3 increases as the O sats. the surface. The kinetics of the oxidation can be described by the equation: $\log(t+t_0) = (\alpha/2.3)q - \log\alpha a$, where q is the amt. reacted, t the time in min. a the original speed of the reaction, and α a const.

29. ARII, KIMIO AND TANSKA, MASAMI. **Sorption of hydrogen sulfide by active charcoal. I. Sorption isotherms.** *J. Chem. Soc. Japan, Pure Chem. Sect.*, **69**, 91-4 (1948).—*C.A.* **44**, 9209*h*.
Sorption expts. at 20°, 30°, and 40°C below 1 atm. were studied statistically with a quartz-spring balance and a spring manometer. The amt. of sorption α in mg/g charcoal at equil. pressure p (mm Hg) was $\alpha_{20°} = 1.63936\ p/(1+0.01092\ p)$, $\alpha_{30°} = 1.09785\ p/(1+0.00752\ p)$ and $\alpha_{40°} = 0.73528\ p/(1+0.00515\ p)$. Equations for sorption at const. wt and at const. pressure, a general equation of sorption, and the differential heat of sorption were obtained or calcd.

30. SAVAGE, ROBERT H. AND BROWN, CALLAWAY. **Chemical and physical adsorption of gases on carbon dust.** *J. Am. Chem. Soc.* **70**, 2362-6 (1948).—*C.A.* **42**, 8574b.
Carbon dust formed by the high wear of graphite rods rubbing against a rotating disk in vacuum adsorbed H_2, N_2, O_2, CO, CO_2, and CH_4 irreversibly at room temp. The chemically active sp surface of the dust was calcd. to be 5.12 m² per g from the H_2 adsorption at room temp.; this was compared to the B.E.T. surface of 435 m² per g. The B.E.T. areas of graphite powder used as raw material in making graphite rods, the graphite rods themselves, and the powder formed by pulverizing the rods in a high-speed impact grinder were 7.7, 1.3, and 4.6 m² per g. The graphite dust was in the form of platelets about 20 A. thick and 3500 A. in diam. Presumably the chemisorbed gases were held by the atoms on the edges of these platelets where fresh valence bonds were opened by the wearing process used in producing the dust.

31. TOMLINSON, R. H. AND FLOOD, E. A. **Flow of gases and vapors through adsorbing porous media.** *Can. J. Research* **26B**, 38-53 (1948).—*C.A.* **42**, 4003*h*.
The flow rates of gaseous He, H_2, N_2, CO_2, Et_2O, and EtCl through highly activated charcoal rods were measured. The adsorbable gases flowed at rates greater than those calcd. on the basis of the Adzumi equation, while the gases that were not highly adsorbed could be satisfactorily correlated by this and similar equations. This new phenomenon may possibly involve mobility of the adsorbed material and rapid surface diffusion. Detailed exptl. methods and data were presented.

32. ETTINGER, I. L. **Sorption of nitrogen by hard coal.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk* **1949**, 1719-22.—*C.A.* **45**, 9831i.
Kusnetsk coal was subjected to evacuation for 1.5 months under a pressure of about 10^{-4} mm at 60°C. For each of the samples of coal, representing different stages of metamorphism, isotherms were obtained, at 25° and at 40°C. The point of sorption equil. was completely reversible; this reversibility seemed to confirm the existence of phys. van der Waal's sorption in contrast to chemisorption. All but 1 of the N_2 isotherms were straight lines. The sorption increased with the degree of carbonization of the coal; i.e., as the degree of metamorphism of the coal increased, the sorbing surface increased.

33. FASTOVSKIĬ, V. G. **Determination of small amounts of krypton.** *Zavodskaya Lab.* **15**, 1417-20 (1949).—*C.A.* **44**, 4370f.
To det. 0.1% of Kr in gas mixts. all active gases were removed and the residual Kr, N_2, and A freed of N_2 by powd. Ca at 650-700°C. The residue was analyzed for Kr either by d. detn. on the gas balance, or by detg. the vapor pressure at 90°K.

34. KEĬER, N. P. AND ROGINSKIĬ, S. Z. **Kinetics of desorption of hydrogen adsorbed in an activated process.** *Zhur. Fiz. Khim.* **23**, 897-916 (1949).—*C.A.* **44**, 18f.
H_2 was adsorbed on sugar charcoal. The pressure was then lowered to 10^{-4} mm Hg, and the amt. (D) desorbed was detd. at different times t. Between 510° and 565°C, $D^{1/3} = b(RT\ln t - RT\ln\alpha - E_0)$ where T was °K, ln α was a const. (e.g. −22) and E_0 was another const. (e.g., 32,000 cal/mole). If desorption was stopped before complete degassing and more H_2 added, this was adsorbed more rapidly than during the "primary" adsorption. If the adsorption of H_2 was stopped before equil. was attained, the temp. rose from 565° to 650°C for an hr and again lowered to 565°C, the adsorbed amt. was greater than it would have been at a const. temp. of 565°C. Repeated adsorption-desorption cycles at 565°C were reproducible. When D_2 was brought into contact with the charcoal, it exchanged with 0.5-0.7% H_2 present in the charcoal, so that adsorption of D_2 could not be measured.

35. SCHAEFFER, W. D.; SMITH, W. R., AND WENDELL, C. B. **The adsorption of helium on carbon black at liquid helium temperatures.** *J. Am. Chem. Soc.* **71**, 863-7 (1949).—*C.A.* **43**, 6037b.
The adsorption was measured on 2 carbon blacks, Spheron 6 and Spheron C at 4.2°K. The isotherms were represented by the B.E.T. equation. Heats of adsorption were calculated by assuming a negligible entropy for the adsorbed phase and ranged from 34 to 93 cal per mol.

36. BARTELL, F. E. AND DODD, CHARLES G. **Surface areas of crystalline carbon and carbide powders as measured by adsorption of nitrogen.** *J. Phys. & Collid Chem* **54**, 114-28 (1950).—*C.A.* **44**, 6228h.
N_2 adsorption isotherms (77.3 to 78.1°K) were detd. for relative pressures up to 0.6 for purified powd. samples of four graphites (B, C, D, E), a furnace black ("Standard Gastex"), silicon carbide, and diamond (particle size ~ 2 μ). The results were compared upon application of the Brunauer, Emmett, and Teller (B.E.T.) "complete" and "simple" equations and the Harkins and Jura (H-J) equation to the exptl. data. For silicon carbide and diamond dust the B.E.T. equation was required for establishing unambiguous values for the surface areas and no. of adsorbed layers (n) of N_2. The value of N = 3 and a slight desorption hysteresis for diamond indicate an activated adsorption of N_2. Areas in m²/g were: for graphites B 25, C 105, D 21, E 8.4; furnace black 27; SiC 3.9 (B.E.T.), 3.8 and 4.3 (H-J); and diamond 9.2 (B.E.T.), 9.2 and 11.5 (H-J).

37. CAMPBELL, J. R. AND SKILLING, W. J. **Adsorption of hydrogen sulfide by peat in the presence of ammonia.** *J. Soc. Chem. Ind.* **69**, 153-60 (1950).—*C.A.* **44**, 9657d.
Adsorption of H_2S by peat from gas mixts. contg. NH_3 were investigated to det. the effi-

ciency of the peat for this operation. To explain the results, it was suggested that NH_3 combined with the humic acids of the peat, followed by a decompn. of the ammonium humates with H_2S, and oxidation of the resulting NH_4SH to produce free S and release NH_3 to continue the process.

38. Fulkerson, S. D. and Lambert, F. J. **Apparatus for determining gas permeability of carbon and graphite.** *Anal. Chem.* **22**, 1310-12 (1950).—*C.A.* **45**, 396*i*.

The app. consists of two glass flasks, each provided with manometer and vacuum connection, between which the test specimens is clamped. One of the flasks is also provided with means for introduction of gas under controlled conditions.

39. Gerling, E. K. and Baranovskaya, N. V. **Quantitative separation of argon from small quantities of krypton and xenon by multiple adsorption and desorption.** *Zhur. Anal. Khim.* **5**, 131-8 (1950).—*C.A.* **44**, 6230*b*.

The adsorption of A and Kr on charcoal were detd. at pressures of $1\text{-}1 \times 10^{-3}$ mm and lower, and temps. of -80°, -100°, and -120°C. The Freundlich equation was followed. The coeff. $1/n$ for A was 1 and less that 1 for Kr. The amt. of adsorbed gas that could not be desorbed at 1×10^{-4} mm increased as the temp. decreased: for A it was 0.1% at -80°C and at -120°C 0.5% per g of charcoal; for Kr at -80°C it was 1.7% per g of charcoal. Since Kr was desorbed with more difficulty, a method was worked out to sep. A from shall quantities of Kr. The adsorbed gases were desorbed and readsorbed consecutively in 4 adsorbers. The gases retained in each were desorbed at +100°C. The gases were purified by passing over metallic Ca at 650°C, the charcoal reactivated at 400°C, and the cycle repeated. By this procedure all of the A was recovered and 99% of the Kr remained adsorbed. Xe, if present, remained with the Kr.

40. Goldsmith, M. **The magnetic susceptibility of bromine-graphite.** *J. Chem. Phys.* **18**, 523-5 (1950).—*C.A.* **44**, 9201b.

The magnetic susceptibilities of graphite and graphite-Br were detd.: graphite pure, (298°K) $= -5.29 \times 10^{-6}$ c.g.s. units per g; graphite pure, (75°K) $= -7.43 \times 10^{-6}$; Br/C (wt ratio = 0.051) (298°K) $= 4.17 \times 10^{-6}$; Br/C (=0.051) (75°K) $= -5.42 \times 10^{-6}$; Br/C (= 0.67) × (298°K) $= -0.31 \times 10^{-6}$; Br/C (= 0.67) (75.6°K) $= -0.29 \times 10^{-6}$; Br/C (= 0.71) (299°K) $= -0.31 \times 10^{-6}$; Br/C (= 0.71) (75.6°K) $= -0.29 \times 10^{-6}$. Neither the assumption of free Br atoms nor Br_2 leads to a value of the magnetic susceptibility comparable to the exptl. value.

41. Juza, Robert and Grasenick, Fritz. **The magnetic susceptibility of oxygen sorbed on charcoal, silica, and platinum black at -183°C.** *Z. Elecktrochem.* **54**, 145-52 (1950).—*C.A.* **44**, 6690i.

The magnetic susceptibilities of O_2 sorbed on charcoal, silica, and Pt black were detd. at -183°C by use of a magnetic balance. The values depended on the thickness of the sorbed layer. This varation was related to the displacement of the equil. between paramagnetic O_2 and diamagnetic O_4. The susceptibility for a monolayer on charcoal was at first equal to that of the O_2 mol.; it then decreased to the value for liquid O_2 and lower. The first O adsorbed on silica was equiv. to O_2, but when several layers were present, the value for liquid O_2 was obtained, the original monolayer retaining the value for O_2. The situation on Pt black was similar to silica.

42. Mukherjee, Bibhuti. **Purification of carbon rod by resistance heating.** *J. Sci. Ind. Research* (India) **9B**, 266-8 (1950).—*C.A.* **45**, 5463*h*.

Carbon electrode for spectrum analysis was purified by passing a current of 570 amp. for 90 sec through a rod, 10 cm long and 7 mm in diam. A gas atm. was maintained around the electrode by means of a continuous stream of N_2 which was bubbled through CCl_4. Traces of Fe and Mg were almost completely removed. Cu, which was not completely removed by resistance heating in air, also was almost completely removed. Slight traces of B remained in the rod.

43. Swenson, C. A. **The catalysis of the ortho-para conversion in liquid hydrogen.** *J. Chem. Phys.* **18**, 520-2 (1950).—*C.A.* **44**, 9223f.

This catalysis was of importance for the quantity production of pure para-hydrogen. If liquid H_2 were to be kept for any considerable length of time, it would be much more economical to store liquid para-hydrogen than normal (25% para) liquid H_2. Rough detns. of the conversion const. both in the adsorbed layer of the catalyst and in the actual liquid were given for activated charcoal and for silica gel onto which O_2 had been adsorbed. The heat of mixing of ortho- and para-hydrogen was also measured, and found to be smaller than the accuracy of measurement, 1/2 cal.

44. Szabó, Zoltán. **The examination of a system carbon and hydrogen in the temperature range 1100-2600°C.** *J. Am. Chem. Soc.* **72**, 3497-3502 (1950).—*C.A.* **44**, 10474g.

The concn. of CH_4 in the reaction as a function of temp. shows a min. at 1450°C and a max. at 2000°C. C_2H_2 and C_2H_4 are also obtained above 2000°C. The results indicate that above 1450°C some lower hydride, probably CH_3 or CH_2, is present at higher concn. on the surface of hot carbon rod.

45. Trotter, I. F. **Thermodynamics of carbon disulfide production.** *Ind. Eng. Chem.* **42**, 570 (1950).—*C.A.* **44**, 3773i.

Calcd. equil. consts. of the reaction C (graphite) + $S_2(g)$ combined with vapor pressure data gave results which indicated that the true reactant may be $S_2(g)$. If allowance was made for the varying partial presures of diat. S, no neg. free energies were obtained.

46. Barrett, Elliott P. and Joyner, Leslie G. **Determination of nitrogen adsorption-desorption isotherms. Estimation of total pore volumes of porous solids.** *Anal. Chem.* **23**, 791-2 (1951).—*C.A.* **45**, 8320i.

Observations suggest that pore vol. cannot be estd. accurately by gas adsorption in the case of type II and III isotherms. To be certain of obtaining reliable desorption isotherms of these types, total pore vol. should be measured by d. detns. to assure that the sample has actually attained satn. before desorption.

47. CORRIN, M. L. **Areas of carbon blacks and other solids by gas absorption.** *J. Am. Chem. Soc.* **73**, 4061-5 (1951).—*C.A.* **45**, 9332*h*.

The adsorption isotherms of N_2, A, C_5H_{12} and 1-pentene were measured on 8 carbon blacks, rutile, and rouge. B.E.T. areas are self-consistent for the various gases if the area occupied per mol. in the monolayer is detd. on a solid of known area. It is further shown that 4 condensed films may appear in the isotherm. The use of the Harkins and Jura isotherm method thus involves a choice of the proper const. If only one film is obtained, the choice of the proper H.J. const. involves a knowledge of the area of the solid as detd. by an abs. or the B.E.T. method.

48. CREMER, E. AND PRIOR, F. **Application of chromatographic methods to the separation of gases and determination of adsorption energies.** *Z. Elektrochem.* **55**, 66-70 (1951).—*C.A.* **45**, 9334*h*.

Gaseous compds. in H_2 as a carrier were passed through columns of silica gel and activated charcoal and studied in relation to flow rate, concn. and temp. Thermal cond. was used as an indicator. Difference in av. adsorption energies ($\Delta\lambda$) of a pair was given $\Delta\lambda = RT \ln t_2/t_1$, where t_1 and t_2 were the elapsed times prior to breakthrough. Values of $\Delta\lambda$ for the pairs CO_2/C_2H_2, C_2H_2/CH_2CHCl, and C_2H_4/C_2H_2 were 0.39, 0.65, and 0.67 ± 0.02 kcal/mol., resp. Values of $\Delta\lambda$ were independent of temp.; values of *t* depend on carrier-gas velocity, gas concn., and temp. A mixt. such as C_2H_4/C_2H_2 could be sepd. completely.

49. DAVIS, S. G.; FORAN, M. R.; OGILVIE, J. D. B.; PEARCE, JESSE A., AND WINKLER, C. A. **Dynamic adsorption of ammonia, of butane, of cyanogen chloride, and of water vapor by charcoals.** *Can. J. Technol.* **29**, 190-216 (1951).—*C. A.* **45**, 7844*h*.

The steam activated adsorbents used were coconut shell charcoal, Cu impregnated coal and wood charcoals, and Cu-Cr impregnated nutshell charcoals. The isotherms, the distribution of adsorbate in the adsorbent bed, and the effect of gas concn. and flow rate on break time were all normal. Measured heats of adsorption of *n*-C_4H_{10} on coconut charcoal were related to adsorption wave characteristics.

50. GÜBELI-LITSCHER, O. AND STAMMBACH, K. **The adsorption of radon on activated charcoal and silica gel.** *Helv. Chim. Acta* **34**, 1257-63 (1951). (in German).—*C.A.* **46**, 1329h.

Rn was adsorbed with air as the carrier gas. Measurements were made in ionization chambers with quartz-thread electrometers. At the same temps. charcoal was the better adsorbent. Heats of adsorption were: Silica gel 6800 cal./mole Rn, elmwood charcoal 7510 cal. Both heats of adsorption were based on the Rn concn. of 10^{-13} to 10^{-15} cc./g of adsorbent at 0°C and 760 mm.

51. HITZ, KURT; SCHELLER, WALTER, AND TREADWELL, W. D. **The mixed adsorption of hydrogen, oxygen, and nitrogen with carbon dioxide on linden charcoal.** *Helv. Chim. Acta* **34**, 1783-90 (1951) (in German).—*C.A.* **46**, 2872e.

The conventional method was used at 0, 20, and 40°C; total pressure 730 mm; and permanent gas partial pressure 670-730 mm. The results were represented by the empirical equation: $\Delta\alpha = K_1 [\alpha_{CO_2} - K_2 p^n_{CO_2}]$, where $\Delta\alpha$ is the difference in adsorptions of pure and mixed permanent gas, α_{CO_2} was the adsorption of CO_2 at a partial pressure of p_{CO_2}, and K_1, K_2 and *n* were empirical consts.

52. JOYNER, LESLIE G.; BARRETT, ELLIOTT P., AND SKOLD, RONALD. **The determination of pore volume and area distributions in porous substances. II. Comparison between nitrogen-isotherm and mercury-porosimeter methods.** *J. Am. Chem. Soc.* **73**, 3155-8 (1951).—*C.A.* **45**, 9332*f*.

Pore-vol-distribution curves were detd. for adsorbents (bone char and Synthad) by means of a high-pressure Hg porosimeter. Agreement was obtained with a method based on low-temp. N_2 adsorption.

53. JURA, GEORGE AND CRIDDLE, DEAN. **Phase transitions of argon adsorbed on graphite.** *J. Phys. & Colloid Chem.* **55**, 163-72 (1951).—*C.A.* **45**, 4521*i*.

The adsorption of A on graphite at 65°C and at low surface coverage was detd. Four first-order phase changes were observed, due either to a heterogeneous surface or to polymorphic changes in the adsorbed film. The latter was favored because the heats of transition were low, 50-100 cal/mole, and the structure of graphite would permit many symmetrical arrangements of the adsorbed mols. in the region in which the transitions were observed. The adsorption of A on graphite was sigmoid at coverages of less than one monolayer.

54. LAD, R. A. AND YOUNG, T. F. **Adsorption of xenon on charcoals at room temperature.** *Natl. Nuclear Energy Ser., Div. IV*, **9**, Radiochem. Studies: The Fission Products, Book 3, 1833-43 (1951).—*C.A.* **46**, 5928e.

Two types of charcoal were used: a $ZnCl_2$—activated wood-flour charcoal with an area of about 2500 m^2/g and steam-activated charcoals with areas from 400 to 660 m^2/g. Flow expts. with radioactive Xe as a tracer in large amounts of He showed that the coal charcoal having the smallest area was most effective in removing Xe if the quantity to be removed was small. This was shown to be due to the fact that the absorption isotherms crossed at about 20 mm. It was suggested that the use of successive beds may be more effective for high concns. than any one charcoal used alone.

55. MALHERBE, P. LE R. **Microstructure of some South African coals.** Fuel **30**, 97-109 (1951).—*C.A.* **45**, 5387i.

The low temp. adsorption of A by a no. of South African coals had been studied. B. T. surface areas were calcd. Although these calcns. were rendered somewhat uncertain by a secondary slow sorption process, they indicated that the surfaces accessible to diffusing gas were only about $\frac{1}{16}$ to $\frac{1}{68}$ of the surface areas calcd. from heats of wetting in MeOH.

56. MCDONNELL, F. R. M.; PINK, R. C., AND UBBELOHDE, A. R. **Physical properties associated with "aromatic" electrons. III. Pseudometallic properties of potassium-graphite and graphite-bromine.** *J. Chem. Soc.* **1951**, 191-7.—*C.A.* **45**, 4979*e*.

The marked diamagnetism in graphite is destroyed in both compds. C_8Br is weakly diamagnetic, and C_8K shows a temp. (90, 195, and 288°K) -independent paramagnetism of the same order as for metallic Ca. Both compds. have better elec. cond. than graphite. Magnetic and elec. data on the compd. C_4F, whose structure has not yet been established by other means, suggest a general similarity in behavior with graphite.

57. Miyahara, Yutaka. **The state of adsorbed molecules.** *J. Chem. Soc. Japan, Pure Chem. Sect.* **72**, 455-6 (1951).—*C.A.* **46**, 4880*e*.

The partition functions of adsorbed mols. were estd. from the adsorption data of H_2S, Cl_2, and $COCl_2$ by charcoal. The model in which the adsorbed mols. translate and rotate freely in a space of certain dimensions was in line with the exptl. results.

58. Penchev, N. P. and Iordanov, N. **A new apparatus for rapid determination of helium in natural gas.** *Bulgar. Akad. Nauk. Otdel. Geol.-Geografi. Khim. Nauki, Izvest. Khim. Inst.* **1**, 265-75 (1951) (French summary).—*C.A.* **46**, 7737*b*.

App. for the detn. of He by measuring its vol. after adsorption of the residual gas on nut coal at liquid-air temp. was improved by using Hg stopcocks. The gas quantity required for one detn. could be reduced to 0.1 of that formerly required.

59. Wayne, Lowell G. **A method for obtaining approximate pore-size distribution curves from nitrogen desorption isotherms.** *J. Am. Chem. Soc.* **73**, 5498-501 (1951).—*C.A.* **46**, 9377*c*.

The basis of the method was a rapid graphic approximation of the Wheeler distribution function. The absorbate vol. was obtained from data of the desorption isotherm and expressed in terms of the variable ρ_p (actual radius of a pore) rather than the relative pressure. The transformed isotherm was differentiated graphically or otherwise.

60. Anderson, R. B. and Emmett, P. H. **Surface complexes on carbon blacks. II. The adsorption of NH_3, C_2H_2, C_4H_{10}, CH_3NH_2, and water vapor.** *J. Phys. Chem.* **56**, 756-61 (1952).—*C.A.* **47**, 20d.

For Spheron 6, Black Pearls 1, Mogul, and Lampblack T the surface areas were calcd. by the B.E.T. method, both for the original and for the samples from which the complex had been removed by degassing at 1200°C. The adsorption of C_2H_2 at -78°C and of C_4H_{10} at 0°C appeared phys. in nature and yielded areas in satisfactory agreement with those obtained by N_2 isotherms at -195°C. NH_3 and Me-NH_2 isotherms for Lampblack T gave apparent areas several-fold greater than those obtained from N_2. For after-treated Lampblack and for a lampblack sample degassed at 1200°C the areas obtained from the NH_3 adsorption isotherms at -46°C were in satisfactory agreement with those obtained from N_2 adsorption at -195°C. The water adsorption isotherms were shifted in the direction of higher relative pressures as the complex was removed from the surface by high-temp. degassing.

61. Antropoff, A. v.; Propfe, H. A.; Weil, K.; Kalthoff, F.; Schmitz, L., and Cronenthall, G. Ritter Hänel v. **Investigations of adsorption of gases from very small to very high pressures. III. Adsorption isotherms of the noble gases and of nitrogen at pressures below atmospheric.** *Kolloid-Z.* **129**, 1-10 (1952).—*C.A.* **47**, 3651*a*.

Isotherms on charcoal were found for He, Ne, A, Kr, Xe, and N_2 at temps. up to 20°C and pressures less than 1 atm. Except at pressures below 100-200 mm a linear relation was shown for the ratio of pressure to adsorption *vs.* pressure. Adsorption was slightly greater on charcoal degassed at 600° than at 360°C. The sp. vol. of the charcoal was between 0.617 (as detd. with liquids in a picnometer) and 0.496 (as detd. with He). Calcns. using these vols. gave adsorption values differing by a const. percentage (1.3-1.4%) over the pressure range studied.

62. Antropoff, A. v.; Steinberg, F.; Schaeben, L.; Schröder, H. J.; Jünger, R., and Jüngerich, W. **Investigations of adsorption of gases from very small to very high pressures. IV. Adsorption isotherms of argon and nitrogen up to a pressure of 400 kg/cm^2.** *Kolloid-Z.* **129**, 11-19 (1952).—*C.A.* **47**, 3651*c*.

Adsorbed gas was detd. differentially in an app. having 2 parts: a metal section where gases could be handled up to 400 atms. including the charcoal and pressure gages, and a glass, low-pressure section where vols. of gas taken off were measured, starting at about 400 kg/cm^2 and detg. the "desorption isotherm." Exptl. data were reported for A and N_2 at 20°, 0°, -25°, and -76°C and pressures of 4 to 385 atms. All isotherms passed through max.

63. Bastick, Jack. **The adsorption of ammonia, phosphine, and arsine on activated charcoal.** *Bull. soc. chim. France* **1952**, 169-71.—*C.A.* **46**, 6459*c*.

Adsorption isotherms between -78° and 132°C and pressures up to 600 mm are given. The curves for NH_3 are linear above 50 mm, but the AsH_3 curves follow typical Langmuir isotherms. The adsorption is partially chem. in nature as shown by the differences between the adsorption measured calorimetrically and the isosteric heats derived from these isotherms. The differences are greatest at low concns.

64. Geballe, T. H.; Lyon, D. N.; Whelan, J. M., and Giauque, W. F. **Carbon thermometer-heaters for use at low temperatures. Effects of particle size and adsorption of hydrogen or helium.** *Rev. Sci. Instr.* **23**, 489-92 (1952).—*C.A.* **47**, 1991*a*.

Elec. resistances of 5 carbon blacks, with av. particle sizes ranging from 2×10^{-6} to 12×10^{-6} cm, were measured from 1 to 295°K. The smaller sizes had larger negative temp. coeffs. of resistance. The effect of adsorption of He at low pressures on the elec. resistance was very small at 20°K. At the temps. of liquid He the resistance at first increased and then decreased below the original value, as the pressure of He was increased to its vapor pressure. A similar effect was observed when H_2 was adsorbed at 20°K. When adsorbed H_2 or He gases were pumped off, the effect was found to be reversible within the small limit of error.

65. Kirkpatrick, Harry B. **The adsorption of nitrogen on carbon black.** *Univ. Microfilms* (Ann Arbor, Mich.) *Pub.* No. **3424**, 73 pp (microfilm $1.00, paper enlargements $7.30); *Dissertation Abstracts* (formerly *Microfilm Abstracts*) **12**, 132-3 (1952).—*C.A.* **46**, 7396f.

66. Lavrovskaya, G. K. and Voevodskiĭ, V. V. **Recombination of atoms on solid surfaces.** *Zhur. Fiz. Khim* **26**, 1164-6 (1952).—*C.A.* 47, 958*b*.

The probability of recombination of H atoms was detd. on MoO_3, an aluminosilicate catalyst, and activated charcoal. The values were, resp.: 0.05 to 0.1, 10^{-2}, and 2×10^{-3}. Special expts. confirmed the mechanism $H \rightarrow H_{ads.}$, $H_{ads.} + H \rightarrow H_{2\ ads.}$, $H_{2\ ads.} \rightarrow H_2$. It was observed that the rate of recombination on various surfaces was higher (but reproducible) after the first run. Only after high-vacuum cleaning of the surface could the data of the 1st run be reproduced. This was attributed to the slow rate of desorption $H_{ads.} + H_{ads.} \rightarrow H_2$ which was thus excluded as rate-detg. step in the recombination mechanism.

67. Los, J. M. and Fergusson, R. R. **Measurements of thermomolecular pressure differences on argon and nitrogen.** *Trans. Faraday Soc.* **48**, 730-8 (1952).—*C.A.* 47, 2561*a*.

Data for A and N_2 were required for measurements of the thermodynamic properties of these gases in the adsorbed state at low temps. The integration of the fundamental differential equation for the pressure gradient was expanded into 2 forms. Data for A fit one form and those for N_2 the other. The thermomol. pressure differences were calcd. for all values of pressure, temp., and tube radius, and values fit the exptl. data for 3 glass capillaries with a max. uncertainty of 1 micron. The deviations were less than 2.5 microns in a metal capillary.

68. Mertins, Arnold G. **Fine structure of natural coals.** *Braunkohle* **4**, 353-66 (1952).—*C.A.* 47, 4059*i*.

Gas adsorption (H_2, N_2, CO_2, CH_4) and heat of wetting (H_2O, MeOH, EtOH, PrOH, AmOH, C_6H_6) data gave information on internal surface area, nature of pore systems, and mechanism of swelling due to sorption. The apparent d., true d., vol. % porosity, pore radius (mμ, method *A*), pore radius (mμ, method *B*), particle radius in mμ, and internal surface in m^2/g are given for a no. of coals. Coal structure is pictured as comprising micelles with coordinate valences of peripheral functional groups providing cohesive forces. As coalification advances, these forces are gradually replaced by true valence bonds leading to a coalescence of the micelles and ultimate formation of a graphite-like structure. The application of these concepts to the coking process is discussed.

69. Moench, Guenther C. **The glass Dewar Flask—its quality and a possibility of improving it for the insulation of liquids at low temperatures.** *Glas u. Hochvakuum-Tech.* **1**, No. 1, 9-13 (1952).—*C.A.* 47, 1987*f*.

Dewar flasks for low-temp. liquids can be improved by increase of the vacuum in the double wall and by reduction of radiation from the glass walls. Vacuum can be improved by gas-adsorbing carbon blacks between the 2 glass walls. Radiation is reduced by introduction of a third wall in the vacuum space.

70. Norman, W. S. and Sawyer, C. H. V. **Construction and performance of graphite-block heat exchangers.** *Ind. Chemist* **28**, 317-20 (1952).—*C.A.* 47, 3049*f*.

A heat exchanger is described in which the transfer element is a block of graphite of high thermal conductivity perforated by rows of parallel passages conveying the fluid stream. In the case of gases, narrow slots instead of circular passages have been employed. Heat-transfer coeffs. for this type of graphite-block heat exchangers are given.

71. Smith, Thomas D. **Amorphous carbon.** *J. Chem. Soc.* **1952**, 923-7.—*C.A.* 46, 6458i.

Carbons were prepd. by heating from 400 to 1000°C O-contg. compds. in N_2; mellitic acid; Ba, Hg(ic), and Hg(ous) mellitates; inositol; benzenepentacarboxylic acid; quinol humic acid; methylated humic acid; melanoidin; and oxidized Busty vitrain. The av. dimensions in the *c* direction were about 10 A. for all. The areas (m^2/g) ranged from 8 for melanoidin to 1650 for Ba-mellitate carbonized at 800°C and to 2125 for hexachlorobenzene. The higher values are attributed to intercryst. penetration of the adsorbate, in support of a cross-linked aromatic structure. B.E.T. surface areas were detd. from N_2 adsorption isotherms.

72. Kahle, Heinrich. **Reversible adsorption in the preliminary purification and separation of gas mixtures.** *Chem.-Ing.-Tech.* **25**, 144-8 (1953).—*C.A.* 47, 5733*b*.

Two com. processes are described. The effects of cycle time, operating pressures and temps., partial satn. of adsorbent, and flushing procedure are discussed.

73. Maslan, F. D.; Altman, M., and Aberth, E. R. **Prediction of gas-adsorbent equilibria.** *J. Phys. Chem.* **57**, 106-9 (1953).—*C.A.* 47, 5211*d*.

By considering the adsorbate as a highly compressed gas, its vol. and fugacity can be calcd. by the Polanyi-Dubinin equation. The method is satisfactorily applied to the adsorption of (1) O_2 and N_2 on activated carbon, silica gel, and activated Al_2O_2, both above and below the crit. temp., and (2) H_2 on activated carbon above the crit. temp. The method does not apply to such gases as propane and propylene on activated carbon at 0 to −30°C. With further modification, the equation can be applied to the prediction of binary gas adsorption. Its application is successful for O_2 and N_2 adsorbed on activated carbon.

74. Mignolet, J. C. P. **Simple and multiple gas microintroductors for adsorption studies.** *J. Sci. Instr.* **30**, 15-17 (1953).—*C.A.* 47, 3624*c*.

Volumes from 0.2 to 50 mm^3 can be introduced into the app. at pressures below 10 cm Hg. Diagrams show devices for varying rate of flow, for filling the gas reservoirs, and for multiple introductions.

I-2. Organic Gases on Carbon Adsorbents

75. Chernyaeva, Yu. I. **Determination of benzene hydrocarbons in coke-oven gas by adsorption by activated charcoal.** *Trudy Khar'kov. Nauch.-Issledovatel Uglekhim. Inst.* **1939**, No. 1, 16-17, 155-212; *Khim. Referat. Zhur.* 4, No. 1, 86 (1941).—*C.A.* **37**, 1582^7.

The adsorption capacities of charcoals with respect to benzene were given. The losses during steam-distn., the effect of the gas velocity on the completeness of the adsorption of benzene, and the effect of H_2S and moisture on the activity of charcoals were discussed. The AG charcoal was the most active of all those investigated. Steam-distn. was necessary for the regeneration of charcoal. The optimum velocity of the gas was 200-300 liter/hr. The presence of H_2S decreased the accuracy and the length of the time required for a detn. A method to det. aromatic hydrocarbons in coke-oven gas was described.

76. Radulescŭ, Dan and Radulescŭ, Flŭor. **Discontinuity of capillary adsorption and desorption isotherms and the nature of the capillary layer which delimits the liquid phase.** *Bul. Chim. Soc. Chim. Romania* [2], 1, 38-55 (1939) (in French).—*C.A.* **37**, 3315^9.

Methods and apparatus were described. The adsorption and desorption in charcoal of C_6H_6 (10°, 15°, and 20°C), CCl_4 (0°C) and BzCl (17°C) were studied by both the static and dynamic methods. Desorption occurred in steps. From the breaks in the desorption curves it was deduced that at the surface of contact of a liquid and a solid such as charcoal there existed 3 layers of liquid with different physicochemical properties: a unimolecular or bimolecular adhesive layer in which the molecules were almost immobile as if chemically combined with the surface of the solid, a 2nd capillary layer wherein the molecules were condensed to the point where they were in contact tangentially, and a layer of normal liquid.

77. Figurovskiĭ, N.A. and Feinberg, M.M. **Influence of sorption upon the electrical conductivity of pulverized sorbents.** *Compt. rend. acad. sci. U.R.S.S.* **31**, 344-6 (1941) (in English).—*C.A.* **37**, 1072^5.

Various kinds of activated carbon were deposited from suspensions on small cylinders of pumice, ebonite, porcelain, and other dielectrics. The resistances of the carbon as affected by adsorbed vapors of benzene, toluene, aliphatic alcs., ether, CCl_4, etc., in various concns. decreased in all cases. The rate of decrease and the final value depended on the nature of the adsorbed substance. When the adsorbed substances were desorbed, the resistance increased again. The speed at which equilibrium was attained indicated that only the surface and the macropores were affected.

78. Tamamushi, Bun-ichi **Polarity of molecules and adsorption. The adsorption of isomeric disubstituted benzenes.** *Sci. Papers Inst. Phys. Chem. Research (Tokyo)* **38**, 446-54 (1941).—*C.A.* **41**, 5771*i*.

The adsorption by Al_2O_3 in benzene and by charcoal in MeOH was measured. In nitrophenol and nitroaniline, the *m*-isomer was adsorbed more strongly by Al_2O_3 in benzene, and more weakly by charcoal in MeOH than was the *o*-isomer. Hence, a more polar solute was adsorbed more strongly by a polar adsorbent in a more apolar medium. In dinitrobenzene, the *p*-isomer with a smaller dipole moment was adsorbed more strongly by the apolar adsorbent in the polar medium than the *m*-isomer with a greater dipole moment, which fact was in accord with the other exptl. results. This order of adsorption was, however, not reversed when they were adsorbed by Al_2O_3 in benzene.

79. Engle, H.C., and Coull, James. **Adsorption studies of vapors in carbon-packed towers.** *Trans. Am. Inst. Chem. Engrs.* **38**, 947-65 (1942).—*C.A.* **37**, 16^7.

Data on the adsorption efficiency of carbon-packed towers, as obtained by thermal conductivity measurements on $CHCl_3$ vapor-air mixtures, were successfully correlated. Equations were developed expressing: (1) the efficiency vs. time relations for different concentrations, velocities and bed heights and (2) a correlation between the constants in these equations and the process variables.

80. Sastri, M.V.C. and Krishnaswami, K.R. **Studies on active carbon. I. Evaluation of activated charcoal.** *Quart. J. Indian Inst. Sci.* **5**, No. 2, 1-42 (1942).—*C.A.* **40**, 196^7.

Six com. varieties were evaluated by porosity detns., adsorption of I_2 and of methylene blue from aq. solns., adsorption of benzene vapors, and heat of wetting in benzene. Porosity had little bearing on activity. The adsorption of I_2 and methylene blue were approx. proportional to the adsorption of benzene vapors at very low vapor pressures and the heat of wetting. The heat of wetting was a measure of the "specific activity" or retentivity of an absorbent, but not the cohesive or capillary forces.

81. Bratzler, K. **Sorption methods for the analytical and preparative separation of gases.** *Oel u. Kohle* **39**, 953-60(1943).—*C.A.* **38**, 6154^9.

The difference in the relative volatilities of various adsorbed gases is sufficiently great to make sepns. at temps. that would be too high for effective sepn. by fractional distn. Pure C_3H_8 is obtained from a mixt. with C_2H_6 and C_4H_{10} by passing it slowly at 0° or room temp. over activated charcoal (degassed at 200°C and 0.1 mm Hg). After atm. pressure has been reached, an elec. oven is placed over part of the adsorption tube and some of the gas is desorbed; the desorbed gas comes in contact with the adsorbed gas in the cold part of the tube and exchange of the heavier and lighter components of the gas takes place. The light impurities are driven off first, followed by pure C_3H_8, and the heavy impurities remain adsorbed. The same principle is applied to analytical methods which give satisfactory results if allowance is made for the material that remains adsorbed. This difficulty is avoided by carrying out the desorption under vacuum. If the hydrocarbon mixt.

to be adsorbed contains olefins, the break-through of olefins can be controlled automatically by bromination of the olefins.

82. Poggi, A. Raoul. **A simple apparatus for determination of the adsorbent power of active carbon, and its applications.** *Ann. chim. applicata* **33**, 191-3(1943).—*C.A.* **40**, 7572⁹.

A gas is passed at const. pressure over the active carbon in a special simple app. which contains indicator papers to show when adsorption ceases. The same app. may be used for collecting heavy gases or vapors, to det. the hydrocarbon content of natural emanations, to det. the C_6H_6 derivs. in the gas obtained in the distn. of the coal, etc.

83. Alekseevskiĭ, E.V. and Gorchakov, N.D. **Recovery of vapors of volatile solvents on solid sorbents. VI. Thermal phenomena in sorption of vapors of volatile solvents under conditions of its recovery. Sorption of benzene vapor and ethanol vapor on charcoal.** *J. Applied Chem. (U.S.S.R.)* **17**, 289-98(1944) (English summary).—*C.A.* **39**, 2434⁵.

Under conditions of dynamic sorption of C_6H_6 and EtOH vapors in the packing of activated charcoal in the range (15-30mg/liter) heating was observed which affected the various factors influencing the rate of sorption. It was particularly great in short layers of the sorbent. The temp. gradient along the charcoal layer may be used as a measure of the distribution of concns. of the solvents along the length of the packing.

84. Alekseevskiĭ, E. V. and Gorchakov, N. D. **Recovery of vapors of volatile solvents on solid sorbents. VII. Sorption of vapors of binary solvents on activated charcoal. Sorption of mixed vapors of ethyl alcohol and benzene on charcoal AG.** *J. Applied Chem. (U.S.S.R.)*, **17**, 394-408 (1944) (English summary).—*C.A.* **39**, 3466⁹.

The sorption of mixts. of EtOH and C_6H_6 at const. gas velocity on charcoal "AG" was greatly affected by the warming of the effective layer of the charcoal by the heat of sorption. The distribution of the sorbed components was changed by this heat effect. A method was developed for calcn. of fractional sepn. of the mixt. by sorption in the interval of practical concns.

85. Alekseevskiĭ, E. V. and Gorchakov, N. D. **Recovery of vapors of volatile solvents on solid sorbents. VIII. Sorption of vapors of binary solvents on active charcoal and desorption from charcoal of mixtures of ethyl alcohol and benzene.** *J. Applied Chem. (U.S.S.R.)* **17**, 487-94 (1944) (English summary).—*C.A.* **39**, 3978⁹.

In fractional vapor desorption of ethanol and benzene mixts. on activated charcoal AG (initial mixt. of 80% EtOH), the frontal section of the sorbent displays the displacing tendency of benzene. With a 50-50 original mixt. the displacing tendency of benzene is very much more pronounced, so that the tail of the sorbent layer contains pure EtOH. The effect is rapidly intensified as the benzene concn. in the original mixt. is increased.

86. Amphoux, B. **Selective adsorption of binary or ternary mixtures of various organic vapors.** *Ann. chim.* **19**, 1-57(1944).—*C.A.* **39**, 853².

Marked differences were found with active charcoal according as the static or the dynamic method of adsorption was used. The dynamic method led to a higher ratio of EtOH/water in the adsorbate than in the vapor phase, whereas the static method resulted in an adsorbate that was relatively richer in water than the mixt. of the vapors. Regardless of the method, the adsorption of an alc. was stronger the higher its mol. wt. Mixts. of vapors of benzene and cyclohexane showed no selective adsorption in a static system, but a considerably higher rate of adsorption for benzene than for cyclohexane. In mixts. of isomers such as o-xylene and m-xylene, neither the static nor the dynamic method resulted in the preferential adsorption of the one or the other component of the mixt. of the vapors. The rate of adsorption of benzene was higher than that of any of the alcs.

87. Maggs, F. A. P. **Adsorption of vapors on carbonized coal.** *Proc. Conf. Ultra-fine Structure of Coals and Cokes, Brit. Coal Utilisation Research Assoc.* **1944**, 147-50.—*C.A.* **39**, 1276⁹.

Isotherms at 25°C were detd. by the McBain balance technique for MeOH, water, C_6H_6, n-hexane, BuOH, and benzyl alc. on weakly caking Northumberland coal. No adsorption was detected for BuOH or benzyl alc. Similar expts. with MeOH, EtOH and PrOH were made on the same coal carbonized at 600°, 708° and 807°C. Wts adsorbed per g of coal were extrapolated to satn. vapor pressure. Heats of MeOH wetting and elec. resistivity values were detd. and the monolayer capacity was calcd. from the area given by the heats of MeOH wetting. Time required for MeOH adsorption increased from about 1 hr to about 14 days for the temp. range studied. Desorption also took place with increased difficulty with increased carbonization temp. The difference was ascribed to increased time required for MeOH to penetrate into the pores.

88. Sawyer, Frederick G. and Othmer, Donald F. **Adsorption of solvent vapors on commercial activated carbon.** *Ind. Eng. Chem.* **36**, 894-901 (1944).—*C.A.* **38**, 6155⁵.

Adsorption equil. were detd. for acetone, MeEtCO, iso-BuMeCO, MeOH, CS_2 and Et_2O. Rapid measurement of equil. adsorbate concn. used a cathetometer to observe the elongation of a sensitive Be-Cu spring carrying the adsorbent. The data were plotted first as isotherms, and then isosteres were crossplotted by a graphical method. Heats of adsorption were calcd. by the same method.

89. Alekseevskiĭ, E. V. and Vanyushina, Z. S. **Recovery of vapors of volatile solvents on solid sorbents. IX. Desorption of volatile solvents from charcoal.** *J. Applied Chem. (U.S.S.R.)* **18**, 193-207 (1945) (English Summary).—*C.A.* **40**, 3306⁷.

The desorption of EtOH and benzene from charcoal AP by means of steam proceeded simultaneously with sorption of water vapor. The latter was a function of charcoal temp., time, the nature of the displaced solvent, and the retaining capacity of the charcoal. The poorer the miscibility of the solvent with water, the less intense was the sorption of water in the above displacement. Generally, 10 min. were sufficient to displace 45-85% of the adsorbed solvent.

90. ALEKSEEVSKIĬ, E. V. AND VANYUSHINA, Z. S. **Recovery of volatile solvent vapors on solid sorbents. XI. Desorption of solvents from solid sorbents by water vapor. Desorption theory.** *J. Applied Chem. (U.S.S.R.)* **18**, 658-65 (1945) (English summary).—*C.A.* **40**, 6316^7.

Desorption of benzene and alc. from charcoal using water vapor was investigated further. The desorption rate was connected with the residual amt. of solvent vapor by the equation: $-da/dt = bu^n$, where a = solvent concn., t = time, b = exptl. const., as was n, and da/dt was the rate of sorption. Benzene was desorbed more rapidly than alc. and the amt. of desorbed vapor was linearly dependent on the depth of the charcoal layer.

91. GORCHAKOV, N. D. AND POGODIN, I. I. **Desorption of solvents from activated charcoal by inert gases. I.** *J. Applied Chem. (U.S.S.R.)* **18**, 538-47 (1945) (English summary).—*C.A.* **40**, 5616^5.

Charcoal AP was statically tested for activity to benzene, EtOH, and Et_2O vapors. The results showed the highest retentivity for benzene and least for EtOH. Desorption of EtOH by CO_2 was studied and the optimum values were 125-30°C, CO_2 flow 0.5 liter/cm²/min., and a time of 15 min. Under these conditions up to 89% EtOH was desorbed.

92. GORCHAKOV, N. D. AND POGODIN, I. I. **Desorption of solvents from activated charcoal by inert gases. II.** *J. Applied Chem. (U.S.S.R.)* **18**, 666-8 (1945).—*C.A.* **40**, 6316^4.

The desorption rate of EtOH from charcoal by CO_2 was detd. at various rates of CO_2 flow (from 0.1 to 1.5 liter/cm²/min.). The optimum conditions were 125-30°C, CO_2 flow rate of 0.5 liter/cm²/min. and 15-min. duration. In such a case up to 88.4% of adsorbed EtOH was desorbed with utilization of 1 m³ of CO_2 per kg of EtOH.

93. GORCHAKOV, N. D. AND POGODIN, I. I. **Desorption of solvents from activated charcoal by inert gases. III.** *J. Applied Chem. (U.S.S.R.)* **18**, 669-79 (1945).—*C.A.* **40**, 6316^5.

Desorption of EtOH from charcoal AP was studied by using CO_2 for desorbent at 95-8°C, 110-12°C, 125-30°C. The optimum condition was 125-30°C with CO_2 at 0.5 liter/cm²/min. Desorption by CO_2 and N_2 was also studied under conditions of const. use of the charcoal layer. The only amt. of CO_2 actually needed was that required to fill the app. The method was considerably superior to the commercially used steam desorption.

94. ROBSON, G. W. **Benzene recovery by activated carbon.** *Gas World* **123**, 399-400(1945); *Gas J.* **246**, 687, 689(1945).—*C.A.* **40**, 443^7.

The Morpeth plant has a capacity for 400,000 ft³ of gas per day. Each of the two adsorbers contains about 300 lb. of charcoal. The complete cycle comprises: (1) adsorbing light oil from the gas, (2) steaming the light oil out of the charcoal, and (3) drying the charcoal with stripped gas from the outlet of the plant. The temp. of the drying gas is raised in a preheater 33-39°C above the normal gas temp. The longest cycle is 60 min. adsorbing, 30 min. steaming, and 30 min. drying. The general life of a charge of charcoal is about 100 days. Spent charcoal can not be satisfactorily reactivated at the plant. Drying of the charcoal is a very important factor in maintaining its life.

95. DANBY, C. J.; DAVOUD, J. G.; EVERETT, D. H.; HINSHELWOOD, C. N., AND LODGE, R. M. **Kinetics of the adsorption of gases from an air steam by granular reagents.** *J. Chem. Soc.* **1946**, 918-34.—*C.A.* **41**, 1145^a.

A theoretical treatment of the removal of a gas from an air stream by passing it through a granular solid with which it reacts or by which it is irreversibly adsorbed. The following relations were studied in particular: (a) escaping concn. as a function of time, column length, flow rate, and initial concn., (b) distribution of gas or reaction product in the column, and (c) effect of granule size. Special consideration was given to charcoals contg. various addn. agents.

96. DOLE, MALCOLM AND KLOTZ, IRVING M. **Sorption of chloropicrin and phosgene on charcoal from a flowing gas stream.** *Ind. Eng. Chem.* **38**, 1289-97 (1946).—*C.A.* **41**, 897^f.

The break times did not change much with temp. The slope of the c/c_0-time curve (c = concn.) at the mid-point was, however, directly proportional to k (and also to c_0) according to theory. From an estimate of the slopes at 0° and 22°C the activation energy for adsorption of chloropicrin was about 3000 cal. per mole. The mass transfer of the gas to the charcoal surface from the flowing air stream could not be the entire rate-detg. process, because the crit. bed depths did not extrapolate to zero at zero particle size, the max. slope of the c/c_0-time curve was not so dependent on flow rate as the gas phase diffusion theory required, and the max. slopes depended so markedly upon influent concn., contrary to predictions of the diffusion theory.

97. DUBININ, M. M. AND TIMOFEEV, D. P. **Adsorption of vapors on active charcoals in relation to the properties of the adsorbate.** *Compt. rend. acad. sci. U.R.S.S.* **54**, 701-4 (1946) (in English).—*C.A.* **41**, 7198f.

The characteristic curves for different vapors were all described by an equation relating adsorption potential, coeff. of affinity, and the vol. of adsorbed vapor in the liquid state. The affinity could be detd. from a knowledge of polarizabilities, van der Waals' attraction consts., or diamagnetic susceptibilities. The polarizability of mols. approx. varied directly as the molar vol. of the adsorbate in the liquid state. Exptl. values were detd. by using a sorption wt method and compared with values calcd. The suggested method seemed to give close exptl. agreement. The vapors used were: C_6H_6, C_5H_{12}, C_6H_{12}, C_7H_{16}, toluene, MeCl, CH_2Cl_2, $CHCl_3$, CCl_4, EtCl, MeOH, EtOH, HCOOH, AcOH, Et_2O, Me_2CO, CS_2, CCl_3NO_2, NH_3.

98. GORCHAKOV, N. D. AND VANYUSHINA, Z. S. **Desorption of solvents from activated charcoal by inert gases. IV.** *J. Applied Chem. (U.S.S.R.)* **19**, 97-101 (1946).—*C.A.* **40**, 6316^6.

The dynamic activity of charcoal AP at a layer depth of 100 cm and benzene concn. of 30 mg/liter was 20-30%, in desorption of benzene by means of

CO_2. The optimum time for desorption was 15 min. at 180°C at 0.5 liter/cm^2/min. rate of CO_2 flow. It was possible to condense 72% of benzene which was adsorbed on the charcoal under the above conditions.

99. JURA, GEORGE; HARKINS, WM. D., AND LOESER, EDWARD H. **Surfaces of solids. XVII. A first- and a second-order phase change in the adsorbed film of heptane on graphite.** *J. Chem. Phys.* **14,** 344-7(1946).—*C.A.* **40,** 4275^6.

Films of n-C_7H_{16} between 25° and 40°C exhibited a 1st-order transition between the gaseous and liquid expanded phases and a 2nd-order transition between the liquid expanded and liquid intermediate phases, and between the gaseous and liquid intermediate phases above the crit. temp. The crit. consts. for the gaseous film were detd.: temp. 31°C, area 400 A^2. per mol., film pressure 1.05 dynes per cm. These values differed from those found for n-C_7H_{16} on Fe_2O_3. The heat of transition for the 1st-order change was estd. as 13,000 ± 5000 cal. per mole at 25°C.

100. KIRILLOV, I. P. AND RAKHLIN, E. S. **Adsorption of methane by charcoal.** *J. Applied Chem. (U.S.S.R.)* **19,** 511-16(1946) (in Russian).—*C.A.* **41,** 2299^c.

Activated charcoal (BAU 20) retains initially almost all CH_4 from a mixt. with N_2 and H_2. At 16°C, flow rate of 16 ml/min./cm^2, 3.3% CH_4 concn. in the mixt., the time of protective action is given by $\theta = 4.4L - 0.8$, where θ is the time of protective action in min., L is the thickness of the layer in cm. The temp. effect is given by $\theta = 15.5 - 0.1$ t, where t is temp. Increase of pressure increases the quantity of CH_4 adsorbed by a unit of the charcoal.

101. LUÁCES, E. L. **Vapor-adsorbent carbons.** *Colloid Chemistry* **6,** 840-8(1946).—*C.A.* **40,** 2039^3.

The mechanism of adsorption and nature of active carbon is discussed. Other topics are: recovery of volatile solvents and app.; recovery of gasoline from natural gas, of alc. from fermentation gases, and of CS_2 vapors in rayon production.

102. VOLMAN, D. H. AND KLOTZ, I. M. **Adsorption isotherms for hydrogen-bonded liquids on charcoal.** *J. Chem. Phys.* **14,** 642 (1946).—*C.A.* **41,** 1906^d.

In van der Waals adsorption on charcoal, a plot of the wt adsorbed as a function of the relative pressure (p/p_0) of the vapor gives curves roughly the same for most compds. The exceptions are characterized by strong H-bonds in the liquid state. There is a strong parallelism between the adsorbability and condensation properties of a gas. In the absence of H-bonding, water would boil at -80° to -100°C, and would have a vapor pressure of 20,000 mm at room temp.

103. BARROW, R. F.; CANBY, C. J.; DAVOUD, J. G.; HINSHELWOOD, C. N., AND STAVELY, L. A. K. **Re-distribution desorption of absorbed gases.** *J. Chem. Soc.* **1947,** 401-16.—*C.A.* **41,** 4992i.

The adsorption of gases by active charcoal from a current of air consists of the following stages: (a) adsorption, in which enough gas is introduced to sat. only the initial layers of the charcoal; (b) re-distribution, in which the gas diffuses along the column; and (c) desorption, in which the gas reaches the final layer of the column and is desorbed into the effluent stream of air. HCN, CCL_4, CNCL, and water are used as the exptl. gases. Equil. between the gas stream and small finite elements is assumed to be reached very rapidly. The math. treatment is not rigorous, but good approximations are obtained.

104. COFFIN, C. C. AND LONG, B. F. **The heterogeneity of activated cocoanut-shell charcoal.** *Can. J. Research* **25B,** 502-8(1947).

The individual adsorption capacities of over 500 pieces of 6 to 10 mesh activated cocoanut-shell charcoal for CCl_4 vapor were detd. by weighing each piece separately on a microbalance before and after saturation. The particle capacities were found to be distributed over a probability curve represented by the following equation: $y = 14.6\ e^{-0.0036x^2}$. Small particles adsorbed more CCl_4 than large ones and dense particles more than those of lesser density.

105. COURTY, CLEMENT. **Comparative adsorptions of chloropicrin and carbon disulfide on active carbon.** *Compt. rend.* **224,** 1638-9 (1947).—*C.A.* **41,** 7198*e*.

The adsorption on active charcoal of water, chloropicrin, and CS_2 was investigated by magnetic susceptibility measurements. The av. amts. adsorbed at ordinary temps. were resp., 0.48 g, 0.60 g, and 0.73 g. With water and CS_2 air was displaced, whereas with chloropicrin air was adsorbed.

106. DOLE, MALCOLM. **The rate of adsorption of phosgene and chloropicrin on charcoal.** *J. Chem. Phys.* **15,** 447-54(1947).—*C.A.* 41, 6105*i*.

It is possible to det. an abs. rate of adsorption of $COCl_2$ and CCl_3NO_2 on charcoal from exptl. data. Diffusion to the most accessible part of the charcoal surface will occur faster than the observed rate, but more slowly to the least accessible surface areas. Rates of adsorption calcd. by use of statistical equations are of the correct order of magnitude when plausible assumptions are made concerning the nature of the activated state. Both diffusion and surface-reaction mechanisms must be postulated for a complete model of the adsorption rate of the two gases, but with diffusion being less important in the case of $COCl_2$.

107. DUBININ, M. M. AND TIMOFEEV, D. P. **Adsorbability and physicochemical properties of vapors. I. Adsorption of vapors by active carbons.** *J. Phys. Chem. (U.S.R.R.)* **21,** 1213-22 (1947) (in Russian).—*C.A.* **42,** 2489*c*.

Adsorption of 14 vapors by active charcoal, from hazel-nut shells (ash 0.23%) and from anthracite + wood tar (ash 1.18%) was detd. at 20°C from 0.0001 mm Hg to satn. Quartz spiral balances allowed simultaneous measurement of 4 isotherms. The amt. adsorbed at 10 mm Hg increased for anthracite charcoal in the order $CH_3Br < C_2H_5Cl <$ pentane < heptane < hexane < cyclohexane < toluene < $CCl_4 < CHCl_3 < C_6H_6 < CH_3OH <$ AcOH $< HCO_2H < H_2O$. The order for nut charcoals differed little, but it was much altered when the adsorbed amts. were compared at 0.1 mm Hg: $CH_3Br < CH_3OH < C_2H_5Cl <$ pentane $< CHCL_3 < HCO_2H <$ cyclohexane < hexane < $CCl_4 < C_6H_6 <$ heptane < toluene < AcOH.

108. DUBININ, M. M. AND TIMOFEEV, D. P. **Adsorption of vapors on active charcoals in relation to the physical properties of the adsorbate.** *Compt. rend. acad. sci. U.R.S.S.* **54**, 137-9(1947) (in English).—*C.A.* **41**, 7198i.

Introduction of a coeff. of affinity into the characteristic equation of the Polanyi theory led to expressions with 2 consts. characterizing the adsorbent and relating adsorbability to the molar vol. of the vapor and the relative vapor pressure. Measurements at 20 °C at 0.1, 1.0, and 10mm Hg on charcoal for C_6H_6, C_5H_{12}, C_6H_{12}, $C_6H_5CH_3$, C_7H_{16}, CH_3OH, CH_3COOH, HCOOH, C_2H_5Cl, and $CHCl_3$ confirmed the equations, with exception of the data for CH_3OH.

109. DUBININ, M. M.; ZAVERINA, E. D., AND RADUSHKEVICH, L. V. **Sorption and structure of active carbons. I. Adsorption of organic vapors.** *J. Phys. Chem. (U.S.S.R.)* **21**, 1351-62 (1947) (in Russian).—*C.A.* **42**, 5209b.

Nine active carbons were prepd. by heating sugar charcoal at 850° or 1000 °C for different lengths of time in CO_2. The wt loss of 850 °C ranged from 3.7% to 62.5%. The C_6H_6 adsorbed (liquid vol.) at 20 °C from the vapor at the relative pressure $p = 1$ ranged from 0.101 cc/g to 0.880. These values should be equal to the vol. of the micropores, if the pores are not too small for the C_6H_6 mol. The adsorption of C_6H_6 and MeOH vapors by these carbons was completely reversible. A 10th specimen was made by heating CO with Fe at 450 °C. The adsorption of C_6H_6 and MeOH by this carbon was accounted for by the B.E.T. theory and the specific surface was 164 m^2/g.

110. GARD, C. D. AND BOYD, T. F. G. **Development of air-fractionated charcoal test method and procedure.** *Calif. Oil World* **40**, No. 24, 15-23 (1947).—*C.A.* **42**, 2086*h*.

When a pure hydrocarbon gas is adsorbed on activated charcoal, the mols. form a thin layer of liquid over the intragranular surface of the pores. Whether the liquid layer completely fills the pores or not depends on the thickness of the liquid layer and the diam. of the pores. When CH_4 is adsorbed on an av. 50-min. activated cocoanut-shell charcoal at atm. pressure and 80 °F, approx. 7 cc. of CH_4 at S.T.P. is adsorbed on 1 cc. of bulk charcoal and the pore space in the charcoal is not completely filled with liquid methane. The pore space is not completely filled with liquid because the same vol. of bulk charcoal, under the same adsorbing conditions would have adsorbed approx. 85 cc. of C_3H_8 at S.T.P.

111. HAINES, R. S. AND MCINTOSH, R. **Length changes of activated carbon rods caused by adsorption of vapors.** *J. Chem. Phys.* **15**, 28-38 (1947).—*C.A.* **41**, 2299*g*.

The length variations of two $ZnCl_2$ activated charcoal rods caused by the adsorption of EtCl, C_4H_{10}, Me_2O, methylpropene, MeOH, n-C_6H_{14}, and H_2O were reported. A relation between % extension of the rod and calcd. spreading pressure of the adsorbed film agreed well with expt. for org. vapors about 1/3 satn. of the monolayer capacity. It did not agree in the low adsorption region nor along the desorption branch of the water isotherm. A marked contraction of the rod below its original length was noted when water was desorbed.

112. INNES, W. B. AND ROWLEY, H. H. **Adsorption isotherms of mixed vapors of carbon tetrachloride and methanol on activated charcoal at 25°C.** *J. Phys. & Colloid Chem.* **51**, 1154-71 (1947).—*C.A.* **42**, 1101*d*.

The adsorption from a mixt. of CH_3OH and CCl_4 on activated charcoal was studied. The mole fraction of each adsorbate when the surface was completely covered agreed satisfactorily with an equation which assumed that the areas occupied by each mol. species were independent of those occupied by the other. Partial and total spreading pressures were calcd. from the adsorption data.

113. MCINTOSH, R.; HAINES, R. S., AND BENSON, G. C. **The effect of physical adsorption on the electrical resistance of activated carbon.** *J. Chem. Phys.* **15**, 17-27 (1947).—*C.A.* **41**, 2299^e.

The changes of elec. resistance of several rods of activated carbon on the adsorption of vapors of Me_2O, C_4H_{10}, iso-C_4H_{10}, SO_2, H_2O, EtCH:CH_2, methylpropene, He, CO_2, EtCl, and NH_3 were detd. The direction and extent of change appeared to depend on the adsorbate and were not necessarily due to the variations in contact resistance between the granules.

114. RADUSHKEVICH, L. V. **Theory of dynamics of adsorption on a real particulate adsorbent.** *Doklady Akad. Nauk S.S.S.R.* **57**, 471-4 (1947).—*C.A.* **46**, 4880i.

The adsorption of a gas passing through a layer of granular adsorbent, making use of the Einstein-Fokker equation for summation of individual transfers in irregularly packed aggregate, is derived. It is confirmed in general terms by following interferometrically the adsorption of EtOH and CCl_4 vapors on activated charcoal.

115. TAYLOR, HAROLD N. AND BONILLA, CHARLES F. **Adsorption of butadiene on activated charcoal.** *Ind. Eng. Chem.* **39**, 871-6(1947).—*C.A.* **41**, 6106d.

Adsorption and desorption isotherms on a $ZnCl_2$-activated wood charcoal were detd. at 0°, 25°, 56.7°, 76.5°, and 100 °C up to 1000 mm Hg. Repeated cycles indicated that the adsorptive capacity did not fall off with time at 76.5 °C and lower. A Polanyi plot showed agreement of all results below 100 °C. The heat of adsorption of butadiene on charcoal was about 290 B.t.u. per lb. The presence of water or the previous degassing of the charcoal did not decrease polymerization of butadiene on the charcoal at 100 °C.

116. BROUGHTON, D. B. **Adsorption isotherms for binary gas mixtures.** *Ind. Eng. Chem.* **40**, 1506-8 (1948).

An equation based on the second law of thermodynamics is derived between the isothermal adsorption equilibria for single components and their binary mixts. at const. total pressure. It provides a method for analyzing data to det. whether true equil. has been obtained in binary gas mixts. The equation is derived from an extension of the Langmuir theory to binary mixts. Available data for adsorption of A and N_2 on two silica gels are analyzed by the proposed method.

117. DUBININ, M. M. AND TIMOFEEV, D. P. **Adsorbability and physicochemical properties of vapors. II. Rules from the viewpoint of the potential**

theory of adsorption. *J. Phys. Chem. (U.S.S.R.)* **22**, 133-43 (1948) (in Russian).—*C.A.* **42**, 5298*g*.

If *p* is the relative pressure of a vapor, *a* the adsorption at *p*, and *v* the mol. vol. of the liquid adsorbate, then $RT\ln p = \beta f\ (av)$, the function f being characteristic for the adsorbent and independent of temp. and the nature of the vapor, and β being a factor characteristic of the vapor. If β of C_6H_6 is set equal to 1, the β of MeOH, MeBr, HCO_2H, EtCl, C_3H_8, $CHCl_3$, butane, AcOH, cyclohexane, CCl_4, pentane, toluene, hexane, and heptane is 0.40, 0.57, 0.61, 0.76, 0.78, 0.86, 0.90, 0.97, 1.04, 1.05, 1.12, 1.25, 1.35, and 1.59, resp.; its values are almost identical for the two carbons used. The adsorbability depends on more than one property of the vapor and also on the adsorbent.

118. Dubinin, M. M. and Timofeev, D. P. **Calculation of adsorption isotherms of vapors on active carbons.** *Doklady Akad. Nauk S.S.S.R.* **60**, 821-4(1948).—*C.A.* **43**, 16f.

Affinity coeffs., permitting calcn. of the isotherm of a given vapor from that of another vapor, were calcd. or recalcd., partly from new detns. These were tabulated for all pairs formed between C_6H_6, MeOH, EtOH, EtCl, CS_2, Me_2CO, CCl_4, Et_2O, chloropicrin, C_3H_3, C_4H_{10}, C_5H_{12}, C_6H_{14}, C_7H_{16}, cyclohexane, $CHCl_3$, MeBr, HCO_2H, AcOH, and PhMe.

119. Dubinin, M. M. and Zaverina, E. D. **Structure and sorption properties of active carbon from phenol-aldehyde resins.** *Doklady Akad. Nauk S.S.S.R.* **61**, 1053-6(1948).—*C.A.* **43**,838*b*.

Bakelite was heated in a covered crucible gradually to 500°C; the grain-size fraction 0.5-1.0 mm of the coke was heated 1/2 hr at 1000°C *in vacuo*. The product was subjected to activation with excess CO_2 at 1000°, 850°, and 750°C. Combustion occurred throughout the whole mass of the grains and their dimensions underwent no appreciable change; the rate of combustion in CO_2 was, consequently, proportional to the mass, *m*, of the sample: $-dm/dt = km$, the rate const. for 1000°, 850°, and 750°C being, resp., 0.14, 0.019, and 0.011 hr^{-1}. The rate consts. for charcoal from sucrose were: $k = 0.13$ and 0.010 at 1000° and 850°C, resp. In sorption of C_6H_6 vapor at 20°C, the time necessary to attain equil. along the initial portion of the adsorption isotherm, increased from 10 to 30 min. for prepns. from 1000° to 750°C, at not too great depths of combustion; this effect was even more marked in sorption from soln. Consequently, at low pressures or concns. establishment of sorption equil. was slower, the finer the micropores.

120. Josefowitz, Samuel and Othmer, Donald F. **Adsorption of vapors. A new apparatus, and data for the lower ketones, benzene, and hexane on activated carbon.** *Ind. Eng. Chem.* **40**, 739-43(1948).—*C.A.* **42**, 4422*b*.

A modified McBain-Bakr adsorption balance using a Be-Cu spring permitted degassing at 500°C to 10^{-5} mm, and the detn. of adsorption up to 550°C at pressures below the vapor pressure of the adsorbate at room temp. This was used to det. the adsorption of C_6H_6, n-C_6H_{14}, Me Et Ketone, Me iso-Bu Ketone, and acetone on 3 commercial activated carbons. No hysteresis was observed between 40° to 200°C. Equilibria seemed to be attained faster on adsorption than desorption.

121. Khodot, V. V. **Potential methane content of some bituminous coals.** *Izvest. Akad. Nauk S.S.S.R. Otdel. Tekh. Nauk* **1948**, 1753-72.—*C.A.* **45**, 8737*a*.

Four samples of bituminous coal, characterized by different stages of metamorphism and different petrographic compn., were studied with respect to their potential CH_4 content in the pressure range from 0 to 1000 atm. at a temp. of 25°C. Study of the sorption isotherm of CH_4 on activated charcoal of two different kinds showed that both curves had the same analytical expression and deviated only in const. ratio. On the basis of the behavior of the activated charcoal, bituminous coal was considered as a kind of colloidal structure, in which the elasticity or brittleness studied was related to the stage of metamorphism shown by the sample.

122. McBain, James W. and Sessions, R. F. **Sorption of vapors by sugar charcoal over a period of twenty years.** *J. Colloid Sci.* **3**, 213-18 (1948).—*C.A.* **42**, 6198e.

The sorption of various vapors by sugar charcoal at 120°C were detd. using silica-spring sorption balances. CCl_4, $Cl_2C{:}CCl_2$, PrCOOH, $CHCl_3$, and toluene were sorbed to a satn. value that did not change during the entire period, but the sorption of Et_2NH, Et_3N, and pyridine increased slightly during the 19.5 years. The isotherm obtained with H_2O was completely altered by the water-gas reaction that occurred between H_2O and charcoal over long periods of time. The silica springs did not stretch to any appreciable extent in the presence of org. vapors for 19.5 years, but stretching did occur in the presence of H_2O vapor. The springs that had been exposed to CCl_4 and $Cl_2C{:}CCl_2$ vapors for 19.5 years did not stretch under these conditions, but they stretched over 1% when removed from the org. vapors and exposed to air for one day.

123. Mennessier, André and Boucher, Raymond. **Rates of adsorption by active carbon.** *Compt. rend.* **226**, 914-16 (1948).—*C.A.* **42**, 4422*a*.

The rate of adsorption by dry C_6H_6 on active carbon during the first 60 sec, was linear, exponential in the interval 60-800 sec, and tended towards and asymptotic value, m_o, after 800 sec. It was proposed that the value, $m_o/2$ was a valid comparison between the activities of various samples of active carbon provided that the ratio of final pressure to satn. pressure was in the range 0.005-0.4.

124. Pal'velev, V. T. **Sorption of methane on active carbon under high pressures.** *Doklady Akad. Nauk S.S.S.R.* **62**, 779-82 (1948).—*C.A.* **43**, 1237*h*.

Isotherms of excess adsorption (in cc./g of CH_4 at 25°C) on two different samples of active charcoal pass through a max. at about 100 kg/cm^2, then fall to zero at about 700-900 kg/cm^2. The fall is due to increasing predominance of neg. term involving the vol. of the adsorption space; zero excess adsorption corresponds to equality of the d. of the gas in the free space and in the adsorption space. The true d. of the adsorption layer becomes max. and const. at 200 kg/cm^2. From the vol. of the adsorption space, 0.18 and 0.24 cc., resp., for the 2 samples (as against a micropore vol. of, resp., 0.31 and 0.35 cc.), the limiting adsorption is, resp., 3.8 and 4.5 millimoles/g. The effective diam. of a CH_4 mol. in the adsorbed layer, 4.8 and 5.0 A., resp. is about 20% higher than in the CH_4 crystal. The pore surface areas of the 2 samples are 572 and 677 m^2/g, resp. Langmuir's equation fits the true adsorption isotherm satisfactorily, and surface heterogeneity is present only at lowest pressures.

125. PAPPAS, ALEXIS C. **Porous fillers for dissolved acetylene (storage).** *Tids. Kjemi, Bergvesen Met.* **8**, No. 4, 48-52, No. 5, 68-75 (1948).—*C.A.* **45**, 287*g*.

Fillers used in C_2H_2 cylinders with Me_2CO as the solvent were: (a) powd. filler contg. peat, kieselguhr, and charcoal; (b) pumice and kieselguhr; (c) charcoal; (d) kapok; and (e) a charcoal, kieselguhr, asbestos, and binder mixt. The latter was found to be most satisfactory after consideration of the chem. reactions between C_2H_2 and the fillers, the phys. properties of the fillers, and the resistance of the full cylinder to shock, heat, and internal explosion.

126. TUCK, N. G. M.; MCINTOSH, R. L., AND MAASS, O. **The density of adsorbates.** *Can. J. Research* **26B**, 20-37(1948).—*C.A.* **42**, 4422*f*.

The apparent d. of the adsorbate and the adsorption isotherm were detd. for CCl_4 and Et_2O on charcoal. The apparent d. of the adsorbate was lower than the normal liquid. These low d. could not be explained on the basis of co-existence of vapor and liquid adsorbed phases, but agreed with the postulation that the adsorbate blocked off internal voids of the charcoal. The Langmuir equation and the Harkins-Jura equation were used in interpreting the data and the regions of validity for each detd. Ne was appreciably adsorbed on charcoal at 25°C and hence could not be used in comparison with He to study the effect of mol. size on the apparent d. of the adsorbate.

127. VOLMAN, DAVID H. AND ANDREWS, LAWRENCE J. **Configuration and adsorption. A comparison of the adsorption of the cis and trans isomers of dichloroethylene on activated carbon.** *J. Am. Chem. Soc.* **70**, 457-62(1948).—*C.A.* **42**, 3639*f*.

Cis- and *trans-* dichloroethylene was adsorbed on activated carbon from 30° to 90°C. The B.E.T. areas and isosteric heats of adsorption for const. surface fraction covered were detd., with no comparative differences being found between *cis* and *trans* isomers. The selection of the two isomers offered a study of adsorption on two compds. varying widely in dipole moment (zero for trans and 1.8 Debyes for the cis isomer). By using a modification of the B.E.T. equation, where n was between 1 and 2, it was shown that the considerably lower and more const. monolayer areas were obtained over the temp. range for n = 1.6 than for n = 1.0. The values of isosteric heat of adsorption for equal areas covered were: 8.5 kcal/mole for *trans* and 9.0 kcal/mole for *cis* compd.

128. WILLIAMS, H. LEVERNE. **Adsorption and decomposition of nickel carbonyl on the surface of respirator charcoals.** *Can. J. Research* 26B, 541-9(1948).—*C.A.* **42**, 9122*g*.

Ni carbonyl is adsorbed by activated (impregnated or unimpregnated) coconut-respirator charcoals without decompn. in the absence of O_2. The amt. adsorbed is reduced if the charcoal has previously adsorbed Ni carbonyl, CCl_4, $COCl_2$, or H_2As and has not been degassed thereafter. The adsorbed Ni-carbonyl is oxidized rapidly by O_2, liberating CO_2, CO, and leaving an amorphous deposit on the charcoal. This deposit is slightly more than half Ni and does not yield an x-ray diffraction pattern. Ni carbonyl is adsorbed in a manner similiar to CCl_4 and upon oxidation forms a hydrous Ni carbonate-Ni oxide complex. Assuming that adsorption is in the form of unimol. films the area of the charcoal is 858 m^2/g.

129. BARNARTT, S. AND FERGUSON, J. B. **The isopiestic method applied to sorption isotherms.** *Can. J. Research* **27B**, 87-100 (1949); **27B**, 25 (1949).—*C.A.* **43**, 4922b.

The sorption of CCl_4 and H_2O vapors was detd. on activated coconut-shell charcoals. Duplicate samples exhibited differences in activites ranging from 1 to 5%; adsorption and desorption were run on some samples. Isotherms formed by plotting the isopiestic charges of 2 charcoals one against the other consisted of 3 linear sections for both CCl_4 and H_2O. If the pressure isotherm of one charcoal was known, those of other charcoals could be calcd. from it by weighing relatively few isopiestic charges. The linear relation between the isopiestic charges afforded a simple criterion of rejection for the Langmuir and Freundlich equations proposed to fit the pressure isotherms. It also threw into relief the structural regularities in activated charcoals. The existence of discontinuities in the sorption process was supported by the isopiestic data.

130. BARNARTT, S. AND FERGUSON, J. B. **An isopiestic investigation of charcoal activation.** *Can. J. Research* **27B**, 101-15 (1949).—*C.A.* **43**, 4922*e*.

CCl_4, H_2O, MeOH, and C_7H_8 was adsorbed on a series of coconut shell charcoals at different stages of activation by steam. The sorption of H_2O by 2 charcoals of this series impregnated by benzoic acid was also investigated. The isopiestic charges of this activation series were linearly related over wider pressure ranges than were those of unrelated charcoals. The activation process created surfaces, probably of a heterogeneous character, that were active to all the vapors studied. The various types of surfaces increased in abundance with activation at the same relative rate up to a certain stage where the production of the surfaces active at relatively low pressures began to decline. This indicated that new pores were being created more slowly in comparison with the widening of existing pores. The activation process also produced some chemically selective centers that were active at minute relative pressures.

131. DUBININ, M. M. AND ZAVERINA, E. D. **Structure and adsorptive properties of zinc chloride-activated carbon.** *Doklady Akad. Nauk S.S.S.R.* **68**, 91-4 (1949).—*C.A.* **43**, 8790*b*.

Charcoals were prepd. by heating sucrose with $ZnCl_2$ in various wt proportions ($i = ZnCl_2/\text{sucrose}$) for 1 hr at 600° or 850°C and willow lignin with $ZnCl_2$ at 650°C. Yields from sucrose ranged from 25 to 36% and adsorption isotherms of C_6H_6 at 20°C were linear in the plot of log a vs. $(\log p_s/p)^2$

for i from 0.04 to 0.40 (1st structural type), and in log a vs. log p_s/p from $i = 1.0$ to 5.0 (2nd structural type). In the 1st type the const. W_o (limiting vol. of the adsorption space) of the adsorption isotherm equation increased with i. A very marked increase of the vol. of micropores resulted in a decrease of the sp. surface area. Similar results were obtained in activation by K_2CO_3 or KCNS.

132. DUBININ, M. M. AND ZAVERINA, E. D. **Structure types of active carbons.** *Doklady Akad. Nauk S.S.S.R.* 65, 295-8(1949).—*C.A.* 44, 10441i.

Activated carbons were classified by the variation of adsorption potential (ϵ) with the diam. of the pores. The 1st type, represented by moderately activated carbons, up to 50% wt loss, was characterized by a relation of the form $W = W_o exp(-k\epsilon^2)$ (where W_o = limiting vol. of the adsorption space), and a corresponding adsorption isotherm equation $a = (W_o/v)\exp[-B(T^2/\beta^2) \log (p/p_s)^2]$, where a = adsorption at the relative pressure p/p_s and temp. T, v = mol. vol. of the liquefied vapor at T, β = affinity coeff., and k and B are consts. This equation held for moderately activated carbons in a p/p_s range of 1×10^{-5} to 0.4-0.5, W from 0.15 to 0.95. The equation became inapplicable altogether at activations corresponding to over 75% wt loss. This type was illustrated by various carbons activated to 80-95% at 850-1000°C, different kinds of lampblack, and adsorption data of C_6H_6 vapor at 20°C. It included, besides coarse-porous highly activated carbons, also nonporous highly dispersed carbon prepns.

133. ETTINGER, I. L. **Sorption of methane by the hard coals of the Kuznets basin.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk* 1949, 986-90.—*C.A.* 45, 8738*a*.

Nine samples of coal were studied by the static-vol. method for which 28 sorption isotherms of CH_4 were taken. Expts. were made with pressures from 0 to 800 mm Hg and from 0° to 40°C. The sorption of CH_4 by coal was phys. in nature and the CH_4 capacity of hard coal increased in the direction from rich to poor coal. It was shown that the Freundlich equation for sorption isotherms was applicable for the interval of temp and pressure studied.

134. NAY, M. A. AND MORRISON, J. L. **The molecular adsorption areas of hydrocarbon gases on charcoal.** *Can. J. Research* 27B, 205-14 (1949). *C.A.* 43,6488*f*.

The low-temp. adsorptions of C_2H_2, C_4H_{10}, iso-C_4H_{10}, C_2H_6, C_2H_4, CH_4, N_2, and C_3H_8 were detd. on a series of coconut charcoals of various degrees of activity. Langmuir isotherms were obtained and measurements indicated horizontal orientation of the hydrocarbon mols. on the charcoal surface. By assuming a mol. adsorption area of 16.2 A.^{2} for N_2, the following av. adsorption areas were obtained: C_2H_2 19.8, C_4H_{10} 42.1, iso-C_4H_{10} 47.4, C_2H_6 24.9, C_2H_4 23.1, CH_4 19.4, C_3H_8 36.0 A.^{2}.

135. PAL'VELEV, V. T. **Interaction between molecules in the sorbed layer under high pressures.** *Doklady Akad. Nauk S.S.S.R.* 65, 875-8 (1949).—*C.A.* 44, 7616c.

The observed adsorption isotherms of CH_4 on active charcoal and on natural coal increased in both cases up to 50-100 kg/cm^2, but then decreased with further rising pressure to zero at p = 700-900 for charcoal, but remaining const. (up to p = 1000) on coal. The sorbed CH_4 occupied no addnl. space other than the vol. of the coal and the later did not increase as the result of sorption. If it was borne in mind that, under the given exptl. conditions of drying, the coal had retained considerable amts. of H_2O, it was obvious that under sufficiently high P the adsorbed CH_4 formed with H_2O a solid hydrate $CH_4 \cdot H_2O$. This process was completed at about 100 kg/cm^2. The amt. of H_2O necessary to bind the total CH_4 adsorbed at room temp., about 0.7 millimole/g, was about 8%, and that amt. was retained by the coal after low-temp. drying *in vacuo*.

136. PHILLIPS, C. S. G. **The chromatography of gases and vapors.** *Discussions Faraday Soc.* **1949**, No. 7, 241-8.—*C.A.* 45, 1460*f*.

A simplified arrangement is described for the chromatographic analysis of gas and vapor mixts. by employing a carrier gas (N_2) contg. a const. concn. of a more strongly adsorbed material (EtOAc). N_2 obtained from a cylinder through a large buffering vol. is passed (50-100 ml/min.) through a simple compensating flowmeter, a saturator contg. EtOAc (0°), the column, 3-10-cm tubes (internal diams. of 15 mm, 8 mm, and 2 mm) and finally the analyzer, a thermal cond. cell connected to an automatic recorder. Samples are brought on to the column by condensing them in a liquid-air trap through which the N_2 can be passed. Activated charcoal (40 mesh) and dried at 120°C is used as the adsorbent. The sepn. of various hydrocarbons, ethers, ketones, alcs., and esters are presented.

137. PIERCE, CONWAY; WILEY, J. W., AND SMITH, R. NELSON. **Capillarity and surface area of charcoal.** *J. Phys. Colloid Chem.* 53, 669-83 (1949).—*C.A.* 43, 6036*g*.

Isotherms were detd. on graphite, Saran charcoal, and steam-activated Saran charcoal for EtCl at 0° and -78°C, CCl_4 at 0°C, NH_3 at -78°C, and H_2O at 28.9°C. All detns., except NH_3, were made gravimetrically by removing and weighing the sample tube after each addn. of vapor. When capillary condensation occurred, it was impossible to det. the surface area of a porous solid from an adsorption isotherm and the commonly accepted values were much too large. In capillaries a few mol. diam. in width the Kelvin equation was inapplicable. Retentivity was greater for slightly activated samples than for more highly activated ones.

138. SHEFFER, H.; WALDOCK, K. T., AND FERGUSON, J. B. **The testing of activated charcoals by the isopiestic method.** *Can. J. Research* 27B, 25-34(1949).—*C.A.* 43, 4536d.

The "activities" or sorptive capacities of nine different activated charcoals were detd. by the isopiestic method using CCl_4, H_2O, AmCl, C_6H_6, MeOH, hexane, mustard gas, and phosgene. The results, as ratios of vapor adsorbed at satn., were compared with those obtained by a flow method. A simple method for testing activated charcoals was included.

139. Taylor, R. J. **The activation of alumina.** *J. Soc. Chem. Ind.* **68**, 23-6 (1949).—*C.A.* **43**, 3981*i*.

Methods of prepg. Al_2O_3 of predetd. activity and porosity from Gibbsite, crystalline $Al_2O_3 \cdot 3H_2O$, were given. Samples (5 g) were heated and removed from the oven at intervals over a period of hrs; the following studies were made at 225° and 300° to 1000°C steps. The dehydration curves showed a conversion to the monohydrate at 225°C in about 7 hrs, while between 225° and 500°C, a state of equil. was reached quickly. The X-ray photographs could be fully explained if there was no intrinsic temp. for conversion of the monohydrate. The conclusion was that activated Al_2O_3 was a transitional product in a heat-controlled, solid reaction, at first highly disordered but rearranging to an orderly state. In no case was a significant change in particle size distribution found, showing that it could be controlled by the hydrate from which it was produced. The results showed that Al_2O_3 of any given activity, within a wide range, could be prepd. by merely heating Gibbsite at a specific temp. for a specific time.

140. Toropov, S. A. and Pylaev, A. V. **Adsorptive properties of oxidized carbon for hydrogen sulfide and benzene vapor.** *Zhur. Priklad. Khim. (J. Applied Chem.)* **22**, 568-71 (1949).—*C.A.* **44**, 18i.

Activated carbon (oxidized by 1-8 hrs boiling in 10, 90, or 100% HNO_3, dried at 105-110°C and heated 1 hr to red glow) showed high adsorption for H_2S (1.8 mg/liter air flowing at 1.57 liter/min.), in contrast to unoxidized material which did not adsorb H_2S. Activation with 10% HNO_3 resulted in optimum adsorptive capacity. Adsorption of C_6H_6 was highest if the length of the treatment with HNO_3 did not exceed 1-3 hrs; longer treatment impaired the adsorptive capacity for C_6H_6. Preliminary adsorption of H_2S on oxidized carbon raised its adsorptive capacity for C_6H_6.

141. Turkeltaub, N. M. **Chromatographic titrimetric gas analyzer.** *Zavodskaya Lab.* **15**, 653-60(1949).—*C.A.* **44**, 9747e.

An elaborate gas analyzer is described in which part of the gas stream is oxidized on heated Pt wire to give total hydrocarbon content. The other part is adsorbed on charcoal and eluted stepwise by air with subsequent combustion, giving CH_4, C_2H_6, and the sum of higher hydrocarbons. A relative error of 5% is claimed.

142. Zabezhinskii, Ya. L.; Zukhovitskii, A. A., and Tikhonov, A. N. **Occlusion of gas from an air current by a layer of granular material. III.** *Zhur. Fiz. Khim.* **23**, 192-201 (1949).—*C.A.* **43**, 5255b.

Vapor of Et_2O (10-20 mg/liter) was forced at 14°C and a rate (k) of 300-2000 cm/min. through a layer of active charcoal of particle diams. (d) between 0.17 and 0.22 mm and a length of 1, 2, 3, 5, and 8 cm. The adsorption of Et_2O yielded a Langmuir-type isotherm. The kinetic coeff. β was approx. proportional to $\rho^{0.5}/d^{1.5}$, similar to the heat transfer to a bundle of tubes. The time for the Et_2O concn. behind the adsorbent to reach 1/2 the original concn. was proportional to the length.

143. Chipalkatti, V. B. and Giles, C. H. **Use of glass springs for adsorption measurements.** *Nature* **165**, 735(1950).—*C.A.* **44**, 7094i.

Spiral annealed Pyrex springs were used at temps. up to 100°C for 6 months in the McBain and Bakr balance. Example: original length at 25°C with a 0.4-g load, 16.209 cm; length after heating at 200°C for 8 hrs, and cooling to 25°C, 16.239 cm; after heating at 100°C for 3 hrs, and cooling to 25°C, 16.236 cm. The dimensions were: fiber diam. 0.008 in., coil diam. 0.75 in., turns per in. 12, sensitivity 17.45 cm/g.

144. Dubinin, M. M. and Zaverina, E. D. **Adsorption of gases by active carbons.** *Doklady Akad. Nauk S.S.S.R.* **72**, 319-22 (1950).—*C.A.* **44**, 7615*h*.

The equation of the adsorption isotherm applicable to active carbons with relatively fine micropores was: $a = (W_o/v)\ \exp.\ [-B(T^2/\beta^2)\ \log\ (p/p_s)^2]$, where W_o = limiting vol. of the adsorption space, v = mol. vol. of the liquefied gas, and the concomitant equation $W = W_o\ \exp.\ [-k(\epsilon^2/\beta^2)]$ relating the occupied vol. W of the adsorption space and the adsorption potential ϵ. These were tested by the linearity $\log a = E - F\ [\log\ (31.4\ T/bp]^2$, where $E = \log\ (W_o/b)$ and $F = 9.05\ kT^2/\beta^2$. The linearity between $\log a$ and $[\log\ (31.4\ T/bp]^2$ was confirmed for 3 types of charcoal (from sugar, wood, and coal) of moderate activation (loss not over 50%), in the adsorption of C_2H_4 and of C_6H_6 vapor at 20°C. From the graphically detd. const. B, the coeffs. k were calcd.: $k = (B/2.30\ R)^2 - (B/20.75)$.

145. Ettinger, I. L. and Lidin, G. D. **The effect of moisture on the sorption of methane by coal.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk* **1950**, 1198-1203.—*C.A.* **46**, 1227c.

The amt. of CH_4 sorbed by coal at 25-38°C and any given pressure (range: 200-900 mm Hg) decreases regularly as the moisture content of the coal increases. The presence of 2-3% H_2O reduces the CH_4 sorption by approx. one-half.

146. Eyraud, I. **Automatice adsorption balance.** *J. chim. phys.* **47**, 104-7(1950).—*C.A.* **44**, 7095*a*.

The details of construction are given for a sensitive adsorption balance capable of automatically recording and plotting a curve for the rate of adsorption of a gas by a solid.

147. Lewis, W. K.; Gilliland, E. R.; Chertow, B., and Cadogan, W. P. **Adsorption equilibria. Pure gas isotherms.** *Ind. Eng. Chem.* **42**, 1326-32 (1950).—*C.A.* **44**, 8731i.

Adsorption-desorption isotherms were obtained from CH_4, C_2H_2, C_2H_4, C_2H_6, C_3H_8, C_3H_6, $i\text{-}C_4H_{10}$, and 1-butene on coal-base and coconut-shell activated charcoals, and silica gel. When the adsorbent became satd. with gas, the amt. adsorbed was related to the molal vol. of the gas. With the charcoals, vapor pressure seemed to be the predominant factor detg. adsorption, although unsatn. plays a part when volatilities are close. With silica gel, unsatn. had a significant effect in increasing adsorption. A method of correlation based on Polanyi's adsorption potential theory gave good results for 18 adsorption isotherms on 3 different adsorbents at 25°C over the pressure 0.2 to 20 atm. Satd. and unsatd. gases showed different correlation curves on silica gel and at low temp. on charcoal. The temp. dependence of the adsorption isotherm up to 200°C was also correlated by this method.

148. Lewis, W. K.; Gilliland, E. R.; Chertow, B., and Cadogan, W. P. **Adsorption equilibria. Hydrocarbon-gas-mixtures.** *Ind. Eng. Chem.* 42, 1319-26(1950).—*C.A.* 44, 8732d.

The use of activated charcoal and silica gel in the adsorption sepn. of binary and ternary mixts. of gaseous hydrocarbons (0.3 to 20 atm. and at from 0° to 40°C) was investigated. Mol. wt, structure, and liquid b.p. affected the adsorption on silica gel more than on charcoal. The pure gas for which an adsorbent had the greatest capacity was preferentially adsorbed from a mixt. In mixts. each component adsorbed interfered with the adsorption of another, and, at const. pressure, the quantity of gas mixt. adsorbed per g of adsorbent lay between the values for the pure gas. By means of a modified Polanyi adsorption-potential method, the relative volatities of gases in mixt. over the gel could be calcd. from adsorption data for pure gases. The calcn. was more accurate for silica gel than for charcoal. The methods were fully developed for binary systems and could be extended for ternary systems.

149. Lewis, W. K.; Gilliland, E. R.; Chertow, B., and Hoffman, W. H. **Vapor-adsorbate equilibrium. I. Propane-propylene on activated carbon and on silica gel.** *J. Am. Chem. Soc.* 72, 1153-7(1950).—*C.A.* 44, 5180*c*.

The adsorption isotherms of C_3H_8 and $CH_3CH{=}CH_2$ on activated charcoal and on silica gel were detd. at 25.0°C and also the equil. behavior of binary mixts. at the same temp. All adsorptions were entirely reversible. There was very little difference in the relative volatilities of these gases over activated charcoal; there was substantial difference over silica gel. However, the adsorption capacity per unit wt of charcoal was greater for these hydrocarbons than that for the gel. In both these vapor-adsorbate equil. C_3H_8 was the more volatile component, whereas in the vapor-liquid equil. for this hydrocarbon system C_3H_8 was the less volatile component.

150. Lewis, W. K.; Gilliland, E. R.; Chertow, B., and Milliken, W. **Vapor-adsorbate equilibrium. II. Acetylene-ethylene on activated carbon and on silica gel.** *J. Am. Chem. Soc.* 72, 1157-9 (1950).—*C.A.* 44, 5180*d*.

Adsorption-desorption isotherms were measured for C_2H_2 and for C_2H_4 on silica gel and on activated charcoal at 25°C. Vapor-adsorbate equil. curves at barometric pressure and 25°C were detd. for mixts. of these two gases on each adsorbent. C_2H_2 was more volatile than C_2H_4 over the activated charcoal and was the less volatile component over the silica gel used. The adsorption phenomena reported were reversible.

151. Lewis, W. K.; Gilliland, E. R.; Chertow, B., and Bareis, D. **Vapor-adsorbate equilibrium. III. The effect of temperture on the binary systems ethylene-propane, ethylene-propylene over silica gel.** *J. Am. Chem. Soc.* 72, 1160-3 (1950).—*C.A.* 44, 5180*f*.

Adsorption-desorption isotherms at 0°,25°, and 40°C were detd. for C_2H_4, C_3H_8, and C_3H_6 on silica gel. Vapor-adsorbate equil. curves at one atm. were obtained for the binary systems C_2H_4-C_3H_8 and C_2H_4-C_3H_6 at 0°,25°, and 40°C. C_2H_4 was relatively more volatile than C_3H_8 or C_3H_6 in the isobaric, isothermal binary systems. C_2H_4 exhibited a much greater relative volatility in the C_3H_6 system than in the C_3H_8 system; this demonstrated the influence of the double bond. The adsorption phenomena reported were reversible.

152. Pierce, Conway and Smith, R. Nelson. **Adsorption-desorption hysteresis in relation to capillarity of adsorbents.** *J. Phys. & Colloid Chem.* 54, 784-94(1950).—*C.A.* 44, 9768i.

Adsorption and desorption isotherms were shown for EtCl at 0°C on graphon H_2O on graphon, at 28.9°C, EtCl on charcoal at −78°C, H_2O on charcoal at 28.9°C, and H_2O on graphite at 28.9°C. Water on graphon showed hysteresis closing at 0.8 relative pressure, and H_2O on graphite showed hysteresis closing at 0.5 relative pressure. EtCl on graphon showed no hysteresis. It was postulated that hysteresis resulted from small clumps of water mols. formed around active spots coalescing at higher relative pressures into larger clumps. In the large clumps it was assumed that long-range forces from the surface would extend a greater distance than if only small clumps were present. The adsorbate in large clumps during desorption would have lower vapor pressure than when the same amount of adsorbate during adsorption was in smaller clumps.

153. Poggi, A. Raul. **Adsorptive powers of active carbons.** *Ann. chim. (Rome)* 40, 63-7(1950).—*C.A.* 45, 7388f.

A streaming app. in which air is first satd. in a wash bottle contg. CCl_3NO_2, CCl_4, or $COCl_2$ and aspirated through the column of active carbon is described. Experiences on the uptake of various European active carbons are tabulated.

154. Ray, G. C. and Box, E. O. Jr. **Adsorption of gases on activated charcoal.** *Ind. Eng. Chem.* 42, 1315-18(1950).—*C.A.* 44, 8731i.

Fundamental adsorption data are presented for H_2, N_2, CO, CO_2, C_2H_4, C_2H_2, CH_4, C_2H_6, C_3H_6, C_3H_8, and n-C_4H_{10} on a single sample of coconut charcoal at pressures from 0 to 215 lb/in^2 and from 100° to 450°F.

155. Roginskii, S. Z. and Yanovskii, M. I. **Desorption of gases in dynamic conditions.** *Zhur. Fiz. Khim.* 24, 137-43 (1950).—*C.A.* 44, 6230*f*.

Mixts. of air with CO_2, ethylene, or propene were passed at 20°C through 4 tubes filled with activated charcoal (bulk d. 0.47, particle size 1.5–2.75 mm) until the outgoing gas had the concn, of the incoming gas (approx. 0.012 mol./liter). Then pure air (a few cc./min.) was forced through the 4 tubes and 4 addnl. tubes, equally filled, all in series, and the concn. c was detd. after every tube as function of the vol.(V) that passed through. The rate of displacement increased from propene to ethylene to CO_2; e.g., the concn. after the 4th tube became 0.002 mol./liter after V = 4500, 2500, and 100, resp. The adsorption isotherms of CO_2, in the mixts. were detd. up to 0.04 mol./liter. The equation $V/XM = (da/dc)[1-(c/c_o)]^2$ was valid; X was the distance from the inlet, M the amt. of adsorbent per cm of the column, and c_o is the total concn. of air and the mixt.

156. SMITH, R. NELSON; PIERCE, CONWAY, AND CORDES, HERMAN. **Adsorption of benzene and cyclohexane by graphite.** *J. Am. Chem. Soc.* **72**, 5595-7 (1950).—*C.A.* **45**, 4995c.

Adsorption isotherms were detd. on "Graphon," a partially graphitized carbon black, at 5.5° and 28.6°C. The Vm values and the av. area covered per mol. (in $A.^2$) were calcd. from the location of point B in the isotherms: These were cyclohexane 38 $A.^2$, and benzene 41 $A.^2$, compared with computed values of 32 and 28 $A.^2$ for sym. mols. (from $V^{2/3}$), and with values of 39 and 41 $A.^2$ from mol. models for mols. lying flat on the surface. Both mols. lay in the adsorbed state flat on the surface. The same conclusion applied to the mols. of MeOH, EtCl, butane, pentane, and decane in their adsorbed state on Graphon. The isotherms and the isosteric heats of adsorption computed from them showed that, in the first adsorption layer, cyclohexane was more strongly held than benzene.

157. TURKEL'TAUB, N. M. **Chromatographic method for separate determinations of microconcentration of hydrocarbons in air.** *Zhur. Anal. Khim.* 5, 200-10(1950).—*C.A.* **44**, 9856*b*.

A chromatographic titrometric gas analyzer for detg. hydrocarbons in air under field conditions was devised. A gas sample was freed of acidic components and divided into 2 parts. On one of these total C was detd. by combustion over a hot Pt wire and titration of the $BaCO_3$ formed by absorption in $Ba(OH)_2$. The other part was passed through a column of activated charcoal which absorbed all of the hydrocarbons. The latter were eluated by passing air through the adsorber column. The first 400 cc. of air removed all the methane. The next 500 cc. was free hydrocarbons and was used as check. The following 2000 cc removed all the ethane. The content of CH_4 and C_2H_6 in the eluant was detd. separately by combustion.

158. VREEDENBERG, H. A. **Adsorption of carbon disulfide vapor flowing through a tube filled with activated charcoal.** *Rec. trav. chim.* **69**, 1233-51 (1950).—*C.A.* **45**, 1837d.

The course of the adsorption of CS_2 vapor from a mixt. of air and CS_2, which flows through a long tube filled with Norit, was calcd. as a function of the time and place in the tube. Nomograms were constructed for the detn. of consts. involved in the math. relations. Conclusions derived from the theory were applied to total adsorption, relative pressures, velocity, and place in the adsorption tube, with good agreement.

159. AVGUL, N. N.; DZHIGIT, O. M.; DUBININ, M. M., AND KISELEV, A. V. **Structure of active carbons and their properties towards different vapors.** *Doklady Akad. Nauk S.S.S.R.* **79**, 451-4(1951).—*C.A.* **46**, 18*a*.

The early stage of sorption of org. vapors by active charcoal was pure adsorption, whereas later stages involved simultaneous adsorption and capillary condensation. The ratio of the two depended on the pore structure type of the active charcoal. Adsorption isotherms were detd. of H_2O (at 25°C), MeOH, C_7H_{16}, C_6H_6, and BuOH vapors (at 20°C), on a fine-pore charcoal prepd. by activation of sucrose charcoal with CO_2 at 1000°C until a loss of wt of 45%, and on another sucrose charcoal activated with a 5-fold excess of $ZnCl_2$ heat-treated at 650°C and washed. Org. mols. filled the whole pore vol. of the former already available to adsorption during the 1st stage. There was no capillary condensation of the org. compds.; on the other hand, the major part of the adsorption of the smaller H_2O mols. was due to capillary condensation in the micropores. In the $ZnCl_2$ charcoal capillary condensation was responsible for the major part of the adsorption of the org. vapors also. In accord with the pore-structure types the adsorption isotherms on the sucrose charcoal were representable by $a = (W_o/V_m) \exp [-B(T^2/B^2) \log (Ps/P)^2]$ with the values (for C_6H_6, C_7H_{16}, BuOH, MeOH) $W_o = 0.59, 0.55, 0.54, 0.61$ cc./g., $10^6B/\beta^2 = 1.00, 0.43, 1.01, 0.76$, $\beta = 1.00$ (by convention), 1.53, 0.99, 0.36. The isotherms on $ZnCl_2$ activated charcoals were given by $a = (W'_o/V_m)$ emp $[-A(T/\beta) \log (Ps/P)]$, with $w'_o = 1.50$, 1.60, —, 1.85 cc./g, $10^3A/\beta = 2.83$, 1.93, —, 8.52, $\beta = 1.00$, 1.47, —, 0.33.

160. CARMAN, P. C. AND RAAL, F. A. **Diffusion and flow of gases and vapors through micropores. III. Surface-diffusion coefficients and activation energies.** *Proc. Roy. Soc.* **A209**, 38-58 (1951).—*C.A.* **46**, 6997a.

When less than a complete monolayer is present, surface-diffusion coeffs. decrease rapidly with decreasing coverage. This is attributed to variation in heats of adsorption over the adsorbent surface. Diffusion is due to the most loosely bound mols., and these tend to disappear first as coverage decreases. Surface diffusion coeffs. compared at const. temp. and const. coverage differ for various mols. according to differences in mol. size, shape, and polar character. Measurements in this region have only limited reproducibility. The importance of pore structure for the shape of adsorption isotherms is stressed. The systems studied were SO_2 and CF_2Cl_2 on Linde silica II and CF_2Cl_2 and CO_2 on Carbolac 1. Data are discussed for comparison of surface diffusion coeffs. and activation energies for the following systems: C_7H_{16}—charcoal, C_7H_{16}—silica gel, MeOH—silica gel, toluene—silica gel, CF_2Cl_2—silica, SO_2—silica, CF_2Cl_2—carbon black, and CO_2—carbon black.

161. CRAMER, ERIKA AND MILLER, R. **Separation and determination of small quantities of gases by chromatography.** *Mikrochemie ver. Mikrochim. Acta* 36/37, 553-60(1951).—*C.A.* **45**, 5057h.

A formula is derived for the migration velocity of the zones in the chromatographic sepn. procedure. It is shown that a characteristic quantity (difference of the adsorption energies of the adsorbed materials) can be calcd. from every 2 migration rates. Sepns. are made with N_2, C_2H_4, C_2H_2, CO_2, and $CH_2{:}CHCl$ by passing 1-10 mg over an adsorption medium such as charcoal or silica gel with H_2 as the eluting gas. The detn. of the thermal cond. is used in the analysis. Plotting the galvanometer deflections of the measuring setup against the time gives curves from which the above-mentioned quantities of energy can be calcd. with an accuracy of 0.02—0.06 kcal. per mole. A mixt. of C_2H_4 and C_2H_2 is completely sepd. in 8 min. at 30°C.

162. DRESEL, E. M.; DRYDEN, I. G. C., AND FARENDEN, P. J. **An approximate adsorption**

isotherm for the ethylenediamine-coal system. *Research (London)* 4, 579-81(1951).—*C.A.* 46, 4195b.

The adsorption of ethylenediamine by a coal having an internal surface area of 2×10^6 cm²/g was studied by means of a sorption balance and also by passing the gas through a packed bed of coal and detg. changes in vapor concn. in the gas stream. Adsorption data at 25°C were given in curves. At a relative pressure of 0.5 mm Hg the coal adsorbed 40 g of ethylenediamine per 100 g.

163. Dubinin, M. M.; Zaverina, E. D., and Timofeev, D. P. **Affinity coefficients for carbons of the second structure type.** *Doklady Akad. Nauk S.S.S.R.* 77, 823-6(1951).—*C.A.* 45, 6453 g.

Adsorption isotherms of vapors of C_7H_{16}, PhMe, C_6H_6, EtCl, and MeOH at 20°C, were detd. on 3 samples of coarse-pore (2nd-type) carbons, activated by impregnation with $ZnCl_2$, activated by CO_2 at 950°C to a wt of 80%, nonporous lampblack with spherical particles. The values of W_o' (cc./g) and 10^3A in the adsorption equation $a = (W_o'/v) \exp [-AT \log (P_s/P)]$ were resp.: 1.210 and 2.36 (P/Ps $1 \times 10^{-5} - 0.05$); 1.140 and 2.12 ($1 \times 10^{-5} - 0.25$); 0.089 and 3.63 (0.01-0.50). Curves of the adsorption potential $\epsilon = RT \ln (Ps/P)$ as a function of the surface coverage for all 5 substances on each adsorbent showed satisfactory affinity. The affinity coeffs. $\beta = \epsilon/\epsilon_o$ relative to C_6H_6 ($\epsilon_o = 1$), on the three carbons compared with β on fine-pore carbons of the 1st structure type were: C_7H_{16} 1.50, 1.63, 1.70, and 1.59; PhMe 1.16, 1.27, —, and 1 25; C_6H_6 1; PhCl 0.70, 0.77, 0.78, and 0.76; MeOH 0.35, 0.39, 0.41, and 0.40.

An app. for low-temp. distn. of coal consists of a hard-glass tube divided by constrictions into 3 parts, one at the sealed end for the sample, one for dried asbestos, and a third for active charcoal. The sample is heated in an elec. furnace and the "light oil" and "heavy oil" are retained in the charcoal and asbestos, resp., both of which are maintained at 105°C by an elec., heater. Water and H_2S are retained by U-tubes filled with $CaCl_2$ and $CuSO_4$, resp. Gas is measured in a gasometer. Components are detd. by weighing the adsorbents after the app. is cut apart. Complete data on repeatability are given for a series of 8 detns. on an Aragonese lignite.

165. Hammar, C. G. Bertil. **A simple apparatus for adsorption analysis of gases.** *Svensk Kem. Tid.* 63, 125-35(1951).—*C.A.* 45, 10551g.

An app. is described for the sepn. of hydrocarbons according to mol. wt by selective adsorption on activated charcoal. The dried and measured sample (100-200 ml) is forced into the previously evacuated adsorption column (1.5—2 g adsorbent) to a max. adsorption pressure of 300 mm Hg abs., the column being cooled with Dry Ice and alc. When inerts (H_2, N_2) are present, the gas is vented through a Cartesian manostat and more sample introduced at the same time, while keeping the pressure approx. const. This "enrichment" is stopped before C_2 hydrocarbons appear in the vented gas (this point is detd. by preliminary analysis). For desorption, the column is heated in steps by an elec. oven which travels upward around the column. Each time the desorption pressure reaches 300 mm Hg, controls are activated to stop and brake the motor, and at the same time the Cartesian manostat opens to pass the desorbed gas to a cond. cell in which the fractions are identified. Desorption usually is incomplete and a developer (pentane vapor) is fed through the system until the C_5 level is reached in the cond. cell. Known mixts. of pure compds. and hydrocarbon fractions from shale oil were analyzed. The method gives sharp sepn. of components with different C nos., and also of isobutane from butane.

166. Innes, W. B.; Olney, R. B., and Rowley, H.H. **Adsorption isotherms of mixed vapors of benzene and methanol on activated charcoal at 25°.** *J. Phys. & Colloid Chem.* 55, 1324-34 (1951).--*C.A.* 46, 7398g.

Isotherms were detd. by a method that entails keeping the adsorbate compn. nearly const. by introducing vapor of fixed compn. to the adsorbent and then measuring the compn. and total vapor pressure of the vapor phase in equil. with the adsorbate. The amt. adsorbed when the surface was completely covered was detd. as a function of the mole fraction in the adsorbate and found in fair agreement with a relation derived by averaging the mol. areas of the adsorbed phase. This was in agreement with the earlier results on CCl_4-MeOH. All the partial-pressure data for a given component fit common curves regardless of surface compn. when the fraction of the surface covered was plotted against the relative partial pressures. Total spreading pressures were evaluated and the data discussed from kinetic and mol. standpoints.

167. Khodot, V. V. and Yanovskaya, M. F. **Sorption and filtration volumes of coals.** *Izvest. Akad. Nauk S.S.S.R. Otdel. Tekh. Nauk* **1951**, 593-600. *C.A.* 46, 11629f.

The sorption vol. of coal was detd. by the method of sorption of CH_4 at high pressures and by the method of sorption of vapors of MeOH at relative vapor pressures up to 0.5. Satisfactory quant. results were obtained. The extent of the pores of coal, detd. by the He method, led to a sorption vol. of 46 to 60% (av., 55%) and to a filtering vol. of 54 to 40% (av., 45%) of the total pore vol. The expts. made permit one to evaluate the applicability of the equation of subterranean hydraulics to cases of finely porous sorbing media and to give an explanation of the relatively small porosity, filtering capacity of coal.

168. Wiig, Edwin O. and Smith, Stanton B. **Vacuum desorption of ethyl chloride from activated carbon.** *J. Phys. & Colloid Chem.* 55, 27-44 (1951).—*C.A.* 45, 3221c.

Adsorption and desorption isotherms and measurements of the rates of desorption were made for EtCl at 25-56.5°C for a series of charcoals prepd. from a char made from bituminous coal and subjected to steam activation for periods of 30,90, 150, 270, and 300 mins., resp. B.E.T. surface area for the various charcoals were detd. Pore distributions were calcd. from water desorption isotherms for pores smaller than approx. 10^3 A. For larger pores the distributions were obtained by a Hg porosimeter method. A log-log plot of the fraction of the EtCl retained at time t placed all of the samples from the base char to the one that was most highly activated on a uniform series of curves which in all cases were linear for the last fraction of the EtCl removed. These curves became steeper the greater the amt. of activation. Values for the isosteric heats of adsorption decreased from about 14.7 kcal. for the first portion of EtCl adsorbed down to about 7.8 kcal. for the last portion adsorbed. The adsorption isotherms were shown to fit the equation of Sips $\theta = A_p{}^n/(1 + A_p{}^n)$, where θ was the fraction of the surface covered by adsorbate at pressure P and n was a const. less than unity. Curves for the heat distribution were detd. similar to the pore distribution curves for the various charcoals.

169. Akahira, Takeo; Shimamune, Shoji, and Tsuboyama, Mitsuru. **Carbon film resistor. I. Improvement on the preparation of carbon film resistors.** *Repts. Sci. Research Inst. (Japan)* **28**, 205-11 (1952).—*C.A.* 47, 4767*h*.

Benzene vapor was passed under steady low pressure (adjusted through a tubing system with a gas reservoir attached to a vacuum pump) into a vacuum quartz tube in an elec. furnace to be pyrolyzed at 1020°C (optimum) to deposit carbon on porcelain rods or cylinders placed within the tube. The carbon-film resistor thus prepd. showed a resistance of 100 kilo-ohms/unit area.

170. Avgul, N. N.; Dzhigit, O. M., and Kiselev, A. V. **Adsorption of vapors on a nonporous active carbon, lampblack.** *Doklady Akad. Nauk S.S.S.R.* **86**, 95-8(1952).—*C.A.* 47, 1458*a*.

On a Spheron lampblack (100 m^2/g) preliminarily heated *in vacuo* 2 days at 900°C the adsorption isotherm of C_6H_6 had the normal S shape, and was reversible up to $p/p_s = 0.8$; hysteresis appeared at higher p/p_s. The H_2O vapor adsorption isotherm had an entirely different shape. The adsorption was very small up to $p/p_s = 0.3$ at which point not more than 15-20% of the surface was occupied by H_2O. Adsorption increased sharply with further increasing p/p_s, particularly in the range 0.45-0.50; at 0.6-0.7, the amt. adsorbed was sufficient to cover all of the surface with a dense unimol. layer. With further increasing p/p_s, the increase of the adsorption became slower. The adsorption isotherm of MeOH was intermediate between that of C_6H_6 and of H_2O. At very small p/p_s, the adsorption was approx. proportional to the pressure, then became slower as the 1st layer was completed; there appeared to be an inflection at about $p/p_s = 0.5$, where a bimol. layer was approx. completed. A trimol-layer thickness was reached at approx. $p/p_s = 0.8$-0.9; from then on, the adsorption increased rapidly. Considerable hysterisis, apparently due to very slow release of adsorbed MeOH, was found below $p/p_s = 0.3$.

171. Bering, B. P. and Serpinskii, V. V. **Simultaneous adsorption of ethylene and propylene on active carbon.** *Doklady Akad. Nauk S.S.S.R.* **85**, 1065-8(1952).—*C.A.* 47, 4684*g*.

The adsorption of C_2H_4 and C_3H_6 was measured by the same method and on the same active charcoal at 7° and at 25°C between 0-300 mm Hg. From the adsorption of C_3H_6 at $p_1 = 0$, 50, 100, 150, 200, 250 mm, it was seen that C_2H_4 even in large amts. lowered the adsorption of C_3H_6 only slightly, and did not change the shape of its adsorption isotherm. In contrast, even small amts. of C_3H_6 lowered the adsorption of C_2H_4 considerably and brought its shape closer to linear. The adsorption isosteres of C_3H_6 between 0.6 and 2.5 millimoles/g were practically straight lines, whereas the family of the C_2H_4 isosteres between 0.05 and 1.0 represented a system of curves with a curvature progressively diminishing with increasing p_1. Isosteres of the total adsorption were straight lines throughout, both at 25° and at 7°C. With the aid of Gibbs' equation, the integral heat of adsorption of the binary gas mixt. was calcd. The adsorption isotherms of C_2H_4 could be adequately described by a Langmuir isotherm.

172. Bering, B. P. and Serpinskii, V. V. **Adsorption of mixtures of gases. II. Adsorption of ethylene and propylene on active carbon.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* **1952**, 997-1007.—*C.A.* 47, 5756*f*.

Measurements of the amts. adsorbed a (in millimoles/g) as a function of the pressure p (mm Hg) at 7° and at 25°C, were given: C_2H_4, 7°C, p_1 4.5 ($a_1 = 0.214$) to 338.3 ($a_1 = 1.928$); 25°C, p_1 4.1 ($a_1 = 0.093$) to 771.3 ($a_1 = 2.030$); C_3H_6, 7°C, p_2 0.2 ($a_2 = 0.161$) to 333.8 ($a_2 = 3.240$); 25°C, p_2 3.3 ($a_2 = 0.570$) to 325.5 ($a_2 = 2.760$). For mixts. $(C_2H_4 + C_3H_6)$, a_1 and a_2 was given as functions of p_1 and p_2, over the whole range of variation of p_1 and p_2 in the total pressure range 0-300 mm. Sections of the surface a_2 by planes $p_1 =$ const. $= 0$, 50, 100, 200, and 250 mm, at 25°C, showed that, even at high concns., C_2H_4 decreased the adsorption of C_3H_6 only slightly.

173. Berkowitz, N. and Schein, H. G. **Calculation of surface areas from room-temperature adsorption isotherms.** *Nature* **169**, 373(1952).—*C.A.* 46, 5400*d*.

Monolayer capacities calcd. from adsorption isotherms for CH_3OH on lignites at 25°C were up to 50% higher than those calcd. from the B.E.T. graph. Where the slope of the linear portion of a sigmoid isotherm increased with temp., the B.E.T. method yielded reliable results only at very low temp.

174. Bonnetain, Lucien; Duval, Xavier, and Letort, Maurice. **Stepwise adsorption isotherms for methane on graphite and various other solid adsorbents.** *Compt. rend.* **234**, 1363-6 (1952).—*C.A.* 46, 6896*d*.

The authors found stepwise phys. adsorption isotherms for CH_4 at −195°C on 5 different types of graphite, on MoS_2, $CdCl_2$, CdI_2, and $CdBr_2$. A nearly vertical rise in the adsorption isotherm occurred at a relative pressure of about 0.35 and 0.75 for the graphite as well as for the MoS_2. The upper end of the vertical rise corresponded to the completion of about 2 layers at 0.35 relative pressure and 3 layers at 0.75 relative pressure. At −166°C with CH_4 and at −195°C with N_2 the discontinuities in the adsorption isotherms were absent. The vertical rises in the isotherms at about 0.35 relative pressure were as sharp as those that have been interpreted in the past as 1st-order phase changes.

175. Chernyshev, A. B.; Kel'tsev, N. V., and Khalif, A. L. **Adsorption equilibrium of a propane-butane gas mixture on activated carbon.** *Doklady Akad. Nauk S.S.S.R.* **82**, 75-7(1952).—*C.A.* **46**, 4881*f*.

Mixts. of dry C_3H_8 and C_4H_{10} (mixts. of normal and iso) of different compns. were passed over activated charcoal (grain size 0.4-1 mm), preliminarily evacuated 3 hrs at 100 °C, in an adsorption column 2 cm in diam., 50 cm long, at the rate of 100 cc./min. The outgoing gas was initially C_3H_8; after more prolonged passage, the ds. of the incoming and the outgoing gas became equal. The amt. and compn. of the adsorbed gas were detd. by fractionation after desorption with superheated steam and freezing out. With gas mixts. of 40.30, 58.80, 77.10, 87.65 mole % C_3H_8, the mole % of C_3H_8 in the adsorbed phase was, at 20 °C, resp., 14.80, 23.60, 40.60, 63.88, and at 100°C, 14.86, 30.20, 44.00, 61.98. The "coeff. of sepd. capacity" $K = y_1x_2/y_2x_1$, where y = mole fraction in the gas, and x = mole fraction in the adsorbed phase, was, at 20°, 3.89, 4.63, 4.93, 4.03, and at 100°, 3.87, 3.31, 4.28, 4.35.

176. Chernyshev, A. B.; Kel'tsev, N. V., and Khalif, A. L. **Separation of butane-propane mixtures in a moving layer of adsorbent.** *Doklady Akad. Nauk S.S.S.R.* **84**, 757-60 (1952).—*C.A.* **46**, 10774*g*.

The sepn. (coeff. $K = x_2y_1/x_1y_2$ where the x are the mole fractions of the components in the adsorbed, and the y the mole fractions in the gaseous phase), after n consecutive passes of the initial mixt. over the adsorbent is given by $n \log K = \log (y_2/y_1)_n - \log (y_2/y_1)_1$, where the subscripts n and 1 refer to the gas-phase compn. after the nth and the 1st pass, resp. The same sepn. effect can be obtained in one single pass if the adsorbent layer is made to move countercurrent to the desorbed gas. The compns. of the gaseous and of the adsorbed phases change continuously along the height of the column and the countercurrent operation is analogous to a no. of repeated sepns. With Z being the height of the adsorbent column equiv. to one single stage of sepn., and L the height of the whole column, one has $n = L/Z$, and hence $\log (y_2/y_1)_n - \log (y_2/y_1)_1 = (L/Z) \log K$. Exptl. results with $C_3H_8 + C_4H_{10}$ mixts., plotted in the coördinates $[\log (y_2/y_1)_n - \log (y_2/y_1)_1]$ as a function of L, give a straight line which at higher L curves upwards; at this point, further increase of the height of the column evidently results in no further improvement of the sepn.

177. Davies, R. G. **The use of benzene adsorption isotherms in evaluating surface and pore characteristics of activated carbons.** *Chemistry & Industry* **1952**, 160-5.—*C.A.* **46**, 5928*c*.

Adsorption and desorption isotherms on 13 charcoals are detd. by passing air contg. a fixed partial pressure of C_6H_6 over the charcoal until const. wt is obtained. Surface area and heat of adsorption are calcd. from the Langmuir form of the B.E.T. equation and pore-size distributions from the Kelvin equation by using the desorption branch of the isotherms. Hysteresis begins in all cases at a vapor pressure corresponding to a capillary radius of about 14 A. The decolorization of molasses depends on the presence of pores of radius in the range 20-40 A. as well as the area. Charcoals prepd. from certain nutshells contain relatively fine pores, those from briquetted coals larger pores, and those from wood, lignite, and different type nutshells still larger pores.

178. Dryden, I. G. C. **Thermodynamic functions of the coal ethylenediamine system.** *Chemistry & Industry* **1952**, 193-5.—*C.A.* **46**, 5817*b*.

The thermodynamic properties of the coal ethylenediamine system are detd. from available data. The "adsorption" isotherm at 25°C appears to consist of 3 parts: chemisorption (up to 7% adsorbed), normal phys. adsorption, and the process of soln. and diln. Abs. values of Gibbs function, heat function, and entropy are tabulated. The system appears to resemble the agar—agar—water system rather than the "regular" polymer-solvent system such as rubber and benzene.

179. Dubinin, M. M. **Influence of a porous structure of the adsorbents on the form of the adsorption isotherm of vapors.** *Doklady Akad. Nauk S.S.S.R.* **84**, 539-42 (1952).—*C.A.* **46**, 9378*a*.

The previously reported coincidence of adsorption isotherms referred to unit surface area of MeOH vapor and of N_2 on different adsorbents was evidence of the preponderant role of the electrostatic factor in the adsorption of these mols. on various silica gels. With C_7H_{16}, the dispersion factor became significant, and hence, on account of the increase of the adsorption potentials in fine pores, the adsorption was higher on a fine-pore gel. In contrast to the polar silica gels, phys. adsorption even of polar org. mols. on the nonpolar active carbon was due mainly to dispersion interaction. In active carbons with well-developed micropores, adsorption isotherms for carbons with different micropore dimensions could not coincide. In carbons with the dimensions of micropores approaching those of intermediate pores, adsorption isotherms should coincide and this was actually observed.

180. Evdokimov, V. B.; Ozeretskovskii, I. N., and Kobozev, N. I. **Paramagnetism of catalytically active layers of iron.** *Zhur. Fiz. Khim.* **26**, 135-44 (1952).—*C.A.* **46**, 9960*g*.

Magnetic properties of adsorbed iron on sugar charcoal are studied by the Faraday method. Samples are prepd. by impregnating the charcoal with $Fe(CO)_5$ in abs. ether, decompn. of the carbonyl, and subsequent reduction in H_2 at 400-450 °C. Surface coverage θ is varied between 0.000052 and 1.0. Up to $\theta = 0.005$, the magnetic susceptibility does not depend on field strength. From $\theta = 0.118$ upward, a weak ferromagnetism becomes apparent; the latter becomes pronounced at $\theta = 0.86$. Crystn. takes place during oxidation of the sample, as shown by the magnetic susceptibility after subsequent reduction. Anomalously high values per g are measured when θ decreases, for $\theta \sim 10^{-3}$, 6×10^{-3}. This effect is also observed with dil. monolayers of $Ni(NO_3)_2 \cdot 6H_2O$ on charcoal.

181. Griffiths, J.; James, D., and Phillips, C. **Adsporption and partition methods. Gas chromatography.** *Analyst* 77, 897-904(1952).—*C.A.* 47, 1530*b*.

Examples are given of the chromatographic sepn. and analysis of volatile org. mixts. from charcoal columns at 100°C with results within 1%. An account is also given of some elution analyses by the use of partition columns. The sepns. have been followed by a thermal-cond. cell, but a most promising device depends on surface-potential changes and is sensitive to extremely low concns. of vapor and enables gas-chromatographic methods to be extended to relatively nonvolatile materials.

182. Kadaner, D. G.; Luk'yanovich, V. M., and Radushkevich, L. V. **Adsorption and capillary condensation of vapors on non-porous carbon black.** *Doklady Akad. Nauk S.S.S.R.* **87**, 1001—4 (1952).—*C.A.* **47**, 6734*f*.

Calcns. of the relative roles of adsorption and of capillary condensation of C_6H_6 were made for a lampblack, heated at 1000°C in H_2, with spherical particles ranging from 800 to 3000 A. in diam. (mean 1600 A.) and surface area 19.4 m^2/g. On pelleting under pressure, the porosity increased up to 0.41 under 800 atm., and then remained const. up to 5000 atm. With a model consisting of 160 smooth paraffin-coated balls of 9 mm diam., compressed to the same porosity of 0.41, the av. no. of contacts per sphere was found to be 8. On that basis, it was estd. that up to relative pressures of 0.5, sorption of C_6H_6 on the pelleted carbon black consisted predominantly of adsorption on the free surface.

183. Koble, Robert A. and Corrigan, Thomas E. **Adsorption isotherms for pure hydrocarbons.** *Ind. Eng. Chem.* **44**, 383—7 (1952).—*C.A.* **46**, 5398*d*.

Published data for the range 180° to 480°C show that the concn. C_A of CH_4, C_2H_6, C_3H_8 C_2H_4, C_3H_6, and C_4H_{10} on activated charcoal can be represented by the equation $C_A = LKp^n/(1 + Kp^n)$, where p is the pressure of the adsorbate and L, K, and n are consts. A logarithmic plot of $(1/C_A) - (1/L)$ against $1/p$ is made linear by proper selection of L. The consts. n and L are independent of temp.; n is in the range 0.5 to 1 for the hydrocarbons adsorbed. Log K is linear with $1/T$.

184. Malherbe, P. le R. and Carman, P. C. **Swelling of coals by methanol and its significance.** *Fuel* **31**, 210-19 (1952).—*C.A.* **46**, 4764*c*.

A study was made of adsorption of O_2, Freon-12, MeOH, and methylamine on a single coal sample up to high relative pressures. The results with Freon-12 and C_4H_{10} confirmed those for low-temp. gas adsorption, giving an internal surface of a lower order of magnitude than by heat of wetting in MeOH. MeOH sorption was completely different in character and was in accord with expectation from heats of wetting. Sorption of water vapor and of MeOH vapor by coal was closely analogous to sorption of water vapor by proteins, starch, and other high polymers and should be interpreted similarly as sorption at definite sites, presumably where H-bonds could be formed. Methylamine could not only form H bonds, but could also form salt links so that it should be strongly chemisorbed. Hence, methylamine was much more strongly sorbed than MeOH, thus producing much greater swelling.

185. Minchin, L. T. **Methane from coal mines.** *Coke and Gas* **14**, 93-6, 131-5, 167-73 (1952).—*C.A.* **46**, 7305*c*.

The occurrence of CH_4 in coal mines and its liberation during mining operations is discussed. The transformation of wood to coal, the adsorption of CH_4 by coal, and the availability and compn. of CH_4 are reviewed. The more important methods of extn. employed on the Continent and in England include boreholes in the roof, headings in the overlying seam, pack cavities, drainage from underlying virgin seam, and drainage of old workings and blowers. The uses of CH_4, cracking plant, colliery boilers, power for compressor stations, gas for road transport, and coke ovens are reviewed.

186. Smith, R. Nelson. **Phase transitions in surface films on solids.** *J. Am. Chem. Soc.* **74**, 3477-9 (1952).—*C.A.* **46**, 10779*h*.

Isotherms of heptane on Fe_2O_3 and graphite were redetd. at several temps. by a gravimetric method and with a McLeod gage. No evidence of the phase transitions was found for either system.

I-3. Carbon Dioxide on Carbon Adsorbents

187. Wicke, E. and Kallenbach, R. **Surface diffusion of carbon dioxide in activated charcoals.** *Kolloid-Z.* **97**, 135-51 (1941).—*C.A.* **37**, 814³.

Sintered glass, granulated clay and granules of medicinal, activated charcoal were cemented into glass tubes. A mixt. of N_2 and CO_2, at a const. partial pressure of CO_2 (100 mm), was kept flowing by one side of the diffusion plug. A second stream (N_2) swept the CO_2 away from the other side of the plug, the CO_2 content of the resulting mixt. being detd. in a sensitive heat-conducting app. empirically calibrated. The N_2 partial pressure varied from 0 to 660 mm, the temp. from 0° to 300°C. The transport in the sintered glass took place mainly by normal diffusion except at low pressures, whereas Knudsen flow prevailed in the granulated clay below 1 atm. The charcoal was intermediate in behavior. Similar measurements on two technical activated charcoals gave isotherms and isobars which showed that in this case surface diffusion accounted for an appreciable part of the total transport.

188. Hoehne, Karl. **Determination of the reactivity of coke.** *Gluckaüf* **79**, 166-70 (1943).—*C.A.* **37**, 6111⁴.

The continuous measurement of the reactivity of coke towards CO_2 was detd. The method depended upon the action of CO_2 on hot coke, whereby CO was formed. An equil. was reached and the amt. of unchanged CO_2 measured. The ratio of changed to unchanged CO_2 in percentage was designated as reactivity. Samples of coal having various origins were tested.

189. VREEDENBERG, H. A. AND NOUHUYS, H. L. VAN. **The adsorption of carbon disulfide vapor and water vapor by active charcoal.** *Rec. trav. chim.* **65**, 235-45 (1946) (in English).—*C.A.* **40**, 6931^7.

The isotherms and rates of adsorption of CS_2, H_2O, and mixts. of the two were measured for Norit charcoal. From a mixt. contg. 0.0068 and 0.95 relative pressures of CS_2 and H_2O, resp., in air, the total CS_2 adsorption went through a max. and then decreased, whereas the adsorption of the H_2O increased continually with time. All exptl. results were explained by a theory differing from that of Langmuir by the assumption that the rate of desorption of mols. was proportional both to the fraction of the surface covered and to (1-x), where x is the relative pressure of the adsorbate.

190. MUNEMORI, MAKOTO. **Adsorption of carbon dioxide by charcoal in water.** *Science Repts. Tohoku Univ.* **35**, 165-72 (1951).—*C.A.* **46**, 9931d.

The adsorption of CO_2 at 400 mm Hg at 0°C in the absence of water was about 64, 47, and 39 cc. per g of grainy charcoal (probably Norit), a com. active charcoal, and Kahlbaum's active charcoal, resp.; the corresponding values in the presence of water were about 12, 8.5, and 7 cc., resp. For these 3 charcoals 2, 2.5, and 3.4 cc. of water per g of charcoal, resp., were used. The adsorption data obeyed the Freundlich adsorption equation over the 30 to 730-mm pressure range covered. Calcd. heats of adsorption based on runs at 0° and 30°C showed heat values of 5.8 to 5.6 kcals. per mole in the absence of H_2O and 6.3 to 6.7 in the presence of H_2O.

191. SIDILLO, MICHAL AND PIOTROWSKI, TADEUSZ. **Adsorption of the carbon dioxide by coals of the Lower Silesia coalfield.** *Prace Glównego Inst. Górnictwa, Komun.* No. **87**, 7 pp. (1951) (English summary).—*C.A.* **46**, 11631*a*.

Coals originating from seams, where frequent outbursts occurred, showed great tendency towards CO_2 adsorption. These tendencies were shown especially by soft and brittle coals of high vitrain content. Coals of low volatile content behaved similarly. Adsorption and desorption detd. in autoclaves under pressure gave different curves for various coals. Under atm. pressure coals ceased to adsorb CO_2 at 90°C. The rate of desorption increased with the decrease of size of the grain.

192. BERING, B. P. AND SERPINSKII, V. V. **Adsorption of mixtures of gases. I. Adsorption of ethylene and carbon dioxide on active carbon.** *Zhur. Fiz. Khim.* **26**, 253-69 (1952).—*C.A.* **47**, 4683*i*.

Adsorption separately and in mixts. at 25.4°C was measured in the equil. total pressure range from 0 to 300 mm Hg (thermocond. analysis of the gas phase). C_2H_4 was adsorbed more abundantly than CO_2. Adsorption of CO_2 was described by a Freundlich isotherm, $a_1 = 0.0197\ p_1^{0.656}$, where the amt. adsorbed was expressed in millimoles/g, and the pressure p in mm Hg. The adsorption of C_2H_4 was not described by a Freundlich isotherm. Langmuir-type equations did not apply accurately. Very good agreement was found with the equation $\log a = [\log(W_0/b)] - 0.434 \times 20.8\ k(T^2/\beta^2)\ [\log(31.4\ T/bp)^2]$, where b was the van der Waals const., and β the affinity coeff. of the characteristic curve of the gas relative to a standard gas. The less adsorbable gas (CO_2), even at high concns., lowered the adsorption of the more adsorbable gas (C_2H_4) only slightly; but even small amts. of the more adsorbable gas lowered considerably the adsorption of the less adsorbable gas and also brought the adsorption isotherm closer to linear.

193. GORING, G. E.; CURRAN, G. P.; TARBOX, R. P., AND GORIN, EVERETT. **Kinetics of carbon gasification by steam. Effect of high temperature pretreatment on reactivity of low temperature char to steam and carbon dioxide.** *Ind. Eng. Chem.* **44**, 1051-7 (1952).—*C.A.* **46**, 7733*h*.

By using the integral gasification rate by steam or CO_2 at 1600°F and 1 atm. as an index of reactivity, the effect on a low temp. char of various pretreatment times (0 to 24 hrs) in N_2 at 1600°F was detd. Differences in gasification rate of over twofold were observed, although the differences diminished asymptotically with increasing pretreatment time. All exptl. work was carried out in a fluidized bed, operated batchwise with respect to the charge of 65- to 150-mesh char and continually with respect to the fluidizing gas.

194. GULBRANSEN, EARL A. AND ANDREW, KENNETH F. **Reactions of artificial graphite. Reaction of carbon dioxide with pure artificial graphite at temperatures of 500° to 900°C.** *Ind. Eng. Chem.* **44**, 1048-51 (1952).—*C.A.* **46**, 7734*g*.

The reaction of graphite with CO_2 at 500°C and 7.6 cm Hg corresponded to the formation of 1/40th or less of a monolayer of surface oxide. Elemental Fe greatly accelerated this reaction. Preoxidation was found to change the initial rate of reaction with only a minor effect on the long-term reaction. The surface oxide observed on degassing was not a preliminary step in the reaction.

I-4. Water Vapor on Carbon Adsorbents

195. SCOTT, G. S. **Mechanism of the steam-carbon reaction.** *Ind. Eng. Chem.* **33**, 1279-85 (1941).—*C.A.* **35**, 7806^6.

Published data are reviewed. It is probable that the initial reaction is $C + 2H_2O = CO_2 + 2H_2$, though some of the data appear to disagree with this interpretation. Possible causes of disagreement among the various data are discussed. The most logical first step for further research would be a crit. study of lab. methods.

196. DUBRISAY, RENE AND AMPHOUX, BERNARD. **Separation of volatile liquids by selective adsorption.** *Compt. rend.* **215**, 157-9 (1942).—*C.A.* **38**, 6155^7.

An aq. alc. soln. was distd. and the vapor passed over active charcoal and then condensed (liquid A). The adsorbed vapors were desorbed by heating in a vacuum then condensed (liquid B). "A" contained less, "B" more, alc. than the original vapor. The enrichment of "B" in alc. was caused by a more rapid rate of adsorption of alc. as compared with water.

197. Warner, B. R. **Mechanism of the steam-carbon reaction.** *J. Am. Chem. Soc.* **65**, 1447-51 (1943).—*C.A.* **37**, 5640^8.

The primary products of the reaction were CO and H_2; CO_2 was formed from the water-gas reaction which reached or tended to reach equil. The rate of gasification was governed by an adsorption isotherm for the steam, and a steam satn. pressure existed (its value depended on the carbon and the temp.) above which the rate of gasification at a given temp. became const. The postulated reaction scheme was: $C + H_2O \rightleftarrows C, (H_2O)_{ads.} \rightleftarrows (CH_2O)_{ads.} \rightleftarrows CO + H_2$, and $CO + H_2O \rightleftarrows (CO)_{ads.}(H_2O)_{ads.} \rightleftarrows (HCO\text{-}OH)_{ads.} \rightleftarrows CO_2 + H_2$.

198. Emmett, P. H. and Anderson, R. B. **The adsorption of water vapor on carbon black.** *J. Am. Chem. Soc.* 67, 1492-4 (1945).—*C.A.* **39**, 5149^7.

Evacuation of two typical carbon blacks at 1000 to 1200°C so altered the nature of their surfaces as to yield water adsorption isotherms resembling those found for steam-activated charcoal. However, N_2 adsorption isotherms before and after this evacuation showed that the samples did not develop porosity and did not increase their surface areas during degassing.

199. Courty, Clément. **The penetration of water into active charcoal.** *Compt. rend.* **222**, 880-2 (1946).—*C.A.* 40, 5317^3.

Gas-mask charcoal that had been dried to const. wt at 110°C and subjected to vacuum at room temp. adsorbed 0.08% O_2 in 1 month; the same charcoal if satd. with H_2O before being subjected to vacuum at room temp., adsorbed 2.2% O_2 in the same time. Four different samples of gas-mask charcoal were dried to const. wt at 110°C and then held in an atm. of 90% relative humidity for 2 yrs. The samples were removed and dried to const. wt at 110°C at the end of each 3-month period, and then returned to the humid atm. The dry wts decreased gradually. The total loss in wt was 0.2-1.2% at the end of 2 yrs.

200. Courty, Clément. **The slow penetration of water vapor into active carbon.** *Compt. rend.* **222**, 1385-6 (1946).—*C.A.* 40, 5976^9.

Data were presented on the quantity of water adsorbed, the quantity lost on later drying, and the quantity of air displaced during humidification or adsorbed during drying. The coeff. of magnetization of the active carbon was greater as more air was adsorbed. Magnetic measurements are of value in a study of adsorption.

201. Fineman, M. N.; Guest, R. M. and McIntosh, R. **The pore structure and adsorptive properties of some activated charcoals. I. The adsorption of water vapor and its dependence on pore size.** *Can. J. Reserach* **24B**, 109-23 (1946).—*C.A.* 40, 7573^2.

The influence of the structure of charcoal adsorbents on the form of the water-adsorption isotherm was studied by detns. of (1) surface areas of a series of charcoals of varying degrees of activation (N_2 and butane as adsorbates); (2) total pore vol. of each adsorbent by d. measurements in He and in Hg; (3) d. of adsorbents when immersed in water; (4) adsorption isotherms for water vapor; and (5) surface areas of charcoals partly satd. with water vapor. Certain very small and certain very large voids in charcoal were not occupied by water vapor at any relative pressure. Estimates of the submicro, micro, and macro pore sizes showed fair agreement when these are based upon either the capillary condensation theory or measurements of the total area and vol. of the charcoal pores.

202. Givaudon, J.; Delion, R. and Boivin, C. **The relation between the volatile content of charcoals and their capacity for adsorbing atmospheric humidity.** *Ann. mines & carburants, Mém.* **135**, 104-12 (1946).—*C.A.* 40, 6788^9.

The adsorption of H_2O from air, satd. at 25°C was studied. Charcoals prepd. in the woods from pine and a leafy wood and similar factory-prepd. samples were used. The charcoal was heated until the volatile content was at a predetd. value between 23% to 2.5%. The initial moisture adsorption rate was higher for samples of high volatile content. The adsorption rate of sample of low volatile content became much higher after 6-8 hrs. The equil. was usually reached in 28-32 hrs; sample of low volatile content showed greatest adsorption in all cases.

203. South Metropolitan Gas Co. **Moisture sorption of coals and its relation to their coking quality.** *Fuel* **25**, 42-50 (1946).—*C.A.* **42**, 5644h.

The agglutinating, coking, and swelling properties of a coal depended largely on the sorptive power of the infusible humic components for the "resinic" components during the fusion stage of the latter. If the sorptive power was naturally high, or if it was increased by slight oxidation (activation, weathering), the plastic stage, and thence the tendency to cohesion, was partly or wholly suppressed by sorption of the fused material.

204. Dubinin, M. M. and Zaverina, E. D. **Sorption and structure of active carbons. II. Sorption of water vapor.** *J. Phys. Chem.* **21**, 1373-86 (1947) (in Russian); *Doklady Akad. Nauk S.S.S.R.* **56**, 715-18 (1947).—*C.A.* **42**, 5299*f*; 44, 8194*i*.

The adsorption of H_2O vapor by carbons B-1 and B-2 and by a nonporous carbon from CO was reversible. Hysteresis was more pronounced with other carbons which had greater pore vol. The H_2O adsorption of porous carbons increased first very little and then rapidly. Except for specimens with very fine pores, the "hydrophobicity" increased with the pore vol. and with the temp. of activation (850° and 1000°C). Also, the liquid vol. of H_2O adsorbed at 20°C from vapor was almost identical with the vol. of micropores detd. by means of MeOH. The adsorption of H_2O by the carbon from CO agreed with B.E.T. between $p = 0.3$ and $p = 0.65$. A carbon was oxidized by moist air at 350°C adsorbed NaOH; when heated to 950°C it did not. Oxidized charcoals were less hydrophobic.

205. Dulhunty, J. A. **Determination of maximum inherent moisture in coal by controlled vaporization of adherent moisture.** *J. Proc. Roy. Soc. N. S. Wales* **81**, 60-8 (1947).—*C.A.* **42**, 4325h.

Values of capillary-held moisture in coals of all rank and texture from peat to nathracite were obtained. Maintaining wet coal at a const. temp. (± 0.01°) in an atm. of water vapor and approx. satd. air, under pressure which just vaporizes water, caused vaporization of adherent moisture. Inherent moisture with subnormal vapor pressure will remain in the coal and can be detd. by drying at 105°C in a current of dry N_2. The method is recommended for standardizing more simple industrial lab. tests.

206. Imada, Fusao. **Carbons. XVIII. The sorption of mixtures of gases.** *Kogaku Iho, Kyushu Univ.* **19**, 247-55 (1947).—*C.A.* **47**, 5819i.

In addn. to the sorption of H_2 on active carbon, the sorption of air and H_2O was investigated. The mechanism of electromotive reaction of the dry air-cell was discussed qualitatively on the basis of the quantum theory.

207. Strickland-Constable, R. F. **Interaction of steam and charcoal at low pressures.** *Proc. Roy. Soc. (London)* **A189**, 1-10 (1947).—*C.A.* **42**, 1481i

The reaction was studied up to 700°C and at pressures of less than 1 mm. Water vapor, H_2, and CO were reversibly adsorbed. H_2 was adsorbed strongly and rapidly; CO was adsorbed in considerably smaller quantity and much more slowly. When charcoal reacted with water vapor at low pressures, the pressure fell during the rapid initial adsorption of the water vapor, and subsequently rose during the desorption of the product gases. The kinetics of the reaction at higher pressures was explained on the basis of the adsorption data. Reasons were given for supposing that the water vapor was adsorbed as H_2O. When water vapor is allowed to react with a charcoal previously outgassed at a much higher temp., the water adsorbed and the pressure fall to a very low figure. The water in the absorbed condition reacts to form CO and H_2 but these are likewise retained by strong adsorption on the surface.

208. Terent'ev, A. P.; Kadaner, D. G., and Kopchenova, Yu K. **Determination of active hydrogen by Grignard reagents in a carbon dioxide atmosphere. V. Determination of moisture in technical products.** *J. Gen. Chem. (U.S.S.R.)* **17**, 913-16 (1947).—*C.A.* **42**, 1527b.

The active H-detn. was used successfully to det. moisture in tech. products. MeMgI was used in 2.5 N concn. in dry Et_2O: Place 0.1-0.05 g of sample in the reaction flask, cover with 1-3 cc. dry Et_2O, and carry out the detn. as described. Activated charcoal gave, after satn. with H_2O vapor, 19.2% H_2O by drying at 110°C, 19.0% H_2O by drying over H_2SO_4, and 22.02-22.3% H_2O by the MeMgI method. Charcoal heated to 800°C failed to show H_2O by any method.

209. Campardou, J. **The decomposition of water by the metalloids. III. Special case of carbon.** *Bull. Soc. chim. France* **1948**, 364-9.—*C.A.* **42**, 5789e.

Carbon reacted endothermically with water vapor at 700-1100°C to give H_2, and either CO_2 or CO, or both; it also reacted exothermically below 500°C to yield CH_4 and CO_2. Occluded gas must first be eliminated by prolonged treatment with a current of steam at 300°C. At 420°C a continuous evolution of gas was obtained which contained 20-30% CH_4, 50-55% CO_2, and a little H_2 and CO. Natural fuels treated similarly gave a mixt. of liquid and solid hydrocarbons, mostly saturated, comparable to natural petroleum.

210. Dubinin, M. M. and Zaverina, E. D. **Sorption of water vapor on active carbons.** *Doklady Akad. Nauk S.S.S.R.* **61**, 79-82 (1948).—*C.A.* **42**, 8575*e*.

Shift of the steep portion of the S-shaped adsorption isotherm to higher relative equil. pressures, as a result of progressive activation and decrease of the differential heat of adsorption, was brought about by preliminary adsorption of small amts. of readily adsorbable vapors, blocking the region of the finest micropores. Such shifts, increasing with the amt. of C_6H_6 preliminarily adsorbed at 20°C were observed on carbon, pure and with 0.535, and 1.96 millimoles C_6H_6/g; with increasing amt. of C_6H_6 the adsorption-desorption hysteresis loops increased in width and area. Along the initial portions of the isotherm, H_2O can be desorbed completely by evacuation at 20°C, but only on prolonged evacuation did desorption of C_6H_6 become noticeable; it was quant. only at 450°C. The shift to lower pressures, due to the formation of new micropores, was observed after de-ashing, by extn. with HCl and HF, followed by washing and drying, of granulated anthracite activated with H_2O at 850°C. The max. amts. of H_2O adsorbed coincided for all samples with the vols. of the micropores.

211. Emmett, P. H. **Adsorption and pore-size measurements on charcoals and whetlerites.** *Chem. Revs.* **43**, 69-148 (1948).—*C.A.* **42**, 7598*g*.

The B.E.T. method appeared to yield reliable surface areas for finely-divided or coarsely-porous solids. Take-up of H_2O vapor by activated charcoals was a combination of adsorption and capillary condensation at relative pressures above 0.5; its desorption was invariably accompanied by marked hysteresis. The decrease in surface area with H_2O in the sample yielded a pore distribution ranging from 16 to 500 A. These curves for several hundred charcoals joined smoothly those obtained by a Hg porosimeter for the range 1000-150,000 A. Steaming, hydrogenation, or oxidation by air (with or without impregnation by oxides of Fe, Cr, Ni, and Cu) modified a given charcoal to a great variety of pore distributions. Surface complexes on charcoal differed in the temp. at which they can be removed in the range 25-1000°C. Surface complexes formed with Cl and S were tightly held and profoundly affected the adsorptive properties. H_2S, PH_3, CNCl, BF_3, HCl, C_2H_2, and NO on A-whetlerites reacted in excess of a monolayer even at room temp.; H_2S, CNCl, BF_3, and HCl reacted rapidly with the entire mass of CuO. CO, SO_2, H_2O, C_2H_2, and NH_3 were chemisorbed to less than a monolayer on the CuO in the whetlerite.

212. Kramer, W. J. and McKee, J. H. **The drying of coal.** *Bull. Brit. Coal Utilisation Research Assoc.* 12, 157-75 (1948).—*C.A.* 42, 9113g.
The occurrence of water in coal is reviewed and the nonthermal and thermal methods of drying described.

213. Lyons, Orville R. and Richardson, A. C. **The thermal drying of fine coal.** *Am. Inst. Mining Met. Engrs. Coal Technol.* 3, No. 3, Tech. Pub. No. 2399, 23 pp (1948).—*C.A.* 42, 9113f.
Factors considered as affecting the drying rate of 24 driers were surface moisture of the wet and dried coal, wt of inlet gases, temp. of inlet and exhaust gases, and the av. particle size of the coal being dried. The total heat input to the furnace per unit wt of H_2O removed in the drier was found to correlate with most of the factors thought to influence drier effectiveness, and apparently was a usable indicator of drier effectiveness.

214. Dubinin, M. M. and Zaverina, E. D. **Sorption and structure of active carbons. III. Alteration of the porosity characteristics of carbon and sorption of water vapor.** *Zhur. Fiz. Khim.* 23, 57-70 (1949).—*C.A.* 43, 4075g.
Charcoal contg. adsorbed dibutyl phthalate adsorbed less C_6H_6 than did the original. If the vol. of H_2O (as liquid) adsorbed by charcoal at 95% relative humidity is a_o and the vol. of contaminating C_6H_6 (as liquid) is a_1, the vol. of H_2O adsorbed by the contaminated charcoal is approx. $a_o - a_1$. The ash of an anthracite charcoal had a very small adsorption capacity. Dissolving away the ash of the charcoal increased a_o.

215. Johansson, C. H.; Persson, G., and Svensson, Borje. **Sorption in flow through a granular layer.** *Acta Polytech. No.* 29 (Chem. Met. Ser. 1, No. 7), 5-31 (1949) (in English); *Ing. Vetenskaps Akad. Handl. No.* 200.—*C.A.* 43, 6872*h*.
The flowing medium contained a low concn. of one component taken up in the granular layer by pure phys. sorption, so that change in flow velocity and heat of sorption could be disregarded. Exptl. detns. were made at 18°C of the sorption of chloropicrin and water vapor in activated charcoal and of water vapor in silica gel. Complete analyses by isotherms and isochrones were given. The process was studied for an isotherm concave towards the abscissa and for a linear isotherm. The sorption process was to a large degree dependent on the form of the isotherm and on the position of the operating point on the isotherm.

216. Ledoux, Edward. **Redistribution of adsorbate by diffusion.** *J. Phys. & Colloid Chem.* 53, 960-6 (1949).—*C.A.* 43, 7288f.
The redistribution of H_2O in a bed of charcoal was expressed mathematically. By expressing data for known systems in terms of dimensionless variables, it was possible to det. the diffusivities in other systems.

217. Pearse, J. F. Oliver, T. R. and Newitt, D. M. **The mechanism of the drying of solids. I. The forces giving rise to movement of water in granular beds during drying.** *Trans. Inst. Chem. Engrs.* (London) 27, 1-8 (1949).—*C.A.* 46, 6870i.
The theoretical aspects of moisture movement in granular solids is discussed and an over-all equation developed based upon the assumption that the movement was due to capillary, gravitational, and frictional forces acting on the liquid. Exptl. data were presented which indicated that, while the theoretical treatment was applicable to relatively coarse granular solids, it was not equally valid for beds composed of fine particles. This limitation might be due to vaporization of H_2O within the bed arising from the high suctions developed.

218. Wiig, Edwin O. and Juhola, A. J. **Adsorption of water vapor on activated charcoal.** *J. Am. Chem. Soc.* 71, 561-8 (1949).—*C.A.* 44, 402*c*.
As successive increments of water were adsorbed, activated charcoal underwent an initial contraction followed by an expansion such that the original length was exceeded. The d. of water adsorbed at 24°C on two activated charcoals was less than normal and decreased with decrease in relative pressure. Both observations were in qual. agreement with the assumption of capillary condensation of the water.

219. Courty, Clément. **Magnetic measurements applied to adsorption.** *Compt. rend.* 230, 745-7 (1950).—*C.A.* 44, 5661g.
The adsorption of water and air on activated charcoal was studied by measuring the magnetic susceptibility of the adsorbent contg. air and water. The value for pure water, -0.72×10^{-6}, was found const. for adsorbed water also. The value for air, $+24.16 \times 10^{-6}$ decreased slowly to $+14.94 \times 10^{-6}$ at 20°C.

220. Ettinger, I. L. **Sorption of carbon dioxide by mineral coal.** *Izvest. Akad. Nauk U.S.S.R., Otdel. Tekh. Nauk* 1950, No. 5, 721-8.—*C.A.* 45, 9991*h*.
In the sorption of purified CO_2 by coal, by the static vol. method, the temp. was maintained to within 0.1°C. Previously the coal to be used had been subjected to a vacuum of 10^{-4} mm and at a temp. of 60-70°C. Thirty samples of coal from 4 basins were studied, ranging from long-flame coal to anthracites. Sorptions were studied at 20°, 30°, and 40°C and at 50-900 mm Hg. Other expts. were performed using graphite as the sorbent. The formula of Langmuir was valid for the sorptions carried out. The sorption of CO_2 by coal was of a purely phys. nature and was 3.5-4.5 times greater than that of CH_4, and 15-20 times greater than that of N_2.

221. Hendry, R. and Scott, A. W. **Some fundamental aspects of air-drying of solids.** *J. Inst. Fuel* 23, 286-94 (1950).—*C.A.* 45, 399*d*. The properties of air-water vapor mixts. were summarized. The construction of the psychrometric chart and its application to the analysis of drier performance were outlined. Different methods of presenting exptl. data on drying were described, and consideration given to application of such data to the calcn. of drying times in full-scale driers.

222. Kurbatov, L. N. **The dielectric properties of adsorbed vapors.** *Zhur. Fiz. Khim.* 24, 899-912 (1950).—*C.A.* 45, 1398*f*.
The orientation polarization of adsorbed dipolar mols. of little vibration and free rotation of

the dipole within a limited space was detd. The adsorption study was made by measurement of the dielec. const. of the adsorbate. The transition from single-layer to double-layer adsorption was accompanied by a change in the dielec. properties. The degrees of polarization of Me_2CO and H_2O were calcd. and these values interpreted in terms of the derived formula.

223. McDermot, H. L. and Tuck, N. G. M. **Density of water sorbed on charcoal.** *Can. J. Research* **28B**, 292-7 (1950).—*C.A.* 45, 1404*d*.
The apparent vol. of water sorbed by a $ZnCl_2$-activated charcoal was greater over the whole course of the isotherm than the vol. of an equal wt of water in the liquid state. It was slightly higher on desorption than on adsorption. The app. used was designed to eliminate water carry-over and subsequent sorption.

224. Razouk, R. I. and El Gobeily, M. A. **The expansion of charcoal on the adsorption of gases and vapors.** *J. Phys. & Colloid Chem.* **54**, 1087-98 (1950).—*C.A.* 45, 3220*i*.
The expansion of a piece of willow-wood charcoal was measured with a silica extensometer as a function of the adsorption of MeOH at 25°C; CO_2 at -78°, -38°, 0°, and 25°C; NH_3 at -78°, -38°, 0°, and 30°C; O_2 at -185° and -78°C; and SO_2 at 0°C. The expansion was found to be proportional to the lowering of surface free energy accompanying the adsorption. The proportionality const. was independent of temp. and of the adsorbate. The adsorbed films appear to be mobile. The surface of the charcoal was estd. to be 575 m^2/g; the amt. of adsorption in all cases corresponded to less than a monolayer.

225. Belcher, R. and Mott, R. A. **Observations on the inefficacy of a desiccator in determining the moisture in coal.** *J. Applied Chem. (London)* **1**, 204-9 (1951).—*C.A.* **45**, 7773*h*.
Dried coal in an uncovered dish in a desiccator absorbed moisture regardless of the efficiency, age, or location of the desiccant used. The amt. of moisture absorbed increased with the time of standing after cooling. The rate of adsorption increased markedly as the particle size decreased to about 100 mesh, but remained almost const. with further reduction in particle size. Dried coal in dishes covered with well-fitting lids adsorbed only slight amts. of moisture whether they were in the open air, an empty desiccator, a desiccator contg. water, or a desiccator contg. silica gel, and there was little difference in the rates of adsorption of water by the coal.

226. Carpeni, Georges. **Interpretation of the dielectric absorption curves ϵ'' of adsorbed water in the kilometer-wave range. I. Relations and numerical data. II. Determination of the real surface and the point of rupture of the adsorbent.** *Compt. rend.* **233**, 158-60, 249-51, 309-11 (1951).—*C.A.* 46, 3351g.
The curves ϵ'' (T) presented 2 bands, one of which was independent of the degree of hydration (abscissa fixed at approx. -100°C), while the other varied with hydration. Linear relations existed between hydration and the intensities of both bands. The sum of the band heights was const. The exptl. detn. of the absorption, ϵ'', as a function of temp. and of the degree of hydration of the adsorbent permitted, on the basis of the relations previously established and through linear extrapolation, the evaluation of 2 consts.: the active surface and the point of rupture of the adsorbent.

227. Davies, D. A. **Artificial stimulation of rain at Kongwa.** *Nature* **167**, 614 (1951).—*C.A.* 45, 8306d.
The expts. were based on the principle that AgI particles may act as sublimation nuclei in supercooled clouds. Two methods were used, namely: (1) charcoal impregnated by immersion in an acetone soln. of AgI is burned in a ground generator relying on natural vertical currents to convey the particles to levels where they become effective; and (2) the AgI particles are produced by explosion of small charges of gunpowder. Each charge was carried into suitable clouds by H_2-filled balloons, the explosion being effected by a time-fuse set to explode at about 15,000 ft, the freezing level.

228. Hills, D. C. and Holmes, C. R. **Moisture content of various coke sizes.** *Ind. Eng. Chem.* **43**, 1635-8 (1951).—*C.A.* 45, 8232i.
The moisture content of by-product coke tended to increase as the size of the coke decreased, with the exception that the moisture content decreased with the pea and breeze sizes. Hot coke when immersed in water until completely cool absorbs more moisture than does cooler coke. Decrease in size of coke is assocd. with increase in moisture due to the drying caused by the heat retained in the larger sizes. Explanations for the increase in dryness of the smaller sizes appear to be their segregation on the floor of the quenching car, and greater drying than intermediate sizes owing to heat from the larger sizes.

229. Honda, Hidemasa and Kurihara, Fukuji. **Fundamental studies on the manufacture of binderless briquet. X. Evaporation of moisture in pulverized coal by heating.** *J. Chem. Soc. Japan*, Ind. Chem. Sect. 54, 171-2 (1951).—*C.A.* 47, 1914i.
The change of wt accompanying heating was studied by means of a thermobalance for samples of different moisture contents. The evapn. of moisture starts at 60° and proceeds step by step at about 85°, 105°, and 125°C, resp. The combined water is driven off above 125°C and the coal begins to decomp.

230. Kreulen, D. J. W. **The adsorption water of coal.** *Chem. en Pharm. Tech.* (Dodrecht) 7, 23-4 (1951).—*C.A.* 46, 2778e.
Coal is satd. with H_2O, then exposed *in vacuo* at 30°C to a relative humidity of 97% (over satd. K_2SO_4 soln.). Moisture is then detd. by heating the coal in N_2 at different temps., 100-400°C. The loss in wt was const. until 250°C, when a rapid increase in loss occurred, indicating decompn. of the coal. The moisture detd. at 250°C was appreciably greater than that at 105°C. The temp. now used in the detn. of adsorption water is too low, especially for high-moisture coals.

231. Lecky, J. A.; Hall; W. Keith, and Anderson, Robert B. **Adsorption of water and methanol on coal.** *Nature* **168**, 124-5 (1951).—*C.A.* **46**, 11630e.

The true surface area of coal is probably not measured by adsorption of MeOH and H_2O, since these polar compds. are not physically adsorbed in the usual sense. Hence they are not amenable to the treatment for derivation of surface area.

232. Lyons, Orville. **Filter-cake particle size and moisture relationships.** *Trans. Am. Inst. Mining Met. Engrs., Tech. Pub.* No. **3165-F** (in *Mining Eng.* 3, 868-70) (1951).—*C.A.* **45**, 9921i.

Relations between the av. particle size of the cake and cake moisture (surface moisture for coal and total moisture for minerals) in dewatering fine solids by a variety of makes and types of filters are shown graphically.

233. Miller, H. M. S. **Drying of peat.** *J. Inst. Fuel* **24**, 49-50 (1951).—*C.A.* **45**, 4427b.

Water occluded or held mechanically in spongy peat can be removed by mech. pressure, but the capillary water was difficult to remove completely by mech. means. In thermal drying of milled peat of 55% moisture content, or sod peat of 35% moisture content, most colloidal and capillary water was removed. For economic reasons it was not practicable to remove water by thermal methods from peat with a moisture content above 60%. None of the methods so far devised for drying peat entirely by artificial heat were com. feasible.

234. Nadziakiewicz, Julian; Warmuziński, Janusz, and Balczewski, Antoni. **The influence of moisture content in coal on the coking process.** *Prezglad Górniczy* 7, 160-3 (1951).—*C.A.* **45**, 8741g.

A decrease in H_2O content of the coal from 9.6% to 8.3% reduced the coking time by 4.1%. A decrease from 10.4 to 8.3% H_2O raised the yield of crude benzene by 4.6%, of $(NH_4)_2SO_4$ by 6.6%, and of gas by 6.3%, while tar decreased by about 1.4%. Despite the lower H_2O content, no appreciable increase in fines occurred during the usual grinding of the coal charge to an 80% content of particles less than 3 mm size.

235. Nukherjee, P. N.; Basak, N. G., and Lahiri, A. **Chemisorption of moisture on coal.** *Fuel* **30**, 215-16 (1951).—*C.A.* **45**, 9242*h*.

Desorption and sorption isotherms of water vapor on coal indicated that, contrary to expectations, the amt. adsorbed increased with temp. Apart from oxidation, some other factor was involved which was responsible for increased sorption of moisture at progressively higher temp. The surface of the coal was activated by the rise of temp. and part of the moisture was held on the surface by chemisorption which increased with rise of temp. within the range investigated.

236. Pierce, Conway; Smith, R. Nelson; Wiley, J. W., and Cordes, H. **Adsorption of water by carbon.** *J. Am. Chem. Soc.* **73**, 4551-7 (1951).—*C.A.* **46**, 4317f.

H_2O isotherms were given for porous and nonporous carbons. A nonporous carbon adsorbed little H_2O as compared with other vapors, but activated charcoals hold nearly the same liquid vol. of H_2O as of other vapors. The net heat appeared to be zero for the initial adsorption of H_2O, then as more mols. were adsorbed, the net heat became pos. At elevated temps. the initial net heat of adsorption appeared to have a large neg. value. H_2 and CO_2 were produced in the reaction and some of the O_2 held as a surface complex, which increased the surface affinity for H_2O. An upturn in a H_2O isotherm below 0.95% p_0 appeared to be assocd. with the presence of capillaries. Water isotherms were used to detect capillaries in certain carbon blacks.

237. Wenzel, Leonard A. **The drying of granular solids in superheated steam.** *Univ. Microfilms* (Ann Arbor, Mich.), *Pub.* No. **2474**, 332 pp. (microfilm $4.15, paper enlargements $33.20); *Microfilms Abstracts* **11**, No. 2, 243-4 (1951).—*C.A.* **45**, 7387e.

238. Westlin, Arne. **The dehydration of peat.** *Tek. Tid.* **81**, 717-23 (1951).—*C.A.* **46**, 2779h.

Dry peat substance is essentially a colloidal org. material of extremely complex and variable compn. By virtue of its colloidal structure, adsorption plays a major role in its water-carrying properties and since heats of adsorption are of a lower order of magnitude than those of evapn., theoretically at least dehydration should be effected by desorption rather than by evapn. This can be done with reduction of swelling and filter pressure by adjusting pH to the optimum point; by adding org. liquids, e.g., acetone, MeOH and EtOH; by conditioning with salts and tannins and with filter aids in the form of peat dust or peat char; or even by freezing the hydrated mass. At present the only practical method for artificial drying is with air with either direct or indirect heating. In the main it is reserved for the final drying (below 25% water) of naturally dried peat; in other applications it cannot compete in cost. The most promising procedures are desorption followed by mech. pressing, use of superheated steam, and high-temp. extn. processes.

239. Aleksandrov, V. A.; Dubinin, M. M.; Zaverina, E. D.; Plachenov, T. G., and Chepurnoi, S. G. **The porous structure of active carbons.** *Doklady Akad. Nauk S.S.S.R.* **84**, 301-4 (1952).—*C.A.* **46**, 9377g.

In adsorption of H_2O vapor the micropore vol. is filled mainly as a result of capillary condensation; the coarser transition pores are not filled. The distribution of the micropore vol. over pore radii is detd. from the desorption branch of the isotherm for H_2O vapor. The differential distribution curves have a max. located for different active carbons between 1.1×10^{-7} and 2.5×10^{-7} cm. One active carbon sample showed a max. at $r = 1.8 \times 10^{-7}$ cm corresponding to micropores with a vol. $v = 0.19$ cc./g and a sp. surface area $s = 240$ m^2/g; 2nd max., at $r = 1.4 \times 10^{-6}$, $v = 0.49$, $s = 150$, corresponds to intermediate pores; 3rd max., at $r = 7.9 \times 10^{-5}$ cm, $v = 0.43$, $s = 1.9$, corresponds to coarse pores. In general, active carbons have all 3 types of pores. In many kinds of carbons, the vol. of intermediate pores is very small; on activation, micropores go over into intermediate pores, and the micropore vol. may become very small.

240. Dubinin, M. M. **Porous structure of adsorbents.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* **1952**, 577-82.—*C.A.* 47, 940*b*.

Active carbons show 3 types of porosity. Macropores may attain a few thousandth of a cm; the surface area does not exceed 1-2 m^2/g. Intermediate pores, visible under an electron microscope, can be derived from the hysteresis in desorption-adsorption of org. vapors; the most frequent diams. of these pores lie between 70 and 170 A., and their surface depending on the pore vol., can vary from a few to 100 m^2/g. Micropores can be detd. from adsorption measurements with mols. of different known sizes. Sorption of org. vapors by active carbons consists essentially in filling the vol. of the micropores, and capillary condensation filling the vol. of intermediate pores; multimol. adsorption at the surface of the intermediate pores is secondary. An exception is sorption of H_2O vapor, which consists essentially in filling the micropores through capillary condensation, whereas the coarser intermediate pores do not as a rule become filled. Silica gels show only one type of porosity; specifically, macropores are largely absent, as pores with $r > 1000$ A. have at most a vol. of 0.05 cc./g, more frequently less.

241. Goring, G. E.; Curran, G. P.; Tarbox, R. P., and Gorin, Everett. **Kinetics of carbon gasification by steam. Effect of pressure and carbon burn-off on rate of interaction of low-temperature char with steam-hydrogen mixtures at 1600°F.** *Ind. Eng. Chem.* 44, 1057-65 (1952).—*C.A.* 46, 7734*a*.

The kinetics of the char-steam system at 1600°F covered the effects of 3 independent variables on the gasification rates: (1) percent gasified (carbon burn-off), 0 to 50%; (2) total pressure, 1 to 30 atms.; (3) gas compn., H_2/H_2O ratio varied from 0.1 to ~1.0. Sporadic runs were also made with a feed gas of pure H_2. By using a graphical extrapolation technique, the directly measured integral gasification rates were processed to yield, indirectly, a set of differential gasification rates. Two types of differential rates were detd., the total gasification rate ($CO + CO_2 + CH_4$) and the methane-formation rate. These are unique functions of specific values of the 3 variables and gave basic information on the mechanism of char-steam interaction.

242. Juhola, A. J.; Palumbo, A. J., and Smith, S. B. **A comparison of pore-size distributions of activated carbons calculated from nitrogen and water desorption isotherms.** *J. Am. Chem. Soc.* **74**, 61-4 (1952).—*C.A.* 46, 2872d.

Pore-size distribution curves for several activated carbons computed from the low-temp. N_2 desorption isotherms were compared with pore-size distribution curves computed from water desorption isotherms. A semiquant. agreement was found between the curves obtained by the 2 methods in the 22 to 300-A. radius range. Below 22A. radius the method based on N_2 adsorption was not theoretically applicable. The water-adsorption method was applicable to the complete gamut of pores in activated carbons, and the method yielded distribution curves from which surface areas were computed. B.E.T. areas were in essential agreement with these values.

243. Klyucharev, A. E. and Shalygina, V. S. **Thermal moisture conductivity in peat.** *Torfyanaya Prom.* **29**, No. 5, 25-6 (1952).—*C.A.* 46, 8829*e*.

The simultaneous gradient of moisture and temp. was designated the thermal-moisture cond. For lowland peat 40% decayed, the value of this function was of the order of 0.25-0.50% moisture/degree. The max. value was at 85% moisture content. The moisture content at max. thermal moisture cond. was the max. admissible moisture content for drying a particular peat.

244. McDermot, H. L. and Arnell, J. C. **Charcoal sorption studies. I. Pore distribution in activated charcoals.** *Can. J. Chem.* **30**, 177-84 (1952).—*C.A.* 46, 8458c.

Results of pore-distribution calcns. using H_2O isotherms were compared with those using low-temp. N_2 isotherms. Charcoal *A* was a steam-activated coconut-shell charcoal, *B* was *A* further activated in a stream of H_2 at 1000°C, and *C* was a $ZnCl_2$-activated maple sawdust charcoal. All samples were degassed by evacuating 12 hrs at 200°C. Pore vols. were detd. from the difference in d. of the charcoals when immersed in Hg and in C_6H_6. Surface areas (m^2/g) and pore vols. (cc./g) for *A*, *B*, and *C*, resp., were 1375, 0.81; 1610, 0.95; and 1530, 1.10. Curves show the exptl. results for H_2O and low-temp. N_2 isotherms for *A*, *B*, and *C* for both adsorption and desorption. If cos θ in the Kelvin equation (where θ is the wetting angle) is assigned a value of 0.65 (instead of 1), the pore distributions calcd. from the H_2O isotherms are in general agreement with those from the N_2 isotherms. There is a difference in the mechanism of desorption of N_2 and H_2O from charcoal, and the assumption of capillary evapn. with residual multilayers in the case of N_2 and capillary evapn. alone in the case of H_2O appears adequate to account for the difference.

245. Peck, Ralph E.; Griffith, Russell T., and Rao, K. Nagaraja. **Relative magnitudes of surface and internal resistance in drying.** *Ind. Eng. Chem.* 44, 664-9 (1952).—*C.A.* 46, 5899f.

Equations were developed relating the effective diffusivity to the av. total moisture content of material and the drying conditions for application in design calcns. Drying schedules were calcd. according to the equation: $(C/C_o)^{1-n} - 1 = (1-n) M'\theta/C_o^{1-n}$, where C and C_o were av. and original water concns., resp.; M' was a const. and θ the time in hrs.

246. Volman, D. H. and Doyle, G. J. **The retentivity of charcoals by the approximate isotherm method. The effect of moisture on the retentivity for methyl ethyl ether, neopentane, and methanol.** *J. Phys. Chem.* 56, 182-5 (1952).—*C. A.* 46, 8457i.

Approx. isotherms for MeOEt, neopentane, and CH_3OH were detd. by the retentivity method for charcoal equilibrated with H_2O vapor at 80% relative humidity. The presence of moisture on the charcoal had a highly deleterious effect on the retentivity for neopentane, which is insol. in H_2O; it had an appreciable lessening of retentivity for MeOEt, which is somewhat sol. in H_2O; but it had no effect on the adsorption of CH_3OH, which is completely miscible with H_2O. If the total sorption of a given adsorbate consists of one part in the displacement of H_2O from the surface, and another to the soln. of the adsorbate in H_2O on the surface, it was possible to calc. quantitatively the retentivity isotherm for the adsorbate in the presence of H_2O vapor from the isotherm in the absence of H_2O vapor together with the adsorption isotherm for H_2O.

247. Hunt, B. E.; Mori, Shiro; Katz, Sidney, and Peck, R. E. **Reaction of carbon with steam at elevated temperatures.** *Ind. Eng. Chem.* **45**, 677-8 (1953).—*C.A.* 47, 6633*h*.

Data at 1150°C on product-reactant ratios of 4 principal reactions and on conversion ratios in 3-, 5-, and 7-in. fuel beds showed that the only reaction reaching equil. was: $CO + H_2O = CO_2 + H_2$. There was a possible transition from a chem. or surface- to diffusion-controlled reaction above 1150°C.

248. Mukherjee, P.; Basak, N. G., and Lahiri, A. **Moisture in coal.** *J. Sci. Ind. Research (India)* **12B**, 15-24 (1953).—*C.A.* 47, 6633*i*.

The sorption and desorption of moisture on coals were studied with air and N_2 moisture carriers. Static and dynamic methods gave curves quite similar in shape. The moisture content should be estd. between 0 and 95% relative humidity in N_2 instead of air. The coal sample should be kept under water to avoid shrinkage effects. The desorption branch of the first cycle should be chosen and sorption expts. should be carried out at temps. below 40°C to avoid enhanced sorption due to activation effects. The B.E.T. area from sorption isotherms at 110°F was 94.3 m^2/g and at 130°F 151.9 m^2/g. The heat of wetting in CH_3OH at 35°C indicated a surface of 177 m^2/g.

249. Parry, V. F.; Landers, W. S.; Wagner, E. O.; Goodman, J. B., and Lammers, G. C. **Drying and carbonizing fine coal in entrained and fluidized state.** *U.S. Bur. Mines, Rept. Invest.* No. 4954, 43 pp. (1953).—*C.A.* 47, 6116d.

Fluidized or entrained drying is a process of mixing fine coal with hot gases (as hot as 2500°F) in such proportions that the resultant mixt. reaches a temp. of 275 to 325°F. The coal must remain in this environment long enough to be heated to about 250°F, where 90 to 95% of the inherent moisture is evapd. Approx. 50 sec. is required for particles of $\frac{1}{4}$ in. by 0 size. Fluidized carbonization involves heating the dried coal particles to about 900°F while they are in suspension in a vertically moving gas stream. The particles remain in the reactor for 10 to 15 min. yielding a mixt. of tar vapors, process gas, char, and H_2O vapor which moves out of the system at high velocity into cyclone separators to remove the solids. Any coal contg. over 12% O in the pure coal (ash- and moisture-free) can be carbonized by these processes.

250. Fieldner, A. C.; David, J. D.; Selvig, W. A.; Thiessen, R.; Reynolds, D. A.; Holmes, C. R., and Sprunk, G. C. **Carbonizing properties of West Virginia coals and blends of coals from the Alma, Cedar Grove, Dorothy, Powellton A, Eagle, Pocahontas and Beckley beds.** *U.S. Bur. of Mines, Bull. No.* **411**, 162 pp. (1938).—*C.A.* **33**, 1910^{3}.

Complete data on the compn., phys. and chem. properties, and carbonizing properties of 7 West Virginia coals were given. Ash was 2.9 to 6.8, S, 0.4 to 1.5%; and softening temp. of ash 2370° to 2910° F. None of the coals contained enough fusain to affect coking power appreciably. Largest coke was produced at 700°C; at higher temps., shrinkage cracks developed. Resistance to shock and abrasion (shatter and tumbler tests, resp.) rose to a max. at 800°C.

251. Chukhanov, Z. F. and Karzhavina, N. A. **The combustion of carbon. V. Combustion of a charcoal layer.** *J. Tech. Phys. (U.S.S.R.)* **10**, 1256-67 (1940); *Fuel* **20**, 186-94 (1940).—*C.A.* **35**, 3060^{1}; **37**, 2542^{6}.

The velocity of combustion was proportional to the 1.6 power of the O_2 concn. The proportionality coeff. depended on the linear velocity of gas flow. Its dependence on temp. was very complicated. Formulas were developed for computation of the amt. of O_2 used, the rate of gas formation, and the compn. of gas. The theory agreed well with exptl. results.

252. Kimoto, Toraki; Morikawa, Kiyoshi, and Abe, Ryonosuke. **Direct determination of oxygen in organic compounds by hydrogenation. IV. Determination of oxygen in coal.** *J. Chem. Soc. Japan* **62**, 1001-5 (1941).—*C.A.* **41**, 2658e.

When the sample contained S, the H_2S formed interfered with the detn. of O. By placing diatomaceous earth contg. 20% reduced Cu before the Ni catalyst, H_2S was removed.

253. Martin, O. **A derivation of the thermochemical equilibrium.** *Mitt. Forsch.-Anstalt. Gutehoffnungshutte-Konzern* **9**, 77-84 (1941).—*C.A.* **37**, 2250^{7}.

The free enthalpy G, was defined by $G = TS - H$ instead of $G = H - TS$. The relation of equil. const. to degree of reaction and total pressure was generally derived for the reaction $A_2 + 1/2B_2 = A_2B$ and represented in the form $K_p = \beta p\gamma$, where β was the degree of reaction. Values for β and pressure exponent γ were tabulated for some reactions (γ with reversed sign). The relation between equil. const. and degree of dissociation was illustrated for the reaction $[C] + CO_2 = 2CO$, and by various homogeneous and heterogeneous gas reactions.

254. Sihvonen, A. **The phenomena in carbon oxidation.** *Chimie & industrie* **45**, Suppl. to No. 3, Special No., 332-3 (1941).—*C.A.* **37**, 3245^{3}.

A review chiefly of the author's investigation.

255. Kantarovich, B. V. **Thermal conditions of the gasification process in a layer of carbon particles.** *J. Tech. Phys. (U.S.S.R.)* **12**, 647-56 (1942).—*C.A.* **37**, 4225^9.

An increase of velocity of gas blowing through the layer first caused a sharp increase in temp. and then a more gradual increase. A decrease of reaction surface caused retention of heat and, therefore, the temp. in the burning zone increased. An excessive decrease of reaction-surface caused the production of gas of lower quality.

256. Oza, T. M. and Shah, M. S. **The mechanism of the action of charcoal on potassium nitrate. I. The effect of temperature, time, etc.** *J. Univ. Bombay* **11**, Pt. 3, 56-69 (1942).—*C.A.* **37**, 4642^4.

Expts. with mixts. of KNO_3 and 20% (of wt of KNO_3) charcoal for 1 hr showed that the amt. of KNO_3 used increased with rise in temp. and the amts. of K_2CO_3, N_2, and CO_2 increased. A comparison of the amts. of N_2, CO_2 and K_2CO_3 produced up to 390°C showed a regular rectilinear relation between the amts. of N_2 and K_2CO_3 formed. The amts. of NO, CO, and N_2O_3 up to 380°C were smaller than in expts. at 390°C. The expt. could not be continued at 390°C for 1 hr, as the reaction steadily gained speed and flashed in about 25 min. Expts. with KNO_3 and 20% charcoal to the pt. where the evolved gas exerts the same pressure showed that KNO_2 was always produced in the interaction. Expts. with KNO_3 and 20% charcoal allowed to proceed to different stages at 375°C showed that at the start of reaction the amt. of CO_2 was higher and of N_2 smaller than at high pressures.

257. Tachibana, Taro. **The effect of inorganic substances on the combustion of paper.** *J. Chem. Soc. Japan* **63**, 924-8 (1942).—*C.A.* **41**, 3357*a*.

Sheets of filter paper were dipped into aq. solns. of various salts, and dried at room temp., and ignited. There was a lowering, in the presence of the salt, of the ignition temp. of the carbon formed by the decompn. of cellulose.

258. Courty, Clément. **Magnetic properties of oxygen adsorbed in active charcoal.** *Compt. rend.* **216**, 769-71 (1943).—*C.A.* **38**, 4481^4.

Coconut charcoal was dried and degassed without heating, and its magnetic susceptibility measured. The sample was then satd. with O_2 and measured again. The value for the magnetic susceptibility thus obtained agreed with results by other methods. Possibly, the difference when charcoal was degassed at high temps. might be due, among other things, to the presence of water.

259. Fuchs, Walter; Polansky, T. S., and Sandoff, A. G. **Coal oxidation.** *Ind. Eng. Chem.* **35**, 343-5 (1943).—*C.A.* **37**, 1845^6.

A central Penna. coal was oxidized in a rotary furnace 30-60 min. up to 350°C with countercurrent air or air-O_2 mixts. Formation of acid groups in the coal was followed by titration with NaOH, and acid strength of the oxidized product was estd. by its ability to release HOAc from $Ca(OAc)_2$. NH_4NO_3 was the most effective catalyst. Treatment of 100 g of this preoxidized coal with 100 cc. of concd. HNO_3 1-2 hrs at 100°C gave 120 g of hydroxycarboxylic acids 90% sol. in furfural.

260. Imada, Fumio. **Studies on carbon. V. Effect of activation of charcoal on chemical reactivity. Oxidation.** *Technol. Repts. Kyushu Imp. Univ.* **18**, 67-71 (1943).—*C.A.* **43**, 5572*c*.

Active carbon and charcoal were heated with dry O_2 at a definite temp. for 15-30 min. in a combustion tube and the O_2-consumption was detd. at definite intervals (also continuously with a quartz spring balance). The active carbon prepd. at the optimum temp. consumed O_2 rapidly at first and slowly later. A surface oxide, such as—C_xO_y, formed first then after an equil. was reached, rearranged and finally released CO, CO_2, $(COOH)_2$ and perhaps formed a complex C_nO_m.

261. Imada, Fumio and Iki, Hiroshi. **Studies on carbon. VIII. Sorption of oxygen by active carbon. A preliminary experiment.** *Technol. Repts. Kyushu Imp. Univ.* **18**, 81-7 (1943).—*C.A.* **43**, 5572*e*.

At 30° and 45°C the observed adsorption agreed with that calcd. by Freundlich's formula when the pressure was below 400 mm Hg. Under higher pressure agreement was with that calcd. by the Langmuir formula, indicating that the adsorption was phys. in nature.

262. Imada, Fumio. **Studies on carbon. XII. Sorption of oxygen under low pressure and preparation of graphitic acid and pyrographite.** *Technol. Repts. Kyushu Imp. Univ.* **18**, 242-56 (1943).—*C.A.* **43**, 5572*h*.

The adsorption of O_2 by active charcoal at 30-45°C and 70-200 mm seemed physical at the beginning. On supplying more thermal energy the O_2 migrated deeper and entered into chem. adsorption (forming excited complex compds.). Natural and Acheson graphites were oxidized with dry air by Brodie's method to graphitic acid (O content 19.86, 20.79, 22.05, and 21.31%) which was converted into pyrographite by removing the O by heating in vacuum until an explosion occurred.

263. Klibanova, Ts. M. and Frank-Kamenetskiĭ, D.A. **Ignition of carbon and the kinetics of its reaction with oxygen.** *Acta Physicochim. U.R.S.S.* **18**, 387-405 (1943).—*C.A.* **39**, 857^8.

A study of the kinetics of the reaction of O_2 on a carbon filament, made smooth by prolonged heat-treatment in hydrocarbon vapors, showed that at 1200°K, the abs. reaction velocity was approx. 10^{-4} moles/cm^2 sec. The energy of activation was 100 ± 30 Cal./mole, and the order of reaction was between 0.4 and 0.8 with respect to O_2.

264. Radspinner, John A. and Howard, H. C. **Determination of surface oxidation of bituminous coal.** *Ind. Eng. Chem., Anal. Ed.* **15**, 566-70 (1943).—*C.A.* **37**, 6435^5.

Three typical bituminous coals were oxidized at 75°, 100° and 125°C for varying periods in equipment which permitted the analysis of gases leaving the coal. Carboxyl-group detn. of the coal showed that from a few to 40% of the total fixed O_2 reacted as carboxyl. A linear relation was found between fixed O_2 and oxides of C evolved by thermal decompn. of the oxidized coals at 350°C in the vacuum. Detn. of carboxyl groups was based on decompn. of Ca acetate by acid groups and detn. of acetic acid by the liberation of CO_2 from $CaCO_3$.

265. Audubert, Rene and Racz, Charles. **The function of the large quanta of energy in the phenomenon of carbon combustion.** *Compt. rend.* **219**, 254-6 (1944).—*C.A.* **40**, 1380^{5}.

Above 1500°C the over-all reaction was represented by the equation $3C + 2O_2 = 2CO + CO_2$, energy of activation 90 kcal. The combustion of carbon was accompanied by an ultraviolet radiation (2500-2000 A). The energy of activation of the emitting process, detd. from its spectrum, was 84 kcal. The above reaction, responsible for this radiation, was probably due to the reverting to a normal state of activated CO_2 mols. This type reaction was of zero order, and it was very probably a chain reaction made possible by the large energy quanta set free: $3C + 2O_2 \rightarrow C_3O_4 \rightarrow 2CO + CO_2^*$; $CO_2^* + C_3O_4 \rightarrow 2CO + CO_2 + CO_2^*$.

266. Hiles, J. and Mott, R. A. **The effect of particle size on the combustion reactions in a bed of coke.** *Fuel* **23**, 134-9 (1944).—*C.A.* **39**, 403^{7}.

Hand-screened coke 2-1/2 to 1/8 in. made from compressed charges of S. Yorkshire slacks in 21-in. coke ovens on 30-hr coking time was used in an 8-in. diam. furnace with forced draft. When the O_2 content of the gases exceeded 1%, CO was not present in appreciable quantities; when O_2 was less than 1%, the CO content of the gas might rise almost to 30%. Two definite zones were shown: a lower one in which the reaction, $C + O_2 \rightarrow CO_2$, predominated; an upper zone where the reaction occurring was $CO_2 + C \rightarrow 2CO$. The oxidation reaction occurred on the coke surface and required 8 ft^{2} of surface per ft^{2} of grate area for the coke sizes tested. For normal fuel beds (50% voids), the oxidation zone was 2.66 times the mean particle size. The reduction reaction was complete 1 to 1-1/2 in. from the grate when 1/4- to 1/8-in. coke was used. The max. temp., near the top of the oxidation zone, was substantially the same, 1400°C, for all coke sizes of the same coke.

267. Kondrat'ev, V. N. **Combustion of oxygen + carbon monoxide mixtures in quartz vessels.** *J. Phys. Chem. (U.S.S.R.)* **8**, 110-14 (1944).—*C.A.* **39**, 2245^{8}.

When an equimol. mixt. of O_2 and CO (with little H_2O or H_2O and H_2) was passed through a quartz tube at 650-700°C, the CO oxidized was often less than 1% and independent of the length of the tube (15-50 cm). When the mixt. was passed through 2 tubes, the second of which was kept at 700°C, the CO oxidized in the first tube increased with temp. (540-600°C), but that in the second tube simultaneously diminished so that the total remained nearly const. The effect must be due to trapping of water mols. in the vessel, as addn. of water to the mixt. between the tubes raised the CO oxidized in the second tube; about 70 mols. of CO_2 were produced for 1 H_2O. The trapping was not a simple adsorption.

268. Roberts, John. **The combustion of carbon.** *Coke Smokeless-Fuel Age* **6**, 211-14 (1944).—*C.A.* **39**, 1282^{7}.

Fuels with low ignition temps. burned with shallow beds, but those with high ignition temps. required deep fuel beds and air streams of relatively high velocity. Ignition temps. ranged from 180°C for earthy lignite to 516°C for anthracite, from 484° to 550°C for high-temp. cokes, and from 405° to 475°C for low-temp. coke. Coke buttons prepd. by carbonizing 50:50 mixts. of coal and coke breeze at various temps. from 450° to 1000°C were ground to pass a 60-mesh I.M.M. sieve and their ignition temps. detd. At 850°C there was a crit. stage in carbonization of the particular coal used.

269. Romwalter, A. **Coalification and carbonization.** *Hung. Palatine-Joseph Univ. Tech. Econ. Sci. Pubs. Dept. Mining Met.* **16**, 77-89 (1944-47).—*C.A.* **42**, 6282a.

The role of bacteria in coal formation ended with the destruction of proteins and saccharoids and the re-synthesis of the resultant fragments into giant mols. did not involve living organisms. O_2 dissolved in H_2O could produce anthracite from either sapropelic or xyloidal peats, with the catalytic aid of S. Graphitic structure could result eventually from thermal agitation.

270. Strickland-Constable, R. F. **Interaction of oxygen and carbon filaments at high temperatures.** *Trans. Faraday Soc.* **40**, 333-43 (1944).—*C.A.* **38**, 6168^{4}.

The principal product (CO) of the interaction of O_2 and a graphite filament between 900° and 2000°C was a primary product and only small quantities of CO_2 were produced. Between 0.02 to 0.05 mm, the reaction was of the 1st order. The rate of reaction rose from 900° to 1100°C, and was const. between 1600° and 2000°C. There was a zone in between in which the rate was very sensitive to the immediate past history of the filament. Precautions must be taken at the high temp. to avoid reactions due to the activation of gas mols. by thermionic emission from the filament. O_2 was not sorbed as surface oxides in appreciable quantities by a freshly outgassed filament at high temps.

271. Warner, B. R. **Pressure dependence of the rate of gasification of carbon.** *J. Am. Chem. Soc.* **66**, 1306-9 (1944).—*C.A.* **38**, 5131^{3}.

Data were given for the rate of gasification of carbon in the presence of steam. Isotherms and the satn. pressures in the reaction were similar in form to those for monomol. adsorption on a solid adsorbent.

272. Akamatsu, Hideo and Hamada, Hiroshi. **Ignition temperature of carbon.** *J. Chem. Soc. Japan* **66**, 8-9 (1945).—*C.A.* **42**, 7145b.

The ignition temps. of charcoal and carbon black were measured with a thermobalance. Carbons with a sharp X-ray diffraction pattern had the higher ignition temp. The ignition temp. depended on the ash content, mainly on cations and not so much on anions. Alkali metals, especially K, had a great effect. Cu and Ag were next, then alk. earths, Zn and Ca. Al scarcely affected the ignition temp., Fe-group elements resembled the alk. earths, whereas Pb resembled K and Cu.

273. Alekseevskiĭ, E. V. and Musin, Ya. D. **Instrument for determination of ignition temperature and kinetics of oxidation of activated charcoal.** *J. Applied Chem. (U.S.S.R.)* **18**, 505-8 (1945) (English summary).—*C.A.* **40**, 5625^{8}.

The oxidation kinetics and ignition temp. of charcoal were observed in a combustion chamber (vertical tube) that was connected to a $Ba(OH)_2$ absorption tube.

274. Audubert, René and Racz, Charles. **Emission of ultraviolet radiation in the combustion of carbon and the mechanism of the oxidation of carbon.** *Bull. soc. chim.* **12**, 318-29 (1945).—*C.A.* **40**, 278^{5}.

Carbon filaments were heated to 1000-1300°C in a stream of N_2 contg. 5% O_2. The ultraviolet radiation produced was detd. by a photocounter. Blackbody radiation from the filament was negligible compared to chemiluminescence. Detns. with a monochromator showed the intensity of the radiation was roughly independent of wave length at 2000-2800 A. The apparent activation energy E for production of the radiation over the range 1050-1250°C was approx. 68 kg-cal. at 250 mm pressure, 84 at 100 mm and 90 at 50 mm. Emission of 2000 A. indicated accumulation of 150 kg-cal. in a single mol. This might be derived from the heat of combustion of C to CO_2 (94 kg-cal.) plus the heat of activation (80 kg-cal.) (assumed to be activated adsorption); a great part of this total energy went to the CO_2 mol., which occasionally lost it by radiation. Ordinarily the excited CO_2 mol. gave up its energy to a surface complex of C and O_2, causing reaction with formation of a new excited CO_2. The chain was broken by emission of a quantum of radiation.

275. Audubert, René and Racz, Charles. **Mechanism of the oxidation of carbon.** *J. chim. phys.* **42**, 40 (1945).—*C.A.* **40**, 5323^{7}.

Oxidation below 1500°C was expressed by $4C + 3O_2 \rightarrow 2CO + 2CO_2$. Above that temp. the reaction was essentially $3C + 2O_2 \rightarrow 2CO + 2CO_2$ with the emission of ultraviolet of 2600-2000 A. (measured by means of CuI photometer). This was a chain reaction and could be expressed $3C + 2O_2 \rightarrow 2CO + CO_2^{*}$ (activated); $CO_2^{*} + 3C + 2O_2 \rightarrow 2CO + CO_2 + CO_2$. The sum of these reactions was expressed $CO_2^{*} \rightarrow CO_2 + h\nu$.

276. Courty, Clément. **Oxidizing properties of active carbon saturated with air.** *Compt. rend.* **221**, 27-9 (1945).—*C.A.* **40**, 2062^{4}.

The oxidizing properties of active carbon were attributed to the O_2 adsorbed by it. The activity of the O when thus adsorbed was due to its being in the atomic state. Results with As_2O_3 were considered particularly satisfactory and were given in some detail.

277. Eichner, Ch. and Prettre, M. **Kinetics of the system: carbon dioxide-carbon monoxide-combustible solid.** *Mem. services chim. etat* **32**, 240-52 (1945).—*C.A.* **42**, 4430*b*.

The change in CO on passing mixts. of CO and CO_2 over charcoal, activated carbon, and coke was measured at 1000°, 1100°, and 1200°K. The initial "reactivity" of all samples decreased with time at 1000°K; this decrease was less pronounced at 1100° and disappeared at 1200°K. The presence of CO in the gas mixt. strongly inhibited the reduction of CO_2 and vice versa. The quantity of CO_2 reduced was essentially independent of the flow rate between 1 and 4 liters per hr. These observations were explained on the basis of the adsorption of CO and CO_2 on the solid.

278. Jones, R. E. and Townend, D. T. A. **Mechanism of the oxidation of coal.** *Nature* **155**, 424-5 (1945).—*C.A.* **39**, 2859^{2}.

Freshly ground coal exposed to air accumulated peroxide-O, attaining a max. of 0.06 wt % after several weeks. The rate of formation increased at higher temps., but above 80°C the max. fell, owing to decreasing stability. In 6 coals the rate of weathering paralleled the max. of peroxidation. If an exposed coal was heated above 80°C in an inert atm., the peroxide O disappeared.

279. Jones, R. E. and Townend, D. T. A. **Institution Gas Research Fellowship Report, 1943-44. The mechanism of the oxidation of coal.** *Inst. Gas Engrs., Commun.* No. **271**, 21 pp. (1945).—*C.A.* **40**, 6784^{9}.

The formation of peroxidic bodies was followed by a colorimetric method depending upon the formation of $Fe(CNS)_3$ by reaction of a peroxide with a soln. contg. ferrous Fe and NH_4CNS. The estn. was carried out in a sealed system in N_2. At room temp. finely-divided fresh coal had been found to accumulate peroxygen on exposure to the atm., a max. content being reached after several weeks. At high temps. its rate of formation progressively increased, but ultimately the max. content fell owing to increasing stability. Expts. with 6 bituminous coals have shown the known ease of weathering to fall into line with the degree of peroxidation.

280. Jones, R. E. and Townend, D. T. A. **Institution Gas Research Fellowship Report, 1944-45. The mechanism of the oxidation of coal. II.** *Inst. Gas Engrs., Commun.* No. **287**, 23 pp. (1945); *Gas World* **123**, 619, 623 (1945).—*C.A.* **40**, 6785^{5}.

The initial reaction appeared to involve chemisorption, which, in the presence of water, was followed by the formation of a C-O-water complex. The normal, inherent water content of coals was a function of their internal surface; this was a min. with coals contg. about 89% C. The peroxygen content of coals showed a similar variation with C content, but was unstable above approx. 70°C. Below 70°C the complex was formed easily and remained relatively stable. Above 70°C, the complex started to break down, although with C it did not appear to be completely destroyed until 350°C was reached. Oxidation above 70°C was also marked by a big increase in the O content of a coal. CO_2 then preponderated over the CO.

281. Kodama, Tatsuhiko and Kimura, Osamu. **Ignition temperature of active charcoal.** *J. Chem. Soc. Japan* **66**, 33-4 (1945).—*C.A.* **43**, 7668*c*.

The influence of minute quantities of various salts on the ignition temp. of active charcoal was studied. The ignition temp. was lowered by the addn. of salts. The temp. variation was nearly linear with the square root of the amt. of the salt.

282. Kolodtsev, Kh. I. **Dynamics of gas formation in a carbon layer.** *J. Phys. Chem. (U.S.S.R.)* **19**, 417-28 (1945).—*C.A.* **40**, 1722^{9}.

A layer of electrode carbon (C 98.63, ash 1.01%) was ignited from the top, and air blown through it from above. The layer was 19 cm deep, and 7 cm under its top surface gas samples were taken and temp. (T) measured. The C grains were either 3.1 ± 0.6 cm or 5.4 ± 0.6, 6.6 ± 0.6, and 8.1 ±0.9 mm. During the first stage T increased rapidly and the gas contained no O_2; the concn. of CO passed through a max. and that of CO_2 through a min. During the sec. stage T rose slowly, the concn. O_2 increased rapidly, and CO and CO_2 rapidly fell.

283. KOLODTSEV, KH. I. **Computation of the laminar combustion of carbon.** *J. Phys. Chem. (U.S.S.R.)* **19**, 657-64 (1945).—*C.A.* **40**, 3247².

Equations were given for the rate of combustion of a carbon bed through which air was forced. If it was assumed that the rate of oxidation of CO to CO_2 was negligible and the rate of oxidation of C to CO_2 was very high, the theoretical outcome agreed with the expt. From the exptl. dependence of the reaction consts. on the rate of air blow and the C-particle radius it was concluded that both the oxidation and the reduction processes took place only on the surface of the C grains.

284. ARTHUR, J. R. **Combustion of carbon.** *Nature* **157**, 732-3 (1946).—*C.A.* **40**, 5221⁹.

An electrically heated carbon tube was used to approximate the conditions which would occur in a single channel in a fuel bed. Probes for gas sampling were very fine and were water-cooled to the extreme tip. CO, in concns. of 0.5-2.0% adjacent to the wall, nearly disappeared in the remainder of the tube as long as there was an excess of O_2. In the presence of 0.9-1.8% of the inhibitors Cl_2, CCl_4, or $POCl_3$, 14-22% CO appeared at the expense of CO_2, while there remained 1.2-4.4% O_2. Very rapid quenching was of the first importance when a reliable analysis was required of a hot gas mixt. contg. CO and O_2.

285. BLINOV, V. I. **Combustion of ash coal. I.** *Compt. rend. acad. sci. U.R.S.S.* **52**, 507-10 (1946) (in English).—*C.A.* **41**, 4291c.

The rate of combustion was deduced for the case of a sphere, a cylinder, and parallel walls of coal. It was assumed that reaction occurred at the ash-coal boundary which moved slowly forward and that the O-distribution was governed by the usual diffusion relations.

286. BLINOV, V. I. **Combustion of ash coal. II.** *Compt. rend. acad. sci. U.R.S.S.* **52**, 683-6 (1946) (in English).—*C.A.* **41**, 4291d.

The temp. distribution in coal for 3 shapes was deduced by assuming that the delivery of heat from the coal obeyed Newton's law.

287. BRIDGER, G. W. **Combustion of carbon and carbon monoxide.** *Nature* **158**, 236 (1946).—*C.A.* **40**, 6782¹.

In the combustion of coke with air, the $CO/(CO + CO_2)$ ratio was increased by the addn. of small amts. of Cl_2, HCl, or CCl_4 to the air. The effect was not due to catalysis of $CO_2 + C \rightarrow 2CO$, since no change in gas compn. occurred when $Cl_2 + CO_2$ was passed through coke at 1000°C. The combustion of 10% CO in air + N ($O_2/CO = 1$) could be inhibited by Cl_2; it was 0.55 vol. % at 1000°C. Starting with a CO + air mixt. contg. slightly less than the crit. concn. of Cl_2, inhibition became complete when the temp. was decreased sufficiently and did not cease when the temp. was raised. Larger voids in the fuel bed favored the production of CO_2. The compn. of combustion gases was considerably controlled by conditions in the fuel bed above the combustion zone, where the reduction of CO_2 was the predominant reaction.

288. CASSAN, HENRY. **The kinetics of heterogeneous reversible reactions—application to the reactivity of solid fuels.** *Chaleur et ind.* **27**, 75-84, 103-13 (1946).—*C.A.* **40**, 6236⁵.

The concept of reactivity of the solid surface was extended to cover complex reversible heterogeneous reactions involved in water-gas formation. An expression was developed which correctly represented the exptl. results; this was extended to water-gas manufacture with excellent concordance. The method could be applied to all reactions in which a gaseous phase was in contact with a solid phase comprising a catalyst or an autocatalyst.

289. CONSTANTINIDES, GIORGIA. **Coal-autoxidation measurements.** *Ann. Triestini* **18**, No. 1/2, 3-18 (1946); *Pubb. facoltà sci. e ing. univ. Trieste, Ser. B*, No. **13** (1947).—*C.A.* **46**, 8345*f*.

Published results were compared by the equation $x = cT^b$, where x was the total amt. of O_2 consumed, expressed as percentage of dry coal, T was time in days, and b and c were const. Reliable results were obtained up to 50°C, where the amts. of CO_2 and of CO evolved were too small to influence the manometric readings.

290. GADSBY, J.; HINSHELWOOD, C. N., AND SYKES, K. W. **The kinetics of the reactions of the steam-carbon system.** *Proc. Roy. Soc. (London)* **A187**, 129-51 (1946).—*C.A.* **41**, 1533i.

Essentially similar results were obtained with coconut shell charcoal at 700°C and coal charcoal at 800°C in the range 10-760 mm. The reaction, the primary product of which was CO, was of fractional order with respect to steam and strongly retarded by H_2. The CO_2-carbon reaction was of fractional order with respect to CO_2 and strongly retarded by CO. The rates of both these reactions could be represented closely by an expression of the form rate $= k_1p_1/(1 + k_2p_2 + k_3p_1)$, where p_1 and p_2 were, resp., the pressures of steam and H_2 for the steam reaction, and of CO_2 and CO for the CO_2 reaction. The water-gas reaction $CO + H_2O = CO_2 + H_2$ took place predominantly on the charcoal surface, and the approach to equil. was studied from both sides. In the water-gas reaction, no simple expression was applicable, and the lack of reproducibility, possibly occasioned by changes in catalytically active impurities, made it difficult to distinguish between various types of more complicated expressions.

291. GOSSELIN, A. **Remark on the paper of Audubert and Racz: Emission of radiation during combustion of carbon.** *Bull. soc. chim.* **1946**, 271.—*C.A.* **40**, 7003².

The quanta of 150, 128, and 105 kg-cal. per mole, previously observed, were ascribed to chemiluminescence on combination of free C and O atoms to give CO in 2 different states, and C atoms with O_2 mols. to give CO_2. The weakness of the luminescence was due to the low concn. of free atoms.

292. Kartvelishvili, G. A. **Spontaneous inflammability of Tkvibuli coal.** *Ugol* **21**, No. 12, 34-5 (1946).—*C.A.* **41**, 4291b.

A study was made of samples of coal taken from various beds of the Tkvibuli (Georgian SSR) coal deposit to det. the cause of numerous mine fires. The oxidizability, content of volatile matter, and the ignition temp. characterized this coal as safe. However, the low C and high H content increased its ability to adsorb O_2. Thus, the coal was not spontaneously inflammable yet quite dangerous and required carefully worked out mining procedures and ventilation.

293. Kramers, W. J. **The action of oxygen on coal at moderate temperatures.** *Bull. Brit. Coal Utilisation Research Assoc.* **10**, 395-404 (1946).—*C.A.* **41**, 2553*a*.

The oxidation of coal on storage was reviewed and the humic acids and sol. acids obtained from coal described.

294. Kucera, Eduard and Klima, Josef. **The determination of reactivity of coke.** *Paliva a voda* **26**, No. 2-3, 17-20 (1946).—*C.A.* **41**, 5704*e*.

The reactivity of solid fuels, which depended on the relation between the temp. of the fuel in contact with a stream of O_2 and the temp. of the heating medium, were compared. An improved arrangement was recommended. On aging for several months, some samples slightly increased, whereas others decreased in reactivity.

295. Letort, Maurice and Martin, Jean. **The mechanism of the formation of surface oxides in the combustion of graphite.** *Compt. rend.* **222**, 1049-51 (1946); *Nature* **157**, 874-5 (1946).—*C.A.* **40**, 4280^9.

Acheson graphite (200-mesh) was degassed in a vacuum for 1 hr at 900°C. Then it was burned in a bed 6 mm deep at 510°C by a const. stream of air dried over P_2O_5. The mean speed of combustion was 8.5 and the $CO_2 + CO$ formed analyzed 23.5% CO. Standing in pure N_2 1 hr at 900°C and burning at 510°C checked the vacuum degassing results. Burning at 495°C after 2 hrs degassing at 800°C gave a speed of 10.55, and CO was 19.3% of $CO + CO_2$. If the burning was stopped after 3 to 15 min. by a N_2 stream, then restarted an hour later, the speed of combustion increased to 1.6 to 2.7 times the previous value, resp., the percentage CO dropping in the meantime. On repeating the stopping and restarting of combustion the speed decreased about 20%.

296. Ravich, M. B. **Surface combustion, its theoretical bases, and prospects of application in connection with the utilization of fuel gas.** *Bull. acad. sci. U.R.S.S.; Classe sci. tech.* **1946**, 833-46 (in Russian).—*C.A.* **41**, 2550f.

The rate of combustion of gases in quartz tubes was increased when the tube was packed with crushed refractories; the effect began to be noticeable at 400°C and was very pronounced at 900°C. Further substantial acceleration was obtained by activation of the refractory (chamotte) with oxides of Fe, Ni, V, Ce, or Th; at 400°C, combustion of firedamp in an empty quartz tube amounted to 10% in 1 hr, with chamotte filling 20%, while in the presence of Fe or Ni oxides combustion was complete in 0.5 min. The accelerating effect of the activators was also confirmed in the combustion of H_2 and CO under atm. pressure.

297. Šimek, Břeislav G.; Kučera, Eduard, and Klíma, Josef. **The effect of inorganic additives on the reactivity of coke.** *Paliva a voda* **26**, 49-55 (1946).—*C.A.* **41**, 5704*f*.

Lab. coke samples were prepd. by using various coking conditions, coal blends, and mineral additives, (Fe_2O_3, CaO, a blend of $Fe(OH)_3$ and $Ca(OH)_2$, magnetite, MgO, Na_2CO_3, Cu salts, magnesite). The reactivity of the coke was measured by the initial temp. of reaction with O_2. More-active coke was produced by lower coking temp. and more rapid coking; less-active coke, by using coal blends of higher bulk d. and by longer maturing time. Mineral additives varied in their effects on the reactivity. Low-ash coal yielded coke of higher reactivity.

298. Trombe, Félix and Foëx, Marc. **The combustion of graphite in air.** *Compt. rend.* **222**, 442-4 (1946).—*C.A.* **40**, 3247^4.

Below 1300°C O_2 penetrated into graphite and the reaction was proportional to the pressure. Above 1500°C the reaction took place on the surface and was independent of pressure. The combustion of graphite rods in air showed that the temp. limit between the two reactions was higher in air (1500°C) than in O_2 (mean 1400°C). The velocity of the convection current depended on the temp. of the rod and the combustion increased strongly with the temp. of the rod. Above 1500°C, it was shown that the velocity of the combustion increased very slowly with the temp., because convection currents no longer intervened.

299. Vulis, L. A. **Calculation of the absolute rate of combustion of carbon.** *J. Tech. Phys. (U.S.S.R.)* **16**, 83-8 (1946).--*C.A.* **40**, 7559^7.

From data on 15 kinds of graphite, electrode carbons, cokes, it appears that the consts. k_0 and E (activation energy) in Arrhenius' equation are related by $\log k_0 = a + bE$. The consts. for the combustion reaction, $C + O_2$ (subscript 1) and those for the reduction reaction, $C + CO_2$ (subscript 2) are: $a_1 = a_2 = 1.5$; $b_1 = 1.75 \times 10^{-4}$; $b_2 = 125 \times 10^{-4}$. $E_2/E_1 = \epsilon = 2.2$. $T^*_1 = 1240°K$, $T^*_2 = 1740°K$, and $T^*_3 =$ approx. 2620°K are termed "universal temperatures." At $T = T^*_1$ or $T = T^*_2$, resp., the rates of combustion or of reduction, resp., of all types of carbon are the same; at $T < T^*$, the rate of reaction (combustion or reduction) decreases with increasing E, whereas at $T > T^*$ it increases. At $T = T^*_3$, for a given type of carbon, the rate of combustion and that of reduction are the same. It accounts for the increased content in CO in accelerated combustion of coal.

300. Vulis, L. A. **Calculation of the time of combustion of coal particles.** *J. Tech. Phys. (U.S.S.R.)* **16**, 89-94 (1946).—*C.A.* **40**, 7560^2.

From the equation of the material balance of the quasi-stationary combustion process the effective rate const. of combustion can be represented as $1/K_e = (1/K) + (1/\alpha)$, where K = true rate const. of the chem. reaction and α = coeff. of material exchange, formally analygous to the coeff. of heat transfer. These are limiting cases, for complete combustion of the general formulas developed for partial combustion from an initial radius R to a final radius r. The formulas are checked against exptl. data on combustion of electrode carbon ($K_0 = 3.5 \times 10^6$ cm/sec) and gas coal coke ($K_0 = 1.87 \times 10^7$ cm/sec) coked at various temps. (1000°, 800°, and 400°C). Calculations at 1200°, 1500°, and 1800°K, by assuming the initial Reynolds no. 1, combustion to CO, activation energies of 20 and 30 kg-cal/mole, lead to the correct order of magnitude of the time of combustion of coal dust and show the actually observed shift of the combustion to the kinetic region with decreasing particle size.

301. Vulis, L. A. **Velocity of combustion of coal particles with a high-ash content.** *J. Tech. Phys. (U.S.S.R.)* **16**, 95-100 (1946).—*C.A.* **40**, 7560⁷.

The effect of a growing layer of ash on the rate of combustion of coal particles is treated mathematically and laws are derived for the rate of thickening of the inert coat. For curve-shaped, hemispheric, and cylindrical particles this growth may lead not only to a slowing down but, in special cases, to an acceleration of the combustion.

302. Audubert, René. **Activation energy accompanying oxidation of carbon at high temperature.** *Compt. rend.* **225**, 114-16 (1947).—*C.A.* **41**, 7230*b*.

The kinetics of the chain reaction are discussed. The energy of activation for maintaining the chain and the energy of deactivation are nearly the same, the former being greater by 6 kcal. per mole.

303. Audubert, René. **Mechanism of the oxidation of carbon.** *Compt. rend.* **225**, 1311-13 (1947).—*C.A.* **42**, 2846*f*.

When carbon was burned at temps. higher than 1500°C and at low pressures, the oxidation was a chain reaction with activated CO_2 mols. as the probable chain carriers. The chain length of this reaction at 2354°K was calcd. from the difference in activation and deactivation energy of the chain, which was about 6 kcal./mol. The calcd. value ($1\text{-}3 \times 10^5$) was in good agreement with exptl. results.

304. Chufarov, G. I. and Antonova, M. F. **The retardation of the Bell reaction $2CO = C + CO_2$.** *Classe sci. tech.* 1947, 381-9 (in Russian).—*C.A.* **42**, 3648*i*.

The decompn. of CO on an Fe catalyst was a first-order reaction over a CO pressure range 2-200 mm between 350-750°C. Between 350-450°C the reaction rate changed according to the Arrhenius equation with the activation energy of 34,000 cal./mole. The addn. of $CuSO_4$, $Al_2(SO_4)_3$, or $MnSO_4$ to the Fe catalyst caused a marked retardation around 450°C, 5% of $CuSO_4$ or $Al_2(SO_4)_3$ completely inhibiting the reaction. At 650-750°C 5% $CuSO_4$ retarded the reaction by a factor of 40, whereas 5% $Al_2(SO_4)_3$ retarded it by a factor of 12. Na_2SO_4, $MgSO_4$ and $CaSO_4$ were less effective in retarding the reaction.

305. Courty, Clément. **Oxidizing properties of active carbon saturated with air.** *Bull. soc. chim. France* **1947**, 642-52.—*C.A.* **42**, 1102*h*.

Arsenious acid was oxidized by the adsorbed-O on active carbon, as well as being adsorbed directly by the carbon itself. The ratio of the two actions was extremely variable—depending on the carbon, its condition, time, etc. Magnetic measurements over long periods of time (up to a year) indicated that an equil. content of at. O was slowly established.

306. Duval, Xavier. **The elementary reactions for the oxidation of graphite.** *J. chim. phys.* **44**, 296-301 (1947).—*C.A.* **42**, 7145*d*.

The observed CO/CO_2 ratios have been explained in terms of different modes of adsorption of O in the graphite lattice: (1) penetration of O_2 into the lattice; (2) adsorption of O_2 on marginal C atoms. Objections to this interpretation are: (1) at the pressure involved (10^{-3} mm Hg) preferential adsorption of O_2 on glass walls of the reaction vessel would leave no O_2 for more than an incomplete unimol. layer with the C; (2) the increased elec. resistance of the filament in the presence of O_2 can be explained simply in terms of surface adsorption in that the filament is porous; (3) even mols. as small as H_2 show difficulty in penetrating the graphite lattice. Consequently, a mechanism involving adsorption of O_2 on marginal C atoms is to be preferred. The reactions of graphite with CO_2 or H_2O are both of zero order with an activation energy of 90.

307. Fast, J. D. **Reaction between carbon and oxygen in liquid iron.** *Philips Research Repts.* **2**, 205-27 (1947).—*C.A.* **42**, 439*c*.

The reaction $[FeO] + [C] = [Fe] + CO$ is investigated, the brackets indicating the components of a homogenous liquid phase. If a liquid mixt. of Fe and FeO is assumed to have a Gibbs entropy of mixing and a Van Laar heat of mixing, the activity of FeO is related to the observed soly., x_{FeO} (mole fraction). The equil. const. for the reaction $C + CO_2 = 2CO$ is given by the relation $\log K = \log ((p^2_{CO})/(p_{CO_2})) = -(8435/T)^2 + 8.835$, where the activity of carbon, a_c, is related to the mole fraction, x_c, by the relation $a_c = x_c \exp. [(1800/T) -1.5]$.

308. Gumz, W. **Chemistry and physics of combustion, gasification, and metallurgical processes.** *Bergbau-Arch.* **7**, 96-110 (1947).—*C.A.* **44**, 2729*g*.

The methods of calcn. of combustion temp. and equil. consts. are given, and the extent to which equil. will be attained in gas producers and furnaces is examd. The metallurgical processes of the blast furnace are treated thermodynamically and among the reactions considered are the following: $C + O_2 = CO_2$, $CO_2 + C = 2CO$, $H_2O + C = H_2 + CO$, $2H_2 + C = CH_4$, $MnO + CO = Mn + CO_2$, and the reactions of CO and H_2 with FeO, Fe_2O_3, and Fe_3O_4.

309. Hagerbaumer, W. A. and Lee, Russell. **Combustion of coke deposit on synthetic bead cracking catalyst.** *Oil Gas J.* **45**, No. 45, 76-80, 97 (1947).—*C.A.* **41**, 3941*h*.

The major process variables affecting the rate of burning were found to be O_2 concn., temp., and the concn. and distribution of coke on the catalyst particles. The effects of these variables have been correlated by graphical methods. Data for regenerating bead catalyst were presented and discussed. The correlated data have been applied successfully in designing com. kilns.

310. Howie, T. W. and Mackenzie, J. **The stability of carbon bricks in carbon monoxide.** *Trans. Brit. Ceram. Soc.* **46**, 161-73 (1947).—*C.A.* **41**, 7078*f*.

The action of CO on exptl. carbon bricks was detd. with addns. of Fe and Fe_2O_3, and on 3 com. brands of brick. The nature of the gas will influence the result obtained. With wet gas the major part of the CO_2 formed resulted from the interaction of CO and water vapor and C and water vapor, and was not due to the normal dissociation reaction, $2CO \rightarrow C + CO_2$. Metallic Fe, in an active state, appeared to be the catalyst of the dissocn. reaction. The 3 com. brands of brick examd. showed neither C deposition nor disintegration in tests of 100-hr duration.

311. Marskell, W. G. **Combustion on traveling-grate stokers.** *Inst. Fuel (London), Bull.* **1947**, 100-7, 116.—*C.A.* **41**, 4288*c*.

The fuel ignites at the surface and a plane of ignition travels down through the fuel bed distg. off the volatile matter. At low air rates the combustion rate is less than the ignition rate, so that the ignition plane leaves a coke bed behind, which does not burn until all the volatile matter has been evolved, presumably because the O_2 is consumed by the volatile matter in lower fuel bed layers. The coke combustion starts from the bottom. At high air rates the grate and fuel bed are cooler than at low air rates. Primary air temps. up to approx. 300°F do not essentially alter the course of combustion. Once the fuel bed is thoroughly ignited the higher the air rate the better the fuel bed conditions, but in practice the max. air rate is limited by the ejection of fine material from the fuel bed and blow-hole formation.

312. Mueller, Wm. A. **Oxygen and the combustion process.** *Ohio State Univ. Eng. Expt. Sta. News* **19**, No. 5, 21-4 (1947).—*C.A.* **42**, 2740*i*.

Calcns. are presented showing the effective heat losses above 2000°C due to dissocn. of CO_2, H_2O, blast-furnace gas with 10% excess O_2, and producer gas of heating value 152.6 B.t.u. with 10% excess O_2. Recombination of dissocd. gas as it leaves the high-temp. zone liberates heat. Disadvantages which may be encountered when O_2 is substituted for air in combustion are dissocn. losses and damages sustained by exit ports because of recombination.

313. Nérot, Georges and Marianvalle, Albert. **The reactivity of cokes.** *Compt. rend. congr. ind. gaz* **64**, 225-48 (1947).—*C.A.* **44**, 8624*i*.

The behavior of coke toward CO_2 and H_2O (the latter in a current of N_2) at 700-1100°C was investigated by analyzing the gaseous reaction products. A 2nd series of expts. was carried out in which CO_2 was decompd. in a bed of coke, the undecompd. CO_2 was removed by absorption, and the CO formed was then burned in a current of O_2. This was assumed to give a direct measure of the reactivity. The coke was gasified in a generator, but the results so obtained did not agree with those obtained in the lab. In the generator the behavior of the ash appeared to outweigh the influence of the reactivity.

314. Pourbaix, Marcel. **Method for studying complicated equilibriums.** *Rev. Met.* 44, 292-301 (1947).—*C.A.* **42**, 4438*b*.

All variables characterizing a given equil. are divided into two groups, one comprising two factors which are the same for all equil. and which are considered as independent variables, and the other combining all other factors and considered as a parameter. The method is illustrated by the treatment of equil. of the following systems: O_2, C-O (O, O_2, O_3, solid C, gaseous C, gaseous C_2, and gaseous CO, CO_2), Zn-O, and Zn-C-O.

315. Predvoditelev, A. S. **The process of gas formation in the combustion of coal in beds.** *Izvest. Akad. Nauk S.S.S.R. Otdel. Tekh. Nauk* **1947**, 1329-40.—*C.A.* **42**, 7004*g*.

There are 3 possible chem. mechanisms: (1) CO_2 is formed on the surface or in the interior of the coal and CO results from the secondary reduction on the coal surface; (2) CO and CO_2 are formed simultaneously on the surface or in the interior of the coal and consumption produces either oxide; (3) CO forms on or near the coal surface, where there is sufficient O_2 and the reduction of CO_2 on the surface is possible, especially outside the limit of the O_2 zone. All consumption of O_2 occurs on or near the surface.

316. Rowley, L. N. and McCabe, J. C. **How fuel burns.** *Power* **91**, No. 8, 71-3 (1947).—*C.A.* **41**, 7073*c*.

The mechanics of combustion are outlined. Heat is essential to accelerate the chem. reaction between air and fuel and adequate mixing with O_2 and sufficient time are necessary. These factors are applied to the burning of solid as well as pulverized coal.

317. Spooner, C. E. **The direct determination of oxygen in coal.** *Fuel* **26**, No. 1, 15-23 (1947).—*C.A.* **41**, 2553*b*.

Coal (0.5 g with moisture content in equil. with lab. air) was heated to 1200°C in a stream of N_2 freed from O_2, H_2O, and CO_2. The resultant products were passed over charcoal at 1200°C, converting all H_2O and CO_2 to CO. The gas mixt. was then passed through a filter and through Cd-acetate soln. to remove H_2S; air was drawn into the stream and the mixt. passed through activated alumina, soda asbestos, anhydrone, and P_2O_5, thence through Hopcalite catalyst maintained at 90-95° to oxidize the CO to CO_2; the latter was absorbed in a tared soda asbestos absorption tube. The O_2 was calcd. and corrected for the moisture in the coal sample. The app. was standardized with benzoic acid. Results were in good agreement with those calcd. from ultimate analysis.

318. Thau, Adolf. **Status of low-temperature carbonization of bituminous coal in Germany.** *Gas—u. Wasserfact* **88**, 97-101 (1947).—*C.A.* **42**, 4729*a*.

Three types of ovens are in use: the heated-surface oven, the recirculated-gas oven, and the ceramic-chamber oven; the latter appear to predominate, especially in Upper Silesia. Since the German coking coals are used entirely in gas plants and coke ovens, use must be made of the geologically younger coals, high in O_2 and tar, which are not adapted to coke manuf. by the usual means.

319. TSUKHANOVA, O. A. **The effect of secondary reactions on the combustion of carbon.** *Bull. acad. sci. U.R.S.S., Classe sci. tech.* **1947**, 375-80.—*C.A.* **42**, 1719*h*.

The combustion at the walls of tubes of electrode carbon (520° to 1400°C) was followed by detg. the concn. of CO_2, CO, and O_2 in the exit gas. Data were given for an air flow of 20 liter/min. through a tube 12 mm in diam. and 95 cm long and for an air flow of 5 liter/min. through a tube 6 mm in diam. and 23 cm long. In the latter case the input air contained I_2 vapor. The results were interpreted from a consideration of the 2 reactions $2C + O_2 \rightarrow 2CO_2$ and $2CO + O_2 \rightarrow 2CO_2$. I_2 vapor, known to inhibit the combustion of CO, was found to increase the CO yield markedly between 700-900°C. Above 900°C, the CO concn. became unstable; it might be either higher or lower than the concn. at 900°C, depending on the conditions of ignition.

320. TSUKHANOVA, O. A. **Reduction of carbon dioxide by carbon along the walls of a carbon channel.** *J. Phys. Chem. (U.S.S.R.)* **21**, 653-8 (1947) (in Russian).—*C.A.* **42**, 2164g.

When CO_2 (concn. C_0) streamed through a carbon tube, the amt. reacting per unit area of the wall in unit time, divided by the gas concn. next to the wall, was 6.94×10^6 exp.(-44250/RT) between 800° and 1400°C for rates of flow between 0.7 and 8.3 liters/min. This value did not represent a true reaction const. because the reaction took place within a relatively thick surface layer of carbon, not only along its surface. The carbon tubes once heated in CO_2, but not in N_2, gave at once steady C/C_0 values. When C_0, the other component being N_2, was varied between 8 and 96%, the concn. of CO in the outgoing gas was proportional to the av. concn. of CO_2 within the tube, in agreement with the theory. The tube of electrode carbon was 37 cm long and 0.7 cm in diam. The CO_2 stream was preheated to 600-700°C.

321. TSUKHANOVA, O. A. **Approximate solution of the equations for the combustion of a carbon tube, considering the reaction of carbon monoxide with oxygen.** *Classe sci. tech.* **1947**, 717-21.—*C.A.* **42**, 3928f.

Equations were derived giving the concn. of O_2 and CO integrated along the cross-section of a carbon tube through which hot gases were flowing. The variables were the gas velocity, tube radius, diffusion const., velocity consts. of the combustion reactions, and the ratio of CO to CO_2 formed at the tube wall. For a tube 6 cm long and 5 mm in diam. with gas flow rate of 1-10 liter/min. at temps. of 400-900°C, the CO:CO_2 ratio at the wall was found to be approx. 1:1 above 850°C. The temp. coeff. of the $C + O_2$ reaction suggested an activation energy of approx. 22,000 cal/mol. The agreement with the exptl. data was sufficient for practical purposes.

322. ZAREMBO, K. S. **Secondary processes in the thermal decomposition of solid fuels.** *Bull. acad. sci. U.R.S.S., Classe sci. tech.* **1947**, 857-62 (in Russian).—*C.A.* **42**, 1719*a*.

Shale was heated to 540°C ± 10° in a tube 20 mm diam. and 111.5 cm length, composed of 6 sections of equal length assembled by ground joints. The yields of half-coke were detd. in each section. The yield had a distinct max. towards the middle of the tube, on the av. in the 3rd section from the bottom. This can be conceived as a result of a secondary process taking place at the interface of the grains, following primary cracking of org. matter in the bulk of the grain; the products were carried to more outlying layers of the column and there were adsorbed on the grain surface.

323. BLINOV, V. I. **Combustion of ash-containing coal. III.** *Doklady Akad. Nauk S.S.S.R.* **59**, 257-60 (1948).—*C.A.* **43**, 5569*h*.

The differential equation governing the combustion zone around a sphere is $(dT/dx) = (3\beta/ckx)(aT - aT_0 - kq)$, where x is the ratio of the radius of the unburned carbonaceous core to the radius of the sphere, β is the O/C ratio in the reaction products, c is the sp. heat of carbon, k is the sp. velocity of burning, a is a reduced heat transfer coeff., T_0 is the temp. of the surrounding atm., and q is the heat of reaction. This and related equations are applied to coal under various sets of conditions.

324. BREWER, R. E.; REYNOLDS, D. A.; STEINER, W. A., AND VAN GILDER, R. D. **Carbonizing properties of coking coals--effect of oxidation in storage.** *Ind. Eng. Chem.* **40**, 1243-54 (1948).—*C.A.* **42**, 6088*i*.

Eleven coking coals were subjected to accelerated oxidation and stored at room temp. A correlation was found between the agglutinating value and time of storage whereby the effect of storage on the coking properties (durability of coking power) of coals can be estd. The av. time in storage at room temp. before the coke-strength index was decreased by 15% was estd. at 5 years.

325. BRIDGER, G. W. AND APPLETON, H. **Inhibition of the combustion of carbon and carbon monoxide.** *J. Soc. Chem. Ind.* **67**, 445-9 (1948).—*C.A.* **43**, 3592*f*.

Oxidation of 95% of the CO at 1000°C in the presence of excess O_2 may be prevented if the inhibitor is present in the inlet gases at a concn. greater than a crit. value which increases with an increase in temp. HCl 5-11, CCl_4 0.1, and Cl_2 0.5-2.5% are satisfactory inhibitors when air is passed into a bed of burning coke. The inhibition is at the expense of the CO_2. Inhibition of the oxidation is most effective when the surface area of the reaction vessel is greatest. In an empty reaction tube and with the CO and Cl_2 preheated separately, no crit. Cl_2 concn. was found and inhibition was poor. CO_2 is produced by the oxidation of CO.

326. CAHEN, PAULE AND LETORT, MAURICE. **Determination of small quantities of carbon monoxide in a rapid stream of air.** *Bull. soc. chim. France* **1948**, 1163-5.—*C.A.* **43**, 2892*i*.

The study of the kinetics of combustion of graphite necessitates the detn. of traces of CO in a very rapid stream of air (0.1-0.2% by vol., 30 liter/hr). Oxidation of CO on CuO, hopcalite, I_2O_5, or Pt (platinized or smooth) is unsatisfactory for various reasons. A method which gives results within about 1% is based upon the catalytic oxidation of CO in contact with platinized glass, and absorption of the CO_2 formed by Ascarite.

327. Chukhanov, Z. F. **Nonisothermal combustion of carbon tubes under laminar conditions.** *Doklady Akad. Nauk S.S.S.R.* **62**, 333-6 (1948).—*C.A.* **43**, 2495*a*.

The combustion of hot carbon tubes with O_2 flowing through them is given by: $(dc/dz) = fkc$, where c is the concn. of O_2, z is the distance along the tube, f is a transfer coeff. related to the Reynolds no., and k is a const. This equation fits the exptl. data for O_2 flowing through a tube at 1000°C and a Reynolds no. of 500, under which conditions the process is controlled by diffusion. The limiting temp. below which combustion is nonisothermal can be calcd. if the O_2 concn., Reynolds no., and tube diam. are known.

328. Cohen, J.; Jonakin, P.; Corey, R., and Jain, B. **Measurement of the reactivity of solid fuels by the crossing-point method.** *Am. Soc. Testing Materials, Proc.* **48**, 1269-89 (1948).—*C.A.* **43**, 6805*f*.

In a modified reactivity app. the order of reaction with respect to O_2 was 0.81 for a Pittsburgh Bed coal, 0.65 for an Indiana No. 5 Bed coal, and 0.71 for a 900°C exptl. coke. The heating rate per unit surface varied only slightly with the sieve size of the Pittsburgh coal and coke, but varied considerably with that of the coarsely-banded Indiana coal.

329. Diehl, Harvey; Hach, Clifford C.; Harrison, George C.; Liggett, Lawrence M., and Brouns, Richard J. **Apparatus for determining the capacity and rate of oxygenation of solid materials.** *Iowa State Coll. J. Sci* **22**, 150-64 (1948).—*C.A.* **42**, 6692*e*.

For detg. both capacity and rate of oxygenation a differential manometric method was used. Four pressure chambers (2 of approx. 75 ml and 2 of approx. 700 ml) were interconnected by tubes fitted with stopcocks, so that the 2 large, the 2 small, or 1 large and 1 small chamber could be connected. A weighed sample of deoxygenated material was placed in 1 small chamber, both small chambers, were evacuated, and all 4 chambers were placed in a bath at the chosen absorption temp., both large cambers charged with O_2 at a pressure somewhat higher than the desired absorption pressure and cut off from the O_2 supply and from each other. Simultaneously, the 2 large chambers were connected to the 2 small chambers. A differential manometer recorded the difference in pressure in the 2 systems. Methods of measurement, calibration, and calcn. were given.

330. Dufraisse, Charles. **Oxygen and carbon.** *Rev. gen. caoutchouc* **25**, 471-3 (1948).—*C.A.* **43**, 2477*g*.

The roles of O_2 and carbon in nature and the possibilities of making profitable use of their reactivity by biochem. and artificial means are discussed.

331. Gadsby, J.; Long, F. J.; Sleightholm, P., and Sykes, K. W. **The mechanism of the carbon dioxide-carbon reaction.** *Proc. Roy Soc.* **A193**, 357-76 (1948).—*C.A.* **43**, 3694*i*.

The exptl. techniques for the static and dynamic study using coconut-shell charcoal were described. The pressures of the gases were varied from 10 to 760 mm and the temps. from 700° to 800°C. The first step in the reaction was the decompn. of the CO_2 into an atom of O, which was adsorbed by the carbon, and a mol. of CO, which passed into the gas phase. Only certain sites on the carbon surface seemed to take part in the reaction; they represented about 0.5% of the total area and probably consisted of some less firmly bound C atoms situated at lattice discontinuities. The rate of the first step was accounted for by assuming that reaction occurred in those collisions in which the combined energy of the active C atom and the indicent CO_2 mol. exceeds 68 kcal. The 2nd step was the evapn. of the adsorbed O atom, together with an atom of C from the solid to form gaseous CO; the activation energy was thought to be 38 kcal., and the low value of the frequency factor, 10^7/sec, was discussed.

332. Juza, R. **Magnetochemical investigation of oxygen sorption on various active materials.** *Angew. Chem.* **60A**, 254 (1948).—*C.A.* **46**, 9358*a*.

The magnetic susceptibility of O_2 sorbed at −183°C was measured. On active SiO_2 the first 100 mg per g of SiO_2 was sorbed as O_2, while susceptibility at satn. 530 mg per g of SiO_2, corresponded with the degree of assocn. of liquid O_2. On active charcoal, O_2 showed no definite assocn. steps. Initial assocn. corresponded to O_2 and finally surpassed the degree of assocn. of liquid O_2. On Pt black O_2 at 7 mg per g the susceptibility of the total O_2 sorbed was equal to that of liquid O_2, in contrast to the two previous systems investigated.

333. Kantorovich, B. V. **The motion of a carbon particle during its combustion in an air stream.** *Izvest. Akad. Nauk S.S.S.R. Otdel. Tekh. Nauk* **1948**, 1079-84.—*C.A.* **44**, 5183*c*.

The relative linear velocity of a particle of burning carbon is characterized in terms of the ratio of outer to inner reaction surface and the fraction of the original particle radius remaining. The math. treatment is based on considerations of particle dynamics and the kinetics of combustion.

334. Key, Arthur. **53rd Report of the Joint Research Committee of the Gas Research Board and the University of Leeds. The investigation of the use of oxygen and high pressure in gasification. V. The reactions between coke and steam at high pressure.** *Gas Research Board,* Copyright Pub. No. **40**, 36 pp. (1948).—*C.A.* **41**, 3277*c*.

Preliminary expts. with an app. designed for high-pressure experimentation at temps. up to 1100°C indicated that appreciable quantities of CH_4 were produced by the action of steam on cokes at all temps. within the limits of the app., and where the velocity of reaction was appreciable. The value of the product $(CO)(H_2O)/(CO_2)(H_2)$ was always higher than its equil. at ordinary pressure. The CH_4 produced in the reaction probably arose from the direct action of H on a coke surface which was at the same time undergoing erosion by steam. Cokes contg. Na_2CO_3 produced smaller amts. of CH_4. An investigation of 2 cokes with widely different reactivities has indicated that the most important factor in detg. reactivity is the proportion of the coke surface covered with the complex under standard conditions.

335. Khitrin, L. N. **Characteristics of the heterogeneous reaction in the combustion of carbon.** *Izvest. Akad. Nauk. S.S.S.R., Otdel. Tekh. Nauk* **1948**, 341-8.—*C.A.* **42**, 6622*h*.

An appropriate approx. boundary condition was given for the case of the combustion ($C+O_2$) taking place wholly at the outer surface of the solid or at both the surface and inside the solid. Equations of this type held for any of the heterogeneous processes taking place at the surface; not only for $C+O_2 \rightarrow CO_2$, but also for $C+CO_2$.

336. Khitrin, L. N. **Combustion of a spherical carbon particle. The effect of secondary reactions on the fundamental characteristics of the process.** *Izvest Akad. Nauk S.S.S.R. Otdel.Tekh. Nauk.* **1948**, 561-78.—*C.A.* **43**, 5268*a*.

A rate equation was derived for carbon burning in immobile gas (i.e., the diffusion-dominated conditions). This equation gave results in qual. agreement with available exptl. data for burning spherical carbon particles in air streams. It seemed to have broader significance than for the selected case for which it was developed, and can be used to calc. coeffs. of reaction interchange and diffusion transfer in practical problems involving the combustion of small carbon particles.

337. King, R. O. **The oxidation, ignition, and detonation of fuel vapors and gases. IV. The cause of detonation or combustion knock in engines.** *Can. J. Research* **26F**, 228-40 (1948).—*C.A.* **42**, 7514*c*.

A nuclear theory of self-ignition was described which was based on the substitution of finely divided carbon for the nuclear drops of the Callendar theory. The finely divided carbon appeared in the gaseous combustible mixt. as a result of pyrolysis of lubricating oil or of the fuel. Previous expts. have shown that flameless oxidation of fuel occurred solely on hot surface, not in the body of the gas. In an engine these surfaces might comprise areas of metal, metallic oxides, adherent carbonaceous matter, or carbon distributed in the combustible mixt. as fine particles.

338. Kunugi, Masanaga; Uda, Hiromu, and Jinno, Hiromu. **Combustion of solid fuel. I, II, III.** *J. Japan. Ceram. Assoc.* **56**, 27-30, 141-43 (1948), **57**, 4-5 (1949).—*C.A.* **45**, 7334*i*.

Cylindrical test pieces 1 cm high and 1.2 cm in diam. were made with a mixt. of coke 90% and clay 10%. The loss in weight of these test pieces at 700° to 1200°C was measured with the thermobalance. The velocity of combustion, i.e., the weight decrease, was expressed by a curve of second degree in which the diffusion velocity of O_2 through the layer of ash plays a controlling role. The combustion of a single coke briquet in a stream of air was discussed. Combustion in a bed of coke was discussed. The temps. of the solid and the gas phase were measured, and the gases were analyzed.

339. Long, F. J. and Sykes, K. W. **The mechanism of the steam-carbon reaction.** *Proc. Roy. Soc.* **A193**, 377-99 (1948).—*C.A.* **43**, 3694*e*.

The static and dynamic exptl. techniques were described for a study with coconut-shell charcoal. The pressures of the gases varied from 10 to 760 mm, and the temps. 680° to 800°C. Steam first reacted to give O and H atoms separately adsorbed on neighboring sites; an initial dissocn. into an adsorbed H atom and OH radical was probably followed by the more rapid transfer of the 2nd H atom to the C. Only about 2% of the total surface took part in the reaction, but these sites were thought to be atoms at the edges of the lattice planes. Adsorbed O_2 reacted more slowly to form gaseous CO; this CO had no retarding effect and was not appreciably adsorbed by the sites accessible to steam.

340. Majumdar, K. K. **Burning rates of Indian graphites.** *J. Sci. Ind. Research* (India) **7B**, 187-8 (1948).—*C.A.* **45**, 7772*a*.

Burning rates and ash contents have been detd. for graphites from Madagascar, Ceylon, Travancore, East Godavari, and Patna State. The results are tabulated.

341. Majumdar, K. K. **Identification of different types of graphite.** *J. Sci. & Ind. Research* **7B**, No. 12, 201-2 (1948).—*C.A.* **43**, 4180*f*.

Dry 0.5 g of powder at 110°C for 2 hrs, spread uniformly in a porcelain boat and heat in a tube furnace at 900°C ± 5°. Det. the loss in wt after heating 20 min.; then complete the combustion and weigh the ash. Calc. graphitic C by deducting ash from wt of original sample, ignoring volatile matter. Rate of oxidation is 31.5-33.5 mg/g/min. for amorphous and 42.6-44.4 mg/g/min. for flaky (cryst.) graphite under identical conditions. The diff. in rate suffices to distinguish between the 2 varieties.

342. Orning, A. A.; Mallov, S., and Neff, M. **Reactivity of solid fuels to air and oxygen.** *Ind. Eng. Chem.* **40**, 429-32 (1948).—*C.A.* **42**, 3549*h*.

New app. and procedure were described in detail. Duplicate detns. for bituminous coals and for high-temp. cokes gave a precision of ±3° and ±10°, resp., which was poorer than with the old procedure. Sensitivity to preheating was regarded as a factor causing the lower precision. On the basis of the new values, the equations for the reactivity indexes T_{15} and T_{75} defined as those temps. at which the self heating rates would be 15° and 75°C per min., as a function of the volatile content, V, were: $T_{15} \pm 8.1°C = 229.7 - 0.01022 (V-27.5)^3$ and $T_{75} \pm 11.2°C = 285.9 - 0.01282 (V-27.5)^3$.

343. Parent, J. D. and Katz, Sidney. **Carbon oxygen steam reactions studied.** *Am. Gas Assoc. Monthly* **30**, No. 1, 21-4 (1948).—*C.A.* **42**, 2417*f*.

Equil. concns. of gaseous products resulting from the interaction of graphite and steam were calcd. for a range of 1 to 100 atm., 900° to 1750°K., and a molar O_2-to-steam ratio of from 0 to 0.70. Increased pressure and decreased temp. favored the formation of CH_4 and CO_2, both of which have pos. heats of formation from their elements. Of course, these equil. values are not attained in practice. The reaction of carbon and steam increased rapidly with temp., although it was very slow below 2000°F unless the carbon was in a very highly activated state. At temps. exceeding 1800°F the only stable products were CO and H_2 in equimolar proportions if the pressure was one atm. Little steam should remain undecompd. in this range if adequate time of contact can be allowed.

344. PARENT, J. D. AND KATZ, SIDNEY. **Equilibrium composition and enthalpy changes for the reactions of carbon, oxygen, and steam.** *Inst. Gas Technol., Research Bull.* **2**, 110 pp (1948).—*C.A.* **43**, 2076*g*.

The equil. compns. and enthalpy changes (ΔH) of the reaction of graphite, O_2, and steam were computed from 900° to 1750°K and at pressures from 1 to 100 atms. for O_2-steam ratios between 0.0 and 0.70 in presence of an excess of C. At temps. above 1800°K and atm. pressure the equil. products are almost completely CO and H_2. At elevated temps. CO_2 and CH_4 formation are suppressed and steam decompn. is promoted. An increase in the O_2:steam ratio is necessary to maintain a const. ΔH with reduction of p. For a fixed O_2:steam ratio, the ΔH increases as p increases.

345. POSPEKHOV, D. A. **Mechanism of the formation of metal carbonyls.** *Zhur. Obshchei Khim.* **18**, 610-11 (1948).—*C.A.* **43**, 56*f*.

The fact that no lower carbonyls seemd to exist than $Ni(CO)_4$ and $Fe(CO)_5$ might be explained by intermediate formation of polymeric mols. $(CO)_n$. These appeared probable on account of the known existence of C_5O_4, C_4O_3, or C_5O_3, possibly formed through $C_nO_n \rightarrow C_{n-1}O_{n-2} + CO_2$. Formation of such polymers should be favored by high pressures, which are known to favor formation of metal carbonyls; it might also be heterogeneously catalyzed in the adsorbed layer on the metal.

346. PUSHKIN, V. S. **Problems of burning.** *J. Tech. Phys. (U.S.S.R.)* **18**, 49-60 (1948).—*C.A.* **45**, 4019*g*.

Three problems are considered: (1) combustion of coal particles, (2) burning-out of coal seams from the surface, and (3) combustion of coal walls in a channel.

347. RILEY, H. L. **Some structural aspects of carbon oxidation.** *Chemistry & Industry* **1948**, 569-71.—*C.A.* **43**, 26*a*.

The relation of crystal structure and the chem. purity of a carbon to the kinetics of its combustion and of its oxidation by liquid reagents are discussed.

348. RUESS, G. L. AND VOGT, F. **Exfoliated carbon from graphitic oxide.** *Monatsh* **78**, 222-42 (1948).—*C.A.* **42**, 7126*h*.

Carbon prepd. by the explosion of graphitic oxide has a different structure than any other form. Studies indicate that it consists of very thin graphite layers which show the property of increasing specific resistance with increasing pressure. From detns. of the methylene blue adsorption and the catalytic activity in synthesizing HBr, it is concluded that the crystal faces are active rather than only the unsatd. atoms in the edges of the faces.

349. SCHMIDT, L. D.; MCGEE, J. P., AND SLONE, M. C. **A pilot plant for gasifying powdered coal entrained in oxygen and steam.** *Chem. Eng. Progress* **44**, 737-44 (1948).—*C.A.* **43**, 378*a*.

A pilot plant built at West Virginia Univ. was described and some of the factors involved in its design are considered. Coal of the fineness ordinarily used in pulverized fuel steam plants was entrained in highly superheated steam contg. O_2. Gasification took place in a simple, high-temp. generator working at nearly atm. pressure.

350. WEISZ, R. S. AND JAFFE, S. S. **Mechanism of the reduction of oxygen at the air electrode.** *J. Electrochem. Soc.* **93**, No. 4, 128-41 (1948).—*C.A.* **42**, 3680*b*.

In acidic solns. the reduction of O_2 to H_2O_2 at carbon electrodes is irreversible. A tentative explanation for this is offered. In acidic and in alk. air-depolarized cells H_2O_2 disappears by catalytic decompn. alone. The mechanism by which O passes through air-depolarizing electrodes is shown to be diffusion, and a method for obtaining the diffusion coeff. is described.

351. WELLER, SOL AND YOUNG, T. F. **Oxygen complexes on charcoal.** *J. Am. Chem. Soc.* **70**, 4155-62 (1948).—*C.A.* **43**, 2840*d*.

Treatment of a low-ash charcoal with O_2 at 400°C increases its power to remove alkali from soln. and decreases its ability to remove acid. The rate of adsorption, but not the limit, increases from 25 to 40°C or on grinding to pass a 60-mesh screen. The limit is itself a function of concn. and approaches a limit as concn. is increased. Most of the HCl adsorbed by untreated charcoal is not readily extd. with water, but it can be removed by aq. NaOH. Both Na and OH ions are removed from soln. by a base-adsorbing charcoal. Similarly, both H^+ and Cl^- are removed by an acid-adsorbing material. The high-temp. outgassing of a treated charcoal reverses the changes in acid- and base-adsorptive properties produced by treatment with O_2. When O_2 is pumped off (as CO_2 etc.), the vol. of the charcoal decreases correspondingly, so that the apparent d. changes very little. O_2 treatment increases the surface area of a charcoal. In addn., there is a striking increase in the adsorption of H_2O at low pressures.

352. ZAWADZKI, J.; GAJEWSKI, W., AND GLETKIER, H. **The kinetics of the Boudouard reaction.** *Bull. intern. acad. polon. sci., Classe sci. math. nat., Ser. A.* **1940-1946**, 113-18 (1948) (in English).—*C.A.* **43**, 7309*b*.

The velocity of the reaction, $CO_2 + C \rightleftharpoons 2CO$, was measured in both directions over a wide range of temp. Pure CO_2 or CO, or the mixt. was passed through heated carbon at elevated temp. and at various speeds. The resulting gases were analyzed. A provisional formula was suggested for evaluating the velocity of reaction under the conditions.

353. ARTHUR, J. R.; BANGHAM, D. H., AND THRING, M. W. **Combustion in fuel beds.** *J. Soc. Chem. Ind.* **68**, 1-6 (1949).—*C.A.* **43**, 3592*c*.

Evidence indicates that the total energy of the gas increases as it passes through the fuel bed. Apparently CO, the primary combustion product of the C and O_2 surface reaction, reacts with surviving O_2 in the voids between the particles. Mere thermal quenching seems insufficient to "freeze" the reaction between CO and surviving O_2. The introduction of small quantities of volatile Cl-contg. materials with the carefully dried ingoing air appears to inhibit the gas-phase reaction. After the ingoing air travels a path length equiv. to a single particle length, virtually all tech. fuel beds begin to function as producers. Since the phys. mixing of the broad stream of producer gas with secondary air is otherwise incomplete, it is ordinarily necessary to run with excess air.

354. Arthur, J. R. and Bowring, J. R. **The combustion of carbon: Inhibition of secondary reactions by volatile reagents added to the oxidizing gas.** *J. Chem. Soc.* **1949**, S1-12.—*C.A.* **43**, 9417*a*.

The effects on the combustion of electrode carbon at 858°C under identical conditions of concn., temp., and time of contact were examd. quantly. Inhibitors used in order of effectiveness were: $POCl_3$, PCl_3, Cl_2, CCl_4, $CHCl_3$, $SnCl_4$, CH_2Cl_2, HCl, I_2, and SO_3. All inhibitors used increased the CO/CO_2 ratio in the combustion gases. The increases in CO and O_2 and the decrease in CO_2 agreed with the gas-phase reactions consuming CO and O_2. In all cases these changes occurred at <1% of the added inhibitor. Further addn. did not appreciably alter the analyses. The inhibition produced by CCl_4 was largely destroyed by addn. of H_2 or H_2O to the air-stream. The results were interpreted in terms of an interruption of the chain cycle responsible for CO oxidation.

355. Bergkampf, E. Schwarz. **A general combustion diagram.** *Radex Rundshau* **4**, 135-43 (1949).—*C.A.* **44**, 3234*d*.

The stoichiometric principles of the fuel combustion process are summarized in a diagram. The fuels are expressed in vol. %, as detd. from analyses. Generally, all combustions with either a surplus or deficiency of air can be traced, as well as those with extraneous O_2 and CO_2.

356. Blinov, V. I. and Rozet, T. A. **Some problems of the theory of coal combustion.** *Doklady Akad. Nauk S.S.S.R.* 67, 521-4 (1949); **73**, 363-6 (1950).—*C.A.* 44, 2729*i*; 45, 2648*b*.

If combustion of coal is a reaction of the first order and $c_w = \bar{c}_w$, where c_w is O_2 concn. on the surface of the burning object and $\bar{c}_w$ is av. value of O_2 on the surface, then $\bar{k}_s = k\bar{c}_w = \alpha(c_o - \bar{c}_w)$ and $\bar{k}_s = kc_o/(1 + k/\alpha)$ where k is const. of reaction of O_2 with C, α is coeff. of gas exchange, and c_o is concn. of O_2 in surrounding medium. The values of k_s/kc_o calcd. differed by not more than 5% combustion of plates and not more than 6% for cylinders.

357. Brewer, R. E. and Ghosh, J. K. **Desulfurization of coal during carbonization with added gases.** *Ind. Eng. Chem.* **41**, 2044-53 (1949).—*C.A.* **43**, 9414*b*.

A lowering of the S content in the coke produced by carbonizing coal was effected (1) by addn. of NH_3, H_2, or N_2 during coal carbonization, (2) by introduction of these gases at temps. lower than the final carbonization or reaction temp., (3) by continued treatment of the coal or coke sample at the reaction temp. with these added gases, and (4) by use of fine-size coke. Carbonization of coal with added NH_3 gas caused a large percentage of the S to be converted to volatile S compds. NH_3 was superior to H_2 and H_2 was more effective than N_2. The desulfurizing effects of NH_3, H_2, and N_2 when added to sized coal samples and their lump cokes were studied at 700°, 800°, and 875°C. Numerous tests were made with NH_3 introduced at 500°C and with H_2 at room temp.

358. Burshtein, R. Kh. and Miller, N. B. **The state of oxygen adsorbed by carbon and its ability for forming hydrogen peroxide and water.** *Zhur. Fiz. Khim.* **23**, 43-9 (1949).—*C.A.* **43**, 4075*i*.

Sugar charcoal was heated in H_2 at 950°C, degassed, cooled, and introduced into gas-free aq. H_2SO_4. Then it was filtered off either directly or after a 10-min. contact with O_2 of 2×10^{-4} to 245 mm Hg. In the first case H_2SO_4 was titrated in the filtrate and the amt. ("molecularly") adsorbed (A_1) calcd. In the 2nd case, the amt. adsorbed (A) was detd. as before, but the amt. X of O_2 adsorbed and the amt. Y of H_2O_2 formed also were detd. When the final concn. of H_2SO_4 was 0.0081, 0.1442, and 0.8455 N, A_1 was 0.008, 0.186, and 0.312, resp. the ratio X:Y varied irregularly between 15 and 63. The difference ($A - A_1$) was the acid adsorbed by displacing adsorbed-O.

359. Busch, H. W.; Berger, L. B., and Schrenk, H. H. **The "carbon-oxygen complex" as a possible initiator of explosions and formation of carbon monoxide in compressed-air systems.** *U. S. Bur. Mines, Rept. Invest.* No. **4465**, 22 pp. (1949).—*C.A.* **43**, 5952*c*.

Expts. have shown the existence of a C-O complex on carbon deposits from air compressors. Two samples of deposits produced definite evidence of exothermic reaction, by measurement of sensible heat, when heated to 250° in air. Decompn. of the C-O complex on the carbons studied began at somewhat below 100°. The use of automatic, temp. actuated, shut-off mechanisms reflecting excessive temp. in discharge lines of air compressors should prove effective in averting accidents.

360. Busso, Raoul H. **Identification of molecules activated by photogenesis in the combustion of carbon.** *Compt. rend.* **228**, 683-4 (1949).—*C.A.* **44**, 25*h*.

Two components are identified in the activated combustion of carbon with liquid air and CCl_4. These are relatively long-lived (some sec) mols. of activated CO at lower pressures than 3 cm. Hg and short-lived (some 10^{-3} sec) mols. of activated CO_2 at higher pressures than 3 cm Hg.

361. Busso, Raoul H. **Explanation of the kinetic changes in the oxidation of carbon at 1450°.** *Compt. rend.* **228**, 1946-8 (1949).—*C.A.* **43**, 7798*c*.

The rate of oxidation of graphite passes through a max. at 1450°C. The oxidation proceeds on the edges of the graphite planes where active centers attract O_2 and the reactivity of these active centers increases with increasing temp. From 1300° to 1400°C graphite begins to recrystallize, and the active centers are destroyed; thus the rate of oxidation is decreased so that a max. is reached at 1450°C. At 2000°C the active centers have too short a life to be effective, but the C atoms start to sublime so the rate oxidation again starts to increase.

362. Busso, Raoul H. **Application of the methods of theoretical chemistry to the study of the reactivity of graphite.** *Compt. rend.* **229**, 619-21 (1949).—*C.A.* **44**, 895*b*.

The index of free valence of graphite is calcd. to be 0.215, compared with 0.458 for benzene. The atoms in the graphite planes are very slightly reactive. Activation of carbon consists in increasing the ratio of the no. of atoms in prismatic surfaces to the no. in planes. Chemisorption takes place at crystal edges, where the index of free valence is high. The instability of the atoms of high free valence at high temps. explains the change in the kinetics of graphite combustion at 1500°C.

363. Chukhanov, Z. F. **Nonisothermal combustion of carbon tubes under turbulent conditions.** *Doklady Akad. Nauk S.S.S.R.* **64**, 675-8 (1949).—*C.A.* **43**, 6896*a*.

The differential equation governing combustion of hot carbon tubes through which O_2 is flowing turbulently is $(dc/dz) = -fkc - [(b+1)dkcx/Rp]$, where c is the O_2 concn., z is the distance along the tube, f is the transfer coeff. along the stream, b is a function of the ratio of c to the sum of the individual concns. considered, d is the tube diam., x is a function of the temp. gradient, R is the Reynolds no., p is the Prandtl no., and k is a const. not otherwise identified. The practical verification of the math. relations developed is difficult in view of the lack of exptl. data.

364. Chukhanov, Z. F. **Nonisothermal combustion of carbon particles in a layer.** *Doklady Akad. Nauk S.S.S.R.* **65**, 673-6 (1949).—*C.A.* **45**, 425*f*.

The previously-derived equations governing combustion of hot carbon tubes through which O_2 is flowing were found to conform to exptl. data given O_2 concn. as a function of the distance along the tube.

365. Clusius, Klaus and Huber, Max. **Flames. II. Does carbon suboxide burn in dry air?** *Helv. Chim. Acta* **32**, 2400-15 (1949).—*C.A.* **44**, 2832*i*.

Yes, but the character of the flame differs when C_3O_2 is burned in moist or dry air. A flame that has become nonluminous by the addn. of dried air is extinguished when addnl. dry air is added. In a dry C_3O_2 flame, CO is formed, which disproportionates into CO_2 and C. The luminosity is due to C. The explosive limit for dry mixts. of air and C_3O_2 at 490 mm is 16 to 31%; for moist, 6 to 30% C_3O_2.

366. Dunoyer, Jean M. **Theoretical kinetic study of the reaction of a gas on a solid in which it diffuses.** *Compt. rend.* **228**, 1729-31 (1949).—*C.A.* **44**, 1309*h*.

The effect of diffusion is considered in the reaction of a finely divided solid with a gas in which it is suspended. An equation is derived for the no. of gas mols. contained at a given time in a homogeneous spherical portion of the solid.

367. Fredersdorff, C. Von. **Continuous gasification of powdered-coal suspensions by air-oxygen and air-oxygen-steam mixture.** *Proc. Am. Gas Assoc.* **31**, 705-24 (1949).—*C.A.* **44**, 8623*c*.

Although a satisfactory gasification was accomplished from the standpoint of gas calorific value, it will be necessary to employ steam superheated to at least 2000°F to (1) decrease the make-gas CO_2 content, (2) decrease the O_2 required for gasification, (3) increase the carbon conversion, and (4) shift the point of max. thermal efficiency to closer correspondence with the point of max. calorific value.

368. Golovina, E. S. **Oxidation of coal.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk* **1949**, 1343-51.—*C.A.* **45**, 4425*e*.

Spherical samples of about 1.5 cm diam. were prepd. by compression and coking of finely powd. material (below 43 μ grain size), or by turning from electrode carbon, anthracite dust, Moscow-region coal, massive natural anthracite. The diam. of the samples varied from 1.45 to 1.57 cm and the d. 1.15-1.17 g/cc. Rates of combustion in a stream of air (3-60 cm/sec), detd. by the loss of wt, are expressed in $k = g/cm^2$ sec. With electrode carbon oxidation became noticeable at 416°C; above 525°C the temp. rose spontaneously very rapidly, ending in ignition. Twelve-fold variation of the velocity of the air stream (5-60 cm/sec) had no effect on the rates of oxidation. The apparent activation energy E, from plots of log k as a function of $1/T$, was const. (35.5 kcal/mole) up to about 490°C, but showed a break above that temp., indicating a slowing-down of the process. The preponderant role of phys. structure appeared from samples both chemically identical (anthracite). The slowing-down of the reaction above 500°C was ascribed to changing penetration of O_2 into the interior of the sample; in the higher-temp. range, the reaction took place mainly in a spherical layer following the surface of the sample.

369. Jones, R. E. and Townend, D. T. A. **Oxidation of coal.** *J. Soc. Chem. Ind. (London)* **58**, 197-201 (1949).—*C.A.* **43**, 9412*d*.

The initial reaction appears to involve chemisorption which is followed by the formation of a $C\text{-}O\text{-}H_2O$ complex. The oxidation of coals follows a similar course to that of hydrocarbon oils, rubbers, and some food. The presence of adsorbed water is necessary for the formation of the complex. With coals the amt. of the complex formed in the course of a given exposure to air is a function of particle size and pore structure. The complex formed on moist charcoal is stable on heating to 50°C in vacuo; it breaks down slowly at 80°C but is still detectable after heating in vacuo at 350°C. On coal exposed to air at ordinary temps. the peroxygen complex builds up to a max. concn. and then decays. The overall oxidation proceeds without interruption even when the peroxygen concn. has become very small.

370. Juza, R.; Lübbe, H., and Heinlein, L. **The sorption of oxygen and bromine on charcoal, estimated by magnetic measurements.** *Z. anorg. Chem.* **258**, 105-20 (1949).—*C.A.* **43**, 6038*b*.

The total O_2 adsorbed on sugar charcoal increased 2.5-fold with increase in the outgassing temp. from 20° to 1150°C. The proportion bound as mol. O_2, as estd. by magnetic measurement, decreased from 100% at 20° and 100°C to 47-49% between 950° and 1150°C. Outgassing at the higher temps. frees more surface for chemisorption. Sorption of O_2 on charcoal, outgassed at 700°C was studied for various pressures and times. As the total increased, the wt of chemisorbed-O_2 increased sharply at first followed by a gradual, linear increase. The wt of physically adsorbed-O_2, at first negligible, rose steeply and linearly. As a result, the O-bound as oxide decreased rapidly from 100 to 18-27%. The sorption of Br_2 by activated and recrystd. sugar charcoals and Ceylon graphite was studied. With activated carbon, surface adsorption predominated but intercalation may be involved in adsorption of the first Br_2.

371. KWIECIŃSKI, ALFRED W. **Processes of the combustion of carbon regarded in a new light.** *Przeglad Górniczy* **5**, 1133-5 (1949).—*C.A.* **44**, 5203*c*.

The difference between the heat of combustion of carbon to CO_2 and to CO (97 − 29.3 = 67.7 kcal/mole) involves other factors besides the purely thermal effect. The joining of each O atom to the C atom by a double bond consumes 167.6 kcal/mole, the inactivation of two valencies of C (i.e. the change from C^{IV} to C^{II}) accounts for 40.8 kcal/mole, and one-half of the energy of dissocn. of the O mol. accounts for 59.1 kcal/mole. Thus, for $CO + \frac{1}{2}O_2 \rightarrow CO_2$, the combustion heat is 167.6 − 40.8 − 59.1 = 67.7 kcal/mole.

372. LEWIS, W. K.; GILLILAND, E. R., AND MCBRIDE, GUY T., JR. **Gasification of carbon by carbon dioxide in fluidized powder bed.** *Ind. Eng. Chem.* **41**, 1213-26 (1949).—*C.A.* 43, 6807*h*.

The reaction rates at atm. pressure of CO_2 with two types of carbon were detd. between 1465° to 2000°F. The data have been correlated by a Langmuir-type equation, where the rate of reduction of CO_2 per unit quantity of carbon in the bed equals: $k_1p_{CO_2}/(1+k_2p_{CO_2})$, where the k terms are functions of temp. only, and the p terms represented the partial pressures of each component. For each carbon, k_1 rose rapidly with temp. while k_2 and k_3 fell. The observed conversions fell far below the values calcd. from the equation at low reaction temps., and were far higher than calcd. at high reaction temps.

373. LOEBENSTEIN, W. V. **Quantitative prediction of the combustion of carbon adsorbents.** *Proc. Tech. Session Bone Char* **1949**, 271-83.—*C.A.* **43**, 8648*f*.

The fraction of C burned was expressed as a function of time for any carbon adsorbent under conditions of const. temp. and O_2 concn. These conditions were realized in containers constructed of wire screening which support the samples during the oxidation in a lab. muffle furnace with temp. control. Two samples of a given char were burned for known periods of time according to the procedure described and carbon detd. in the residues. It was then possible to predict the time required to reduce the carbon in the original sample to any designated value.

374. LOEBENSTEIN, W. V.; GLEYSTEEN, L. F., AND DEITZ, V. R. **Kinetic study of the reaction of carbon adsorbents with oxygen.** *J. Research Natl. Bur. Standards* **42**, 33-41 (1949) (Research Paper No. 1948).—*C.A.* **43**, 4546*h*.

The results for activated carbons and bone chars were expressed in terms of the fraction of C burned per hr at known values of O_2 between 250° and 390°C and total rate of flow. The rate of oxidation could be expressed either in terms of simple first-order or retarded first-order relations. A nomograph was developed to obtain a rapid estimate of the total fraction of C burned at any time for a given rate const. and degree of retardation. The relation between the reaction-rate const. and O_2 was linear for a given adsorbent under the same conditions of temp. and flow. The effect of temp. on the rate disclosed deviations from the Arrhenius equation even over a 100°C interval. The necessary conditions for attaining the optimum uniformity in the carbon content of bone char were discussed.

375. LOEBENSTEIN, W. V. AND PENNINGTON, N. L. **Fundamental aspects of the reaction of oxygen with carbon adsorbents.** *J. Research Natl. Bur. Standards* **43**, 87-96 (1949) (Research Paper No. 2009).—*C.A.* **43**, 8839*g*.

The rate const., k, for the oxidation by O_2 of coconut-shell charcoal and of various bone chars was independent of sample wt and only slightly affected by flow rate. The ratio of CO_2 to CO increased with increased sample wt, indicative of a catalytic oxidation of CO to CO_2. A plot of k against x, the mole fraction of O_2, was linear for any one temp. Both the positive intercept on the k axis and the slope increased with temp. The equation: $k = A \exp(-E_1/RT) + Bx \exp(-E_2/RT)$, where A, B, E_1, and E_2 are parameters, can account for the data. For coconut charcoal $A = 2.93 \times 10^6$ hr^{-1}, $B = 6.09 \times 10^5 hr^{-1}$, $E_1 = 21{,}800$ cal., and $E_2 = 16{,}900$ cal. For a typical bone char, $A = 1.16 \times 10^6$, $B = 1.63 \times 10^{13}$, $E_1 = 19{,}700$, and $E_2 = 34{,}800$.

376. MANTEL, WALTHER. **Determination of the oxygen content of solid fuels.** *Brennstoff-Chem.* **30**, 92-6 (1949).—*C.A.* **43**, 7661*d*.

The O-content in a no. of low-ash Ruhr coals was calcd. from lab. carbonization products: aq. condensate, CO, CO_2, and the O_2 in tar and coke. When the percentage of volatile matter (pure coal basis) was plotted against the O_2 percentage a smooth curve resulted. The low point on this curve (around 19-20% volatile matter) corresponded to the min. volatile matter content of coal to form a good solid coke.

377. NOVELLA, ENRIQUE COSTA. **Gasification of coal in a fluid medium with carbon dioxide.** *Anales real soc. españ. fís. y quím.* **45B**, 627-46 (1949).—*C.A.* **44**, 3697*i*.

The data (785° to 985°C at atm. pressure) were related by two equations of the Langmuir type: reduction rate of CO_2/ unit wt coal $= \alpha P_{CO_2}/(1 + B'P_{CO_2}) = \alpha P_{CO_2}/(1 + \gamma P_{CO} + BP_{CO_2})$. CO_2 partial pressure varied from 0.1 to 1.0 atm. The consts.

in both were only a function of temp., a increased rapidly with increasing temp., B', B, and γ decreasing. Both equations related equally well the data obtained in this study.

378. RHEAD, T. F. E. AND PICKERING, E. T. **Coke for use in open fires from continuous vertical retorts. Some aspects of its production and characteristics.** *Inst. Gas. Engrs.*, Copyright Publ. No. **343/156**, 41 pp. (1949).—*C.A.* **44**, 308*f*.

Ease of combustibility was detd. by the time required for the fire to reach a "cheerful" state, which was considered to have been achieved when a radiation emission of 5600 B.t.u. per hr was reached. The time, taken in min., for a fire to reach the "cheerful" state was regarded as the initial combustibility index. The ease of combustibility of the domestic-size sales coke was affected mainly by the quality of the dry coke substance, the size grading, and the moisture content. The radiation emitted was measured by means of a set of thermopiles which operated a recording milli-voltmeter.

379. SCHMITZ, GEORGE. **Temperature distribution in free-burning carbon arc lamps.** *Z. Physik* **126**, 1-11 (1949).—*C.A.* **43**, 8915*a*.

The d. distribution in the atm. around a carbon arc in air was detd. interferometrically and the temp. distribution calcd. The true arc column can be distinguished from the external region. The effect of convection air currents was important in the external region but not in the arc column.

380. TAYLOR, J. AND POLLOK, F. **Effect of various chemicals, more particularly sodium bicarbonate, on the ignition of cellulose, coal dust, and activated charcoal.** *Fuel* **28**, No. 4, 77 (1949).—*C.A.* **43**, 4468*c*.

Pure cotton cellulose in the form of ash-free filter paper when heated in an air bath showed incipient decompn. at about 200°C and ignited at about 340°C. When $NaHCO_3$ was in contact with the paper, marked decompn. occurred with smoldering at about 200°C. In tests with about 400 chemicals, which were listed and classified, all those which promoted smoldering lowered the ignition or smoldering point to about 200°C, but the rate at which they caused decompn. of the cellulose varied. Oxidizing agents lowered the ignition point below 200°C. In tests in a different app. the ignition points of bituminous coal dust and activated charcoal were lowered in the presence of $NaHCO_3$.

381. ARTHUR, J. R. AND BANGHAM, D. H. **The mechanism of energy release in the combustion of solid carbonaceous fuels.** *J. chim. phys.* **47**, 559-62 (1950).—*C.A.* **44**, 10473*b*.

Recent investigations are reviewed of the effect of inhibitors on the compn. of combustion products of various carbonaceous solids. The expts. indicate a two-stage mechanism, with CO forming at the carbon surface and being oxidized to CO_2 in the gas phase. Certain aspects of the process are still obscure.

382. ARTHUR, J. R. AND BOWRING, J. R. **Effects of inorganic impurities on the mode of combustion of carbon.** *J. chim. phys.* **47**, 540-2 (1950).—*C.A.* **44**, 11058*g*.

Addn. of salts ($CuCl_2$, $ZnCl_2$, KCl, KI, NaCl, Na_2CO_3) to electrode carbon increased the rate of gasification in air at 500-700°C. The CO_2/CO ratio was also increased in each case. It was proposed that the two effects were related.

383. AUDUBERT, R. AND BUSSO, R. H. **Production of light and mechanism of oxidation of carbon.** *J. chim. phys.* **47**, 331-8 (1950).—*C.A.* **44**, 7177*b*.

Ultraviolet light (2000-2600 A.) was emitted during the oxidation of graphite, by excited gaseous mols. By means of a flow system and a CuI photo-elec. cell, mean life of these "active centers" was measured as a function of pressure. Two types of emitters were present, with different mean lives; tests with a liquid air trap and CCl_4 inhibitor identified these as activated CO (2 ± 0.5 sec) and activated CO_2 ($2 \pm 1 \times 10^{-3}$ sec). At 1500°, the CO predominated below 30 mm and the CO_2 above 30 mm.

384. BANGHAM, D. H. AND DRYDEN, I. G. C. **Accessible oxygen of bituminous coals.** *Fuel* **29**, 291-2 (1950).—*C.A.* **45**, 1322*d*.

There appeared to be some connection between the heat of wetting of British coals, their natural O-content, and their degree of oxidation. Heat of wetting in MeOH was of such an order as to indicate merely phys. interaction, while heat of wetting in ethylenediamine is 2 or 3 times greater for low-rank bituminous coals. Oxidation of the coals caused an increase in both the heat of wetting in MeOH and the difference in heat of wetting between MeOH and ethylenediamine.

385. BANGHAM, D. H. AND TOWNEND, D. T. A. **The combustion of carbon: an outline of the work of the B.C.U.R.A. Laboratories 1939-49.** *J. chim. phys.* **47**, 315-21 (1950).—*C.A.* **44**, 7044*h*.

Various types of evidence indicate that CO rather than CO_2 is the primary product of the carbon-oxygen reaction. The down-jet burner is described. Internal burning within fuel particles is discussed. An explanation of the anomalous increase of the sum of thermal and chem. energy of the gas on passing through the fuel bed is offered.

386. BOWRING, J. R. AND CRONE, H. G. **Rate of combustion of carbon. Some effects of internal structure and inorganic impurities.** *J. chim. phys.* **47**, 543-7 (1950).—*C.A.* **44**, 10469*h*.

Temps. of single particles of various solid fuels were measured as combustion proceeded in a furnace of controlled temp. Temp. rises were observed when about 90% of the wt loss had occurred. Studies with ash-free carbon revealed a tendency to disintegrate, especially when the air was very dry or when $POCl_3$ was added to the air. Addn. of Na_2CO_3 or Li_2CO_3 to the C prevented disintegration.

387. CHAKRAVORTY, S. L.; LONG, R., AND WARD, S. G. **Formation and decomposition of peroxygen in low temperature air-oxidation of coals.** *Fuel* **29**, No. 3, 68-9 (1950).—*C.A.* **44**, 3695*i*.

Peroxygen formation was studied for 7 Indian coals and 1 British coal. The thermal decompn. of the peroxygen in an inert atm. at different temps. was found to approx. a 1st order reaction. The energy of activation for the decompn. was found to approx. that for hydroperoxide decompn.

388. Courty, Clément. **On the evolution of the magnetic properties of oxygen adsorbed on activated charcoal which has been activated in a vacuum at elevated temperature.** *Compt. rend.* **230**, 1588-9 (1950).—*C.A.* **44**, 10403*e*.

The coeff. of magnetization was calcd. for O_2 adsorbed on charcoal activated at 0.02 mm for 6 hrs at 900°C. When this charcoal was put into contact with O_2, the adsorption was accompanied by the release of 5.6 cal. This was attributed to the formation of CO_2. The decrease in the paramagnetism is of the same order for charcoal which has been activated either in the cold or at high temps.

389. Crone, H. G. **Modes of burning of solid fuel.** *J. chim. phys.* **47**, 563-4 (1950).—*C.A.* **44**, 11058*g*.

The stages in the combustion of solid fuels are discussed, with particular reference to the formation of ash deposits bonded by alkali sulfates and phosphates.

390. Deringer, H. **A simple calculation of the composition of gasification gases in equilibrium with carbon.** *Festschr. Paul Schlapfer* **1950**, 57-61.--*C.A.* **46**, 708*f*.

Equations are set up and solved to det. the gas compn. in several gasification processes.

391. Duval, Xavier. **Reaction of oxygen with carbon filaments at high temperatures and very low pressures.** *J. chim. phys.* **47**, 339-47 (1950).--*C.A.* **44**, 7177*c*.

The oxidation was studied from 5×10^{-5} to 3×10^{-3} mm Hg and 1200° to 2200°K. When the Hg vapor from the McLeod gage was condensed, the high-temp. reaction gave almost pure CO. The reaction was first order, starting at 2000°K, and the rate was nearly independent of temp. (1900°-2200°K). When Hg vapor was present, CO_2 appeared in appreciable quantities and the combustion rate was accelerated considerably. Data were presented below 1800°K where CO is again the primary product.

392. Friedman, Louis D. and Kinney, Corliss R. **Humic acids from coal. Controlled air-oxidation of coals and carbons at 150° to 400°.** *Ind. Eng. Chem.* **42**, 2525-9 (1950).—*C.A.* **45**, 1748*f*.

Coals were oxidized to alkali-sol. acids by air oxidation in electrically heated tubes; reaction times were 120-180 hrs. At first the rate of air flow was limited to keep the temp. const.; after 25-75 hrs it was possible to admit a large excess of air. The max. temp. of oxidation of lignitic and subbituminous coals was 250°C, that of bituminous coals 300°C, that of anthracite, carbon, and lamp-black 350°C, and that of graphite 400°C. Ease of oxidation decreased with increasing percentage of fixed C. All oxidation products oxidized at 200°C were at least 90% sol. in alkali.

393. Fritsche, Wolfram. **The water-gas equilibrium and its relation to practical gasification processes.** *Brennstoff-Chem.* **3**, 337-50 (1950).—*C.A.* **45**, 1749*c*.

The heterogeneous equil. (reactions of H_2O with carbon) is not completely established during the gasification process and equil. is reached only at a higher temp. than that corresponding to the equil. const. Two heterogeneous water-gas reactions exist simultaneously during the gasification process. The equil. const. for the water-gas reaction is characterized by the product of the consts. of the two sep. reactions, corresponding to the extent to which they occur, and not by the quotient, as has been erroneously concluded. The decompn. of steam first occurs at a higher temp. than the decompn. of CO_2 on carbon. The conversion of CH_4 with steam and the decompn. of steam over carbon is practically complete at the temps. under consideration. Consideration of the effect of temp. on the consts. for CH_4 splitting with CO_2 indicate that steam can be partly replaced with CO_2; however, no saving in steam is actually realized.

394. Gel'd, P. V. and Esin, O. A. **Effect of salts on the rates of dissociation and reduction processes.** *Doklady Akad. Nauk S.S.S.R.* **73**, 541-4 (1950).—*C.A.* **45**, 27*a*.

The rate of the reduction of chromite ($FeO\cdot Cr_2O_3$) by H_2 or graphite to $Fe + Cr_2O_3 + H_2O$ (or CO) was detd. by the amt. reduced in 1 hr at const. temp. between 300° and 1200°C. It was strongly accelerated by the addn. of 3% K_2CO_3. Expts. remained far below the equil., which cannot be reached even in 15 hrs. Reduction by graphite was faster than by H_2. The dissocn. $CaC_2 \rightarrow 2C + Ca$ (vapor), very slow at 1200°C, was markedly accelerated by 5% CaF_2 or $CaCl_2$, and even more by 5% $BaCl_2$. At 1300°C, the order of increasing accelerating effectiveness was 5% CaF_2, $CaCl_2$, K_2CO_3, NaCl.

395. Gol'denberg, S. A. **Turbulent heterogeneous combustion.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk* **1950**, 1154-64.--*C.A.* **46**, 1336*i*.

The combustion of carbon was investigated by passing O_2 under turbulent flow conditions (22-145 m/sec.) through heated cylindrical carbon tubes at 500-1050°C. The coeff. of gas exchange in the equilibria between O_2 and CO_2 is approx. $8.5\times10^5 \exp(-18{,}000/RT)$.

396. Grosskinsky, Otto. **New knowledge of the action of oxygen on coal.** *Gluckauf* **86**, 988-95 (1950).—*C.A.* **45**, 3144c.

Various kinds of coal were heated in air at 200-300°C to form O-contg. products, which on further heating can be converted to activated carbon. If the products of the "pre-oxidation" are further oxidized in the liquid phase, these result in cyclic C acids of varying comp. which can be used to make lacquer, resin, plasticizers, drugs, etc.

397. Jones, R. E. and Townend, D. T. A. **The role of the peroxidic complex in the low-temperature oxidation of carbon.** *J. chim phys.* **47**, 348-52 (1950).—*C.A.* **44**, 7128*h*.

Dry carbons, on exposure to moist air, form a peroxygen complex, the amt. of which is roughly proportional to the amt. of water adsorbed. This holds for different carbons. The complex is not removed by the removal of adsorbed moisture at ordinary temps.; it is stable at 55°C, breaks down slowly at 80°C, and rapidly but measurably at 350°C. Abnormally high heats of adsorption of O_2 on carbon that have been reported are attributed to this complex. It is proposed that the presence of H atoms is essential for formation of the complex.

398. Juza, Robert. **Chemisorption, adsorption, capillary condensation, and adsorption estimated by magnetic measurements.** *Chem.-Ztg.* **74**, 55-7 (1950).—*C.A.* **44**, 6699*i*.

On outgassing at room temp. 3 mg of O are bound per g of charcoal by phys. adsorption; on outgassing at higher temp. the phys. adsorption remains about the same, but chemisorption increases with temp. and at 1150°C the chemisorption amounts to 3.5 mg per g and the total amt. bound is 7.2 mg. The oxide decreases from 100 to 20% as the amt. of O sorbed increases to 12 mg per g of charcoal. Magnetic susceptibility can also be used to study the sorption of O_2 on SiO_2 at -183°C. The liquid O_2 curve is parallel to the actual curve above 100 mg of O_2 per g of SiO_2, indicating that the liquid phase is bound by capillary condensation in this region.

399. Karzhavina, N. A. **Effect of pressure on the rate of the reduction of carbon dioxide by carbon.** *Doklady Akad. Nauk S.S.S.R.* **73**, 971-3 (1950).—*C.A.* **44**, 10467*h*.

The yield of CO in the passage of CO_2 mixts. with N_2 (300 ml/min.) over a layer of charcoal or electrode carbon at 990°C does not vary with the total pressure between 1 and 13 atm., at any fixed concn. of CO_2. The yield is approx. of the 1st order up to about 50% CO_2, but then becomes and remains independent of it (zero order). In terms of the height of the layer (grain size 2-3 mm), the CO content increases with increasing height of column, but is not proportional to it.

400. Lesher, C. E. **Low-temperature coke as a reactive carbon.** *Trans. Am. Inst. Mining Met. Engrs.* **187**, Tech. Pub. No. **2874-F** (in Mining Eng. **187**, 805-10) (1950).—*C.A.* **44**, 7514*e*.

The reactivities of 950° and 1650°F cokes were measured by relative rates of reduction of Fe oxides up to 2200°F. Three standardized combinations of Lake Superior brown Fe ore with coke were tested: (1) mech. mixt. of carefully sized high-temp. 1650°F coke with the ore; (2) mech. mixt. of the ore with Disco obtained by carbonizing the identical coal at 950°F, and (3) agglomerate prepd. by carbonizing the coal and ore at 950° F, premixed in proportions to give as nearly as possible the same relative amts. of coke and ore as the mech. mixts. The agglomerate was most active, the mixts. of Disco and ore next, and coke the least reactive.

401. Letort, Maurice and Magrone, Robert. **Influence of particle shape in the study of the rate of combustion of graphite.** *J. chim. phys.* **47**, 576-82 (1950).—*C.A.* **44**, 10469*e*.

Two graphites were studied, one with 0.22% ash and the other with less than 0.01% ash. The combustion rate at about 600°C of the first decreased with time while that of the second increased with time, in each case approaching an asymptotic value. The rate depended not only on grain surface, but also on penetration of combustion into the interior. Activation energies of 48 and 50 kcal were reported for the two graphites.

402. Letort, Maurice; Petry, Mme. J.; Barret, P.; Collart, F.; Labaeye, P., and Martin, J. **Work in progress on the mechanism of graphite combustion at low temperature (450-600°): phenomenon of "excess combustibility." Desportion of the reaction gases.** *J. chim. phys.* **47**, 548-58 (1950).—*C.A.* **44**, 11059*d*.

Dry air was passed over powd. graphite in a heated tube. A phenomenon of "excess combustibility" was found wherein the oxidation proceeds several times as fast when stagnant air is left in the tube as when air is flowing; this effect was assocd. with traces of Cu in the graphite. Evolution of surface-bound oxides was studied by a N_2 purging technique with analysis of this exit gases.

403. Leye, Alexander R. **The "available" hydrogen and sulfur content in combustion calculations.** *Brennstoff-Chem.* **31**, 278-80 (1950).— *C.A.* **45**, 2176*c*.

It is assumed that the "available" H is equal to total H—(O/8), on the assumption that all of the combined O is in the form of H_2O. The available H is really equal to total H—(β O/8) in which β is a min. of 0.45 for low-volatile coals and a max. of 0.55 for high-volatile coals, av. 0.53 for most gas coals. S corrections are required only for high-S coals.

404. Long, F. J. and Sykes, K. W. **The catalysis of the oxidation of carbon.** *J. chim. phys.* **47**, 361-78 (1950).—*C.A.* **44**, 7132*d*.

The reactions of coconut-shell charcoal with steam and CO_2 were studied after removing catalytic impurities. The range 700° to 884°C and pressures of the gases from 10 to 760 mm were used. The general form of the reaction mechanism was not changed by the presence of the catalysts, but the rates of certain stages were increased. The activation energies of processes in which O_2 was transferred to the charcoal were slightly reduced. The no. of active sites was not significantly altered by removal of the impurities.

405. Loon, W. van and Smeets, H. H. **Combustion of carbon.** *Fuel* **19**, No. 5, 119-21 (1950).— *C.A.* **44**, 5563*b*.

A simple test was outlined in which a carbon particle was burned in a vortex chamber with O_2. The $CO/(CO+CO_2)$ ratio in the combustion products increased with the rate at which the O_2 was supplied. Primarily CO was formed at the carbon surface and this CO may be secondarily burned to CO_2 in the diffusion layer on the particle. Under certain conditions traces of O_3 were formed in the combustion gases.

406. Mertens, E. **The primary combustion of carbon.** *J. chim. phys.* **47**, 353-5 (1950).—*C.A.* **44**, 7177*e*.

O_2 was passed over graphite, and the product sampled with a water-cooled probe; there were obtained 81.4% CO_2 and 18.2% CO. Addn. of CCl_4 (80 mg or more of Cl_2 per liter of O_2) suppressed CO_2 formation, giving 9.2% CO_2 and 90.6% CO. Thus, CO was the primary reaction product.

407. Meyer, Lothar. **The primary reaction of graphite with oxygen, carbon dioxide, and water vapor.** *J. chim. phys.* 47, 328-30 (1950).—*C.A.* **44,** 7128*i*.

Published results differ as to nature of primary products, order of reaction, activation energy, sorption of O, and effect of impurities and structure of the graphite filaments. The differences are due to cracks present. Reaction products formed in such a crack would return to the hot surface many times before leaving, thus leading to secondary reactions.

408. Omori, T. T. and Orning, A. A. **Effect of pressure on the combustion of pulverized coal.** *Trans. Am. Soc. Mech. Engrs.* **72,** 591-7 (1950).—*C.A.* **44,** 7511*b*.

Exptl. investigation, in the absence of an extended flame (so that the source of radiant heat could be independently controlled), showed an adverse effect of elevated pressures upon completeness of combustion of a suspended sphere which was much larger than the beneficial effect of increased partial pressure of O_2. Apparently the increased pressure, through a lower initial heating rate, produced less reactive combustion residues which lost ignition before combustion was complete.

409. Oreshko, V. F. **Oxidation of hard coal under nonisothermal conditions.** *Zhur. Priklad. Khim. (J. Applied Chem.)* **23,** 306-16 (1950).—*C.A.* **45,** 2174h.

Expts. with a hard coal (C 88.34, H 5.11, N 1.33, S 1.50%; ash 3.48, moisture 0.95, volatile 23.0%; grain size 0.2 ± 0.1 mm), (1-g) in a stream of O_2 at 65 ml/min. showed an initial stage of gain of wt followed by a loss of wt, a min., then a rapid rise of the wt up to a sharp peak, and finally steep fall of the wt leading to rapid loss of wt as a result of inflammation. The temps. corresponding to the min. were 132-4°C, of beginning increase of wt, 146-8°C, and of the peak of wt, 235-7°C. In the range between the 146°C and the peak, the rate of formation of C-O complexes stable at these temps., exceeded the sum of the rates of formation of peroxides + decompn. of the stable C-O complexes. In the range of decreasing wt, between ~70 and ~130°C, the (predominating) rate of decompn. of the peroxides must be proportional to their surface concn. at any given moment.

410. Oreshko, V. F. **Oxidation of hard coal.** *Doklady Akad. Nauk S.S.S.R.* **70,** 445-8 (1950).—*C.A.* **45,** 5388*i*.

Oxidation of coal in a stream of O_2 proceeds in 2 stages. On the 1st stage, the decrease of wt x follows the law $dx/dt = k_1(a - x)e^{-E_1/RT}$, where a = max. decrease of wt (approx. proportional to the initial concn. of peroxides in the coal) and k_1 depends on the surface area and the concn. of O_2; a and x are expressed in mg/g, t in min. In the 2nd stage at higher temps., the rate of increase of wt is $dx/dt = k_2e^{-E_2/RT}$. These relations were tested and confirmed in expts. with coal samples. The near constancy of E_1 (6500 cal) indicates close similarity of the nature and compn. of the peroxides in coals of different ages. The effect of the nature of the coal is much more pronounced in the 2nd stage, that of formation of more stable C-O complexes.

411. Oreshko, V. F. **Rates of oxidation of Kuznetsk coals.** *Doklady Akad. Nauk S.S.S.R.* 74, 327-30 (1950).—*C.A.* **45,** 2175*f*.

The rate of change of wt dx/dt of 11 samples of Kuznetsk-basin coals with volatile matter contents ranging from 7.07 to 42.29% followed the same law as previously reported for Donets-basin coals, i.e., at lower temps., at the stage of decompn. of the peroxide complexes, $dx/dt = k_1(a - x) e^{-E_1/RT}$, and at higher temps., at the stage of formation of stable oxidation complexes, $dx/dt = k_2e^{-E_2/RT}$. The av. $k_1 = 3.6 \times 10^3$ min.$^{-1}$, av. $E_1 = 7.5$ kcal/mole, independently of the volatile matter. In the 2nd stage of the oxidation, E_2 is const. (~16.5 kcal/mole) up to 26%, volatile matter then fell with further increase.

412. Orleanskaya, G. L. **Oxidation as a factor in the self-ignition of coal.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk* **1950,** 1071-9.—*C.A.* **45,** 8739b.

The self-ignition of coal was measured by placing a sample, ground to 0.15 mm, and an oxidizing agent (optional), such as $NaNO_2$, in a thermostatic block 5.5 cm in diam. and 10 cm high having a centrally mounted thermocouple. In a typical expt., the ratio of coal to oxidizing agent was 2:1, the charge formed a layer 0.5-1.0 cm high, and the heating rate was 5°/min. The temp. registered by the thermocouple at the instant of self-ignition was recorded as T, the observed values of which were of the order of 300-400°C. Treating coal with dil. aq. solns. of surface-active agents was effective in lowering self-ignition, but others have the opposite effect and were inhibitors of self-ignition.

413. Parker, W. G. and Wolfhard, H. G. **Carbon formation in flames.** *J. Chem. Soc.* **1950,** 2038-49.—*C.A.* **45,** 934g.

The carbon formation in simple diffusion flames of C_2H_2 and O_2 or air was pressure dependent in a reproducible manner for a given burner regardless of mass flow for the range investigated. The particles were of uniform size over the entire luminous area in a nonsmoky flame, but in a smoky flame some larger particles are found. No aromatic absorption bands were observed during the pyrolysis of C_2H_4 and C_2H_2. In the C_6H_6 diffusion flame the C_6H_6 bands disappeared before the luminous zone was reached. Two possible mechanisms were: (1) Higher hydrocarbons, formed by pyrolysis, build up a concn. great enough for fine droplets to condense; (2) Large, unstable mols. are formed. In either case graphite crystallites are then produced.

414. Parry, R. W. and Comings, E. W. **Reactions between ammonium nitrate and charcoals. Alkali metal salts as combustion catalysts.** *Ind. Eng. Chem.* 42, 557-60 (1950).—*C.A.* 44, 4654*d*.

Pressed blocks of NH_4NO_3 and charcoal, with and without linseed-oil binder and acid or salt additives, were burned in the open and in vol. flowmeters. The burning rate was increased by aging, by alkali nitrates, sulfates, carbonates, and mono-H phosphates; chlorides, cyanides, and alk. earth salts were less effective; H_3PO_4 decreased the burning rate. Carbonates, org. salts which produce CO_3^{--} upon combustion, and salts of oxidizing acids were most effective in catalyzing the oxidation.

415. Parry, R. W.; Comings, E. W., and Raila, M. H. **Reaction between ammonium nitrate and charcoals. Surging in combustion.** *Ind. Eng. Chem.* **42**, 560-5 (1950).—*C.A.* **44**, 4654*f*.

Cyclic combustion or "surging" was observed, i.e., alternating fast and slow burning in a cycle ranging from 2 to 50 sec. The surge tendency and violence increased with gas pressure. Surging was promoted by increasing the pH, lowering the preignition temp., and storing at room temp.; it was reduced by addn. of linseed oil and by increasing the amt. of charcoal. The surging charcoal was difficult to wet. The trough (slow) reaction produced more NO_2(CO_2: CO ratio was about 16) than the crest (fast) reaction.

416. Patai, Saul and Hoffmann, E. **The oxidation of carbon black by solid potassium perchlorate.** *J. Am. Chem. Soc.* **72**, 5098-5101 (1950).—*C.A.* **45**, 2806*g*.

The reaction between solid $KClO_4$ and carbon black was studied with different initial amounts of the reactants in the range 320-85°C, $dx/dt = k_1(a-x)(b-0.5x)$ and $dx/dt = k_2(a-x)(b-0.5x)/0.5x$, resp., correspond to the 1st and 2nd parts of the exptl. curves.

417. Perry, H.; Corey, R. C., and Elliott, M. A. **Continuous gasification of pulverized coal with oxygen and steam by the vortex principle.** *Trans. Am. Soc. Mech. Engrs.* **72**, 599-610 (1950).—*C.A.* **44**, 7510*h*.

The basic principles of reactor design and an illustrative example of their application were given. The carbon conversions were low, and the resultant gas high in CO_2. The uniformity and the method of coal distribution strongly influenced the amt. of carbon conversion, the quality of the gas produced, and the max. and min. throughputs.

418. Riley, H. L. **Chemical and crystallographic factors in carbon combustion.** *J. chim. phys.* **47**, 565-72 (1950).—*C.A.* **44**, 11059*c*.

The structure of graphite and amorphous carbons are reviewed. The solid C-O complex, chemically combined foreign matter in carbons, and modes of O_2 attack are discussed.

419. Sands, A. E.; Wainwright, H. W., and Egleson, G. C. **Organic sulfur in synthesis gas: occurrence, determination and removal.** *U.S. Bur. Mines, Rept. Invest. No.* **4699**, 51 pp. (1950).—*C.A.* **44**, 9136*e*.

This is a progress report on exptl. work. No thiophene was found in synthesis gas made from pulverized coal, steam, and O. Addn. of 0.038 lb of hydrated lime per lb of coal lowered the org. S content of the gas but had no effect on H_2S content. Increasing the steam to coal ratio greatly decreased the org. S concn. in the gas. A modified I.G.T. combustion method appeared to be best for the detn. of total organic S. Expts. were made with catalysts which simultaneously removed organic S and H_2S (Huff catalysts gave good results). Purification can be effected to leave less than 0.1 grain of total S per 100 ft^3 of purified gas.

420. Sawai, I.; Kunugi, M., and Jinno, H. **The rate of reaction in carbon dioxide-coke system.** *Mem. Faculty Eng. Kyoto Univ.* **12**, 87-94 (1950).—*C.A.* **46**, 2782*c*.

A quant. formulation was given under conditions where either diffusion or chem. reaction may be expected to control the reaction rate. In the range of 900-1400°C either diffusion or chem. reaction can be rate detg. The importance of the ash layer overlying unreacted coke was emphasized.

421. Scartazzini, Hubert. **Combustion of pulverized coal in oxygen and in oxygen-nitrogen mixtures.** *Compt. rend.* **231**, 1144-5 (1950).—*C.A.* **45**, 5904*b*.

Flames of pulverized coal in O_2, in air, and in intermediate mixts. were prepd. and their spectra studied between 6800 and 2800 A. Their brightness and true temps. were detd. pyrometrically.

422. Silver, R. S. **Application of the Reynolds analogy to combustion of solid fuels.** *Nature* **165**, 725-6 (1950).—*C.A.* **44**, 7509*g*.

Above a certain temp., the rate of transport of O_2 to the surface of a solid fuel becomes more important than the temp. of the surface. With air as the fluid, carbon as the fuel, and CO_2 the product, $R = 0.0825\ h/c_p = 0.0875\ pvf/2$, where R is the reaction rate (wt of C/unit area), h is the heat-transfer coeff., c_p is the sp. heat, p is the fluid d., v is the mass velocity, and f is the friction coeff. For air, h/c_p is about 10^{-3} g/sec/cm^2 and R about 10^{-4} g/sec/cm^2.

423. Strickland-Constable, R. F. **The kinetics of the oxidation of carbon. A survey of some recent results.** *J. chim. phys.* **47**, 322-6, discussion 326-7 (1950) (in English); *Chemistry & Industry* **1948**, 771-4.—*C.A.* **44**, 6710*e*; **43**, 1632*g*.

H_2O and CO_2 react with carbon at 800°C in a reaction that is between first and zero order to give a common product, CO. Expts. with carbon filaments between 900° and 1600°C appear to show a remarkable degree of similarity in the behavior of N_2O, CO_2 and H_2O, indicating a similar reaction mechanism. N_2O, however, reacts at 400°C with charcoal to give CO_2, whereas CO_2 and H_2O do not react with charcoal below 700°C; N_2O also reacts with CO in the presence of charcoal to give CO_2.

424. Strickland-Constable, R. F. **Some comments on the work of Key on the reactions between coke and carbon dioxide and between coke and steam.** *J. chim. phys.* **47**, 356-60 (1950).—*C.A.* **44**, 7044*d*.

The reactions of CO_2 and H_2O with coke proceed by a 2-stage mechanism: 1st, a surface oxide is formed; 2nd, which is common to both reactions, the surface oxide decomposes to give CO. The H_2O reaction is strongly retarded by H_2 due to strong adsorption of H_2. The rate of the CO_2 reaction with coke is much slower than the reported rate with charcoal.

425. Strimbeck, G. R.; Holden, J. H.; Rockenback, L. P.; Cordiner, J. B., Jr., and Schmidt, L. D. **Pilot-plant gasification of pulverized coal with oxygen and highly superheated steam.** *U.S. Bur. Mines, Rept. Invest.* No. **4733**, 41 pp. (1950).—*C.A.* **45**, 844*f*.

Exptl. work was reported on the gasification of 90% through 200-mesh, strongly coking Sewickley-bed coal with O_2 and with steam in temp. ranges of 2700 to 3400°F, 1600 to 2000°F, and 230 to 250°F. The av. requirements per 1000 standard ft^3 of $CO + H_2$ produced at a steam temp. of 2904°F were 33.3 lb coal, 171 ft^3 O_2, and 81.1 lb steam. At a steam temp. of 1899°F the requirements were coal 37.3 lb, O_2 326 ft^3, and steam 42.5 lb. At 238°F coal 42.3 lb, O_2 394 ft^3, and steam 29.1 lb were required.

426. Strimbeck, G. R.; Holden, J. H.; Rockenback, L. P.; Cordiner, J. B., Jr., and Schmidt, L. D. **Pilot-plant gasification of pulverized coal with oxygen and highly superheated steam.** *Am. Gas Assoc. Proc.* **32**, 501-3 (1950).—*C.A.* **46**, 10582*d*.

In the pilot-plant gasification of pulverized coal to produce low cost synthesis gas from raw coal, 31 runs were made with a total of 56,000 pounds of 90% through 200 mesh, strongly coking coal, at feed rates of 200 to 450 lb of coal per hr. Gasification with steam was carried out in 3 temp. ranges.

427. Totzek, Friedrich and Osthaus, K. H. **The basis of the Koppers-Totzek process for gasification of powdered coal.** *Brennstoff-Chem.* **31**, 173-80 (1950).—*C.A.* **44**, 8622*i*.

Diffusion is shown to be the predominant factor in high-temp. gasification. Since the diffusion velocity is comparatively low, a short diffusion path with a high concn. gradient must be maintained during gasification. The relative velocity between the gaseous and the therein suspended solid reactants should be relatively slight to give the optimum conditions for diffusion. O_2 must be used as the gasification medium rather than air.

428. Vaidyeswaran, R. and Iyengar, M. S. **Carbon formation in flames.** *Rept. Proc. Symposia on Fuels, Fats & Oils and Research & Ind.* (India) **1950**, 94-6.—*C.A.* **46**, 10833*c*.

Expts. were conducted on the effect of CO_2 on the luminosity of flames produced from several org. materials (hexane, heptane, octane, decane, EtOH, iso-PrOH, BuOH, iso-BuOH, and AmOH). The crit. rate of CO_2 addn. required to suppress the luminosity decreases with increase in mol wt in a given homologous series.

429. Vaidyeswaran, R. and Iyengar, M. S. **Combustion of noncaking Hyderabad coals in a fuel bed.** *Rept. Proc. Symposia on Fuels, Fats & Oils and Research & Ind.* (India) **1950**, 97-9, discussion 99-100.—*C.A.* **46**, 8346*b*.

Expts. were conducted on the combustion of coal in a pipe, 6 in. in diam. and 9 in. tall in which the fuel bed was supported on a metal grate 3 in from the bottom. The introduction of flue gas (CO_2) with the primary air for combustion of Hyderabad coal will minimize boiler depositions and hence improve boiler efficiency.

430. Veselovskiĭ, V. S. and Terpogosova, E. A. **The temperature of ignition of coals as a characteristic of their tendency toward self-ignition.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk* **1950**, 1204-11.—*C.A.* **46**, 1227*d*.

Hot air is blown through a bed of coal that may contain an oxidizing agent (e.g., $NaNO_3$) and the temp. difference between the inlet air and selected points in the bed is measured with thermocouples. The temp. of ignition is a useful index of the tendency of a given coal to self-ignition.

431. Whittingham, G. **Spectrum of the glow of burning carbon.** *Fuel* **29**, 244 (1950).—*C.A.* **45**, 327*h*.

Dry air was passed through a cylinder of electrode carbon placed in a quartz tube maintained at 850°C. This resulted in a blue glow which was recorded on a small quartz spectrograph. A banded spectrum superimposed on a continuous background extended through the ultraviolet region and no OH bands were present. Strong Na D-line emission was given and the faint bands appearing in the blue-green were probably due to the abnormally high B content of the C.

432. Wilson, J. H. and Bolam, T. R. **Chemisorbed oxygen on charcoal and the sorption of strong inorganic bases and acids.** *J. Colloid Sci.* **5**, 550-66 (1950).—*C.A.* **45**, 3681*d*.

The sorption is due to the presence of chemisorbed O, not chemisorbed H_2O. The chemisorbed O exists in 2 types of complex, one with 2 atoms of O per mol. of sorbed NaOH, and the other with 4 atoms O per NaOH. Sugar charcoal and C_6I_6 charcoal fix large quantities of O at 400°C. All, or almost all, of this O is involved in the sorption of bases from aq. solns., but plays no part in the sorption of acids.

433. Yohe, G. R. **Coal oxidation: active oxygen and Russell effect.** *Fuel* **29**, 163-5 (1950).—*C.A.* **44**, 7510*b*.

Materials which are capable of producing images when placed on contact with a photographic film in the dark are substances susceptible to peroxide formation. The earliest exptl. evidence for peroxygen intermediate in coal oxidation was that obtained by Russell in his expts. with photography.

434. Arthur, J. R. **Reactions between carbon and oxygen.** *Trans. Faraday Soc.* **47**, 164-78 (1951).—*C.A.* **45**, 10011*a*.

An artificial graphite and a coal char (made by carbonization of Warwickshire coal in a stream of com. O_2 free N_2) were studied with a flow method. From 480° to 900°C, the CO/CO_2 ratio with both carbons (uniquely detd. by temp.) increased exponentially with temp. $POCl_3$ vapor was added to the oxidizing gas to suppress the formation of CO_2 from CO. Two reactions were responsible for the gasification of carbon by O_2 and one leads to CO_2 formation, the other to CO formation. The relative rates for both carbons are given: $CO/CO_2 = 10^{3.4} \exp(-12{,}400/RT)$.

435. Arthur, J. R.; Bangham, D. H., and Crone, H. G. **Topochemistry of fuel beds.** *Ind. Eng. Chem.* **43**, 525-8 (1951).—*C.A.* **45**, 3144f.

Expts. with actively burning fuel beds showed the extreme localization of the gasification zone.

An apparent anamolous increase in total energy of the gases as they traversed the bed was probably due to combustion within the gas-sampling probes. Expts. with single carbon tubes in the presence and absence of inhibitors showed the entirely different pattern of gasification with distance through the tube. The high CO contents of gases sampled in the presence of inhibitors are compared with the concns. obtained during the last stages of burning of under-feed fuel beds.

436. Arthur, J. R. and Bowring, J. R. **Physiochemical aspects of the combustion of solid fuels.** *Ind. Eng. Chem.* **43**, 528-33 (1951).—*C.A.* **45**, 3143*c*.

Materials with a strong affinity for H_2 or H_2O increased the proportion of CO to CO_2 in the combustion products from the carbon tubes. Most of the inhibitors were halogens or volatile halides. When inorg. halides were added to the fuel, only small inhibiting effects were observed. The formation of CO_2 during the combustion of solid fuels at high temps. was dependent on the presence of sufficient H-contg. species which propagate the CO-combustion reaction. By controlling the concn. of these species it was possible in principle to control the nature of the end product, and so obtain CO or CO_2 as desired.

437. Baetke, F. W. **The reaction mechanism of combustion of carbon at atmospheric pressure.** *Z. Elektrochem.* **55**, 655-7 (1951).—*C.A.* **46**, 4407*h*.

Dry air was passed through a carbon tube at 1000°C and 1 atm. at velocities from 30 to 100 m per sec, producing mainly CO. The exit gas contained a considerable amount of unburned O_2. By addn. of 0.15% CCl_4 or by lowering the pressure to 0.1 atm., the yield of CO increased to 90-95%, based on total CO+ CO_2 produced. CO was the primary combustion product at atm. pressure.

438. Banerjee, S. and Sarjant, R. J. **Reactivity of coke.** *Fuel* **30**, 130-9 (1951).—*C.A.* **45**, 6823*e*.

Coke was burned in a fuel bed under specific conditions, which involve a const. size, a const. rate of air supply, and controlled temp. of preheat of air and of the walls of the reaction chamber. The temp. of the fuel bed was maintained at 1300°C. Two charts have been prepd. which help to present in concise form the relationship between reactivity and available heat in industrial fuel beds. The most significant factor that influenced the reactivity of coke was the character of the parent coal from which the coke was made; reactivity was also affected by the carbonizing temp.

439. Behrens, Hans. **Mechanism of the Boudouard reaction and carbon combustion at high temperature.** *Naturwissenschaften* **38**, 187 (1951).—*C.A.* **46**, 2266*e*.

The Boudouard reaction at high temp. was studied by the temp. at which it freezes in cooling gases. It consisted of $CO+OH=CO_2+H+25$ Cals; $H+CO=C_{sol.}+OH+16$ Cals. The freezing temp. of the latter reaction, which detd. the rate, was about 1500°K. The heat effect of the last reaction was only enough to give soot at flame temp. The presence of small amts. of H accelerated the combustion of solid carbon.

440. Bonner, Francis and Turkevich, John. **Study of the carbon dioxide-carbon reaction using C^{14} as a tracer.** *J. Am. Chem. Soc.* **73**, 561-4 (1951).—*C.A.* **45**, 4535*h*.

The reaction between CO_2, CO, and charcoal was studied in a recycling system with continuous monitoring of C^{14}. Radiochem. measurements were correlated with changes of compn. of the gas and with pressure measurements. A rapid reaction of the CO_2 with the surface was postulated to give an oxygenated surface and a radioactive CO and a subsequent slow two-stage unimol. decompn. of the oxygenated surface into nonradioactive CO and charcoal.

441. Casamassima, G. and Meo, F. **Oxidation of coal.** *Riv. Combustibili* **5**, 143-55 (1951).—*C.A.* **45**, 7774*h*.

The complex reactions of the oxidation of coal with atm. O_2 and the production of coke are discussed. The use of the dilatometric method furnishes important information in the range of 20 to 600°C and permits estn. of the degree of oxidation of the coal.

442. Cines, M. R. **Surface oxidation of furnace black and resulting rubber properties.** *Rubber Age* (N.Y.) **69**, 183-8 (1951).—*C.A.* **45**, 5962*f*.

Surface oxidation of an MAF black (Philblack-A) and an HAF black (Philblack-O) can yield pH values from 9.5 to 3 by treatment with O_2 at 700-1000°F. Surface oxidation increased progressively the C-O complex, with consequent increase of content of volatile substances and lowering of the pH value. Surface oxidation increased the content of volatile substances and the surface area, but did not lead to any loss of carbon oxides. Expts. on the reinforcing effects of these oxidized blacks in natural rubber vulcanizates showed that the state of cure is a more determinant factor than is the pH value of the oxidized black.

443. Ershov, V. N. and Pomerantsev, V. V. **Reduction of carbon dioxide by coke.** *Zhur. Priklad. Khim.* **24**, 520-6; *J. Gen. Chem.* **21**, 569-76 (1951).—*C.A.* **46**, 8829*a*.

Coke was obtained by calcination of a natural coal at 850°C in a stream of N_2 until cessation of the sepn. of volatiles. The ground particles (70-80 μ) were again placed in N_2 at 900°C until const. wt. The heating and cooling of the samples (1.5 to 2 hrs) between reaction with CO_2 were done in N_2. Expts. were made in a range of 600-1000°C. Consumption of CO_2 amounted to 1.2 cc/sec. The kinetic characteristics of the reaction $C+CO_2=2CO$ were detd. for different coals at temps. below 950°C.

444. Euler, Joachim. **Changes in activated charcoal in air-oxygen cells.** *Z. Elektrochem.* **55**, 316-22 (1951).—*C.A.* **45**, 8375*d*.

The electrodes consisted of active charcoal, acetylene black, graphite, and NH_4Cl; the electrolyte was aq. NH_4Cl and $ZnCl_2$, with a small amt. of $HgCl_2$. After discharge, the electrode was crushed, the NH_4Cl leached out with water, and the residue extd. with benzene. The amt. of benzene ext. was between 1 and 15 mg. After the oxidation was initiated, it continued at the same rate even when the discharge was stopped. The initiation occurred when the gas used was air or O_2; in the latter case, O_3 or oxides of N were detected. Initiation could be accomplished without discharge by using O_2 contg. O_3 or N oxides. The oxidation product had a mol. wt, detd. by lowering of freezing pt., of 800 ± 40°C.

445. Gillet, A. **The solubility-conferring oxidation of coal.** *Fuel* **30**, 181-7 (1951).—*C.A.* **45**, 8230*b*.

Coal is an assembly of micro-mols. of various sizes, strictly definable only in terms of the "monomer" from which they are produced by polymerization. This substance appears to have the approx. formula $C_{29}H_{22}O_2$. When this substance is oxidized, the no. of C atoms remaining in the oxidized coal is close to 20; the empirical formula $C_{20}H_8O_8$ appears to apply to all of the products of oxidation of the various coals. Possible structural formulas are presented which account for the products of oxidation beyond the anthraxylic acid stage.

446. Givaudon, J. and Nessler, Andrée. **The reactivity of the fixed carbon of spent (oil) shales.** *Oil Shale and Cannel Coal Conf., Inst. of Petroleum, London* **2**, 467-88 (1951).—*C.A.* **47**, 1365*b*.

O_2 was completely removed from the gas mixt. passed up through a bed of crushed spent shale at 750-950°C. When a current of air, or of 40% air in CO_2 and N_2, was passed through a bed of spent shale at 300°C the temp. increased; this indicated reignition. The index of reactivity of the fixed C with CO_2 is given as $p = 100x/(x + 2z)$, where $x =$ the CO and $z =$ the CO_2 content of the exit gas. Allowance must be made for any decompn. of carbonates. The indexes of the shales ranged from 57 to 97 at 800° but from 97 to 100 at 900°C.

447. Gol'denberg, S. A. **Study of turbulent combustion taking into account secondary reactions.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk.* **1951**, 657-66.—*C.A.* **46**, 2775*g*.

Turbulent heterogeneous combustion, as carried out experimentally by flow of O_2 at 500-1000°C through cylindrical carbon tubes, is affected significantly by the secondary reactions of CO_2 reduction and CO combustion. Under these conditions the coeff. of gas formation $= 4.3 \times 10^7$ exp-$(-28{,}500/RT)$.

448. Helfinstine, Roy J. **Correlation of domestic stoker combustion with laboratory tests and types of fuels. IV. Combustion tests of Illinois and other coals.** *Illinois State Geol. Survey, Rept. Invest.* No. **151**, 46 pp (1951).—*C.A.* **46**, 3730c.

The uniformity of heat release during combustion, with some exceptions, increased with decrease in the percentage of ash. The relationship of uniform heat release was poor with: clinker formation and ash fusion, the free swelling index of the coal and the fluid properties of the coal. No relationship was observed for the percentage of volatile matter. Other combustion criteria showed little or no correlation with lab. tests. Actual combustion tests were the only satisfactory way to det. the suitability of a coal for stoker combustion.

449. Jílek, Jaromír. **Self-ignition and storage of brown-coal semi-coke.** *Paliva* **31**, 225-30 (1951).—*C.A.* **46**, 709e.

The semi-coke of brown coal in bulk storage tends to ignite spontaneously, particularly in summer. Heat is generated by processes such as adsorption of gases, oxidation, and absorption of H_2O. Granular semi-coke of grain sizes larger than 10 mm is safe. Finer particles tend to self-ignite at the base of the pile, with the ashes formed preventing further burning. Large piles can be stored safely when sprayed with a H_2O suspension of lime.

450. Karavaev, N. M.; Sevast'yanov, Yu. L.; Dolgopolov, N. N., and Bur'yan, Yu, L. **Pyrolysis of coal under the action of a high-frequency current.** *Doklady Akad. Nauk S.S.S.R.* 77, 871-4 (1951).—*C.A.* **45**, 6819*i*.

Heating to 1000°C was done with the aid of a tube generator of 7 m wave length (frequency 4.3×10^7 sec^{-1}). The compn. of the semicoke produced in the dielec. heating is little different from that obtained in conventional heating to the same temp. However, the yields of tar and of gas were considerably lower.

451. Karzhavina, N. A. **The combustion of carbon in a stratum.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk* **1951**, 1165-77.—*C.A.* **47**, 7187*i*.

Gas formation by combustion of electrode carbon or of charcoal was studied at temps. of 300-1100°C, blast speed of 0.05-0.4 m/sec, and O_2 concns. in the blast of 2.5-21%. For the combustion of particles of 1-2 mm, the depth of the O zone (at temps. higher than 700°) was from 1 to 2 rows of particles.

452. Kiyama, Ryo and Osugi, Jiro. **The ignited combustion of dispersed powders.** *J. Chem. Soc. Japan*, Pure Chem. Sect., **72**, 982-5 (1951).—*C.A.* **46**, 7770*f*.

The lowest ignition temp. of starch, charcoal, coal, biocellulose, active carbon, coke, resin, and S have been detd. The ignition temp. of active carbon falls in the presence of salt in the order: $KOH > NaOH > K_2CO_3 > Na_2CO_3 > NaHCO_3 > Ca(OH)_2$.

453. Kowalski, Jerzy and Lewandowski, Wladyslaw. **Sulfur recovery in brown coal low-temperature carbonization.** *Przeglad Górniczy* 7, 237-42 (1951).—*C.A.* **45**, 9244*d*.

The method is applicable to brown coals containing 0.5%-4% S. The process is divided into two phases: (1) absorption of H_2S in the Alkacid system and (2) combustion: $H_2S + O \rightarrow H_2O + S$ in Claus furnaces. For the absorption stage NH_4CH_2COOH or $CH_3CH_2NH_2COOH$ or mixture of both are used. By heating desorption occurs. The modified Claus furnace gives a 2-stage reaction: $H_2S + 3/2\ O_2 = SO_2 + H_2O$; $2\ H_2S + SO_2 = 3\ S + H_2O$. Impurities in resulting S are less than 0.1%.

454. Loon, W. van. **The combustion of carbon.** *Chem. Weekblad* **47**, 233-9 (1951).—*C.A.* **45**, 7774*i*.

When air or O_2 is injected into an incandescent layer of coke, the temp. of the layer is controlled by the O_2 concn. The relation between the layer temp. and O_2 concn. is computed to det. the min. layer temp. and min. O_2 temp. required for maintaining stable conditions in operation. This was between 1000° and 1300°K.

455. LORENZEN, GERHARD. **Low-temperature carbonization of bituminous coal.** *Brennstoff-Chem.* **32**, 324-31 (1951).--*C.A.* **46**, 1227*f*.

It is more economical both from the viewpoint of coal requirements and cost of operation to convert bituminous coal into liquid fuels by low-temp. carbonization rather than by hydrogenation. The use of a limited amt. of recirculated gas is desirable. The capacity of two types of coking ovens is relatively high, owing to the relatively short carbonization times as compared with high-temp. ovens; the coke has satisfactory properties.

456. MAEZAWA, MASATAKE. **Oxidation of coal and its ignition temperature.** *J. Fuel Soc. Japan* **30**, 190-7 (1951).—*C.A.* **46**, 1734*b*.

The ignition temp. of coal, might be detd. from activation energy relating to the chem. properties of coal and a const. relating to frequency index and coeff. of thermal cond., which, in turn, depend on the phys. conditions.

457. MARSH, J. D. F. **Some aspects of the mechanism of gasification of carbon by carbon dioxide and steam.** *Inst. Gas Engrs.*, Copyright Pub. No. **393**, 21 pp. (1951).—*C.A.* **46**, 3238*i*.

When the sample was reduced with H_2 and then treated with CO_2 at a temp. below that necessary for gasification, CO and a surface layer of O was produced. The vol. of CO_2 reacting depended on the temp., the B.E.T. surface area of the carbon, and the nature of the surface, which is modified by ash constituents. The surface-O could be removed as H_2O by subsequent treatment with H_2. In a series of consecutive runs with high-temp. coke, the av. wt of water formed was equiv. to the av. vol. of CO formed during the CO_2 treatments. Most of the surface-O could be removed as CO_2 by treatment with CO. The vol. of CO_2 reacting to give CO and surface-O on a sample of high-temp. coke did not vary greatly with the partial pressure of the CO_2.

458. NADZIAKIEWICZ, J. AND PAMPUCH, R. **The thermal decomposition temperature of coals.** *Prace Glównego Inst. Górnictwa Komun.* No. **79**, 16 pp. (1951).—*C.A.* **46**, 8827*f*.

Volatile-matter content was inversely proportional to thermal decompn. temp., with a correlation coeff. $r = -0.841$. The tested coals could be sepd. into 2 groups: (1) flame-coals and ortho-coking coals, and (2) lean-coals and anthracite-coals. The thermal stability of the 1st group probably depended on the polar-atom (O, S, N) content, since thermal stability is an inverse function of polar-atom content. When the polar-atom content was less than about 5%, all types of tested coals showed high thermal stabilities.

459. ORESHKO, V. F. **Oxidation of petrographic ingredients of hard coal.** *Doklady Akad. Nauk S.S.S.R.* **81**, 663-6 (1951).—*C.A.* **46**, 9826*b*.

The fusain from long-flame coal gives a considerably higher temp. of ignition (323°C) than vitrain from the same coal (240°C), just as the fusains of coking coal give lower temps. of ignition (340-342°C) than the vitrains of coal (376°C). The fusain concentrate has an ignition temp. like that of coked coal (345°). The screening and classifying of coal to remove dust and fines can promote safety of storage of the coal.

460. ORESHKO, V. F. **Oxidation of coals of various degrees of metamorphism.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk* **1951**, 1031-40.—*C.A.* **46**, 10579*d*.

If the yield of volatile matter (*Y*), (7 to 42%) was less than 26%, the max. temp. on oxidation in O_2 was 235°C and the min. temp. on oxidation in O_2 or air was 145°C. If *Y* was higher, these temps. were inverse functions of *Y*. In air oxidations, the max. temp. decreased uniformly with increasing *Y* throughout the range studied. Special significance was attached to the limiting value of $Y = 26\%$. For most of the coals studied, the over-all oxidation process was approx. represented by: $\text{coal} + O_2 \rightarrow CO_2 + 2/3CO + 5/2H_2O$.

461. OYAMA, YOSHITOSHI; KUWAI, GENTEI, AND OGATA, KATSUHIKO. **Effect of oxygen concentration upon the combustion rate of carbon.** *Repts. Sci. Research Inst.* (Japan) **27**, 183-90 (1951).—*C.A.* **46**, 6526*b*.

The combustion rate of a carbon rod for arc-lamp electrodes in a stream of O_2 mixed with N_2 in various ratios in an elec. furnace preheated at 710-29° increased with higher O_2 concns. (e.g., with 99% 6.45 times that with 20.5%), and at 0.7-0.8 power of the temp., but linearly when the concn. was kept const. Since higher concns. raised the temp., both affected the rate simultaneously.

462. PANCHENKOV, G. M. AND GOLOVANOV, N. V. **Kinetics of the regeneration of aluminosilicate catalysts. Nature of the processes of oxidation of the "coke" on aluminosilicate catalysts.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk* **1951**, 1513-21.—*C.A.* **47**, 4717*c*.

On 2 granular catalysts, 1 hr operation at 475°C at a space velocity of the gas oil of 0.7 gave carbon deposits of 3.9 and 6.1%, resp., of the wt of the catalyst. In the initial stages of the oxidation at 464-555°C, the rate of the oxidation increases with the flow velocity of the gas only up to a certain limit, after which it increases no further. At very low velocities of flow, the rate of oxidation becomes practically independent of the temp. At const. feed rate, the initial rate of oxidation varied little with the temp. up to 470°C, and began to increase rapidly with the temp. from 470°C up, at different rates of different catalyst prepns. For each catalyst, plots of log (relative rate of oxidation) as a function of 1/T were linear below a certain temp.; different catalysts were nearly equal to an activation energy of 31 kcal/mole.

463. POUND, G. S. **The development of low-temperature carbonization of coal.** *J. Inst. Fuel* **24**, 61-8 (1951).--*C.A.* **45**, 4424*i*.

Low-temperature carbonization processes should be of increasing importance in the production of smokeless fuel and a high yield of liquid products. The latter products include fuel oil, creosote, pitch residue, motor fuel, and Diesel oil; the whole range of tar acids from phenol to the high-boiling tar acids; and many other materials having specialized uses.

464. Ríus, A. and Fuentes, M. **The combustion of carbon at low temperature.** *Anales real soc. españ. fis. y quím.* **47B**, 555-66 (1951).—*C.A.* **46**, 3731h.

The reaction of Merck's activated, coconut char, a granulated Spanish carbon, and graphite, with atm. O_2 was studied at temps. below 300°C and at 774 mm. The oxides were dislodged by purging with gases or vapors that are preferentially adsorbed, viz., CCl_4, SiF_4, HCl, and N_2. Humidified air is more active than dry air except in the case of graphite. No formation of CO or CO_2 was observed at room temp. nor at 100°C. At 155° in a 5-hr flow of 265 cc. of air over 65 g of Merck's carbon previously washed with HCl, 0.180 and 0.005 cc. of CO_2 and CO, resp., were formed per g of carbon. At 230° and at 320° 107 g of graphite over which 2000 cc. of air passed a 2-hr period, yielded 0.005-0.210 cc. CO_2 and 0.0008-0.017 cc. CO per g C. Adsorption activity and rates of combination with O_2 were not necessarily proportional.

465. Rius, A.; Molera, M. J., and Fuentes, M. **A kinetic-chemical study of the reactivity of a sample of carbon.** *Anales real soc. españ. fis. y quím.* **47B**, 109-20 (1951).—*C.A.* **45**, 6022d.

Coconut charcoal was oxidized by mixts. of pure N_2 and O_2 at const. temps. between 190 and 300°C. The product was a mixt. of CO and CO_2 for all temps. and ratios of N_2/O_2. The activation energy was the same for the production of CO_2 as for CO. During the combustion the activation energy increased, but the oxidation effect and the relation CO_2/CO decreased. The order of the reaction was between 1 and 0.

466. Ruof, Clarence H.; Savich, T. R., and Howard, H. C. **Nuclear structure of the water-soluble polycarboxylic acids from oxidation of bituminous coal.** *J. Am. Chem. Soc.* **73**, 3873-9 (1951).—*C.A.* **46**, 3729*h*.

Mixed aromatic acids (50-60%) were obtained from 15 lb of 100-mesh Pocahontas No. 3 coal in 15 gal water contg. 45 lb com. flake NaOH treated for 2-3 hrs with O_2 at 900 lb/in^2 and 270°C. The phys. and chem. properties of the products demonstrated the presence of significant amts. of compds. with nuclear structures more complex than the C_6H_6 ring. Certain fractions of the hydrogenolysis products contained appreciable amts. of O and had properties corresponding closely to phthalans.

467. Sabel, Franz. **The oxygen slagging gas producer.** *Gas-u Wasserfach* **92**, No. 19 (Gas) 273-7 (1951).—*C.A.* **46**, 708*c*

The slagging gas producer using O_2 requires a fuel bed only about 10 to 12 ft deep. A wide variety of fuels can be used varying from waste coke (from water gas generators) to noncaking bituminous coals, both high and low-volatile. While steam is normally used with O_2 other gases, including CO_2 and coke-oven gases, can be used. In the latter case, the two gases are introduced separately; the coke-oven gas is reformed by the glowing coke to a mixt. of CO and H_2. The life of the refractories is relatively long, and the O_2 slagging producer can be shut down and again restarted without difficulty.

468. Satterfield, Charles N.; Kavanagh, Geo. M., and Resnick, Hyman. **Explosive characteristics of hydrogen peroxide vapor.** *Ind. Eng. Chem.* **43**, 2507-14 (1951).—*C.A.* **46**, 1767*a*.

The explosive limits were detd. by using hot wire, heated surfaces, and catalytic surfaces for ignition. At 1 atm. vapors contg. 26.0 mole % or more could be exploded. The lower limits at 200 and at 40 mm Hg were 33 and 55 mole %, resp. At 1 atm. vapors within the explosive region could be exploded by contact with a noncatalytic surface at 150°C or with a catalytic surface initially at room temp. The min. concn. for explosive vapor over aq. H_2O_2 was about 74 mole %.

469. Sawai, Ikutaro; Kunugi, Masanaga, and Jinno, Hiroshi. **The reaction between coke and carbon dioxide. I. Influence of diffusion velocity.** *J. Chem. Soc. Japan,* Ind. Chem. Sect. **54**, 301-3 (1951).—*C.A.* **47**, 2962*f*.

A formula was derived for the rate of reaction between coke and CO_2, taking both factors, diffusion and reaction rate, into consideration. It has been shown that below 1000°C the influence of reaction rate, and above 1400°C, that of diffusion predominate. Between 1000 and 1400°C the combined effect of the two factors should be considered.

470. Spalding, D. B. **Combustion of fuel particles.** *Fuel* **30**, 121-30 (1951).—*C.A.* **45**, 6817*i*.

The combustion of small particles of oil and carbon under conditions where convection was absent was extended to the cases of variation of thermal cond. with temp. and dissocn. of the gases. Dissocn. had the effect of doubling the combustion rate of carbon particles, above a certain temp. level, by producing a zone outside of the particle where CO burned; its effect on the combustion rates of oil droplets was likely to be small. Oil droplets burned about 13 times faster than carbon particles of the same size.

471. Terada, Hiroshi. **The relation among carbonizing temperature, carbonizing time, and width of chamber of coke oven.** *Chem. Eng.* (Japan) **15**, 348-53 (1951).—*C.A.* **46**, 1233*i*.

The carbonizing process in a coke oven is compared with the practice. An approx. formula is obtained as follows: $\epsilon = (536.99T - 68.051T^3 + 8.2646T^5) \times 10^{-4}\, {}^1\!/_2\, t$, where ϵ = width of chamber; $T = c_1/1000$; c_1 = temp. of the inside wall of the carbonizing chamber; and t = carbonizing time. This is found to coincide fairly well with the exptl. results carried out in a test oven (width = 450 mm).

472. Veselovskiĭ, V. S. and Orleanskaya, G. L. **The initial state of oxidation in hard coal.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk* **1951**, 1041-5.—*C.A.* **46**, 10579*c*.

For a harder coal, the ignition temp. did not show a systematic variation with depth, but could be correlated with the petrographic character of the coal. The ignition temp. was highly sensitive to the oxidation character of the test conditions. Pretreatment with H_2O_2 consistently lowered the ignition temp. by 10°C or more. In one case, addn. of benzidine increased the ignition temp. by 31°C.

473. VOZNESENSKIĬ, N. P. AND CHERNYSHEV, A. B. **The structure of the boundary layer in the burning of solid fuel.** *Doklady Akad. Nauk S.S.S.R.* 77, 433-4 (1951).—*C.A.* **46**, 703*e*.

The combustion of charcoal particles was subjected to motion picture studies under a 250-fold magnification. When burning was carried out in a gaseous stream of velocity = 3 m/sec, the combustion formed an ash layer 0.2-0.3 mm thick on surfaces parallel to the stream. Perpendicular to the stream the ash layer was 0.03-0.04 mm thick in some regions corresponding to "dead gas" zones and 0.2 mm or more elsewhere. The existence of such "dead gas" zones emphasized the importance of the structure of the boundary layer in the combustion of solid fuels.

474. WICKE, E. **Flow diffusion and reaction in the combustion of coal.** *Chem.-Ing.-Tech.* **23**, 420-2 (1951).—*C.A.* **46**, 235*b*.

Data were presented for CO formation as function of coal sample size, temp. and reaction time. The $CO:CO_2$ ratio was influenced equally by reaction kinetics and transport processes.

475. WILDENSTEIN, RAOUL. **New method of direct determination of oxygen particularly applicable to coals.** *Chaleur & ind.* **32**, 293-8 (1951).—*C.A.* **46** 705*i*.

The sample was pyrolyzed in a current of purified H_2. The effluent gas was cracked on platinized pumice at 900°C. Then S was removed by reduction on Ni, NH_3 was absorbed with H_3BO_3, H_2O was absorbed by $Mg(ClO_4)_2$, and CO_2 by NaOH plus asbestos. The residual CO was then oxidized to CO_2 with I_2O_5. The CO_2 was absorbed in 0.1 *N* NaOH contg. a little $Na_2S_2O_3$, which prevented discoloring effects of HOI and HI.

476. ANDERSON, R. B. AND EMMETT, P. H. **Surface complexes on carbon blacks. I. High-temperature evacuation studies.** *J. Phys. Chem.* **56**, 753-5 (1952).—*C.A.* **47**, 20c.

Surface complexes were studied by heating the carbon blacks during evacuation at temps. as high as 1200°C and collecting and analyzing the evolved gases. Much of the water vapor and CO_2 was given off at or below 600°C. The CO and H were evolved primarily in the 600-900° and 900-1200°C regions, resp. Surface-area measurements showed that the gas evolution from Spheron 6, Black Pearls 1, and Mogul could be accounted for by a unimol. layer of surface complexes. The gas from Lampblack T was several fold too great to be attributed to a single layer of surface complex.

477. ARTHUR, J. R. AND BLEACH, J. A. **Mode of energy release in combustion of carbon.** *Ind. Eng. Chem.* **44**, 1028-33 (1952).—*C.A.* **46**, 7733*d*.

Glow in a burning fuel bed was traced to the oxidation of CO and was found to depend largely on the rate of air flow and the quantity of water vapor present in the air. The intensity of the flow could be increased by pretreating the fuel with Na_2CO_3 or $CuCl_2$.

478. BASTICK, MARTHE. **Direct determination of oxygen in coal. I. Carbon reduction method.** *Bull. soc. chim. France* **1952**, 308-9.—*C.A.* **46**, 7304*i*.

The sample was pyrolyzed in a current of N_2, and O-contg. decompn. products transformed to CO on a carbon column at 1200°C. The best method of oxidizing the CO to CO_2 was found to be by means of platinized Pyrex beads as a catalyst. The interference caused by mineral matter was studied. The O content of $CaSO_4$ and $CaCO_3$ was included in the detn., that of Fe oxides partly.

479. BEHRENS, H. **Elementary processes in the combustion and gasification of coal.** *Chem.-Ing.-Tech.* **24**, 349-52 (1952).—*C.A.* **46**, 8345*f*.

A treatise based on new exptl. data reported by English and Russian authors interpreted by reaction kinetic studies. The presumable reactions of the 3 reaction stages are: $C(s) + \frac{1}{2}O_2 = CO$, $CO + \frac{1}{2}O_2 = CO_2$, and $CO_2 + C(s) = 2CO$.

480. BLACKWOOD, J. D. AND BOWDEN, F. P. **The initiation and thermal decomposition of gunpowder.** *Proc. Roy. Soc.* (London) **A213**, 285-306 (1952).—*C.A.* **46**, 10623f.

Initiation is due to formation of local hot spots which may be formed by adiabatic compression of air pockets or by friction of grit particles. The necessary hot-spot temp. is 130°C which suffices to melt the S. The formation of liquid phase is important, and it is suggested that the process starts with the reaction of molten S with oxyhydrocarbons present. The initial reaction develops until the oxidation of charcoal by KNO_3 is established. High-speed camera reveals that the gunpowder grains burn slowly layerwise. The rapid propagation from grain to grain is probably due to emission of hot spray of molten droplets of K salts.

481. BLANZAT AND BARBE. **Rapid method of determining oxygen in coal.** *Bull. soc. chim. France* **1952**, 569-73.—*C.A.* **46**, 9825*i*.

The coal is pyrolyzed in a current of N_2, the O-compds. formed are reduced to CO with benzene black at 1200°C, the CO is oxidized to CO_2 in the cold with I_2O_5 on SiO_2 gel, and the CO_2 is absorbed in ascarite and weighed. The method differs from others of similar type by using com. N_2, a reaction tube of fritted Al_2O_3, and a very efficient I_2O_5 reagent. S compds. in coals do not interfere, but a correction is needed for the O-content of the ash.

482. BRENDER Á BRANDIS, G. A. AND FELSBOURG, J. **The reactivity of coke especially to steam.** *Gas World* **135**, 689-90 (1952).—*C.A.* **46**, 7742*e*.

The quantity of steam which is passed through the column of hot coke during a certain time can be accurately detd. on completion of the test. The proportion of steam decompd. can be accurately detd. The results of tests on the reactivities of 6 cokes in this app. are included.

483. BROWN, F. **Exchange of carbon^{14} between elementary carbon and its oxides.** *Trans. Faraday Soc.* **48**, 1005-14 (1952).—*C.A.* **47**, 5223*g*.

Sugar carbon or graphite acquires C atoms from the gas $C^{14}O$ or $C^{14}O_2$. At room temps. to 700°C no reaction takes place and no activity is acquired by the surface. The radioactivity acquired above 700°C is due to elementary C; the sample could be pumped out repeatedly as high as 1000°C without any change in its radioactive counting rate; also, treatment of the sample with boiling water and hot acids did not remove the activity. When CO_2 is reduced on a surface, a fraction (perhaps 1-2% with sugar carbon) of the reacting CO_2 deposits C atoms into the surface so that the O atoms depart, as CO, with two new C atoms derived from the surface. In the remaining majority of cases only one C atom is taken from the surface and no deposition made. The fraction of CO_2 reacting in this special way is much lower with graphite.

484. CEDERQUIST, K. N. AND BERING, P. **Wet combustion, a process for the utilization of peat.** *Acta Polytech., Chem. Met. Ser.* **3**, No. 1, 5-34 (1952).—*C.A.* **47**, 2959*f*.

The crude peat, contg. 85-95% water, is heated by oxidation of 10-20% of the solid material with O_2 or air under a pressure of 15-30 kg/cm^2 to a temp. of 170-200°C. The colloidal form of the peat is broken down and the material becomes a free-flowing suspension. Filtration and pressing reduce the water content to about 50%.

485. CHÉREAU, JEAN. **A thermogravimetric study of the air oxidation of a coal between 100° and 270°.** *Compt. rend.* **234**, 1165-6 (1952).—*C.A.* **47**, 289*g*.

A coal contg. 34% volatile material was heated for periods up to 3 days. A plot of percent change in wt *vs.* time gave a group of isochronic curves, all of which showed an initial gain in wt followed by a loss at the higher temps. The max. of each curve was at a point corresponding to a 6.7% gain in wt. A test of the same coal showed that I_2 was adsorbed in an amt. equiv. to 6.8% of O_2. The expts. indicated that O_2 was adsorbed by the coal by adding to double bonds.

486. CHÉREAU, JEAN. **An anomaly in thermogravimetric isothermal curves registered with coal heated in contact with air.** *Compt. rend.* **234**, 1368-70 (1952).—*C.A.* **46**, 6807*f*.

On heating powd. coal in a thermobalance at const. temp., a sharp max. in the mass-time curve appeared as soon as the moisture was expelled, in the presence of air but not N_2 alone. This anomaly became more marked the higher the temp. and the smaller the particle size. This was attributed to a surface activation owing to grinding.

487. DEINUM, H. W. AND GOEDKOOP, M. L. **The direct gravimetric determination of moisture in coal.** *Chem. Weekblad* **48**, 170-3 (1952).—*C.A.* **46**, 6807*d*.

Approx. 2 g of coal (less than 0.3 mm) is accurately weighed in a Ni boat which is then immediately placed in a combustion tube. The coal is heated for 30 min. at 105°C while a stream of O_2 free N_2 (36 liter/hr) carries the H_2O into an absorption tube filled with Anhydrone. Excellent checks are obtained by either weighing the Anhydrone with the H_2O or by weighing the residual coal sample. Heating of the coal sample to 150°C during the analysis has very little influence on the results.

488. DONNELLY, R. P.; BROADBENT, R. AND O'LEARY, B. J. **Influence of iron oxide on the reactivity of low-rank coals from Collie, Western Australia.** *Fuel* **31**, 418-28 (1952).—*C.A.* **46**, 11634*f*.

The reactivity of perlignitous coals is low when Fe_2O_2 is absent from the intrinsic ash but high where it is present. Fe_2O_3 in the extraneous ash has no effect. HCl vapor removes Fe_2O_3 from reactive surfaces and thereby reduces reactivity towards CO_2; but where Fe_2O_3 is already absent from reactive surfaces HCl enhances reactivity. Fe_2O_3-free coals, because of low reactivity, are used preferentially as a substitute for coke in water-gas plants and on cupolas.

489. DUVAL, XAVIER. **Study of oxygen adsorption by its thermoelectric emission.** *Compt. rend.* **234**, 208-10 (1952).—*C.A.* **46**, 4881*e*.

The thermoelec. emission was measured for a carbon filament at 1150° to 2000° K in a highly evacuated tube to which O_2 was admitted at 5×10^{-5} to 5×10^{-4} mm. The O_2 had no detectable influence on emission, and hence forms no surface film. Absence of previous O contamination of the C surface was shown by measurements before and after the filament was heated to 2800° K.

490. EDMISTER, WAYNE C.; PERRY, HARRY; COREY, R. C., AND ELLIOTT, M. A. **Thermodynamics of gasification of coal with oxygen and steam. Charts for material and enthalpy balance calculations.** *Trans. Am. Soc. Mech. Engrs.* **74**, 621-36 (1952).—*C.A.* **46**, 7733*a*.

The heat balance and product-gas yield and compn. for the gasification of coal with O_2 and steam were detd. on the assumption that the water-gas shift equil. is attained for the product gases. The charts were of general applicability for any rank of coal; they covered a wide range of operating conditions through the use of multiple parameters and can be used for pressures as high as 30 atm.

491. ELLIOTT, M. A.; PERRY, HARRY; JONAKIN, JAMES; COREY, R. C., AND KHULLAR, M. L. **Gasification of pulverized coal with oxygen and steam in a vortex reactor.** *Ind. Eng. Chem.* **44**, 1074-82 (1952).—*C.A.* **46**, 7733*e*.

Effects of ratio of O_2 to coal and depth of reactor on carbon conversion and production of synthesis gas are discussed. Diffusion is an important factor in these gasification reactions, and one of the most effective means for obtaining controlled relative velocity is to gasify in a vortex reactor equipped with multiple entrant tangential slots.

492. FRANKE, N. W.; KIEBLER, M. W.; RUOF, C. H.; SAVICH, T. R., AND HOWARD, H. C. **Water-soluble polycarboxylic acids by oxidation of coal.** *Ind. Eng. Chem.* **44**, 2784-92 (1952).—*C.A.* **47**, 1917*a*.

A description of lab. and pilot-plant equipment and procedure for oxidations of coals with gaseous O_2 and aq. NaOH up to 270°C and 900 lb/in^2. Humic acid formation reaches a max. when 1.5 *N* NaOH is used and decreases, with increased formation of sol. acids, as the NaOH concn. is increased. Sol. acids up to about 50% of the C in the original coal are isolated by acidification and extn. with MeCOEt; these contain benzene carboxylic acids and aromatic acids with more complex nuclei.

493. GEL'D, P. V.; VLASOV, V. G., AND SEREBRENNIKOV, N. N. **Reactions of oxides and their compounds with solid carbon.** *Zhur. Priklad. Khim.* **25**, 121-33 (1952).—*C.A.* **47**, 4704*h*.

Reduction of oxides (Cr_2O_3, MnO, ZnO, $Ca_3(PO_4)_2$) by carbon was investigated by the loss of wt of pressed mixts. of the oxide with graphite on heating at a const. temp. (~850-1150°C). CO_2 produced proved to be remarkably const. with batches $Cr_2O_3 + 4.5C$ and MnO+ 4C. In the case of $Ca_3(PO_4)_2$, the rate of reduction was slower under 1 atm. than *in vacuo*, and the activation energy fell to 17,000 cal/mole. The contrast between the behavior of $Ca_3(PO_4)_2$ and the other oxides can be explained by accumulation of P_2 vapor, according to $Ca_3(PO_4)_2 + 5\ CO \rightarrow 3\ CaO + 5\ CO_2 + P_2$, as a result of which the partial pressure of CO_2 in the system depended also on the total pressure and on the pressure of P_2.

494. GEORGIADIS, C. **Direct oxygen determination in coal. Improved Spooner method.** *J. usines gaz* **76**, 188-90 (1952).—*C.A.* **47**, 6115*d*.

O_2 is detd. directly in coal by passing purified N_2 through a tube 60 cm long, 20 mm in diam., and heated over 21 cm to 1150°C; 6 cm are required for the boat contg. the coal sample and 16 cm for the 3-5 mm plug of charcoal following the sample. The O of the coal is converted to CO, the gases are passed through Cd acetate to remove the H_2S and through various agents to remove the H_2O and CO_2, the CO is then oxidized over hopcalite catalyst, and the CO_2 is absorbed and detd.

495. GUÉRIN, HENRI AND BASTICK, MARTHE. **Determination of oxygen in coal.** *Compt. rend.* **234**, 218-20 (1952).—*C.A.* **46**, 7935*a*.

Heat 0.5 g of coal *in vacuo* (5 mm) at 1000°C and trap the H_2O, CO_2 and carbides formed at -195°C while CO, CH_4, and N are adsorbed on silica gel. After gasometrically detg. H_2O, CO_2 and CO, calc. the O_2 present in the original coal. Carbonization at successive temp. increments up to 1000°C permits the process of gas liberation to be followed, and the actual compn. of different coals to be investigated.

496. GULBRANSEN, EARL A. AND ANDREW, KENNETH F. **Reactions of artificial graphite. Kinetics of oxidation of artificial graphite at temperatures of 425° to 575° and pressures of 0.15 to 9.8 cm of mercury of oxygen.** *Ind. Eng. Chem.* **44**, 1034-8 (1952).—*C.A.* **46**, 7734*c*.

The oxidation was studied by means of the microbalance method. Rate data can be fitted to the equation $W = Kt + Ct^2$ where K and C are consts. and t is time. The calcd. energy of activation was 36,700 cal/mole. As a function of pressure, K followed the equation $K = A + BP$, where A and B were consts.

497. GULBRANSEN, EARL A. AND ANDREW, KENNETH F. **Surface oxide formation and surface roughness studies in relation to oxidation of artificial graphite at temperatures of 25° and between 425° and 575°C.** *Ind. Eng. Chem.* **44**, 1039-44 (1952).—*C.A.* **46**, 7734*d*.

The effect of pretreatment of graphite with O_2 on the rate of reaction with O_2 was investigated. The formation of the surface oxide at 500°C was a gradual and not an instantaneous process. Surface roughness as detd. by adsorption of Kr at liquid-N_2 temps. can be correlated to the value calcd. from the extent of surface-oxide formation. Heating at 950°C increased surface roughness as does oxidation at 500°C while oxidation at room temp. decreased surface roughness.

498. GULBRANSEN, EARL A. **Mechanism of the oxidation of graphite at temperatures of 425° to 575°C.** *Ind. Eng. Chem.* **44**, 1045-7 (1952).—*C.A.* **46**, 7734*f*.

Theoretical rate expressions for the oxidation of graphite were compared with exptl. rates of reaction. Two adsorption processes, immobile adsorption with dissociations and mobile adsorption, were shown to be possibly the rate-controlling processes for the oxidation of pure graphite.

499. GUMZ, WILHELM. **Gasification of solid fuels at elevated pressures.** *Ind. Eng. Chem.* **44**, 1071-4 (1952).—*C.A.* **46**, 7733*b*.

Gasification of solid fuels under pressures of 20 to 30 atm. offers advantages in high capacity and high fuel rates, low O_2 consumption, and decrease in cost of labor and product gas. The effect of pressure on gas compn., pressure drop in the fuel bed, and terminal velocity of suspended particles is calcd. and compared with exptl. data.

500. HÖNL, H. AND WOLFF, W. T. E. v. **Quantitative analysis of the combustion process in a coal tube. I. Theoretical.** *Z. physik. Chem.* **201**, 278-301 (1952).—*C.A.* **47**, 7188*f*.

The combustion process with O_2 proceed at the surface of the coal: (1) $2C + O_2 = 2CO$; (2) $C + O_2 = CO_2$; (3) $2CO + O_2 = 2CO_2$. The combustion process is discussed and calcd. quantitatively for the case that only reaction 1 takes place, reactions 2 and 3 being inhibited. The further assumption is made that no convection or diffusion of the reacting gases occurs.

501. INGLES, O. G. **Water gas shift reaction in fuel systems. I. Water gas shift on carbon.** *Trans. Faraday Soc.* **48**, 706-12 (1952).—*C.A.* **47**, 2457*e*.

The reaction in the presence of a pure sugar charcoal was studied by means of a flow technique between 750 and 850°C. The experimentally observed characteristics of the reaction were explained on the basis of a chain mechanism: $H + H_2O \rightleftharpoons OH + H_2$, $OH + CO \rightleftharpoons CO_2 + H$. The role of the charcoal was that of a chain initiator. The chain length was estd. to be very short. The extent to which the reaction, $2CO \rightarrow CO_2 + C$, occurred under the exptl. conditions was detd. by passing CO alone over the charcoal. Formation of CO_2 was found to be less than 0.0002 g/min.

502. JOHNSTONE, H. F.; CHEN, C. Y., AND SCOTT, DONALD S. **Kinetics of the steam-carbon reaction in porous graphite tubes.** *Ind. Eng. Chem.* **44**, 1564-9 (1952).—*C.A.* **46**, 8349*h*.

The integral and differential techniques were used. Individual rate coeffs. were detd. for the component reactions at temps. between 862° and 938°C. The mechanism of the reaction consisted of adsorption of water mols. on dual active centers, followed by relatively slow reaction with the carbon to form CO and H_2. The latter was strongly adsorbed and acted as a retardant to the over-all reaction. The water-gas shift reaction rapidly approached equil. in this system.

503. Kinney, C. R. and Friedman, L. D. **Ozonization studies of coal constitution.** *J. Am. Chem. Soc.* 74, 57-61 (1952).—*C.A.* 47, 1353*i*.

Moist O_3 converts a significant fraction of the C of carbon black and lamp black directly to water-sol. products without intermediate formation of humic acids. The results of ozonization of aq. alk. solns. of humic acids depend on the source of the acid and the temp. of prepn. of the soln.

504. Kleier, N. P. and Man'ko, N. M. **Kinetics of the activated adsorption of oxygen and of hydrogen on carbons with different contents of mineral impurities.** *Doklady Akad. Nauk S.S.S.R.* **83**, 713-16 (1952).—*C.A.* **46**, 6911*f*.

Salts of K, Ca, Fe, Ni, Ag, and Pt, in the amt. of 1%, were introduced by impregnation into activated birch charcoal, purified by treatment with NaF in HNO_3. Rates of adsorption were followed over 200 min., with O_2 at 182°C and with H_2 at 485°C. Addn. of Fe decreased whereas Ca, K, and Pt increased the rate of the adsorption. On silica gel, which is a poor adsorbent for H_2, the mineral salts had practically no effect on the rate of adsorption. Addns. of Ca, K, Pt, and Ni increased the no. of sites with low activation energies whereas Fe practically suppressed such sites. The effects of the salts on the adsorptions of O_2 and of H_2 differed; this was attributed to these 2 gases being adsorbed on different parts of the surface.

505. Kuchta, J. M.; Kant, A., and Damon, G. H. **Combustion of carbon in high-temperature high-velocity air streams.** *Ind. Eng. Chem.* **44**, 1559-63 (1952).—*C.A.* **46**, 8351c.

The kinetics of the combustion of spectroscopic-grade electrode carbon was studied for air velocities between 28 and 540 ft/sec and for air temps. between 900° and 1200°C. The reaction could be described by a diffusion-type equation in which the specific reaction rate was proportional to the square root of the air velocity or inversely proportional to a film-resistance parameter and relatively independent of the ambient temp. The exptl. data agreed in general with the Arrhenius-type equation in which the specific reaction rate was primarily dependent on the surface temp. of the reacting C. It appears that the reaction of C and O_2 under these exptl. conditions lay in an intermediate or transition region where both diffusion and chem. reactivity were rate-controlling factors.

506. Lebedev, A. N.; Volkov, I. I., and Efremov, M. A. **The combustion of ASh (anthracite dust) and mixtures of it with low-grade coal.** *Izvest. Vsesoyuz. Teplotekh. Inst. im. Feliksa Dzerzhinskogo* **21**, No. 5, 17-20 (1952).—*C.A.* **46**, 8346*e*.

The exptl. continuous combustion of ASh over a period of 8 hrs and mixts. with low-grade coals over a period of 100 hrs in a two-stage, completely insulated furnace operating at only 65-70% of capacity steam production, occurred smoothly and safely.

507. Mandal, A. K. and Orning, A. A. **A test of a reported effect of pulverization upon the carbonization properties of coal.** *Fuel* **31**, 33-6 (1952).—*C.A.* **46**, 1734*e*.

Pulverized samples formed into 1-g pellets were heated as in the volatile matter test. Swelling was prevented by oxidation, even for a strongly coking coal, but was not eliminated by pulverization alone. As judged by the yield of oxides of C upon thermal decompn. under vacuum at 350°C, the extent of swelling was closely related to the degree of oxidation of the coals. Oxidation rather than pulverization was concluded to be responsible for the observed effects on carbonization properties.

508. Mehta, M. M.; Kini, K. A.; Moitra, A. K., and Lahiri, A. **Absorption of oxygen by Indian coals.** *J. Sci. Ind. Research* (India) **11B**, 418-22 (1952).—*C.A.* **47**, 3543*a*.

Investigations of O_2 absorption by Indian coals of varying stability show low values for stable coals. CO_2:CO ratio in the oxidation products is greater than 1 for the coals tested and increases with humidity. O_2 absorption reaches a max. at 40% relative humidity.

509. Oreshko, V. F. and Tislin, T. S. **Effect of thermal treatment of coal on its oxidation.** *Zhur. Priklad. Khim.* (J. Applied Chem.) **25**, 373-83 (1952).—*C.A.* **46**, 7303*g*.

Coal heated in a N_2 stream to 270-340°C suffers thermal decompn. with loss of the least polymerized components which form part of the lyophilic cover of coal micelles which can react with O_2 forming low-temp. complexes. After removal of these products, the residue shows a sharp rise of formation of high-temp. complexes with O_2, although the ignition temp. remains the same even after treatment at 390-400°C. Thermal treatment at 430-40°C causes a rise of ignition temp. with higher rate of formation of high-temp. O_2 complexes and accelerates crystn. processes in the coal mass.

510. Panchenkov, G. M. and Golovanov, N. V. **Kinetics of the regeneration of aluminosilicate catalysts. Mechanism of the reaction of oxidation of "coke" on aluminosilicate catalysts.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk* **1952**, 384-94.—*C.A.* 47, 4717*h*.

In the earliest initial stages of the oxidation of the "coke" deposited on aluminosilicates, there is observed at 270-428°C not a decrease but an increase of the wt. No wt increase is found with a gas rigorously free from O_2; the effect, therefore, must be due to an adsorption of O_2 by the coke. With increasing concn. of O_2 in the gas the kinetic order of the rate of oxidation, at 415°C, passes from 1st to zero order; at 500°C the rate is 1st-order in O_2 up to 30% O_2 in the gas, and becomes self-accelerated at higher O_2 contents as a result of heat evolution. The initial increase of wt, followed by a period of decreasing wt, indicates that the oxidation is a 2-stage process; the 1st stage consists in the formation of a complex C_xO_y; this complex can remain stable in an inert atm., but undergoes further oxidation to CO_2 and CO in the presence of O_2. A certain amt. of the C_xO_y complex is present in the coke before the start of the oxidation.

511. Panchenkov, G. M. and Golovanov, N. V. **Kinetics of the regeneration of aluminosilicate catalysts. Oxidation of the coke on the catalyst in tubes at variable concentration of oxygen along the catalyst layer.** *Izvest. Akad. Nauk S.S.S.R., Otdel, Tekh. Nauk* **1952**, 1031-6.—*C.A.* **47**, 4718*i*.

The general expression of the rate of a heterogeneous chem. reaction in which the reactant occupies a surface area σ per unit surface area of catalyst, and S_o is the surface area of catalyst per unit length of layer in the direction of the flow, is $n_o(dy/dl) = k'S_o\,\sigma$, where n_o is the feed rate at the entrance, and y is the mole fraction of mols. reacting at the distance l from the entrance; S_o is proportional to the vol. v_c of catalyst per unit length of layer. In application to the regeneration of a catalyst in a stream of O_2, under pressure P_o, Langmuir's scheme for a 1st-order surface reaction gives $\sigma = bP_o$; the sp rate of consumption of O_2 per unit length under $P_o = 1$ is $w_l = kb$, and the rate of its consumption if the mole fraction of O_2 in the gas is a, is $w_a = w_1 a$.

512. Parts, A. G. **The water-gas-shift equilibrium in the gasification of lignite with steam.** *Australian J. Appl. Sci.* **3**, 257-61 (1952).—*C.A.* **46**, 10582*b*.

It is shown that the compn. of the exit gases from a lignite-pilot plant always corresponded to the establishment of equil. of the water-gas-shift reaction at a theoretical temp. of 1000°K. At such low temp., establishment of the water-gas-shift equil. is thought to be due to catalysis by the fly-ash. Reactions leading to the formation of methane, ethane, and illuminants do not lead to an equil., but the sum of the formed hydrocarbons is proportional to the fraction of total decompd. steam.

513. Reif, Arnold E. **A study of the reactions of carbon monoxide with coke.** *J. Phys. Chem.* **56**, 778-84 (1952).—*C.A.* **46**, 8828*h*.

The reaction between CO and degassed coke has been investigated between 700-1000°C and 1-63 mm Hg. The initial process was an adsorption of CO on the coke. The adsorbed complex (CO) reacted with another CO: $CO + (CO) \rightarrow CO_2 + C$. Increasing CO_2 concn. causes: $C + CO_2 \rightarrow CO + (CO)$ and $CO_2 \rightarrow (O) + CO$. At 700° and 800°C the amount of CO_2 formed after a 90 min. period was only 2 and 17%, resp., of the equil. values and adsorption had practically ceased; at 900° and 1000°C, however, 44 and 66%, resp., were reached and adsorption was still appreciable.

514. Reif, Arnold E. **The mechanism of the carbon dioxide-carbon reaction.** *J. Phys. Chem.* **56**, 785-8 (1952).—*C.A.* **46**, 8828*g*.

The reaction of degassed coke with CO_2 at 900°C is given by the equations: $CO_2 \rightleftharpoons (O) + CO$ and $C + O \rightleftharpoons CO$, where (O) represents a mol. chemically bonded to the surface. These equations hold for all carbonaceous fuels, but the rate consts. vary widely with compn. and reactivity.

515. Riddiford, A. C. **Temperature coefficient of heterogeneous reactions.** *J. Phys. Chem.* **56**, 745-8 (1952).—*C.A.* **46**, 8940*h*.

The Nernst diffusion theory of heterogeneous reaction rates was extended to the general case of a solid-fluid system wherein the observed rate depends on both the chem. reaction rate at the surface and the transport process rate. These two rates were used to produce a simple, general treatment of the temp. coeff. of heterogeneous reactions. An example of a case where the transition from chem. to transport control occurred with temp. was the combustion of carbon spheres in a flowing gas stream.

516. Sebastian, John J. S. **Powdered-coal gasification. Effect of variables.** *Ind. Eng. Chem.* **44**, 1175-84 (1952).—*C.A.* **46**, 6363*b*.

Young, high-volatile coals yield better results than high-rank, low-volatile coals. High-ash or high-S coals can be gasified in entrainment with equal ease as high-grade coals, whether the coal is strongly coking or non-coking. For a given coal of predetd. particle size gasified in preliminary tests, the O:coal ratio, steam:coal ratio, and steam temp. can be so selected from graphs that, in all probability, good conversion with lowest O_2 and steam requirement will be obtained in large-scale pilot gasifiers.

517. Sevenster, P. G. **The oxygen-absorption characteristics of South African coals.** *J. Chem. Met. Mining Soc. S. Africa* **53**, 163-76 (1952).—*C.A.* **47**, 7189*b*.

The O_2 absorption was 100-700 ml at 30°C and 170-1200 ml at 60°C per 100 g of coal. A rough relationship was found to exist between O_2 adsorption and moisture content, both on the air-dry and inherent bases.

518. Thring, M. W. **Physics of fuel-bed combustion.** *Fuel* **31**, 355-64 (1952).—*C.A.* **46**, 7729*c*.

To evaluate the phys. reaction rates it is assumed, first, that O_2 diffuses through a stagnant layer to the surface where it reacts infinitely quickly to form CO which diffuses back to the turbulent core of the gas flow in the space between the fuel particles where it reacts infinitely quickly to form CO_2 as long as any O_2 remains in this core. Any of the resulting CO_2 that diffuses back to the fuel surfaces reacts with infinite rapidity to produce CO. Second, it is assumed that the diffusion processes obey Stefan's law, and this can be approximated as diffusion through a nonreacting gas present in much greater quantity. From these assumption the partial pressure of O_2 in the voids between the particles is related to the distance through the bed. For a fuel bed of particles 3 cm in size at 1200°, the distance for pO_2 to vanish is then found to be 3 to 4 cm, in good agreement with expt.

519. Traustel, S. **Industrial testing of the reactivity of cokes.** *Metall* **6**, 298-302 (1952).—*C.A.* **46**, 8832*d*.

Methods for detg. the reactivity of various cokes are discussed, based upon their reaction with a mixt. of CO_2 and CO.

520. Weisz, H. L. and Orning, A. A. **Reactivity of cokes.** *Fuel* **31**, 288-301 (1952).—*C.A.* **46**, 7742*b*.

A reactivity test is based on measurements of adibatic self-heating rates of a fuel sample in a stream of air or O_2. Temps. at which the solid fuel attains self-heating rates of 15° and 75°C per min. are reported as reactivity indexes T_{15} and T_{75}, resp. These indexes were detd. for 122 cokes in air and 92 cokes in O_2. The relations show a dominant influence of the chem. nature of the solid as measured by the volatile content, which in turn is detd. primarily by the max. temp. of carbonization. The effect of pore-surface distribution is significant but small as compared to the dominant influence of the nature of the solid.

521. Wicke, E. **Primary processes in the burning of graphitic carbon.** *Z. Elektrochem.* **56**, 414-20 (1952).—*C.A.* **47**, 294*i*.

Exptl. studies of graphite combustion are reviewed, and conclusions drawn from these investigations are summarized.

522. Wynne-Jones, W. F. K.; Blayden, H. E., and Marsh, H. **The reactivity of carbon.** *Brennstoff-Chem.* **33**, 238-41 (1952).—*C.A.* **46**, 10578*d*.

The most important single factor in the reactivity of carbons is the presence of traces of metallic impurities, probably as carbides. The nature of the carbon also has an influence, and different forms show very great differences in reactivity, at least in the presence of impurities. This may not be entirely a surface effect. The formation of gaseous oxides is invariably accompanied by the formation of oxides at the surface, and there is a const. relation between combined O and the pressure of the gaseous C oxides.

523. Zollikofer, H. **Oxygen content of coal and effect on gas production.** *Schweiz. Ver. Gas-u. Wasserfach Monats.-Bull.* **32**, 386-7 (1952).—*C.A.* **47**, 7189*c*.

A discussion and data on the relation between the O in coal and the CO content of resulting carbonization gas.

524. Adam-Gironne, Jean. **The thioreactivity of fuel. II. Study of the catalytic action of certain mineral compounds.** *Bull. soc. chim. France* **1953**, 446-7.—*C.A.* **47**, 7196*g*.

The influence of metallic salts on the reaction of S vapor with wood charcoal to form CS_2 was studied. An optimum concn. of catalyst existed for each salt. Na, K, Ca, Mg, and Pb salts increased the reactivity of the charcoal, while Mo, Ag, Ni, Fe, Co, Th, V, Cu, Mn, and Al did not. The large effect of Na did not appear to diminish appreciably even after 40% of the charcoal has been transformed to CS_2.

525. Busso, R. H. **A study of the production of light and the occurrence of metastable active centers in the combustion of graphite.** *J. chim. phys.* **50**, 53-9 (1953).—*C.A.* **47**, 6258*d*.

Ultraviolet of wave length 1900-2800 A. was produced in the course of the oxidation of graphite at 1500°C in air at pressures of 10^{-2}–15 cm Hg. Above 5 cm Hg, the light was formed by excited metastable CO_2 (mean life of several tenths of a sec) returning to its normal state, while at pressure below 5 cm Hg, excited metastable CO (probably in the $A^3\Pi$ state) with a mean life of about a sec was present as the light source.

526. Godsave, G. A. E. **Rates of combustion of solid-fuel particles.** *Nature* **171**, 86 (1953).—*C.A.* **47**, 4577*i*.

When a carbon sphere was burned in an air stream with a surface temp. greater than about 800°C, the rate-controlling process was the diffusion of O_2 through the gas film to the surface. This rate can be predicted by a semiempirical equation for mass transfer as a function of Reynolds no. (Re) and Schmidt no. (Re between 2 and 800). For spheres between 800 and 1400°C, the equation reduced to $S = 0.347\ (1 + 0.272\ (Re)^{1/2})\ Dp/d$, where S was specific reaction rate (g/cm²-sec), D was diffusion coeff. of O_2 in the gas (cm²/sec), p was gas density (g/cc.), and d is sphere diam. (cm).

527. Guérin, Henri and Adam-Gironne, Jean. **The thioreactivity of combustible solids. I. Test method and comparison of combustibles of various types and of charcoals made from woods of various species.** *Bull. soc. chim. France* **1953**, 302-3.—*C.A.* **47**, 5664*i*.

A test procedure is described in which S vapor flows at a constant rate over a carbonaceous sample at 800°C, and the gaseous products are analyzed. The index of thioreactivity is defined as the percentage of S transformed to CS_2. Results reported for 13 species of wood charcoal show that the index varies between 45.6 (olive wood) and 59.1 (beech wood). The index is 24.7 for anthracite, 2.9 for gas coke, and 0.6 for graphite.

528. Guérin, Henri and Bastick, Marthe. **The direct determination of oxygen in coals. III. Method of pyrolysis in vacuum.** *Bull. soc. chim. France* **1953**, 304-6.—*C.A.* **47**, 6115*e*.

The sample is heated to 1000°C and the gaseous products are passed over a silica cracking column heated to 900°C. The CO, CO_2, and H_2O which are formed are detd. separately and the total-O is calcd. The ratios of these 3 products remain const. for each type of coal and their formation can be studied as a function of temp.

529. Pourbaix, M.; Gottignies, L., and Berger, R. **Method of measuring the reactivity of cokes.** *Chaleur & ind.* **34**, 70-6 (1953).—*C.A.* **47**, 5664*g*.

Exptl. arrangements are described for studying the reaction of CO_2 with coke in the temp. range 800-1100°C. Some typical results are given which show the CO/CO_2 ratio obtained for several metallurgical cokes.

I-6. Hydrogen on Metals

530. Hofsten, Sven von; Kalling, Bo; Johansson, Folke, and Knös, Oof. **Absorption and desorption of hydrogen in the manufacture of steel.** *Jernkontorets Ann.* **123**, 485-526 (1939).—*C.A.* **34**, 2302^2.

A series of measurements were carried out in full-scale furnaces on gas compn. and the H-content of the molten metal. Samples of the molten metal were analyzed for H_2 by vacuum melting, and for carbon. The H-content of the gas dropped as the carbon was burned out. This was attributed to the diffusion of dissolved H_2 into bubbles of CO formed during the decarbonization process. If the furnace gas contained H_2 or any of its compds., the dehydrogenation was incomplete and reached an equil. value. The absorption of H_2 was promoted by a high partial pressure in the gas and partly hindered by a protective surface slag, but the rate of decarbonization seemed to have no influence.

531. Barrer, R. M. **Stationary and nonstationary states of flow and hydrogen-palladium and iron.** *Trans. Faraday Soc.* **36**, 1235-48 (1940).—*C.A.* **35**, 2382^9.

The diffusion consts. and permeability of H_2 were detd. for Pd from room temp. to 350°C and for Fe over the interval 0 to 80°C. The systems studied were: thermal diffusion of H_2 through a Pd disk; H_2 through Fe and Pd cathodes having "inactive surfaces" and "active surface conditions"; H_2 from HCl through rolled Fe sheet and through steel; H_2 by electrolysis through Fe. Phase-boundary reactions and diffusions were the variables, but not adsorption effects.

532. Eilender, W.; Chiu, Y. C., and Willems, F. **The effect of hydrogen in steels of different composition.** *Arch. Eisenhüttenw.* **13**, 309-16 (1940).—*C.A.* **34**, 2307^1.

Plain and alloy steels were melted with different methods of deoxidation, the H-content was artifically increased, and structure, H-content and H_2 escape were detd. The H_2 escape became more difficult in unalloyed steels with increasing C content, and also in low-C steels by addn. of alloying elements, except in Cb steels, in which the velocity of the escape of gas increased with increasing Cb content.

533. Herasymenko, P. and Combroski, P. **Hydrogen equilibria in the production of steel.** *Arch. Eisenhüttenw.* **14**, 109-15 (1940).—*C.A.* **35**, 718^9.

To prevent loss of H_2 that occurs on sampling and cooling in the air, 100 g steel was poured into an iron tube which could be connected to a vacuum app. H_2 was determined by heating in an elec. furnace to 900-950°C. The H-content increased considerably during reduction in the arc furnace; it varied much during oxidation. For open-hearth melts, the H-content was independent of the boiling of the melt. A parallel course was found between Mn-content and H-content.

534. Lepp, Henry. **The oxygen-hydrogen-molten iron system.** *J. Iron Steel Inst. (London)*, Advance copy, May, **1940**, 9 pp.—*C.A.* **34**, 3158^7.

Previous studies of the reaction between H_2 and molten Fe neglected the absorption of H_2. The action of water vapor with molten Fe was represented by $2FeO + 2FeH + H_2 \rightleftarrows 4Fe + 2H_2O$ for which the equil. const. was $\log K = 23585.82/T - 7.5526$. The concn. of H_2 absorbed by molten Fe increased with temp. and decreased with FeO.

535. Newell, W. C. **The estimation of hydrogen in steel and other metals.** *J. Iron Steel Inst. (London)*, Advance copy, May, **1940**, 11 pp.—*C.A.* **34**, 4013^2.

The vacuum-heating method is designed to det. the H-content of a dozen or more metal samples consecutively with a min. of elaborate app. The sample is heated *in vacuo* for one hr at 600°C. No further evolution of H_2 occurs when these samples are melted *in vacuo*. The accuracy of the heating method is ten times that of the fusion method. From 400° to 700°C the rate of H_2 evolution increases with temp. Above 700°C the curves show an irregularity which causes them to cross.

536. Norton, Francis J. **Diffusion of hydrogen from water through steel.** *J. Applied Phys.* **11**, 262-7 (1940).—*C.A.* **34**, 3564^1.

Using a metal radio tube with a steel shell as an ionization gage, the diffusion of H_2 through the steel into the interior was measured. When dipped into water, diffusion rates averaging 0.13 μ/hr at 25°C and 0.80 μ/hr at 100°C were observed for a plain sand-blasted surface; the shell was 0.0635 cm thick, the area exposed to water was 30.7 cm², and the free vol. inside was 15.0 cc. No diffusion occurred when exposed to water vapor alone. The rate of diffusion was less for the regular painted tube, and also for coatings of Ni, Sn, Cd, and Cu, but a porous Cu coating increased the rate to that for water on the bare steel.

537. Balandin, A. A.; Erofeev, B. V.; Pecherskaya, K. A., and Stakhanova, M. S. **The nickel hydrides.** *J. Gen. Chem. (U.S.S.R.)* **11**, 577-89 (1941).—*C.A.* **35**, 7305^9.

Absorption of H_2 considerably exceeding 4 atoms of H indicated other processes which use up H_2: (1) soln. of H_2 in the hydride and (2) catalytic hydrogenation of the benzene nucleus in excess of PhMgBr or in the product of the reactions $NiCl_2 + 2PhMgBr + 2H_2 = NiH_2 + 2C_6H_6 + MgBr_2 + MgCl_2$ or $NiCl_2 + 2PhMgBr + 2H_2 = NiH_4 + Ph_2 + MgBr_2 + MgCl_2$. The existence of NiH_2 and NiH_4 was proved analytically and that of NiH kinetically, The stability of the sols of Ni hydrides depended on the stabilizing effect of the org. Mg compds. adsorbed on their surfaces.

538. Hibbard, Henry D. **Control of hydrogen in steel.** *Steel* **108**, 69-70, 103-4 (June 16, 1941); *Metals and Alloys* **14**, 574 (1941).—*C.A.* **36**, 3134^6.

The most important sources of H_2 in steel is probably the H_2O vapor in the gases in the furnace chamber. The only apparent means of removing H_2 from the molten metal is the boil. The temp. during the working period should be low enough for a vigorous boil to take place. A reduction of the C and Mn contents by a prolonged boil may also decrease the H content, since C and Mn may have some solvent power for H.

539. Holm, V. C. F. and Thompson, G. **Determinations of hydrogen in ferrous materials by vacuum extraction at 800°C and by vacuum fusion.** *J. Research Natl. Bur. Standards* **26**, 245-59 (1941) (RP No. 1373).—*C.A.* **35**, 3555^{6}.

Vacuum fusion was satisfactory for the examn. of steels which often contain H_2 in an unstable form as a result of cathodic charging or heating in H_2. Warm extn. at 800°C was better for such steels. With them about 90% of the H_2 may be lost on standing for a few days. The quantities of H_2 found in most samples approximated the soly. of H_2 in the materials.

540. Houdremont, E. and Schrader, H. **Flake formation and embrittlement by hydrogen absorption of the steel in annealing. I. The combined action of hydrogen and stresses in the creation of flake cracks.** *Tech. Mitt. Krupp Forschungsber.* 4, 67-78 (1941).—*C.A.* **35**, 7334^{1}.

With increased cooling velocity the no. of flake cracks increases, and lower H-contents at higher cooling velocities suffice to cause formation of flake cracks. In a material that is free of H, stresses alone cannot produce flaking. In a H-contg. steel, stresses can essentially affect the orientation of the flakes and even cause flaking in cases where the H-content alone is not sufficient to cause flaking at a definite cooling velocity.

541. Itterbeek, A. van. **The relation between adsorption and the catalytic activity of metals.** *Meded. Kon. Vlaamsche Acad. Wetensch., Letteren Schoone Kunsten België, Klasse Wettensch.* **3**, No. 10, 3-20 (1941); *Chem. Zentr.* **1942**, II, 742.—*C.A.* **37**, 4958^{3}.

On the very pure Ni film the adsorption of H_2 and CO up to 500°C and pressures below 1 mm was studied with the help of a thermal-cond. gage. Comparison of the H_2 and CO isobars showed that at 167° and 329°C the ratio of H_2:CO was 3:1 and at 2 other temps. the ratio was 2:1 corresponding, resp., to the synthesis of CH_4 and benzene. On a copper film, neither H_2 nor CO was adsorbed until a small quantity of thorium was electrodeposited.

542. Kimura, Osamu. **Effect of sorption on the electric conductivity of pulverized metals. I.** *Bull. Chem. Soc. Japan* **16**, 378-81, (1941).—*C.A.* **41**, 4347*i*.

The elec. conds. of pulverized Pt, Au, Ni, Co, Cu, and Ag were measured in H_2. As the pressure increased, the cond. of Pt increased, those of Ni, Co, Cu, and Ag decreased, and that of Au remains unaltered. For Ni, oxidation and reduction velocities, temp. dependence of cond., relation between current and voltage, and the dependence of cond. on pressure of H_2 were studied in detail.

543. Kodama, Shinjiro; Matsumura, Shoichi, and Tarama, Kimio. **Physicochemical investigations on gasoline synthesis. IV. Velocity of adsorbing hydrogen by cobalt.** *J. Soc. Chem. Ind. Japan* **44**, 823-5 (1941).—*C.A.* **42**, 2080*b*.

H_2 at atm. pressure was brought into contact with Co at 14.5-275°C, and the velocity of adsorption measured. With t in min. and x as the cc. H_2 adsorbed per g of Co, this equation held $t = x(t/A + 1/A^2K)$, [which is the integrated form of $dx/dt = K(A - X)^2$], where A and K were consts. characteristic of each temp. There were active adsorbing centers on the surface of Co of various degrees of activity, and at low temp. the centers of greater activity react. When the temp. was raised such centers soon become satd. with H_2 and then the centers of less activity began to exhibit a measurable velocity of adsorption.

544. Kodama, Shinjiro; Matsumura, Soichi, and Ando, Tatsuo. **Physicochemical investigations on gasoline synthesis. V. Velocity of adsorption of hydrogen by a catalyst of cobalt and infusorial earth.** *J. Soc. Chem. Ind. Japan* **44**, 920-4 (1941).—*C.A.* **42**, 8439i.

The mechanism of adsorption of H_2 under atm. pressure by Co pptd. on infusorial earth is the same as in case of pure Co. The equation $t = x(t/A + 1/A^2K)$ holds. The const. A, detd. by the number of active adsorbing centers, is much greater for the supported catalyst. The values of K, measuring the velocity of adsorption, are small, perhaps because the activity of adsorbing centers increases and most of them are instantly satd.

545. Kodama, Shinjiro; Matsumura, Soichi, and Ando, Tatsuo. **Physicochemical investigations on gasoline synthesis. VI. Velocity of adsorption of hydrogen by cobalt-thoria-infusorial earth catalyst.** *J. Soc. Chem. Ind. Japan* **44**, 920-4 (1941).—*C.A.* **42**, 8440i.

With a catalyst of Co, ThO_2, and infusorial earth in the ratio 100: 18: 150, there was no change in the mechanism of adsorption. Addn. of thoria not only increased the number of active adsorbing centers, but also produced centers of greater activity at lower temp., so that it greatly decreased the temp. of activated adsorption of H_2.

546. Newell, W. C. **Third report of the oxygen subcommittee of the committee on the heterogeneity of steel ingots. Section II. The vacuum fusion and vacuum heating methods. Part C. The determination of hydrogen (vacuum-heating).** *J. Iron Steel Inst. (London)*, Advance Copy, May, **1941**, 93 pp. (Paper No. 5/1941 of the Heterogeneity of Steel Ingots Committee (Submitted by the Oxygen Sub-Committee)) 26-7.—*C.A.* **35**, 4703^{3}.

The previously described app. has been improved by replacing the single-stage Hg-vapor pump by a two-stage pump; thus the pumping rate and degree of vacuum were increased.

547. Zapffe, C. A. and Sims, C. E. **Hydrogen embrittlement, internal stress and defects in steel.** *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. **1307**, 37 pp. (1941).—*C.A.* **35**, 7916^{3}.

H-embrittlement entails occlusion of H_2 under high pressure in "interblock disjuctions." These appear to be a fundamental part of the crystal structure and one related to slip and cleavage phenomena. When the occlusion pressure exceeds the elastic strength of the steel, the disjunctions are sprung and slip and cleavage planes operate much as during cold deformation. If H_2 is contained in cavities, not block disjunctions, such as in weld metal, H_2 can dissolve in injurious quantities at temp. somewhat below the transformation temp.

548. Andrew, J. H.; Bose, A. K.; Geach, G. A., and Lee, H. **The formation of hairline cracks. I.** *J. Iron Steel Inst. (London)*, Advance copy, Sept., **1942**, 10 pp. (Paper No. 5/1942 of the Alloy Steels Research Comm.).—*C.A.* **37**, 61^2.

Internal defects similar to hairline cracks were produced by rapid cooling. An aging period after quenching was required. All of the results so far obtained support the view that H_2 was the most important single factor involved in hair-crack formation.

549. Andrew, J. H.; Bose, A. K.; Lee, H., and Quarrell, A. G. **The formation of hairline cracks. II.** *J. Iron Steel Inst. (London)*, Advance Copy, Nov., **1942**, 41 pp. (Paper No. 6/1942 of the Alloy Steels Research Committee).—*C.A.* **37**, 1114^1.

H_2 is the fundamental cause of hairline cracks. It is present as a H-rich constituent formed on rapid cooling through the $\gamma - \alpha$ change. H_2 from the decompn. of this constituent diffuses into voids and builds up disruptive pressure. The cracks also contain methane which is a cause of trouble in preventing hairline cracks. Alloying elements affect the stability of the H-rich constituent and thus the susceptibility to hair cracks. Decompn. at low temp. leads to hairline crack formation.

550. Andrew, J. H.; Lee, H., and Quarrell, A. G. **The determination of solubility of hydrogen in iron and iron alloys.** *J. Iron Steel Inst. (London)*, Advance copy, Sept., **1942**, 12 pp.—*C.A.* **37**, 62^4.

The specimen prepd. in a current of H_2 at 1000° to 1050°C for at least 30 days to remove all traces of C and O_2 was heated in H_2 at a known temp. and pressure until equil. was reached, and the amt. of H_2 dissolved by the metal was measured. An abrupt change in soly. occurred between 950° and 900°C on cooling. The temp. coeff. of soly. was greater in γ Fe than in α Fe. Typical values in cc. per 100 g of Fe were: at 500°, 1.00; 700°, 1.8; 900°, 3.1; 1100°, 7.5.

551. Dingenen, Walter van. **Active adsorption of gases on pure and activated metal surfaces and its relation to the general physical properties of the metals.** *Verhandl. Kon. Vlaamsche Acad. Wetensch., Letteren schoone Kunsten België, Klasse Wetensch.* 4, No. 4, 59 pp. (1942).—*C.A.* **38**, 4849^7.

Measurements of activated adsorption of H_2 on pure Ni surfaces conformed to activated adsorption. Adsorption isotherms and isobars were detd. from room temp. to 500°C. From the velocity of adsorption conclusions were drawn about the energy of activation of the adsorption process. Measurements were made of the adsorption of H_2, D_2 and CO by Carbotox (activated carbon of Lurgi Co., Frankfurt), on electrolytically Cu-plated carbon, and on pro-motor-activated carbon-Cu. Promotors used were ThO_2, BaO, Cs_2O and SrO, for which the "work of emergence" of electrons is small, and Se_8, which has a large potential. The expts. covered the range −183° to 600°C. Adsorption of Ni and Cu at higher temps. was a so-called activated (atomic) adsorption, related to other physical properties of the material such as electron emission and cond.

552. Fast, J. D. **Gas permeability of metals.** *Philips' tech. rundschau.* **7**, 73-81 (1942).—*C.A.* **38**, 2910^9

The penetration of gases through metal walls presents at least 5 successive steps: (1) dissocn. of mols. into atoms or ions at the entrance surface, (2) infiltration of the atoms or ions thus formed into the metal, (3) diffusion in the metal, (4) transition from the dissolved to the adsorbed state at the emergent surface, (5) recombination of adsorbed atoms or ions into mols. There are thus 5 different instances conceivable, for which one or more examples are given: (1) H_2 through Fe, (2) H_2 through Fe with very rough entrance surface, (3) H_2 through Cu, (4) O_2 through Zr, (5) H_2 through Pd and O_2 through Cu or Ni. Selective permeability of walls can be employed to purify and analyze gases.

553. Ishikawa, Yoshioki. **The desorption of the adsorbed hydrogen on a platinum plate by the impact of slow electrons. I.** *Proc. Imp. Acad. (Tokyo)* **18**, 246-50 (1942).—*C.A.* **43**, 5279*e*.

A diode with an oxide-coated filament was used as a reaction chamber. Pure H_2 was passed over the anode of the Pt plate and was adsorbed. After evacuation slow electrons were emitted and the gas desorbed by this impact was measured by a Pirani gage. The electronic current of impact was 100-500 microamp. The atom produced by the dissocn. had kinetic energy of more than 3.55 v. which was obtained by subtracting the dissocn. energy 4.45 v. from the excitation energy 8 v. It easily overcame the adsorptive force of the metal (1 e.v.).

554. Ishikawa, Yoshioki. **The desorption of the adsorbed hydrogen on a platinum plate by the impact of slow electrons. II.** *Proc. Imp. Acad. (Tokyo)* **18**, 390-4 (1942); *Rev. Phys. Chem. Japan* **16**, 117-38 (1942).—*C.A.* **43**, 5280*b*; **46**, 4357*b*.

After heating the diode to about 200°C and immersing in liquid air the range of applied voltage was 7-60 v. Five max. were caused by the interaction between the H_2 mol. and the impinging electron. This indicated: (1) The stable H_2 mol. existed on the surface of Pt in the $1\Sigma_g$ ground state and was not perturbed by adsorption. (2) The desorption of the adsorbed mol. from the Pt surface was caused by an inelastic collison, (3) The adsorbed H_2 may be ionized by the electron impact to H_2^+ and remains stable in this state. (4) Adsorbed atoms and protons were not desorbed by this mechanism but may exist on the surface.

555. Itterbeek, A. van and Borghs, J. **The van der Waals adsorption of gases (H_2, D_2, CH_4, N_2, and Ne) on nickel flakes.** *Z physik. Chem.* **B50**, 128-42 (1942).—*C.A.* **37**, 2242^2.
The measurements were made in the temp. range of liquid N_2 and for Ne, H_2 and D_2 in the range of liquid H_2 also. At 60 to 69°K the van der Waals adsorption of D_2 was about 10% greater than that of H_2. At 18-20° K the difference was 15%. Although at higher temp. activated adsorption predominated, measurements at lower temps. followed the B.E.T. theory. The no. of adsorption layers reached about 6 for H_2 and D_2. The measurements with CH_4, N_2, and Ne can be explained either by the multilayer theory or by Polanyi's potential theory. With H_2 and D_2, however, there was a different potential curve for each temp. in the range of liquid H_2, in which the potential for H_2 was greater than that for D_2.

556. Kodama, Shinjiro; Matsumura, Shoichi; Tarama, Kimio; Ando, Tatsuo, and Yoshimori, Keisuke. **VII. Velocity of adsorption of hydrogen by iron.** *J. Soc. Chem. Ind. Japan* **45**, 254-8 (1942).—*C.A.* **43**, 2412i.
H_2 was adsorbed by Fe in the dissocd. form in the case of Co. The surface of Fe was not homogeneous, and adsorption at the centers of the weaker activity was observed at higher temps. No reason for the irregularity found at 99.6°C was given. Above 150°C the no. of active centers of adsorption suddenly increased.

557. Kodama, Shinjiro; Matsumura, Shoichi; Tarama, Kimio; Ando, Tatsuo, and Yoshimori, Keisuke. **VIII. Velocity of adsorption of hydrogen by iron on infusorial earth.** *J. Soc. Chem. Ind. Japan* **45**, 254-8 (1942).—*C.A.* **43**, 2413a.
Fe hydroxide was pptd. on infusorial earth and dried. Some irregularity was observed in the velocity of H_2 adsorption. Infusorial earth had an effect of increasing the no. of active centers and increasing the activity of those centers.

558. Kodama, Shinjiro; Matsumura, Shoichi; Tarama, Kimio; Ando, Tatsuo, and Yoshimori, Keisuke. **IX. Velocity of adsorption of hydrogen by a composite iron catalyst.** *J. Soc. Chem. Ind. Japan* **45**, 254-8 (1942).—*C.A.* **43**, 2413*b*.
The catalyst contained Fe, Cu, Mn, and infusorial earth in the ratio 100:25 : 2:125, resp. Results similar to the case of pure Fe were obtained, except that the t/x vs. t curve was irregular at 25° and 60°C, and above 100°C it was a broken line, showing that the adsorption of H_2 above 100°C conformed to the 2nd-order reaction velocity equation. There was no marked change in the amt. of H_2 adsorbed at higher temp., but below 100°C the amt. of H_2 adsorbed increased. This increase was considered to be caused by Cu.

559. Moreau, Léon; Chaudron, Georges, and Portevin, Albert. **Single-crystal and polycrystalline iron charged with hydrogen.** *Génie civil* **119**, 246-7 (1942).—*C.A.* **38**, 3179^8.
Comparison of data on single-crystals with existing data for polycryst. Fe indicated that H_2 diffuses through faults.

560. Ogawa, Eijiro; Tada, Masatomi, and Okuno, Toshiro **Studies of catalytic action by conversion between para-hydrogen and ortho-hydrogen. I. (a) Conversion by magnetized nickel wire; (b) Conversion by catalyst for ammonia synthesis.** *J. Soc. Chem. Ind., Japan* **45**, Suppl. binding, 387-9 (1942).—*C.A.* **44**, 7637*a*.
At 73°C the activation energy of the ortho-para-H_2 conversion over Ni was 3000 cal for unmagnetized and 6000 cal for magnetized catalyst. At 112°C the effect of magnetization disappeared, indicating that the conversion changed from a magnetic to activated adsorption mechanism. For the $H_2 + C_2H_4$ reaction at 150-200°C, the magnetic mechanism acted on C_2H_4 but not on H_2.

561. Portevin, Albert; Chaudron, Georges, and Moreau, Léon. **The path of hydrogen in monocrystalline and polycrystalline iron.** *Compt. rend.* **215**, 351-3 (1942).—*C.A.* **38**, 3234^8.
Iron charged with electrolytic H_2 was degassified by annealing in vacuum. Study of the residual gas content, micrography, fragility and Brinell hardness of samples annealed at different temps. and a comparison of the behavior of polycryst. and monocryst. iron showed that the gas freed from the lattice followed the intergranular boundaries. This effect may cause trouble at annealing temps. around 300°C.

562. Portevin, Albert; Chaudron, Georges, and Moreau, Léon. **The two manners of hydrogen evolution by heating iron.** *Métaux corrosion-usure* **17**, 175-7 (1942).—*C.A.* **39**, 4037^5.
The greatest hardness of iron was obtained by electrolytic loading with H_2 for 8 hrs at −10°C. The samples were then heated at different temps. in vacuo and the progress of the evolution of H_2 was observed. After heating polycryst. samples at 250° and 300°C only about one-third of the H_2 remained in the crystal lattice, yet by heating to 900°C the intercryst. H_2 went into the lattice. In samples consisting of a single crystal almost the entire H_2 content was left in the lattice after heating to 300°C. This showed that the escape is through the intercryst boundaries.

563. Rostagni, Antonio and Sandrin, Italo. **Sources of protons with a palladium anode.** *Atti reale ist. Veneto sci.*, Pt. 2, *Sci. mat. e nat.* **101**, 283-7 (1942).—*C.A.* **45**, 4550*f*.
The possibility that H_2 occluded on Pd might be a good source of protons was investigated, with and without electron bombardment. The results were unfavorable.

564. Rostagni, Antonio and Sandrin, Italo. **Nature of ions produced by electronic bombardment of palladium.** *Atti reale ist. Veneto sci.*, Pt. 2, *Sci. mat. e nat.* **101**, 343-8 (1942).—*C.A.* **45**, 4550*f*.
A mass spectrograph was used to analyze the products obtained by bombarding a Pd tube contg. H_2. H_1^+, H_2^+, H_3^+ were present but not in sufficient intensity to provide a source of protons.

565. Widemann, M. **The solubility of hydrogen in iron.** *Anz. Maschinenwes.* **64**, No. 11, Suppl. 17-19 (1942).—*C.A.* **38**, 2603^3.
Absorption of H_2 by liquid Fe, by Fe products during heat-treatment in H_2-contg. atms., and by Fe during pickling is explained. Dissolved and absorbed H_2 are partly lost during hot and cold working or by exposure of metal to the atm. X-ray

examn. shows H_2 is dissolved in the α and γ lattices, produces an increase in lattice const., and acts especially on the intercryst. material.

566. ZAPFFE, C. A. **"Fish-eyes" in steel welds caused by hydrogen.** *Metal Progress* 42, 201-6 (1942).—*C.A.* **36**, 5761⁴.
The major portion of H_2 occluded at ordinary temps., after the welding operation, is "extra-lattice." The shiny, central blowhole in steel welds is the locus to which H_2 diffused during cooling. Gas pressure within the entire "fish-eye" exceeds the elastic, or cohesive, strength of the metal.

567. ZAPFFE, C. A. **Defects in cast and wrought steel caused by hydrogen.** *Metal Progress* 42, 1051-6 (1942).—*C.A.* **37**, 592⁴.
Checks and tears along tensile test specimens are ordinary indications of H_2-embrittled spots known as "snowflakes," "white spots" or "silver streaks." Flakes in forgings, shatter cracks in rail heads and "pin holes" near the surface of steel castings are other manifestations of H_2.

568. ARMBRUSTER, MARION H. **The solubility of hydrogen at low pressure in iron, nickel and certain steels at 400° to 600°C.** *J. Am. Chem. Soc.* **65**, 1043-54 (1943).—*C.A.* **37**, 4283⁷.
The soly. (s) of H_2 was measured over a range of pressure (p) from 0.001 to 1.5 mm in carefully pretreated samples of α-iron (initially carbonyl iron), Ni and certain steels at 400°, 500°, 600°C and at pressures up to 350 mm in the iron at 600°C. The results were reproducible, and were in accord with the linear relation $s = a\ p^{1/2}$. The measurements on Fe and Ni at all 3 temps. were accurately reproduced by the resp. equations: $\log (s/p^{1/2}) = -1454/T + 1.946$ and $\log (s/p^{1/2}) = -645/T + 1.732$, where T was °K.

569. BALANDIN, A. A. AND EROFEEV, B. V. **Progressive poisoning of H_2 sorption in the process of formation of Ni hydrides.** *Acta Physicochim. U.R.S.S.* **18**, 494-8 (1943); *J. Gen. Chem. (U.S.S.R.)* **12**, 168-70 (1942).—*C.A.* **37**, 2675²; **39**, 251⁴.
The progressive poisoning of the catalyst in hydrogenation of aromatic hydrocarbons, the formation of Ni hydrides, and the solution of H_2 in these hydrides are considered predominantly to be localized on certain definite elements of the complex surface of Ni.

570. DOTY, PAUL M. **The attainment of thermal equilibrium between a gas and a hot surface.** *J. Chem. Phys.* **11**, 557-9 (1943).—*C.A.* **38**, 908⁹.
Thermal equil. is complete for the dissocn. $H_2 \rightarrow 2H$ in contact with a hot wire at 1148-1420° K. Complete attainment of thermal equil. is possible only for mols. and surfaces like H_2 and W, where chemi-adsorption occurs.

571. ITTERBEEK, A. VAN; MARIENS, P., AND PAEMEL, O. VAN. **Activated adsorption by nickel foil between 200° and 500°C.** *Ann. Phys.* **18**, 135-44 (1943).—*C.A.* **38**, 5708⁷.
The adsorption of H_2 and D_2 by Ni foil was detd. at temps. of 250-500°C and at pressures of 1-4 mm. Curves of the amt. adsorbed at const. pressure vs. temp. showed at approx. 360°C a definite hump, which was more pronounced the higher the pressure. With D_2, but not with H_2, a second hump also appeared at about 410°C. The hump at 360°C may be due to an increase in surface, as the coeff. of expansion of Ni was known to have a max. at this temp.

572. MURATA, YOSHIO; NAKAGAWA, MASAYUKI; TASHIRO, EIICHI, AND UMEMURA, TADASHI. **LXV. Reduction by hydrogen and heat-treatment of iron catalysts.** *J. Soc. Chem. Ind. Japan* **46**, 52-68 (1943).—*C.A.* **43**, 2401*b*.
Fe catalysts lose their activity when reduced with H_2 depending on the temp. and time; thus, they totally lose their catalytic power when reduced in H_2 4-8 hrs at 450°C while those reduced at 250°C for 4-10 hrs regain their activity in the course of 1-2 days of normal operation. The activity of the catalysts reduced with H_2 is not recovered by oxidation with air at 250-450°C. Fe catalysts slightly increase their activity when heated in an air current at 100-400°C, but above 400°C, the activity is gradually reduced with the elevation of temp. until it is completely lost at 600°C.

573. MURATA, YOSHIO; NAKAGAWA, MASAYUKI; TASHIRO, EIICHI, AND UMEMURA, TADASHI. **LXVI. Reduction of iron catalysts.** *J. Soc. Chem. Ind. Japan* **46**, 52-68 (1943).—*C.A.* **43**, 2401*d*.
The effect on the activity of the catalyst of reducing with various gas mixts. was studied in detail. The activity of the catalyst was increased when it was reduced by H_2 to which a small amt. of CO was added. The effect of adding CO was nearly linear up to $CO : H_2 = 1:2$ and diminished gradually when more CO was added. When the ratio of $CO : H_2$ exceeded that of the gas mixt. used in the synthesis, the activity of catalyst was greatly reduced.

574. ZAPFFE, C. A. **Sources of hydrogen in steel and means for its elimination.** *Metal Progress* **43**, No. 3, 397-401 (1943).—*C.A.* **37**, 1969⁷.
The principal source of H_2 is H_2O—liquid, vapor or chemically combined as Fe rust. Recommended procedures are given for enameling, heat-treatment, electroplating and melting.

575. ZAPFFE, C. A. **Effects of hydrogen in steel.** *Proc. Open Hearth Conf., Am. Inst. Mining Met. Engrs.* **26**, 240-51 (1943).—*C.A.* **38**, 5186⁸.
Absorbed H_2 in steel causes brittleness and cracks by segregation at certain loci within the metal and congesting it so that slip mechanism is unable to operate; the mechanism is a simple aging function. Sources of H_2 preventing it from being absorbed by careful melting practice, and its removal by N_2 and vaporizing solids are discussed.

576. ZAPFFE, A. AND MOORE, GEO. A. **A micrographic study of the cleavage of hydrogenized ferrite.** *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. **1553**, 19 pp. (1943).—*C.A.* **37**, 1967¹.
Ferrites of 3 different origins were rendered ductile in H_2 with subsequent treatment in vacuo and were then embrittled by addn. of H_2 alone. Occlusion of H_2 by Fe at ordinary temps. occurred as the retention of fluid, compressed gas in microscopic openings or rifts into which the gas ppts. form supercooled or supersatd. solid solns. The

failure of H-embrittled Fe occurred by direct cleavage through these gas-filled rifts, which had no ductility.

577. AUSTIN, J. B. **Determination of hydrogen in steel.** *Proc. Conf. Natl. Open Hearth Comm., Iron Steel Div., Am. Inst. Mining Met. Engrs.* **27**, 178-81 (1944).—*C.A.* **39**, 675^7.

Methods for detg. H_2 in steel are adequate and have not shown a definite relationship between H_2 content and mech. properties.

578. FRANKENBURG, WALTER G. **The adsorption of hydrogen on tungsten. I.** *J. Am. Chem. Soc.* **66**, 1827-8 (1944).—*C.A.* **39**, 451^4.

Data were given at equil. pressures between 1×10^{-5} and 30 mm and from -194° to 750°C. W powders were used with B.E.T. surfaces about 7000 to 20,000 cm^2 per g. The W powders were reduced in H_2 at 750°C and outgassed at 750°C in a high vacuum for 35 to 50 hrs. Such powders showed well-reproducible values of H adsorption with negligible gas evolutions. The adsorption was characterized by the uptake of relatively large quantities of the gas at low pressure (about 25% of the satn. value, at 10^{-4} mm and 0°C). Extrapolation of the adsorption isotherms to high pressure led to a satn. value of adsorption corresponding to 1 H_2 per 2 W atoms in the metal surface. The quantities of H_2 adsorbed per cm^2 of the W surface at a given temp. and pressure were identical, within the limits of exptl. error, for 2 different powders the surfaces of which differed by the factor 3.

579. FRANKENBURG, WALTER G. **The adsorption of hydrogen on tungsten. II.** *J. Am. Chem. Soc.* **66**, 1838-47 (1944).—*C.A.* **39**, 452^1.

Langmuir's formula is adapted to the rapid decrease of the differential heats of adsorption with increasing covering of the W surface with H_2. A detailed discussion leads to the evaluation of the satn. value (S) of 1 adsorbed H_2 per 2 W atoms on the surface. The adsorbed H_2 exists on the surface in the form of atoms, at all surface coverings below 0.008 S, and as "mols." at all surface coverings above 0.008 S. Q, the differential heat of adsorption of H_2, is temp.-independent for a given surface covering up to 529°C; a sharp decrease with increasing temp. then takes place.

580. KJERRMAN, H. **Indirect determination of hydrogen in steel.** *Jernkontorets Ann.* **128**, 1-12 (1944).—*C.A.* **39**, 4309^6.

Basic open-hearth steel is higher in H_2 than acid open-hearth steel. Killed basic open-hearth steel contains more H_2 than rimming basic open-hearth steel. Burning damp wood in the gas producer supplying fuel to the steel furnace causes the H-content of the steel to be greater than when coal is used. A moist ladle increases the H-content of the steel, and a leak in the water-cooled mechanism operating and butterfly of the reversing valve increases the H_2 in the steel.

581. OWEN, E. A. **Note on the solubility of hydrogen by palladium.** *Phil. Mag.* **35**, 50-7 (1944).—*C.A.* **38**, 4176^5.

The occlusion of H_2 below 1 atm. by Pd was examd. by X-ray methods between 60°-130°C range. The β-phase, when first formed, was finely dispersed through the α-phase and remained finely divided when the whole material consisted of β-phase. Likewise, the α-phase, when it reappeared, was finely divided through the β-phase and when all the latter had gone the newly formed α-phase remained finely divided unless annealed for some time at a higher temp. than the isothermal. No improvement in line sharpening was detected if the system was kept for 5 days at the temp. of the isothermal. No evidence was obtained that metallic hydrides were formed in the temp. range examd.

582. OWEN. E. A. AND WILLIAMS, E. ST. J. **X-ray study of the hysteresis effect observed in the palladium-hydrogen system.** *Proc. Phil. Soc. (London)* **56**, 52-63 (1944).—*C.A.* **38**, 4176^8.

Pure Pd filings were mounted on a fiber and then charged with H_2. The hysteresis curve was detd. at 100°C and found to be essentially the same as that reported formerly; other curves were detd. (60-130°C). Only those parts of the ascending and descending isothermals where a single component existed could be retraced by altering the pressure. The reversibility disappeared immediately when the 2nd component was formed. The effect of charging the Pd with H_2 for long periods was examd. The behavior of charged Pd under varying conditions in the pressure region of hysteresis was very definite, although the system was not in final equil. Expts. with charging times up to 90 hrs were recorded.

583. ROLLASON, E. C. **The influence of hydrogen on weldability of high-tensile alloy steels.** *Inst. Welding (London) Quart. Trans.* **7**, 74-5 (1944).—*C.A.* **39**, 1615^3.

Normal mild steel welds contain more than enough H_2 to cause embrittlement. The max. appears to be about 4 cc/100 g; decrease to 1-2 cc/100 g greatly extends the weldability. The H-content of austenite welds can be considerably higher than that of ferritic welds without loss of weldability.

584. UHLIG, H. H. **Influence of hydrogen on mechanical properties of some low-C Mn-Fe alloys and on Hadfield Mn steel.** *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. **1701**, 19 pp. (1944).—*C.A.* **38**, 5782^3.

Low-C Mn-Fe alloys contg. 9-22% Mn, H_2 treated at 1000°C and quenched are embrittled. Specimens of electrolytic Fe 0.406 cm in diam. and 3.3% Mn-Fe alloy are not embrittled because H_2 is not retained no matter how rapid the quench. Alloys vacuum treated at 1000°C and quenched in vacuum lose H_2.

585. VILLNER, L. AND NORRÖ, A. **Furnace atmospheres in arc furnaces and their effect on hydrogen and nitrogen contents of steel.** *Jernkontorets Ann.* **128**, 105-34 (1944).—*C.A.* **39**, 3772^9.

There was no marked absorption of N_2 in the period between removing the first slag and prepg. the refining slag in spite of the high N-content of the furnace atm. In the refining period a certain amt. of N_2 was absorbed by the steel, an av. for 12 charges being 0.002%; N_2 in the slag rose steadily in this period and could be as high as 0.15%. The steel took up a considerable quantity of H_2 from the H_2O in the burnt CaO during the building up of the furnace slag and some was still present on tapping. H_2 absorption could be reduced by prepg. the slag first with limestone and then with burnt CaO.

586. Wagner, Carl. **Solubility of hydrogen in palladium alloys.** *Z. physik Chem.* **193**, 407-16 (1944); **194**, 85 (1944).—*C.A.* **41**, 1520^a.

Soly. of H_2 in Pd is changed considerably by alloying with Ag or B. These effects are explained by the assumption that in pure Pd the lattice units are Pd ions, while in the alloys the units are Pd atoms and Ag ions. The chem. potential of electrons in these lattices is detd. by the relative amts. of these two varieties of units.

587. Zapffe, C. A. and Sims, E. **Hydrogen and nitrogen as causes of gassiness in ferrous castings.** *Trans. Am. Foundrymen's Assoc.* **51**, 517-62 (1944).—*C.A.* **38**, 1453^3.

Melts flushed with H_2 yielded porous castings. Steam was more effective than H_2 in promoting porosity. The soot deposited in ingot molds by a C_2H_2 flame was a good H_2 adsorber. There was no porosity in castings poured from metal that had been flushed with N_2 alone. Flushing with H_2 followed by N_2 yielded sound castings, but gassiness occurred when H_2 was passed through the bath after the N_2 flow.

588. Balandin, A. A. **The kinetics of catalytic hydrogenation.** *Bull. acad. sci. U.R.S.S., Classe sci. chim.* **1945**, 339-58 (English summary).—*C.A.* **40**, 4593^8.

Two kinds of active centers are assumed: I, capable of activating the adsorbed H_2, the II, activating only the hydrogenatable org. substance. Both adsorb H_2 and the initial, intermediate, or final products; the establishment of the adsorption equil. is faster than the subsequent reaction. In the case of benzene on Ni, the I centers would be located along the lattice edges with the inter-atom distances of 3.52 A., the II centers are constituted by the sextet in a place with the distance 2.49 A. A simple expression is obtained for the rate of dehydrogenation showing independence of pressure and confirmed by the example methylcyclohexane-toluene, between 200° and 300°C. The rate remains const. for the hydrogenation under high pressure as long as there remains a sufficient amt. of hydrogenatable substance. This is confirmed for toluene at 75°C and 120 atm. and at 120°C and 35 atm.

589. D'yakonov, I. A. and Samarin, A. **Analysis of the process of absorption of gases by metals.** *Bull. acad. sci. U.R.S.S., Classe sci. tech.* **1945**, 813-20 (in Russian).—*C.A.* **41**, 2367^d.

Hydrogen absorption isobars of various metals fall into 2 distinct groups: one with weaker absorption rising with temp. at 400-1600°C (Si, Cu, Ag, Cr, Fe, Co, Ni), the other with stronger absorption falling with rising temp. (Ti, Zr, Th, V, Cb, Ta, La, Ce, Pr, Pd). Isotherms in the first group, corresponding to simple solid soln., are straight lines in terms of the square root of the gas pressure, p. In the second group, this plot is linear only at low pressures; the isotherm then bends upward and attains a horizontal satn. level at high pressures. The generalized isotherm of absorption consists of 3 continuous branches: (1) a first linear portion corresponding to soln. of atoms of the gas in the metal, (2) a second linear portion of steeper rising slope corresponding to soln. in the metal of a gas-metal compd., and (3) a final horizontal 3-phase branch of complete satn.

590. Eborall, R and Ransley, C. E. **The reaction of an aluminum-magnesium alloy with water vapor, and the absorption of hydrogen.** *J. Inst. Metals* **71**, 525-52 (1945) (Paper No. 1004).—*C.A.* **40**, 305^4.

The gas obtained from wrought and cast Al-Mg alloy, contg. 7% of Mg, was almost entirely H_2; at 500°C and atm. pressure, the soly. of H_2 was approx. 0.05 cc. per 100 g. Diffusivity of H_2 in the alloy can be expressed by $D = D_o exp(-E/RT)$ where $D_o = 340$ cm^2/sec and $E = 24{,}600$ cal/g-atom. Annealing in damp air gave the same results as annealing in H_2O vapor. At room temp., diffusivity of H_2 in the alloy was approx. 2×10^{-16} cm^2/sec.

591. Griffin, Carroll W. **The sorption of hydrogen by poisoned copper. Temperature-variation experiments.** *J. Am. Chem. Soc.* **67**, 62-4 (1945).—*C.A.* **39**, 1342^5.

The sorption of H_2 with temp. variation on pure massive Cu was detd. and compared with that of H_2 on the same Cu poisoned with a small quantity of CO. The effect of the poison was largely to prevent the soln. of H_2 in Cu.

592. Hall, M. N. A., Mrs.; Martin, S. L. H., and Rees, A. L. G. **Solubility of hydrogen in zirconium and zirconium-oxygen solid solutions.** *Trans. Faraday Soc.* 41, 306-16 (1945).—*C.A.* 39, 5147^3.

The soly. of H_2 in Zr contg. O_2 in solid soln. from 0 to 50 atom % was detd. isothermally up to 1000°C and at pressures 1 to 760 mm. Special precautions were taken for the elimination of surface contamination of the Zr by oxide or nitride films. Desorption expts. demonstrated the existence of hysteresis, but this was not fully investigated. Degassed powders contg. O in solid soln. were found to be more liable to spontaneous ignition on exposure to air at room temp. than were samples contg. little O.

593. Hasegawa, Shigeo. **Physicochemical studies of copper catalyst. IV. The adsorption of hydrogen by cupric oxide.** *Rev. Phys. Chem. Japan* **19**, 132-9 (1945).—*C.A.* 44, 2356*d*.

CuO (10 g) was reduced in a sealed vessel under H_2 pressure after being heat-treated at various temps. At 120°C, the rate of decrease of H_2 was gradual, and there was no marked inflection point in the rate curve. The rate of the pressure decrease was smaller when the temp. of heat-treatment was higher. Above 160°C, the course of the pressure decrease immediately after the start was similar, but there was a difference after a short time, and a break in the rate curve. In the part before the inflection point, H_2 was not in adsorption equil. with CuO, and after it, the observed decrease in H_2 pressure was the true reaction.

594. Hurst, J. E. **Cast iron. Residual elements and gas contents.** *Iron and Steel (London)* **18**, 635-40 (1945).—*C.A.* **40**, 1125⁷.

An addn. of 0.10% Te to an iron normally solidifying gray brought about complete whitening. The rate of scaling of 2 pieces 6% Si iron was not the same, although their compns. were similar. The difference in machinability between 2 cast iron cylinders was attributed to slight variations in compn., the cylinder having good machinability contained 0.09% Ti and 3.3 ml H_2 per 100 g of metal. The poor-machining casting contained 0.05% Ti and 7.8 ml H_2 per 100 g, all other elements including O_2 and N_2 being almost identical. The greatest single trouble in the production of sound castings arose from the gas content. H_2 in excess of 2 ml per 100 g of metal invariably caused unsoundness.

595. Itterbeek, A. van; Mariëns, P., and Verpoorten, I. **Activated adsorption of hydrogen in the neighborhood of the Curie point.** *Nature* **155**, 668 (1945).—*C.A.* **39**, 3989³.

The adsorption of H_2 (at pressures of 0.2, 0.4, 0.6, and 0.8 mm) on Ni is reported in cc./m² at 250°, 300°, 350°, 360°, 370°, and 400°C. Equil. is attained in 30 sec. Adsorption increases with temp. There is a pronounced discontinuity in the isobars near 358°C (the Curie point). The adsorption is partially reversible.

596. Michel, André; Bénard, Jacques, and Chaudron, Georges. **Mechanism of the diffusion of hydrogen in palladium at ordinary temperatures.** *Bull. soc. chim.* **12**, 336-40 (1945).—*C.A.* **40**, 259⁵.

A Pd wire was hydrogenated by electrolysis at 8 ma./cm² and all the H_2 dissolved in the metal. As electrolysis proceeded, the lattice parameter a of the ordinary Pd α phase increased from 3.882 to 3.885 A., whereas its pattern became diffuse. The hydride phase β appeared right from the start, but the intensity of its pattern did not appreciably increase until a for the α phase had reached its max.; then β began to replace α. A superficial layer of β phase was first formed; H_2 diffused from this layer into the body of the α metal until the phase was satd. with H_2; then further addn. of H_2 transformed α to β.

597. Mravec, J. G. **Determination of hydrogen in molten steel by the gas-tube method.** *Trans. Am. Inst. Mining Met. Engrs.* **162**, 298-403 (1945).—*C.A.* **40**, 7064⁶.

The gas tube is suitable for production control and research work. Results are based on a 3-5 lb sample.

598. Naughton, John J. **Determination of hydrogen by vacuum extraction and tin fusion.** *Trans. Am. Inst. Mining Met. Engrs.* **162**, 385-90 (1945).—*C.A.* **40**, 7064⁸.

In detg. H_2 in Fe-Mn alloys by any heating method, volatile Mn might absorb the H_2. To limit this loss, the samples were stored in a chamber immersed in liquid air. Gas-cooled samples of 3.5, 6, 10, 12, 17, and 22% Mn-Fe alloys contained approx. 0.0001, 0.00015, 0.0004, 0.00046, 0.00055, and 0.0006% H_2 by wt, resp. H_2O-quenched samples contained 0.0002-0.0007% H_2, the increase being due to the high soly. of H_2 and low rate of diffusion in the austenitic phase.

599. Post, C. B. and Schoffstall, D. G. **Determining the hydrogen content of molten steel by vacuum extraction.** *Trans. Am. Inst. Mining Met. Engrs.* **162**, 390-8 (1945).—*C.A.* **40**, 7064⁵.

A sample of liquid steel from the furnace bath was cast in a bomb. A portion of the cast steel sample was heated at 600-800°C under high vacuum, and the gases were collected and measured. The H-content could be detd. within ± 6% by this method.

600. Potter, E. V.; Hayes, E. T., and Lukens, H. C. **Hydrogen content of electrolytic manganese and its removal.** *Trans. Am. Inst. Mining Met. Engr., Inst. Met. Div., Tech. Pub.* No. **1809**, 9 pp. (1945).—*C.A.* **39**, 3735⁹.

Approx. 250 cc. of H_2 was sorbed in 100 g of electrolytic Mn and effectively removed by heating to not over 500°C for longer than 1 hr, in air or in an O_2-free atm. at atm. pressure, or in a partial vacuum. Heating to 500°C for 1 hr in a vacuum will reduce the H_2 content to less than the amt. sol. at 500°C and 650 mm H_2 pressure without increasing the O_2 or N_2 content to over 0.03%. A product free of H_2, and contg. no impurities not present in the original metal, can be obtained by heating in an atm. of some inert gas, or in H_2.

601. Rozental, K. I.; Dolin, P. I., and Ershler, B. V. **Kinetics of ionic discharge and ionization of adsorbed deuterium atoms on a platinum electrode.** *J. Phys. Chem. (U.S.S.R.)* **19**, 601-14 (1945).—*C.A.* **40**, 3323⁵.

A Pt wire contg. adsorbed H_2 was polarized. The capacity was high at low polarization voltages and low frequencies (e.g., 10 cycles per sec) of the polarizing a.c., and low at high frequencies (up to 6000 cycles per sec), when it is almost independent of the voltage; at high frequencies it was chiefly that of the elec. double layer. The capacity values in 0.14 N D_2SO_4 + 2 N Na_2 SO_4 in D_2O were lower than those in H_2O for all voltages and frequencies, and the conductance values were lower except at low frequencies. At a const. potential the adsorbed D_2 was greater than that of H_2; the difference of the energies of adsorption of D_2 and H_2 by Pt was calcd. to be 1.7 cal per mole.

602. Scafe, R. M. **Determination of hydrogen in steel sampling and analysis, by vacuum extraction.** *Trans. Am. Inst. Mining Met. Engrs.* **162**, 375-84 (1945).—*C.A.* **40**, 7064².

By using an evacuated tube and cylinder for sampling, samples were taken from various grades of steel covering a range from low-C rimming to high-C killed and fine-grained steels. The H-content varied from 0.0008% in a 0.08% C rimmed steel to 0.0033% in a fine-grained 0.52% C open-hearth steel.

603. Sloman, H. A. **Application of the vacuum-fusion method to the determination of oxygen, hydrogen, and nitrogen of nonferrous metals, alloys, and powders.** *J. Inst. Metals* **71**, 391-414 (1945) (Paper No. 998).—*C.A.* **39**, 4562⁴.

Data are given for steels, Ni, Co, Cu, Cr, Mn, Si, W, ferro-Cr, ferro-Si, ferro-Mn, Al, and Al-base alloys. Discussion of results includes the effects of d., degassing elements, fluxes, and furnace atms. during the original melting or sintering. The method is not suitable for Mg and Mg-alloys.

604. THOMPSON, J. G. **Determinations of hydrogen in iron and steel by vacuum extraction at 800°C.** *Trans. Am. Inst. Mining Met. Engrs.* **162**, 369-74 (1945).—*C.A.* **40**, 7064^4.

This method was preferred to the vacuum fusion method for the detn. of small amts. of H_2 on the grounds of greater speed and precision. Specimens of plain carbon and low-alloy steels retained approx. 0.00035% H_2 after annealing in H_2 at 1100°C. Remelted electrolytic Fe retained about 0.0005%, and 14-18% Cr steels quenched from 1100°C in H_2 retained more than 0.0007% H_2.

605. VIALLARD, RODOLPHE. **The fixation of hydrogen and deuterium by cerium.** *Compt. rend.* **221**, 144-6 (1945).—*C.A.* **40**, 1715^6.

When 0.1 g of Ce was exposed at room temp. to D_2, 24,200 cc of D_2, measured manometrically and referred to S.T.P., was absorbed per g atom of Ce. The reaction was exothermic.

606. VIALLARD, RODOLPHE. **Equilibriums of hydrogen and of deuterium with cerium and gadolinium.** *Ann. chim.* **20**, 5-72 (1945).—*C.A.* **40**, 4283^4.

D_2 and H_2 are fixed by Ce even at room temp. The product contains less D_2 than required by the formula CeD_3; it is closer to CeD_2. Both H_2 and D_2 react with Gd above 150°C. The absorption of the gases above 250°C proceeds according to the laws of diffusion and dissocn. The products obtained are Gd hydride and deuteride, corresponding to the formula Gd_2H_3 and Gd_2D_3, resp. If these compds. are cooled in the presence of H_2 and D_2, resp., GdH_2 and GdD_2 are obtained. Hydrides and deuterides of the rare earths are real chem. compds., but their compn. does not correspond to the formula MH_3.

607. YAVOĬSKIĬ, V. I. **Determination of hydrogen in steel.** *Zavodskaya Lab.* **11**, 406-15 (1945).—*C.A.* **40**, 3365^5.

The total H_2 content of steel can be divided into 3 fractions: (a) the H_2 liberated in a vacuum at 150-200°C, (b) that oxidized at 900-1000°C which comprises the H_2 dissolved in the steel, and (c) that oxidized close to or above the m.p. of the steel, which comprises the H_2 not liberated from the center of the sample at 900-1000°C and the chemically combined H_2. The fractions (b) and (c) are detd. as water vapor absorbed by P_2O_5. Fraction (c) is detd. after the complete oxidation of the steel.

608. BUSK, R. S. AND BOBALEK, E. G. **Hydrogen in magnesium alloys.** *Am. Inst. Mining Met. Engrs., Inst. Metals Div., Metals Technol.* **13**, No. 7; *Tech. Pub.* No. **2105**, 15 pp. (1946).—*C.A.* **41**, 77*c*.

H_2 forms an interstitial solid soln. with Mg to the extent of 15 to 20 cc. per 100 g of metal. This puts Mg in the same group as Ni, Fe, Co, Cu, or Mn. The soly. is sensitive to both alloy compn. and phase distribution. The addn. of most elements to Mg raises the tolerance for H_2; with the exception of Al, which first increases, then decreases the H_2 soly.

609. D'YAKONOV, A. AND SAMARIN, A. **Analysis of the adsorption process of gases by metals. II. Adsorption of hydrogen and nitrogen by iron.** *Bull. acad. sci. U.R.S.S., Classe sci. tech.* **1946**, 121-6.—*C.A.* **40**, 4932^2.

The neg. heat effect of adsorption and the close adherence of this phenomenon to "square-root rule" at all temps. and pressures indicated soln. of H atoms in Fe. The soly. const. of H_2 was given for α-Fe by $\log K_H = -(1250/T) - 2.51$; γ-Fe, $\log K_H = -(1220/T) - 2.335$; δ-Fe, $\log K_H = -(1340/T) - 2.46$; and liquid Fe, $\log K_H = -(1590/T) - 1.71$. The allotropic form of Fe had a slight effect on the soly. of H_2. N_2 was less metallic than H_2; and, therefore, it had a greater chem. activity toward Fe.

610. ITTERBEEK, A. VAN; MARIËNS, P., AND VERPOORTEN, I. **Van der Waals and activated adsorption on nickel and silver sheets.** *Mededeel. Koninkl. Vlaam. Acad Wetenschap., Belg.* **8**, No. 1, 8-24 (1946).—*C.A.* **41**, 5771b.

The amount and rate of adsorption of H_2 on pure Ni and Ag sheets were detd. between 200° and 500°C, and at 90°K in the case of Ag. A reproducible rate is realized only after repeated cleanings and activations by means of repeated heating in H_2 and evacuation. The adsorption on Ni corresponded to the formation of a unimol. layer. A discontinuity appeared in the isobars between 350° and 400°C. The adsorption on Ag was very slow, and maxima occur in the isobars at 200°C. Langmuir's equation represented the data.

611. KIPERMAN, S. AND TEMKIN, M. **Kinetics of the ammonia synthesis on tungsten.** *J. Phys. Chem. (U.S.S.R.)* **20**, 623-7 (1946).—*C.A.* **41**, 332*i*.

Mixts. of H_2 and N_2 were passed through a W catalyst. The temp. was varied between 582° and 678°C, the ratio H_2 to N_2 between 1 and 3, and the space velocity V of flow between 12,000 and 104,000 hr^{-1}. The yield of NH_3 divided by the yield corresponding to equil. could be expressed by the equation $k = -0.5\, \gamma^{1.5}\, VP^{0.5} \ln (1 - x^2)$, k being a const., $\gamma = P_h/0.75\, P$, P_h the partial pressure of H_2, and P the total pressure. The apparent energy of activation on Fe and Mo catalysts were very similar, the mechanism of the NH_3 synthesis on these 3 catalysts seemed to be identical.

612. LIANG, HUNG; BEVER, MICHAEL B., AND FLOE, CARL F. **The solubility of hydrogen in molten iron-silicon alloys.** *Am. Inst. Mining Met. Engr., Iron and Steel Div., Technol. Pub.* No. **1975**, 9 pp. (1946).—*C.A.* **40**, 2096^9.

The soly. of H_2 in 9 alloys contg. Si (0.08 to 63.7%) was detd. from 1350-1650°C at 50° intervals, under 1 atm. pressure. The soly. decreased rapidly from 32.5 ml per 100 g metal for the 0.08% Si iron at 1650°C to 7.3 for the 31.7% Si alloy. It then increased with further Si addns., being 23.8 ml for the 63.7% Si alloy at 1650°.

613. PORTEVIN, ALBERT. **Hydrogen in metals.** *Metal Progress* **50**, 1206-8 (1946).—*C.A.* **43**, 6553e.

At very low temp., H_2 mols. are superficially fixed according to the ordinary laws of adsorption, but as room temp. is approached the mols. dissociate; the result is a superficial fixation of H atoms, which then diffuses into the metal atom by atom. There is no major transformation of the metal structure.

614. Potter, E. V. and Lukens, H. C. **Solubility of hydrogen in electrolytic manganese and transition points in electrolytic manganese.** *Metals Technol.* **13**, No. 6; *Am. Inst. Mining Met Engrs., Inst. Metals Div., Tech. Pub.* No. **2032**, 12 pp. (1946).—*C.A.* **41**, 18*a*.

The soly. of H_2 in electrolytic Mn was detd. by a method not requiring complete degassing of the metal and checked by direct soly. detns. on degassed, electrolytic, and vacuum-distd. metal. The variation of soly. with temp. was detd. for electrolytic Mn from 25° to 1300°C, and the variation of soly. with pressure was detd. for const. temp. The variation in soly. of vacuum-distd. Mn with temp. was also detd.

615. Tucker, R. C. **Sources of hydrogen in cast iron.** *Foundry Trade J.* **79**, 129-132, 144 (1946).—*C.A.* **40**, 4992^2.

To avoid surface eruptions during the solidification of cast Fe, it was necessary to avoid excessive H_2 in the metal by maintaining the moisture content of the coke used below 2%. To detn. H_2 the sample residue was mixed with a measured vol. of air or O_2 and combustion was carried out by leading through a fused silica tube contg. Pd on asbestos. The use of fused silica was found advisable. After the combustion, the gas can be transferred into the measuring burette. This app. will det. 0.5 ml H_2 in 15 ml of a H_2-N_2 mixt. with an accuracy of ±0.03 ml.

616. Watanabe, Teizo. **The oxygen and hydrogen reaction-potassium chloride effect on the surface of steel.** *Rev. Phys. Chem. Japan, Shinkichi Horiba Commen.* **1946**, 68-72.—*C.A.* **44**, 1309i.

The space between the glass tube and the manometer was heated to 100°C to reduce condensation of the reaction products. Before each expt., the tube was thrice heated to 540°C and exhausted for several hrs, then filled with H_2 and pumped out again. The exhausted tube was brought to the temp. of the expt., and $H_2 + 1/2\ O_2$ by vol. were added. Runs were made (397°, 447° and 396°C and at 250, 500 and 750 mm initial pressure) with the tube coated with KCl, with a bare steel plate in the tube, and with the steel plate coated with KCl. The steel plate retarded reaction and became coated with a yellowish brown deposit. Coating the steel plate with KCl caused increases in pressure which were much greater than those observed in the glass tube alone.

617. Zapffe, C. A. **The behavior of hydrogen in steel during pickling.** *Wire and Wire Products* **21**, 149-57 (1946).—*C.A.* **40**, 2096^4.

Pickling and cathodic electrolysis form H atoms which either enter the grain of the steel or form gaseous H_2. H_2 entering the sheet from pickling travels through the metal and forms bubbles in oil on the opposite side. The embrittled metal breaks through the grain, not through the grain boundary. H_2 embrittlement is regarded the trapment under under high pressure of H gas within the microscopic voids that traverse the interior of each grain.

618. Andrew, J. H. and Lee, Hsun. **Internal stresses and the formation of hairline cracks in steel.** *J. Inst. Metals, Symposium on Internal Stresses in Metals and Alloys*, Preprint No. **1099**, 9 pp. (1947).—*C.A.* **42**, 84c.

Hairline cracks in steels were caused by internal pressures from H_2. H_2 could be accommodated at the mosaic disjunctions or boundaries and the variation in the size of the mosaic blocks might account for the different behaviors in which steels of different chem. compns. and treatments respond to hairline-crack formation.

619. Andrew, J. H.; Lee, H., Lloyd, H. K., and Stephenson, N. **Hydrogen and transformation characteristics in steel.** *J. Iron Steel Inst. (London)* **156**, 208-53, (1947).—*C.A.* **41**, 6860*g*.

H_2 evolution was studied for 22 steel compns. soaked in H_2 and cooled in vacuum. There was an increase in the rate of evolution corresponding to the γ-α change. Nascent H was generated by electrolytic action on the surface. The rate of diffusion and the soly. at room temp. depended upon the structure. The best temp. for isothermal H_2 removal corresponded with a rapid transformation. H_2 was the fundamental cause of hairline cracks.

620. Bénard, Jacques and Albert, Philippe. **Chemical activity of hydrogen desorbed from palladium and its alloys.** *Compt. rend.* **224**, 45-7 (1947); *Bull. soc. chim. France* **1947**, 904-9.—*C.A.* **41**, 2632*a*; **42**, 1102*g*.

Pd foils, 0.1 mm thick, were satd. with H_2 by electrolysis and suspended in solns. of $Fe_2(SO_4)_3$ or $KMnO_4$. The solns. were reduced at a rate which remained const. until the reaction stopped; 160 hrs were required for completion at 20°C. The total amt. of reduction found at 0°C was equiv. to 80cc. H_2 per g Pd, which accounts for nearly all that taken up by the foils. With increasing temp. the reaction rate increased but the total amt. of reaction decreased. With Pd-Au alloys, the total amt. of reaction was about half as great at 0°C, but dropped very little with increasing temp.

621. Bevington, C. F. P.; Martin, S. L., and Mathews, D. H. **The absorption of gases by titanium and zirconium.** *Proc. Intern. Congr. Pure and Applied Chem.* **11**, 3-16 (1947).—*C.A.* **44**, 7617*b*.

Isotherms and isobars are given. The soly. in Zr is 5 at. % for H_2, 30% for O_2, and smaller for N_2. In Ti the absorption is 30 at. % for H_2, 30% for O_2. Nonmetal atoms can take up positions in the octahedral holes of the metal lattice where they assume a slightly neg. change, becoming strongly bound but mobile, and as a result expand the metal lattice, increase the d., and decrease the elec. cond. Presence in the metal lattice of other atoms considerably lowers the H_2-sorbing capacity. The O, N, and C atoms cause a shift in discontinuous regions of the isotherms toward higher temp. and pressures.

622. Cameron, J. **The evolution and absorption of hydrogen by steel in industrial reheating furnaces.** *J. Iron Steel Inst. (London)* **157**, 609-15 (1947).—*C.A.* **42**, 4884i.

The rate of evolution or absorption of H_2 from solid steel is expressed as an exponential function of the time. At 1100°C the values of the const. are such that the limiting concn. is reached in 24 hrs. The local concns. of H_2 occurring due to the action of water vapor are not likely to exceed 2% H. Because of the large masses of steel and the relatively short soaking times the H-content of reheating-furnace atms. has practically no effect on the H-content of the steel ingot. H is usually present in very small concns. (of the order of 10^{-3} to 10^{-4}%).

623. Chufarov, G. I. and Nosyreva, S. S. **Methods of oxidation and hot extraction in determining hydrogen in metals.** *Zavodskaya Lab.* **13**, 287-8 (1947).—*C.A.* **42**, 3283a.

The detn. of H_2 by oxidation of the metal with O_2 at moderate temps. has a limited field of application. The method cannot be used for high-C steels because of the absorption of CO_2 by the plugs in the absorption tubes contg. P_2O_5. It is also impossible to det. H_2 by this method at temps. of 800-1000°C in the case of nichrome, heat-resistant steels, and many other metals and ferrous alloys.

624. Dubovol, V. Ya. and Ramanov, V. A. **Apparatus for the rapid determination of hydrogen in steel.** *Zavodskaya Lab.* **13**, 883-4 (1947).—*C.A.* **43**, 64*d*.

The sample was placed in a reaction tube and evacuated to eliminate all gases adsorbed by the sample and by the app. It was heated to 650-700°C and kept at this temp. for 25-30 min. and then cooled to room temp. The vol. of the gas was detd. The app. was suitable for plant labs.

625. Halsey, G. and Taylor, Hugh S. **The adsorption of hydrogen on tungsten powders.** *J. Chem Phys.* **15**, 624-30 (1947).—*C.A.* **41**, 7200f.

Frankenburg's data from −194° to 750°C were interpreted on the basis of a nonuniform surface without interaction, the heterogeneity of the surface being specified in terms of an exponential distribution of sites given by the distribution function. Such a heterogeneity was especially significant in W metal which hitherto had been treated as an essentially uniform surface.

626. Prettre, Marcel and Goepfert, Olivier. **Activated-adsorption isotherm for a heterogeneous surface.** *Compt. rend.* **225**, 681-2 (1947).—*C.A.* **42**, 1101c.

The adsorption of H_2 by a Ni-kieselguhr catalyst at 438°K does not follow the Langmuir isotherm. It is assumed that the surface of the catalyst is heterogeneous in the sense that different regions have different values of the parameters. The data can be reproduced within exptl. error by the sum of a no. of Langmuir isotherms equal to the no. of regions assumed. In the present instance 3 terms suffice.

627. Ransley, C. E. and Neufeld, H. **Absorption of hydrogen by aluminum attacked in caustic soda solution.** *Nature*, **159**, 709-10 (1947).—*C.A.* **41**, 5358*c*.

Specimens of cast 99.99% Al were immersed in 0.01 *N* NaOH for 49 days, with frequent renewal of the soln. The samples were washed in 1% acetic acid and dried. On degassing 0.47 cc. H_2 per 100 g Al was evolved with a much smaller vol. of other gases, mainly CO_2. The bulk of the gases other than H_2 was assocd. with the oxide film. A H-content of 0.4 cc./100 g was normal for cast Al.

628. Schumb, W. C.; Sewell, E. F., and Eisenstein, A. S. **Observations on the stability of the barium-hydrogen and zirconium-hydrogen systems.** *J. Am. Chem. Soc.* **69**, 2029-33 (1947).—*C.A.* **41**, 7217h.

The equil. gas pressures in the systems Ba-H_2 and Zr-H_2 were measured up to 600° and 650°C, resp. In a finely divided condition or in thin layers, Ba reacted readily with H_2. At 600°C the dissocn. pressure of BaH_2 was not greater that 0.24 mm, which was low in terms of H_2-thyratron requirements. Above this temp. Ba evapd. rapidly; this renders its use as a H_2 reservoir impractical. In the Zr-H_2 system the dissocn. pressure rose from 0.16 to 2.1 mm as the temp. was raised from 150° to 500°C.

629. Sykes, C.; Burton, H. H., and Gegg, C. C. **Hydrogen in steel manufacture.** *J. Iron Steel Inst. (London)* **156**, 155-180 (1947).—*C.A.* **41**, 6853*h*.

H-content is reported for typical heats of carbon and alloy steel made in elec. arc, and open-hearth furnaces and taken from ingots, billets, and forgings. Ductility is reduced if H_2 is in excess of 2 cc. per 100 g. Even under carefully controlled melting conditions H_2 content of 4-6 cc. per 100 g may occur; this amt. will decrease ductility. High H_2 in itself does not cause cracks.

630. Weiss, Joseph. **Some electron-transfer processes in heterogeneous systems. I. Electrodeposition of hydrogen.** *Discussions Faraday Soc.* No. **1**, 68-71 (1947).—*C.A.* **42**, 8667*d*.

Energy states for electrons on the surface can be produced through impurities, through the solvent producing chem. changes, or through adsorbed H atoms. In the last case the mechanism of the discharge is identical with that of the slow electrochem. recombination.

631. Wells, J. E. and Barraclough, K. C. **The determination of hydrogen in liquid steel.** *J. Iron Steel Inst. (London)* **155**, 27-32 (1947).—*C.A.* **41**, 7305*e*.

The best method of sampling the bath is a modified pencil test in which the sample is taken from the mold as soon as possible and then quenched in water.

632. Zhabina, V. A. **Method of hot extraction for determining hydrogen in steel.** *Zavodskaya Lab.* **13**, 275-81 (1947).—*C.A.* **42**, 3283d.

A simple vacuum resistance furnace was constructed to obtain temps. as high as 3000°C for detg. H_2. The service life of the heater can be extended to 8-10 months. The chief components of the furnace were shown. Two app. for detg. H at low temps. (up to 900°C) were described. In one app. the H was detd. by measuring the pressure drop after gases have passed over heated CuO and through P_2O_5 soln.; in the other app. the extd. gases were collected and analyzed for its components.

633. Beeck, Otto. **Surface catalysis.** *Revs Modern Phys.* **20**, 127-30 (1948).—*C.A.* **42**, 4435*b*.

Traces of H_2O and H_2S lowered the decompn. temp. of hydrocarbons. Mol. ray expts. also indicated the decompn. of CH_4 into CH_3 and H_2 and ethane into 2 CH_3 radicals. There was evidence that the CH radical was formed in the decompn. of acetylene. The adsorption step was the crucial step in surface catalysis and the reaction of ethylene and H_2 was cited as an example.

634. Beeck, O.; Ritchie, A. W., and Wheeler, A. **The adsorption of hydrogen on nickel catalysts. I. The effect of sintering.** *J. Colloid Sci.* **3**, 505-10 (1948).—*C.A.* **43**, 2079*f*.

High-vacuum-evapd. Ni films prepd. at 23°C adsorb H_2 practically instantaneously. There is little difference in the amt. adsorbed at −196°C and at room temp. This is in marked contrast to the results obtained with Ni catalysts prepd. from NiO by H_2 reduction. If the vacuum-evapd. films are sintered at 100-400°C, slow sorption of H_2 is observed. The ratio of slowly sorbed H_2 to rapidly adsorbed H_2 increases with increasing sintering temp. The so-called "activated adsorption" of H_2 on Ni is not adsorption on the metal surface, but is slow sorption into the interior of the metal structure.

635. Bernstorff, H. **The course of the sintering process in iron powder.** *Arch. Metalkunde* **2**, 103-6 (1948).—*C.A.* **43**, 2556*h*.

Powder was produced by pouring molten Fe or steel through a H_2O jet against a rotating disk. This material was annealed 1 hr in H_2 at 950°C. A coarse and a fine powder fraction were molded in the form of tensile specimens with approx. 40 tons/in^2. These were sintered at 850°, 1000°, 1150°, and 1300°C for periods ranging from 2 to 10 hrs. The differences observed in these tests were in degree or time of property changes. The differences observed between the fine and coarse powders were also attributed to the higher activation of the former. The finer powder either reached better properties, or if they were merely equal, they were reached with lower temp. or shorter time of sintering.

636. Bianchi, G. **Diffusion of cathodic hydrogen into platinum.** *Atti accad. nazl. Lincei, Classe sci. fis., mat. e nat.* **4**, 206-11 (1948).—*C.A.* **42**, 8557*h*.

Diffusion of H_2 into Pt is greatly influenced by the structure of the metal, as well as its previous history. When an electrode is Pt-plated to reduce the value of the cathode potential, the amt. of H_2 diffusing into the Pt is reduced proportionately.

637. Darken, L. S. and Smith, Rodney P. **Behavior of hydrogen in steel during and after immersion in acid.** *Corrosion* **5**, No. 1, 1-16 (1948).—*C.A.* **43**, 1301*h*.

The quantity of H_2 absorbed by steel during acid-pickling increased approx. linearly with square root of time until a limiting quantity, after which no H_2 was absorbed. This satn. value was very small for hot-rolled steel but increased markedly with cold work, and varied for different steels. The satn. value was decreased slightly by long-time annealing of cold-worked steel, but the rate of absorption was decreased considerably by annealing.

638. Derge, G.; Peifer, W., and Richards, J. H. **The sampling and analysis of steel for hydrogen.** *Am. Inst. Mining Met. Engr., Iron and Steel Div. Metals Technol.* **15**, No. 4 Tech. Pub. No. **2362**, 28 pp. (1948).—*C.A.* **42**, 5816*e*.

When a standard vacuum fusion equipment for the analysis of gases in steel is modified so that samples can be analyzed immediately after introduction to the vacuum, blank corrections are small. The gas reservoirs and pressure measurement are adjusted to the small amts. of H_2 which are present and it is possible to analyze steel for H_2 with a probable error of ±0.00001%.

639. Dialer, K. **The system misch metal-hydrogen.** *Monatsh.* **79**, 296-310 (1948).—*C.A.* **43**, 2840*h*.

The vols. of very pure H_2 absorbed by samples of misch metal (about 48% Ce, 30% La, 20% Nd) were measured. The metal surfaces were cleaned by repeated evacuations and exposures to a stream of N_2. The amt. absorbed was only 0.37% from the theoretical amt. for CeH_3 and did not depend on whether or not the Ce had peen previously heated. The dissocn. pressure of the CeH_3 was 375 mm at 800°C and above 200°C did not depend on the past history of the sample. The absorption energy was calcd. from the isosteres by van't Hoff's relation and was const. to about 160 cc. H_2 per g Ce corresponding to CeH_2. The energy dropped sharply with further absorption. These results and the ease of pumping some H_2 from CeH_2 suggested that the final H_2 was loosely bound.

640. Harashima, Akira; Tanaka, Tomoyasu, and Sakaoku, Kiichiro. **I. Coöperative phenomena in the palladium-hydrogen system.** *J. Phys. Soc. Japan* **3**, 208-13 (1948).—*C.A.* **44**, 5180*g*.

The theoretical calcn. of the H_2-Pd isotherms is improved at high temp. and low concn. by considering the dependence of potentials between protons and sites and between neighboring protons on the vol. of the Pd. The vol. change of Pd on absorption of H_2 and the unsym. isotherms are explained.

641. Hurst, J. E. and Riley, R. V. **A study of the hydrogen, oxygen, and nitrogen content of foundry pig iron.** *J. Iron Steel Inst. (London)* **159**, 130-6 (1948).—*C.A.* **42**, 6288*d*.

A vacuum fusion gas analysis method was used. In pig irons with high O-content, the N-content had a tendency to be above the av. The total oxygen was reported with no possibility of sepg. that due to CO evolved as gaseous form from that due to the reduction of oxide inclusions present in the Fe. The N-content was in the range from 0.001 to 0.006%. A Northamptonshire iron gave a gas vol. of over one-half the vol. of the solid specimen. Other residual elements detd. spectrographically were Ni, Cr, Cu, Mo, V, Ti, Al, As, Sn, and B. With the exception of B and Sn, significant amts. of all of these elements were found in all of the specimens.

642. Hurst, J. E. and Riley, R. V. **Residual gases in cast iron.** *Foundry Trade J.* **85**, 407-14, 429-34 (1948).—*C.A.* **43**, 4199*f*.

H_2, CO, N_2, O_2 can be detd. in cast iron. Samples for estg. the gases are obtained in an evacuated or N_2-purged steel tube sealed at the lower end with a Cu disk and at the upper end with a rubber balloon. The cast iron is further degassified by vacuum fusion at 1800-2000°C and the gases are pumped off by a diffusion pump and stored in inverted test tubes over Hg. The original gas content in the cast iron dets. the effect of remelt on gas content; remelts have reduced H_2 from 16.0 to 2.5 p.p.m., O_2 from 190 to 20 p.p.m., and N_2 from 20 to 10 p.p.m.

643. KODAMA, SHINJIRO; MATSUMURA, SHOICHI; YOSHIMORI, KEISUKE; NISHIBAYASHI, YOSHIBUMI; KADOTA, NORIAKI, AND IWAMURA, EINOSUKE. **Physicochemical studies on gasoline synthesis. XIII-XV. Influence of potassium carbonate and boric acid on the activated adsorption of hydrogen and carbon monoxide on iron catalysts.** *J. Chem. Soc. Japan, Ind. Chem. Sect.*, **51**, 98-100 (1948).—*C.A.* 44, 9136*c*.

By adding K_2CO_3 to the catalyst (100 Fe + 25 Cu + 2 Mn + 125 kieselguhr) the activated adsorption of CO above 200°C increased, while that of H_2 did not, especially when 6% K_2CO_3 was added. By adding H_3BO_3 to the same catalyst, adsorption of CO was decreased and of H_2 increased at 200°C. When 20% H_3BO_3 and 2% K_2CO_3 were added, adsorption of both CO and H_2 at 200°C increased.

644. NOSYREVA, S. S. **Measurement of the diffusion of hydrogen in steel.** *Zavodskaya Lab.* **14**, 307-10 (1948).—*C.A.* 43, 2559*i*.

The rate of diffusion of H atoms through sheets 0.5 mm thick (surface area 7 cm^2) was detd. by the displacement of a Hg column, by the H_2 gas issued from recombination, after diffusion across the sheet. The H atoms were produced by electrolysis of 0.1 *N* H_2SO_4 at 0.014 amp./cm^2, at room temp. Armco iron transmitted a total of 7.78 ml H_2 in 72 hrs, transformer steel a total of 6.37 ml. With austenitic stainless steel, no diffusion was noticed in 72 hrs. The soly. of H_2 after 24 hrs electrolysis was 6.93, 15.9, 46.5, and 25.0 ml/100 g in martensite, troostite, sorbite, and normalized steel, resp.

645. OBRUCHEVA, A. D. AND RUBINSHTEIN, I. L. **Polarization capacity of the iridized electrode.** *Doklady Akad. Nauk S.S.S.R.* **63**, 403-6 (1948).—*C.A.* 43, 2521*i*.

Curves of the potential against the charge (coulomb/g), in 1 *N* HCl, HBr, H_2SO_4, and KOH, resemble the corresponding curves obtained on platinized Pt. The strength of the bond between Ir and H_2 increases in the order HBr < HCl < KOH < H_2SO_4, as against the order HBr < HCl < H_2SO_4 < KOH on Pt. The O_2 arrest in KOH begins immediately and without transition after the H_2 portion, in H_2SO_4 at 0.5, in HCl at 0.73 and in HBr at 0.97 v.; the nearly horizontal arrest in HBr is evidently linked with evolution of Br_2.

646. PERRIN, MARCEL. **Reduction with hydrogen of nickel Fischer catalysts.** *Compt. rend.* **227**, 476-8 (1948).—*C.A.* 43, 26*i*.

The wt loss and amt. of H_2O and CO_2 formed during heating (with or without simultaneous reduction) of a Ni-promoter-kieselguhr Fischer catalyst (pptd. with alkali carbonate) were measured as a function of time and temp. Upon heating in streaming H_2 up to 450°C in 127 min., a wt loss of 24.8% was noted. A similar expt. but in streaming N_2 gave a loss of 24%. Heating in air at 900°C resulted in a loss of 26.4%; this showed that heating up to 450°C had eliminated almost all volatiles.

647. REINEBECK, LIESELOTTE. **Spectroscopic investigations of the surface interchange reactions between hydrogen and a copper cathode.** *Funk u. Ton* **1948**, 223-6.—*C.A.* **45**, 1426h.

The carrier gas was He or A, to which H_2 was added through a Pd tube. The spectroscopically observed CuH mols. must have formed on the cathode surface. The tube temp. was 600-800°K but owing to ionization local hot spots exist on the cathode surface, leading to evapn. In CuD the intensity distribution of the rotation lines corresponds to a temp. of 2000°K. Further work dealt with the exchange in the presence of water of H_2 and D_2 on a metal surface covered with H_2. BiH and AlH can be detected in the spectrum even when no H_2 is added. The hydrides of Pb and Te were not formed. These expts. show the effect of the surface on hydride formation.

648. SAUERWALD, F. **Method for determining hydrogen, particularly in magnesium.** *Z. anorg. Chem.* **256**, 217-25 (1948).—*C.A.* 43, 2119*g*.

The direct detn. of H_2 by a method similar to that used for the detn. of H_2 in steel was not satisfactory in the analysis of Mg because the metal itself had too high a vapor pressure. It was found possible to chlorinate all of the H_2 at 750°C and by passing the HCl together with pure O_2 through a combustion tube (400°C) contg. CuO, H_2O was formed which can be absorbed in weighed $MgCl_2$ and P_2O_5 tubes.

649. SIMPKINSON, T. V. **Melting of quality basic electric steel.** *Can. Mining Met. Bull.* No. **431**, 127-37 (1948).—*C.A.* 42, 4110*b*.

The phys. chemistry of steelmaking is discussed in simple terms, with emphasis on oxidation, deoxidation, and the role of H_2.

650. SIMS, C. E. AND MOORE, G. A. **Apparatus for the hot-extraction for hydrogen in steel.** *Am. Inst. Mining Met. Engrs., Iron and Steel Div., Metals Technol.* **15**, No. 4, Tech. Pub. No. 2369, 10 pp (1948).—*C.A.* 42, 5724*h*.

App. is described for conducting hot extn. of steel in a high vacuum up to 1050°C (1925°F), for periods of 40 hrs or more. The accuracy of the results obtained is entirely controlled by errors in sampling methods and in analysis of the evolved gas, since the evolution app. is currently more precise than available assocd. equipment.

651. SMITH, DONALD P. **Note on some theoretical discussions of palladium-hydrogen and cognate systems.** *Phil. Mag.* **39**, 477-81 (1948).—*C.A.* 43, 4070*h*.

The effect of occulsion in rifts is discussed. Theoretical treatments that assume the existence of simple solid-soln. systems, in which the hydrogen is uniformly distributed, disregard exptl. evidence to the contrary.

652. SUTRA, GENEVIÈVE AND DARMOIS, EUGÈNE. **The passage of hydrogen through iron.** *Compt. rend.* **226**, 177-9 (1948).—*C.A.* **42**, 2842*i*.

One face of a film of Fe (53 μ thick) was exposed to solns. of varying pH and the opposite face to a vacuum. With acid solns., a part of the liberated H_2 diffused through the Fe. The proposed mechanism involved H atoms, formed when adsorbed H^+ were discharged at the surface. The relation between loss in wt of the Fe and H-ion concn. had the same form as the Langmuir adsorption isotherm.

653. TANAKA, TOMOYASU; SAKAOKU, KIICHIRO, AND HARASHIMA, AKIRA. **II. Coöperative phenomena in the palladium-hydrogen system.** *J. Phys. Soc. Japan* **3**, 213-18 (1948).—*C.A.* **44**, 5180*h*.

A further refinement of a previous calcn. to take into consideration D_2 and the variation of the thermal vibration of the proton in its site in the Pd lattice yielded isotherms agreeing more closely with the exptl. curves.

654. ZAPFFE, C. A. AND HASLEM, M. E. **The relationship between cold-working and hydrogen embrittlement.** *Wire & Wire Products* **23**, 475-8, 527, 528, 529 (1948).—*C.A.* **42**, 5396*d*.

Both the mech. movements of the cold-work and the formation of H_2 within steel operate along planes of looseness within the grain of the metal. Cold-working increases the capacity of the metal for absorbing H_2, leaving the metal more liable to embrittlement. Removal of the effects of cold-work by annealing renders the metal more resistant to H_2 embrittlement. Cold-working a metal already contg. H_2 causes removal of much of the gas by opening communications among the individual gas occlusions and allowing them to escape.

655. ZAPFFE, C. A. AND HASLEM, M. E. **Sensitivity of different steels to pickling brittleness.** *Wire & Wire Products* **23**, 563-9, 609-12 (1948).—*C.A.* **42**, 6729*h*.

In cathodic pickling, where surface concn. of the H_2 can be closely controlled by regulation of c.d., factors within the steel are disclosed which affect susceptibility to H_2 embrittlement. In acid pickling, results are modified by the degree of metal attack, because it controls the hydrogenizing conditions.

656. BARTZ, M. H. AND RAWLINS, C. E. **Hydrogen blistering of steel a source of damage to vessels.** *Petroleum Processing* 4, 898-906 (1949).—*C.A.* 44, 1388*h*.

The blistering of vessel walls and other refinery steel equipment results from acid corrosion which liberates at. H. This diffuses through the steel until it encounters a break or discontinuity in the metal, where the reaction $H + H \rightarrow H_2$ takes place. The H_2 is not capable of diffusing further, and the pressure of the trapped gas eventually results in blisters in the metal.

657. BASTIEN, PAUL AND AZOU, PIERRE. **The action of subzero temperatures on the ductility and deformation characteristics of steel which has been charged electrolytically with hydrogen.** *Compt. rend.* **228**, 1337-9 (1949).—*C.A.* **43**, 5717*a*.

Tensile strength and elongation of annealed, 0.15% C steel, charged electrolytically in HCl with H_2, were detd. over the range +15° to −70°C. The effect of H_2 on strength was minor. Localized concn. of H_2 in imperfections in the steel crystals interfered with slip on plastic deformation.

658. BASTIEN, PAUL AND AZOU, PIERRE. **Influence of hydrogen on the cohesion of steel.** *Compt. rend.* **228**, 1651-3 (1949).—*C.A.* **43**, 8331*g*.

The difference between a steel charged in H_2 and the same steel not charged, was in the cohesion, which was 115 kg/mm² for uncharged and 74 for charged steel annealed to 0.15% C. These values were correct to ±5-10%.

659. BASTIEN, PAUL AND AZOU, PIERRE. **The occurrence of a reversible hydrogen embrittlement of iron and steel at low temperature.** *Compt. rend.* **229**, 549-51 (1949).—*C.A.* **44**, 511*h*.

The decrease of tensile strength and elongation, caused by charging with H_2 in acid or electrolytically, disappeared reversibly below −110°C. Below −110°C the feeble activated adsorption of H_2 on the walls of the voids of the metal was changed into stronger phys. adsorption reducing the H_2 pressure and eliminating the embrittlement. On heating above −110°C the processes were reversed.

660. BRUGGEMANN, T. **Penetration of hydrogen into steel.** *Chem. Tech.* **1**, 178-82 (1949).—*C.A.* **44**, 6794*f*.

A review.

661. COUPER, A. AND ELEY, D. D. **Parahydrogen catalysis by transition metals.** *Nature* **164**, 578-9 (1949).—*C.A.* **44**, 2355*a*.

The activation energy E and frequency factor A_o for the catalytic activity of Pd-Au alloys for the para H_2 conversion were measured. Little change was noted as the concn. of Au was increased up to 60 at. %, but at higher concns. there was an abrupt increase in E and decrease in A_o. The catalytic activity of pure Pd fell to zero when H atoms were dissolved in the Pd. The results were attributed to the filling of the *d*-band of Pd with electrons from the added Au or H.

662. DARMOIS, E. **The penetration of hydrogen into iron and several consequences.** *Bull. soc. chim. France* **1949**, D170.—*C.A.* **43**, 7304*h*.

The passage of H_2 through Fe in acid soln. takes place when H^+, as a free proton, is adsorbed on the Fe surface. The protons diffuse into the Fe, and Fe^{++} ions go into soln. The protons diffusing ensemble of electrons and protons is equiv. to H atoms. Values are consistent with and adsorption process based on the Langmuir isotherm

663. DASTUR, M. N. AND CHIPMAN, JOHN. **Equilibrium in the reaction of hydrogen with oxygen in liquid iron.** *J. Metals* **1**, No. 8, Trans. 441-5 (1949).—*C.A.* **43**, 8822*e*.

The reaction was studied between 1563°-1760°C. The exptl. results were represented by: $K_1 = p_{H_2O}/(p_{H_2} \times \%O)$; $\log K_1 = 7050/T - 3.17$.

664. DEDRICK, J. H. AND GERDS, A. **A study of the mechanism of sintering of metallic particles.** *J. Applied Phys.* **20**, 1042-4 (1949).—*C.A.* **44**, 506*b*.

Single layers of spherical Cu particles were sintered under varying conditions of time and temp. in a dry H_2. Analysis of the rate of interface contact between the particles had shown metallic sintering to be a diffusion process. The heat of activation of self-diffusion of Cu had been calcd. and found to be 55,000 cal/mole.

665. EUCKEN, A. **The hydrogenation of unsaturated hydrocarbons on nickel contacts. I. The adsorption of hydrogen on nickel.** *Z. Elektrochem.* **53**, 285-90(1949).—*C.A.* **44**, 3342*h*.

The adsorption of H_2 on Ni powder prepd. by reduction of NiO at 280°C (surface 1.60 cm^2/g) was studied by measuring (1) the adsorption equil. between 318° and 539°K at 0.0009 to 0.25 mm Hg pressure, (2) the heats of adsorption at various coverages of the surface, (3) the adsorption rate. Adsorption isobars detd. with increasing temp. exhibited two max. at 200° and 270°K, resp. The apparent heterogeneity of the adsorbing surface was due to the fact that adsorbed H atoms diminish the surface activity for further adsorption. This also caused a decrease of the heat of adsorption with increasing coverage.

666. GALAKTIONOVA, N. A. **The role of hydrogen in flake formation.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk* **1949**, 1666-74.—*C.A.* **46**, 74*f*.

A series of 30-kg Cr-Ni-Mo steel melts was made in a high-frequency furnace, either *in vacuo* or with injection of H_2 into the melt. The H_2 melts contained 0.0057% H_2 as compared to 0.00034% for vacuum melts. X-ray studies made on the various samples to det. lattice parameter and secondary x-ray spectra indicated that H was in the ionized form as protons which penetrated deep into the electron shells and produced more stable atoms.

667. GULBRANSEN, EARL A. AND ANDREW, KENNETH F. **Kinetics of the reactions of zirconium with oxygen, nitrogen, and hydrogen.** *J. Metals* **1**, No. 8, Trans. 515-26 (1949).—*C.A.* **43**, 8817*b*.

The kinetics of the reactions of ductile Zr with O_2N_2, and H_2 were studied as a function of time, temp., pressure, surface prepn., and stability. The oxidation reaction showed an appreciable rate at 200°C. No evidence was found for an unstable oxide. The nitride reaction was found to be very sensitive to traces of O_2 and H_2 in the reacting gas. The rate of reaction of Zr with N_2 was much slower than the reactions with O_2 and H_2. The nitride was found to be stable to at least 900°C. The hydride reaction obeyed the sq. root of pressure law. In this case, a film was not formed and it appeared that H_2 diffused into the Zr lattice as atoms.

668. GULBRANSEN, EARL A. AND ANDREW, KENNETH F. **Reactions of zirconium, titanium, columbium, and tantalum with the gases, oxygen, nitrogen, and hydrogen at elevated temperatures.** *J. Electrochem. Soc.* **96**, 364-76(1949).—*C.A.* **44**, 961*b*.

A systematic study is made of the kinetics of the reactions including a study of the time, temp., and pressure variables. The reaction rates are studied by the vacuum microbalance method and the surface structures by the electron-diffraction method. Diffusion consts. and energies of activation are calcd. where possible and the several reactions for the different metals are compared.

669. HOTOT, G. **Determination of hydrogen in steels.** *Rev. universelle mines* 5, 277-8 (1949).—*C.A.* **43**, 8964*h*.

An app. is described with which H_2 and other gases can be detd. in steel with samples of as little as 10 g and up to 300 g. The method is based on the diffusion of H_2 in a vacuum at 700°C. The sample taken from the ingot is held under Hg during transport to the app. consisting of a quartz tube heated externally.

670. HURST, J. E. AND RILEY, R. V. **Gases in cast iron.** *Foundry Trade, J.* **87**, 393-7 discussion, 397-400 (1949).—*C.A.* **44**, 509*f*.

H_2 had proved to be the major constitutent. Substantial amts. of CO and N_2 were always present and the combined vol. often equaled and sometimes exceeded the H_2. Chill-cast white irons, free from graphite, gave a gas which was 70-90% H_2, whereas phosphoric gray irons yielded only 40-70% H_2. The hot-extn. technique, giving accurate results with steels, did not apparently work so precisely with cast iron., The compn. of the gas evolved at 600-800°C *in vacuo* was not predominantly H_2; it contained appreciable amts. of N_2 and CO. Further amts. of H_2 (and CO and N_2) were obtained on (a) raising the extn. temps., (b) machining off the outer layers of the specimen, (c) allowing the specimen to be exposed to the atm., and (d) melting the iron.

671. JORDAN, CHARLES B. AND DUWEZ, POL. **The densification of copper powder compacts in hydrogen and in a vacuum.** *J. Metals* **1**, No. 2, Trans. 96-9(1949).—*C.A.* **43**, 2556*e*.

The densification of Cu powder compacts in H_2 and in a vacuum can be approx. described as a rate process governed by a heat of activation. Cu powder compacts densify more slowly in a vacuum than in H_2. The oxide film on the surface of the particles influences the rate of densification.

672. KWAN, TAKAO. **Adsorption of hydrogen on nickel, cobalt, and platinum at low pressures.** *J. Research Inst. Catalysis*, **1**, 81-94 (1949).—*C.A.* **44**, 4304*e*.

Adsorption isotherms of H_2 between 10^{-3} and 1 mm Hg on Ni, Pt, and Co powders were detd. between 50° and 300°C with special care as to hysteresis. Surface areas of the samples were detd. by the B.E.T. method. Initial H_2 adsorption occurred at const. differential heat of adsorption equal to 26, 18, and 19 kcal/mole for Ni, Pt, and Co, resp., at 300°C. After about 0.1 of the surface was covered, there was a gradual decrease in the heat of adsorption.

673. KWAN, TAKAO. **Rate of hydrogen adsorption on reduced copper.** *J. Research Inst. Catalysis*, **1**, 95-9(1949).—*C.A.* **44**, 4303*i*.

Adsorption of H_2 at about 0.1 mm Hg pressure and temps. of 300°, 350°, and 400°C, on Cu powder (prepd. by reduction of $CuCO_3$), occurred at a slow rate; the sorption did not reach equil. after 66 hrs. The heat of activation of adsorption was 20 kcal/mole.

674. KWAN, TAKAO. **Research on pure iron and synthetic-ammonia catalyst by means of hydrogen adsorption.** *J. Research Inst. Catalysis*, **1**, 100-9(1949).—*C.A.* **44**, 4304*h*.

Adsorption isotherms of H_2 at pressures between 10^{-4} and 1 mm Hg on pure Fe and synthetic-NH_3 catalyst were detd. at 0°, 25°, 50°, and 100°C. Differential heats of adsorption diminished continuously from 17.5 kcal./mole at the lowest pressure to 5 kcal./mole at the highest pressure. Calcns. from the rate of decrease of the differential heat of adsorption yielded surface areas 70 and 14 times, resp., the B.E.T. areas of the Fe and catalyst and were in contrast to results on Ni and Co powders.

675. McQuillan, A. D. **Effect of small quantities of hydrogen and grain-size on the α-β transformation of titanium.** *Nature* **164**, 537 (1949).—*C.A.* 44, 4320*h*.

An almost isothermal change in the equil. pressure was noted in a coarse-grained sample of Ti contg. 0.02 at. % of H at 882 ± 3°C. Thermal analysis and resistance-temp. curves showed single discontinuities for Ti contg. 0.02 at. % of H, and no change was detected when the H_2 was removed.

676. Roginskii, S. Z.; Tretyakov, I. I., and Shekhter, A. B. **Electron-microscopic study of the surface of working catalysts. II. Change of the surface of palladium during catalytic oxidation of hydrogen.** *Zhur. Fiz. Khim.* **23**, 1152-60 (1949).—*C.A.* 44, 1313*a*.

Electron photomicrographs (shadow replicas method) of Pd plates were not altered by treating Pd with O_2 or H_2O. Heating in H_2 at 175°C caused change in gloss of the Pd plates, but almost no alteration in the electronograph. When Pd was used as catalyst (the conditions of expt. were not given), its surface became pitted, the depressions being of very different dimensions; after long usage, the surface appeared etched.

677. Sauerwald F. **The solubility and retention of hydrogen in liquid and solid magnesium and magnesium alloys.** *Z. anorg. Chem.* **258**, 27-32 (1949).—*C.A.* 43, 5355*i*.

At 760°C 41 cc. of H_2 dissolved in 100 g of tech. Mg. The low soly. of H_2 in Al and Zn caused low soly. in alloys of Mg with these metals. The particularly low soly. of H_2 in the alloy contg. 33.3 at. % Zn was attributed to the stability of the Zn-Mg compd. The change in tenacity and extension was sharpest for H-contents between 19.5 and 21.8 cc./100 g of melt. The H-content of the melt could be decreased by passing Cl_2 through it provided the flow of Cl_2 was rapid so that HCl was not reduced by the Mg.

678. Shaler, A. J. **Seminar on the kinetics of sintering.** *J. Metals* **1**, No. 11, Trans. 796-813 (1949).—*C.A.* 44, 506*c*.

The role of oxide films, of the thickness commonly found on metal powders, needed quant. treatment. In view of the extensive use of a H atm., the kinetics of sintering in the presence of diffusible gases was a field in which more work must be done. In addn. to the changes known to occur during the heat-treatment of massive metals-recrystn., grain-growth, etc.-the presence of a large surface-to-vol. ratio increased the effects of transient phenomena such as the reactions and desorptions that occurred at the surfaces of metals.

679. Shuler, K. E. and Laidler, K. J. **The kinetics of heterogeneous atom and radical reactions. I. The recombination of hydrogen atoms on surfaces.** *J. Chem. Phys.* **17**, 1212-17(1949).—*C.A.* 44, 4760*d*.

The data on the kinetics of the recombination of H atoms on various types of surfaces are analyzed in the light of the theory of abs. reaction rates. For the reaction on dry oxides and dry glass, good agreement is found assuming that reaction occurs between a gas-phase H atom and an adsorbed H atom, the adsorption being of the van der Waals type at low temps. and chemisorption at higher ones. The mechanism of surface poisoning by water vapor is due at high-temp. to an increase in activation energy, the mechanism being $S{-}{-}{-}{-}OH + H \rightarrow S{-}{-}{-}{-}O + H_2$; in the low-temp. region to a decrease in the no. of active centers, the reaction being between a gaseous atom and a van der Waals adsorbed H atom above the water layer.

680. Shuler, K. E. and Laidler, K. J. **The kinetics of heterogeneous atom and radical reactions. II. The recombination of hydroxyl radicals.** *J. Chem. Phys.* **17**, 1356-7 (1949).—*C.A.* 44, 4760*d*.

Considerations show that previous exptl. investigations as to the rate of recombination of OH radicals really gave information as to the rate of the gas-phase reaction. The surface reaction is very much slower.

681. Tarama, Kimio; Miyakawa, Toshio, and Morishima, Naomasa. **Adsorption of hydrogen on palladium.** *Repts. Inst. Chem. Research, Kyoto Univ.* **17**, 108-11(1949).—*C.A.* 45, 9993*c*.

The adsorption of H_2 on Pd black was detd. statically under a const. pressure within the range of 0-180°C and 0.125-1 atm. The results agreed with those calcd. by Fowler-Guggenheim's equation of equil. between Pd and H (which is assumed to be dissolved in Pd as proton) at high temp. under low pressure, but were larger below 90°C under high pressure. The excess satisfied Freundlich's equation $a = p^{1/n}$ when evaluated with $n = 1.8$-2.

682. Wentrup, Hanns; Fucke, Herbert, and Reif, Otto. **Hydrogen contents of liquid steel made by different processes.** *Stahl u. Eisen* **69**, 117-22 (1949).—*C.A.* 43, 8331*h*.

The sampling method by suction was described. Acid open-hearth steel showed lowest H-content, amounting to 6.5 cm^3/100 g. The elec.-arc furnace produced steel with H-content of 9.3 cm^3/100 g.

683. Zapffe, C. A. and Haslem, M. E. **Hydrogen embrittlement in copper electroplating.** *Plating* **36**, 906-13 (1949).—*C.A.* 43, 8903*f*.

Wire bend tests showed serious embrittlement of AISI 440-C stainless steel by plating in acid, CN, and proprietary Cu baths. Since even very high efficiency plating processes caused more embrittlement than cathodic pickling, unexplained surface chemistry rather than the amt. of H_2 discharged must det. cathodic H_2 absorption.

684. Bastien, Paul. **Physics of metals. Diffusion of gases in metals. Fe-H system.** *Métaux & corrosion* **25**, 248-62 (1950).—*C.A.* 45, 9439*h*.

Characteristic phenomena of gas diffusion in metals are expressed for the Fe-H_2 system. The quantity absorbed by Cu, Co, Ni, and Fe increases with temp. Th, Ti, and V can absorb 10^3 to 10^5 times more H_2 at the same temp. than Fe, Ni, or Cu, the amt. decreasing with increasing temp. The brittleness of steel is indicated as due to H_2 absorption.

685. Beeck, O.; Givens, J. W., and Ritchie, A. W. **The adsorption of hydrogen on nickel catalysts. II. Sorption isobars from 20°K to room temperature.** *J. Colloid Sci.* **5**, 141-7(1950).—*C.A.* **44**, 6228*f*.

Sorption isobars were detd. for H_2 at 0.1 mm Hg pressure on evapd. Ni films between −253° to 25°C. Slow activated sorption, interpreted as absorption of H_2 into the interior of the metal structure, was observed in agreement with previous results. The process was exothermic and, after initiation by raising the temp. to approx. −150°C, continued at much lower temps.

686. Bénard, J. and Albert, P. **The chemical activity of hydrogen desorbed from palladium.** *J. chim. phys.* **47**, 449-53(1950).—*C.A.* **44**, 9783c.

Reducing action at a distance was obtained by H_2 desorbed from Pd into a stream of pure water or a stream of pure N_2.

687. Bénard, Jacques and Moreau, Jean. **Kinetics of the reduction of ferrous oxide by hydrogen.** *Compt. rend.* **231**, 904-6 (1950).—*C.A.* **45**, 5051e.

Homogeneous sheets of FeO were obtained by oxidizing plates of pure Fe in air at 850°C. Reduction at const. temp. between 450° and 700°C was followed by measuring the change in mass as a function of time. An initial laten period was explained by the formation of Fe nuclei through thermal decompn. of FeO according to $4FeO \rightarrow Fe_3O_4 + Fe$. Reduced Fe then accumulated concentrically around these centers giving rise to a period of acceleration. The Fe formed gradually recrystallized, however, and formed a less permeable material so that the reduction rate decreased toward the end of the process.

688. Bhat, U. V. **Diffusion of hydrogen in steel.** *Trans. Indian Inst. Metals* **4**, 279-89 (1950).—*C.A.* **46**, 7019*i*.

The effect of grain size, compn., and heat treatment of steel on the H_2 diffusion at room temp. has been studied. Grain size of the steel has no notable effect on H_2 diffusion, so diffusion must take place through the lattice. H_2 diffusion decreases with increasing amts. of C or Cr.

689. Couper, A. and Eley, D. D. **The parahydrogen conversion on palladium-gold alloys.** *Discussions Faraday Soc.* **1950**, No. 8, 172-9, discussion 179-84.—*C.A.* **45**, 9988*a*.

Magnetic measurements indicate that 40 and 30 at.% Pd correspond to the complete filling of the *d*-band, or at. *d*-orbitals, with electrons. Vacant *d*-orbitals are essential for the low-temp. catalysis, and they appear to bond the chemisorbed H atoms M—H. The reaction goes through a H_3 complex formed by entry of H_2 from the van der Waals layer. It is postulated that each site exerts 2 bonds to the activated complex, employing atomic *d* and hybrid $d^{2.56}\ sp^{2.22}$ metallic orbitals.

690. Craxford, S. R. and Poll, A. **The reduction of catalysts with a cobalt and kieselguhr base utilized in the Fischer-Tropsch synthesis.** *J. chim. phys.* **47**, 253-6, discussion, 256-7 (1950).—*C.A.* **44**, 8086*i*.

Catalysts having the compn. Co:-ThO_2:MgO: kieselguhr in the ratio 100:6:12:200 were used. The most active catalyst was obtained by reduction at 400°C in pure, dry H_2 at a flow rate of 6000 vols. per vol. of catalyst per hr. The percentage reduction of Co oxide was 29.8% at 300°, 53.2% at 350°, 71.2% at 400°, 81.3% at 450°, and 91.5% at 500°C. Reduction at 400°C caused the least diminution of the surface area after vacuum treatment at 450°C for 4 hrs. A reduction in surface area from 229 m^2/g of Co to 180 m^2 occurred when the catalyst was used in synthesis.

691. Dunoyer, J. M. **Mechanism of the action of gas on a solid body.** *Le Vide* **5**, 905-11 (1950).—*C.A.* **45**, 2755*h*.

An equation was established for the kinetics of a gas-solid reaction, that takes into account the diffusion of the gas into the solid. The reaction studied was the reduction by H_2 of MoO_3 dust, prepd. by dissocn. of $Mo_7O_{24}(NH_4)_6 \cdot 4H_2O$ at 400°C. The reduction to MoO_2 took place at ~400°C. The reaction rates were measured by weighing the reaction tube at different time intervals. The calcd. activation energy was 48 kcal./mol.

692. Emmett, P. H. and Kummer, J. T. **Physical and chemical adsorption studies on catalysts.** *J. chim. phys.* **47**, 67-73 (1950).—*C.A.* **44**, 6711*i*.

$N_2{}^{28}$ and $N_2{}^{30}$ react rapidly to form $N_2{}^{29}$ over Fe catalysts at 450° to 500°C. Singly-promoted Fe synthetic-ammonia catalysts rapidly catalyze the reaction $H_2 + D_2 \rightleftharpoons 2HD$ at −195°C, even though D_2 does not remove from the surface at −195°C, H_2 adsorbed at 78° or 100°C. Adsorption measurements indicate the existence of a new type of activated adsorption on iron capable of occurring rapidly at −195°C. Chemisorption measurements using normal CO as well as radioactive CO indicate that Fe synthetic ammonia catalysts behave as though half the surface were homogeneous and half were heterogeneous.

693. Freidlin, L. Kh. and Ziminova, N. I. **Differentiated outgassing of nickel. Two forms of binding of hydrogen in a catalyst.** *Doklady Akad. Nauk S.S.S.R.* **74**, 955-8 (1950).—*C.A.* **45**, 1836*h*.

Differentiation between the H_2 adsorbed on and the H_2 dissolved in H_2-satd. Ni was realized, and the nonequivalence of the 2 forms of H was demonstrated by expts. of hydrogenation of org. compds. with the H_2 contained in Ni. The org. compds. were hydrogenated, in a N_2 atm., with Ni satd. with H_2 for 10 min. prior to the expt. The compds. investigated fell into 3 groups: I, represented by Michler's ketone, withdrew from the Ni only a definite fraction of its H_2 content. Thus, 2.33 g Ni gave up a total of 49-50 ml H_2. Group II, represented by styrene, cinnamic acid, or its esters, 2.33 g of Ni gave up 198-200 ml H_2, and, on subsequent satn., took up only 19-21 ml. Compds. of group II withdrew from the Ni, in addn. to the adsorped H_2, also part of the dissolved H_2. Group III, e.g. $PhNO_2$ and vinyl butyl ether, withdrew the total amt. of both the H_2 adsorbed and that dissolved in the Ni. The no. of H atoms dissolved in Ni was about 3.5 times the no. of H atoms adsorbed.

694. FREIDLIN, L. KH. AND ZIMINOVA, N. I. **Promotion of nickel catalyst by hydrogen.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* **1950**, 659-61.—*C.A.* **45**, 6029*i*.

Leaching of Al_3Ni_2 2 hrs at 105°C with NaOH, followed by washing with H_2O, EtOH, and toluene gave the basic catalyst contg. 2.33 g Ni per ml. After satn. with H_2 for 10 min., residual H_2 was displaced with N_2 and the unsatd. compd. was introduced; thus hydrogenation was caused at the expense only of H_2 retained by the catalyst. After washing with toluene the operations were repeated. $PhNO_2$, CH_2:CHOBu, etc., were most satisfactory for the removal of the retained (adsorbed) H_2 from the catalyst. Removal of as much as 210 ml adsorbed H_2 from 2.33 g Ni still left certain activity (hydrogenating) in the catalyst, and the latter was pyrophoric; but removal of 223-4 ml H_2 (24-hr contact of the unsatd. compd.) completely inactivated the catalyst, which was then nonpyrophoric. Thus, skeletal Ni was a catalyst that was promoted by adsorbed H_2; possibly other forms of Ni catalyst were similarly promoted.

695. FRIZ, HANS. **Chemical adsorption of hydrogen and other gases on tungsten disulfide.** *Z. Elektrochem.* **54**, 538-40(1950).—*C.A.* **45**, 4994h.

WS_2 was prepd. by decompn. at 400°C of $(NH_4)_2WS_4$ and by reaction at 600°C of WO_3 and CS_2. The H_2 adsorption was the same on both when referred to the same surface area (a detn. by phys. adsorption of CO_2 and SF_6). Between 20° and 450°C the surface adsorbed the gas; above 200°C it was dissolved in the lattice. Similar effects were noted with C_2H_4, although the adsorption maxima were 50-100°C lower.

696. GELLER, W. AND SUN, TAK-HO. **Influence of alloying additions on the hydrogen diffusion in iron and contribution to the system iron-hydrogen.** *Arch. Eisenhüttenw.* **21**, 423-30 (1950).—*C.A.* **45**, 1933*h*.

From the H_2 permeability at higher temps. the diffusion coeffs. and their dependence on temp. were detd. for ferritic alloys with 1-4% Si or 27% Cr and for an austenitic steel with 18% Cr and 8% Ni. Addn. of Si and Cr reduced the diffusion coeffs. strongly. Between diffusion coeff. and giving off H_2 at room temp. a qual. relation existed; below a value of about 10^{-10} cm^2/sec no evolution of H_2 can be expected.

697. GHOSH, J. C.; SASTRI, M. V. C., AND KINI, K. A. **Mixed adsorption of hydrogen and carbon monoxide of Fischer-Tropsch catalysts.** *Research (London)* **3**, 584(1950).—*C.A.* **45**, 3578*h*.

The catalyst was composed of Co 34, Cr_2O_3 4, Cu 4, ThO_2 2.33, Ce_2O_3 0.24%, and kieselguhr balance. The adsorption of either H_2 or CO was found to be greater from that mixt.(1CO:2H or a 2:1 mixt.) in which its concn. was lower. The adsorption of each constituent was found to increase with temp. at much lower temps. in the presence of the other gas than in its absence. The results suggest the formation of a CO-H complex on the surface of the catalyst.

698. GIBB, T. R. P. JR. AND KRUSCHWITZ, H. W. JR. **The titanium-hydrogen system and titanium hydride. I. Low-pressure studies.** *J. Am. Chem. Soc.* **72**, 5365-9(1950).—*C.A.* **45**, 3744*e*.

Stoichiometric Ti hydride was prepared and density detd. as function of Ti-H ratio. Vol. expansion of 17.2% was observed when Ti reacted to form the hydride. The dissocn. pressure was measured for the Ti-H system from 500° to 800°C. The 600°C isotherm showed hysteresis. Ti contg. small amts. of H reacted rapidly with pure H_2 even at room temp. and atm. pressure.

699. HIGUCHI, IZUMI AND KAWANA, YOSHIO. **Calcium and hydrogen system. III. A theoretical consideration of the mechanism involved in the growth of the nucleus consisting of calcium hydride or deuteride.** *J. Chem. Soc. Japan*, Pure Chem. Sect. 71, 624-7(1950).—*C.A.* **45**, 7461*e*.

The specific rate of absorption of H_2 or D_2 by metallic Ca was computed. A formula for the partition function of the activated complex supposed to be formed around the nucleus on the boundary was derived. The theoretical rate of absorption agreed well with the exptl. values.

700. HIMMLER, WILHELM. **Solubility of hydrogen in copper-zinc and copper-nickel alloys.** *Z. physik. Chem.* **195**, 244-52(1950).—*C.A.* **45**, 8326*i*.

H_2 dissolves in metals as protons and electrons. Since alloying affects the chem. potential of the electrons in the metal, it affects the soly. of H_2. Addn. of Zn (to Cu) decreases, and of Ni increases, the soly. of H. In each case the soly. increases with increasing temp.

701. HIMMLER, WILHELM. **Solubility of gases in some alloys of silver, copper, and iron.** *Z. physik. Chem.* **195**, 253-9(1950).—*C.A.* **45**, 8327*a*.

Addn. of Zn or Sn decreases the soly. of H_2 in Cu to about the same extent; addn. of Al decreases it to a greater extent. Addn. of Pt increases the soly. of H_2 but not so much as the same amt. (mol. %) of Ni. Addn. of Pd increases the soly. of H_2 in Ag. Since O_2 dissolves in metals as neg. ions, its soly. should be affected oppositely to that of H_2. This conclusion is not completely substantiated by expts. with Pd-Ag alloys at 800-900°C.

702. ISHIKAWA, FUSAO AND FUJII, SABURO. **Palladium electrode occluding hydrogen for pH measurement.** *J. Electrochem. Soc. Japan* **18**, 187-9 (1950).—*C.A.* **45**, 3260*c*.

The best conditions for prepg. a pair of Pd-H_2 electrodes to be used for pH measurement were detd. With these electrodes, the measurement of pH was made within a mean error of 0.1 mv. (0.002 pH) and max. error of 0.6 mv. (0.01 pH). For this electrode there was no need to arrange equipment to produce H_2.

703. KAWANA, YOSHIO. **Calcium-hydrogen system. I. The rate of absorption of hydrogen by metallic calcium.** *J. Chem. Soc. Japan*, Pure Chem. Sect., 71, 494-6(1950).—*C.A.* **45**, 6468*h*.

Formation of the nuclei of Ca hydride begins after a certain induction period. The rate of growth of the nuclei, being proportional to the boundary area of the nuclei, is expressed by the equation: $dV/dt = K V^{2/3} = K_a S$, where V denotes the vol. of absorbed H_2, K apparent rate const., K_a the sp rate const. of the reaction, and S the boundary area of the nuclei. The activation energy of the reaction was calcd. to be 13.8 kcal/mole from the data over a range of temp. from 251° to 325°C.

704. Kawana, Yoshio. **Calcium-hydrogen system. Rate of absorption of heavy hydrogen by metallic calcium.** *J. Chem. Soc. Japan, Pure Chem. Sect.*, **71**, 554-5 (1950).—*C.A.* **45**, 6468*i*.

The velocity of absorption D_2 by metallic Ca was measured. The general aspects of the absorption process were similar to that of H_2. The activation energy of 13.9 kcal/mole obtained was nearly identical with that of H_2, whereas the sp rate const. was generally smaller by 18% than the corresponding value of H_2.

705. Keel, C. G. **The hydrogen content of steel to be welded.** *Berg-u. hüttenmänn. Monatsh. montan. Hochschule Leoben* **95**, 318-25(1950).—*C.A.* **45**, 4632*b*.

In unalloyed and alloyed C steels 4 cc. H_2/100 g is apparently an upper admissible limit; higher contents lead to formation of cracks in the weld or transition zone. Much higher amts. are allowable in austenite, but in martensite, not more than 1-2 cc. H_2/100 g. To avoid the unfavorable effects of H_2 on the phys. properties (1) electrodes should be used with a min. of H_2O and H-contg. constituents, (2) austenitic electrodes be used, (3) the basic material should be preheated and slowly cooled, (4) the C content of the steel should be reduced, and (5) the piece should be annealed several hrs at 200-400°C.

706. Klyachko, Yu. A.; Atlasov, A. G., and Chistyakova, E. M. **Determination of gases in ferrous metals. I. Construction of apparatus for vacuum melting methods.** *Zavodskaya Lab.* **16**, 17-23 (1950).—*C.A.* **44**, 6741*b*.

A complete description with diagrams of a high-frequency furnace for vacuum work which permits operation at 1500-1600°C with tubular graphite electrodes in a quartz vacuum-tight envelope. H_2 and O_2 can be satisfactorily detd. in all cases and N_2 in many instances.

707. Klyachko, Yu. A. and Atlasov, A. G. **Determination of gases in ferrous metals. II. Apparatus and microanalytical technique for determining hydrogen by heating in a vacuum.** *Zavodskaya Lab.* **16**, 283-90(1950).—*C.A.* **44**, 6765*a*.

Use of vacuum melting and vacuum heating give satisfactory agreement in detg. H_2 in steel (U-12 grade) without microanalysis of the gases. High Ni and Cr steel require such an analysis, since appreciable amts. of C and N oxides are liberated together with the H_2. It was noted that CuO dissocs. into Cu_2O and O_2 at 300-350°C and at 327°C the equil. pressure is 6.3×10^{-12} mm of O_2.

708. Kühne-Sauter, Eva. **Concentration-dependent hydrogen-deuterium exchange process on the surfaces of aluminum cathodes.** *Z. Naturforsch.* **5a**, 499-501(1950).—*C.A.* **45**, 10037*c*.

The exchange between H_2 adsorbed in Al and D_2 in H_2O was investigated spectroscopically in the silect elec. discharge to an Al cathode. For the ratios of D to H in the H_2O of 1:500, 1:100, and 1:50 the equil. D to H ratios in the Al cathode were smaller than the original H_2O ratios, whereas for D-to-H ratios in H_2O of 1:200, 1:300, and 1:400 the equil. ratios were greater.

709. Kwan, Takao. **Rate of hydrogen adsorption on reduced copper.** *Bull. Chem. Soc. Japan* **23**, No. 3, 73-5 (1950).—*C.A.* **45**, 3221*b*.

710. Kwan, Takao and Kujirai, Masaharu. **Absolute rate of the chemisorption of hydrogen on reduced copper.** *J. Chem. Phys.* **19**, 798-9(1951).—*C.A.* **45**, 7845*b*.

The no. of active sites on Cu for the adsorption of H_2 is calcd. to be $4.2 \times 10^{14}/cm^2$. at 623°K. and 5.4×10^{14} at 673°K. All surface atoms of Cu are equally capable of chemisorbing H_2 and that adsorption is not limited to a few "active spots."

711. Kwan, Takao and Kujirai, Masaharu. **Absolute adsorption rate of hydrogen.** *Kagaku* (Science) **21**, 420-1 (1951).—*C.A.* **46**, 3366*b*.

Every adsorbed H_2 is assumed to have only a vibrational degree of freedom, the partition function of that part being unity. The no. of active sites, G, per unit area available to H_2 was calcd. as 4.2×10^{14} and 5.4×10^{14} at 623°K and 673°K, resp., using observed activation energy 20.5 ± 0.5 kcal./mole. If pairs of Cu atoms at 3.615 A. sepn. on the 110 plane are taken as the available sites, G is estd. 1×10^{15}. The adsorption site is not a specified active center but every lattice point on crystal surfaces.

712. Lanyi, Bela. **The reaction of alumina with hydrogen.** *Magyar Kem. Folyoirat* **56**, 51-4 (1950).—*C.A.* **45**, 5007*c*.

The free energy or the affinity of the chem. reaction between alumina and H_2 was calcd. at room temp. and at 100° and 1200°K. There appeared to be no decrease of free energy during the reaction; thus theoretically no metallic Al could be produced this way. The calcns. were extended to the reaction of at. H. This latter reaction seemed to be a spontaneous one at 1400° and 1600°K with a decrease of free-energy values. Above this temp. the free-energy values again increased.

713. McQuillan, A. D. **The α-β transformation in titanium.** *J. Inst. Metals* **78**, 249-57 (1950).—(Paper No. 1279).—*C.A.* **45**, 1481*f*.

The α-β transformation in Ti was studied by the changes of H_2 equil. pressure with temp. The Ti contained very dil. solns. of H_2. The transformation in one material occurred sharply at 882.5°C, but that in the Mg-reduced material took place gradually over a temp. range of 860° to 960°C.

714. McQuillan, A. D. **An experimental and thermodynamic investigation of the hydrogen-titanium system.** *Proc. Roy. Soc. (London)* A204, 309-23(1950).—*C.A.* 45, 6033*c*.

The temp.-pressure-concn. relations of the H_2Ti system were studied. The values of the latent heat and entropy of the transformation in Ti and Zr were of the same order of magnitude, and in each case were much higher than those for the corresponding quantities for the transformations that occur in Fe and Mn.

715. Meunier, F. and Demarez, A. **Influence of hydrogen on the ductility of steel.** *Mém. centre natl. recherches mét., Sect. Hainaut* Dec. 1950, 5-10.—*C.A.* 45, 7497*c*.

Steel samples were charged with H_2 by immersion in 10% HCl for 24 hrs at room temp. Two types of absorbed H_2 were distinguished: that removed by heating at 250°C, and that removed by heating under high vacuum at 600°C. Thermal treatment restored the steel to its original capacity for absorbing H_2. Samples were charged with H_2, exposed to air for increasing periods of time, and ductility increased with increase in time of exposure to the atm.

716. Mignolet, J. C. P. **Contact potentials. I. Adsorption of some gases on evaporated nickel films.** *Discussions Faraday Soc.* 1950, No. 8, 105-14.—*C.A.* 45, 9986*f*.

The chem. films studied are: Ni-H_2, -0.345 v.; Ni-C_2H_2, 1.0 v.; Ni-C_2H_4, 0.83 v. Contact potential is suitable for studying surface reactions involving hydrogenation of C_2H_2 and C_2H_4 on Ni. Van der Waals films of nonpolar gases exhibit surface potentials: Ni-Xe, 0.85 v.; Ni-N_2, 0.21 v.; Ni-C_2H_6, 0.77 v.

717. Miller, A. R. **Statistical aspects of chemisorption.** *Discussions Faraday Soc.* 1950, No. 8, 69-79.—*C.A.* 45, 9986*c*.

The exptl. data for O_2 and H_2 on W lead to the conclusion that for adsorption on an array of localized sites, the distinction between mobile and immobile films is important.

718. Misch, R. D.; Berstein, R. B., and McDonald, H. J. **Influence of certain surface-active compounds upon the hydrogen permeability of a palladium cathode.** *J. Phys. & Colloid Chem.* 54, 681-4(1950).—*C.A.* 44, 8264*b*.

The effect of various org. addition agents on the electrodeposition of H_2 on a Pd cathode was studied by using an electrolyte of 0.2 N H_2SO_4 and a c.d. of 15 ma./cm^2. The ratio of diffused to evolved H_2 was observed to increase with addn. of thiourea, diisopropylthiourea, BuI, styrene, and benzyl sulfide in concns. up to 10^{-4} M. Further increase in concns. with the exception of thiourea, decreased the ratio.

719. Nikolaeva, M. I. and Shlygin, A. I. **Study of the sintering process of platinized platinum by electrochemical methods. I. Thermal treatment in hydrogen atmosphere.** *Zhur. Fiz. Khim.* 24, 427-31 (1950).—*C.A.* 44, 8263*d*.

A platinized Pt spiral was immersed in 0.1 *N* H_2SO_4, its polarization curve taken, then H_2O_2 added, the electrode rapidly rotated, and the const. *k* of the decompn. of H_2O_2 detd. at 20°C. Then the spiral was heated in H_2 for 1 hr each at 40, 60, 80, 100, 120, 150, 200, and 250°C, and the polarization curve and *k* detd. after each heating. The *k* decreased to about 25% after 60°C heating, rose to about 40% after 80°C, and then gradually decreased to 3% after 300°C. H_2 greatly accelerates sintering rather than to stabilize the surface by adsorption.

720. Nikolaeva, M. I. and Shlygin, A. I. **Sintering platinized platinum by electrochemical methods. II. Heat-treatment in air.** *Zhur. Fiz. Khim.* 24, 534-8 (1950).—*C.A.* 44, 8749*b*.

Platinized Pt was heated for 1 hr, cooled to room temp., and either (a) treated with H_2 in 0.1 *N* H_2SO_4 until complete reduction and electrolytically changed, (b) cathodically polarized to det. the amt., *x*, of O_2 adsorbed during heating, or (c) immersed in a H_2O_2 soln. to det. the const. *k* of the H_2O_2 decompn. The *k* was 100%, 34%, 127%, and 105% at 0°, 100°, 300°, and 400°C, resp. The sintering in air was much smaller than in H_2; *x* was 100%, 210%, and 60% at 20°, 200°, and 400°C, resp. The max. of adsorption at 200°C was due to greater rate of adsorption.

721. Opie, W. R. and Grant, N. J. **Hydrogen solubility in aluminum and some aluminum alloys.** *J. Metals* 188, Trans., 1237-41 (1950).—*C.A.* 44, 10640*c*.

The soly. of H_2 in Al, Al-Cu, and Al-Si alloys followed an equation of the general form $\log_{10} S = -(A/T) + B$, where S is the soly. in cm^3 of H at standard conditions per 100 g of metal. Cu and Si both decreased the soly. of H_2 in Al; Cu was more effective than Si.

722. Opie, W. R. and Grant, N. J. **Effect of hydrogen on mechanical properties of some aluminum alloys.** *Foundry* 78, No. 10, 104-9, 209-10(1950).—*C.A.* 45, 2839*b*.

The amt. of dissolved H_2 which precipitates during solidification causing pinhole porosity arose from reaction of Al with water vapor in the atm. above the molten metal. No evidence was found that dissolved H_2 embrittles Al, probably because of the small amt. that the lattice will hold.

723. Pecherskaya, A. G. and Stender, V. V. **Catalytic properties of electrode surfaces.** *Doklady Akad. Nauk S.S.S.R.* 75, 831-3(1950).—*C.A.* 45, 3261*d*.

Fe cathode potentials for evolution of H_2, in solns. of NaOH 100 + NaCl 190 g/l., at 70°C, at 650 amp./m^2, were shifted by 0.2-0.4 v. to more pos. values by coating with W-Ni. As the coating did not change the surface area of the cathode, the effect was attributed to its greater catalytic action as compared with Fe. Typical catalyst poisons, (Hg salts or surface-active substances) counteracted the lowering of the potential, more so on W-Ni than on Fe.

724. Rideal, E. K. and Trapnell, B. M. W. **The adsorption of hydrogen by tungsten, and the mechanism of para-hydrogen conversion at tungsten surfaces.** *J. chim. phys.* 47, 126-38 (1950).—*C.A.* 44, 7118*h*.

The adsorption of H_2 was measured between -185° to 0°C and pressure range 1.5×10^{-7} to 10^{-2} mm on a film of W formed by evapn. of W atoms from a wire. The equil. adsorption increased only 9% at 0° for a 10^4 pressure increase and only 14% on dropping from 0° to −183°C at 10^{-2} mm. If the surface area of the film is judged from the chemisorption of O_2, the measurements represented coverages in the range 60 to 90%. The heats of adsorption calcd. by the Clausius Clapeyron equation were 14, 11, 7, 3, and 2 kcals. per mole at coverages of 70, 75, 80, 85, and 90%, resp. The data fit a Freundlich isotherm.

725. Rideal, E. K. and Trapnell, B. M. W. **The mechanism and temperature coefficient of the parahydrogen conversion.** *Discussions Faraday Soc.* 1950, No. 8, 114-18.—*C.A.* 45, 9986*g*.

The chemisorption of H_2 by evapd. W films indicates that the probable mechanism of the conversion is the condensation and reevapn. of chemisorbed gas. The significance of the temp. coeff. of velocity is discussed.

726. Sadek, Hussein and Taylor, Hugh S. **The heterogeneity of catalyst surfaces for chemisorption. III. Metallic nickel.** *J. Am. Chem. Soc.* 72, 1168-75 (1950).—*C.A.* 44, 5199*e*.

The adsorptions at −195°C were analyzed to det. the relative amts. of van der Waals adsorption and chemisorption of H_2 and to show that 6 different prepns. adsorbed different relative amts. of the two types. The velocity of the H_2-D_2 exchange reaction on Ni-Cr_2O_3 and Ni-ThO_2 was studied to support these findings. There were marked differences in rates with activation energies of 0.45 and 2 kcal, resp. The data did not support an interpretation based either on soly. of H_2 in the lattice or an exothermic entry of H_2 into the Ni lattice at temps. between −195 and −78°C.

727. Sastri, M. V. C. and Srikant, H. **Adsorption of hydrogen at elevated pressures on a promoted iron-synthetic ammonia catalyst.** *Current Sci.* (India) 19, 313(1950).—*C.A.* 45, 9993*b*.

The adsorption of H_2 on a Fe-K_2O-Al_2O_3-TiO_2 catalyst from 50° to 350°C and at pressures from 15 to 50 atms. was studied. Two distinct types of activated adsorption of H_2 were found, one with a max. at about 150°C, the other with a max. at about 300°C. The results indicated the superposition of adsorption on the chemisorption of the H_2.

728. Shekhter, A. B. and Tret'yakov, I. I. **The "zonal" character of the changes in a palladium catalyst in the course of the oxidation of hydrogen.** *Doklady Akad. Nauk S.S.S.R.* 72, 551-4(1950).—*C.A.* 44, 7638*a*.

A polished Pd plate placed in a stream of undild. $2H_2 + O_2$ attained high catalytic activity much faster than an unpolished plate, and its temp. (measured with the aid of a thermocouple soldered to the plate) attained 700°C at a furnace temp. of 160°C. On diln. of the gas mixt. with 40% N_2, the temp. of the plate did not exceed 450°C and the plate showed distinct structural changes after 3 hrs service. With 70% N_2, the temp. did not rise beyond 350°C and no structural changes were noticeable even after 20 hrs. Heating of the Pd to 500-600°C either in vacuo or in H_2, O_2, or H_2O alone caused no structural changes. Electron-microscopic examn. of a Pd plate operated as catalyst in a gas mixt. dild. with 40% N_2 revealed far-reaching heterogeneity of the surface.

729. Troesch, A. **Application of the kinetic laws of adsorption and desorption to the study of catalysts.** *J. chim. phys.* 47, 148-56(1950).—*C.A.* 44, 8754*d*.

Measurements of the rate of desorption of H_2 indicate 3 types of active centers for which energies of activation of desorption are 9, 12, and 16.8 kcal, resp. The action of adsorbed H_2 and C on the kinetics of CH_4 adsorption on Ni is discussed.

730. Turkevich, John; Bonner, Francis; Schissler, Donald, and Irsa, Peter. **Stable and unstable isotopes in catalytic research.** *Discussions Faraday Soc.* 1950, No. 8, 352-6.—*C.A.* 45, 9990*i*.

Results are reported on the interaction of ethylenes and D_2 on a Ni wire at 90°C as analyzed with a mass spectrometer. With 2 vols. of D_2 the exchange reaction proceeds more rapidly than does the addn. reaction; the concn. of light ethylene decreases exponentially, while the concn. of the substituted ethylenes goes through a max. before it becomes zero. The surprising result is the discovery of completely light ethane from the reaction.

731. Vosskühler, H. **Influence of hydrogen upon the corrosion resistance, anodic resistance, and workability of aluminum-magnesium-alloys.** *Metall* 4, 6-9(1950).—*C.A.* 45, 6562*c*.

Corrosion and stress corrosion resistance decreases with increasing H-content. The presence of H_2 can be recognized in that plates which are H-free or low in H_2 remain bright on aging, while plates with considerable H_2 become light gray in color and lose their metallic appearance.

732. Wilzbach, Kenneth E. and Kaplan, Louis. **Exchange reaction between hydrogen and lithium hydrides; preparation of lithium hydride-t and lithium aluminum hydride-t.** *J. Am. Chem. Soc.* 72, 5795-6(1950).—*C.A.* 45, 3694*g*.

The exchange reaction of H_2 gas with solid LiT was studied between 25° and 200°C. The rate was controlled by a diffusion process within the solid. The equil. const. at 200°C was 3.7. $LiAlT_4$ has been used to prep. T-labelled compds. Ethanol-1-t was obtained in 80% yield by reduction of EtOAc.

733. Wright, P. **The effect of occluded hydrogen on the electrical resistance of palladium.** *Proc. Phys. Soc.* (London) 63A, 727-39(1950).—*C.A.* 45, 1402*h*.

Resistance-pressure isotherms from 75° to 150°C are obtained for pressures increasing and decreasing between zero and atm. A decrease in resistance, which is observed when H_2 is added to the alloy in the β phase, is attributed to completion of the *d* shells of Pd. Hysteresis phenomena are discussed. The general characteristics of the resistance isotherms in the system Pd-H_2 can be satisfactorily explained by assuming that the occluded H_2 is held entirely in solid soln. The incomplete *d* shells of the Pd atoms become filled when the ratio of H to Pd atoms in solid soln. is approx. 0.6.

734. Bernstein, Richard B. and Cubicciotti, Daniel. **The permeability of zirconium to hydrogen.** *J. Phys. & Colloid Chem.* 55, 238-48 (1951).—*C.A.* 45, 4511*b*.

The rate of flow of H_2 through Zr between 375 and 920 °C decreased with time exponentially, varied as the square root of the pressure and had a large temp. coeff. The time decrease of the permeability was partially ascribed to surface contamination and partially to a change of structure of the Zr.

735. Buzzard, R. W. and Cleaves, H. E. **Hydrogen embrittlement of steel. Review of the literature.** *Natl. Bur. Standards Circ. No.* 511, 29 pp. (1951).

A review of the literature (1191 references) established the fact that steel absorbed H_2 on exposure at an elevated temp. or in the environment of a chem. reaction. The H_2 so absorbed tended to cause porosity and blowholes in the cast metal. Defects attributed to H_2 included flaking, pickling embrittlement, shatter cracks, hairline cracks, weldment failures, etc. The published data failed to establish quant. proof that H_2 was the sole cause of these defects, but when procedures for maintaining the H-content at a min. were utilized, certain defects generally ascribed to H_2 could be eliminated.

736. Chatterjee, B. and Ghosh, P. C. **Mechanism of decarburization of cast iron in hydrogen.** *Science and Culture* 17, 258-9(1951).—*C.A.* 46, 6570*b*.

A layer low in C near the surface of cast iron heated to 1000 °C in moist H_2 (1.2% H_2O by vol.) is caused by $CH_4 + 2H_2O \rightarrow CO_2 + 4H_2$, the H_2 from the oxidized CH_4 speeding the decarburizing process, $Fe_3C + 2H_2 \rightarrow 3Fe + CH_4$. The diffusion of the H_2, H_2O vapor, and CH_4 permit these reactions to occur within the metal as well as at the surface. The activity of C in Fe_3C is higher than its activity in nonsatd. austenite and H_2 reacts with Fe_3C more rapidly than with C in solid soln.

737. Cook, R. M. and Hobson, J. D. **Determination of hydrogen in liquid steel.** *Iron Steel Inst.* (London) 169, 24-5 (1951).—*C.A.* 46, 61*c*.

Satisfactory agreement is shown for comparative results of the modified notched-pencil mold method and the sealed-mold method of sampling. For control purposes the notched-pencil mold detn. has the advantage of requiring less time.

738. Eley, D. D. **Molecular hydrogen and metallic surfaces.** *J. Phys. & Colloid Chem.* 55, 1017-33, discussion 1034-6(1951).—*C.A.* 46, 30*d*.

The quant. aspects of H_2 catalysis are reviewed and a working hypothesis outlined.

739. Eucken, A. and Weblus, B. **Adsorption of hydrogen on platinum according to measurements of the capacity of polarization.** *Z. Elektrochem.* 55, 114-19(1951).—*C.A.* 45, 9393*c*.

By measurements of the capacity of polarization with a special cell and superimposed a.c. it is found tha 2 max. occur. This indicates the presence of 2 mechanisms of H_2 adsorption, one independent of the concn. of other ions, the other influenced thereby. It is postulated that the 1st max. is caused by the adsorption of H_2 upon O atoms on the electrode surface, forming reversibly something in the nature of a surface hydroxide, while the 2nd max. is caused by adsorption of H_2 upon the Pt atoms themselves.

740. Freidlin, L. Kh. and Ziminova, N. I. **The active structure of the nickel-hydrogen catalyst.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* **1951**, 145-9.—*C.A.* 45, 6031*a*.

H_{ads} gave a measure of the active centers present at the surface. This was directly related to the amt. of dissolved H_2 as shown by its progressive removal with the aid of increasing amts. of 1-methyl-1-cyclopentene in the absence of free H_2. The amt. of H_2 adsorbed by a given sample of the Ni catalyst (2.33 g, contg. 47.4 ml H_{ads} and 177 ml dissolved H_2) was a linear function of the remaining dissolved H_2. Likewise, the catalytic activity in hydrogenation of allyl alc. was a linear function of the dissolved H_2, and both adsorption of H_2 and catalytic activity fell to zero when it was all removed. CH_2:CHOBu was used as H-remover.

741. Fry, A. **Gases in steel—hydrogen.** *Inst. hierro y acero*, Suppl. to Vol. 3, 24-35(July-Sept., 1950); *J. Iron Steel Inst.* (London) **168**, 330(1951).—*C.A.* 45, 7936c.

H_2 is one of those gases which are sol. in steel and do not form solid compds. Part of the H_2 retained in steel can be extd. by heating *in vacuo*. A test is described to confirm the 2 types of H_2 diffusion (at. and mol.). Krupp tests to prove the "flake theory" include blowing H_2 into the bath, heating a steel free from flakes for a long period at 1150 °C in H_2, and annealing steel in H_2 at high pressure at 550 °C. All these methods produce flakes.

742. Garstens, Martin A. **Internal motion of hydrogen absorbed in tantalum.** *Phys. Rev.* **81**, 288(1951).—*C.A.* 45, 3209*a*.

With powd. Ta contg. 53.5 at. % H, it was found that proton motion was frozen at about 215 °K. Above 235 °K the H atoms were not bound to the metal atoms.

743. Gibb, T. R. P., Jr.; McSharry, J. J., and Bragdon, R. W. **The titanium-hydrogen system and titanium hydride. II. Studies at high pressure.** *J. Am. Chem. Soc.* 73, 1751-5 (1951).—*C.A.* 45, 6914*e*.

The equil. pressure of H_2 over the metallic Ti-H_2 system was measured as a function of H-content of the solid phase. Measurements were made over the range 175° to 100 °C at pressures ranging up to 5000 cm. Plots of log P *vs.* 1/T°K were a series of straight lines whose slope increased with decreasing H-content. From these slopes the differential heats of dissocn. were calcd. A family of isotherms showed plateaus at compns. approaching TiH_2.

744. Halsey, G. D. Jr. **Para-hydrogen conversion on tungsten.** *Trans. Faraday Soc.* 47, 649-56 (1951).—*C.A.* 45, 9993*e*.

Data on the para-H_2 conversion on clean W surfaces were considered from the standpoint of the heterogeneous surface. The mechanism finally adopted was that of exchange between chemisorbed H and mol. H_2 adsorbed on van der Waals sites of varying energy. These sites were located between 2 bare chemisorption sites. An activation energy of adsorption of several kcal was necessary for the success of any mechanism.

745. HAUSNER, HENRY H. **The formation of metal from its compound during sintering.** *Powder Met. Bull.* 6, 41-3(1951).—*C.A.* 46, 5498*h*.

Superior properties were obtained when using ZrH_2 as raw material for sintered Zr. Higher d. at lower sintering temps. was obtained as compared to compacts made from plain Zr powder. ZrH_2 powder was pressed at 25 tons/in^2 and sintered at 1150°C for 3 hrs. The remarkable sintering behavior of ZrH_2 was attributed to the great atomic mobility which was experienced at the decompn. range of the hydride.

746. HOBSON, J. D. AND SYKES, C. **Effect of hydrogen on the properties of low-alloy steels.** *J. Iron Steel Inst.* (London) 169, 209-20 (1951).—*C.A.* 46, 2982*b*.

H_2 was detd. by heating the entire fractured specimen in an evacuated furnace at 650°C. Of the 17 steels studied, 8 contained 3% Cr and 0.5% Mo and the others contained 3.5% Ni, 1% Ni, and 2.5% Ni, 0.4% Cr, and 0.4% Mo. The main effect of H_2 was loss of ductility accompanied by some loss of notched-bar impact strength. H content alone did not decide whether hairline cracks would form. The embrittling effect, particularly in the presence of stress raisers, made low H-desirable in finished steel.

747. KAWAI, MASAYOSHI. **Behavior of hydrogen in steel. II.** *Tetsu to Hagane* 37, 23-9 (1951).—*C.A.* 46, 7961*a*.

The discussion covers the H_2 pressure in cavities and the effect of cavities on diffusion of H_2 in steel. In an ideal case, when the H_2 equil. between metal and cavities is realized without loss of H_2 from the metal, the H_2 pressure reaches a max. at about 150°C, and the max. value increases with the H-content and with the reciprocal of the cavity vol. It takes time to attain the H_2 equil. if phys. conditions are varied and the lower the temp. the longer the time. On the other hand, the greater part of the H_2 in steel ppts. into cavities at the lower temp., and yet, if the total vol. of the cavities is large, the quantity of H_2 in the cavities cannot be neglected up to higher temp., especially in the α-phase.

748. KINJYO, KISEI AND IWATA, SHIGEO. **Preparation of highly pure tungsten. I. Reduction of tungsten trioxide in a current of hydrogen.** *J. Chem. Soc. Japan*, Ind. Chem. Sect. 54, 573-5 (1951).--*C.A.* 47. 6321*b*.

The reduction of WO_3 (calcined at various temps.) by H_2 was studied by means of a thermobalance. The reduction into metallic W took place through various lower oxides according the calcination temp. of WO_3. The reduction temp. was 550°C for the WO_3 calcined at 300-800°C and 670° for 1000°C.

749. KINOSHITA, TOSHIHIRO AND HARA, TORAKICHI. **Determination of hydrogen in cast iron.** *Tetsu to Hagane* 37, 102-7(1951).—*C.A.* 46, 8571*a*.

The test pieces (15 mm) were cast in a Cu mold and quenched rapidly in a Hg bath. By this method test pieces of white iron were obtained with no quenching cracks. The extn. temp. of H_2 should be 900°C. The results were reliable. By this procedure, analyses were made in cast iron samples of almost the same compn. There was less H_2 in cupola-melted cast iron than in elec.-furnace-melted cast iron. The Si contents of the cast iron affected the analysis, and H_2 detd. in high-Si cast iron was less than in low-Si cast iron.

750. KUME, SANSHIRO AND OTOZAI, KIYOTERU. **Activation energy. II. Some applications of the empirical rule. III. Activation energy for the adsorption of hydrogen on reduced copper.** *Bull. Chem. Soc. Japan* 24, 257-64(1951).—*C.A.* 47, 4176i.

The activation energies for the addn. of H_2 or halogen to ethylene, for at. reactions involving Na and halogen, and for the adsorption of H_2 and ethylene on Ni were detd. The calcd. values agreed well with expt. except that those for the addn. of H_2 to ethylene were high. The initial rate of adsorption of ethylene on Ni from the calcd. activation energy were 7.73×10^{13} sec^{-1} cm^{-2}. The [110] and [111] surfaces of Cu adsorbed H_2 more quickly than do the [100] surfaces.

751. KUMMER, J. T. AND EMMETT, P. H. **The amount of hydrogen left on the surface of a reduced and evacuated iron synthetic-ammonia catalyst.** *J. Phys. & Colloid Chem.* 55, 337-46(1951).—*C.A.* 45, 5502*h*.

Tracer expts. with D_2 show that promoted Fe synthetic NH_3 catalysts after thorough reduction retain sufficient H_2 to cover as much as 35% of the metallic surface even after 24 hrs evacuation at 500°C. Unpromoted Fe catalysts do not retain a detectable amt. of H_2. It is not known whether the H_2 retained by the promoted Fe catalyst is held as H_2 on Fe or as either H_2 or H_2O on the Al_2O_3 promoter.

752. LAIDLER, KEITH J. **Mechanisms of surface reactions involving hydrogen.** *J. Phys. & Colloid Chem.* 55, 1067-77, discussion 1077-8 (1951).—*C.A.* 46, 26*e*.

The combination of H atoms involved, under most conditions, interaction between a gaseous atom and an adsorbed atom, gave rise to 1st-order kinetics when the surface was nearly fully covered. The production of atoms involved interaction between a gaseous H atom and a bare surface site, one atom being absorbed and the other passing into the gas phase. The hydrogenation of C_2H_4 involved adsorption of C_2H_4 and H_2 on neighboring sites. The exchange reaction between D_2 and NH_3 perhaps occurred by interaction between an adsorbed D atom and a gaseous NH_3 mol. Usually surface reactions between 2 species involved adsorption of both species, both of which undergo activation by the surface. If, however, the product was strongly adsorbed, reaction might occur more readily by interaction between an adsorbed mol. and a gaseous one.

753. MCQUILLAN, A. D. **The application of hydrogen equilibrium-pressure measurements to the investigation of titanium alloy systems.** *J. Inst. Metals* 79, 73-88(1951)(Paper No. 1298).—*C.A.* 45, 4627*h*.

The method depends on the measurement of H_2 pressures in equil. with a very dil. soln. of H_2 in the alloys. The method is applied to a series of alloys in a limited region of the Ti-Cu and Ti-Fe systems. Both Cu and Fe depress the $\alpha \rightleftarrows \beta$ transformation in Ti. The effect of these addn. elements on the soly. of H_2 in the Ti-rich β solid soln. is described.

754. McQuillan, A. D. **The titanium-hydrogen system for magnesium-reduced titanium.** *J. Inst. Metals* 79, 371-8(1951)(Paper No. 1311).—*C.A.* **45**, 7505*h*.

The constitutional diagram of the Ti-H_2 system was studied by using Mg-reduced Ti. The system Mg-reduced Ti-H_2 could not be treated as a simple binary, but had to be considered as a section through a multi-component system. The results obtained in the study of systems of Mg-reduced Ti with other metals were likely to be affected in the same way.

755. Opie, W. R. and Grant, N. J. **Solubility of hydrogen in molten lead.** *J. Metals* **3**, *Trans.* **191**, 244-5(1951).—*C.A.* **45**, 3223*f*.

The soly. of H_2 in molten Pb can be expressed by the equation: $\log S = (-2450/T) + 2.19$. The heat of soln. of H_2 in Pb is 22,300 cal per mole of H_2.

756. Pavlyuchenko, M. M. and Rubinchik, Ya. S. **Reduction of copper oxide by hydrogen.** *Zhur. Priklad. Khim. (J. Appl. Chem.)* **24**, 666-70 (1951).—*C.A.* **47**, 389*i*.

The rates of reduction were detd., at 201° (±0.5°), in a static system under an initial H_2 pressure of 714 mm Hg, for dark brown CuO made by pptn. with alkali, CuO obtained by calcination of the salt, and gray CuO obtained by oxidation of Cu in air. All curves pass through a max. Samples of partially oxidized Cu, with 20, 30, 40, 60, and 100% CuO, and 80, 70, 60, 40, and 0% Cu, all contg. 0.04 g, were reduced practically at the same speed along a rate curve with a max. Artificial admixing of Cu to CuO had no effect on the rate of reduction. Once the reduction had started, H_2O vapor had no effect on the rate. In the presence of Hg vapor, at 203°C, the rate decreased by a factor of 10, and passed through 2 maxima and one min. Variation of the initial pressure of H_2 (200, 350, 700 mm) had only an insignificant effect on the rate of reduction.

757. Podol'skaya, E. V. and Shumovskiĭ, E. G. **Macroscopic determination of hydrogen in hard pig iron.** *Vestnik Mashinostroeniya* **31**, No. 4, 47-52(1951).—*C.A.* **46**, 1940*f*.

The relative content of H_2 was estd. from the appearance of glazed specimens. There was a relationship between the H-content and the microstructure; the higher the H-content the less was the extent of austenite decompn. This was taken to indicate that H_2 pressure interfered with phase transformation. A high H content was assocd. with an austenite-ledeburite structure while a ferrite-pearlite structure was characterized by absence of H.

758. Saitô, Tsunezô. **Adsorption of diatomic gas by binary alloys. I.** *Science Repts. Research Insts., Tohoku Univ., Ser.* **A**, **3**, 502-12(1951).—*C.A.* **47**, 2106*a*.

Gas atoms, dissolved in the interlattice positions in quasi-crystals of molten alloy, were not distributed uniformly. The distribution depended upon the amt. of reaction energies of gas and metal atoms. N atoms had a tendency to cluster around Cr or Mn atoms where N_2 was absorbed by molten Fe-Cr or Fe-Mn alloys. A formula was derived to be used in connection with the absorption of diatomic gas by binary alloys. It explained the results formerly found for Fe-Cr, Fe-Mn, and Fe-Ni alloys. The theory was also checked for H_2 and O_2.

759. Sastri, M. V. C. and Srikant, H. **Mixed adsorption of hydrogen and nitrogen at elevated pressures on a promoted iron synthetic-ammonia catalyst.** *Current Sci.* **20**, 15-16(1951).—*C.A.* **45**, 10018*d*.

An $Fe-K_2O-Al_2O_3-TiO_2$ catalyst was used. The individual adsorptions of H_2 and N_2 from a 3:1 mixt. were detd. on the same catalyst between 50° and 350°C and at a total gas pressure up to 50 atms. The adsorption of H_2 increased regularly with its partial pressure at all the temps. studied, whereas that of N_2 exhibited this regularity only at the highest temp. In practically every case the adsorption of H_2 at a given partial pressure from the mixt. was considerably higher than that from the pure gas at an equiv. pressure. At 350° when the partial pressure of N_2 exceeded 7 atms., the ratio of N_2 to H_2 adsorption varied successively from 1N:1H, to finally 1N:3H.

760. Schuit, G. C. A. **Adsorption as a method for determining the structure of a catalyst.** *Chem. Weekblad* **47**, 453-65 (1951).—*C.A.* **46**, 2383*i*.

Phys. adsorption gives information about the surface area and the distribution of pore sizes, but not about the nature of the surface. For the latter, chemisorption promises to be valuable. The activated adsorption of H_2 on Ni is due to surface O atoms. Sintering is prevented in these catalysts by the spongy SiO_2 skeleton.

761. Schuit, G. C. A. and Boer, N. H. de. **Activated adsorption of hydrogen on nickel catalysts.** *Nature* **168**, 1040-1 (1951).—*C.A.* **46**, 4338*h*.

The thermodynamics and kinetics of the chemisorption of H_2 on metals were studied on a catalyst consisting of 100 parts Ni to 29 parts SiO_2 by wt. For this type of catalyst reduction was incomplete below 400°C, but substantially complete above 500°C. O_2 was adsorbed at -196°C on a well-reduced catalyst then the O-covered sample was slowly heated to a higher temp., and thereafter the adsorption of H_2 detd. Results indicated that with increasing amts. of O coverage, the amt. of rapidly adsorbed H_2 decreased, whereas the total adsorption remained more or less const. Any procedure that involved heating the catalyst sample at 400°C without the presence of H_2, such as heating under N_2 or *in vacuo*, caused a decrease in H_2 adsorbed.

762. Schuit, G. C. A. and Boer, N. H. de. **Activated adsorption of hydrogen on nickel catalysts.** *Rec. trav. chim.* **70**, 1067-84 (1951) (in English).—*C.A.* **46**, 4881*i*.
The adsorption consisted of a very rapid process followed by a much slower one, the latter increasing in velocity with increased temp. The transition between the 2 was not sharp but gradual. However, some distinction could be made by observing the amts. of H_2 adsorbed at 78°K and very low pressure (type I) and the amts. that could be adsorbed in excess of this quantity (type II). A more thorough reduction of the catalyst resulted in an increase of the type I adsorption at the cost of type II. Adsorption of O_2 on a well-reduced catalyst, on the contrary, decreased the type I and increased the type II adsorption, the change being linear with the amt. of O_2 adsorbed. O_2 adsorption occurred in 2 different manners, depending on the conditions, one adsorption site being occupied by either an O atom or O_2 mol.

763. Shushunov, V. A. and Shafiev, A. I. **Kinetics of the reaction between calcium and hydrogen.** *Doklady Akad. Nauk S.S.S.R.* **78**, 1181-4 (1951).—*C.A.* **45**, 8331*h*.
The reaction $Ca + H_2 = CaH_2$ begins with a significant rate at 150-170°C. The reaction is not self-accelerated. With initial pressures of H_2 of the order of 5-10 mm Hg and at temps. above 200°C, the fall of the H_2 pressure *p* is first-order. At lower temps. or at higher initial *p*, the 1st-order falls with the progress of the reaction, and consecutive expts. with the same film give decreasing rates. However, when the thickness of the layer has attained a few tenths of a mm, the rate can again be described by the 1st-order law; this will occur when the CaH_2 layer has become sufficiently thick for the change of its thickness during the reaction to become negligible.

764. Smith, Donald P. **The widened lattice interval and its essential role in the behavior of crystalline metal.** *Science* **113**, 348-52 (1951).—*C.A.* **45**, 5084*h*.
The widened lattice intervals produced by work hardening of metals are evidently "rifts" in the crystal lattice. These rifts are produced by plastic deformation and are capable of healing or extension as conditions are altered. The existence and nature of the rifted state are demonstrated chiefly by the behavior of metals with H_2. Presumably the ionization of H_2 occurs with facility only in the rifts.

765. Soliman, A. **Formation of metallic hydrides and nitrides and their significance in the synthesis of ammonia.** *J. Applied Chem.* (London) **1**, 98-104 (1951).—*C.A.* **45**, 6911*h*.
The activation energy of adsorption of N_2 on Li was evaluated at 47 kcal/g-mol. Adsorption of H_2 was relatively slow at 500-25°C, and Li sublimed freely at higher temps. and pressures below atm. Metallic promoters increased the adsorption by Li of H_2 markedly but had little appreciable effect with N_2; Mn and Ni (1:1) were most effective for H_2, and Cs for N_2. At 30 atm., pressure equil. was attained in 30 sec in the adsorption of N_2 and H_2 by Ca, as compared with upwards of 1 hr at atm. pressure.

766. Thon, N.; Kelemen, Denis G., and Yang, Ling. **Porosity of electrodeposited metals. X. Hydrogen content of electrodeposited metals.** *Plating* **38**, 1055-8 (1951).—*C.A.* **46**, 1366*a*.
Detns. of H_2 in Ni foils 0.0003 in. thick gave H:Ni atom ratios of about 1:300 for Ni baths without addn. agents, and considerably smaller ratios for baths with disulfonate addn. agents. Increasing pH and temp. decreased the H-content slightly. The H-content decreased with increasing foil thickness. The nature of the base metal was also important, a foil deposited on mech. polished Cu contained 5 times as much H_2 as one deposited on electrolytic Cu.

767. Trapnell, B. M. W. **Adsorption on evaporated tungsten films. II. The chemisorption of hydrogen and the catalytic para-hydrogen conversion.** *Proc. Roy. Soc.* (London) **206A**, 39-50 (1951).—*C.A.* **47**, 5758*a*.
Isotherms for the adsorption of H_2 on W films from 0 to −183°C and up to 10^{-2} mm pressure are given. At each temp. there is an initial fast H_2 adsorption followed by a slow reaching of equil. The Freundlich isotherm is obeyed at all temps., with heats of adsorption falling with increased adsorption from 15.4 to 2.8 kcal./mole. By extrapolation this min. becomes 2.4 kcal./mole; this indicates a true case of chemisorption and an almost complete coverage of surface area with 1 atom of H per surface atom. Calcns. based on these exptl. results would indicate the para-H_2 conversion to proceed as: $2\ W + H_2 \rightleftharpoons 2\ WH$.

768. Tsukagoshi, Osamu. **Cleaning-up of hydrogen by barium getter films.** *Repts. Sci. Research Inst. (Japan)* **27**, 1-5 (1951).—*C.A.* **46**, 1367*i*.
Ba deposited on a glass wall by pyrolysis *in vacuo* of BaN_6 painted over a W wire was found to absorb H_2 until H/Ba in the layer approached 2; that is until BaH_2 was formed almost entirely. The reaction velocity increased with higher temp., was relatively unchanged by the H_2 pressure (within the range of $1\text{-}2.4 \times 10^{-4}$ mm Hg), and remained relatively const. up to H/Ba 0.8 and thereafter decreased at higher values of H/Ba.

769. Wagner, G. and Blaha, F. **Action of dilute sulfuric acid on magnetized iron.** *Nature* **168**, 74 (1951).—*C.A.* **46**, 325*h*.
When spectroscopically pure Fe, first heated in H_2 and then degassed *in vacuo*, was allowed to react in the magnetized state with H_2SO_4, less than 10^{-6} by vol. of O_2 was found in the H_2 formed. Similar results were obtained with unmagnetized Fe.

770. Wahlin, H. B. **The transmission of hydrogen through metals.** *J. Applied Phys.* **22**, 1503 (1951).—*C.A.* **46**, 6569b.
To test the hypothesis that H_2 diffuses into some metals by surface dissocn. followed by diffusion of at. H, a Pd tube was made the cathode in a H_2SO_4 bath. A pressure of 50 atm. was built up in the tube. Fe, Ni, Nb, Ta, and Mo all show slight transmission. Cu transmitted so slowly, if at all, that no pos. results were obtained.

771. Brown, W. G.; Kaplan, L., and Wilzbach, K. E. **The exchange of hydrogen gas with lithium and sodium borohydrides.** *J. Am. Chem. Soc.* **74**, 1343-4 (1952).—*C.A.* **47**, 4686*b*.

The direct exchange of solid borohydrides with H_2 provides a simple route to the isolation of isotopic compds. The exchange occurs at a convenient rate with $LiBH_4$ at 200°C, and with $NaBH_4$ at 350°C. Thermal decompn. is negligible.

772. Chang, P. L. and Bennett, W. D. G. **Diffusion of hydrogen in iron and iron alloys at elevated temperatures.** *J. Iron Steel Inst.* (London) **170**, 205-13 (1952).—*C.A.* **46**, 7974*i*.

The effects of Cr, Ni, and Mo on the rate of H_2 permeation in Fe are expressed in the form of an exponential equation. Cr has little effect on permeation in the gamma range, but greatly reduces the rate in the alpha range. Ni and Mo have little effect. The soly. values calcd. from the data are of the same order of magnitude as those obtained by different methods.

773. Charlton, M. G. **Hydrogen reduction of tungsten trioxide.** *Nature* **169**, 109-10 (1952).—*C.A.* **46**, 6537*b*.

Time curves for the reduction of WO_3 by H_2 were obtained by a continuous weighing technique. They showed well-defined inflections that corresponded to the β- and γ-oxides intermediate in compn. between WO_3 and WO_2. The av. compns. for the β- and γ-oxides were $WO_{2.86}$ and $WO_{2.70}$, resp. It was probable that the formation of these oxides by reduction would tend to give O-deficient compds. The presence of H_2O vapor increased the induction period that occurred before one oxide is reduced to the next lower oxide.

774. Chufarov, G. I., Averbukh, B. D., Tatievskaya, E. P. and Antonov, V. K. **Retarding action of gaseous reaction products on the rate of reduction of manganese oxides by hydrogen and carbon monoxide.** *Zhur. Fiz. Khim.* **26**, 834-41 (1952).—*C.A.* **46**, 10813*d*.

Reduction of Mn_3O_4 by H_2 (50-150 mm Hg, 450°) was retarded by H_2O more than reduction of Mn_2O_3. Adsorption (a in 10^{-6} g mol./m^2) at 100°C and 50 mm Hg was for H_2, CO, and CO_2 on MnO_2 20.50, 3.35, and 1.55; on Mn_2O_3 5.5, 8.1, and 4.9; on Mn_3O_4 0.25, 1.00, and 1.70; and on MnO 0.85, 1.30, and 5.80. Between 20° and 100°C, a of CO and H_2 on Mn_3O_4 and of H_2 on Mn_3O_4 increased with temp., and a of CO_2 on Mn_2O_3 and CO on Mn_3O_4 decreased. At 10 mm Hg and 100°C, a for H and H_2O on Mn_2O_3 was 2.6 and 8.0, on Mn_3O_4 0.1 and 3.8, and on MnO 0.2 and 8.6, resp.

775. Cooper, Charles M. **Steel lining eliminates failure of pressure vessels due to hydrogen.** *Chem. Eng. News* **30**, 2942 (1952).—*C.A.* **46**, 9499*c*.

H_2 greatly reduces the mech. properties of high-strength steels usually used in high-pressure vessels. Some fail in brittle fashion at 2000 atm., the same types withstanding 7000 atm. oil pressure. Type 316 stainless steel withstands H_2 as well as it does oil pressure.

776. Couper, A. and Eley, D. D. **Electronic basis of catalyst activity. II. The reversible dissociation of hydrogen molecules and the para-hydrogen conversion.** *Proc. Roy. Soc.* (London) **A211**, 536-43 (1952).—*C.A.* **46**, 10819*i*.

An examn. of the hypothesis that the rate of the para-H_2 conversion on W is detd. by the rate of condensation of H_2 into an almost full monolayer of chemisorbed atoms. The calcd. values of abs. rate, activation energy, and pressure dependency are in disagreement with those observed experimentally.

777. Couper, A. and Eley, D. D. **Electronic basis of catalyst activity. III. The activation energy of the para-hydrogen conversion on tungsten.** *Proc. Roy. Soc.* **A211**, 544-63 (1952).—*C.A.* **46**, 10820*a*.

A study of the activation energy and frequency factor for the conversion of para-H_2 on W. All expts. were made at around 1 mm pressure. The values were independent of variations in wire length, bath temp. and wall thickness, factors likely to change the temp. distribution along the wire. The values varied somewhat from one wire to another, and may be more markedly modified by exposure to H atoms or Na vapor.

778. Duflot, Jean. **The supersaturation of iron by cathodic hydrogen.** *Pubs. sci. et tech. ministere air* (France) No. **265**, 1-56 (1952).—*C.A.* **47**, 3666*e*.

Quantities of H_2 of the order of 130-140cc./100 g were introduced into Fe by electrolysis in 10 *N* H_2SO_4. After the sample was charged with H_2, the amt. and rapidity with which it could be degassed were unaffected by abrasive treatment. Approx. 80% of the dissolved H_2 could be removed by vacuum treatment at 115°C, whereas 100% of the H_2 could be removed by fusion in Sn at 1150°C under vacuum. Charging with H_2 had the following effects on the mech. properties: (1) The Brinell hardness was increased from 55.6 to 65.7 and was decreased to 61.8 by degassing; (2) Young's modulus was not affected; (3) the tensile properties were related to the duration of charging.

779. Gibb, T. R. P. Jr.; McSharry, J. J., and Kruschwitz, H. W. Jr. **Metal-hydrogen systems. III. The uranium-hydrogen system.** *J. Am. Chem. Soc.* **74**, 6203-7 (1952).—*C.A.* **47**, 3675*i*.

Measurements were made for the range 500-4900 cm at temps. from 357 to 650°C for compns. ranging from $UH_{2.85}$ to $UH_{3.00}$. The equation for the dissocn. pressure (p, cm) of $UH_{3.00}$ is $p = -(1730/T) + 5.78$, where T was the temp., °K. After removal of several tenths of a mode of H_2, the solid phase reverted to normal behavior.

780. Heath, H. R. **Diffusion of electrolytic hydrogen through metals.** *Brit. J. Applied Phys.* **3**, 13-18 (1952).—*C.A.* **46**, 5938*d*.

Fe and Pd were permeable to H_2, but Ni, Co, Cu, Zn, Ag, Pt, and Pb were not. The app. consisted of a cylindrical glass electrolytic cell contg. an anode. The base of the cell was fabricated from the test metal which served as the cathode. For Fe (1 cm^2 by 0.08 mm thick), after about 40 min., when steady state was reached (under given conditions), 1 part in 83 of the H_2 produced passed through the plate. The rate of diffusion was linear with reciprocal of plate thickness only for thicknesses less than 0.7 mm.

781. Higuchi, Izumi; Kawana, Yoshio; Hattori, Shin, and Chiba, Hiroshi. **System of calcium alloy and hydrogen. I. Calcium-aluminum-hydrogen system.** *J. Chem. Soc. Japan, Pure Chem. Sect.*, **73**, 198-200 (1952).—*C.A.* **46**, 5397*h*.

The absorption of H_2 by Ca-Al alloy was detd. and the ternary alloy Ca-Al-H was detd. The Ca-Al alloy contg. a greater proportion of Ca than that of $CaAl_2$ absorbed H_2 above 200°C. The amt. V of the absorbed gas per unit wt of the alloy plotted as a function of time t showed a sigmoid curve without an induction period. In the early stage, V was proportional to t^3. The absorbed H combined with Ca atoms in the Ca phase to form CaH_2 and with a part of Ca atoms in the $CaAl_2$ phase.

782. Higuchi, Izumi and Chiba, Hiroshi. **The system of calcium alloy and hydrogen. II. Calcium-magnesium-hydrogen and calcium-aluminum-magnesium-hydrogen systems.** *J. Chem. Soc. Japan, Pure Chem. Sect.* **73**, 400-2 (1952).—*C.A.* **47**, 4270*d*.

When Ca is present in a greater amt. than that corresponding to the compn. Ca_3Mg_4, a free Ca phase exists in the alloy. It has been observed that both Ca-Mg and Ca-Al-Mg alloys adsorb H_2 at 1 atm. in the presence of free Ca.

783. Higuchi, Izumi and Chiba, Hiroshi. **The system of calcium alloy and hydrogen. III. The absorption rate of hydrogen by calcium-magnesium alloy.** *J. Chem. Soc. Japan, Pure Chem. Sect.* **73**, 420-5 (1952).—*C.A.* **47**, 4270*d*.

The influence of temp. and pressure upon the initial rate of H_2 adsorption of the Ca-Mg alloy contg. 70.61% Ca has been studied. The rate does not depend upon the outer area of alloy. The activation energy is estd. to be 20.59 kcal./mole. The influence of pressure appears in line with the adsorption isotherm.

784. Jackson, J. S. **The problem of hydrogen diffusion in the pickling of spring steel.** *J. Electrodepositors' Tech. Soc.* **29**, 89-101 (1952).—*C.A.* **47**, 3780*e*.

H_2 is believed to be adsorbed and to diffuse through steel in the at. state, then to collect as H_2 in discontinuities in the metal lattice. Both ductility and endurance properties may be permanently impaired, although low temp. heat-treatment brings considerable recovery.

785. Kawai, Masayoshi. **Behavior of hydrogen in steel. III.** *Tetsu-to-Hagane* **38**, 9-17 (1952).—*C.A.* **47**, 4819*f*.

The time necessary to remove H_2 from steel by heating was found to be at an optimum 900°C for 2 hrs instead of heating at 800°C for 1-2 hrs. The problem of H_2 escape from steel at ordinary temp. was studied.

786. Kiperman, S. L.; Rybakova, N. A., and Temkin, M. I. **Catalyst reduction by atomic hydrogen.** *Zhur. Fiz. Khim.* **26**, 621-3 (1952).—*C.A.* **47**, 393*f*.

Reduction of WO_3 during 90 hrs at room temp. and then at 300°C during 82 hrs is attempted by means of at. H from a 5000-v. discharge. The resulting catalyst shows higher activity for NH_3 synthesis at atm. pressure than that investigated before. Similar conversions are now obtained at temps. that are 220-30° lower than are necessary with a catalyst reduced with NH_3.

787. Kivnick, Arnold and Hixson, A. Norman. **The reduction of nickel oxide in a fluidized bed.** *Chem. Eng. Progress* **48**, 394-400 (1952).—*C.A.* **46**, 8941*g*.

The course of the reaction was followed by the change in H_2 of the fluidizing gas mixt. between the inlet and outlet of the reactor. The specific-reaction const. was observed to vary as a function of gas velocity, at const. temp., and as a function of temp. at const. velocity. The energy of activation for the over-all reaction was of the order of magnitude of the energy of activation for the adsorption of H_2 on metal oxides. The kinetic step which is effective may be the adsorption of H_2 on NiO.

788. Kostron, H. **Aluminum and gas. II. Blisters and pores.** *Z. Metallkunde* **43**, 373-87 (1952).—*C.A.* **47**, 5855*c*.

H_2 is the only gas which dissolves in Al and its alloys above and below the m.p. The equil. amt. dissolved increases with the square root of the H_2 partial pressure in the atm. and follows an exponential temp. law. The soly. upon solidification drops to $^1/_{19}$ of the original value. Blister formation in melts are discussed from the viewpoint of chemisorption. H_2 is accepted by Al as H^+ and forms solid solns.

789. McGraw, L. D.; Snavely, C. A.; Moore, H. L.; Woodberry, P. T., and Faust, C. L. **A fundamental study of the mechanism by which hydrogen enters metals during chemical and electrochemical processing.** *Natl. Advisory Comm. Aeronaut. Tech. Note* No. **2696**, 43 pp. (1952).—*C.A.* **46**, 7486*g*.

Reagents were found that increase or decrease the H_2 permeability of steels during pickling or plating. H_2 in metals can reduce CCl_4. Hydride formation of the depositing metal during metal deposition can account for embrittlement, even when there is no apparent discharge of H_2. Citrate and tartrate are effective inhibitors of H_2 entry from basic solns. In acid soln. they are not effective unless converted to complex salts with Al. H_2, by forming alloys during chem. or electrochem. reactions at the metal surface, plates into the metal surface. Soln. or compd. formation is essential to entry. Whether a H atom reacts with the metal or a proton is reduced, an alloy must be formed in the process and the entry accomplished.

790. Mignolet, J. C. P. **Nonstoichiometric chemisorption of hydrogen on tungsten and nickel.** *J. Chem. Phys.* **20**, 341-2 (1952).—*C.A.* **46**, 8928e.

The formation of a pos. rather volatile film following that of the normal neg. one was observed in the low-temp. adsorption of H_2 on Cr, W, and Ni. The surface potentials for W were -0.65 v. for the satd. neg. film and 0.2 v. for the satd. pos. film. The pos. films were of a nonstoichiometric chemisorbed nature rather than mol.

791. Norberg, R. E. **Nuclear magnetic resonance of hydrogen absorbed into palladium wires.** *Phys. Rev.* **86**, 745-52 (1952).—*C.A.* **46**, 7873*h*.

Nuclear magnetic resonance signals were observed for H_2 which was absorbed into Pd wires. Steady-state absorption and pulsed "echo" expts.

were performed. The wires were connected as circuit elements and the resonance signals observed were caused by protons contained in the skin layer of wires. Samples were loaded by means of a glow discharge to concns. of 0.2 to 0.8 (expressed as atom ratios H/Pd). The diffusion of the protons among the interstices of the Pd lattice and on the interaction of the protons with the conduction electrons were discussed.

792. Ogawa, Shiro and Watanabe, Denjiro. **Electron-diffraction study on nickel surfaces tarnished in the course of heat-treatment in hydrogen.** *Science Repts. Research Inst., Tohoku Univ., Ser.* **A**, **4**, 41-7 (1952).—*C.A.* **47**, 2110*f*.

When Ni plates for vacuum tubes are annealed in H_2 at 900-1000°C, their surfaces often tarnish and show milk-white appearance. The milk-white surfaces generally give diffuse rings which are entirely different from the Ni pattern. The rings are shown to be due to $(Mg,Ca)SiO_3$ and NiO. The presence of the silicates, even in small quantities, gradually aggravates the grain boundaries upon heat-treatment and finally causes tarnishing of the surfaces.

793. Papp, E.; Zombory, L., and Magyarossy, I. **Determination of hydrogen in aluminum.** *Acta Tech. Acad. Sci. Hung.* **3**, 335-54 (1952) (in German).—*C.A.* **47**, 2636*h*.

H_2 in Al was detd. in a quartz tube (500-mm long and 60-mm inside diam.), a "hot wire" app., and an elec. measuring device. After flushing the app. with dry N_2 and heating the wire with an accumulator, a microammeter was brought to the null point. An Al sample 11 × 2.5 × 1.5 cm (100 g) was melted *in vacuo* in an alundum boat at 800°C and then allowed to solidify. The liberated H_2 was swept through the hot-wire app. with N_2 and the variations in heat conductivity measured with the microammeter. The melting and solidification was repeated. The vol. of H_2 was linearly proportional to the deflection of the microammeter or to the area under the curve when deflection is plotted as a function of time.

794. Parravano, Giuseppe. **The reduction of nickel oxide by hydrogen.** *J. Am. Chem. Soc.* **74**, 1194-8 (1952).—*C.A.* **46**, 6475*h*.

The reduction of NiO by H_2 was studied in the range of 150-350°C and initial pressures of H_2 from 200 to 500 mm. The addn. of Ag_2O, Al_2O_3, Cr_2O_3, Li_2O, MgO, $NiCl_2$, ThO_2, and WO_3 to NiO affected both the rate and activation energy for reduction. These effects were related to the change in the electronic properties of the oxide.

795. Perminov, P. S.; Orlov, A. A., and Frumkin, A. N. **Effect on the pressure on the solubility of molecular hydrogen in the β-phase of the system palladium-hydrogen.** *Doklady Akad. Nauk S.S.S.R.* **84**, 749-52 (1952).—*C.A.* **46**, 10796*c*.

The soly. is detd. by comparison of the H_2 pressure, P, in 2 identical bombs of equal vol. (20 cc.), one contg. Pd and the other Ag. Three samples of Pd were used. The results can be represented by the formula $\ln P = a + b\,([H]/[Pd])$, with the soly. [H]/[Pd] expressed in atom ratio. Values of a and b can be derived from measurements of also the potential, ϕ, of a Pd electrode as a function of [H]/[Pd]; these measurements give the linear relation $[H]/[Pd] = a - q\phi$, hence $[H]/[Pd] = a + (RTq/2F) \ln P$, and $b = RTq/2F$. Values of a and b thus calcd. are in very good agreement with the values from soly. measurements at 273° and at 290°K; the agreement is poorer at 241° and at 323°K.

796. Permitina, N. G. and Shlygin, A. I. **The reaction ability of hydrogen after activated adsorption.** *Zhur. Fiz. Khim.* **26**, 874-7 (1952).—*C.A.* **46**, 10974*b*.

A platinized Pt electrode in 0.1 *N* KOH or H_2SO_4 was satd. with H_2, the excess displaced by N_2, some MeEtC(OH)C:CH added to the soln., and the electrode rotated. Its potential changed (e.g., by 0.18 v. in 30 min.) showing that H_2 was leaving the electrode. This proved that adsorbed H is active in hydrogenation reactions. The change of potential in time was first rapid and then slow.

797. Sastri, M. V. C. and Ramanathan, K. V. **Chemisorption of hydrogen on zinc oxide-molybdenum oxide catalysts. Evidence of heterogeneity of the surface.** *J. Phys. Chem.* **56**, 220-4 (1952).—*C.A.* **46**, 8459*a*.

The chemisorption was studied at const. pressure between 186° and 375°C. At all temps. up to 250°C the adsorption steadily increased with time with no intervening decrease in the amt. of adsorption as the temp. was suddenly raised. On the other hand, between 250° and 375°C each rise in temp. was accompanied by a sudden decrease in the amt. of adsorption, followed by a slow steady increase. These abnormal variations in the adsorption at the higher temps. were explained on the basis of heterogeneity of the surface. The energies of activation for adsorption below 250°C were about 21 kcals.; between 250-300°C they dropped from 21.4 kcals. as the adsorption increased from 1.2 to 1.8 cc.; between 300° to 350°C it dropped from 26.8 to 17.6 kcals. per mole as the adsorption increased from 1.6 to 2.1 cc.

798. Sloman, H. A.; Harvey, C. A., and Kubaschewski, O. **Fundamental reactions in the vacuum-fusion method and its application to determination of oxygen, nitrogen, and hydrogen in molybdenum, thorium, uranium, vanadium, and zirconium.** *J. Inst. Metals* **80**, 391-407 (1952) (Paper No. 1360).—*C.A.* **46**, 4952*a*.

Optimum conditions for detg. the gases and their effect upon properties of the metals are given.

799. Stanley, James K. **The embrittlement of pure iron in wet and dry hydrogen.** *Trans. Am. Soc. Metals* Preprint No. **15W**, 10 pp. (1952).—*C.A.* **46**, 391*d*.

Bend tests with 0.1-in. thick strip, after annealing at 1290° to 2100°F, showed embrittlement after 10 hrs in dry H_2 (−65° dew point) and after 1 hr in wet H_2 (3% H_2O by vol.). Specimens broke through grain boundaries. Brittleness was not due to O_2 content of Fe which was as low as 0.002% but to dissocn. of H_2 to at. H. This moved rapidly into the Fe and at elevated temps. collected at some internal surface such as a grain boundary, slip plane or inclusion, and formed H_2.

800. Stetsenko, A. I. and Tverdovskii, I. P. **Disperse platinum-palladium alloys for adsorption and absorption of hydrogen.** *Zhur. Fiz. Khim.* **26**, 647-58 (1952).—*C.A.* 47, 5758d.

Sorption isotherms at 20°C were studied by the electrochem. method (charging curves). The curves for alloys contg. less than 34% Pt consisted of 2 parts: one that depended on the electrolyte and one that did not. With alloys contg. more than 34% Pt, the entire charging curve depended on the electrolyte. The effect of the electrolyte in the first case gave the possibility of calcg. the sorption isotherms of H_2 with a precision of ±10 to 15% at p_{H_2} equal or less than 1 atm. Only adsorption of H_2 can be observed on alloys with more than 34% Pt.

801. Tompkins, F. C. **Sorption of gases on metal films.** *Z. Elektrochem.* **56**, 360-3 (1952) (in English).—*C.A.* **47**, 4164*a*.

Study of the thermal accommodation coeffs. of H_2 on Fe wires shows that the usual H_2 reduction techniques used in the prepn. of industrial catalysts do not lead to a clean metal surface. Adsorption of H_2 on evapd. films of Fe, conditioned by alternate raising and lowering of the temp. in a temp. range outside that used in the adsorption, shows that H_2 is adsorbed instantaneously at room temp. in the form of atoms with no measurable slow process. At temps. lower than 150°K, it proceeds at a measurable rate. No evidence was found for a sepn. of this process into a rapid surface adsorption followed by a slow adsorption into the bulk of the film. The net rate of adsorption of H_2 varies as the square root of the pressure.

802. Tverdovskii, I. P. and Stetsenko, A. I. **Absorption and solution of hydrogen in disperse palladium-rhodium alloys.** *Doklady Akad. Nauk S.S.S.R.* **84**, 997-1000 (1952).—*C.A.* **46**, 9388f.

Curves of potentials ϕ as a function of the elec. charge Q, in 1 N KOH, H_2SO_4, or HBr, were detd. at 20°C for Pd-Ph electrodes (compn. in at. %) prepd. by codeposition from solns. of $Na_3RhCl_6.12H_2O$ and $PdCl_2$ in varying proportions. Along the portion corresponding to soln. Q increased, and along the portion corresponding to adsorption Q decreased with decreasing Rh content in the alloy. With increasing Rh content, the range of divergence of the curves widened at the expense of the range of coincidence. Above 40 at. % Rh, the whole curve became dependent on the nature of the electrolyte, as for the case of pure Rh. Consequently, the binding of H_2 by high-Rh alloys, and by Rh, was purely adsorptive. The lowering of the adsorption of H_2 in HBr was due to sp. adsorption of Br_2.

803. Vandael, C. **Raney nickel.** *Ind. chim. belge* 17, 581-5 (1952).—*C.A.* **46**, 9396*f*.

A gasometric analysis was made of the amt. of H_2 absorbed by the catalyst. After correcting for the Fe and Cu impurities, there were 1.06 and 0.99 moles of H_2 assocd. with each Ni atom in 2 series of detns., resp. The Ni-H system was also analyzed by titrating with $KMnO_4$ soln.; 1.965 atoms of O were needed to oxidize the H assocd. with one Ni atom.

804. Yasumori, Iwao; Shida, Shoji, and Nakada, Kazuo. **Treatment of atomic adsorption by use of linear atomic chain model. I. Adsorption of atomic hydrogen on alkali metal surfaces.** *J. Chem. Soc. Japan*, Pure Chem. Sect. **73**, 892-5 (1952).—*C.A.* **47**, 6213*g*.

805. Gutmann, Joel R. **The exchange reaction between deuterium and ammonia on the surface of metal powders.** *J. Phys. Chem.* **57**, 309-12 (1953).—*C.A.* **47**, 6233*h*.

The reaction was studied on Fe and Ni powders between 210° and 319°C. The exptl. rate of exchange on Fe was independent of the NH_3 pressure and was of 1st order with respect to D_2. The activation energy was 17.5 kcal./mole. The runs were not reproducible with Ni, and in some cases the rate of exchange was slow in the beginning but increased as the reaction proceeded.

806. Keeler, J. H. and Davis, H. M. **Density and hydrogen occlusion of some ferrous metals.** *J. Metals* **5**, Trans. 44-8 (1953).—*C.A.* **47**, 1555*d*.

Densities of SAE 1020 and ingot Fe decreased with cold-rolling to minima at 60% reduction, whereas high-purity Fe was unaffected. H_2 occlusion of high-purity Fe or ingot Fe was barely affected by 60% cold reduction, but that of SAE 1020 was increased a hundred-fold.

807. Krylov, O. V. and Roginskii, S. Z. **Oxidation of hydrogen on oxygen-activated platinum.** *Doklady Akad. Nauk S.S.S.R.* **88**, 293-5 (1953).—*C.A.* 47, 5232*g*.

On a smooth Pt foil (~1 cm^2 apparent surface area), outgassed *in vacuo* at 800°C, oxidation of a 2 $H_2 + O_2$ mixt. under low pressures (0.01 – 0.2 mm Hg) begins at a slow rate, the activity of the catalyst increasing gradually as the reaction progresses. In contrast, Pt foil activated 15 min. with 0.1 mm O_2 at 250-500°C, shows full activity from the very start of the reaction; at 0°C, the reaction (in a static system, vol. of vessel ~600 ml, initial pressure 0.1 mm) is complete in 10-30 min. The amt. of O_2 sorbed by the same Pt foil, in 15 min. exposure, increases steadily and ever more rapidly between 290° and 800°C. At 700°C, the catalytic activity, as a function of the amt. of O_2 sorbed, passes through a max. Thus, O_2 sorbed at a high temp. and in an amt. corresponding to 6 monolayers or more, takes no part in the production of active centers.

808. Laidler, Keith J. **Kinetics of surface reactions in the case of interactions between adsorbed molecules.** *J. Phys. Chem.* 57, 318-19 (1953).—*C.A.* **47**, 6234*f*.

The effect of interactions between adsorbed mols. on the abs. rates of surface reactions, with special reference to the para-H_2 conversion, was considered. The interactions affected the no. of dual surface sites and also the partition function for the surface sites. The 2 effects were shown to cancel exactly for a fully covered surface. In calcg. abs. rates it was therefore correct to omit interaction terms.

809. LAIDLER, KEITH J. **Mechanisms of surface-catalyzed reactions. I. The para-hydrogen conversion on tungsten.** *J. Phys. Chem.* **57**, 320-1 (1953).—*C.A.* **47**, 6234*g*.

The rate was controlled by adsorption of H_2 on a bare dual surface site. If the variation of rate const. *k* with *p* was taken into account, the mechanism explained the low reaction orders of close to zero. It was also consistent with the observed abs. rates. The mechanism involving reaction between an adsorbed atom and a gaseous mol. or a van der Waals adsorbed mol. was incapable of explaining either the order or the abs. rate.

810. MALLETT, M. W.; GERDS, A. F., AND GRIFFITH, C. B. **Determination of hydrogen in magnesium, lithium, and magnesium-lithium alloys.** *Anal. Chem.* **25**, 116-19 (1953).—*C.A.* **47**, 2637*a*.

The alloy was heated *in vacuo* at 500°C. Gas was evolved at about 3 ml per min. for nearly 3 hrs and the H_2 was detd. in an Orsat app. The specimen was also sealed in a welded steel capsule and heated 4-5 hrs in a quartz tube at 750°C. Rather high results were obtained. The sample was also dissolved in molten Sn at 450°C and heated in an evacuated borosilicate glass tube. This method was suitable for detg. H_2 in pure Mg and possibly pure Li if care was taken to protect the sample from air while it was being weighed and loaded into the furnace. The samples tested contained 0.008-0.015% H_2.

811. MARKHAM, MARIA C.; WALL, MARY C., AND LAIDLER, KEITH J. **Molecular kinetics and mechanism of methane-deuterium exchange reactions on nickel.** *J. Phys. Chem.* **57**, 321-3 (1953).—*C.A.* **47**, 6234².

CH_3D was considered to be formed from adsorbed CH_3 and D_2 on evapd. Ni and the rate of production of CH_3D was shown to be approx. equal to the rate of adsorption of CH_4 as CH_3 radicals. CH_2D_2, CHD_3, and CD_4 were considered to be formed by reaction between adsorbed CH_2 radicals and adsorbed D atoms, and a treatment was given for the relevant statistical factors. Calcd. rates for all 4 processes were in agreement with the exptl. rates.

812. SHIELDS, BRUCE M.; CHIPMAN, JOHN, AND GRANT, NICHOLAS J. **Thermal conductivity method for analysis of hydrogen in steel.** *Metals* **5**, *Trans.* 180-4 (1953).—*C.A.* **47**, 2635*h*.

The vacuum Sn-fusion method of analysis for H_2 was modified to permit the analysis of the evolved gases for H_2 by means of a thermal cond. cell. A properly prepd. sample could be analyzed in 10 min. with a probable error of ±0.12 p.p.m. A study of various methods for storage of H-samples showed that samples can be safely held in a Dry Ice-acetone bath as long as 6 days. Storage in liquid N_2 was necessary for samples to be held one week or more.

813. SKEI, T.; WACHTER, A.; BONNER, W. A., AND BURNHAM, H. D. **Hydrogen blistering of steel in hydrogen sulfide solutions.** *Corrosion* **9**, 163-72 (1953).—*C.A.* **47**, 5864*a*..

Extensive damage to some refinery equipment has occurred owing to transmission through steel of the H_2 formed during corrosion of steel by H_2S solns. Damage in the form of H_2 blistering, fissuring, and embrittlement of steel has been particularly severe in catalytic cracking gas plants. The lab. method involved measurement of the vol. of H which passed through to the opposite side of a thin wall of C steel. It was shown that the rate of H_2 transmission can be reduced greatly by indicated changes in chem. environment (presence of O, use of alloys, etc.).

814. YAO, Y. L. AND MILLIKEN, K. S. **Storage of solid steel samples for hydrogen analysis.** *Anal. Chem.* **25**, 363-4 (1953).—*C.A.* **47**, 4245*h*.

After the sample is cut to size, clean in ether, dry, and weigh. Then dip in molten Sn for a few sec. Cover the Sn bath with fused $ZnCl_2$. On immersing the sample in the Sn bath with a quick motion, the smudge coalesces to form a light mass partly covering the Sn. Take the sample from the bare and clean surface of Sn. The wt of Sn in the coating is usually 5-10% of the wt of the sample. It can be stored for a few days without diffusion of appreciable quantities of H_2.

815. BOWDEN, F. P. AND HUGHES, T. P. **The friction of clean metals and the influence of adsorbed gases. The temperature coefficient of friction.** *Proc. Roy. Soc.* **A 172**, 263-79 (1939).—*C.A.* **33**, 8465³.

The removal of oxide and surface films increased the kinetic friction between the outgassed metals, in some instances to 20 times the value for the same metals cleaned in air. The addn. of a trace of O_2 to the clean metal caused an immediate reduction in friction.

816. GOLDOVSKIĬ, M. L. **Friction of pure metals and the influence of adsorbed gases. The temperature coefficient of friction.** *Uspekhi Fiz. Nauk* **25**, 373-6 (1941).—*C.A.* **37**, 3314³.
Review.

817. MÜLLER, ERWIN W. **Tearing off adsorbed ions by high electric field strengths.** *Naturwissenschaften* **29**, 533-4 (1941).—*C.A.* **39**, 4002³.

A monocrystal W point electrode with adsorbed Ba film is focused in an electron microscope as cathode with field electron emission. By changing of polarity a high positive field strength of several 10^8 v. per cm can be applied. The pos. field tears off part of the adsorbed Ba film. The loosening starts with 82×10^6 v. per cm on the 110 plane of W, it spreads to other planes with increasing field strength, the 100 plane comes last; at 120 v. per cm the entire film disappears.

818. ALTPETER, WALTER. **The removal and absorption of nitrogen by molten steel in the basic**

arc furnace. *Stahl u. Eisen* 62, 997-1001 (1942).--*C.A.* 37, 5346^7.

Changes in N_2 content of molten steel from melting to tapping were detd. in 102 com. melts from 3 furnaces. Initial N_2 content at the end of melting depended on furnace atm. which may have been abnormal because of leaks. Final N_2 did not depend on furnace atm., although N_2 contents of 0.001% were obtained only in newly rammed furnaces; usual contents were 0.003 to 0.005%. N_2 removal was most rapid with quick decarburization and the use of fine ore. Temp. of steel was not a controlling factor. Ni, Cr and Mo did not retard removal of N_2 during melting or tapping.

819. ARMBRUSTER, MARION H. **The adsorption of gases at low temperature and pressure on smooth silver.** *J. Am. Chem. Soc.* 64, 2545-53 (1942).—*C.A.* 37, 16^3.

The adsorption of H_2, N_2, A, CO, CO_2, and O_2 at pressures up to 0.1 cm on a substantially plane, reduced surface of Ag was measured over the range 195° to 20°C. H_2 was not measurably sorbed at any temperature; A, N_2, and CO were sorbed at -195° and -183°, but not at -78° or 20°C. CO_2 was not sorbed at 20°, but at -78°C was sorbed to the slight extent of 6 ml at a pressure of 0.02 cm. The adsorption was in each case instantaneous and reversible. O_2 was sorbed at -195° and -183°C and some part of it could not be removed by pumping at that temperature. At -78° and 20°C, there was activated adsorption of O_2. All the isotherms were of the type observed in a plane surface of other metals and were satisfactorily represented by the Langmuir equation. The surface coverage varied from about 20 to 90% of a close-packed monolayer.

820. BAUKLOH, WALTER AND EDWIN, BJORN. **The effect of temperature and pressure on the disintegration of CO and the action of the explosive effect of carbon.** *Arch. Eisenhuttenw.* 16, 197-200 (1942).--*C.A.* 37, 5903^3.

The CO disintegration ($2CO \rightleftarrows C + CO_2$) is a special case of a slow adsorption catalysis which assumes technical importance in the presence of suitable catalyzers such as Fe, Ni or Co. The adsorption of CO by the metallic surface is connected with an increase in its activity. There exists a max. of disintegration which depends on temp. The disintegration increases with increasing pressure (at const. temp.) to an asymptotic max. value. The explosive effect is explained by the growth of carbon preferably in the direction of pressure, and if a resistance is offered in this direction (wall or other metal part) C and also the metal (Fe) particles are deformed.

821. DANKOV, P. D.; KOCHETKOV, A. A., AND SHISHAKOV, N. A. **Oxide films on metals. II. Initial oxide films on aluminum.** *Bull. acad. sci. U.R.S.S., Classe sci. chim.* 1942, 274-85 (English summary).—*C.A.* 39, 1582^3.

Very complex relations exist between the metal and the oxide, with possible existence of unstable oxide forms. The primary Al oxide should be classed with the amorphous substances. Much of the earlier work is controversial and conflicting because of different methods of sample prepn.

822. GRAAF, J. E., DE, AND HAMAKER, H. C. **Adsorption of gases by barium.** *Physica* 9, 297-309 (1942).—*C.A.* 37, 4286^5.

The adsorption of H_2, O_2, CO, CO_2 and N_2 was detd. on a series of Ba films vaporized under various conditions. The adsorptive power of Ba was increased by vaporizing it in A with increasing A pressure up to a max. at 5 mm. Similar notable improvements resulted on vaporizing in Xe and Ne, whereas He proved less effective. Ba films vaporized also in CO_2, CO and N_2 at low pressure (optimum 0.4 mm) had better adsorptive power for N_2, e. g., than Ba films prepd. in vacuum. The chemically active gases such as H_2 and O_2, on the other hand, were ineffective. The improvement in the films went hand in hand with an increase in the surface of the Ba layer. A coarsening of the Ba structure and with it a decrease in the adsorptive power resulted from warming the substrate of the film (glass or metal) during the vaporizing of the Ba.

823. GRIFFIN, CARROLL W. **The sorption of carbon monoxide by metals. Temperature variation experiments.** *J. Am. Chem. Soc.* 64, 2610-13 (1942).—*C.A.* 37, 16^6.

Measurements are made for the sorption of CO on supported Cu and on massive and supported Pt. The results are qualitatively similar to like measurements of H_2 on massive and supported metals. The presence of a secondary sorptive force is probably a general characteristic of metallic sorbents and is present only to a small extent with supported sorbents where the metal is largely exposed as surface. With CO on massive metals, the secondary action is over 3 times as great with Pt, and about ten times as great with Cu, when compared with their respective supported forms.

824. GUILLET, LÉON, JR. **Gases and metals. The influence of the gases absorbed in metals on their properties.** *Génie civil* 119, 134-6 (1942).—*C.A.* 38, 319^4.

The kind and quantity of gases in metals were studied. The influence of the gases on the properties of the metal, how it can be overcome, and how they form inclusions in the forged steel were discussed.

825. GULBRANSEN, E. A. **Thin oxide films on iron.** *Trans. Electrochem. Soc.* 81, 11 pp. (1942).—*C.A.* 36, 2824^7.

A vacuum microbalance technique for the study of chem. reactions occurring on metallic surfaces was described. Preliminary curves were presented for the oxidation of pure electrolytic Fe from 25° to 400°C and at various pressures of O_2. Attempts were made to correlate the data with the various mechanisms proposed for oxidation reactions.

826. HUTTIG, GUSTAV F.; THEIMER, HELLMUT, AND BREUER, WALDEMAR. **Reactions of solids. CXXVI. Degassing of solids.** *Z. anorg. allgem Chem.* 249, 134-45 (1942).—*C.A.* 37, 3658^9.

The loss of volatile foreign components of powd. Cu, Fe, Sn and Al_2O_3 was measured with rising temp. Sep. detns. were made of H_2 (burning with CuO), H_2O (absorption in P_2O_5), and N_2 (absorption in molten Li). The regularities found in the release of gas consisted of 2 maxima in the rate of degassing, at $\alpha = 0.29 \pm 0.02$ and $\alpha = 0.42 \pm 0.01$, in which $\alpha = (273 + t°)/T_F$, T_F being a characteristic temp. of the powd. material. The 1st max. corresponded to a loosening of the surface, the 2nd to that of the crystal lattice.

827. IIJIMA, SHUNICHIRO **Dissociation of silver oxide at low temperature.** *Bull. Inst. Phys. Chem. Research (Japan)* **21**, 737-43 (1942).—*C.A.* **41**, 5366*i*.

By use of a thermal balance with which pressure can be detd., the decompn. of Ag_2O according to $Ag_2O = 2Ag + 0.5\ O_2$, was found to begin at 230-70°C. It was affected only slightly by the O_2 pressure. The oxidation of Ag into Ag_2O did not occur at any temp. when the O_2 pressure was below 760 mm, and the reverse reaction velocity of the dissocn. equil. at low temp. was too small to be detected.

828. LAURENT, A. **Dissolved gases in metallurgical products.** *Métaux, corrosion-usure* **17**, 113-23 (1942).—*C.A.* **38**, 2597⁵.

Comparative tests were made with 99.7% Al: (1) heating to 600°C for 1 month under a pressure of 10^{-4} mm Hg, (2) fusion under the same reduced pressure and (3) bombardment in the cold repeated 3 times (4 bombardments) at intervals of 24 hrs. The vols. of gas liberated (cc. per 100 g of metal) were 12.5 for the first method, 20.0 for the 2nd, and 216 for the 3rd.

829. MORITA, NORIYOSHI. **The catalytic exchange reactions of oxygen atoms between gaseous oxygen and water vapor by iron oxide catalyst. I. Experimental.** *J. Chem. Soc. Japan* **63**, 659-64 (1942).—*C.A.* **41**, 2974*h*.

Four catalysts: (1) α-Fe_2O_3, (2) γ-Fe_2O_3, (3) $Fe_2O_3 + Bi_2O_3$(2:1 by wt), (4) Bi_2O_3 were prepd. Their catalytic activities were detd. in the exchange reactions of O atoms in O_2 and water vapor. (1), (2), and (3) showed about the same activity. The activity of (1) and (2) decreased with repeated use. All 4 catalysts lost their catalytic activity when heated above 800°C. The temp. of the exchange reaction was 300-700°C.

830. MORITA, NORIYOSHI. **The catalytic exchange reactions of oxygen atoms between gaseous oxygen and water vapor by iron oxide catalyst. II. Theoretical.** *J. Chem. Soc. Japan* **63**, 665-7 (1942).—*C.A.* **41**, 2974*i*.

The decrease in the catalytic activity of the catalysts caused by heating above 800°C is attributed to the decrease of the active centers and the elevation of the activation energy.

831. SMOLUCHOWSKI, R. **Diffusion rate of carbon in iron-cobalt alloys.** *Phys. Rev.* **62**, 539-44 (1942).—*C.A.* **37**, 819⁵.

Studies of rates of various transformations and reactions in Fe alloys seemed to indicate that certain elements have a definite effect on the rate of diffustion of carbon in γ-Fe. Direct measurement was made of the rate of diffusion of carbon in Fe-Co alloys. An addn. of 4% Co decreased the activation energy from 32,500 to 30,000 cal., corresponding to an almost twofold increase of the diffusion rate at 1 at. % carbon concn. At higher carbon contents the accelerating effect of Co was smaller.

832. THOMAS, LLOYD B. AND OLMER, FRANCOIS G. **The accommodation coefficient of mercury on platinum and the heat of vaporization of mercury.** *J. Am. Chem. Soc.* **64**, 2190-5 (1942).—*C.A.* **36**, 6404⁷.

The accommodation coeff. of Hg on Pt was measured at low Hg pressures. It was found to approach unity as the temp. difference between the filament and wall approached zero and to fall off about 0.08 for each 100°C of this temp. difference. The data obtained in the measurements allowed a calcn. of the heat of vaporization of Hg.

833. BÉNARD, J. **Role of diffusion in surface oxidation of iron.** *Métaux, corrosion, usure* **18**, No. 2, 20-9 (1943).—*C.A.* **44**, 9781*c*.

The rate of oxidation of pure Fe at 250-900°C was investigated. The chem. nature of the films formed and the mechanism of the diffusion of metal through the oxide film were discussed.

834. CHAUDRON, GEORGES. **Gas problem in aluminum.** *Usine* **52**, No. 21, 8 (1943).—*C.A.* **38**, 5765⁸.

Ionic treatment of Al in the elec. field of 100,000 or better 130-140,000 v. and analysis of the liberated gases showed for a total quantity of 85 cc. per 100 g Al: 15 cc. CO, 58 cc. H_2 and 10 cc. N_2. Errors can be caused by fat or grease films on the Al surface or too great thickness of the sheets. In practice, H_2 was absorbed in the Al electrolysis, in pickling and rolling by dissocn. of moisture and was present in ionic form embedded in the crystal lattice. CO was absorbed from combustion gases and together with H_2 liberated by dissocn. of fat. N_2 was absorbed in at. form (dissocn. takes place at 1200°C) and existed as solid soln.

835. DUHN, J. H. v. **The effect of adsorbed layers of molecules of dielectric substances on the contact difference of potential between two metals.** *Ann. Physik* **43**, 37-52 (1943).—*C.A.* **38**, 1939².

Vapors of a series of dielec. liquids, such as members of the paraffin and alc. series, benzene, chlorobenzene, and toluene, and also H_2 were allowed to form adsorptive layers on a series of metallic surfaces, and the potentials were measured with respect to a standard electrode by the Kelvin method. In some cases the contact difference of potential was found to be a function of the pressure of the vapor; this effect was ascribed to change in the thickness of an adsorbed layer, or change of penetration of the foreign mols. in the lattice of the metal. Correlations with the electron structure of the metal were noted, also with the mol. refraction of the adsorbed material. Values of the order of ±0.8 v. were observed.

836. FRENKEL, YA. I. **Theory of the formation of oxide films on the surfaces of metals.** *J. Exptl. Theoret. Phys. (U.S.S.R.)* **13**, 289-94 (1943).—*C.A.* **39**, 1099³.

The formation of thin oxide films on metals in the presence of air takes place via adsorption of O_2, dissocn. of the adsorbed O_2 into O atoms, and diffusion of the latter via the intercryst. spaces involving a deformation of the lattice into a thin surface layer of the metal itself.

837. Goldfeld, Yu. M. and Kobozev, N. I. **Experimental study of the role of the action of forces in the adsorption process. II. Adsorption kinetics.** *J. Phys. Chem. (U.S.S.R.)* **15**, 275-95 (1943).—*C.A.* **38**, 4481⁹.

The kinetics of desorption of CO, H, C_2H_4 and C_4H_6 on Cu is always markedly greater than first-order. With increase in temp. the abs. value of the desorption velocity increases and the order decreases. If the Cu has previously adsorbed CN, the velocity of desorption of CO and the order of the desorption curve are both raised. Moreover the subsequent introduction of CN to CO adsorbed on Cu increases the desorption of CO manyfold. An equation is derived for the velocity of desorption that represents the exptl. findings qualitatively.

838. Gulbransen, E. A. **The transition-state theory of the formation of thin oxide films on metals.** *Trans. Electrochem. Soc.* **83**, 13 pp. (1943).—*C.A.* **37**, 2251³.

The expression involved an entropy of activation as well as the energy of activation. Exptl. results indicated that the oxidation of Fe, stainless steel and Cu followed the parabolic law for certain temp. ranges and pressure ranges after a certain initial period. The parabolic rate law consts. were shown to follow a straight line when log K was plotted against 1/T. Energies of activation of 22,600, 29,600 and 24,900 were found for Fe, stainless steel and Cu, resp.

839. Hirashima, M. **Carbonization of the thoriated tungsten filament.** *J. Inst. Elec. Engrs. Japan* **63**, 867, (1943).—*C.A.* **42**, 44*d*.

A new type of thoriated W has been produced by coating the W with an aq. soln. of Th nitrate and heating this block in an inert gas to diffuse the Th into the W. The emission characteristic of this new-type cathode was almost the same as that of the usual thoriated W cathode. The W crystals became finer.

840. Hurt, David M. **Principles of reactor design—gas-solid interface reactions.** *Ind. Eng. Chem.* **35**, 522-8 (1943).—*C.A.* **37**, 4001².

Over-all reaction rates were shown to be a function of surface reaction rates and diffusional, or mass-transfer, rates, and these component factors were individually correlated with their resp. important variable. The new terms H.R.U. (height of over-all reaction unit) and H.C.U. (height of catalytic unit or surface reaction unit) were introduced as measures of over-all reaction rate and surface reaction rate, and used in conjunction with a conventional gas-film H.T.U. as a measure of mass-transfer rate. Data for the oxidation of SO_2 on Pt catalysts were given to illustrate the method.

841. Hüttig, Gustav F. and Freitag, Tibor. **Reactions in the solid state. CXXXIII. The fritting of aluminum powders in a vacuum and in hydrogen.** *Z. anorg. Chem.* **252**, 95-111 (1943).—*C.A.* **38**, 3888².

The adsorption of CH_3OH vapor by Al powders, subjected to preheating in vacuo and in H_2, was detd. The adsorption isotherms were interpreted on the basis of Langmuir's theory. The surface activity depended on the preheating and other factors. Slight addns. of HCl to H_2 increased the activity noticeably.

842. Ishikawa, Yoshioki. **Desorption of the water molecules adsorbed on a platinum plate by slow-electron impact.** *Proc. Imp. Acad. (Tokyo)* **19**, 380-4 (1943) (in English).—*C.A.* **41**, 5382*i*.

A Pt plate, composing the anode of a diode after a thorough outgassing at 350°C and introduction of a trace of H_2O vapor, was bombarded by slow electrons. The H_2O desorbed from the Pt surface was detd. by the Pirani gage. When the amt. of H_2O desorbed in 3 min. over i (impinging electrons in ma.) was plotted against the accelerating voltage, the resulting desorption curve showed many breaks between 5 and 30 v. The H_2O mol. dissocd. with rising voltage in 5 steps; $H+OH^+$, H_2+O^+, $OH+H^+$, $O+H_2^+$, and $H+H^++O^-$.

843. Ishikawa, Yoshioki. **Determination of the thickness of an adsorbed molecular layer of water.** *Proc. Imp. Acad. (Tokyo)* **19**, 385-92 (1943).—*C.A.* **41**, 5358*a*.

The thickness of an absorbed layer of H_2O on a Pt plate was detd. by desorption of H_2O by slow electron impact. When the amt. of the desorbed H_2O in 3 min. over i (impinging electrons in ma.) was plotted against the voltage, 3 curves for the uni-, bi-, and tri-mol. layer desorptions were obtained.

844. Matuda, Syoiti. **Theory of self-diffusion of metallic crystals.** *Sci. Papers Inst. Phys. Chem. Research (Tokyo)* **40**, 207-27 (1943).—*C.A.* **41**, 6099*g*.

The diffusion coeff. is discussed from the view point that the atoms travel through vacant lattice positions (the Schottky holes) which are formed in several lattice points in the crystal.

845. McBain, J. W. and Glassbrook, Clarence I. **Electrification and luminescence phenomena accompanying desorption of gases from metals.** *J. Am. Chem. Soc.* **65**, 1908-9 (1943).—*C.A.* **38**, 17⁷.

When various gases are passed over a metal that is cooling during sorption and desorption, the gas stream on the outward side becomes electrified. It causes a luminescence on the walls of a silica tube. These effects are ascribed to very fine electrified ultramicroscopic particles released from the metal.

846. Smoluchowski, R. **Diffusion rates of carbon in iron-molybdenum and iron-tungsten alloys.** *Phys. Rev.* **63**, 438-40 (1943).—*C.A.* **37**, 4608⁴.

The effects of W and Mo on the rate of diffusion of carbon in face-centered Fe was studied at 1000°C. Both elements retarded the diffusion of carbon, the effect of W being more than twice that of Mo. There was no connection between the variation in lattice parameter of face-centered Fe and the variation in the diffusion rate of carbon.

847. Suhrmann, R. and Kundt, W. **Influence of adsorbed oxygen on the secondary emission of evaporated metallic layers at 293° and 83°K.** *Z. Physik* **121**, 118-32 (1943).—*C.A.* **37**, 6543³.

The yield of secondary electrons was studied for Cu, Ag, Au, Cd and Be layers evapd. on glass in a vacuum and exposed to O_2 at room temp. for a short time. The yield at room temp. for Cu, Ag and Au was only slightly affected, but when these O_2-treated layers were cooled to 83°K the yield with 100-v. primary electrons increased reversibly by 100%, and the max. yield shifted to smaller primary-electron energy.

848. THOMAS, LLOYD B. AND OLMER, FRANCOIS. **The accommodation coefficients of He, Ne, A, H_2, D_2, O_2, CO_2 and Hg on platinum as a function of temperature.** *J. Am. Chem. Soc.* **65**, 1036-43 (1943).—*C.A.* **37**, 4609².

The desirability of having uniform temp. throughout the length of the filament for accommodation-coeff. measurements were indicated. A tube designed to give this condition was described. Accommodation coeffs. for the above 8 gases were obtained with this tube over a range of temp. and compared with existing values.

849. ARMBRUSTER, MARION H. AND AUSTIN, J. B. **The adsorption of gases on smooth surfaces of steel.** *J. Am. Chem. Soc.* **66**, 159-71 (1944).—*C.A.* **38**, 1412⁹.

The adsorption on cold-rolled steel of A, Ne, H_2, N_2, CO and CO_2 was detd. at 20°, -78°, -183° and -195°C and at pressures up to 0.1 cm. Measurements were made first on a degreased and outgassed surface and subsequently on the same surface after reduction by H_2. Neither H_2 nor Ne was measurably adsorbed on either surface within the range of temp. or pressure investigated. A unimol. layer of physically held N_2, A or CO was sorbed on the unreduced surface at -183°C, but in each case approx. 15% of the total vol. sorbed could not be desorbed by reducing the pressure at that temp. A similar monolayer of physically held N_2 and A on the reduced surface could be entirely desorbed by evacuation of the system at the temp. in question. On this same surface a complete monolayer of physically held CO was adsorbed along with a partial layer of chemisorbed mols. The isotherms were the low-pressure section of the sigmoid-type characteristic of adsorption on Fe catalysts. The B.E.T. equation appeared to be preferable.

850. DEBEAU, DAVID E. **The effect of adsorbed gases on contact electrification.** *Phys. Rev.* **66**, 9-16 (1944).—*C.A.* **38**, 5446³.

The electrification produced on contact of quartz and of NaCl on Ni in atms. of air, O_2 and N_2 was measured. Contact electrification was a surface phenomenon and depended greatly on the nature of the surfaces involved. At least two layers of adsorbed gas played an important part in the phenomenon of contact electrification. In the pressure range from 760 to 30 mm at least one layer of adsorbed gas was removed. At pressures below 0.1 mm at least a second layer of adsorbed gas was removed. In this pressure range the major contribution to the charge sepn. was made by the surface from which the second layer of gas had been removed. A fit of the data to Langmuir adsorption isotherms was obtained. Water vapor and perhaps H_2 acted as surface-poisons.

851. EICHBORN, JOHANN LUDWIG VON. **Mutual adhesion of substances not miscible spatially. II. Evidence of adhesion in condensed moisture and hysteresis of the borderline of water drops on mercury surfaces.** *Kolloid-Z.* **109**, 62-78 (1944).—*C.A.* **41**, 2959*d*.

Moisture from breath or from distd. water vapor condensed on a clean Hg surface and then evapd. leaves a visible mark on the Hg surface at the point of the Hg-H_2O-air interface. The angle of contact of the surfaces affects this phenomenon.

852. ERICKSON, JAMES L. **Degassing aluminum.** *Light Metal Age* **2**, No. 4, 19-22 (1944).—*C.A.* **38**, 4889².

The topics covered were: gases present in Al, the Al-H_2 system (gas-metal alloy), entrance of gases into the metal, soly. of H_2 and N_2 in Al, methods for the removal of H_2 from Al melts, degassing by the use of an inert gas (N_2), methods advocated for the removal of gases from Al and its alloys, chlorination and the use of Cl-evolving compds. These were discussed from the point of view of foundry technique in the prevention of porosity in Al castings.

853. GALLAGHER, CHARLES J. **Adsorption of thorium on tantalum.** *Phys. Rev.* **65**, 46-50 (1944).—*C.A.* **38**, 2253².

Th was evapd. from thoriated W onto a well-outgassed Ta ribbon, and the thermionic emission at 1390°K was studied as a function of the time of evapn. The work function of the ribbon changed from 4.07 volts to 2.52 volts and the emission const. decreased by a factor of 30. The ribbon was then held at 1550°K and the emission from the two sides was studied separately. The emission from the activated side decreased, whereas that of the clean side increased until both reached the same final level after about 20 hrs. This indicated that the adsorbed Th migrated around the edges of the ribbon and distributed itself uniformly over the emitting surface.

854. GILBERT, F. AND SCHEUER, E. **Factors influencing the moisture content of furnace atmospheres.** *Metallurgia* **30**, 187-90 (1944).—*C.A.* **38**, 5697⁷.

The sources of moisture in order of importance are the H-content of the fuel, the H_2O content of the air used for combustion, the H_2O content of the fuel. If the H-content of the fuel is more than 5%, it is the predominating source of moisture and no changes in the H_2O content of the air or fuel are significant. H_2O content of the fuel plays a significant part only if atm. H_2O and H-content of the fuel are low.

855. GULBRANSEN, EARL A. **A vacuum microbalance for the study of chemical reactions on metals.** *Rev. Sci. Instruments* **15**, 201-4 (1944).—*C.A.* **38**, 6135⁸.

The torsion micro balance consists of a frame constructed of fused quartz rods of 1/8 in. diam. and a beam of 0.073 in. quartz rod. Wires for supporting the beam and weights are of 0.001 in. diam. W attached by means of fused AgCl. The sensitivity is 0.3×10^{-6}g, with a 0.6840 g sample. With the balance, enclosed in a glass tube and with suitable auxiliary app. the kinetics of formation of films from -90° to 1000°C and for pressures of gas ranging from 10^{-5} mm of Hg to 1 atm. can be studied.

856. Hedvall, J. A. **Effect of supersonic waves on surface reactions of metals.** *Tek. Tid.* 74, 625-6 (1944).—*C.A.* 39, 5150².

The rate of formation of surface reaction products was studied when Cu was exposed to I_2 vapor or S fumes, and Fe to O_2. The specimens could be subjected to supersonic waves with a quartz oscillator. A marked increase in the reaction rate was produced by supersonic waves.

857. Kochetkov, A. A. **The kinetics of formation of oxide passivating films on iron.** *Bull. acad. sci. U.R.S.S., Classe sci. chim.* 1944, 390-5 (English summary).—*C.A.* 39, 3196¹.

Pyrophoric Fe (particle diam. about 10^{-4} cm) was prepd. by reducing Fe_2O_3 with H_2 at 280-340°C. This burned in air to α-Fe_2O_3, but at pressures of about 1 mm the rate of oxidation could be measured. In dry air, O_2 was absorbed for 15-20 min., and then absorption stopped. If the Fe was then heated to 210°C, more O_2 was absorbed in accordance with the parabolic law. If moist air was used, O_2 absorption stopped as before, but on long standing there was an increase in wt of about 1 mg per day, owing to corrosion of Fe.

858. Kodama, Shinjiro; Matsumura, Shoichi; Tarama, Kimio, and Yoshimori, Keisuke. **IX. Adsorption of carbon monoxide on cobalt, cobalt-kieselguhr, and cobalt-kieselguhr-thoria catalysts.** *J. Soc. Chem. Ind. Japan* 47, 1-5 (1944).—*C.A.* 43, 2413*d*.

The adsorption of CO was measured at 0°-250°C. In all cases adsorption accompanied by decompn. of CO and formation of metallic carbide took place above 110°C, and ordinary activated adsorption took place below 110°C. The addn. of kieselguhr and ThO_2 greatly increased the no. of centers of activity and promoted the formation of carbide.

859. Kodama, Shinjiro; Matsumura, Shoichi; Tarama, Kimio, and Yoshimori, Keisuke. **XII. Adsorption of carbon monoxide on iron, iron-kieselguhr, iron-kieselguhr-copper-manganese catalysts.** *J. Soc. Chem. Ind. Japan* 47, 1-5 (1944).—*C.A.* 43, 2413*e*.

Adsorption of CO at 0-300°C was measured. Formation of carbide took place above 150°C, and the addn. of kieselguhr and (Cu + Mn) greatly increased the velocity. The effectiveness of kieselguhr as carrier and promoter in gasoline synthesis was thought due to the increase in the number of active centers for H_2 and CO, the increase in the amt. of activated adsorption of H_2, and the velocity of carbide formation. The effectiveness of Cu + Mn as promoter lay in the increase in the no. of active centers for carbide formation.

860. Moreau, L. **Absorption of nitrogen into iron during dry machining.** *Métaux, corrosion, usure* 19, 53-4(Mar.-Apr.) (1944).—*C.A.* 46, 2461*e*.

N_2 was detd. in large test-pieces obtained by cutting and then rolling, in milling chips, and in fine milling powder. The temp. at the surface when test-pieces were obtained by dry-machining was sometimes above the m.p. of the metal and resulted in nitriding.

861. Nakata, Shigeo and Chitani, Toshizo. **Catalytic oxidation of carbon monoxide on the surface of silver. III. Experiment at 150-240°C.** *J. Chem. Soc. Japan* 65, 305-9(1944).—*C.A.* 41, 3354*d*.

The reaction velocity is proportional to the partial pressure of O_2 when the oxide fraction is 0-0.85. The catalyst gradually loses its activity. The activity is recovered when the catalyst is heated at 200°C in the presence of H_2.

862. Norton, F. J. and Marshall, A. L. **The degassing of metals.** *Am. Inst. Mining Met. Engr., Inst. Metals Div., Tech. Pub.* No. 1643, 10 pp. (1944).—*C.A.* 38, 1193⁶.

A comprehensive study was made of the degassing of Mo to det. how rigorous a treatment was necessary to remove completely sorbed gases from Mo electrodes in vacuum tubes. The technique, manipulation, analytical procedures, prepn. of samples, were given and the results discussed in terms of the nature of the gas, the permanence of degassing, the degassing of W and Ni, graphite, the absorption of N_2 and CO by Mo and W.

863. Rolf, Pauline. **The accommodation coefficient of He on Pt.** *Phys. Rev.* 65, 185-9 (1944).—*C.A.* 38, 2867⁷.

Detns. were made at 77°, 193°, 273°, and 373°K and the values obtained at these temps. for a clean Pt surface were 0.090, 0.043, 0.071 and 0.072 (±0.004), resp. When the Pt was allowed to remain in contact with the He for 24 hrs or more, the accommodation coeff. increased to 0.43, 0.071, 0.170 and 0.170 (in the same temp. order). Little adsorption occurred at 193°K, but strong van der Waals adsorption appeared at 77°K and activated adsorption at higher temps.

864. Takayasu, Masaaki. **Copper catalyst. I.** *J. Chem. Soc. Japan* 65, 46-9(1944).—*C.A.* 41, 3353*g*.

The amt. of residual oxygen was detd. in various kinds of Cu prepd. by the reduction of various Cu oxides at 200°, 250°, and 300°C. The results were summarized.

865. Takayasu, Masaaki. **The preparation of contact catalysts.** *J. Chem. Soc. Japan* 65, 686-90 (1944).—*C.A.* 41, 3352*h*.

When Cu wire of 1 mm diam. was heated in a current of O_2 above 500°C, a very stable layer of cupric oxide was formed on the surface of the wire. The catalyst was handy for expts.

866. Tanida, Shigeo. **Mixed catalysts. III. Adsorption of hydrogen, benzene, and cyclohexane by nickel-molybdenum catalyst.** *Bull. Chem. Soc. Japan* 19, 8-17 (1944).—*C.A.* 41, 4368*g*.

The adsorption of H_2, C_6H_6 and cyclohexane on a Ni catalyst promoted by Mo was measured between 0° and 300°C under atm. pressure. The adsorption of H_2 was a max. when the atomic ratio of Mo to Ni was 15:100.

867. YAMADA, NOBORU AND CHITANI, TOSHIZO. **Catalytic oxidation of carbon monoxide on the surface of silver. II. Experiment at 250-300°C.** *J. Chem. Soc. Japan* **65**, 224-7(1944).—*C.A.* **41**, 3354*c*.

When the concn. of CO in the mixt. is greater than 30%, the reaction velocity becomes proportional to the 0.8-0.9th power of the partial pressure of O_2. It is suggested that CO and O_2 are separately adsorbed on the surface of Ag and that the reaction takes place at the boundary.

868. BANGHAM, D. H. **Initial stages of the reaction between copper and oxygen.** *J. Sci. Instruments* **22**, 230-1 (1945).—*C.A.* **40**, 1725^2.

"Clean" electrolytic Cu foil was mounted in a glass bulb which could be jacketed at any desired temp. To maintain the pressure of O_2 sensibly const., however, a jacketed gas buret was provided into which Hg was admitted equal in vol. to the O_2 fixed. In expts. at sufficiently low temps. and pressure, the parabolic time-law was no longer valid and the uptake of O_2 followed a sigmoid course. The delay in the start of the reaction resulted from the difficulty of forming the nuclei of a new phase; the Cu_2O phase spread laterally across the surface after starting from point nuceli.

869. BROWN, HIRAM. **Degassing and pouring aluminum.** *Modern Metals* **1**, No. 2, 12-17(1945).—*C.A.* **39**, 2473^2.

Some alloys, such as the Al-Zn-Mg type and the Al-Si alloys without Cu, have much less tendency toward gas absorption than have other common alloys and can be poured without degassing. Other alloys may pick up H_2 during meltings; this results in pinhole porosity and lowered ductility, fatigue resistance, corrosion resistance, etc. The use of Cl_2 or N_2 for degassing is discussed in detail. Degassing should be effected at 685-740°C and the metal should be raised to pouring temps. when degassing is complete.

870. CAPDECOMME, L. **Surface orientation in the phenomena of corrosion.** *Comm. tech. etats et properties surface metaux, Journess etats surface* **Oct. 1945** 247-50.—*C.A.* **42**, 8765*c*.

Anodically polished Cd oxidized at different rates depending upon the orientation of the crystal face at the surface. The rates of oxidation in decreasing order were (1010), (1013), and (0001). The surface film (probably FeS) formed on a crystal of FeS_2 during mech. polishing was shown by optical means to continue the orientation of the substrata.

871. GWATHMEY, A. T.; LEIDHEISER, H. JR., AND SMITH, S. P. **The chemical action of oils on single crystals of metals.** *Natl. Advisory Comm. Aeronautics, Tech. Note* No. **982**, 52 pp. (1945).—*C.A.* **40**, 7582^2.

The chem. action of lubricant components on large single crystals of metals was studied over a range of temps. in the presence of H_2, N_2, O_2, and air. Ag, Cu, Pb, Fe, Zn, and Ni were tested. Surface reactions were easily detected on the electrolytically polished spheres used, which were machined from the single crystals of the metals. The rates of all surface reactions tested, including oxidation, etching, C formation, rearrangements due to gaseous catalysis, crystal growth, and electrolytic reactions, varied considerably with crystal plane.

872. JURA, GEORGE; LOESER, E. H.; BASFORD, P. R., AND HARKINS, WM. D. **A first-order change which involves the vaporization in two dimensions of heptane on the surface of silver.** *J. Chem. Phys.* **13**, 535-6 (1945).—*C.A.* **40**, 511^8.

A reversible 1st-order vaporization-condensation of n-C_7H_{16} was found on Ag. An adsorption isotherm at 14.90°C showed a 1st-order transition at 0.019 mm Hg. A pressure-mol. area isotherm at 14.90° and 25.00°C showed that the crit. temp. lay between these temps. The crit. area was between 310 and 2200 A^2., and the crit. pressure was >0.18 dyne per cm. Other 1st-order changes of this type include water on graphite, triptane on Ag, N_2 on a fluid cracking catalyst, and n-C_7H_{16} on Fe_2O_3.

873. KAMEYAMA, NAOTO. **Sorption equilibrium of moisture on cuprous oxide.** *J. Soc. Chem. Ind. Japan* **48**, 59 (1945).—*C.A.* **42**, 6199*a*.

Sorption equil. of moisture on Cu_2O was studied. The following exptl. relationship was obtained: $\log p = -(4855/4.57)\ (1/T) + 4.15$. The reaction corresponded to the following equation: $(Cu_2O)_m + H_2O\ (vapor) = (Cu_2O)_m.H_2O + 4.86$ kcal.

874. KAMEYAMA, NAOTO. **Sorption equilibrium of moisture on a graphite brush.** *J. Soc. Chem. Ind. Japan* **48**, 61(1945).—*C.A.* **42**, 6199*b*.

An expt. was made to det. whether moisture in the atm. is adsorbed by Cu_2O on the surface of a Cu commutator or by the graphite brush. Cu_2O had a greater hygroscopicity than the graphite brush.

875. KAMEYAMA, NAOTO. **Sorption equilibrium of moisture on cuprous oxide and the coefficient of friction of the surface of a commutator.** *J. Soc. Chem Ind. Japan* **48**, 64(1945).—*C.A.* **42**, 6199*d*.

The coeff. of friction between commutator and brush varied because of the adsorption or desorption of moisture from the atm. by the layer of Cu_2O on the surface of the Cu.

876. MARSH, J. S. **Slag-metal relations in the basic open-hearth and electric processes.** *Trans. Am. Inst. Mining Met. Engrs.* **162**, 672-84 (1945).—*C.A.* **40**, 7111^4.

It is shown graphically that the slag-metal-O_2 relations applicable to the basic open-hearth also apply to the oxidizing period of the basic elec. furnace.

877. McINTYRE, J. B. **Copper castings. Effect of gas absorption on foundry practice.** *Metal Ind. (London)* **66**, 178-9(1945).—*C.A.* **39**, 2473^3.

The belief that unsoundness in Cu castings is due to O_2 has been found to be incorrect for the amts. usually encountered (0.03 to 0.10%). If electrolytic cathode Cu is used, it should be melted and ingotted, then remelted, and presolidified to remove occluded H_2. Recommended melting practice includes the charging of as much as possible of the wt involved, rapid melting, and avoidance of undue exposure to flame action.

878. Nietzsche, Eugene. **The origin of microcavities.** *Light Metal Age* 4, No. 1, 12-13,31 (1945); *Giesserei* **31**, 43-7(1944).—*C.A.* **40**, 3084⁹.

Some of the lesser-known ways are given in which H_2 and other gases, which cause cavities and porosity, can be detected in the light-metal foundry. Methods of preventing and eliminating these causes of porosity are discussed.

879. Riddle, L. E. **Effect of moisture additions to the air delivered to blast furnaces.** *Blast Furnace Steel Plant* **33**, 965-70 (1945).—*C.A.* **39**, 4823³.

A decrease resulted in Fe production of approx. 0.5% per grain of H_2O added, and an increase in coke rate of approx. 1.2% per grain of H_2O added. Negligible difference in blast-furnace regularity and flue-dust production and no significant difference in Fe quality resulted. Controlled H_2O addns. cannot be justified from an economic standpoint.

880. Washburn, T. S. **Deoxidation of basic open-hearth steel.** *Trans. Am. Inst. Mining Met. Engrs.* **162**, 658-71 (1945).—*C.A.* **40**, 7110⁴.

Some of the considerations that det. the selection of any specific deoxidation practice are reviewed.

881. Amdur, I. **Pressure dependence of accommodation coefficients.** *J. Chem. Phys.* **14**, 339-42 (1946).—*C.A.* **40**, 4274⁸.

It was assumed that the accommodation coeff. varied linearly with the fraction of the surface covered by the adsorbed gas and that the accommodation coeff. had a negligibly small value on a gas-free surface and an asymptotic value on a satd. surface. The assumptions lead to an accommodation coeff. isotherm that reproduced the pressure dependence of 119 accommodation coeff. values for He, Ne, A, Kr, Xe, H, D, N, Co, and O on Pt with an av. abs. deviation of 1.5%.

882. Armbruster, Marion H. **The sorption of water vapor at low pressure on the surface of some cold-rolled steels at 20°C.** *J. Am. Chem. Soc.* **68**, 1342-7(1946).—*C.A.* **40**, 5976¹.

The sorption up to 0.15 cm Hg was measured on two surfaces of cold-rolled, mild carbon steel and on a stainless alloy contg. 18% Cr and 8% Ni. At the highest pressures the steels sorbed a complete layer held physically and a partial layer by chemisorption. The stainless alloy adsorbed 3-4 times as much as the steel and of this amt. 1/3 was chemisorbed. The effective surface area of the two steels was significantly different. About 90% of the total sorption occurred within 3 to 4 hrs,. the remainder in an addnl. 15 hrs.

883. Armbruster, Marion H. and Austin, J. B. **The adsorption of oxygen at low temperature and pressure on smooth iron.** *J. Am. Chem. Soc.* **68**, 1347-54 (1946).—*C.A.* **40**, 5976⁴.

The sorption of O_2 on 3 smooth surfaces of cold-rolled steel was measured at 20°, -78°, and -183°C and at pressures up to 0.1 cm. At -183°C the unreduced surface sorbed a monolayer of O_2 physically, also a small amt. held so strongly that it could not be pumped off at temp.; the amt. of this strongly held O_2 was about that of A, N_2, or CO likewise strongly sorbed. The reduced surface (with H_2) at -183°C chemisorbed O_2 equiv. to a film several mols. thick, but there was evidence that this O_2 penetrated the surface; it also sorbed a monolayer of O_2 physically. At -78°C the O_2 chemisorbed on the unreduced surface was equiv. to less than half a monolayer. At 20°C both unreduced and reduced surfaces chemisorbed an amt. almost twice that sorbed at -78°C. The isotherms deviated from the Langmuir equation at the lowest pressures, but were there represented accurately by the Freundlich relation, the exponent ranging from 3 to 5. The heat of adsorption of O_2 physically sorbed on the unreduced surfaces was about 3.5 kg-cal, in agreement with about 4 kg-cal for O_2 physically sorbed on Fe catalysts as detd. calorimetrically.

884. Bardeen, J.; Brattain, W. H., and Shockley, W. **Investigation of oxidation of copper by use of radio-active-Cu tracer.** *J. Chem. Phys.* **14**, 714-21 (1946).—*C.A.* **41**, 2295*g*.

A very thin layer of Rd-Cu was electrolytically deposited on a Cu blank. The surface was then oxidized in air at 1000°C for 18 min. to give an oxide layer 0.0125 cm thick. After quenching, successive layers of the oxide were removed chemically, and the Cu activity in each layer was measured. The observed self-diffusion of Rd-Cu in the oxide agreed quantitatively with a theory based on the assumptions: (a) The oxide grew by diffusion of vacant Cu^+ sites from the outer surface of the oxide inward to the metal. (b) The concn. of vacant sites at the O-oxide interface was independent of the oxide thickness, and dropped linearly from this const. value to zero at the metal boundary. (c) Accompanying the inward flow of vacant sites, there was a flow of pos. electron holes such as to maintain elec. neutrality. (d) Self-diffusion of Cu ions took place only by motion into vacant sites.

885. Beiler, S. Ya.; Rebinder, P. A., and Gol'denberg, N. L. **Condensation of water vapor on hydrophobized cooling surfaces.** *Bull. acad. sci. U.R.S.S., Classe sci. tech.* **1946**, 1491-5 (in Russian).—*C.A.* **41**, 2626*b*.

Adsorptive hydrophobization of the metallic cooling surface in steam turbines might substantially improve the exchange of heat. Effective and stable hydrophobization could be obtained with chemisorbed substances of the type of flotation collectors. Expts. were made with an app. of 4 Cu tubes 180 mm long, 25 mm in diam., wall thickness 1 mm, with electrically heated outer glass jackets for the water vapor, 9 thermocouples at various levels, stationary water circulation. Emulsol of spindle oil and naphthene soap, and mercaptobenzothiazole proved to be the best hydrophobizing agents. K amylxanthate was of medium efficiency (t = 75 hrs); turbine oil was weak (10 hrs). On brass, spontaneous emulsions of mineral oils with acid soaps gave effects lasting 100 hrs.

886. Bénard, Jacques and Coquelle, Odile. **Recent micrographic investigations of the high-temperature oxidation of iron.** *Compt. rend.* **222**, 796-7 (1946).—*C.A.* **40**, 4011⁷.

Polished sections of Fe oxidized at 900°C showed, outermost, a very thin layer of Fe_2O_3, then a thicker continuous layer of Fe_3O_4, then a still thicker region of Fe_3O_4 dispersed in FeO, gradually fading into pure FeO. The regions contg. FeO comprised 9/10 of the thickness of the oxide layer. On Fe oxidized above 900°C, the Fe_2O_3 and Fe_3O_4 layers became thicker at the expense of the FeO layer. Below 710°C, the Fe_3O_4 layer grew at the expense of the FeO layer. Both phenomena were explained by a decrease in diffusion of Fe atoms into the FeO layer.

887. Bénard, Jacques and Coquelle, Odile. **Kinetic study of the formation of oxides on iron surfaces at high temperatures.** *Compt. rend.* 222, 884-5 (1946).—*C.A.* 40, 5985^2.

The rate of development of Fe_2O_3 layer on fresh Fe surface is linear at 900°, 950°, and 1000°C as measured micrographically by the thickness of the layer formed. The rate for Fe_3O_4 is linear at 700°, 800°, and 900°C, but diminishes as time progresses at 950°C. The rate of production of FeO is parabolic at 650°, 700°, 800°, 900°, and 950°C. Two factors are involved—the diffusion of reactants across the oxide layer, and the rate of interaction of the reactants.

888. Bénard, J. and Coquelle, Odile. **Oxidation of iron at high temperatures determined metallographically.** *Rev. met.* 43, 113-24 (1946).—*C.A.* 41, 3418*b*.

Oxidic film produced on heating iron was a result of Fe diffusion outwards and of O_2 inwards into the metal. These rates of diffusion, which varied with temp., specified the character of the scale. The formation of the scale as a whole followed a parabolic function. Individual constituents of it formed according to other curves, Fe_2O_3 and Fe_3O_4 following a straight line and FeO following a parabolic function. The influence of temp. on total scaling up to 900°C can be presented by the well-known exponential equation.

889. Bosworth, R. C. L. **Contact potential difference as a tool in the study of adsorption.** *J. Proc. Roy. Soc. N. S. Wales* 79, 53-62 (1946).—*C.A.* 40, 4932^1.

The contact potential of a metal catalyst as a function of the amt. and nature of gas chemisorbed is described. For O_2 on W it is shown that the condensation coeff. is 0.4 and that the dipole moment of the adsorbed O_2 is nearly independent of the fraction of the surface covered, being -0.78 Debye units for slight covering and -0.66 for a monolayer.

890. Bosworth, R. C. L. **Properties of films of nitrogen on tungsten.** *J. Proc. Roy. Soc. N. S. Wales* 79, 166-71 (1946) (Reprint).—*C.A.* 41 897^i.

The contact potential method is used to study properties of adsorbed films of N_2 on W. If 1 N atom occupies the same space as 3 H atoms, the condensation coeff. is 1 in 100. The heat of desorption is calcd. as a function of the fraction of the surface covered, with data obtained between 740° and 1180°K, where the N_2 film is shown to be mobile.

891. Bosworth, R. C. L. **Evaporation of oxygen from a tungsten surface.** *J. Proc. Roy. Soc. N. S. Wales* 79, 190-5 (1946) (Reprint).—*C.A.* 41, 898^a.

The heat of evapn. of O_2 from W was calcd. from measurements of the contact potential of a W surface, covered with an oxide film and heated between 1270° and 1930°K. The surface spreading forces were derived, amounting to 2880 dynes per cm for a complete film. The surface structure for a surface concn. of $\theta = 1.0$ should be that of a peroxide, changing to a surface oxide for $\theta = 0.5$. Under the conditions studied, O_2 evapd. from the surface and not atoms.

892. Burshtein, R.; Shumilova, N., and Gol'bert, K. **Adsorption of oxygen on iron and the effect of adsorbed oxygen on the properties of iron electrodes.** *J. Phys. Chem. (U.S.S.R.)* 20, 789-801 (1946) (In Russian); *Acta Physicochim. U.S.S.R.* 21, 785-802 (1946).—*C.A.* 41, 2298d; 6454*b*.

Fe (band, wire, or powder) prepd. by reduction with H_2 of $Fe(NO_3)_3$ or $Fe(CO)_5$ was heated in H_2 and degassed at 500-850°C. When O_2 in small amts. was admitted to this Fe at 20°C, the rate of adsorption was high (0.12 cc./min.) until the adsorbed vol. reached the value V; after this the rate rapidly decreased. For smooth Fe, V was 0.023 cc. per 100 cm^2 (geometric surface area). For Fe powder $V = 0.045$ cc. per g. One g of this powder adsorbed 0.015 cc. of N_2 in conditions corresponding to unimol. adsorption. The volume adsorbed slightly increased from -183° to -138°C, remained const. until -73°C, and rapidly increased at higher temps. At 200°C it was 2.4 cc. per g of Fe. Pure, fully reduced Fe was not pyrophoric and readily sintered at 550-560°C. Admixt. of O_2 or S raised the sintering temp. and made Fe pyrophoric.

893. Cabanes, Ch. **Mechanism of corrosion of iron by water as a function of pH. Role of dissolved oxygen. Degasification by heat, vacuum, or chemical means.** *Chaleur et ind.* 27, 261-70 (1946).—*C.A.* 41, 1194^e.

It may be necessary to remove the last traces of dissolved O_2 by chem. means, but the detn. of small quantities of dissolved O_2 is difficult. With such low O-contents, the pH of the H_2O may be of importance, as a suitably alk. H_2O may be less corrosive than distd. water with the content of dissolved O_2. Air leakage into the condenser, etc., may play a more important role in accounting for dissolved O_2 in boiler H_2O.

894. Davis, Raymond T., Jr. **The activated adsorption of nitrogen on a finely divided tungsten powder.** *J. Am. Chem. Soc.* 68, 1395-1402 (1946).—*C.A.* 40, 5975^8.

The adsorption was detd. over the range 10^{-6} to 35 mm Hg and between 400° and 750°C. The adsorption isotherms on a log-log plot consisted of a curved portion in the low-covering region and of straight lines in the high-covering range. At satn. one mol. of N_2 was adsorbed for every 4 W atoms. The heat of adsorption was const. at about

75.0 kg-cal/mole in the low-covering range and decreased according to the relation $Q = 139.0 \log s/A$ kg-cal/mole in the higher-covering range. The activation energy involved in the adsorption was approx. 10.0 to 25.0 kg-cal/mole and varied with the surface covered.

895. FINE, LESLIE AND MAAK, CHARLES H. **Some observations on the effect of oxygen on carbon in steel.** *Welding J. (N. Y.)* 25, 283s-7s (1946).—*C.A.* 40, 4013^{2}.

Metallographic examn. was made of an $O_2—C_2H_2$ pressure weld deliberately prepd. with a large amt. of dissolved-O_2 along the plane of the weld. The hardness at the weld plane was lowered, which caused "auto-decarburization" (the transport of C from one internal region to another). The consequent lowering in C-content caused the reduction in hardness.

896. GARNER, W. E. AND STONE, F. S. **Activation of metallic copper by oxidation and reduction.** *Nature* 158, 909(1946).—*C.A.* 41, 1920^{g}.

Activation of Cu by repeated oxidation and reduction is due to an increase in surface area, as shown by measurements of the interference color during oxidation. Reduction of CuO films by H_2 at 300°C is not simply a reversal of the oxidation process, but during the reduction oxide particles are enclosed within the metal being formed. After reduction by CO, the metallic film formed is much more compact, so that on repeated oxidation, an oxide film is formed which is more perfect than in the case where H_2 is used as the reducing agent. A second reduction by CO following oxidation is very slow and erratic.

897. GEL'D, P. V. AND ESIN, O. A. **The mechanism of the corrosion of iron by sulfur.** *J. Applied Chem. (U.S.S.R.)* 19, 678-83 (1946) (in Russian).—*C.A.* 41, 4430*a*.

A parallel is drawn between the corrosion of Fe by S and the oxidation by gases (O_2, CO_2, H_2O). The inner layer of the sulfide scale is assumed to be close to pyrrhotite, the outer layer to pyrite; the essential role in the corrosion mechanism is ascribed to solid solns. of S in troilite, the hexagonal lattice of which exhibited a hole structure, corresponding to missing Fe atoms. In corrosion, Fe ions diffuse in the direction from the innermost layer where the "hole concn." is lowest towards the zone of higher hole concn. facing the pyrite layer; the "satd. soln. of holes" corresponds to $FeS_{1.12}$ (at 650°) to $FeS_{1.06}$ (at 1100°). The sulfide layer grows in thickness in both directions.

898. GHOSH, J. C.; SASTRI, M. V. C., AND KINI, K. A. **Adsorption of hydrogen and carbon monoxide and their mixtures on Fischer-Tropsch catalysts. I.** *Current Sci.* 15, 282-3(1946).—*C.A.* 41, 1907^{c}.

The adsorption of H_2 and CO as pure gases and as mixts. was studied up to 178°C on a catalyst whose compn. was: Co 34.2, Cu 4.08, ThO_2 2.33, Ce_2O_3 0.24%, on kieselguhr. In mixts. the presence of one gas promoted the adsorption of the other even at temps. considerably below those where the velocity of reaction became perceptible. The increase of adsorption with H_2 was conspicuous even at 25°C.

899. GHOSH, J. C.; SASTRI, M. V. C., AND KINI, K. A. **Adsorption of hydrogen and carbon monoxide and their mixtures on Fisher-Tropsch catalysts. II.** *Current Sci.* 15, 283 (1946).—*C.A.* 41, 1907*d*.

The logs of the rates of adsorption at const. pressure versus the logs of the corresponding vols. adsorbed gave straight lines which were parallel for different pressures at a given temp. The results suggested $u = k\ P/V^{n}$ as the empirical relation, where u = rate of adsorption in cc/min., P = pressure, V = vol. adsorbed, and n and k consts.

900. GRILLY, EDWARD R.; TAYLOR, WM. J., AND JOHNSTON, HERRICK L. **Accommodation coefficients for heat conduction between gas and bright platinum, for nine gases between 80°K (or their boiling points) and 380°K.** *J. Chem. Phys.* 14, 435-40(1946).—*C.A.* 40, 5316^{3}.

Accommodation coeffs. were calcd. for air, O_2, NO, CO, CO_2, N_2O, CH_4, H_2, and He from thermal-cond. data at frequent intervals (80-380°K). The coeff. for H_2 approached 1, but for other gases it dropped steeply below room temp. The accommodation coeffs. that were derived from 1/K vs. 1/P plots differed slightly from Knudsen accommodation coeffs.

901. HALLOWES, A. P. C. AND VOCE, E. **Attack of various atmospheres on copper and some copper alloys at elevated temperatures.** *Metallurgia* 34, 95-100, 119-22 (1946).—*C.A.* 40, 6391^{4}.

Eighteen metals were tested at 400°C [3 high-concd. and 2 arsenical Cu, 6 Al bronzes (2-12% Al), a group of alloys contg. small amts. of common elements added individually to Cu, and several industrial high-temp. alloys]. Except Ag, all addns. to Cu produced an improvement in its resistance to dry air. Si conferred protection, but the Al bronzes were the most resistant materials. Introduction of 10% H_2O vapor into the air stream made little difference to the scaling rates, but some of the materials showed a slightly decreased attack. The attack upon the Sn bronzes, however, was increased. Approx. 0.1% SO_2 in the air generally increased the attack. The most resistant materials were the Al bronzes contg. 5% or more Al and Everdur.

902. ITTERBEEK, A. VAN AND GREVE, L. DE. **Measurements on thin nickel films.** *Physica* 11, 470-4 (1946) (in French).—*C.A.* 40, 6923^{2}.

Ni films 30 to 700 mμ thick were formed on glass by cathodic sputtering. The elec. resistance was measured at various temps. between 37°K and 650°K before and after standing at the temp. for 24 hrs.

903. JONES, F. LLEWELLYN. **Electric properties of tungsten oxide films.** *Nature* 157, 371-2 (1946).—*C.A.* 40, 3679^{1}.

When the surface was covered with thin oxide layers or dust particles, strong electron currents occurred with fields as low as 100,000 v./cm. The time lag of sparking was inversely proportional to the intensity of cold-cathode emission. With W, the most effective film was a mixt. of the yellow and blue oxides, which together appeared as a white deposit. With the oxidized and a clean electrode, in air and N_2 at atm. pressure, the spark time-lag was low only when the clean electrode was the anode.

904. KEMBALL, C. AND RIDEAL, E. K. **The adsorption of vapors on mercury. I. Nonpolar substances.** *Proc. Roy. Soc. (London)* **A187**, 53-73 (1946).—*C.A.* 41, 1523^{a}.

Reversible results for the adsorption of benzene, toluene, and heptane vapors on Hg were obtained. The films were found to be gaseous and obeyed the equation $F(A-b)=kT$, where F = spreading pressure, A = area per mol., and b = co-area. The possibility that the films might be immobile was considered and the Langmuir equation was applied but found unsatisfactory. A standard state for the surface phase was defined and the free energy, total energy, and entropy of adsorption were evaluated. The heat of adsorption increased with the amt. on the surface. A no. of phase changes were found to occur after the completion of monolayer adsorption, the most striking being interpreted as the changeover from flat to vertical adsorption of the toluene.

905. KEMBALL, C. **II. The entropy and heat of adsorption of nonpolar substances.** *Proc. Roy. Soc. (London)* **A187**, 73-87 (1946).—*C.A.* 41, 1523^{e}.

By denying all rotations of benzene on Hg except in the plane of the ring and denying the 3rd degree of translational freedom, the calcd. entropy of adsorption agreed closely with the exptl. value. The surface mobility of toluene was found to be considerably hindered, and the entropy of adsorption of heptane confirmed the view that the mols. were partially rolled up. An attempt was made to derive the theoretical heat of adsorption of benzene from various relations for the attractive and repulsive potentials for the van der Waals forces near a metal surface. The values obtained were of the same magnitude as the exptl. value. The calcns. for the adsorption of benzene were sufficient to indicate that the values for the heats of adsorption of the nonpolar substances adsorbed on Hg were due to the van der Waals dispersive forces.

906. KHVATOV, A. D. **Changes of catalyst in poisoning.** *J. Gen. Chem. (U.S.S.R.)* **16**, 407-14 (1946).—*C.A.* 41, 904^{f}.

In poisoning a Ni catalyst by CO, there occurred not only an intensive topochem. change of the surface but also the change of structure of the components of the catalyst which changed the basic course of the reaction. Ni was apparently the detg. factor in the changes of the other catalyst components. The greatest drop of activity corresponded to the greatest change of disperse nature of the catalyst and a min. amt. of removed metal. The control reaction was the dehydrogenation of cyclohexane.

907. KONIG, HANS. **The lattice constants of films of aluminum formed from the vaporized metal.** *Naturwissenchaften* 33, 367-8 (1946).—*C.A.* 43, 5653c.

Ag and Cu films produced by vaporization and condensation gave values of lattice consts. in agreement with X-ray. Similarly produced films of Al, however, frequently gave lower values, 4.025 and 4.030 A. instead of 4.041 A. The lower value was due to the water vaporizing along with the metal, which reduced the lattice const. It was known that water was sol. in the Al lattice up to 3%.

908. LEHOVEC, KURT. **Thallium diffusion in crystalline hexagonal selenium.** *Z. Naturforsch.* **1**, 508-11(1946).—*C.A.* 41, 4988c.

Tl diffused in the cryst. hexagonal Se with considerable speed in the region of the Se m.p. Tl ions migrate. The diffusion could be observed spectroscopically, but more conveniently, however, by following the change in cond. No other metals with similar properties had been found.

909. MÜLLER, HERMANN. **The protective inactivation of pyrophoric substances.** *Z. Naturforsch.* **1**, 324 (1946).--*C.A.* 41, 5355*i*.

Pyrophoric substances could be made inactive by opening the container under a substance such as acetylcellulose in acetone, 96% EtOH, and in the case of pyrophoric Co, by hydrocarbons. On evapn. of the solvent the pyrophor was protected against spontaneous ignition. This was attributed to a layer of surface oxidation which took place during the slow evapn. of the solvent.

910. SAYAMA, YOSHIHIRO. **Vapor pressure of the cesium oxide photocathode.** *J. Phys. Soc. Japan* **1**, 13-17 (1946).—*C.A.* 43, 7767*f*.

The photosensitive Cs_2O layer was formed on a Ag base by reducing Ag_2O with Cs vapor. Deposition of metallic Cs on the Cs_2O surface caused a decrease in photoelec. and thermionic emission and a sudden increase in vapor pressure when $Cs/O=2$. When $Cs/O<2$, the Cs atoms were oxidized rapidly and the vapor pressure was very low.

911. SCHWAB, GEORGE-MARIA. **Metal electrons and catalysis.** *Trans. Faraday Soc.* 42, 689-97 (1946).—*C.A.* 41, 1921*b*.

The measurement of reproducible and reliable temp. coeffs. of HCOOH dehydrogenation with alloy catalysts was described. It was applied to homogeneous and heterogenous alloys of Ag, Au, and Cu with other metals. All the described results can be expressed in terms of the wave-mech. theory of the Hume-Rothery phases by a dependence of the activation energy on the degree of electron satn. of the first Brillouin zone of the metal. This led to the concept that catalytic activation consisted in a transition of electrons from the substrate to the metallic catalyst.

912. TIAPKINA, V. V. AND DANKOV, P. D. **Structure of primary films of oxide and bromide on silver.** *Compt. rend. acad. sci. U.R.S.S.* **54**, 415-18(1946) (in English).—*C.A.* 41, 4348*b*.

A Ag_2O film, prepd. by treating Ag on the anode of a gas-discharge tube, had a cuprite-type structure with $a=4.69$A., the same as massive Ag_2O. The x-ray diffraction pattern, however, was weak and strongly fogged owing to the deformation of the crystal lattice, which was more than 12% for Ag-Ag_2O. AgBr film, obtained by immersing Ag in Br_2, had a NaCl structure with $a=5.74$A., similar to massive AgBr. The diffraction pattern was sharp.

913. TWIGG, G. H. **Chemisorption of oxygen and its effect on the electrical resistance of a silver catalyst.** *Trans. Faraday Soc.* **42**, 657-63(1946).--*C.A.* 41, 1920^{1}.

The elec. resistance of a tightly packed Ag-plated glass-wool catalyst increased when O_2 was admitted to the previously cleaned catalyst at 240°-360°C. It decreased to a const. value when the O_2 was pumped out or was removed by chem. reaction with ethylene. The adsorption of O_2 caused an irreversible increase in resistance, but H_2O and CO_2 produced no effect. The relation between the quantity of O_2 adsorbed and the percentage change in resistance was used to study the rates of adsorption and desorption and the adsorption isotherm of O_2 on the Ag.

914. YARNOLD, G. D. **The hysteresis of the angle of contact of mercury.** *Proc. Phys. Soc. (London)* **58**, 120-5 (1946).—*C.A.* **40**, 3953³.

The method involved measurement of the force exerted by a rising or falling Hg surface on a partly immersed suspended sphere. Data were given for spheres of glass and steel, having various radii. The approx. constancy of the receding angle, together with the remarkable adhesion of the Hg to the solid surface, suggested that a solid-liquid interface of more or less const. energy was formed in all cases. On the other hand, the wide variation in the advancing angle suggested that the irreversible work involved in the destruction of the solid-air interface and its replacement by the solid-liquid interface may be extremely variable.

915. ALEXANDER, LEROY; MURRAY, W. M., AND ASHLEY, S. E. Q. **Determination of oxygen in steel by the vacuum-fusion method.** *Analyst* **19**, 417-22 (1947).—*C.A.* **41**, 5053*c*.

Special precautions are taken to avoid surface contamination and superficial oxidation during the prepn. of the sample. The gases evolved by heating in a graphite crucible in a low vacuum are collected, analyzed by conventional methods of gas analysis, and the O calcd. from the quantity of CO formed. A complete analysis requires about 1.5 hrs. Data obtained in the analysis of 354 steel samples give value between 0.003 and 0.1% of a 2-g sample.

916. BASTIEN, PAUL; MISCHONSNIKY, SIMON, AND SENNEVILLE, CHANTEL DE. **The phenomena of adsorption and desorption produced on the surface of iron after etching with acid or after electrolytic etching.** *Compt. rend.* **224**, 126-7 (1947).—*C.A.* **41**, 4351*c*.

Steel wire (2 mm diam.) made from 0.06% C Martin basic steel annealed at 950°C, was charged with H_2 by etching for 48 hrs in 10% HCl, or by cathodic attack in the same medium at a c.d. of 5.25 ma. per sq. cm. for the same period. Samples then exposed to the air after drying, increased in wt rapidly during the first few hrs, then more slowly. In vacuum no such increase was found. In 100 hrs exposure to air after etching, a 100 g sample adsorbed 65.1 cc. N_2 and 17.1 cc. O_2. To study the gases released on desorption a 100 g sample was etched 72 hrs, dried, exposed to the air 2 hrs, then immersed in Hg for 72 hrs. The gas evolved amounted to 39.5 cc. and analyzed 94.7 H_2, 0.3 O_2, and 5.0% N_2.

917. BÉNARD, J. **The mechanism of the surface oxidation of iron at high temperatures.** *J. chim. phys.* **44**, 266-8(1947).—*C.A.* **42**, 5748*d*.

Microscopic and x-ray examn. of Fe pellets heated in O_2 for the same time at different temps. show that below 910° FeO predominates, but above 910°, the proportions of Fe_3O_4 and of Fe_2O_3 increase rapidly. This change is related to the phase change occurring in Fe at 910°C. Curves for the isothermal increase in thickness of the various oxide films show that for thin coatings of FeO, the oxidation step is rate-controlling.

918. BÉNARD, JACQUES AND TALBOT, JEAN. **Effect of crystallite orientation on the thermal oxidation of iron and copper.** *Compt. rend.* **225**, 411-13 (1947).—*C.A.* **42**, 440*c*.

Rolling of sheets produced an increase in the oxidation rate which was proportional to the reduction of cross section for both metals. These changes were paralleled by the appearance of oriented structures. The effect of deformation was due to the anisotropy of the rate of oxidation. It seemed probable that this was caused by inequalities in the rates of diffusion of metal and O_2 through the oxide layers already formed. The oxidation-time curves started out as straight lines and continued as parabolas.

919. BROCKWAY, L. O. AND KARLE, J. **Electron-diffraction study of oleophobic films on copper, iron, and aluminum.** *J. Colloid Sci.* **2**, 277-87 (1947).—*C.A.* **41**, 4693*e*.

Metallographically polished Cu, Fe, Al, and Pt showed adsorbed mols. of actadecylamine, cerotic acid, or stearic acid in oleophobic films to have an av. tilt of 5° from the surface normal. On thin-rolled Pt whose surface had been cleaned by flaming, the mols. of oleophobic films had tilts as high as 30°. The difference was attributed to submicroscopic unevenness of the rolled Pt surface. Roughening the metal surface with emery paper did not prevent the formation of oleophobic films on Cu or Fe, but considerably more time was required for the film to form. Roughening prevented the formation of oleophobic films on Al.

920. BURWELL, ROBERT L., JR.; SMUDSKI, P. ALLEN, AND MAY, THOMAS P. **Ethylene adsorption isotherms at -183°C.** *J. Am. Chem. Soc.* **69**, 1525-9 (1947).—*C.A.* **41**, 5771*g*.

The adsorption of C_2H_4 was used to detn. surface areas on Al foil subjected to various etching and anodic treatments. Sheets of 99.5% pure Al, 28 μ thick, carefully solvent-cleaned, were subjected to one or more of six different treatments with variable time. One- to two-hundred-mesh porous glass was employed as a reference substance. Some of the isotherms were S-shaped; in some the linear portions continued to the exptl. satn. pressure. The results accorded with the hypothesis of porous structure of anodic coatings.

921. DAVIS, R. T., JR.; DEWITT, T. W., AND EMMETT, P. H. **Adsorption of gases on surfaces of powders and metal foils.** *J. Phys. & Colloid Chem.* **51**, 1232-48 (1947).—*C.A.* **42**, 1102*b*.

The adsorption isotherms for N_2, Kr, n-C_4H_{10}, 1-C_4H_8, and $CHCl_2F$ were measured at or below their b.ps. and found to be S-shaped on Ag foil, monel ribbon, glass spheres, W powder, ZnO pigments, Al_2O_3, and silica gel. Mol. cross-sectional areas to bring the calcd. surface into agreement with those obtained for N_2 (16.2 A.²) were: Kr, 20.8 A.² at -195°C; C_4H_{10}, 43.4 A.² at -78°C and 46.9 A.² at 0°C; $CHCl_2F$, 37.5 A.² at -78°C and 40.1 A.² at 0°C; and 1-C_4H_8, 42.7 A.² at 0°C. When $CHCl_2F$, n-C_4H_{10}, and Kr were used and the mol.-area calcd.

from liquid d., the surface areas of the Ag foil and monel ribbon were smaller than the geometric area by as much as 25%.

922. Dobretsov, L. N.; Starodubtsev, S. V., and Timokhina, Ya. I. **Surface ionization of thin layers of calcium and magnesium oxides.** *Compt. rend. acad. sci. U.R.S.S.* **55**, 303-6 (1947) (in English).—*C.A.* **41**, 5355*f*.

The ionization of Ca and Mg on W filaments was found to be many times greater than it should be due to coatings of the alk. earth oxides. Expts. showed that surface ionization was substantially different on oxide films than it was on pure metals.

923. Emmett, P. H. and Cines, Martin. **Surface-area measurements on metal spheres and carbon blacks.** *J. Phys. & Colloid Chem.* **51**, 1329-41 (1947).—*C.A.* **42**, 1104*h*.

A comparison of areas obtained by adsorption isotherms for N_2 at −195°C on metal powders with those calcd. from photomicrographs yields roughness factors in the range 1.1 to 1.8. Areas detd. by the adsorption of CS_2 and C_4H_{10} are 20 to 50% lower than those obtained by using N_2. Pelletizing carbon black produces no appreciable changes in its surface area per g.

924. Evans, U. R. **The mechanism of oxidation and tarnishing.** *Trans. Electrochem. Soc.* **91**, 24 pp. (1947) (Preprint).—*C.A.* **41**, 2376^{b}.

Outward migration of cations and electrons, normally by lattice defects, gives parabolic film growth, but mech. breakdowns due to compressional stresses (of which good evidence exists) may lead to other equations. Blistering should lead to rectilinear or logarithmic thickening according as the rifts in the blister walls do or do not admit O_2(s). Flaking (which is rare but catastrophic) should lead to periodical recommencement of rapid oxidation. Shear-cracking (likely if cohesion is poor and adhesion good) may produce parabolic, rectilinear, or intermediate forms. The theory is applied to explain why conditions prevailing at the time of exposure decide the corrosion-rate.

925. Faĭnshteĭn, S. M. **The mechanism of oxidation of the simplest gases by oxygen on thin silver layers.** *J. Phys. Chem. (U.S.S.R.)* **21**, 37-50 (1947).—*C.A.* **41**, 6121*c*.

Thin Ag layers produced by sublimation on glass adsorb, at −183°C and 0.01 mm Hg, about 5 mol. layers of O_2, assuming geometric areas equals real area. About 0.25-0.5 of this O_2 cannot be removed by evacuation between −183° and 300°C. After evacuation at −183°C less O_2 is adsorbed in a second and subsequent expt. Ag layers prepd. at −183°C and brought to 0°C have no adsorption capacity. Oxygen which cannot be removed by evacuating reacts with H_2 or CO at 7-40°C, the reaction being more rapid (less than 1 hr) with CO. O_2 adsorbed at −183°C loses the capacity of reacting with H_2 after heating to 200°. H_2 reacts also with O atoms on Ag crystals. Neither H_2 nor CO is adsorbed by Ag layers at −183°C.

926. Fontana, M. G. and Beck, F. H. **Nature and mechanism of passivity of 18-8S stainless steel.** *Metal Progress* **51**, 939-44 (1947).—*C.A.* **41**, 4752*b*.

Expts. with type 304 stainless steel of normal compn. from several sources of supply shows that a passivated surface becomes active after exposure to vacuum and again becomes passive by exposure to air; the action is reversible. The effect is due to a physically adsorbed layer of weakly held gas mols.

927. Gulbransen, Earl A. **The kinetics of oxide-film formation on metals and alloys.** *Trans. Electrochem. Soc.*, **91**, 31pp. (1947).—*C.A.* **41**, 4083*a*.

The fundamental factors are: (1) time; (2) temp.; (3) pressure; (4) surface prepn. and passivation treatments; (5) gas in the metal lattice; (6) surface area; (7) crystal orientation; (8) gas flow; (9) cycle oxidation; (10) vacuum effect; and (11) stability of the oxide film. Rate expts. on the metals Al, Mg, W, Mo, Fe, and 18/8 stainless steel are used to illustrate the effect of the various variables. The metals and alloys follow the parabolic rate law over a certain time and temp. range. Deviations are found for higher temps. The deviations are found to be independent of film thickness, surface prepn., and pressure. The energies of activation vary from 22,600 cal/mol. for Fe to 45,650 cal/mol. for W. The entropies of activation vary from −28.7 for 18/8 to 11.2 for W.

928. Gulbransen, Earl A. and Wysong, W. S. **Thin oxide films on aluminum.** *J. Phys. & Colloid Chem.* **51**, 1087-1103(1947).—*C.A.* **42**, 13*d*.

The oxidation of Al of various purities and degrees of polishing was followed by actual gain in wt. Al was not unique in its oxidation behavior. The oxidation followed the parabolic rate law at 350-450° and a linear law at 500-550°. Whereas O_2 pressure had little effect on the oxidation rate, the nature of the Al was important. Chem. and phys. processing treatment, as well as kind and amt. of impurities, played a part in detg. oxidation rates. The type of rate law depended only on temp., not on film thickness or other factors mentioned. Electron-diffraction patterns showed that the oxide film was amorphous.

929. Karnaukhov, M. M. and Morozov, A. N. **Kinetics of solution of nitrogen in liquid iron and in its alloys with silicon.** *Bull. acad. sci. U.R.S.S., Classe sci. tech.* **1947**, 735-47 (in Russian).—*C.A.* **42**, 1482*d*.

Absorption of N_2 by molten carbonyl Fe, outgassed to 0.001 mm Hg at a temp. regulated within 10-15°C and under low pressures, was detd. with an accuracy of 0.03 cc./100 g. The equil. soly. of N_2 in Fe was strictly proportional to $(p)^{1/2}$. The rate of soln. was greater with a smaller amt. of metal and greater relative surface. The final soly. (v) changed but little with the temp. between 1550° and 1750°C: at $p = 22$ mm Hg, $v = 7.03$ and 7.37 cc./100 g; the temp. coeff. was 0.0017 cc./degree. In Fe-Si, prepd. from carbonyl Fe and Si(SiO_2 1.46, Al 0.78, Fe 0.20), the soly. of N_2 was proportional to $(p)^{1/2}$ in all alloys (1.07-12.9% Si). N_2 was dissocd. into N and formed the nitrides Fe_xN and Si_yN, in equil. with N adsorbed at the surface [$Fe_xN \rightleftarrows x\text{Fe} + \text{N}$ and $Si_yN \rightleftarrows y\text{Si} + \text{N}$].

930. Kauki, Yrjo. **A theory of rust formation on iron.** *Trans. Chalmers Univ. Technol. Gothenburg* No. 61, 15pp. (1947).—*C.A.* **42**, 7224*c*.

The potential of Fe in O-satd. water gradually falls to a const. value, dependent on the O_2 pressure over the soln. The passive state of Fe is not dependent on this pressure, however, and is due to the formation of more or less stable compds. O_2 alone cannot lead to heavy corrosion at ordinary temps. The role of H-overvoltage in corrosion is discussed, and the effect of mech. treatment and pressure of O_2 on corrosion cells. The exact conditions for zero corrosion are difficult to calc. because of inaccurate values of the soly. product for $FeCO_3$. Fe $(OH)_2$, and $Fe(OH)_3$, the latter being the least important.

931. KEMBALL, C. **The adsorption of vapors on mercury. III. Polar substances.** *Proc. Roy. Soc. (London)* **A 190**, 117-37 (1947).--*C.A.* 42, 1476*e*.

Water, acetone, and alcs. (Me to hexyl) were adsorbed on Hg. All substances gave reversible adsorption and, except water, gaseous films were formed at low pressures. MeOH and EtOH showed the adsorption of second layer at higher pressures, the double layer having half the co-area of the original monolayer. Acetone gave rise to a double layer and finally a triple layer (with 1/3 of the original co-area). For the gaseous films of butyl, amyl, and hexyl alcs. the co-areas and the thermodynamic data indicated that the mols. were lying flat on the surface. The large entropy and heat of adsorption of water were taken as evidence of the assocn. of the adsorbed water mols., and this probably occurred, to some extent with MeOH as well. The heat of adsorption of acetone was smaller than expected for a substance with a large dipole moment. The co-areas of water and MeOH were much larger than might have been expected. Water vapor was found to be adsorbed on Hg, although not strongly at 50°C.

932. KIPERMAN, S. **Kinetics of the ammonia synthesis on ruthenium.** *Phys. Chem. (U.S.S.R.)* **21**, 1435-48 (1947).—*C.A.* 42, 5320*h*.

Mixts. of N_2 and H_2 were passed through a Ru catalyst deposited on SiO_2 gel at 552, 650, 665, 709, and 736°C. The mol. ratio H_2:N_2 was varied between 0.5 and 16, and the rate of gas flow between 19,000 and 125,000/hr. An equation for reaction rate was derived by assuming that the adsorption of H_2 is important and that there exists a particular relation between the mol. forces within the adsorbed film. The H_2 adsorption was important for understanding the value of activation energy which, on Ru, was 59,250 cal instead of 46,500 cal for other catalysts.

933. KORNILOV, I. I.; DURNOV, A. T., AND PRYAKHINA, L. I. **Rate of oxidation of quaternary alloys of iron-chromium-nickel and manganese.** *Doklady Akad. Nauk S.S.S.R.* **58**, 1665-8 (1947).—*C.A.* **46**, 3934*b*.

Oxidation rates of alloys contg. 17.3-20.5% Cr, 7.8-9.2% Ni, 16.7-2.85% Mn, and 58.2-68.5% Fe were detd. The results, indicated that at 1000°C alloys contg. Mn and Fe oxidize more rapidly than those contg. Cr or Ni. In order of rate of oxidation the series was Mn, Fe, Cr, and Ni. Most of the oxidation fell to Mn and it detns. the general rate of reaction.

934. LAKHTIN, YU. M. **The diffusion of nitrogen into iron.** *Vestnik Inzhenerov i Tekh.* **1947**, 48-55.—*C.A.* 44, 8299*a*.

In the formation of the nitrided layer, N_2 diffused most easily into the α phase of the iron, since less energy was required for the act of diffusion itself in this case. Diffusion of the N_2 into the γ phase was essentially more difficult. On the assumption of a uniform diffusion of N_2, a temp.- time relation was developed for the depth of penetration of the hexagonal ϵ phase.

935. MAMET, A. P. **The corrosion of brass under the influence of ammonia.** *Izvest. Vsesoyuz. Teplotekh. Inst. im. Felix Dzerzhinskogo* **16**, No. 10, 26-32(1947).—*C.A.* 46, 7506*b*.

The corrosion of brass by NH_3 in aq. soln. and in mixts. of water vapor, CO_2, O_2, etc. was studied. In the complete absence of O_2 there was practically no corrosion except at high concns. At very low NH_3 concns. the rate of corrosion was very slight, even in the presence of O_2. The max. attainable rate of corrosion depended exclusively on the rate of diffusion of the O_2 onto the metal surface. This max. rate was reached at about 60°C. Cooled surfaces were corroded at concns. as low as 3 mg NH_3/kg.

936. McCARTNEY, J. T. AND ANDERSON, R. B. **Crystalline aggregation of cobalt powder.** *J. Applied Phys.* 18, 902-3 (1947).—*C.A.* 42, 805*g*.

CoO was pptd. from $Co(NO_3)_2$ by NH_4OH, reduced by H_2 at 250°C, and stabilized by exposure to CO_2 at liquid-air temp. Electron micrographs were shown demonstrating the aggregation of Co metal particles into hexagonal platelets 7-25 μ in diam. The N_2 adsorption method gave 67 m^2/g for the oxide and 2 m^2/g for the metal; this indicated a sintering of the particles during reduction into large smooth droplets of metal.

937. MOTT, N. F. **Theory of the formation of protective oxide films on metals. III.** *Trans. Faraday Soc.* 43, 429-34(1947).—*C.A.* 42, 1471*d*.

It is assumed that the work function is small enough to allow the thermionic emission of electrons from the metal into the conduction levels of the oxide. If O_2 is adsorbed onto the surface of the oxide and oxide ions are formed, a strong elec. field will be set up in the oxide. The soly. of metal ions in the oxide is at the temps. considered too small for any passage of metal by diffusion. Under these very strong fields, migration of ions can take place. A theory based on these assumptions gives a limiting thickness which increases rapidly with temp. up to a certain crit. temp., which should be about 600°K for Al, above which the parabolic law should hold.

938. MOTT, N. F. **The oxidation of metals.** *J. chim. phys.* 44, 172-80(1947).—*C.A.* 42, 5317*e*.

A theory of formation of oxide films on metals in contact with air considered the solubilities and mobilities of ions and electrons from the metals in the oxide film and the resultant fields.

939. POSPEKHOV, D. A. **Oxide films on copper.** *J. Applied Chem.* **20**, 462-4(1947).—*C.A.* 42, 3302*i*.

CuO obtained by calcination of $Cu(NO_3)_2$ and reduction in H_2 at 200°C, gave nonpyrophoric Cu which, in air at room temp., underwent gradual oxidation forming violet and blue oxide films. Metallic Cu obtained from $CuCO_3$ by decompn. at

300°C, reduction in (N_2+3H_2) at 300-330°C, and cooling under the same gas, was oxidized in open air at room temp. within a few hrs to a black film. With limited access of air, dark-red, violet, and blue films were obtained which did not change any further in open air.

940. SHALER, A. J. AND WULFF, J. **Rate of sintering of copper powder.** *Phys. Rev.* **72**, 79-80 (1947).—*C.A.* **41**, 5356*e*.

Exptl. results on the sintering of uniform spherical Cu particles regularly packed and sintered in A, at 1 atm. and in a vacuum, are given. From the value of 1200 dynes/cm for the surface tension of solid Cu, the viscosity coeffs. of 2.4×10^{10} and 5×10^{9} sec/cc. at 850 and 900°C, resp., are calcd. corresponding to a heat of activation of self-diffusion of Cu of greater than 85,000 cal. In the absence of entrapped gas, the small pores disappear first, and all pores eventually disappear; with entrapped gas, the small pores shrink and the large pores expand.

941. SHIRAI, SHUNJI. **Oxidation of a thin single-crystal film of copper.** *J. Phys. Soc. Japan* **2**, 81-3 (1947).—*C.A.* **43**, 6880*f*.

The structures of pure and oxidized Cu films were studied by the transmission method of cathode-ray diffraction. A film, approx. 40 μ thick, was prepd. on the cleavage surface of NaCl at 300°C by evapn. The films were then oxidized by heating 10 min. in an elec. furnace in air between 220° and 280°C (Cu_2O), exposing to air while floating on water for several hrs (Cu_2O), and by heating at 280°C or higher in an elec. furnace for 10 min. (CuO). Films oxidized while attached to the substrate gave less perfect orientations.

942. SHVARTSMAN, L. A.; SAMARIN, A. M., AND TEMKIN, M. I. **The kinetics of consumption of carbon in a steel bath.** *J. Phys. Chem. (U.S.R.R.)* **21**, 1027-32 (1947) (in Russian).—*C.A.* **42**, 2496*d*.

About 2% electrode carbon was dissolved in Armco Fe in a large magnesite crucible, the melt heated and stirred in contact with air, and its C content detd. in samples withdrawn at intervals. If the reduction of the C-content was due to its combustion at the boundary between Fe and air, the rate of the reduction should be that of diffusion of C toward this boundary. The small temp. coeff. between 1520 and 1650°C agrees with this hypothesis. Older observations on combustion of carbon in a Bessemer hearth also agreed with the theory that the rate of combustion was detd. by phys. factors.

943. SOMERS, E. V. AND GUNTHER, D. W. **Adsorbed gases in cast iron.** *Foundry* **75**, No. 3, 66-9, 218, 220, 222, 224, 226, 228, (1947).—*C.A.* **41**, 2676*d*.

The variable amts. of dissolved O_2 and H_2 were related to changes in the phys. properties of gray-Fe castings. Cast Fe (%C plus 1/3 of the % Si) showed a higher tensile strength and a higher chill depth. A correlation of the phys. properties of the Fe with tapping temp. showed the change in chem. compn. could be attributed to oxidation of the Si and combination of oxidation and reduced soly. of the carbon. Indications are that dissolved O_2 is a carbide stabilizer. The lower chill depth, assumed to accompany a lower O_2 content, would indicate a higher H_2 content.

944. STAGER, H.; BRANDENBERGER, E., AND KOBEL, E. **The carburization of steel as reaction in the solid state.** *Schweiz. Arch. angew. Wiss. u. Tech.* **13**, 97-113 (1947).—*C.A.* **41**, 5425*f*.

Under some conditions steel may absorb carbon in the solid state. This reaction depends on the formation of primary particles. Suitable treatments at higher temps. produce secondary cryst. particles (graphitization), which change the conditions of carbon absorption.

945. STRANSKI, I. N. AND SUHRMANN, R. **Electron emission from crystalline metal surfaces and its relation to the crystal structure. I. Pure metal surfaces.** *Ann. Physik.* [6] **1**, 153-68, 169-80 (1947).—*C.A.* **43**, 6492*e*.

The relation between the emission from the faces of W crystals is discussed in relation to the crystal consts. Low surface energy goes with high work function, which explains the phenomenon in which the work function of a surface can be lowered by deposition of a partial layer of the same substance.

946. STRANSKI, I. N. AND SUHRMANN, R. **II. Single-crystal surfaces with impurity atoms.** *Ann. Physik.* [6] **1**, 153-68, 169-80 (1947).—*C.A.* **43**, 6492*e*.

Cs was first adsorbed on the 112 face of cryst. W and next on the 011 face. The covered spots spread and emission increased when the adsorbed film was thick enough, again first on the 112 face. On the 001 face of W only atoms of diams. (given in A.) 3.1, 4.5, 6.3, 8.9, etc. could form films. On the 111 face the values were 4.5, 8.9, etc.

947. TACONIS, K. W. **Properties of the liquid helium film.** *Symposium Grenslaagverschijnselen, Verhandel. Koninkl Vlaam. Acad. Wetenschap., Belg.* **1947**, 64-75 (discussion 76-7).—*C.A.* **43**, 3254*e*.

Layers of adsorbed He grow in proportion to the pressure up to thicknesses of 30 atoms. For supersurface heat transfer as well as subsurface transfer through narrow slots there is a crit. flow below which there is almost no friction.

948. TOKUMITSU, TADASHI AND OKAMOTO, HIROAKI. **Electron-diffraction study of sealing alloys for glass and metals, with special reference to Fernico.** *Proc. Phys. Soc. Japan* **2**, 76-8 (1947).—*C.A.* **44**, 10424*a*.

Oxide films covering the surface of Fe-Cr alloys, Fernico (Ni 28%, Co 15%, Cr 3%, Mn 0.65%, and Fe), and other Fe-Ni alloys are observed by means of electron diffraction. The production of lower oxides $(Cu_2O, NiCr_2O_4)$ improves the nature of metals for metal-to-glass seals and that Co atoms in Fernico produce a kind of spinel. When Fernico is oxidized in air, oxide mols. covering the surface of the metal yield strong orientation, although its nature is different according to the temp. of oxidation.

949. WELLER, SOL. **Kinetics of carbiding and hydrocarbon synthesis with cobalt Fischer-Tropsch catalysts.** *J. Am. Chem. Soc.* **69**, 2432-6(1947).—*C.A.* **42**, 1483*i*.

Rates of formation (carbiding) and hydrogenation of Co_2C and of hydrocarbon synthesis were detd. on a Co-thoria-kieselguhr catalyst by using a flowing system with observation of vol. decrease after freezing out reaction products with liquid N_2. Rapid CO consumption occurred initially diminishing to a fairly steady but much lower rate. Hydrogenation of the Co_2C proceeded at a much higher rate than formation; the diffusion of carbon through the interior was probably not the rate-detg. step for carbiding.

950. WIRTH, J. K. **Corrosion of iron under protective coatings.** *Arch. Metalkunde* **1**, 445-8 (1947).—*C.A.* **42**, 7224*b*.

Depending upon the pH value of the electrolyte, rusting might take place either below a paint layer on the Fe surface (under-coat corrosion) or on top of the coating surface (rust diffusion). Blister formation was usually assocd. with local imperfection in the coat. In addn. to the chem. compn. of the coating, its capillary properties were of great importance.

951. WYLLIE, G. **The hole theory of diffusion.** *Proc. Phys. Soc. (London)* **59**, 694-9(1947).--*C.A.* **42**, 1471*b*.

The diffusion of the solute atoms is detd. by the compd. activation energy which is the sum of the energy necessary for the formation of a hole next to a dissolved atom and the energy of activation for the hole to make one jump around that atom. It applies to cases where diffusion of a foreign metal atom in a lattice has a lower activation energy than self-diffusion in the same lattice, Au in Pb being a conspicuous example. The calcn. of the actual energies involved becomes a very difficult problem in quantum mechanics that has not yet been solved.

952. AGLIARDI, NINO AND MARELLI, SANDRO. **Activated adsorption of hydrogen and of carbon monoxide on cobalt.** *Gazz. chim. ital* **78**, 707-17(1948).—*C.A.* **43**, 3686*e*.

With "cleaved" Co, adsorption of CO was at first more rapid than that of H_2, but subsequently adsorption of CO became less than that of H_2. When the Co was poisoned with CO, the adsorption of H_2 was smaller; nevertheless the adsorption was even then more rapid than by Co not poisoned by CO. Mixts. of CO and H_2 were adsorbed more rapidly than was pure H_2. CoC_2, traces of which were formed in the surface reactions with CO, tended to stabilize the adsorbing surface, and even with successive adsorptions of H_2, the surface did not revert to its original condition.

953. ARIZUMI, TETSUYA AND NARITA, SHIN-ICHIRO. **The effect of oxygen on the oxide-coated cathode.** *J. Phys. Soc. Japan* **3**, 356-60 (1948).—*C.A.* **44**, 5696*i*.

Log of the thermionic emission current from an oxide-coated cathode was inversely proportional to the log pressure of O_2 present in the tube and directly proportional to the temp. of the cathode. If the partial pressure of the O_2 was less than 10^{-7} mm Hg, the latter relationship was linear, and the work function was equal to about 1.0 e.v.

954. ARMBRUSTER, MARION H. **The sorption of gases on a plane surface of two stainless iron-chromium-nickel alloys at 20°, -78°, and -183°C.** *J. Am. Chem. Soc.* **70**, 1734-42 (1948).—*C.A.* **42**, 5398*b*.

The surface of stainless alloy (approx. 18% Cr and 8% Ni) may differ considerably from ordinary steels. H_2, Ne, A, N_2, CO, and O_2 was sorbed at pressures up to 0.1 cm Hg. The sorption of CO_2 was detd. at -78° and -183°C. Ne and H_2 were not measurably sorbed in the range of temp. and pressure studied. A was very slightly sorbed at -183°C and could not be removed by pumping; the magnitude of the sorption was about the same as that of strongly held CO_2 at -78°. CO was the only gas that was physically adsorbed to as great an extent as a complete monolayer.

955. BARANOV, S. M. **Effect of high-silicon silicates on the properties of steel.** *Stal* **8**, 346-52 (1948).—*C.A.* 44, 512*g*.

The silicates referred to were formed when Si was added to molten steel for the purpose of deoxidation. These silicates accumulated on grain boundaries where they acted like surface-active substances during the crystn. of the melt. It was quite possible to control the quantity of surface-active components in steel by deoxidizing the molten metal with C, Al, or other deoxidizers prior to adding FeSi.

956. BARRER, R. M. **Gas-metal equilibria, interstital solutions, and diffusion.** *Discussions Faraday Soc.* **1948**, No. 4, 68-81.—*C.A.* **43**, 4917*e*.

The elements H_2, B, C, N_2, and O_2 sometimes form zeolitic solid solns. in the metals of the transition series. The kinetics and nonequil. processes for H_2 diffusion were discussed, to rate equations for phase-boundary processes and derivations of the conc. dependence of the interstitial diffision coeff.

957. BÉNARD, JACQUES AND TALBOT, JEAN. **The kinetics of the reaction of oxidation of iron in its initial phase.** *Compt. rend.* **226**, 912-14 (1948).—*C.A.* 42, 4430*d*.

The rates of oxidation of Fe specimens, 14 cm^2, were detd. at 850-1050°C. The reaction rate-time curves consisted of a portion (approx. 20 sec) during which the specimen reached thermal equil. with the furnace, a linear segment, and a parabolic segment. The transition from a linear relation to a parabolic relation occurred when the oxide was 1.3μ thick at 850°C and 7μ at 950°C. The heat of activation for the oxidation of α-Fe was calcd. to be 59,000 cal, which is very close to the heat of reaction for the oxidation of Fe to FeO, 63,000 cal. With Cu the linear segment was very short.

958. BÉNARD, JACQUES AND TALBOT, JEAN. **Influence of structure and crystalline orientation on thermal oxidation of copper and iron.** *Rev. met.* 45, 78-85(1948).—*C.A.* 42, 7687*d*.

Flat specimens of cond. Cu were deformed 25, 40, 60, and 80% by cold rolling and by tensioning, were electrolytically polished, and were heated in air at 900° ± 2°C. The oxide layer thus produced was quite adherent and was composed of a thin film of CuO adjoining the metal and columnar crystals of Cu_2O. The percentage of oxidation was detd. by weighing. Singly crystals of Cu were grown and studied for the oxidation characteristic of their crystallographic planes. Oxidation rate increased in the order (123), (100), (111), (211-110), (210-221).

959. Braunbek, Werner. **Resistance of platinum foil as a function of atmosphere.** *Z. Naturforsch.* 3a, 216-20 (1948).—*C.A.* 43, 6481*h*.

A Pt foil 2μ thick had a lower resistance in gaseous atm. than in vacuo. The difference was about 0.5% for O_2, 0.3% for A, and 0.1% for He. The differences corresponded to addnl. metal of approx. 1 monolayer thick which were explained by the setting free at the surface of conducting electrons which had been hindered in vacuo by surface potential deformations.

960. Burshtein, R. Kh. and Surova, M. D. **Effect of oxygen adsorbed on iron on the contact potential difference.** *Doklady Akad. Nauk. S.S.S.R.* **61**, 75-8(1948).—*C.A.* **42**, 8585*d*.

Thermionic current-voltage characteristics were detd. with a W cathode and a pure Fe-wire anode of 0.2 mm diam., surface area 50 cm², without and with known amts. of O_2 adsorbed on the Fe, preliminarily reduced in H_2 at 600°C and heated to 750°C. Adsorption of 2×10^{15} mols. O_2/cm^2, at 100°C, shifted the characteristic curve to higher current intensities by an amt. corresponding to a decrease of the electron-extn. work function by 0.6 v. The decrease as a function of the amt. of O_2 adsorbed passed through a max. at this point; it diminished with further increasing amt. of O_2. The curve at 150°C had a max. at about 3.6×10^{15} mols.

961. Cabrera, N. **Oxidation of aluminum at low temperatures.** *Rev. Met.* **45**, 86-92 (1948).—*C.A.* **42**, 7687*a*.

Metallic ions passed through interstitial positions in the oxide film and diffused until the air-oxide interface was reached. These ions could diffuse through the oxide by means of reticulated metallic voids called ionic openings. Free electrons passed into the cond. layer of the oxide and diffused to the air-oxide interface. In case of Al, only two described mechanisms of migration took place. They were discussed at length. A series of expts. showed that dry O_2 or O_3 did not oxidize Al in the dark, but caused the formation of an oxide layer when subjected to the action of ultraviolet light or in the presence of humidity.

962. Chaudron, Georges. **Micrographic study of the oxidation of iron and of the transformations of ferrous oxide.** *Pittsburgh Intern. Conf. on Surface Reactions* **1948**, 165-7.—*C.A.* **42**, 8133*a*.

The oxide layers formed from 650° to 1000°C had widely different structures. Under 900°C 4 consecutive crystal layers were formed: (1) crystals of FeO oriented by epitaxy on the surface crystals of Fe, (2) crystals of Fe_3O_4 pptd. in this first layer, (3) a regular layer of Fe_3O_4 crystals, and (4) an extremely thin layer of Fe_2O_3. Above 900°C one observed rapid development of magnetite the thickness of which increased rapidly.

963. Chevenard, Pierre and Wache, Xavier. **Selective surface oxidation of alloys and the effect of metallic structure on the process of thermal oxidation.** *Rev. met.* **45**, 121-8 (1948).—*C.A.* 43, 541*f*.

The effect of surface oxidation can be shown by magnetic analysis or by the use of a thermobalance. The thickness of the oxidic film produced for a 92% Ni alloy increased with time. Specimens of Ni-Al and of Ni-Cr alloys were heated to a high temp. in air, then their oxide layer was carefully removed, and cleaned specimens were heated at 1000°C for 3 hrs in vacuum, which showed that no outward diffusion of either Al or Cr took place.

964. Czerski, Lucjan. **Oxidation of copper at high temperatures and low pressures.** *Roczniki Chem.* 2, 83-92 (1948).—*C.A.* 43, 2851*a*.

The oxidation of Cu at 950°C and 20 mm O_2 occurred both at the surface of the Cu_2O layer (87%) and at the surface of the Cu (13%). The Cu_2O layer contained an excess of 0.035% Cu. The av.d. of the 1.55-mm Cu_2O layer was 6.101 ± 0.006 g/cc., whereas the d. of portions of the layer (measured from the external surface) was as follows: 0.30 mm 6.144, 0.25 mm 6.039, 0.40 mm 6.110, and 0.60 mm 6.102.

965. Dankov, P. D. and Ignatov, D. V. **Oxide films on metals. III. Electronographic investigation of oxide films produced on aluminum in gaseous discharge.** *Bull. Acad. sci. U.R.S.S., Classe sci. Chim.* **1948**, 29-39 (in Russian).—*C.A.* 42, 5294*h*.

Al surfaces (prepd. by vacuum condensation of Al vapor on polished Al foils, and by condensation on mica or NaCl and stripping by immersion in H_2O) were exposed to silent discharge in 0.5-0.8 mm Hg of O_2, under 500-600 v., 2-3 milliamp. On massive foils subjected to prolonged discharge at either the anode or the cathode, a visible oxide film formed. Thin Al films, originally translucent and appearing blue in transmitted light, became more translucent and less intensely colored after 10 min. exposure to discharge at the anode.

966. Dontsova, E. I. **Clarification of the oxidation (rusting) process of iron by means of oxygen isotopes.** *Doklady Akad. Nauk S.S.S.R.* 63, 305-6 (1948).—*C.A.* 43, 2564*f*.

Expts. using normal river water and normal air, or water enriched with H_2O^{18} with normal air, or normal water with air enriched by O^{18}, showed that the principal source of O_2 in the compn. of iron oxide (rust) is that in the water in contact with the metal. The atm. O_2 participates in rusting to the extent of about 10 % only.

967. Emmett, Paul H. **Studies of metal surfaces by low-temperature gas adsorption.** *Pittsburgh Intern. Conf. on Surface Reactions* **1948**, 82-90.—*C.A.* **42**, 8057*f*.

Theoretical and exptl. results show that by measuring the low-temp. adsorption isotherms of suitable inert gas (N_2 for example) near the b.p. of this gas, it is possible to obtain a reliable estimate of the abs. surface area of the solid being measured. The results obtained coincide with those obtained by use of the micrographs and electron microscope. Total areas ranging from 100 cm² to 2000 cm² per sample can be measured either on plane or on spherical smooth and nonporous samples. It is possible to det. the av. thickness of corrosion of the protective layer.

968. Evans, U. R. **Mechanism of the formation of films on metals.** *Pittsburgh Intern. Conf. on Surface Reactions* **1948**, 71-6.—*C.A.* 42, 8040*d*.

The growth of films on metals proceeds in four successive stages: (1) Attachment of O_2 to the surface by chemisorption with formation of a two-dimensional layer of a solid soln. (2) lateral growth during which the film (oxide) is in lateral compression. (3) Thickening of the film originating after the entire surface is covered. The thickening of the film, translated by a parabolic law, is believed to result from the outward movement of cations and electrons. (4) Periodic crack-heal growth, due to sudden cracking or blistering resulting from internal stress existing in the film. At lower temps. cracks may occur in the outer layer overlying the inner compact layer. According to the relative resistance of the two layers, the growth will obey either the parabolic or the rectilnear law.

969. FRAUENFELDER, H.; HUBER, O.; PREISWERK, P., AND STEFFEN, R. **Condensation of radioactive cadmium and silver on metallic surfaces.** *Helv. Phys. Acta* **21**, 197-8 (1948).—*C.A.* 42, 8624*c*.

Samples of Cd^{107}, made by the (p,n)-process with Ag, were deposited on a Mo wire. When heated in an evacuated space, it was found that less than 0.5% of the evapd. Cd condensed on a metallic surface placed over the wire, but nearly all of the radioactive Ag (the decay product of Cd^{107}) condensed. If the receiving surface was first plated with Ag, about 50% of the radioactive Cd also condensed.

970. GRAND, M. **Degassing aluminum alloys. Experiments with chlorine and hexachlorethane.** *Metal Ind. (London)* 72, 29-30(1948).—*C.A.* 42, 2215*c*.

Cl_2 constitutes an excellent degassing agent, but is limited because of its toxicity. C_2Cl_6, a solid, suffers partial decompn. to C_2Cl_4 and Cl_2 at 700-800°C. Thus, where 40-60 g of Cl_2 are enough to degas 55-65 lbs of Al-Mg alloy, it is necessary to employ 280g of C_2Cl_6. It is possible to slow down the evolution of Cl_2 and at the same time achieve complete breakdown of the C_2Cl_6 into its elements; in this way C_2Cl_6 consumption is reduced by about 50%. Degassing is not always instantaneous and it is therefore advisable to wait 10-15 min. before proceeding to check the effect of the treatment by means of the vacuum test. KBF_4 has been found particularly suitable in the case of the Al-Mg alloy with 7% Mg.

971. GULBRANSEN, E. A. AND ANDREW, K. **Reactions of metals in high vacuums.** *Pittsburgh Intern. Conf. on Surface Reactions* **1948**, 222-36.—*C.A.* 43, 29*d*.

Basic types of reactions between metals and various gases, found in high vacuums (pressures below 10^{-6} mm Hg) and at 1200°C, were studied. Gas-metal reactions could be classified into three groups: (1) those in which a gas was formed as the result of the reaction, (2) those in which the metal combined with the gases of the vacuum, (3) those in which one gas was exchanged for another. The exptl. investigation concerned the oxidation in vacuo of Zr, W, Mo, and 12% Cr-Fe alloy, the formation of CO as the result of the reaction between the carbon in the metal (Nichrome) and its surface oxide film, the volatilization of MoO_3 and the oxidation and evapn. of Mg.

972. GWATHMEY, ALLAN T. **Preparation of single crystals for the study of surface reactions.** *Pittsburgh Intern. Conf. on Surface Reactions* **1948**, 66-70.—*C.A.* 42, 8057*i*.

Four techniques of growth of single crystals are described. Growth from molten metal is particularly suitable for Al, Cu, Au, and Ag (in Mo-wound vacuum furnace), for Ni (in alundum crucibles) and for Bi, Cd, In, Pb, Sn, and Zn (by sealing the metals under vacuum in glass tubes). Growth of crystals in solid states can be applied to Fe after decarburizing and to Al, with the strain-anneal method. Growth by deposition from vapor is particularly suitable for Zn and W. Growth by electrodeposition is especially practical for Cu. The investigation of gas-metal systems shows that many gaseous catalytic reactions produce definite facets, the nature of which depends on the metal, the reacting gases, and the plane to which the original surface is made parallel.

973. GWATHMEY, ALLAN T.; LEIDHEISER, HENRY, JR., AND SMITH, PEDRO G. **Influence of crystal plane and surrounding atmosphere on chemical activities of single crystals of metals.** *Natl. Advisory Comm. Aeronaut. Tech Note No.* **1460**, 67 pp. (1948).—*C.A.* 42, 8040*i*.

Single crystals of Al, Cu, Au, Pb, Ni, Ag, Cr, Fe, Cd, Zn, Sn, Bi, and In were prepd. and formed into spheres 1/2 in. diam.; the surfaces were prepd. in a smooth and strain-free condition by electrolytic or chem. polishing methods. The processes studied were: oxidation in air at elevated temps., rate of corrosion by hot oils, the extent of roughness produced by corrosion, wetting by stearic acid of Cu, Ni, and Fe, rearrangement and roughening of the surface due to the action of hot gases, electrochem. processes including deposition, etching, metal replacement, and in a few cases, galvanic action.

974. HAASE, L. W. **Corrosion of refined zinc and its alloys.** *Chimie & industrie* 59, 53(1948).—*C.A.* 42, 7224*f*.

Very definite conclusions were drawn from studies regarding the dry or electrolytic coating of Fe and Zn and the use of Zn or its alloys in place of colored metals, more particularly as regards the action of water. No improvement can be expected from increasing the purity of the Zn, and the latter is not suitable as a substitute for colored metals.

975. HICKMAN, J. W. **Metal oxide films at elevated temperatures.** *Iron Age* **162**, No. 7, 90-4, No. 8, 90-4 (1948).—*C.A.* 42, 7693*h*.

Various Al alloys, Nichrome, Inconel, Stellite, Refractaloy, Kovar, Hypernik, mild steel, Hastelloy, and Z-nickel were investigated. It was not possible to predict which oxides would form on the surface of an alloy by considering the thermodynamic stability of the oxides, nor by considering the relative sizes of the metallic ions. The most important factors were the relative rates of formation and diffusion of the metallic ions, and how they were influenced by temp. An analytical method was desirable for analyzing the films while still present on the metal.

976. Kawamura, Hajimu; Shinohara, Akira, and Takahasi, Katsuya. **The active centers of the oxide-coated cathode.** *J. Phys. Soc. Japan* **3**, 301-4(1948).—*C.A.* **44**, 5696*g*.

The difference between the d. of free Ba atoms in the ordinary fine-grained oxide and that in the coarse-grained one having very low emission was investigated. The energy required to produce one active center free Ba could be calcd.: $\epsilon = H + L - E$, where E was the heat of evapn. of the free Ba, $-L$ was the energy required to condense the evapd. Ba atom to Ba metal, and H was the heat of formation of BaO. For coarse-grained crystals $E = 2.3$ e.v., $L = 1.9$ e.v., $H = 5.8$ e.v., and $\epsilon = 5.4$ e.v.; for fine-grained crystals, $H = 4.8$ e.v. and $\epsilon = 4.4$ e.v.

977. Keii, Tominaga. **Adsorption of ethylene by elements.** *Repts. Sci. Research Inst.* (Japan) **24**, 171-6(Chem. Sect., 97-102)(1948).—*C.A.* **45**, 4112*g*.

Assuming that in the adsorption reaction H_2C: $CH_2 + 2Ni \rightarrow H_2C(Ni)C(Ni)H_2$ the Ni-Ni distance (2 adjacent Ni atoms on fixed positions on the carrier) was const. and the C-C distance variable, the potential curve surfaces for the adsorption heat 60 and 38.2 kcal. and the Ni-Ni distance 3.52 and 2.49 A. were calcd. by London's approximation formula. The energy change was not much affected by the activation heat, but was greater with larger adsorption heat; with adsorption heat 38.2 kcal., the energy change was greater by about 4 kcal. when the Ni-Ni distance was 3.52 than when it was 2.49 A.

978. Korovskii, Sh. Ya. **Effect of surface-active substances on the fatigue of steel.** *Doklady Akad. Nauk S.S.S.R.* **59**, 1449-51 (1948).—*C.A.* **42**, 8748*d*.

Specimens of steel were subjected to fatigue tests in (1) air, (2) redistd. petrolatum, (3) petrolatum + 0.2% oleic acid, and (4) petrolatum + 0.3% cetyl alc. The no. of cycles required for destruction at a given load was less for (3) and (4) than for (1) and (2), the decrease being greater for quenched and tempered steel than for normalized steel. The decrease in fatigue strength in certain media was an adsorption rather than a corrosion phenomenon.

979. Krupkowski, A. **The oxidation of metals.** *Hutnicke Listy* **3**, 357-61(1948).—*C.A.* **43**, 4991*a*.

Free-energy values were calcd. for a number of metals and the affinity of individual metals to O_2 at various temps. detd. Classification of metals according to the free energy of oxidation reactions indicated the ease of impurity removal from molten metals at temps. above 1000°C by introducing O_2 or H_2O, particularly if the oxide layer which covered the metal was in a liquid state. At normal temps. and up to nearly 1000°C, a solid and dense oxide layer was formed on solid and also on liquid metals in most cases.

980. Kubaschewski, Oswald and Goldbeck, Ortrun Von. **The rate of oxidation of nickel.** *Z. Metallkunde* **39**, 158-60(1948).—*C.A.* **44**, 8209*g*.

The rate of absorption of O_2 from air by specimens of Ni from various sources was measured at various temps. The abs. value of the rate of oxidation depended upon the purity of the Ni. The purer the Ni the lower was the rate of oxidation. Oxidation was essentially a parabolic function of the time.

981. Lankford, W. T. **Hydraulic bulge testing of sheet metals.** *Symposium on Deformation of Metals as Related to Forming and Service, Am. Soc. Testing Materials, Spec. Tech. Pub.* No. 87, 66-82 (1948).—*C.A.* **44**, 91*g*.

The use of O_2 as an oxidizing agent is discussed in metallurgical high-temp. furnaces, with special reference to reactions in the bath of the open-hearth steel furnace, the purification of Cu in a reverberatory furnace, the production of alloy steels in the elec. furnace, the operation of converters both in the steel industry and in the conversion of Cu mat to blister Cu.

982. Leibu, H. J. **The reduction of iron oxides with hydrogen and carbon monoxide.** *Schweiz. Arch. Angew. Wiss. u. Tech.* **14**, 1-19. 49-59, 76-85(1948).—*C.A.* **42**, 4881*h*.

H_2 is superior to CO as reducing agent. Although below 800° CO is a relatively better reducing agent, at these temps. it tends to decomp. to CO_2 and carbon, and thus gives a reaction product of undesirably high C-content. This decompn. is hastened greatly by reduced Fe. H_2 also removes S from the iron ores in the reduction process.

983. McGinnies, Rosemary T. and Siegel, Benjamin M. **The preparation and optical properties of gold blacks.** *J. Optical Soc. Am.* **38**, 582-9 (1948).—*C.A.* **42**, 6603*i*.

Au smokes deposited on cellulose nitrate films were studied. The conditions of pressure of the inert atm., purity of the gas, rate of evapn. and the distance between source and deposition surface giving the highest infrared absorption per unit mass were found. The Au "blacks" turned yellow and had lower infrared absorption when heated above 110°C. Gold "blacks" with very high infrared transmission (3-15μ) and low transmission at shorter wave lengths were prepd. when oxygen was present in the "inert" atm.

984. Metlay, Max. and Kimball, George E. **Ionization processes on tungsten filaments. I. The electron affinity of the oxygen atom.** *J. Chem. Phys.* **16**, 774-8(1948).—*C.A.* **42**, 7156*g*.

The electron affinity of the O atom was found to be 53.8 ± 0.8 kcal./mole. The detn. was made by measuring the ratio of ions to electrons leaving a hot W filament in contact with N_2O gas at low pressure.

985. Metlay, Max. and Kimball, George E. **II. The adsorption of fluorine on tungsten.** *J. Chem. Phys.* **16**, 779-81 (1948).—*C.A.* **42**, 7156*h*.

F formed a very stable at. layer on the surface of W, which did not desorb below 2600°K. A less-stable layer was believed to adsorb over the first layer. The fraction of the F dissocd. on the W surface was exponential in temp., and the rate of loss of W from the surface was independent of temp. and of pressure, at 2000-2400° K and 1-6μ of Hg. The adsorption caused a low accommodation for the thermal dissocn. of F.

986. Shumilova, N. A. and Burstein, R. Kh. **Passivation of iron by gaseous oxygen.** *Doklady Akad. Nauk S.S.S.R.* 61, 475-8 (1948).—*C.A.* 42, 8585*g*.

Fe was reduced with H_2 at 600°C (in a vacuum-jacketed quartz tube), then out-gassed at 800°C, loaded with a known amt. of O_2, and polarized anodically in 0.1 *N* KOH, with 5.3×10^{-7} amp./cm^2 of true surface area. By detns. of the potential E as a function of the quantity Q of electricity passed, the "electrochem. yield" Q' (i.e. passivity) was detd. as a function of A = no. of O_2 mols./cm^2 of true surface area. The results invalidated the previously made assumption of a removal of the passivating oxide film anodic soln.; a quantity of electricity of 0.11 millicoulombs/cm^2 can dissolve not more than 3×10^{14} atoms Fe, hence, cannot remove an oxide film corresponding to 2×10^{15} mols. O_2/cm^2. Passivation by gaseous O_2 and by anodically evolved O_2 were basically different. Thus, in dil. alkali, Fe was passivated anodically by a fraction of a monolayer of O_2, whereas under the same conditions several mol. layers were required for passivation with gaseous O_2.

987. Terem, Haldun N. **The kinetics of the oxidation of magnesium.** *Compt. rend.* 226, 905-6 (1948).—*C.A.* 42, 4430*g*.

Mg ribbons (2.75 × 0.15 mm) were oxidized in air at 470°, 490°, 510°, and 530°C. All samples oxidized linearly with time. Samples of Mg powder (250-300 mesh) oxidized in a similar linear fashion between 420° and 480°C. When the temp. was increased at a rate of 120° per hr in the case of the ribbon and 240° per hr in the case of the powder, combustion occurred at 540°C and 470-500°C, resp. The rate of reaction was decreased to 1/3 – 1/2 when pure or moist O_2 was used in place of air.

988. Tolley, G. **Catalytic oxidation of sulfur dioxide on metal surfaces. II. Reaction of sulfur dioxide and oxygen at a mild steel surface.** *J. Soc. Chem. Ind. (London)* 67, 401-4 (1948).—*C.A.* 43, 8325*d*.

Sulfide and sulfate formation occurs simultaneously, the sulfide being concd. near the surface of the steel. The rate of sulfate formation is greatest between 580° and 635°C corresponding to the max. catalytic activity of Fe_2O_3. Water vapor inhibits sulfide and sulfate formation, but increases the rate of oxidation.

989. Triche, H. **The application of spectrographic analysis of surfaces to the study of impurities.** *Congr. groupe. avance. methodes anal. spectrograph. produits metal.* 10, 77-8 (1948).—*C.A.* 43, 5694*c*.

Samples of Zn and Sn-Cd alloy are dipped in acid. The impurities (such as Ag) not attacked by the acid become concd. on the surface. Analysis is then accomplished by passing a Tesla spark between the prepd. surface and a counter-electrode of the pure metal (Zn or Sn-Cd alloy).

990. Tyapkina, V. V. and Dankov, P. D. **Kinetics of the oxidation of silver by molecular oxygen in the gaseous electric discharge.** *Doklady Akad. Nauk S.S.S.R.* 59, 1313-15 (1948).—*C.A.* 42, 7156*i*.

Oxidation of Ag, freshly condensed *in vacuo* and unexposed to gases, by dry O_2 under low pressure (initial ~0.3 mm Hg), at 18°C, reaches 5 mol. layers of Ag_2O relative to the macroscopic surface area, and to 1 unimol. layer if the actual surface is assumed to be about 5 times the apparent area. If the oxidation is carried out in a silent elec. discharge (18°C, 700 v., 2 milliamp.) between the Ag film, deposited on the inner wall of a glass tube of 10 – 16 mm diam., and an axial Ag wire serving as cathode, no satn. is reached but oxidation (detd. from the decrease of pressure of the O_2) progresses with time along a parabolic curve, much faster and deeper than in the absence of an elec. discharge.

991. Tyapkina, V. V. and Dankov, P. D. **Electron-diffraction study of primary sulfide films on silver.** *Doklady Akad. Nauk. S.S.S.R.* 59, 1461-3 (1948).—*C.A.* 43, 32*e*.

Thin polycryst. sheet Ag was obtained by condensation of the vapor in a vacuum on celluloid. This Ag was tarnished by exposure for several hrs at 20°C to wet H_2S, with air as an impurity. The layer of sulfide (approx. 100A. thick) was studied by electron diffraction. It was concluded that the small crystallites that formed were acanthite, the rhombic modification of Ag_2S.

992. Wagner, Carl. **Reactions of metals and alloys with oxygen, sulfur, and halogens at high temperatures.** *Pittsburgh Intern. Conf. on Surface Reactions* 1948, 77-82.—*C.A.* 42, 8137*a*.

For oxides contg. an excess of O_2 as compared to the formula, oxidation is detd. by exchange of electrons between monovalent and divalent Cu ions and by motion of Cu ions which takes place by jumping of Cu ions from normal positions to adjacent vacant positions. This is the case in the formation of Ni, Fe, Co oxides, and Cu oxides and halides. The oxidation of Zn (an antithesis of the oxidation of Cu) proceeds by migration of interstitial Zn ions and quasi-free electrons and is nearly independent of the O_2 pressure. The rate of the reaction between Ag and S is controlled by the diffusion potential rather than by the concn. gradient.

993. Wiemer, H. and Fischer, W. A. **Sintered iron and carbon articles.** *Arch Eisenhuttenw.* 19, 125-35(1948).—*C.A.* 43, 1297*g*.

Sintering mixts. of Fe and C in vacuo produces ferritic-graphitic, ferritic-graphitic-pearlitic, and pearlitic structures. The mech. strength (1-60 kg/mm^2) depends on C content and sintering time and temp. The sintering atm. (N_2, H_2, CO) has no appreciable influence.

994. Akamatsu, Hideo and Satô, Kazutoshi. **Catalytic decomposition of carbon monoxide by iron.** *Bull. Chem. Soc. Japan* 22, 127-31 (1949).—*C.A.* 44, 7637*f*.

CO was passed through a quartz reaction tube contg. Kahlbaum's electrolytic Fe as catalyst. The exit gases passed through $Ba(OH)_2$ soln. to follow the reaction: $2CO \rightarrow C + CO_2$. Five to ten hrs were necessary for decompn. to begin at 500°C and CO flow of 400 cc. per hr. Once started, the reaction proceeded smoothly. Electron diffraction patterns of the catalyst were taken just as decompn. had begun and after 15 hrs of decompn.

In the 1st case no free carbon was found, but the Fe lost its metallic luster. The pattern obtained was that of cementite. When the surface was black or gray in parts, the pattern was principally carbon but some cementite spacings also appeared. Prolonged decompn. yielded only carbon spacings.

995. ANTONIOLI, A. **Statistical observations on the oxygen content in steel making.** *Met. ital.* **41**, 71-9 (1949).—*C.A.* **43**, 8331*i*.

Existing data on O-content agree with the hypothesis of reaction between heterogeneous phases, but not between homogeneous phases.

996. BAKER, W. A. **Estimation of oxygen in metals by hydrogen reduction.** *Metallurgia* **40**, 188-9 (1949).—*C.A.* **43**, 8963*f*.

A pot-type Pt-sound furnace heated the inclined part of the SiO_2 combustion tube. The app. was calibrated either by reduction of known wts of an oxide of known compn. (e.g., PbO) or by introducing a known vol. of gas into the exhausted system. Fused Al_2O_3 crucibles should be used in the combustion tube. The method is applicable to Cu, Sn, Pb, and to alloys of these elements. Errors due to volatile constituents (P or Zn in Cu-base alloys) may be minimized by using a relatively large bath of a suitable metal, such as Sn, in the combustion tube, deoxidizing the bath during the initial purification of the H_2, and then adding the sample to be examd. to the molten bath.

997. BISCHOFF, F. **Nitrogen absorption in electric-arc welding.** *Schweisstech. Appendix to Die Technik* **4**, 229-34 (1949).—*C.A.* **43**, 9017*c*.

Mn increases N_2 absorption for both bare and coated electrodes, that of the latter being somewhat weaker. Cr increases N_2 absorption noticeably for both types of electrodes though slag and coating weaken it slightly. Ni reduces N_2 absorption, independently of Ni content. Mn + Cr alloyed wires gave an approx. additive absorption of each single element. With bare Mn-Ni wires higher Ni contents affected the absorption so unfavorably that the N_2 contents of bare electrode welds of Mn wires was not reached.

998. BOSWORTH, R. C. L. **The formation of mobile and immobile films of oxygen on tungsten.** *J. Proc. Roy. Soc. N. S.* **83**, 31-8 (1949).—*C.A.* **45**, 6005*d*.

The condensation of O_2 on W was studied by application of the contact-potential method. Values of the fraction of the surface covered, θ, were detd. as a function of time at fixed O_2 pressures and temps. At values of $\theta = 0.5$, or a little less, the condensation proceeded more slowly the higher the temp. at any fixed pressure, and more than proportionally slowly the lower the pressure at any fixed temp. This is attributed to the activation of some of the absorbed O_2 atoms to a mobile state which proceeded the more rapidly the higher was the temp. and the more completely the lower was the pressure. The surface diffusion coeff. (D) at 830°K and $\theta = 0.5$ was 2.5×10^{-16} cm²/sec., D increased as θ increased. At 830°K and $\theta = 0.7$, $D = 4.8 \times 10^{-16}$ cm²/sec, at 830°K and $\theta = 0.8$.

999. CABRERA, N. **The oxidation of metals at low temperatures and the influence of light.** *Phil. Mag.* **40**, 175-88 (1949).—*C.A.* **44**, 507*c*.

The theory of Mott was extended to oxides, such as Cu_2O for which the metal diffuses through the oxide by the mechanism of vacant lattice points. The logarithmic law would be valid down to very low temps. and for O_2 above $\sim 10^{-4}$ mm Hg independently of the temp. and the oxide considered. The model also explained the influence of light on the oxidation of Al.

1000. CASTRO, R. AND ARMAND, M. **Gases in aluminum and its alloys.** *Rev. met.* **46**, 594-616 (1949).—*C.A.* **44**, 516*i*.

The only gas which appeared to dissolve in liquid Al was H_2, and its soly. of a few cc. per 1000 g rapidly diminished with lowering temp. At the fusion point of Al, H_2 soly. was negligible. Nitrides and oxides could usually be found in H-bearing Al. The gases entered Al through the reaction with the atm. in contact with the metal. H_2O adsorbed on the surface of solid Al eventually caused blisters, and appeared to be the most detrimental substance in metallurgy of Al.

1001. CORDIANO, JOSEPH J. **Some effects of oxygen on the performance of iron powder.** *Proc. Ann. Meeting Metal Powder Assoc.* **5**, 21-35(1949).—*C.A.* **45**, 4184*c*.

Fe mill scale was ball milled to a minus 100-mesh powder and reduced in dry H_2 to produce 7 powders varying in oxide content. An addnl. high apparent d. powder was also included in the group. Zn stearate (1% by wt) was mixed in each powder for lubricating purposes. These were sintered at 2050°F for 20 min. at temp., in dry H_2, followed by cooling in the H_2O-jacketed cooling section of the furnace. After sintering the specimens were of a silver-gray color and no traces of lubricant remained. Internal oxides in Fe powders did not materially affect the mech. properties of sintered Fe compacts, but did have a strong effect on decreasing the d. of green and sintered compacts.

1002. CZERSKI, LUCJAN. **Oxidation of copper with air at high temperatures.** *Roczniki Chem.* **23**, 19-28 (1949).—*C.A.* **43**, 8930*h*.

Cu_2O obtained from Cu and O_2 at 950°C contained 0.07-0.35% Cu (23 analyses) in excess of the stoichiometric amt. In Cu_2O prepd. under reduced pressure of O_2 the excess Cu dropped to 0.035%. The excess Cu was irregularly dispersed throughout the oxide; it did not diffuse toward the CuO layer, and did not oxidize even at 950°C (40 hrs). It might be a result of a reaction at the CuO/Cu_2O surface.

1003. DANKOV, P. D. AND SHISHAKOV, N. A. **The crystallochemical mechanism of formation of oxide film on iron at room temperature.** *Zhr. Fiz. Khim* **23**, 1031-5(1949).—*C.A.* **44**, 893*i*.

Electron-diffraction patterns of Fe films condensed from vapor at 2×10^{-4} mm Hg show lines of expanded Fe lattice (spacing up to 3.00 A.), broad lines apparently due to wuestite FeO, and lines of magnetite and $\gamma-Fe_2O_3$. The intensity of wuestite lines indicates that there are 2 ⅔ atoms of Fe for 4 atoms of O. Presumably, the external layer of Fe ions in the metal is expanded to the spacing of wuestite in the (100) face so that O ions can readily enter it.

1004. DEINUM, H. W. AND DAM, J. W. **Determination of small quantities of oxygen.** *Anal. Chim. Acta* 3, 353-9 (1949).—*C.A.* 43, 8963*d*.
The O_2 reacts with metallic Cu in an ammoniacal NH_4Cl soln., and the dissolved Cu^{++} is detd. iodometrically. SO_2, H_2S, C_2H_2, and mercaptans interfere and must be eliminated. As little as 0.001% O_2 in gaseous mixts. contg. high proportions of C_2H_2 can be detd.

1005. DERGE, GERHARD. **Oxygen in titanium.** *J. Metals* 1, No. 10, 31-3 (1949).—*C.A.* 43, 8963*h*.
Proper modification of the vacuum-fusion analytical procedure as ordinarily applied to steels resulted in the satisfactory analysis of carefully prepd. Ti-O_2 alloys contg. up to 0.5% O_2.

1006. DOCKAR, J. **The influence of some additions on the speed of carburization of steels by charcoal.** *Hutnicke Listy* 4, 345-51, 389-91 (1949).—*C.A.* 44, 3862*d*.
Na_2CO_3 was dissolved in distd. water, the soln. was absorbed by the charcoal which was then dried. Mixts. contg. 10, 8.5, and 6% Na_2CO_3 had a corrossive effect on the steel surfaces. A 3% Na_2CO_3 mixt. gave uniform carburization without loss in intensity and had no corrosive effect on the parts to be carburized during the process. The specimens were all from the same melt for each type of steel and the charcoal taken from the same sack. Charcoal impregnated with "stabilizers" combined with Ba compds. form high grade carburization mixt., and a mixture contg. 5% of Ba compds. combined with Na salts can be used. A mixt. of Be and Na compds. was very effective.

1007. ELLIOTT, K. A. C. **Removal of traces of oxygen from gases.** *Can J. Research* 27F, 299-300 (1949).—*C.A.* 43, 7758*e*.
A furnace for heating metallic Cu in a current of the gas consists of a Pyrex tube which is wrapped with asbestos paper, and wound with Nichrome wire. The wire is covered with a second layer of asbestos paper and with asbestos cord. The tube is packed with CuO wire fragments held in place with rolls of Cu gauze. Windows are provided for observing the condition of the Cu. To reduce the CuO, H_2 mixed with a carrier stream of N_2, or other inert gas, is passed through the hot tube.

1008. ESELGROTH, T. W. **Nitrogen degassing of nonferrous metals.** *Metal Progress* 55, 817-20 (1949).—*C.A.* 43, 5715*d*.
Degassing Al, Cu, 95 Cu-5 Mn, and 89.5 Cu-10.5 Sn with N_2 gave improved mech., elec., and thermal properties, cleaner metal, and freedom from porosity. N_2 was less expensive than A and He, easier to use than Cl_2, and did not form undesirable inclusions.

1009. GILDE, WERNER. **Nitrogen in Thomas low-carbon steel.** *Chem. Tech.* 1, 183-5 (1949).—*C.A.* 44, 6795*b*.
N_2 strongly affected the mech. properties of steel; it especially caused brittleness. To compensate for the effect in Thomas steel, most of the absorbed N_2 was eliminated in the mixer. The oxide-film theory explained the influence of the charging rate to the mixer on the N_2 absorption. The elimination of the N_2 in the pan and in the pig was described.

1010. GRAY, T. J. **The application of semi-conductivity measurements in the study of catalysis on copper oxide.** *Proc. Roy. Soc. (London)* A197, 314-20 (1949).—*C.A.* 44, 2355*g*.
The elec. cond. of thin films of oxides was used to study the effects of adsorbed gases and reactions between them. This was applied to the Cu_2O-CuO system.

1011. GULBRANSEN, EARL A. **Kinetic and structural factors involved in oxidation of metals.** *Ind. Eng. Chem.* 41, 1385-91 (1949).—*C.A.* 43, 7309*d*.
By a sensitive wt-gain method the oxidation of Fe, Mo, W, Al, and Mg was studied as a function of time, temp., pressure, and surface area. At 400°C the order of increasing rate of reaction was Mg, Al, W, Fe, and Mo. After a rapid initial period the parabolic law may be fitted to the data for many metals. The rate law followed an exponential behavior, whereas the effect of pressure was small for most metals in the pressure range studied. An electron-microscope study of stripped oxide films showed the film to consist of crystals of the order of 50 to 2000 A., depending on the temp. and time of reaction. The free energy of activation for the rate-limiting process varied from 36,040 cals per mole at 375°C for Mo to 56,100 for 18-8 stainless steel at 650°C.

1012. GULBRANSEN, EARL A. AND ANDREW, KENNETH F. **Kinetics of the reactions of titanium with oxygen, nitrogen, and hydrogen.** *J. Metals* 1, No. 10, Trans. 741-8 (1949).—*C.A.* 43, 9006*i*.
TiO_2, TiN, and TiC were stable at all temps. up to the transition temp. From a thermodynamic point of view, Ti will remove O_2, N_2, CO, and CO_2 at the lowest pressures used in high-vacuum technique. The reactions of water and CO_2 to form the oxide and H_2 and CO, resp. were possible up to 800°C and perhaps higher in vacuums of the order of 10^{-7} mm of Hg. An energy of activation of 26,000 cal per mol. was calcd. from the temp. dependence of the parabolic rate law consts. The O_2 reaction was found to be insensitive to pressure.

1013. HAYES, E. T. AND ROBERSON, A. H. **Effects of heating zirconium in air, oxygen and nitrogen.** *J. Electrochem. Soc.* 96, 142-51 (1949).—*C.A.* 43, 8910*f*.
Zr metal was heated in N_2, O_2, and air at from 425° to 1300°C. Observations were made on the gain in weight, micro- and macro-hardness, and metallographic structures. N_2 diffused into Zr at a much slower rate than O_2. A marked increase in penetration of both gases was found near 900°C. Practical limits for the heating of Zr in air, O_2, and N_2 were given and the posibilities of producing hard-surface coatings were discussed.

1014. HERRMANN, G. AND KRIEG, O. **The influence of gases and vapors on the emission of oxide cathodes.** *Ann. Physik (6)* 4, 441-64 (1949).—*C.A.* 46, 9968*g*.
The emission E_s of a SrO-BaO cathode (on indirectly heated Ni tubes) was detd. at cathode temps.

T_s of 300-1500 °K. Only after the removal of the whole oxide film did a decrease in E_s occur. Purely chem. influences were observed in the cases of O_2, CO_2, CO, and the hydrocarbons; O_2 combined with the free Ba in the activated cathode. CO_2 and CO reacted both with Ba ($Ba + CO_2 \rightleftarrows BaO + CO$ and $Ba + CO \rightleftarrows BaO + C$) and with the oxide itself ($MO + CO \rightleftarrows MCO_3$ and $MO + 2CO \rightleftarrows MCO_3 + C$). These reactions caused E_s to drop. CH_4, C_2H_6, C_3H_8, C_2H_2, benzene, toluene, and naphthalene poisoned the emission as a result of their decompn.

1015. Huttig, G. F. **The relations between adsorptivity and corrosion.** *Berg-u hutten-mann, Monatsh. montan. Hochschule Leoben* 94, 282-4 (1949).—*C.A.* 44, 1389*b*.

The corrosion of sintered bodies and powders depended in the first place on a quality of the surface since that determined the beginning of corrosion. The quality of the crystal lattice determined only secondarily the velocity of propagation of the corrosion into the interior. There was a definite relationship between corrodability and the adsorptive properties of a metal powder.

1016. Imada, Fusao. **The hydrogenation catalysts for oils. I. The constituents of the spent catalyzers. II. The preparation of catalyzers from the spent catalyzers and the hydrogenation study. III. Chemisorption and catalytic activity.** *Kôgaku Ihô, Kyushu Univ.* 20, 105-9; 21, 1-3, 14-27 (1949).—*C.A.* 47, 1408*i*.

Adhering matter on the spent hydrogenation catalyzers is analyzed. Adsorption of unsaponifiable oil matter to the active centers of the catalyzer is thought primarily to be the reason for aging. Since the sol. metal oxide components in diatomaceous earth play a role as promoters, the addition of new earth is found to be advantageous. The recommended procedure for the prepn. of recovered catalyzers is described. The sorption ability for H_2 and C_2H_4, and hydrogenation properties of catalyzers of Ni, Al-Ni, Cu-Ni, Fe-Ni, Ni-Fe-Al, with or without diatomaceous earth and activated carbon are compared.

1017. Itterbeek, A. van and Greve, L. de. **Measurements on the electrical resistivity of thin metallic films.** *Physica* 15, 80-2 (1949)(in English).—*C.A.* 43, 8771*e*.

The temp. coeff. of resistance for a thin metal film as a function of film thickness became zero at a crit. resistance, R_c, and then became neg. with thinner films. Values of R_c were measured for Ni films, cathodically sputtered in the presence of He, H_2, A, Ne, and N_2. The smallest values of R_c were found with H_2 and A, corresponding to a film thickness of ± 40 mμ. In the other cases, the thickness decreased by about 5 mμ.

1018. Itterbeek, A. van; Greve, L. de., and Celis, R. **The negative temperature coefficent of nickel films.** *Physica* 15, 433-6(1949).—*C.A.* 44, 3324*c*.

New values of the crit. elec. resistance (ohms) of Ni films deposited on Pyrex glass by cathodic sputtering were (gas and film thickness in parentheses): 25,000 (N_2, 20mμ); 4500 (H_2,40mμ); 7500 (Ne,30mμ); 25,000(He, 20mμ); 3000 (A, 40mμ). Voltage changes in the range of 3000 to 4000 had little effect.

1019. Itterbeek, A. van; Greve, L. de.; Lambeir, R., and Celis, R. **Nickel films used as thermometers at low temperatures and superconductivity of lead films.** *Physica* 15, 962-70 (1949).—*C.A.* 44, 5174*h*.

Ni films cathodically sputtered in A, Ne, and H_2 had neg. temp. coeffs. of cond. and could measure temps. in the region of liquid H_2 and liquid He. Films prepd. in Ne were the most stable. Pb films, prepd. by sputtering in N_2 were used in the transition region (range of 1°K) for supercond. The residual resistance of the Pb films was initially very high and disappeared completely at the transition point, for Pb wires, 7.20°K.

1020. Knauer, Friedrich. **The residence time of adsorbed alkalies on heated tungsten.** *Z. Physik.* 125, 278-89 (1949).—*C.A.* 43, 4942*c*.

A mol. beam of alkali atoms (K, Na, Cs) passed through a rotating sector to an incandescent W wire and the resulting ionic current recorded. In each cycle, an appreciable length of time (longer for lower wire temps.) was required for the current to reach its max. value. This was evidence for an adsorbed layer of atoms on the wire. The observed residence times were in the range 10^{-2} to 10^{-5} sec.

1021. Koga, Shozo and Wakabayashi. **Application of surface potential. II. Low-temperature oxidation of metals.** *Repts. Sci. Research Inst.* 25, 306-11 (1949).—*C.A.* 45, 4583*b*.

The potential curves of Cu, Zn, and Al, being oxidized below 200°C, and obtained with an improved oscillatory volumetric surface potentiometer, rose with temp., but not necessarily linearly with the thickness of the oxide layers. The Cu curves showed initial inhibition owing to decreased O_2 partial pressure, the oxide formed being a semiconductor of deficient type, whereas the Zn and Al curves were not so affected.

1022. Kopelman, Bernard and Gregg, C. C. **Particle agglomeration in tungsten metal powder.** *J. Phys. & Colloid Chem.* 55, 557-63(1951).—*C.A.* 45, 6010*c*.

Particle-size distribution of W powder in 11 liquids of different dielec. consts. as detd. by turbidimetric analysis showed the apparent av. particle size (μ) to decrease with increasing dielec. const. (D) up to a max. at $D = 25$. The surface bonds in the metal powder resulting from elec. attraction were completely broken in assocd. liquids for which D exceeds 25. Essentially complete agglomeration of the powder occurs in liquids for which D was less than 2.

1023. Kwan, Takao. **Adsorption of carbon monoxide on platinum catalyst.** *J. Research Inst. Catalysis* 1, 110-16 (1949); *Bull. Chem. Soc. Japan* 23, No. 3, 70-2 (1950).—*C.A.* 44, 4304*d*; 45, 3221*a*.

CO adsorption isotherms were measured at pressures between 0.001 and 1 mm Hg at 180°, 200°, 280°, and 300°C. Data were expressed by $x = CP^{1/n}$, where x was adsorbed quantity, P was the equil. pressure, and $n = 2.7$. The differential heat of adsorption was const. for all quantities adsorbed and equals 11 kcal/mole. An expression was derived for the change in heat of adsorption with fraction of surface covered with best agreement assuming that CO was dissocd. to C and O.

1024. Likhtman, V. I. and Venstrem, E. K. **Effect of the dimensions of metal single crystals on the shape of the strain-stress diagram and on the strength-lowering influence of adsorption.** *Doklady Akad. Nauk S.S.S.R.* 66, 881-3 (1949).—*C.A.* 43, 7768*h*.

The effect is attributed to increased shear due to the presence of numerous micro cracks in the surface layer. The effect of surface-active substances, e.g. 0.2% oleic acid in liquid petrolatum, in the direction of increasing the plasticity, is more pronounced at small ratios of length to diameter, owing to the predominant concn. of micro cracks in the surface layer. Under the action of surface-active substances, the preferential accumulation of stress in the surface layer is smoothed out; this accounts for the observed disappearance of the shift of the yield point in the presence of such substances.

1025. Makolkin, I. A. **Adsorption balance for investigation of metal corrosion at high temperatures.** *Zavodskaya Lab.* 15, 1209-12(1949).—*C.A.* 44, 996*h*.

It consists of a Mo spring, placed in a protective jacket (vertical) with a suitable pointer-scale arrangement; the lower end of the spring terminates in a glass fiber carrying the sample which is located in an upright furnace tube. The fiber passes through a tiny opening in latter and thus eliminates the effect of heat on the measuring spring.

1026. McGeary, R. L.; Stanley, J. K., and Yensen, T. D. **Determination of oxygen in metals by the vacuum fusion method.** *Trans. Am. Soc. Metals, Preprint* No. **10**, 14 pp (1949); *Steel* **126**, No. 10, 81-2 (1950).—*C.A.* 43, 8215*g*; 44, 3841*a*.

The metal was melted in a graphite crucible in an evacuated system to convert oxides to CO which was passed over hot CuO to form CO_2. A part of the system was cooled by liquid N_2 which collected CO_2 and removed other gases by vacuum pumps. The CO_2 was expanded and its vol. measured. Accuracy was ±0.001% in 15 to 20 min. with 0.1-2.0 g samples.

1027. Moreau, L. **Determination of oxygen in steels.** *Rev. universelle mines* 5, 279-83 (1949).—*C.A.* 43, 8962*i*.

The steel sample is melted in a graphite crucible in vacuum under a reducing atm. in a high-frequency furnace consisting of a cylindrical tube of fused silica. With a vacuum of 10^{-3} mm Hg and the temp. necessary for complete and rapid reduction are for FeO and MnO 1050-1150°C, silicates 1150-1300°C, SiO_2 1300-1350°C, Al_2O_3 1575-1600°C. The reaction taking place is FeO (dissolved) + $C \rightarrow CO + Fe$, and the O_2 is detd. from the CO.

1028. Mostovetch, Nicolas. **Reversible effects of the adsorption of gas on the electrical conductivity of metallic films.** *Compt. rend*, **228**, 1702-4 (1949).—*C.A.* 44, 403*c*.

The elec. resistances of thin films of Mo, Pt, Rh, Ni, and Au have neg. temp. coeffs. diminished by the adsorption of gases and reversibly increased by outgassing. The elec. resistance of thicker films of these metals has a pos. temp. coeff. increased by adsorption of gas and decreased by outgassing. The resistance of these films is related to the pressure of the gas by the expression: $\log R = -n \log p + \log b$, where n and b are exptl. consts.

1029. Müller, Erwin W. **Surface migration of tungsten on its own crystal lattice.** *Z. Physik* **126**, 642-65(1949).—*C.A.* 44, 2836*b*.

A very fine W point, sharpened in molten $NaNO_2$ and heated in the highest obtainable vacuum, became a smooth cone with a hemispherical apex whose radius increases with time. The electron emission from individual crystal surfaces can be identified in the resulting images. The condensation of W vapor on these surfaces and the migration of W atoms along them are studied by means of photographs. The activation energy for surface migration is 106,500 ± 8000 cal/mol The presence of foreign adsorbed atoms on the W surface appears to accelerate the surface migration, but the amt. of W that migrates is decreased.

1030. Naeser, Gerhard. **A new method for determining oxygen in soft iron, steel, and some other metal powders.** *Stahl u. Eisen* 69, 19-21 (1949).—*C.A.* 43, 6108*f*.

Formation of CO from the O_2 by reaction with C was done in a stream of N_2. The vol. of CO was detd. by using a buret in an arrangement similar to the one used for steam vol. detn. The CO_2 was found to be between 3 and 12% resulting in an error of ±25% in the O_2 found. It is essential, therefore, to transform all the CO_2 into CO. The app. was operated at 1300°C. The accuracy of the method was checked by treating pure oxides. For pure Fe, the error was ±2.3% av.

1031. Nagasako, Noboru and Miyazaki, Shozo. **The catalytic decomposition of ammonia. I. The decomposition on tungsten.** *J. Chem. Soc. Japan* **70**, 134-6 (1949).—*C.A.* 45, 4124*g*.

Studies were made on the catalytic decompn. of NH_3 on W in the form of filament heated electrically to 700-70°C. When the decompn. products were absent, the reaction was of the zero order. H_2 repressed the reaction below the zero order, whereas N_2 had no effect. This showed that the adsorption of N_2 from the gaseous phase was negligible, but the active surface remained entirely covered with H_2 and NH_3 within the temp. range.

1032. Noga, Ken-ici and Okada, Yoshitaro. **The mechanism of grid emission,** *J. Phys. Soc. Japan* 4, 360-1(1949).—*C.A.* 44, 5696*f*.

BaO mols. were evapd. from a hot oxide-coated cathode and deposited on heated wires of W, Ni, and Au. The emission property of the W wire, as a result of this coating, was found to be of the same order of magnitude as that of the usual oxide-coated cathode. The Ni and Au, however, were lower by factors of 10^{-2} and 10^{-5}.

1033. Novokreshchenov, P. D.; Markova, N. E., and Rebinder, P. A. **The adsorption effect in alternating torsion, in connection with the problem of fatigue of metals.** *Doklady Akad. Nauk S.S.S.R.* **68**, 549-52 (1949).—*C.A.* 44, 507*f*.

In unidirectional torsion of Sn wires (diam. 1 mm, length 10 mm), with simultaneous application of a tensile load, the torque was substantially lower in a surface-active medium (0.2% soln. of oleic acid in nonpolar liquid petrolatum). The effect increased with the deformation, attaining a 94% lowering near rupture. In alternating sinusoidal torsion, with simultaneous static tension, adsorption effects appeared clearly at relatively low periods of 4-8.5 min. The effect was explained by a fine dispersion of the surface layer, owing to which the metal became more plastic and withstood a greater no. of torsions before failure.

1034. Perrot, Marcel and Arcaix, Suzanne. **Effect of the adsorption of gas on the evolution of thin films.** *Compt. rend.* **229**, 1139-42 (1949).—*C.A.* 44, 4302*e*.

Two thin films of Ag of comparable thicknesses were prepd. The reflection (R') for a wave length of 5461 A. and the resistance (R) were measured simultaneously under low pressure. Variations of R' with time (after the end of sputtering) were low and comparable; variations of R differed considerably for the two. The min. in resistance was attributed to adsorption at a pressure of 10^{-5} mm of Hg. With dry air, resistance became const. after rising with pressure to about 50 mm. With lab. air, resistance continued to increase with gas pressure. Satd. air behaved similarly except that the magnitude was greater. Thus, water vapor had a great effect in building up the resistance.

1035. Robertson, A. J. B. **The pyrolysis of methane, ethane, and butane on a platinum filament.** *Proc. Roy. Soc. (London)* **A199**, 394-411 (1949).—*C.A.* 44, 2354*b*.

A mass spectrometer was used to examine the reactions on an incandescent Pt filament at pressures of about 10^{-5}mm. Free radicals were directly detected by ionizing them with low-energy electrons. The primary dissocn. of CH_4 on Pt at about 1000°C gave Me radicals, but no methylene radicals could be detected. About one in 300 of the collisions of the CH_4 on Pt led to reaction. No free Me or Et radicals could be detected in the dehydrogenation of ethane to ethylene at 950°C. The presence of Me radicals from methane in the ethane did not bring about any further dehydrogenation of ethane. Et radicals were detected from the pyrolysis of butane at 1050°C which underwent a selective fission at the central C-C bond.

1036. Rowland, P. R. **Reactivities of different faces of a copper single crystal.** *Nature* **164**, 1091-2(1949).—*C.A.* 44, 3327*c*.

Single-crystal spheres of Cu are exposed to halogen vapors at 1 mm and 444°C. The cuprous halides are sublimed away, leaving a clean Cu surface contg. etch pits. The reflecting surfaces of the etch pits are parallel to certain crystallographic planes and are examd. with parallel light. The facets exposed and the intensities of their reflected beams are: (111) and (011) strong, (001) very weak, (012) strong for I_2 and Br_2 but weak for Cl_2.

1037. Saitô, Tunezô. **Absorption of nitrogen by molten iron alloys. I. Study on pure iron.** *Science Repts. Research Insts. Tôhoku Univ.* **Ser. A, 1**, 411-17(1949)(in English).—*C.A.* 45, 4626*e*.

The absorption was measured between 1530 and 1750°C. The satn. value of pure Fe at 1600°C was 0.039 wt % N_2. The temp. coeff. was 1.4×10^{-5} wt % N_2 per degree. The addn. of small amts. of C, Si, Mn, and Cr increased the velocity and Ni decreased the velocity.

1038. Saitô, Tunezô. **Absorption of nitrogen by molten iron alloys. II. Study on iron-nickel, iron-chromium, and iron-manganese alloys.** *Science Repts. Research Insts. Tôhoku Univ.* **Ser. A, 1**, 419-24 (1949).—*C.A.* 45, 4626*e*.

With Cr alloys the satn. value increased from 0.039% N_2 for pure Fe at 1600°C up to 4% N_2 for Cr at about its m.p. Pure Mn at its m.p. absorbed 1% N_2. In the Fe-Ni alloys the absorption decreased with increase in Ni concn. to a value of approx. 0% at 80% Ni.

1039. Samarin, A. M. and Shvartsman, L. A. **Activities of carbon and of oxygen dissolved in liquid iron.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk* **1949**, 1231-4.—*C.A.* **45**, 4187*e*.

The deviations from ideality for the equil. between C and O_2 dissolved and gaseous CO can be accounted for without assuming significant soly. of CO in Fe. The deviation of the actual O content is explained by the expansion of the free vol. v as a result of the interstitial soln. of C. This is taken to be $v = V - \omega$, where V = sp. vol., and ω is a const. close to the sp. vol. of the solid phase at the m.temp. Increase of the C content decreases the O content as a result of the chem. reaction; on the other hand, the substitutional soly. is increased somewhat as a result of the increase of the free vol.

1040. Shinohara, Shozo. **Oxide layer on the surface of metals.** *Busseiron Kenkyu*, No. **13**, 7-14 (1949).—*C.A.* 47, 3070*i*.

The theory of the rate of growth of protective oxide layer on metals is improved by taking into account the image force in the case in which the logarithmic law holds.

1041. Shushunov, V. A. and Aurov, A. P. **Kinetics of the reaction of lithium with ethyl chloride vapor.** *Zhur. Fiz. Khim.* **23**, 1197-202 (1949).—*C.A.* 44, 1312*g*.

Li was condensed from vapor on the inside of a glass bulb (4 cc.). EtCl was introduced, and the pressure P detd. with a membrane manometer. Below 30°C, P decreased in time, and eventually LiEt (m 95°) formed. After a latent period the decrease of P was proportional to t^n, t being time and $n = 1.4$ at -25°C and 1.1 at +20°C. Up to 3%, O_2 in EtCl did not affect the rate of reaction, but 10% O_2 lowered it because of formation of Li_2O.

1042. Shushunov, V. A. **Kinetics of the reactions of potassium with carbon monoxide.** *Zhur. Fiz. Khim.* **23**, 1322-7 (1949).—*C.A.* 44, 2833*d*.

K was condensed in a vacuum on a Cu foil suspended on a spring balance, and the vessel was filled with CO. The wt gain corresponded to uptake of 1 mol. CO. Then H_2O vapor was admitted and 1 mol. H_2O taken up. The reaction between K and CO started after a latent period r which at a CO pressure of 3 mm Hg was 22 sec at -183°, 37 sec at -90°, 2 sec at -50°, 25 sec at -20°, and 100 sec at -10°C. If p was the CO pressure after time t, $p_o - p = at^n$, a and n were const. which in different expts. varied between 1.4 and 3.

1043. SHUSHUNOV, V. A. **Effect of additions to the gas phase on the rate of reaction between potassium and carbon monoxide.** *Zhur. Fiz. Khim.* 23, 1328-31(1949).—*C.A.* 44, 2833*g*.

The reaction was not affected by H_2 (up to 50 vol. %) and greatly retarded by 5 vol. % AcOEt, presumably because of formation of a K deriv. of AcOEt. It was accelerated by O_2 between 30° and 60°C the initial rate was proportional to the O_2 concn. (0-10 vol. %) and its temp. coeff. was −2. The effect of O_2 might be due to roughening of the K surface.

1044. STARK, B. V. AND FILIPPOV, S. I. **Adsorption phenomena on the surface of liquid steel.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk* **1949**, 413-20.—*C.A.* 45, 5590*f*.

Surface tension of steel melts was detd. in an 8-kg induction furnace by passing N_2 through a capillary inserted in the melt. An increase in the C or O-content of the melt decreased the surface tension. Adsorption of C and O on the phase boundaries was calcd. from the surface tension data. When C and O were in equil. in the melt, the surface tension curve passed a max. which corresponded to equal adsorption of C and O.

1045. STARODURTSEV, S. V. **Investigation of adsorption phenomena by the method of modulated molecular beams.** *Zhur. Eksptl. Teoret. Fiz.* 19, 215-24 (1949).—*C.A.* 44, 6699*b*.

An at. or mol. beam produced by evapn. and collimated through slits was aimed at an incandescent filament. Mech. modulation of the beam gave rise to a modulation of the current due to ionization of the particles adsorbed on the filament. Each adsorbed atom had a definite probability, *w*, of evapg. from the surface either as a neutral atom or as a pos. ion. Exptl. detns. were made with beams of K and of Na on a W filament.

1046. THONON, CL. AND JUNGERS, J. C. **Dehydrogenation of secondary alcohols in the liquid phase with nickel as a catalyst.** *Bull. soc. chim. Belges* 58, 331-49 (1949).—*C.A.* 44, 3876*i*.

The ketone produced during the dehydrogenation of secondary alcs. had a strong inhibitory action on the further reaction. It had a markedly higher adsorption coeff. than the alc. The factors influencing the ratio of the adsorption coeffs. of the ketone and alc. were examd. Different samples of Ni and Cu were used as catalysts. Cu was less active than Ni, but it changed the ratio slightly in favor of the alc.

1047. TROESCH, ANDRÉ. **Inhibition by carbon and hydrogen of the activated adsorption of methane by nickel Fischer catalysts.** *Compt. rend.* 228, 1013-15 (1949).—*C.A.* 43, 6064*a*.

Adsorption of CH_4 at const. vol. on a Ni catalyst contg. Al_2O_3 and SiO_2 was studied at 170°C. The adsorption of CH_4 was inhibited by the deposition of carbon on the active surface, $CH_4 = C + 2H_2$. The rate of adsorption on the available surface remained const. with carbon on the surface although the total amt. of adsorption decreased. The presence of H_2 and C on the surface decreased the amt. of CH_4 adsorbed and decreased the rate of adsorption on the available surface.

1048. TSUKAGOSHI, OSAMU. **Getters—general conditions of making adsorbing vapor films having abnormally large clean-up ability and a search for the method.** *Repts. Sci. Research Inst.* (Japan) 25, Phys. Sect., 1-13(1949).—*C.A.* 45, 4996*g*.

Curves were obtained for O_2 adsorbed under 0.25-0.5 $\times 10^{-3}$ mm pressure on Mg and Ca getter films (from the metals evapd. under 1.5×10^{-3} mm Hg) plotted against the equil. pressure. The gas was adsorbed onto the surface of the gradually crystg. metals; thus the gas was prevented from infiltrating into the crystals or impeding their growth. BaN_6 evapd. at 850°K under the residual N_2 pressure above 4×10^{-3} mm Hg to form a film on the wall at 300°K showed an abnormally large clean-up effect. A Mg getter film with similar ability was also produced.

1049. VEĬS, A. L. AND ROZLOVSKIĬ. **The mechanism of combustion of iron.** *Zhur. Fiz. Khim.* 23, 1305-10(1949).—*C.A.* 44, 2832*f*.

Cutting Fe by burning in O_2 was considered from the view-point of chem. kinetics. Presumably, the rate of reaction was detd. by the diffusion through the oxide film coating the Fe and the flow of this film. The surface temp. of burning Fe was 1550-1600°C (optical pyrometer). There was no "ignition temp." of Fe.

1050. WENTRUP, H. AND REIF, O. **The solubility of nitrogen in iron melts with chromium, manganese and nickel additions.** *Arch Eisenhüttenw.* 20, 359-62(1949).—*C.A.* 44, 4386*d*.

The absorption of N_2 was detd. at 1600 and 1700°C and at the solidification points. Cr and Mn increased the soly. of N_2 in Fe, while Ni decreased it. Increasing the temp. decreased the N_2 soly., and at the solidification point N_2 was evolved. Addn. of Mn to Fe-Cr melts increased N_2 absorption greatly, while addn. of Ni and higher temps. reduced N_2 soly. Solidification of Fe-Cr-Mn and Fe-Cr-Ni melts was also accompanied by N_2 evolution.

1051. WIEMER, H. AND HANEBUTH, R. **Improvement of the mechanical properties of sintered iron by oxygen treatment.** *Arch. Metallkunde* 3, 129-32 (1949).—*C.A.* 43, 9000*i*.

The tensile strength, elongation, and impact strength of sintered plain Fe can be improved by preheating in an oxidizing atm. Hardness and d. are not affected. The optimum oxidation temp. lies between 400° and 500°C. Best results are obtained when between 1 and 3% oxide is formed. The oxidizing treatment is more effective on porous pieces. It is definitely present, but not as marked on reduced spongy powder as on materials having solid particles.

1052. ZAGAR, L. **The activated state of desorbed gas molecules. II.** *Monatsh.* 80, 702-7 (1949).—*C.A.* 44, 7131*i*.

Pt, but not Hopcalite II, activated O_2 for subsequent reaction with CO. Neither back-diffusion of CO nor entrainment of Pt particles can account for the results. The amt. of CO_2 formed increased from 150° to 350°C; it decreased exponentially as the velocity of the O_2 stream increased. It decreased with increasing distance of the catalyst from the point of mixing of the O_2 with CO. The half-life of the active state was about 0.25 sec. Pt also activated H_2 for subsequent reaction with S vapor.

1053. ALLEN, J. A. AND MITCHELL, J. W. **The adsorption of gases on copper films.** *Discussions Faraday Soc.* **1950**, No. 8, 309-12, discussion 312-14.—*C.A.* 45, 9990*g*.

Troublesome dead-space corrections were eliminated and an uncontaminated film of uniform thickness obtained by evapg. Cu from a thoroughly outgassed bead mounted on a W filament at the center of a glass bulb. The results with O_2 in the range − 183° to 74°C indicated that the adsorptive properties of the films at low temps. and their behavior at the higher temps. were stongly dependent on the thermal history of the films.

1054. ARIZUMI, TETSUYA AND KOTANI, SEIICHI. **Oxidation of the evaporated barium films.** *J. Phys. Soc. Japan* 5, 70-5(1950).—*C.A.* 45, 5544*i*.

Typical pressure-cond. curves are given for a "getter" during the introduction of O_2. The "getter" film is granular in most cases. Oxidation proceeds uniformly from the surface at first and then along crystal boundaries. As the thickness of the oxide layer grows, many cracks are induced, recovering the absorption ability.

1055. ARIZUMI, TETSUYA AND IMAEDA, KUNINOSUKE. **Absorption of nitrogen by evaporated film of barium.** *J. Phys. Soc. Japan* 5, 169-73(1950).—*C.A.* 45, 2724*f*.

Pressure changes for const. flow and const. vol. were measured for absorption of N_2 by a Ba getter in an exptl. cathode tube. Effects of temp., of adsorption, and of diffusion are treated.

1056. AVERY, D. G. **Some optical properties of evaporated layers of silver, copper, and tin.** *Phil. Mag.* 41, 1018-31(1950).—*C.A.* 45, 2737*i*.

Multiple-beam interference measurements of the relative phase changes on reflection at a no. of layers of Ag, Cu, and Sn were made, together with measurements of the ellipticity of the light reflected at these layers. The variation of these quantities with the thickness of some layers of Ag was discussed.

1057. BAILEY, G. L. J. AND WATKINS, H. C. **Surface tensions in the system solid copper-molten lead.** *Proc. Phys. Soc.* **63B**, 350-8 (1950).—*C.A.* 44, 7607*h*.

Around 850°C the surface tension between Cu grains was 640 dynes/cm and between Cu and the equil. Pb-Cu liquid-phase 340 dynes/cm. The surface tension of a Cu-gas surface in H_2 or A was 1800 dynes/cm. When Pb vapor was present in the gas atm. at a partial pressure of the order of 0.1 mm Hg the surface tension of the Cu-gas surface had the much lower value of 780 dynes/cm. The reduction was due to the adsorption of Pb at the Cu-gas surface. The failure of Pb to spread readily on Cu appeared to be a feature of the Pb-Cu system, and was not due to contamination of the surface.

1058. BEVAN, D. J. M. AND ANDERSON, J. S. **Electronic conductivity and surface equilibria of zinc oxide.** *Discussions Faraday Soc.* **1950**, No. 8, 238-41, discussion 241-6.—*C.A.* 45, 9989b.

The electronic cond. in air at 500-1000°C varied widely according to prepn. of the oxide. At low O_2 pressures the cond. was quasi-metallic, and fairly reproducible for samples irrespective of their origin. It was suggested that this involves a diffusion process, which promoted a heterogeneous surface. The bulk-phase cond. of zinc oxide was probably high, but electrons were trapped by chemisorption of O_2 on the surface.

1059. BIGUENET, CH. **Photoadsorption in a thin layer of barium.** *Le Vide* 5, 831-6(1950).—*C.A.* 45, 31*i*.

Diode characteristics were affected by illumination. This was attributed to Ba adsorption in thin layers on the W anode. A calcn. of energy data, showed that a part of the Ba was adsorbed as Ba^{++}. Light transformed adsorbed Ba atoms to Ba^+, thus modifying the contact potential between cathode and anode.

1060. BLANC-LAPIERRE, ANDRÉ AND PERROT, MARCEL. **Current-voltage characteristic of very thin silver films for elevated values of the electric field.** *Compt. rend.* **230**, 1641-3(1950).—*C.A.* 44, 10423*f*.

Films of Ag less than 10 mμ thick were studied under elec. fields up to 10,000 v./cm. A considerable departure from Ohm's law was obtained probably through a mechanism of conductibility due to the lacunar structure.

1061. BOORSE, H. A. AND DASH, J. G. **Transport rates of the liquid He II film over various surfaces.** *Phys. Rev.* 79, 1008(1950).—*C.A.* 44, 10419*g*.

The rate of transport was reported at 1.3, 1.5, 1.8, and 2.0°K for Pyrex glass, lucite, stainless steel, Pb, cold-rolled steel machined Cu, polished Cu, etched Cu, and oxidized etched Cu. It was uncertain whether effects obtained with metals in the superconducting state and with magnetized metals were real.

1062. BOSE, B. N. AND HAWKES, M. F. **Kinetics of the eutectoid transformation in alloys of iron and nitrogen.** *J. Metals* 188, No. 2, Trans., 307-16 (1950).—*C.A.* 44, 3423*h*.

The alloy of 2.35 wt-% N, balance Fe, was analogous to the eutectoid Fe-C alloy with respect to transformation to "pearlitic" and "martensitic" structures. Isothermal transformation at all temps. was slower in the N_2 alloy, and the N-austenite was far more stable with respect to transformation to martensite.

1063. BURSHTEĬN, R. KH.; SUROVA, M. D., AND ZAĬDENMAN, I. A. **Effect of oxygen adsorbed on iron upon the contact potential difference.** *Zhur. Fiz. Khim.* 24, 214-23 (1950).—*C.A.* 44, 6743*f*.

A W cathode was kept in a vacuum while an Fe anode adsorbed O_2. After a definite vol., a, of O_2 was adsorbed at temp. T, Fe was cooled to room temp., the vessel was evacuated, W introduced into it, and the potential measured. The temp. of Fe rose to 95°C during this measurement. The true surface S of Fe (wire coil) was detd. from the adsorption of O_2. At T = 100°, 150°, and 270°C the potential increased with a/S to a max. at 0.63 v. and 22 × 10^{14} mol./cm^2, 0.49 v. and 35 × 10^{14}, and 0.19 v. and 72 × 10^{14}, resp., and then decreased. Increase in the potential meant decrease in the work function; this decrease was unexpected and presumably showed that O_2 was adsorbed under the top layer of Fe.

1064. Carli, F. de and Collari, N. **Thermogravimetric study of the oxidation of metals.** *Ann. chim.* (Rome) **40**, 117-31 (1950).—*C.A.* **45**, 5006*c*.

The oxidation at elevated temp. of Armco steel contg.: C 0.019, Mn 0.017, S 0.02, P 0.008, Cu 0.05%, trace Si, and balance Fe (%) is followed by recording wt changes. The temps. were 445°, 480°, 590°, 600°, 700°, 800°C. The activation energies are in cal/mole, for various temp. intervals: (718-753°) 14,090; (753-863°) 19,029; (863-873°) 106,200; (873-973°) 49,210; (973-1073°) 33,475.

1065. Chufarov, G. I.; Zhuravleva, M. G., and Tatievskaya, E. P. **Reduction and dissociation of oxides of cobalt and of nickel.** *Doklady Akad. Nauk S.S.S.R.* **73**, 1209-12(1950).—*C.A.* **45**, 426*i*.

The kinetic curves of the reduction of CoO, prepd. by dissocn. of 98% Co_3O_4 in a N_2 stream at 950° (resulting in a product 99% pure, surface area 0.45 m²/g by the N_2 adsorption isotherm), plotted in terms of the rate (g O_2 taken off the oxide/min.) as a function of the degree of reduction, at 200, 250, 300, and 350°C, in a closed system with circulating H_2 gas under 300 mm Hg, show initial autocatalysis and a max. of the rate at about 25% reduction. The apparent activation energy is 13.0 kcal./mole. Under the same conditions, the curves for Co_3O_4 (98%) show a max., corresponding to reduction of Co_3O_4 to CoO, followed, at least at 350°, by a min. and a 2nd, lower max.; the part of the curve beyond the max. corresponds to reduction of CoO to Co.

1066. Cornuault, P. **The adsorbed phase on catalysts.** *J. Chim. Phys.* **47**, 157-64(1950).—*C.A.* **44**, 8213*h*.

The kinetics of desorption of H_2, CO, CO_2, and CH_4 from a Ni-Al-Mn-kieselguhr Fischer-Tropsch catalyst (reduced in H_2 at 475°C) was measured on samples: (I) sealed off at 450°C immediately after reduction, (II) cooled from 475° to 175°C and maintained 4 hrs in H_2 at this temp., and (III) kept 113 hrs in H_2 at 175°C. The evolution of gas from II as the temp. increased was very similar to that from III. The energy of activation of desorption up to 200°C was about 19 kcal. On both samples II and I, the energy of activation of desorption is about 29 kcal. at 450°. Evolved gas contd. 73 to 100% H_2; the other components were small amts. of CO_2, CO, and CH_4 coming from undecompd. carbonates of the original catalyst.

1067. Cubicciotti, Daniel D. **The oxidation of zirconium at high temperatures.** *J. Am. Chem. Soc.* **72**, 4138-41(1950).—*C.A.* **45**, 1412*e*.

The rate of consumption of O_2 by ductile Zr metal was studied from 600 to 920°C. The oxidation curves were parabolic at all temps. except 920°, where a small deviation toward linear was observed. The oxidation rates were not affected by changing the O_2 pressure from 0.1 to 20 cm.

1068. Dankov, P. D. and Churaev, P. V. **The deformation effect of the surface layer of a metal upon oxidation.** *Doklady Akad. Nauk S.S.S.R.* **73**, 1221-4(1950).—*C.A.* **45**, 1479*g*.

The stresses produced on the surface of a metal as a result of the formation of an oxide film were detd. by measurements of the curvature of a thin mica foil coated on one side with a film of metal deposited by evapn., upon admission of O_2. The curvature was detd. with the aid of a pointer attached to the foil. On oxidation with 10-12 mm Hg of O_2, at room temp., films of Fe and of Ni bended in such a way that the metal-oxide layer was on the convex side, whereas Mg films bended in the opposite direction. The rate of the deformation was greater in the beginning, and then either became const. or slowed down considerably. The oxide films were actually cracked long before the max. stress and strain were reached, and that further oxidation took place at the spots bared.

1069. Devaux, Henri. **Thin layers of acetic, formic, and carbonic acids.** *Compt. rend.* **230**, 1122-4 1950.—*C.A.* **44**, 7120*e*.

A unimol. layer of acetic or formic acid on Hg is indissolubly tied as shown by its complete loss of volatility, even after compression to a small surface area. Further compression causes a rigid state, in which the acid is completely insol. in water. When returned to the liquid state by expansion, the unimol. layer absorbs water, but only in a tangetial sense, expelling it on recompression.

1070. Dravnieks, Andrew. **The kinetics of the zirconium-nitrogen reaction. The oxidation of several metals in activated oxygen at high temperatures.** *J. Am. Chem. Soc.* **72**, 3568-71; 3761-7 (1950).—*C.A.* **44**, 10470*e*; 10470*f*.

The initial rate of the Zr-N_2 reaction between 862° to 1043°C obeyed the parabolic law with an activation energy of 52 kcal. independent of pressure. For reactions of long duration the rate increased as compared with the initial parabolic rate. The rate consts. were sensitive to the origin of the Zr samples. The oxidation of Cu, Ta, Zr, Mo, and Ni in ordinary and in activated oxygen were compared. Only in the case of Cu were reproducible differences caused by the presence of an excess of free O atoms in O_2. Gases in which the monatomic O accelerated, retarded, or did not affect the rate of oxidation were described.

1071. Druyvesteyn, M. J. **The phenomenon of internal oxidation.** *Métaux & corrosion* **25**, 277-82(1950).—*C.A.* **45**, 9448*e*.

In a 1% Mg-Ag alloy the stable MgO which is formed, limits the internal oxidation. In Ag alloys with Cu the surface layer consists of CuO. Cu-Ag alloys have greater hardness than those alloys heated *in vacuo*. Microscopic researches revealed that MgO is very stable while CdO is much less stable in Ag (after oxidation no pptn. is observed in Mg-Ag alloys whereas in Cd-Ag alloys globular ppt. is noted). Application of thermodynamics to internal oxidation is considered in explaining this phenomenon.

1072. Duval, Xavier and Niclause, Michel. **Coefficients of accomodation of acetaldehyde at 273°K on platinum between 1000 and 1300°K.** *Compt. rend.* **231**, 518-19(1950).—*C.A.* **45**, 3226*i*.

The power dissipated by the gaseous heat cond. and the variation of C_v with temp. permitted the detn. of max. and min. values of the coeffs. of accomodation α_i for the internal energy of rotation and vibration. For CH_3CHO these are: 1000°K 0.21-0.37, 1100° 0.19-0.35, 1205° 0.17-0.33, 1310° 0.15-0.31. Since α_i is much less than 1, the mols. of CH_3CHO which leave the Pt filament have an av. internal energy which corresponds to temps. much lower than that of the filament.

1073. Ebert, H. and Trommsdorf, G. **Diffusion of silver in gold.** *Z. Elektrochem.* **54**, 294-6 (1950).—*C.A.* **45**, 1835*c*.

The diffusion of Ag in Au was detd. at several temps. from 806 to 1017°C. The temp. dependence of the diffusion rate obeyed an Arrhenius formula: $D = 2095 \exp. (-37{,}000/RT)$ ($D = cm^2/day$, $R = 1.987$ cal/degree mole and $T = °K$).

1074. Erbacher, Otto. **Active centers on metals.** *Angew. Chem.* **62A**, 403-4 (1950).—*C.A.* **45**, 413*c*.

It is assumed that active center, being disturbed surface areas at at. extent, can be annealed by surface temps. close to about 2/3 of the m.p. of the metal. Migration of atoms can take place, resulting in the smoothing out of the surface defects.

1075. Evans, U. R. **Some aspects of the protection of iron and steel against corrosion.** *J. Oil & Colour Chemists' Assoc.* **33**, 452-8(1950).—*C.A.* **46**, 9856*i*.

Fe oxidizes in dry air, but very slowly, and with no visible change. In H_2O contg. O_2, visible rusting may occur to Fe, even in the absence of acid. If O_2 is supplied to the Fe surface at a slow rate, the $Fe(OH)_2$ formed is converted into the less-sol. FeOOH (rust) at a distance from the metal, and this rust cannot prevent further attack which continues indefinitely. If the O_2 supply is higher, conversion to the ferric condition occurs at the metal-liquid interface, and the reaction soon stifles itself. The inference is that O_2 can sometimes act as a deterrent to corrosion.

1076. Fekete, L. **The theory of the degassing of molten metals by means of vacuum.** *Acta Tech. Acad. Sci. Hung.* **1**, No. 1, 33-49 (1950).—*C.A.* **45**, 4186*h*.

It was possible to calc. the amt. of H_2 escaping in the form of bubbles and the amt. remaining in the melt, in terms of the initial H_2 content. Different pressures and different depths of bath were assumed.

1077. Fischer, W. A. and Ende, H. vom. **The oxygen content of soft iron melts and the solubility of oxygen in solid iron.** *Arch. Eisenhüttenw.* **21**, 297-304 (1950).—*C.A.* **45**, 1480*h*.

Expts. with FeO slags satd. with FeO and SiO_2 in a high-frequency furnace were reported. The reduced O-activity of CaO-satd. FeO slags was ascribed to the presence of Ca ferrite in molten slag in which as much Fe oxide was present as corresponded to binding the CaO as $3CaO.Fe_2O_3$. The soly. of O in solid Fe was found to be 0.05-0.06%.

1078. Fujiwara, Shizuo. **Absorption of nitrogen by zirconium and iron.** *Bull. Chem. Soc. Japan* **23**, 20-2(1950).—*C.A.* **45**, 18*e*.

The wt-increase of Zr and Fe powders due to absorption of N_2 at increasing temps. started at 265° and 650°C, resp. A 1st equil. at 600° and 730°C, and a 2nd at 900-50° and 945°C, resp. was found. Zr-Fe powders contg. 28.1 and 29.9% Zr exhibited starting and equil. temps. similar to the pure Fe powders.

1079. Fukagawa, Shukichi. **Activation of a thoria emitter by zirconium.** *Mem. Coll. Sci., Univ. Kyoto Ser.* **A**, **26**, 45-62(1950).—*C.A.* **47**, 6759*g*.

The work functions of the "ThO_2-Zr-W" emitters were consistently lower than comparable "ThO_2-W" emitters. "ThO_2-Zr-W" emitters gave a large emission without the preliminary heat-treatment necessary in the case of "ThO_2-W" emitters. The activation energy for evapn. of Th atoms from the "ThO_2-W"-type emitter was found to be 5.48-4.02 e.v. as compared with a mean value of 3.0 e.v. for the activation energy for evapn. of Th atoms from "ThO_2-Zr-W"-type emitters. The mechanism of activation by Zr was due to the strong affinity of Zr for O.

1080. Gray, T. J. **Semiconductivity and catalysis.** *Discussions Faraday Soc.* **1950**, No. 8, 331-7:—*C.A.* **45**, 9991*b*.

A technique is described for studying the adsorption of very small quantities of gases by measuring the variation in semicond. of evapd. metal films.

1081. Gulbransen, Earl A. and Andrew, Kenneth F. **Kinetics of the reactions of columbium and tantalum with oxygen, nitrogen, and hydrogen.** *J. Metals* **188**, No. 3, Trans. 586-99 (1950).—*C.A.* **44**, 4359*h*.

At 10^{-6} mm or lower, Cb lost wt below 464°C and Ta lost wt below 605°C, whereas at higher temps. the metals acted as getters. The reaction data of Cb with O_2 (200-375°C) and that of Ta (250-450°C) fitted a parabolic rate law and energies of activation of 22,800 cal/mol., and 27,400 cal/mol. were calcd. from the temp. dependence of the rate-law consts. At 350°C the order of increasing rates of reaction was Ti, Zr, Ta, and Cb. The reactions of Cb and Ta with N_2 were studied between 500-850°C. The H_2 reaction product on Cb was stable under 10^{-6} mm of Hg to a temp. of 250°C. Above this temp. the reaction product decomposed.

1082. Gulbransen, Earl A. and Andrew, Kenneth F. **The kinetics of the reactions of beryllium with oxygen and nitrogen and the effect of oxide and nitride films on its vapor pressure.** *J. Electrochem. Soc.* **97**, 383-95 (1950).—*C.A.* **45**, 1411*i*.

The exptl. data between 350-950°C can be fitted by the parabolic rate law except for the initial period of the reaction. A plot of log K/T vs. 1/T gave an energy of activation of 50,300 cal per mole. Vacuum-treated Be had the smallest parabolic reaction-rate const. at 900°C of any metal or alloy that was studied. The reaction with N_2 was studied over the temp. range of 600° to 925°C.

The data was fitted by the parabolic rate law. A comparison with the O reaction showed that the rate of reaction was somewhat smaller. A plot of log K/T vs. 1/T gave an energy of activation of 75,000 cal per mole. No reaction was observed with H_2 over the temp. range of 300° to 882°C.

1083. Gulbransen, Earl A. and Andrew, Kenneth F. **The kinetics of the reactions of vanadium with oxygen and nitrogen.** *J. Electrochem. Soc.* **97**, 396-404(1950).—*C.A.* **45**, 1412*c*.

The reaction of rolled V sheet with O_2 was studied between 400° to 600°C with specimens weighing 0.1264 g and having a surface area of 1.4 cm^2. The data could be fitted to the parabolic rate law except for the initial period of the reaction. A plot of *log K/T* vs. *1/T* gave an energy of activation of 30,700 cal per mole. The oxidation of V could be compared with the corresponding reactions on Nb and Ta, since the oxide was sol. at high temps. and the extent of reaction was of the same order of magnitude. The rate of reaction with N_2 was much less at a given temp. than the corresponding oxidation reaction.

1084. Harkins, W. D. and Loeser, E. H. **Surfaces of solids. XIX. Molecular interaction between metals and hydrocarbons.** *J. Chem. Phys.* **18**, 556-60(1950).—*C.A.* **44**, 9211*i*.

The energy of interaction between a hydrocarbon and a metal increases rapidly in the order Cu, Ag, Pb, and Fe. The values of the work of adhesion at 25°C for the clean metals are Cu 69, Ag 77, Pb 89, and Fe 93. For the oxide-coated metals the values are only slightly higher. These increase with decrease of temp. For hexane they are essentially the same at 0° as to heptane at 25°C. Isotherms for heptane are given for both 25° and 15°C. The use of adhesion tension should be abandoned, since it is one of the most prolific sources of error in surface science.

1085. Harris, Louis; Jeffries, David, and Siegel, Benjamin M. **The thermal stabilization and sintering of gold smoke deposits.** *J. Chem. Phys.* **18**, 261-5(1950).—*C.A.* **44**, 9211*g*.

Gold smokes made by evapn. in an inert-gas atm. are initially in a thermodynamically unstable state. Measurement at different temps. of the change of resistance assocd. with the loss of vacant sites gave a value of 23.5 kcal./g atom for the activation energy of this process. When heated above 100°C the deposits sintered rapidly and underwent pronounced changes in optical properties. However, a gold smoke deposit could be stabilized, by heat-treatment at 70°C, so that sintering proceeded at an appreciably slower rate.

1086. Heusler, Otto. **Intercrystalline corrosion of coppersilicon alloys by atmospheric oxygen.** *Z. Metalkunde* **41**, 261-4 (1950).—*C.A.* **45**, 102*h*.

Oxidation of Cu-Si alloys in air at 20° to 450°C was increased by small amts. of As, Bi, Ge, Pb, Sb, Sn, and Tl, and decreased by small amts. of Be and Zn. No appreciable effect was produced by Ag, Al, Ca, Cd, Co, Cr, Fe, Hg, Mg, Mn, Mo, Ni, P, Se, Ti, V, and W.

1087. Hüttig, G. F.; Schreiner, H., and Klein, R. **Change of the binding strength between adsorbents and adsorptives.** *Monatsh.* **81**, 101-10 (1950).—*C.A.* **47**, 378*d*.

Exptl. work on Cu/CH_3OH, Fe/CH_3OH, α-Al_2O_5/CH_3OH, and $BaSO_4/CH_3OH$ were tabulated. Known principles were discussed.

1088. Imai, Yunoshin and Ishizaki, Tetsuro. **Nitrogen as alloying element in steel. II. Effect of nitrogen on the temper brittleness of steels.** *Nippon Kinzoku Gakkaishi* **14B**, No. 2, 52-6 (1950).—*C.A.* **45**, 5591*d*.

The effect of 0.1% Al, 0.15% Ti, and 0.3% Ti (as the deoxidizer and denitrifier) on the temper brittleness of steels was studied by means of the impact test. The denitrifying capacity of Ti was higher than that of Al, although more Ti and Al should be added for complete denitrification. The P (0.056-0.057%) in steels promote the effect of N_2 on the temper brittleness. In shortage of N_2, temper brittleness due to C occurred which showed that N_2 had great effect on the behavior of the C in α-Fe.

1089. Imai, Yunoshin and Ishizaki, Tetsuro. **Nitrogen as the alloying element in steels. I. Effect of nitrogen on the temper-brittleness in steels.** *Science Repts. Research Insts. Tohoku Univ. Ser.* **A,2**, 890-908 (1950).—*C.A.* **46**, 4979*c*.

On tempering steels at temps. below 580°C, a brittleness not explained by a carbide soly. theory was correlated with N_2 content of the steel and its heat-treatment. Quenched specimens contg. more than 0.010% N_2 reheated to 400-650°C and slowly cooled gave curves showing increased brittleness when tempering was done at 550-80°C. C, Cr, and Ni did not affect this property, but nitride formers, as Al, Ti, Mo caused its disappearance.

1090. Iwamura, Harero; Shiota, Noburo, and Onozaki, Choei. **Effects of gases on properties of aluminum and its alloys. II.** *Nippon Kinzoku Gakkai-si* **14B**, No. 3, 65-8 (1950).—*C.A.* **46**, 7505*g*.

The effect on torsional properties of gases in Al and its alloys contg. about 4-5% each of Si, Cu, Mg, Zn, or Ni was detd. by impact and corrosion tests. Addn. of a small amt. of H_2 had considerable effect on properties. It improved the impact value but was unfavorable in the corrosion tests in 10% NaOH soln. when compared to ordinary Al and its alloys.

1091. Jungers, J. C. and Coussemant, F. **The effect of adsorption on the course of catalytic reaction.** *J. chim. phys.* **47**, 139-44 (1950).—*C.A.* **44**, 10441*e*.

The kinetics of gas-phase and liquid-phase catalytic reactions are interpreted in terms of the relative adsorptions of reactants and products. Reactions discussed include the hydrogenation of CO and CO_2 to CH_4 over Ni of C_6H_6 to cyclohexane in the presence of CO_2 of acetone to isopropyl alc. acetylene to ethylene and the dehydrogenation of a secondary alc. to a ketone. The hydrogenation of phenol to cyclohexanone takes place through the intermediate formation of cyclohexanone. A quant. evaluation of the adsorption coeffs. and the several reaction velocity consts. is made.

1092. Keier, N. P. **The heterogeneity of the surface of catalytically active nickel oxide.** *Doklady Akad. Nauk S.S.S.R.* 72, 1071-4 (1950).— *C.A.* 44, 9223*i*.

The kinetics of adsorption of C_2H_2 gas by NiO (prepd. by decompn. of $NiCO_3$ at 300°C under not over 10^{-4} mm Hg, and subsequent treatment in vacuo at 400°C) are representable by the equation $q = At^{1/n}$, where q = amt. adsorbed in cc. S.T.P. on 0.75 g NiO, initial C_2H_2 pressure 2.23 mm Hg, T = time in min. Plots of log q against log t are perfectly linear, with the slopes increasing with rising temp. (- 19.6 and 0°C). There is strong evidence for the surface-heterogeneity theory, and against attempts at interpretation on the basis of repulsive interactions between adsorbed mols.

1093, Keidr, N. P. and Roginskii, S. Z. **Investigation of the heterogeneity of active surfaces by the differential isotopic method. I. The active surface of metallic nickel and of zinc oxide.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* **1950**, 27-38.—*C.A.* 44, 5690*g*.

The heterogeneity of the surface of an active Ni catalyst (surface area 1.5-2m^2/g) was demonstrated by expts. of consecutive adsorption, at room temp., of H_2 and of D_2, or D_2 and then of H_2. Prior to the adsorption expts. 1.05-g samples of the catalyst were outgassed at up to 450°C under 10^{-5}mm Hg reduced once more with H_2 at 450°C, and again outgassed at 530°C. Data for a typical run were: 1st adsorption, 0.095 cc. D_2 S.T.P. under 1.48 mm Hg in 9 min. at room temp.; after short evacuation, 2nd adsorption, 0.04 cc. H_2 under 3.08 mm Hg in 9 min. at room temp. followed by 1.5 min. evacuation the % of D_2 and of H_2, resp., in the gas desorbed was: at room temp., 5 and 95; at 2-65°C, 0 and 100; at 170-220°C, 0 and 100; at 300-20°C, 40 and 60; at 420-70°C, 95 and 5; at 520°C, 100 and 0; at 530°C, 100 and 0. Consequently, the isotope adsorbed first was desorbed last.

1094. Kemball, C. **The absorption of vapors on mercury. IV. Surface potentials and chemisorption.** *Proc. Roy. Soc.* **A201**, 377-91 (1950).— *C.A.* 44, 8194*d*.

An app. was constructed to measure the surface potential of adsorbed vapors on Hg. There was a change in potential of 0.055 v. at the phase change assocd. with the alteration in the orientation of toluene mols. adsorbed on the surface of the Hg. CCl_4, hexachlorethane, and $CHCl_3$ vapors reacted with Hg, and the rate of the reaction was detd. The kinetics indicated that the substances dimerize under the action of the Hg surface with negligible activation energy. The rate of reaction with CCl_4 was in agreement with the calcd. rate, assuming that the activated complex consisted of two physically adsorbed mols. loosely held together and able to move over the surface. MeI vapor reacted with Hg only when illuminated with light from a Hg lamp.

1095. Krause, A. **Catalytic properties of rust.** *Przemysl Chem.* **6(29)**, 318-23(1950).—*C.A.* **45**, 10179*c*.

Fe rust formed in moist air at moderate temps. is mainly composed of γ-FeOOH. The catalytic activity of Fe rust is based on the presence of free HO and HO_2 radicals taking part in a chain reaction accompanied by electronic resonance in a complicated oxidation-reduction system.

1096. Kruger, H. O. and Robinson, M. L. **Corrosion of copper by trace constituents of natural gas.** *Gas* **26**, No. 4, 31-5 (1950).—*C.A.* **46**, 2781*e*.

At room temp. the mercaptans were noncorrosive, but H_2S at relatively low concns. caused localized corrosion (black clumps) on Cu surfaces in the field; these clumps grew closer together, finally forming a continuous but lumpy surface. (Uniform corrosion is noted on clean Cu surfaces with H_2S.) These corrosion products had a greater specific vol. than the parent metal and spalled off, and were carried with the gas stream.

1097. Kwan, Takao. **Adsorption of carbon dioxide on reduced nickel.** *J. Chem. Phys.* **18**, 1309-10 (1950).—*C.A.* **45**, 18*f*.

Adsorption isotherms were derived for the adsorption of CO_2 as CO_2, CO + O, and C + 2O. Exptl. evaluation was accomplished at 150° and 200°C, with equil. pressures from 0.0001 to 0.1 mm Hg. The differential heat of adsorption was almost const. at 22 kcal./mole. The exptl. values for fraction of surface covered agreed best with the isotherms for complete dissocn.

1098. Legenchenko, I. A. **Nitrides and kinetics of decomposition of ammonia on iron catalysts.** *Zhur. Fiz. Khim.* **24**, 311-20 (1950).—*C.A.* **44**, 6713*d*.

Dry NH_3 was passed through an Fe catalyst at 400-450°C. The exit NH_3 was sepd. and detd., and the ratio N:H in the residual gas was detd. interferometrically. If this ratio R was less than 1:3, Fe nitride formation took place, and the amt. of it could be calcd. from R. During one expt., the rate of decompn. simultaneously, the rate of nitride formation decreased and became almost zero in 10-20 min. (when the rate of gas flow as 6-19 liter/hr). The decompn. of NH_3 and the formation of iron nitride took place on different surface patches. Decompn. of NH_3 could occur either directly or as a sequence: formation of iron nitride on inactive spots → migration of iron nitride to active spots → decompn. of iron nitride; poisons stopped the migration.

1099. Mallett, M. W. **Purification of argon.** *Ind. Eng. Chem.* 42, 2095-6 (1950).—*C.A.* 45, 1309*h*.

Argon was purified by passing through a bed of Ti heated to 850°C at a rate of 15 liters/hr. The O_2 and N_2 impurities of commercial grade A were gettered by Ti at 850°C. The treated A was sufficiently free of active gases to prevent tarnishing of U heated at 600°C.

1100. McGeary, R. K.; Stanley, J. K., and Yensen, T. D. **How to determine oxygen in metals by a fast vacuum fusion method.** *Steel* **126**, No. 10, 81-2(1950).—*C.A.* 44, 3841*a*.

The metal is melted in a graphite crucible in an evacuated system to convert oxides to CO which is passed over hot CuO to form CO_2. A part of the system is cooled by liquid N_2 which collects CO_2 and removes other gases by vacuum pumps. The CO_2 is expanded and its vol. measured. Accuracy is ±0.001% in 15 to 20 min. with 0.1-2.0 g samples.

1101. Mendelssohn K. and White, G. K. **Helium II transfer on metal surfaces.** *Nature* **166**, 27-8 (1950).—*C.A.* **44**, 8719*e*.

The rate of transfer of He II over different surfaces was investigated. Pt, Ni, and glass beakers were cleaned, polished, and baked *in vacuo* to remove any surface films. The rate of transfer was strongly dependent upon the nature of the surface of the beaker. At 1.2°K, the following rates (in units of 10^{-5} $cm^3/cm/sec$) are given: Pt (cleaned): 15.9; Pt (cleaned and baked) 21.4; Pt (polished and baked); 22.4; Ni (cleaned and baked): 24.3; glass (cleaned: 7.3).

1102. Mertens, E. **Fluidized heterogeneous catalysis by the method of currents.** *J. chim. phys.* **47**, 286-8, discussion, 288-9 (1950).—*C.A.* **44**, 7637*d*.

Results were reported on the hydrogenation of benzene at 200°C with a $Ni\text{-}Al_2O_3$ catalyst with grains 100 μ in diam., and on the oxidation of SO_2 on a Pt-silica gel catalyst with grains 150 μ in diam. In the former case the rate of reaction was approx. 12 times greater with the fluid catalyst than with a similar quantity of stationary catalyst. In the 2nd case the rate of the reation was negligible at very high rates of flow, increased with still slower rates of flow.

1103. Mitani, Kazuo. **The comparison of the exchange of the translational energy with that of the internal energy of gas molecules on solid surfaces. II. Measurement by means of molecular beams. 2.** *J. Chem. Soc. Japan, Pure Chem. Sect.*, **71**, 9-11 (1950).—*C.A.* **45**, 4507*b*.

The relation between accommodation coeff. for the internal energy and the total loss of heat from the heated filament was discussed. By the kinetic theory of gases, the accommodation coeff. was found to be calcd. from the heat loss and the accommodation coeff. for the translational energy. Only the principles of the expt. were given.

1104. Miyazaki, Shozo. **Catalytic decomposition of ammonia gas.** *J. Chem. Soc. Japan, Pure Chem. Sect.*, **71**, 424-6 (1950).—*C.A.* **45**, 6473*a*.

The catalytic decompn. of NH_3 gas in the presence of W was observed at the temp. 730-810°C, under the pressure 15 mm Hg. The theoretical equations explain the observed relations between the reaction velocities and the NH_3 and H_2 gas pressures. The heat of activation and the heat of adsorption of NH_3 gas on W are calcd. They are 46.4 kcal./mol. and 26.6 kcal./mol., resp.

1105. Moore, Walter J. **Parabolic oxidation rates of metals.** *J. Chem. Phys.* **18**, 231 (1950).—*C.A.* **44**, 5686*e*.

Thermodynamic consts. of the transition-state theory for the oxidation of Al, Fe, Zr, Ti, Ni, Cu, Co, Zn, and Be were compared. A schematic diagram of the potential-energy barriers for vacancy formation and diffusion showed that, for equal diffusion barriers, the higher the heat of adsorption, the lower the effective $\Delta H^{\ddagger}$. Since a high heat of adsorption implied an immobile adsorbed film, it may also be assocd. with a large neg. ΔS of adsorption.

1106. Mozgovoĭ, V. S. and Samarin, A. M. **Solubility of nitrogen in liquid chromium and in melts of chromium and silicon.** *Doklady Akad. Nauk S.S.S.R.* **74**, 729-32 (1950).—*C.A.* **45**, 7503*a*.

The equil. concns. of N_2 in wt % in liquid Cr were 1600°C, 4.08; 1650°C, 3.90; 1700°C, 3.84; 1725°C, 3.76; 1750°C, 3.54. The interaction of liquid Cr and N_2 occurred: $2\ Cr + \frac{1}{2}\ N_2 \rightleftarrows Cr_2N$ which $\Delta F = -7594.5 + 1.2727\ T$. The soly. of N_2 in Cr contg. 1.5, 7.25, 10.00, and 20.00% Si was 3.83, 1.98, 0.84, 0.33, at 1600°C; 3.68, 1.89, 0.74, 0.30 at 1650°C; 3.54, 1.72, 0.69, 0.28 at 1700°C; 3.08, 1.68, 0.62, 0.26 at 1750°C. At all Si contents ΔH was about −10,980 cal. At 1600°C the soly. of N_2 decreased with increasing Si content up to 40% Si and no special effect near CrSi was observed.

1107. Myers, Rupert H. **Some properties of tantalum** *Metallurgia* **41**, 301-4 (1950).—*C.A.* **44**, 5776*i*.

Ta absorbs gases strongly at about 1800°C, but they can be removed by heating above 2200°C. The best gettering temps. would be 1700-1900°C. The absorption of gas is accompanied by increases in hardness, elec. resistivity, and lattice parameter. Gas-hardened Ta retains its hardness and chem. resistance to attack by many reagents after heating in a high vacuum up to about 1800°C.

1108. Nickerson, Richard A. and Parker, Earl R. **Surface diffusion of radioactive silver on silver.** *Trans. Am. Soc. Metals* **42**, 376-86 (1950).—*C.A.* **44**, 6224*f*.

Diffusivity values for self-surface-diffusion of Ag, detd. in a vacuum of 10^{-6} mm of Hg, are 0.018, 0.03, and 0.147 cm^2 per hr at 225°, 250°, and 350°C, resp. The activation energy is approx. 10,300 cal per g at. wt.

1109. Parznjpe, V. G.; Cohen, Morris; Bever, M. B., and Floe, C. F. **The iron-nitrogen system.** *J. Metals* **188**, No. 2, Trans., 261-7 (1950).—*C.A.* **44**, 3423*i*.

The Fe-N system was investigated by x-ray diffraction measurements and a controlled nitrogenizing method. The latter was an innovation and depended on the relation between the nitrogenizing power of an $NH_3\text{-}H_2$ mixt. and the N-content of the Fe-N alloy produced. Several heretofore controversial features of the Fe-N phase diagram are clarified.

1110. Rhodin, T. N., Jr. **Single-crystal copper surfaces.** *J. Applied Phys.* **21**, 971-3(1950).—*C.A.* **45**, 16*i*.

Some surface-structure characteristics of single-crystal plates of Cu were detd. By use of phys. microadsorption isotherms of N_2 at 78.1°K, electron diffraction, and x-ray diffraction methods, it was tentatively concluded that the surfaces were essentially planar on a mol. scale, and that the surface atoms were arranged in an approx. undistorted lattice.

1111. RHODIN, T. N., JR. **Studies of copper surfaces by low-temperature adsorption isotherms.** *J. Am. Chem. Soc.* 72, 4343-8(1950).—*C.A.* 45, 3682*b*.

The true surface areas of metal surfaces as small as 10 cm were measured with an error of 6% from low-temp. adsorption isotherms using a specially designed vacuum microbalance technique. The isosteric heats of adsorption corresponding to an adsorption of one monolayer of N_2 were 3500 cal/mole on the (100) face of Cu and 2500 cal/mole on the polycrystal face for the particular surfaces studied. The effect of the progressive oxidation of a rough polycryst. surface of Cu was to decrease the surface area to a point where the roughness factor approached unity.

1112. RHODIN, T. N., JR. **Low-temperature oxidation of copper. I. Physical mechanism.** *J. Am. Chem. Soc.* 72, 5102-6(1950).—*C.A.* 45, 2755*i*.

By use of a sensitive quartz vacuum microbalance, surface areas were detd. from microadsorption isotherms, and the growth of very thin oxide films was followed with an error of 2%. The rate equation was found valid, with some limitations, for film thicknesses in the range of 5-50 A. and temps. from 78 to 300°K: $dx/dt = A$ exp. $(x_1/x - W/kT)$ where x was film thickness at time t, x_1 was a crit. film thickness, W was the energy of activation, and A is a temp.-independent const.

1113. RHODIN, T. N., JR. **The anisotroph of nitrogen adsorption on single-crystal copper surfaces.** *J. Am. Chem. Soc.* 72, 5691-9 (1950).—*C.A.* 45, 3681*h*.

Adsorption isotherms of N_2 at 78.1°, 83.5°, and 89.2°K and pressures of 0.160 cm were detd. on single-crystal and polycrystal surfaces, electropolished and H_2-reduced, with a sensitive quartz-beam vacuum microbalance. The vol. of gas, expressed in 10^{-6} g, required to form a monolayer (calcd. by the B.E.T. equation) decreased from 0.54 to 0.45 for the (110) face, from 0.47 to 0.45 for the (100) face, and remained const. at 0.44 for the (111) face over the measured temp. range. The apparent no. of surface Cu atoms per N_2 was calcd. as 1.8-2.2, 2.7-2.8, and 3.3, for the (110), (100), and (111) faces, resp. The differential heats of adsorption were calcd. and expressed as a function of the fraction of surface covered up to 2.0. The curves showed a max. at monolayer coverage.

1114. RIBAUD, GUSTAVE AND DEVIENNE, MARCEL. **Effect of the nature of the surfaces on the condensation of molecular jets of antimony.** *Compt. rend.* 231, 740-2(1950).—*C.A.* 45, 1842*f*.

Both photographically and by means of Geiger-Muller counters it was found that the ratios of Sb deposited on glass and on Al to that on Cu are 0.52 and 0.44, resp.

1115. SAITÔ, TSUNEZÔ. **Absorption of nitrogen by molten iron alloys. III. Study of iron-carbon and iron-silicon alloys.** *Science Repts. Research Insts. Tôhoku Univ.* Ser. A, 2, 909-16 (1950).—*C.A.* 46, 5508*c*

In the case of Fe-C alloys the satn. value of N_2 decreased with increase in C concn. In Fe-Si alloys the satn. value increased at first and reached a max. at approx. 0.5 wt % Si. It then decreased reaching a min. at a compn. corresponding to Fe_3Si and then increased to the compn. corresponding to FeSi. The effect of alloying elements on the rate of absorption of N_2 was also discussed. The rate was decreased by the addn. of Ni to the Fe and was increased by the addn. of C, Si, Mn, and Cr. The absorption of N_2 was a reaction of the 1st order.

1116. SASTRI, M. V. C. AND SRIKANT, H. **Adsorption of nitrogen at elevated pressures on a promoted iron synthetic-ammonia catalyst.** *Current Sci. (India)* 19, 343(1950).—*C.A.* 45, 7406*h*.

Adsorption isotherms were detd. for N_2 on an $Fe\text{-}K_2O\text{-}Al_2O_3\text{-}TiO_2$ catalyst at 7 temps. between 50 and 350°C, and from 15 to 50 atm. Adsorption at lower pressures (20 and 30 atm.) exhibited only 2 max. at 150° and 300°C, resp.; however, at 50 atm. 3 max. were observed, 100, 200, and 300°C. For an adsorption of 0.05 to 0.15 cc./g at 20 atm. a value of 23 kcal. was obtained for the isobaric head of adsorption.

1117. SHINOHARA, SHÔZÔ AND HOSHINO, RYÔSUKE. **The rectifying mechanism of an electrolytic condenser.** *Busseiron Kenkyû* (Researches on Chem. Phys.) No. 23, 28-34(1950).—*C.A.* 47, 2062*g*.

The thickness of the Al_2O_3 layer on the Al is calcd. from the measurement of the elec. capacity, the dielec. const. of the Al_2O_3 layer being assumed to be 10. It is 1.31, 0.705, and 0.502×10^{-5} cm for films anodized at 95 v. (1 hr), 49 v. (1 hr), and 24.5 v. (3 hrs), resp. The elec. charges are carried by Al ions which diffuse through the oxide layer forming thicker film as well as contributing the elec. current. The diffusion of Al ions is subjected to an elec. double layer of adsorbed anions and pos. charges induced on the surface of the Al anode.

1118. STANLEY, J. K.; HOENE, J. V., AND HUNTOON, R. T. **The oxidation of pure iron.** *Trans. Am. Soc. Metals.* preprint No. 5, 21 pp. (1950).—*C.A.* 44, 9886*h*.

The oxidation of high-purity electrolytic Fe (Puron) in air from 500° to 900°C proceeded by the common parabolic rate law, $W^2 = Kt + C$. The oxidation process as a function of temp. followed the usual exponential law. A Geiger counter x-ray spectrometer showed only one oxide, Fe_3O_4, at 500°C, but 3 oxides $\alpha\text{-}Fe_2O_3$, Fe_3O_4, and FeO at the higher temps.; metallographic examn. resolved the various oxide strata. FeO could be cooled to room temp. without decompn. to Fe and Fe_3O_4.

1119. TANAKA, YOSHIO AND SAKAI, MASATOSHI. **Structure of zinc black.** *Repts Sci. Research Inst.* (Japan) 26, 123-9(1950).—*C.A.* 45, 1835*h*.

Zn black condensed on the inner wall of a glass bell when metallic Zn placed within was vaporized by heating electrically under 1 mm Hg was composed of Zn and O_2 (7-8:1), not chemically combined but Zn microgranules adsorbing O_2. With excessive supply of O_2, ZnO, instead of Zn black, was formed. Zn black could adsorb a large amt. of O_2. This adsorption occurred rapidly in air and is facilitated by moisture if present.

1120. Trambouze, Yves. **Study of Fischer catalysts by differential thermal analysis.** *Compt. rend.* **230**, 1169-71(1950).—*C.A.* 44, 7132*a*.

Ni hydroxide and the gel formed by pptg. Ni with K_2CO_3 were heated to 500°C during 1.5 hrs. Both showed the dehydration of the hydroxide at 360-80°C by a strong endothermic reaction; the 2nd also showed the loss of adsorbed water at 100°C and the decompn. of the basic carbonates into CO_2, H_2O, and NiO at 220-40°C. Four other studies, one with a 1:1 mixt. of kieselguhr and Ni hydroxide heated variously to produce a silicate content of 15%, 8%, and 0% did not show the dehydration curve, but showed the carbonate decompn.

1121. Tsugakoshi, Osamu. **Clean-up of oxygen by barium-getter films.** *Repts. Sci. Research Inst. (Japan)* 26, 73-7 (1950).—*C.A.* 45, 2795*b*.

The Ba-getter film (800 A. thick adsorbed on a piece of mica from BaN_6 pyrolyzed under 2.5-3.5 × 10^{-3} mm Hg) increased its elec. resistance (*r*) parabolically under 10^{-5} mm Hg within a few min. of the end of heating, owing apparently to the growth of BaO on the surface. Ba films 500-4400 A. thick gave a rate of 6-20 cc/sec/cm^2.

1122. Turnbull, D. **Isothermal rate of solidification of small droplets of mercury and tin.** *J. Chem. Phys.* **18**, 768-9(1950).—*C.A.* 44, 7620*f*.

Hg droplets with a mean diam. of 3.8 μ were dispersed in methylcyclopentane; the mixt. was cooled and the vol. changes with time were followed dilatometrically. Most of the droplets solidified between −98 and − 102°C. At const. percentage solidification, the log of the nucleation frequency was a linear function of $1/T(\Delta T)^2$, where ΔT was the super-cooling.

1123. Turnbull, D. **Correlation of liquid-solid interfacial energies calculated from supercooling of small droplets.** *J. Chem. Phys.* **18**, 769(1950).—*C.A.* 44, 7620*h*.

The liquid-solid interfacial energy, σ, can be calcd. from the nucleation frequency at one temp.; the frequency was obtained from the max. supercooling. Values for σ thus obtained, in ergs/cm^2 were: Hg 24.4, Ga 56, Sn 54.5, Bi 54, Pb 33, Sb 101, Ge 181, Ag 126, Au 132, Cu 177, Mn 206, Ni 255, CO 234, Fe 204, Pd 209, Pt 240.

1124. Tylecote, R. F. **The adherence of oxide scales on copper.** *J. Inst. Metals* **78**, 301-26 (1950) (Paper No. 1281).--*C.A.* 45, 2836*d*.

Oxide scales on P-bearing Cu flake off more readily in lab. oxidation tests and in com. hot working than scales on pure or tough-pitch Cu (P-free). Scales on Cu are largely Cu_2O; P-contg. Cu_2O cannot accommodate plastic strains imposed by hot working or by differential contraction during heating and cooling in oxidation tests.

1125. Tylecote, R. F. **The oxidation of copper at 350°-900° in air.** *J. Inst. Metals* **78**, 327-50 (1950)(Paper No. 1282).—*C.A.* 45, 2836*b*.

Oxidation rates of P-free and P-deoxidized Cu were detd. from 350° to 900°C by the continuous weighing method. At 615°C and higher, both oxidize according to the parabolic law, and the rate consts. were similar for the 2 types. At lower temps., the initial stages of oxidation departed significantly from the parabolic mode and the oxidation probably followed a logarithmic law, the rates again being similar for the 2 types of Cu; as the scale thickens, the oxidation conformed more nearly to the parabolic law. At about 450° to 500°C, there was a change of slope in the plot of the parabolic rate const. against the reciprocal of the abs. temp., and at this temp. there was a similar change of slope in the analogous plot of the elec. cond. of the oxide film.

1126. Valensi, Gabriel. **Oxidation of cobalt at high temperatures.** *Métaux & corrosion* 25, 283-91(1950).—*C.A.* 45, 10028*e*.

Intervals of thermodynamic stability of oxides Co_2O_3, Co_3O_4, CoO are, resp., below 300°, between 300 and 900°, and above 900°C. Freshly cut Co forms an invisible film in air, which film reduces the rate of oxide diffusion. Statistical thermodynamics is used in interpreting phys. phenomenon of oxidations.

1127. Veith, W. **The quality and the mechanism of photoelectric emission of cesium-antimony layers.** *J. phys. radium* **11**, 507-13(1950).—*C.A.* 45, 2768*h*.

Photoelec. layers of Cs-Sb produced by evapn. first of a certain thickness of Sb and then Cs are particularly suitable for study since they are extremely sensitive photoelectrically and have a small no. of constituents. At max. sensitivity, the various layers can be considered as semiconductors. The influence of the addn. of O_2 is also studied and discussed. A comparison of these layers with Cs_2O, Ag, Cs, and others indicates that the most sensitive photoelec. layers are the semiconductors.

1128. Vero, J. A. **Theory of the degassing of molten metals.** *Acta Tech. Acad. Sci. Hung.* **1**, No. 1, 130-55(1950) (in Russian).—*C.A.* 45, 4186*i*.

The occlusion of gases in metals is discussed; also methods of removal, such as chilling the melt in the furnace, leaving the melt in a furnace free of the gas, displacement by insol. gases, and fusing under vacuum. Data are given for the various cases, using H_2 in contact with Fe, Ni, and Cu.

1129. Waché, X. **Oxidation of steels and alloys.** *Métaux & corrosion* 25, 267-76(1950).—*C.A.* 45, 9446*h*.

Special consideration is given to oxidation of iron base Fe alloys with Cu and Ni. The oxide in air at 1000°C on Fe, carbon steel, or alloy steels consists of 3 layers: (*a*) outside layers representing 10% of total thickness consisting of Fe_2O_3 and Fe_3O_4, (*b*) intermediate layer, representing 50% of total thickness, a mixt. of FeO and Fe_3O_4, (*c*) internal layer, in contact with the nonoxidized metal, representing 40% of the total, consists essentially of FeO.

1130. Wagener, S. **Method for measuring the efficiency of getters at low pressures.** *Brit. J. Applied Phys.* **1**, 225-31 (1950).--*C.A.* 45, 1836*g*.

A method was described for measuring the rate at which low-pressure air is taken up by a getter. Use was made of a special ionization gage to det. the efficiencies of uptake by Ba, Mg, Th, and Zr.

1131. Walter, Dean I. **Determination of oxygen in titanium.** *Anal. Chem.* 22, 297-303(1950).—*C.A.* 44, 3403*d*.

The vacuum fusion method seems necessary for detg. O_2 in Ti metal. The sample to be analyzed reacts with powd. graphite in the presence of Sn, to form stable Ti carbide and to reduce the various oxides to CO. The gases evolved are collected and analyzed. At a temp. of 1900°C, complete reduction is obtained in 30 min. Analysis of synthetic standards prepd. by diffusing O_2 gas into hot Ti metal indicated practically complete recovery of all O_2.

1132. Weber, Joseph and Laidler, Keith J. **The variation of rate of desorption with extent of surface coverage.** *J. Chem. Phys.* 18, 1418 (1950).—*C.A.* 44, 10412*i*.

Rates of desorption were increased markedly as the surface became more fully covered. This was demonstrated by use of a microwave technique with NH_3 and NH_3 contg. D on a singly-promoted Fe catalyst at 122°C. For example, a pressure of 0.4 mm of Hg increased the rate of desorption of NH_3 by a factor of at least 100. The results were interpreted in terms of repulsive forces between the adsorbed mols.

1133. Wert, C. A. **Measurements on the diffusion of interstitial atoms in body-centered cubic lattices.** *J. Applied Phys.* 21, 1196-7 (1950).—*C.A.* 45, 1835*c*.

The rate of diffusion of carbon in Ta and Nb and of N_2 in α-Fe was measured by effects on internal friction and anelastic after-effect. Data covering a range of 10^4 in rate were reported.

1134. Whitton, W. I. **Corrosion of iron covered by a thin film of neutral salt solution.** *Trans. Faraday Soc.* 46, 927-38 (1950).—*C.A.* 45, 4194*c*.

The corrosion of Fe covered by 0.5 *N* NaCl solns. and O_2 is examd. Owing to the combined effect of the high elec. cond. of the liquid film and the unrestricted supply of O_2 reaching the metal surface, the results are dependent almost entirely on the corrosion properties of the metal itself. Acceleration of corrosion of the "O_2 absorption" type may be caused by the catalytic effect of certain impurities themselves, and not necessarily of oxide films on the O_2 depolarization action.

1135. Wickert, K. and Kroll, J. **Metallic corrosion and absorption.** *Werkstoffe u. Korrosion* 1, 105(1950).—*C.A.* 44, 5785*d*.

Through 3 glass tubes, each contg. a sheet of Fe, water contg. definite amts. of CO_2 or of O_2 was passed. One Fe sheet was covered with $Fe(OH)_3$, one with activated carbon, and the third was bare. The loss in wt of the Fe sheets was used as a measure of the corrosion. If the active constituents of the water (O_2 or CO_2) were physically absorbed by the deposit on the metal, the corrosion rate increased in comparison to that on a deposit-free metal surface. If the active constituents of the water were chemically absorbed, the corrosion rate decreased.

1136. Wilkinson, P. G. and Birks, L. S. **Particle size of evaporated gold.** *J. Applied Phys.* 21, 60 (1950).—*C.A.* 44, 3768*c*.

Evapd. Au formed discrete granules invariably unless a contamination of tungstic oxide was present during evapn.

1137. Worner, H. W. **Surface hardening of titanium.** *Trans. Australian Inst. Metals* 3, 49-51 (1950); *Australasian Engr.* Nov. 7, 1950, 52-5.—*C.A.* 46, 7959*i*.

Ti is surface hardened by heating to 850-1000°C in air or O_2 at 10^{-3} to 10^{-2} mm Hg, or in He or A at atm. pressure with a similar concn. of O_2 and cooling slowly. Brief heating at the lower temp. with higher O_2 gives high surface hardness of shallow depth, while prolonged heating at the higher temp. with low O_2 gives deeper hardening but lower surface hardness.

1138. Zapffe, C. A. and Phebus, R. L. **Embrittlement of stainless steel by steam in heat treating atmospheres.** *Trans. Am. Soc. Metals*, Preprint No. 25, 11 pp. (1950).—*C.A.* 44, 9895*d*.

Bend-tests demonstrated a powerful and unrecognized effect of steam in embrittling the steel through the hydrogenizing effect of the metal-steam reaction. Steels which sustained a full bend of 180° when hardened from a dry atm. failed at angles as low as 20° when steam was admitted to the furnace atm. during heat treating; and steels which fractured at a given angle when quenched from normal air can be markedly improved by drying the furnace atm.

1139. Ziliani, Giuseppe. **Microscopic method for the determination of oxygen in steels.** *Met. ital.* 42, 225-9(1950).—*C.A.* 45, 497*b*.

A method for detg. O_2 in steels is based on the examn. of oxidized inclusions under the microscope (100 ×): $\% O = I_o D_o\, 205n/AP_o$, where I_o is the total area of oxide inclusion, D_o its sp.gr., A, the total area examd., n the no. of O atoms/mol., and P_o the mol. wt of the oxide. In an analogous manner the S content is given by $\% S = I_S D_S 410m/AP_S$, where m is the no. of S atoms and where subscript s refers to the sulfide inclusion. Comparison with data published by the U.S. Bureau of Standards shows good agreement.

1140. Aldrich, L. T. **The evaporation products of barium oxide from various base metals and of strontium oxide from platinum.** *J. Applied Phys.* 22, 1168-74 (1951).—*C.A.* 46, 1345*h*.

The evapn. products of BaO heated on ribbon filaments of Pt, Ta, Ni, Mo, and W, and of SrO on Pt were studied with a high-resolution mass spectrometer for pos.-ion analyses. Only on systems BaO on Pt, and BaO on Ni, and SrO on Pt were the evapn. processes reproducible without particular attention to procedure. BaO on Pt and SrO on Pt differed markedly in evapn. mechanism. At high temps. peaks were found due to Ba_2O^{++}, Ba_2O^{+}, $Ba_2O_2{}^{+}$, and other Ba compds. depending on the base metals used. A measurable ion current was found due to Sr^{+} ions evapd. from Pt.

1141. Arkharov, V. I.; Somova, E. V., and Chukina, T. P. **Internal adsorption of silver in platinum.** *Doklady Akad. Nauk S.S.S.R.* 76, 209-10 (1951).—*C.A.* 45, 6893*i*.

Pt with 0.5% Ag (10 × 15 × 1 mm) was heated 2 hrs to 1180°C (temp. of max. soly. of Ag) and quenched in H_2O. Upon immersion (5 min.) in 250 cc. aqua regia at 20-25°C a layer of about 2.5×10^{-6} cm, corresponding to a loss of wt of about 0.6 mg (for the total surface area of 11.2 cm^2), was etched away. Repeating this 80 times resulted in soln. of 50.5 mg metal. In parallel expts., an identical sample, also heat-treated at 1180°C, was etched in one single operation until wt loss was 50 mg. In a 3rd expt., 50 mg pure Pt and 0.25 mg Ag were dissolved in aqua regia. Comparison of the 3 spectrograms of the 3 solns. showed that the Ag lines were markedly more intense in the first expt. This indicated that in a thin surface layer of the alloy quenched from the temp. of max. soly., the Ag content was substantially higher than its mean bulk concn., i.e. there was pos. internal adsorption.

1142. Bénard, Jacques and Bardolle, Jean. **The oriented growth of iron(II) oxide by the controlled oxidation of iron at high temperatures.** *Compt. rend.* 232, 2217-18(1951).—*C.A.* 46, 1326*e*.

The oxidation of Fe at 850°C and low pressure of O_2 produces iron (II) oxide. The no. and form of the oxide particles depends on the crystallographic orientation of the Fe crystals at the surface, since the rate of growth is different for different crystal faces.

1143. Bowden, F. P. and Throssell, W. R. **Adsorption of water vapor on solid surfaces.** *Nature* **167**, 601-2 (1951).—*C.A.* 45, 8319*g*.

The adsorption of water vapor on Pt foil was detd. by heating the foil to a red heat, allowing it to cool to 20°C *in vacuo* while suspended on a microbalance, and measuring the increase in wt of the foil when water vapor was admitted at different pressures. Confirmatory expts. were made with elliptically polarized light to measure the thickness of the adsorbed water films on metal, diamond, and Zn blende surfaces. The adsorbed layer was at most a few mol. layers in thickness.

1144. Bowden, F. P.; Throssell, F. R. S., and Throssell, W. R. **Adsorption of water vapor on solid surfaces.** *Proc. Roy. Soc. (London)*, **A209**, 297-308 (1951).

The adsorption on Au, Ag, Pt, Al, and ZnS was followed by a direct weighing of the adsorbed film on a microbalance and an examination of polarized light reflected from the surface. Both methods showed that the adsorption of water at vapor pressures near saturation corresponded only to about two molecular layers. Greater adsorption, previously quoted as evidence for long-range surface effects, was due to contamination.

1145. Bowden, F. P. and Young, J. E. **Friction of clean metals and the influence of adsorbed films.** *Proc. Roy. Soc.* **A208**, 311-25 (1951).—*C.A.* 46, 5398*h*.

When sufficiently clean metals were allowed to touch, even at room temp., complete seizure occurred. Various gases and vapors were adsorbed on the clean specimens, and their influences on friction detd. These sp contaminants were most effective as lubricants where they could react with the metal to form a solid and chemically attached film which is several mol. layers thick. Otherwise the friction remained very high, although seizure was prevented. Phys. adsorption might occur in addn., with a significant reduction in the friction. The friction of metals was due mainly to adhesion at the points of real contact. Adsorbed monolayers, or even multilayers of the permanent gases, did not reduce the friction to the low values commonly observed.

1146. Brandt, Werner. **Determination by a flow method of adsorption times of gas molecules on metal surfaces.** *Z. Elektrochem.* 55, 652-4 (1951).—*C.A.* 46, 4317*e*.

Measurements for diffusion through a glass capillary contg. a central metal wire, and through the empty capillary, were used to calc. the adsorption time τ on the metal surface. For C_2H_4 and C_2H_6 τ was about 10^{-7} sec and was $< 10^{-8}$ sec for H. Measurements with C_2H_6 and a series of Pt-Cu alloys were also made.

1147. Carli, F. de and Collari, N. **Thermal oxidation of copper.** *Chimica e industria* 33, 77-80 (1951).—*C.A.* 45, 6021*i*.

At 400°C the wt-increase isotherm was given by $1/P = A - B \ln t$, where t was the time; from 500 to 900°C a parabolic course $P^2 = Kt$ was found. Two curves intersected in the 500-900°C range at about 650°C. This discontinuity was ascribed to the reaction $CuO + Cu \rightleftarrows Cu_2O + 3.5$ kcal. rather than $2CuO \rightleftarrows Cu_2O + \frac{1}{2} O_2 - 34$ kcal.

1148. Chizhikov, D. M.; Khazanov, E. I., and Nikonov, A. G. **Reactions between cadmium and carbon oxides.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk* **1951**, 68-73.—*C.A.* 45, 6949*f*.

Cd vapor above 768°C is not oxidized by either CO or CO_2. Solid Cd is oxidized by CO only below 350°C, according to $Cd + CO = CdO + C$. The oxidation is very slow, even with a fine powder. The velocity of evapn. and of condensation is markedly higher than the rate of oxidation. The gain of wt of Cd powder in 2.5 hrs at 300° in CO_2 was 0.0016%.

1149. Corbett, J. A. **Estimation of oxygen in titanium by chlorination.** *Analyst* 76, 652-7 (1951).—*C.A.* 46, 855*a*.

Ti and metallic impurities were converted into volatile chlorides by treatment with Cl_2 at 400°C. The vacuum fusion method was more expensive and took more time. A careful study with pure Ti and 10 alloys contg. 0.5-1.50% Ti showed that the chlorination procedure gave results which were within 5% of the actual O content.

1150. Crowell, A. D. and Farnsworth, H. E. **Adsorption of carbon dioxide on a nickel single crystal with a radioactive tracer.** *J. Chem. Phys.* **19**, 1206-7 (1951).—*C.A.* 46, 3366*a*.

CO_2 labeled with C^{14} was absorbed on the (111) face of a Ni crystal under pressures of 0.1 to 0.01 mm Hg and at temps. from room to 200°C. Measurable amts. were adsorbed but, owing to exptl. difficulties, the results were not reproducible.

1151. Darken, L. S.; Smith, R. P., and Filer, E. W. **Solubility of gaseous nitrogen in gamma iron and the effect of alloying constituents—aluminum nitride precipitation.** *J. Metals* 3, *Trans.* 1174-9 (1951).—*C.A.* 46, 391*b*.

The soly. of N_2 in purified Fe and low-alloy steels was detd. for the γ-region (930 to 1350°C). The diffusivity of N_2 was estd. from the rate of approach to equil. The investigation of Al-killed steels, held in N_2, disclosed pptn. of AlN, the soly. of which was detd.

1152. Davies, M. H. and Birchenall, D. E. **Oxidation of titanium.** *J. Metals* 3, *Trans.* 877-80 (1951).—*C.A.* 45, 10161*b*.

The rate of oxidation of Ti between 650-950°C was measured. The linear-rate law obtained was explained by interface reaction control of the process. Tracer expts. indicated that O_2 diffuses in at least one phase of the scale.

1153. Deb, S. **Emission decay in oxide-coated cathode due to gaseous adsorption.** *J. Sci. Ind. Research* (India) **10B**, No. 3, 77-8(1951).—*C.A.* 46, 3389*b*.

The adsorption of gases, as O_2, Cl_2, and CO_2, adversely affect the emission from the cathode. By assuming that the concn. of the poisoning particles in front of the cathode is proportional to the c.d. an expression is developed for the rate of decay of current from statistical and thermodynamical considerations. The time required for the current to fall to $1/e$ of its initial value is taken as the time const. of the decay. This const. is calcd. to be about 10^{-3} sec. If the energy of activation is negligible, about 0.1 of the cathode surface is available for adsorption, and the current diminishes from 10 to 0.1 amp.

1154. Dravnieks, Andrew. **Action of hot ionized gases on zirconium and copper.** *J. Phys. & Colloid Chem.* 55, 540-9 (1951).—*C.A.* 45, 6021*h*.

The reaction at 986°C was followed by measuring the change in elec. cond. of Zr strips. The cond. loss (an index of oxidation) was measured as a function of time for 8 different gases that in order from most to least oxidative, were: O_2, air, H_2O, N_2 + 0.5% O_2, com. (O_2-contg.) He, CO_2, CO, C_2H_4. Ionization increased the oxidation rate in CO_2, decreased the rate in CO, H_2O, com. He, and N_2 + 0.5% O_2. The retardation of oxidation by ionization is attributed to a clean-up of the metal surface by the nonreacting components of the gas phase.

1155. Eichborn, J. L. v. **Wetting of metals by water.** *Werkstoffe u. Korrosion* 2, 212-21 (1951).—*C.A.* 45, 9334*d*.

Exptl. results of investigations on the equil. of wetting of air, water, and metal are discussed, including original expts. with Hg. A survey of values for surface tension of solid metals and heats of adsorption of metal catalysts gives a comparative measure of the adsorptive power of various metal surfaces. The competition between the wetting by water and the adsorption of air are compared with the results of others on the adsorption of gases or aq. solns. on metal surfaces.

1156. Eischens, R. P. **Isotopic exchange rates as criteria of surface heterogeneity.** *J. Chem. Phys.* 19, 377 (1951).—*C.A.* 45, 6898*c*.

A monolayer of $C^{14}O$ was chemisorbed on reduced Fe, and the exchange with normal CO in the gas phase at 1 atm. was detd. at −78°C. If X was the fraction of the $C^{14}O$ in the gas phase at time t, the curve of $-\ln[1-(X/X_\infty)]$ *vs.* t consisted of a few linear sections. These sections corresponded to different exchange rates on various portions of the surface, within each of which the Fe-CO bonds were equiv. If, however, the surface were "completely heterogeneous" the exptl. data would plot as a smooth curve.

1157. Eremeev, M. A. **Emission of electrons and reflection of ions from metal surfaces.** *Doklady Akad. Nauk S.S.S.R.* 79, 775-7(1951).—*C.A.* 46, 1346*f*.

The no. of electrons emitted by targets of Ta or W under the impact of pos. ions of alkali metals increases linearly with the energy of the ions. With increasing temp. of the target, the no. of electrons emitted decreases, and so does the no. of ions adsorbed on the target (detd. from the ballistic deflection on sudden desorption). Up to 800°K, the reflection coeff. of the ions is independent of the nature of the target and of the energy of the ions. Above 1000°K, the reflection coeff. for K^+ ions is different for Ta and W. The fact that a perfectly pure Sn surface emits no electrons, indicates that the electron emission is due to adsorption of the pos. ions on the target.

1158. Fisher, J. C. **Calculation of diffusion penetration curves for surface and grain-boundary diffusion.** *J. Applied Phys.* **22**, 74-7 (1951).—*C.A.* 45, 3215*g*.

Diffusion in solids is known to occur along grain boundaries and over free surfaces more rapidly than through the interiors of crystals. In order to facilitate quant. investigation of grain-boundary and surface diffusion, a math. analysis of the problem was made, assuming that grain-boundary diffusion was analogous to the diffusion of heat along a thin Cu foil imbedded in cork.

1159. Fry, A. **Gases in steel—nitrogen and nitriding.** *Inst. hierro y acero*, Suppl. to Vol. 3, 36-47 (July-Sept., 1950); *J. Iron Steel Inst.* (London) **168**, 315(1951).—*C.A.* 45, 7936*b*.

N_2 produced solid, stable compds. in steel at low temps. The laws governing the absorption of N_2 and O_2 by steel were somewhat analogous. The soly. of N_2 in Fe at atm. pressure and in relation to temp. was illustrated. N_2 penetration curves for C steels were given. Advantages and applications of nitriding were described and, finally, the influence of alloying elements on the hardness obtained by nitriding was examd.

1160. Funston, E. S. and Reed, Shermán A. **Determining traces of oxygen in bismuth metal.** *Anal. Chem.* 23, 190-1 (1951).—*C.A.* 45, 3289*i*.

Oxygen is detd. from the quantity of H_2 consumed during reduction of trace oxides in a simple gasometric app. (described and illustrated). From 1 to 10 g, depending on O-content, of the Bi sample is held for 30 min. at 850-900°C in H_2. H_2

consumption is measured with a built-in 5-ml microburet. Accuracy and precision were checked by adding known amts., 2-11 mg, of Bi_2O_3 to 10-g samples of O-free Bi. The method and app. were applied to the *detn. of O in Cu and Fe* and checked by the addn. of CuO and Fe_2O_3, resp., to the pure metals.

1161. GEEL, W. CH. VAN AND SCHOLTE, J. W. A. **Capacity and dielectric loss in a layer of oxide deposited by anodic oxidation on aluminum.** *Philips Research Repts.* **6**, 54-74(1951)(in French)·—*C.A.* **45**, 9395*c*.

The equiv. impedance of the system $Al-Al_2O_3$—electrolyte as a function of frequency was detd. The capacity of different thicknesses of oxide films was measured with an a.-c. bridge and by a ballistic method. At the $Al-Al_2O_3$ boundary, it was assumed that there was a layer contg. excess Al atoms. They resulted in good cond. of electronic character. In a direction toward the electrolyte, the concn. of the excess atom decreased and the cond., therefore, decreased in that direction.

1162. GOLDSZTAUB, STANISLAS AND MICHEL, PIERRE. **Preparation of silver-magnesium alloys in thin layers by the simultaneous evaporation of these constituents in vacuum.** *Compt. rend.* **232**, 1843-5 (1951).—*C.A.* **46**, 2467*i*.

Mg was heated in a helix of W wire and Ag in a helix of Mo. The metals were distd. in vacuo and collected on a grid of brass covered by a collodion film some hundreds of microns thick. The condensed metallic vapors were then studied by electron diffraction.

1163. GULBRANSEN, EARL A. AND ANDREW, KENNETH F. **The kinetics of the oxidation of cobalt.** *J. Electrochem. Soc.* **98**, 241-51 (1951).—*C.A.* **45**, 6469*c*.

In the hexagonal crystal form (cold-rolled), Co had a higher oxidation rate than in the cubic form (annealed) up to 550°C. Reaction rates markedly increased at about 700°C. Below 700° the rate was controlled by the diffusion rate of Co cations through the Co_3O_4 layer, whereas above 700° the rate was controlled by the diffusion of Co cations through the CoO layer, both oxides being capable of coexistence.

1164. HADLEY, C. P. **Thermionic emission from oxide-coated tungsten filaments.** *Mass. Inst. Technol., Research Lab. Electronics Tech. Rept.* No. **218**, 25 pp. (1951).—*C.A.* **47**, 4187*i*.

Single-crystal W filaments were coated cataphoretically with oxides of Ba, Sr, Ca, and Mg. The emission from the oxides was not influenced by variation of work function with crystallographic direction of the W.

1165. HECK, CARL. **Structure of evaporated iron layers.** *Metallkunde* **42**, 10-13 (1951).—*C.A.* **45**, 4986*g*.

Thin Fe layers crystallize, not in a body-centered, but in a face-centered cubic lattice, at room temp. At higher temp. and thicker layers transition into the body-centered type takes place.

1166. HINTENBERGER, HEINRICH. **Thermal ion sources for negative ions.** *Helv. Phys. Acta* **24**, 307-9 (1951).—*C.A.* **46**, 2393*e*.

A directly heated W foil is covered with $ZrOCl_2$ or operated at a low pressure of HI, CCl_4, SnI_4, or AgBr to give neg. ions. An indirectly heated metallic powder of W or Th mixed with a halide is more satisfactory. Measurement of the ion current for such a source which contained 5×10^{-6} g NaCl showed that for W powder, Na-ion emission reached a max. in about 30 min. and Cl-ion about 20 min. later, the intensity of Na-ion emission being greater.

1167. HOGARTH, C. A. AND GRANVILLE, J. W. **Rectification effects at surfaces of germanium and lead sulfide.** *Proc. Phys. Soc.* **64B**, 992-8 (1951).—*C.A.* **46**, 10751*d*.

The effects of vacuum heat-treatment were investigated. Temps. between 500° and 900°C could improve the rectification characteristics considerably. The treatment did not spoil the optical quality of a polished surface. Similar effects were obtained with deficit-conducting PbS. Modifications to the surface structures of the crystals by various treatments were investigated by electron diffraction.

1168. IOFFE, E. SH. AND ROTINYAN, A. L. **Gases in electrolytic nickel.** *Doklady Akad. Nauk S.S.S.R.* **77**, 91-2 (1951).—*C.A.* **45**, 6089*b*.

H_2 found occluded in electrodeposited Ni is attributed solely to adsorption of org. matter from the electrolyte in the course of the deposition. Proof is supplied by simultaneous analyses for C, H_2, and O_2, in various electrolytic Ni deposits. Both the H- and the O-contents are directly proportional to the carbon content of the metal. There is, however, a certain H content even at C = 0 (at 20°C, about 2 vol. H_2/vol. Ni) which is evidently of inorg. origin.

1169. JONES, F. LLEWELLYN AND DAVIES, D. E. **Influence of cathode surface layers on minimum sparking potential of air and hydrogen.** *Proc. Phys. Soc.* (London) **64B**, 397-404 (1951).—*C.A.* **46**, 9409*g*.

Oxide layers on the cathode produced marked irregularities in the Paschen curves for air and H_2. Removal of the oxide layer produced smooth Paschen curves, while a thin film of one metal on a different metal as base gave values which were not characteristic of either metal in bulk. The deposition of thin metallic films had considerable effect on cathode emission.

1170. JOY, A. S. AND DORLING, T. A. **Influence of a chemisorbed film on subsequent physical adsorption processes.** *Nature* **168**, 433-4 (1951).—*C.A.* **46**, 3366*e*.

An alkali-promoted Fe catalyst adsorbed the same amt. of N_2 whether or not first exposed to CO and desorbed at −78°C. Differences in chemisorption of CO in 2 successive cycles (adsorption at −195° and desorption at −78°C at 10^{-4} mm for 0.5 hr) corresponded to 6.5, 11.6, and 21.5% of the surface for 3 samples of catalyst.

1171. KAINUMA, YOSHIRO. **Structure of thin metallic films formed by evaporation on molybdenite.** *J. Phys. Soc. Japan* 6, 135-8 (1951).—*C.A.* 45, 9331*g*.

Au, Cu, Ni, Pt, and Al were evapd. on the cleavage surface of molybdenite to a thickness of 20-100 A. at 25-500°C and a pressure of 10^{-4} mm. Electron-diffraction examns. were made at room temp. When the (111) plane of the metal was parallel to the cleavage surface and the [110] axis of the metal was parallel to the [100] axis of molybdenite, 2 types of arrangements, which were mirror images, were possible. Cu exhibited random orientation at 25° and sym. orientation from 50° to 500°C; Pt exhibited sym. orientation from 250° to 430°C; and Al exhibited random orientation from 75° to 375°C.

1172. KALISH, T. V. AND BURSHTEIN, R. KH. **Effect of oxygen adsorbed on platinum on the contact potential difference.** *Doklady Akad. Nauk S.S.S.R.* **81**, 1093-6 (1951).—*C.A.* 46, 3829*d*.

The contact potential difference was detd. by the current-voltage curve of a diode in which Pt is anode, and W cathode. From measurements with the Pt reduced with H_2 at 400°C, outgassed at 1100-200°C and evacuated to 10^{-6} mm Hg and with Pt exposed to O_2, and then evacuated to remove unadsorbed gas, it followed that at room temp., under 0.1 mm Hg of O, only a fraction of a monolayer was adsorbed. Both the rate of adsorption and the amt. adsorbed increased with the temp.; at 800°C, the amt. O_2 taken up by the Pt corresponds to some 300 layers. The work function ψ of Pt having adsorbed 17.5×10^{15} mols. O/cm^2 at 200° was increased by about 0.2v.; however this increase of ψ disappeared after 11 hrs, and ψ went back to practically the original value for a pure Pt surface. Desorption of O_2 cannot account for these phenomena.

1173. KEMBALL, C. **The reaction of methane and deuterium on evaporated nickel catalysts.** *Proc. Roy. Soc.* (London) **A 207**, 539-54 (1951).—*C.A.* 46, 331*b*.

The production of all 4 deuteriomethanes from the reaction of CH_4 and D on evapd. Ni films in the temp. range 206 to 255°C was followed with a mass spectrometer. The adsorption of D_2 was stronger than the adsorption of CH_4. The surface films were shown by electron diffraction to be unorientated. An activation energy of about 11 kcal./mole was required for the adsorption of CH_4.

1174. KIEHL, JEAN P. **Effect of the adsorption of gases on the velocity of reduction of nickel oxide by tungsten.** *Compt. rend.* **232**, 1666-8 (1951).—*C.A.* 45, 7417*b*.

The reaction $2NiO + W = 2Ni + WO_2$ was studied by magnetic susceptibility measurements for the analysis for metallic Ni. The rate of reaction at temps. below 780°C varied according to the gas surrounding and adsorbed upon the reactants; above 780°C there was little effect.

1175. KIMOTO, SHIZUO. **Orientations of crystallites of metal films evaporated on single crystals of copper.** *Science of Light* (Japan) **1**, No. 2, 106-16 (1951).—*C.A.* 46, 10777*a*.

Thin films 100-400 A. thick of Ag, Au, Ni, Pb, Fe, Sn, and Zn were evapd. onto the etched surfaces of Cu single crystals cut out to have (001), (110), and (111) faces. The evapn. was performed *in vacuo* at various temps., and the orientations of crystallites and diffusion of the evapd. metal layers were studied by the electron-diffraction method. The atoms of evapd. metal were mobile at the moment of arrival at the surface of substrate crystal and came close to each other to form a characteristic atomic plane contg. a few atoms in it. The "expected positions" were the ones where the atoms of substrate crystal should be when the crystal undergoes further growth.

1176. KINOSHITA, TOSHIHIRO AND NAKASHIMA, MASUO. **Oxygen in cast iron.** *Tetsuto-Hagane* **37**, 420-6 (1951).—*C.A.* 46, 1558*i*.

The cupola metal melted from inferior pig iron contained much FeO and the gross casting cracks were liable to appear. When the FeO was 0.04%, the repeated impact value decreased very much. When the FeO was 0.05%, the graphite structure was abnormal.

1177. KNAUER, FRIEDRICH AND KÜHL, WALTER. **Adsorption of potassium on tungsten.** *Naturwissenschaften* **38**, 432 (1951).—*C.A.* 46, 3366*c*.

Depending on temp. of the filament and beam intensity the coverage of the filament varied and the current between filament and auxiliary surrounding electrode showed changing characteristics. With little coverage (less than 0.3% of monatomic layer) all K left the filament each period as ions. With increased coverage the emission of the filament will be more and more at. K.

1178. KOBAYASHI, AKIO AND FURUYA, SABURO. **Reactions of barium films with oxygen. I.** *J. Phys. Soc. Japan* 6, 238-43 (1951).—*C.A.* 46, 5462*i*.

Two kinds of Ba getter were used to obtain Ba metal films; Fe tubes contg. Ba metal, and Ba berylliate mixed with Zr powder. In the range of pressure and temp. measured, the coexistence of BaO and BaO_2 was possible but, even if present, BaO_2 scarcely contributed to the reaction.

1179. KOKHANENKE, P. N. **Absorption bands of excess metal atoms in evaporated films.** *Izvest. Akad. Nauk S.S.S.R., Ser. Fiz.* **15**, 685-9 (1951).—*C.A.* 46, 8976*d*.

The films were prepd.: (1) by multiple vacuum sublimation, (2) by heating an evapd. metal film in O_2, Cl_2, or I_2. Narrow absorption bands in the near ultraviolet selective reflectivity and luminescence were observed in ZnI_2, $ZnCl_2$, ZnO, AgI, AgCl, AgBr, CdI_2, $CdBr_2$, CuI, CuBr, $AuCl_3$, and PbI_2. Cooling with liquid air narrowed the bands and shifted most of them to shorter wave lengths. The absorption was attributed to excess metal atoms.

1180. KÖSTER, WERNER AND RAFFELSIEPER, JOSEF. **The behavior of sintered iron in nitriding.** *Arch. Eisenhüttenw.* **22**, 337-41 (1951).—*C.A.* 46, 1941*i*.

Since sintered bodies were porous, reactions could start not only at the surface but also in the interior, especially if the reactant was a gas. Sintered bodies of different ds. were made of 4 Fe powders (carbonyl Fe, Hametag, sponge Fe, and RZ powder) and nitrided in NH at 500° for 2½-15 hrs. The absorbed N_2 amounted up to 8% depending on the d. The action was much stronger than in ordinary Fe. An almost uniform nitriding through the whole sinter body was obtained in short time except in the carbonyl sample where the nitration at the edges was stronger.

1181. KUMMER, J. T. AND EMMETT, P. H. **Chemisorption of carbon monoxide and the heterogeneity of the surface of iron catalysts.** *J. Am. Chem. Soc.* 73, 2886-9 (1951).—*C.A.* 45, 8335*i*.

Radioactive and nonradioactive samples of CO were added in succession as two separate fractions to a reduced Fe synthetic-NH_3 catalyst at −195° and −78°C. The layer of chemisorbed CO was removed by pumping and analyzed for radioactivity. Although the second fraction of added CO tended to come off first, a partial exchange equiv. to the coverage of about 50% of the Fe surface occurred very rapidly between the two fractions of added CO even if both fractions were added at −195°C.

1182. KUMMER, J. T. AND EMMETT, P. H. **Exchange between $N_2{}^{30}$ and $N_2{}^{28}$ over iron catalysts.** *J. Chem. Phys.* 19, 289-92 (1951).—*C.A.* 45, 9346*d*.

The rates of exchange between $N_2{}^{30}$ and $N_2{}^{28}$ obtained on doubly and singly promoted Fe catalysts was of the right order to be accounted for by assuming that all N_2 evapg. from the surface of the catalyst was completely equilibrated with respect to the N_2 isotope exchange. Large concns. of H_2 (50% H_2in N_2) markedly accelerated the reaction. Small traces of surface oxides poisoned the Fe catalysts severely for the isotope exchange.

1183. KWAN, TAKAO AND FUJITA, YUZABRO. **Adsorption of carbon dioxide on metal catalysts.** *Bull. Chem. Soc. Japan* 24, 46-50 (1951).—*C.A.* 47, 6214*e*.

The adsorption of CO_2 on reduced Ni, Co, and Fe, resp. was studied. Adsorption isotherms were detd. on reduced Ni at 150° and 200°C under pressures ranging from 0.0001 to 0.1 mm Hg. CO_2 adsorption occurred with completely dissociative adsorption at least in the lower pressure region. Adsorption isotherms of CO_2 on reduced Co were detd. at 0° and 40°C below 0.1 mm Hg. The isotherms appeared to be nearly of the Freundlich type in this case. Adsorption isotherms on reduced Fe were detd. at 0° and 25°C under pressures from 0.0001 to 1 mm Hg.

1184. LEVESQUE, PASCAL AND CUBICCIOTTI, DANIEL. **The reaction between oxygen and thorium.** *J. Am. Chem. Soc.* 73, 2028-31 (1951).—*C.A.* 45, 6949*c*.

The reaction of Th with O_2 was studied in the range 250 to 700°C. Above 450°C, the temp. of the sample rose considerably above the temp. of the furnace; below 450°, the oxidations were essentially isothermal. The rate consts. for the linear oxidation between 350°-450°C were measured and the energy of activation was calcd. to be 22 kcal. per mole. From 250 to 350°C, the oxidation proceeded according to the parabolic law. The calcd. energy of activation for the reaction was 31 kcal. per mole.

1185. LIHL, F. **Ferromagnetic properties of half-oxidized iron and iron-cobalt powder.** *Acta Phys. Austriaca* 4, 360-79 (1951).—*C.A.* 46, 1314*d*.

Thermal decompn. of Fe(II) formate or oxalate gave ferromagnetic FeO crystd. in the Fe_3O_4 lattice, unlike ordinary FeO, and contg. C. Reduction of Fe(II) formate or oxalate with H_2 at 300 or 350°C gave mixts. of this oxide, ordinary FeO, and Fe metal, proportions depending on time and temp. of reduction. The pyrophoric properties of the powder could be removed by washing off the adsorbed H_2 with C_6H_6. The powder was pressed into solid form by the methods of powder metallurgy. Mixed crystals of Fe and Co formates were similarly reduced, and the properties of the pressed powder detd.

1186. LILLIE, A. B. AND CONNER, J. P. **Preparation of thin tritium targets.** *Rev. Sci. Instruments* 22, 210-11 (1951).—*C.A.* 45, 7439*f*.

Thin T targets are prepd. by absorbing T gas in Zr metal deposited by evapn. onto a W disk. This is placed in a system at pressures less than 10^{-5} mm Hg, and UT_3, held in a stainless steel trap, is heated to decompd. it into U metal and T gas. The target is heated, then slowly cooled. When the target is cold, the U trap is cooled to take up the remaining T.

1187. MALAGUTI, AMEDEO. **The determination of active oxygen in the higher oxides of silver.** *Ann. chim.* (Rome) 41, 241-6(1951).—*C.A.* 45, 10131*g*.

The active O_2 of the higher oxides of Ag can be detd. by either $FeSO_4$ or $H_2C_2O_4$ in H_2SO_4 soln.; the results obtained are comparable to those obtained by the H_2O_2 or the iodometric method. The reaction between $K_2S_2O_7$ and Ag_2SO_4 results not in the sesquioxide, but in a mixt. corresponding to the formula $Ag_2O_2.Ag_2O_3$.

1188. MASSINON, J.; STOLL, N., AND URBAIN, M. **Determination of oxygen in steels by the method of Gotta.** *Rev. universelle mines* 7, 265-81 (1951).—*C.A.* 46, 4425*f*.

The method is based on the high-temp. reduction of O-contg. constituents (FeO, MnO, SiO_2) by Al. The Al diffuses into the sample which is heated to 1300°C in a mixt. of 1 part Al with 3 parts of special Al_2O_3. This method is compared with the usual methods of detg. O_2 by reduction *in vacuo* in a graphite crucible. The results of all the methods are in good agreement.

1189. McCLELLAN, A. L. AND HACKERMAN, NORMAN. **The sorption of gases on metals at room temperature.** *J. Phys. & Colloid Chem.* 55, 374-82 (1951).—*C.A.* 45, 5483*e*.

Isotherms for the sorption of O_2, NO, NO_2, and Cl_2 at 30°C were measured at 0 to 10-mm pressure on reduced and unreduced samples of S.A.E. 1020 steel, 18-8 stainless steel, and pure Cr powders. Sorption decreased in the order steel, stainless steel, and Cr; reduction increased the sorption of O_2 and Cl_2 on steel. The gas pickup was apparently due largely to chem. reaction and was equiv. to 2 to 66 layers of adsorbate; no phys. adsorption was detected.

1190. METSON, G. H. **Activation of high-vacuum oxide-cathode valves.** *Vacuum* **1,** 283-93 (1951).—*C.A.* **46,** 8952*g*.

Successive doses cause a permanent lowering of the level of total emission and, therefore, a permanent decrease of excess Ba content regardless of the coulombs spent for recovery. The destruction is, at const. cathode temp., proportional of O_2 up to a crit. temp. at which each Ba atom diffused to the surface is destroyed. Above that the attack is independent of pressure. At const. O_2 the attack is proportional to the cathode temp. O_2 poisoning does not lead to complete destruction. An instantaneous and irreversible Ba-matrix formation is assumed during the transition from carbonate to oxide and removal of O_2 at that moment by pumping and by core Mg and Si internal gettering action.

1191. MEYER, LOTHAR AND LONG, EARL. **The thermomechanical effect in adsorbed layers of helium II.** *Phys. Rev.* **84,** 551-2 (1951).—*C.A.* **46,** 1839*f*.

An expression is derived for the thermomech. effect in adsorbed films, by use of the methods of quasithermodynamics. The results are discussed in comparison with the fountain effect in bulk liquid He II, and with the existing qual. measurements on adsorbed He II films.

1192. MITCHELL, E. W. J. AND MITCHELL, J. W. **The work functions of copper, silver, and aluminum.** *Proc. Roy. Soc.* (London) **A210,** 70-84 (1951).—*C.A.* **46,** 10854*c*.

Thin films of the metals were deposited onto aged surfaces of W and the work functions measured on the basis of contact p.ds. with W.

1193. MOORE, WALTER J. AND LEE, JAMES K. **Kinetics of the formation of oxide films on zinc foil.** *Trans. Faraday Soc.* **47,** 501-8 (1951).—*C.A.* **45,** 10017*i*.

The study was made between 300 and 400 °C and from 1.0 to 40.0 cm Hg. Below 350 °C the rate followed $dy/dt = ae^{-by}$, where y was the oxide-film thickness. Above 370°C, the rate followed $dy/dt = k/y$. The rate const. of the latter was markedly pressure dependent, following an expression $k = k_0 bP/(1 + bP)$, and was explained in terms of an activated adsorption of O_2 at the ZnO surface. The activation energy of k_0 was 28.5 kcal./mole, and $b = b_0$ exp $(-42.2$ (kcal.)$/RT)$.

1194. MOORE, WALTER J. AND LEE, JAMES K. **Oxidation kinetics of nickel and cobalt.** *J. Chem. Phys.* **19,** 255(1951).—*C.A.* **45,** 3695*f*.

The rate const. for the oxidation of Ni is $k = 3.09 \times 10^{-5}$ exp. $(-38,400/RT)$ cm^2/sec; for Co, $k = 7.60 \times 10^{-4}$ exp. $(-38,400/RT)$ cm^2/sec. The activation energies for cationic diffusion, by a vacancy mechanism, are the same in both NiO and CoO, but that CoO contains about 25 times as many vacancies as does NiO.

1195. MOORE, WALTER J. AND SELIKSON, BERNARD. **The diffusion of copper in cuprous oxide.** *J. Chem. Phys.* **19,** 1539-43 (1951).—*C.A.* **46,** 5923*f*.

Cu_2O strips were prepd. by the oxidation of Cu at 1000 °C. The diffusion of radiocopper in this material at 800° to 1050 °C gave a self-diffusion coeff., $D = 0.0436$ exp. $(-36,100/RT)$, where R was the gas const. and T the abs. temp. Virtually the same D was obtained from expts. in which radiocopper plated on Cu strips. It was suggested that parabolic rate consts. with large neg. entropies of activation and low heats of activation may be due to grain-boundary diffusion.

1196. MORGULIS, N. D. AND ZINGERMAN, YA. P. **Experimental investigation of the oxide cathode.** *Doklady Akad. Nauk S.S.S.R.* **81,** 783-5 (1951).—*C.A.* **46,** 3880*b*.

The potential distribution across the thickness of an oxide cathode layer (on Ni) was detd. with the aid of fine Pt probes at different c.ds. The total potential drop was composed of 3 portions, the contact, the vol., and the surface-potential drop. The outer surface layer, of a thickness of the order of 40μ, had an increased elec. resistance as compared with the bulk of the film. The resistance of the surface layer fell with rising temp. somewhat faster than that of the body. The surface layer was the seat of a strong elec. field which may exceed 10^5 v./cm.

1197. NASINI, ANTONIO G. AND SAINI, GUIDO. **Accommodation coefficients of gases on metals.** *Chimica e industria* (Milan) **33,** 67-70 (1951).—*C.A.* **45,** 6003*i*.

Gas-adsorption expts. on metal surfaces up to 2500 °K were reported. The systems comprise He on Pt, W, and Ni; A on Pt; Ne on W. McLeod-type manometers must be avoided, since they introduce another metallic surface in the system, and glass-fiber manometers are employed.

1198. NOGA, KIN'ICHI AND OKADA, YOSHITARO. **Prevention of grid emission of electron tubes. I. The structure of an evaporated barium oxide film.** *Oyo Butsuri (J. Applied Phys.)* **20,** 21-5 (1951).—*C.A.* **46,** 2425*f*.

The emission current I_ρ and the work function A were measured for a W filament on which BaO had been evapd. BaO mols. were adsorbed on W at 800 °K and $\theta < 1$ with a definite orientation as regards their dipoles to form elec. double layers and they caused the depression of A and an increase of thermoelectronic emission. BaO was oriented on the W surface in such a manner that the electroneg. O atom was directed towards the metal and the electropos. Ba atoms away from the surface. As θ was increased, BaO mols. tend to gather to form crystallites with increasing intermol. interaction, and the proportionality between log I_ρ and the amt. of BaO was no longer fulfilled. BaO mols. were adsorbed at room temp. with random orientation before they were allowed to rearrange at elevated temp. The thick BaO layer adsorbed on Ni was also examd. and the thick layer $(\theta \approx 20)$ on Ni below 700 °K was the aggregate of BaO crystallites in which many free Ba atoms were dispersed.

1199. ŌYA, SHIGEO. **Absorption of gases by aluminum castings.** *Repts. Casting Research Lab.* No. 2, 33-7 (1951).—*C.A.* **46,** 3471*g*.

Aluminum contg. Si 0.34, Fe 0.29, Cu 0.01% was melted electrically in different amts., and the amt. of gas absorbed was detd. by measuring the sp.gr. of the metal. The oxide film covering the metal prevented gas absorption, and its continuous removal increased the vol. of absorbed gas. Moisture in the atm. led to the greatest gas absorption, while dry air caused comparatively few blowholes.

1200. PAIDASSI, JEAN. **High-temperature oxidation of pure iron.** *Ing. Quim.* **10**, No. 10, 5-17 (1951).—*C.A.* **46**, 9486*h*.

A study of the oxidation of Fe in air between 700 and 950°, from 3 min. to 16 hrs. The constant was verified as $K = 3.8e\ (-39{,}000/RT)$. Careful measurements of the 3 layers (FeO, Fe_3O_4, and Fe_2O_3) suggested that the outside layers Fe_3O_4 and Fe_2O_3 follow the parabolic laws of growth.

1201. POMOSOV, A. V.; ROGATKINA, T. N., AND LEVIN, A. I. **The effect of ammonium salts upon the corrosion of copper powder.** *J. Appl. Chem. U.S.S.R.* **24**, 817-19 (1951) (Engl. translation); *Zhur. Priklad. Khim.* **24**, 720-1 (1951).—*C.A.* **47**, 4271*f*.

Corrosion is enhanced by all the compds. tested at 40° for 12 hrs, but the intensity depends upon the nature of the acid involved in the salt. The rate of corrosion depends upon the quantity and nature of the vapors and gases dissolved in the liquid adsorption layer. The volatility of the acid which constitutes the anion of the ammonium salt is the principal factor controlling the corrosive action on Cu powder.

1202. POMOSOV, A. V. AND LEVIN, A. I. **The atmospheric corrosion of copper powder.** *J. Appl. Chem., U.S.S.R.* **24**, 821-4 (1951) (Engl. translation); *Zhur. Priklad. Khim.* **24**, 723-6 (1951).—*C.A.* **47**, 4271*h*.

Corrosion expts. were conducted in H_2S, HCl, NH_3, and CO_2. In each case, the powder treated with a nonwetting agent was more resistant and in H_2S and CO_2 there was no marked change when H_2O was admitted. After prolonged exposure to dry and moist H_2S it developed that the hydrophobized powder corroded more slowly but that attack eventually progressed. Atm. corrosion did take place even in the absence of moisture films. Plain copper was corroded more severely in anhyd. H_2S than in the presence of water.

1203. REDDEN, THOMAS AND FIELD, MARY JANE. **Metallography of alloys of titanium with oxygen, carbon, and nitrogen.** *Steel* **129**, No. 21, 88-90 (1951).—*C.A.* **46**, 398*h*.

Photomicrographs illustrated typical structures of the alloying effect of 0.25% carbon, N_2, and O_2. Increases in hardness were greatest from N_2 and least from carbon.

1204. RIDEAL, E. K. AND TRAPNELL, B. M. W. **Adsorption on evaporated tungsten films. I. Oxygen and carbon monoxide chemisorption and the determination of film surface areas.** *Proc. Roy. Soc.* (London) **A205**, 409-21 (1951).—*C.A.* **46**, 317*d*.

The chemisorption of O_2 and of CO by evapd. W films was studied between 20 and −195°C and at pressures up to 10^{-2} mm. The film areas were detd. within an error of about 5%. Chemisorption of O_2 was followed by probably an oxidation which slowed very rapidly as gas was taken up, and for which an activation energy of 7000 cal was evaluated. The heat of CO chemisorption was so low in densely packed layers that measurable equil. gas pressures were required even at liquid-air temps. for completion of chemisorption. For CO the fraction of the surface covered varied very slowly with temp. and pressure. This was to be attributed to the rapid fall in heat of adsorption with increasing adsorbed amt. When the heat of adsorption had fallen to values typical of a van der Waals adsorption, the fraction of the surface covered exceeded 100% by an amt. greater than the exptl. error; this showed commencement of 2nd-layer formation.

1205. SAITO, TAIICHI. **Influence of oxygen on properties of iron and steel. II.** *Tetsu-to-Hagane* **37**, 282-90 (1951). **III.** *Ibid.* **38**, 18-25 (1952).—*C.A.* **47**, 4816*c*.

O_2 is one of the greatest influences on grain size and hardenability of iron and steel. Al steel contg. little Al_2O_3 had a greater tendency for large and uniform grain size, but that contg. much Al_2O_3 was apt to form fine grain size and overheated structure. The abnormal structure was apt to appear in Al steel contg. little Al and much Al_2O_3, but in steel contg. much Al_2O_3 and more than 0.4% Al the abnormal structure was not observed.

1206. SASAKI, NOBUJI; UEDA, RYUZO, AND OZASA, MINORU. **Physicochemical properties of tungsten metal powder.** *Bull. Inst. Chem. Research, Kyoto Univ.* **25**, 66-7 (1951) (in English).—*C.A.* **46**, 8463*c*.

The effect of pressing on the structure of W powder produced 2 different sorts of oxide. The pressing greatly decreased the particle size of the original powder and halved the sedimentation vol., but the surface area or the mean particle diam. remained almost unchanged. This indicates that pressing disintegrated almost completely the secondary and tertiary particles to the primary ones without producing any fresh surface by deforming or crushing the primary particles themselves.

1207. SCHNEIDER, ARMIN AND SCHMIDT, WERNER. **Surface reaction between aluminum fluoride and iron at higher temperatures.** *Z. Metallkunde* **42**, 73-5 (1951).—*C.A.* **45**, 5586*h*.

Gaseous AlF stable at higher temp. can be made to react with Fe at 720 to 980°C to form a diffusion layer consisting of $AlFe_3$. This results in considerable increase of hardness and corrosion resistance.

1208. SCHOPPER, HERWIG. **Examination of "thick" metal films and their surface layers by means of the absolute phase.** *Z. Physik* **130**, 427-44 (1951).—*C.A.* **46**, 1322*c*.

Layers can be observed with normal incidence of light; thereby avoiding errors due to possible anisotropy. Equations and procedures were developed for the detn. of n within metal films (for Ag $n = 0.11$ at $\gamma = 546$ mμ) and for the detn. of the thicknesses of transition layers between metal and support and between metal and air (tarnishing layers).

1209. SCHREINER, H. AND MAYR, H. H. **Diffusion of silver in copper.** *Monatsh.* **82**, 748-51 (1951).—*C.A.* **46**, 3420*i*.

Metallographically polished plates of the Cu and of Ag contg. Ag^{110} were placed in intimate contact in a vacuum chamber. After 30 min., A gas at 20°C was flushed through the chamber. The expts. were conducted for 630 min. at 460°C, 288 min. at 500°C, and 144 min. each at 550° and 600°C. The plates were then sepd. and the Ag activity in the Cu plates were measured. The diffusion const. $D = Ae^{-Q/RT}$ was detd. to be 1.10×10^{-20} cm^2/sec at 460°C, 3.72×10^{-19} cm^2/sec at 500°C, 1.023×10^{-17} cm^2/sec at 550°C, and 7.72×10^{-15} cm^2/sec at 600°C.

1210. SHEKHTER, A. B.; ECHEISTOVA, A. I., AND TRET'YAKOV, I. I. **Structure of thin metal layers sputtered on asbestos and on lampblack.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* **1951**, 42-6.—*C.A.* **45**, 4986*h*.

Electron-microscopic examn. of Ag or Au sputtered on asbestos fibers shows discrete grains which change to coarser aggregates on heating to above 220°C in the case of Ag, and to above 320°C in the case of Au. The same phenomena of recrystn. and coarsening, due to mobility of atoms of the metal, are observed after wet impregnation of the asbestos, e.g. with a colloidal Ag soln. On spherical particles of lampblack, sputtered Ag aggregates on heating to 230°C, in the form of parallepipedons growing perpendicularly to the surface of the spheres. Above 350°C, the lampblack particles become increasingly transparent and finally disappear, owing evidently to combustion catalyzed by Au; without Au, combustion takes place only on heating to above 600°C.

1211. SHIMOKAWA, YOSHIO AND TANOUE, TOYOSUKE. **Evolution of gases from rimming-steel ingots.** *Tetsu-to-Hagane* **37**, 555-6 (1951).—*C.A.* **47**, 1560*f*.

The rate of gas evolution from the rimming-steel ingots (0.12-0.18% C) came to a max. at 1-5 min. after filling the mold and then decreased gradually towards the end of solidification. The max. rate of gas evolution was 100-300 cc/min. The total gas (60 to 150 liters) contained CO, 80 to 92; CO_2, 1-4; H_2, 4-11; and N_2, 0.5-4%. As the solidification proceeded, the CO and CO_2 percentage decreased gradually, but the H_2 and N_2 percentage increased.

1212. SINGLETON, J. H.; ROBERTS, E. R., AND WINTER, E. R. S. **Reaction between deuterium and ammonia on evaporated metal catalysts.** *Trans. Faraday Soc.* **47**, 1318-31 (1951).—*C.A.* **46**, 6475*i*.

The exchange reaction was examd. on evapd. films of Fe, W, and Ni above 500°K Fe and Ni catalysts after sintering can be used for long periods without change in activity. The activity of W increased slowly on heating to 700°K *in vacuo* or in the presence of reactants. The energies of activation of exchange were: Fe, 21.0, 20.9, 19.1; W, 16.0, 16.4, 15.4, 11.7; Ni, 14.8, 14.7, 16.1, 15.0 kcal./mole.

1213. STANLEY, J. K.; HOENE, J. VON, AND WIENER, GEORGE. **Determination of oxygen in zirconium metal by the vacuum-fusion method.** *Anal. Chem.* **23**, 377-9 (1951).—*C.A.* **45**, 3752*e*.

The addn. of Zr to molten Fe must give a dil. soln. of Zr in Fe. This can be obtained by using 50-100 mg of Zr and 15-20 g of Fe. Thereafter, about 1.5 g Fe should be added before another sample is analyzed. The temp. should be 1850-1950°C although temp. as low as 1650° is sometimes successful. The addn. of 25% Sn helps the reduction of ZrO by carbon. It is best to introduce the Zr wrapped in annealed Fe foil. Good results can be obtained in about 10 min.

1214. STRANSKI, I. N. **Reactions on crystal surfaces.** *Trans. Chalmers Univ. Technol. Gothenburg, Sweden* No. **114**, 21 pp. (1951) (in German).—*C.A.* **47**, 373*c*.

The use of the electrostatic field microscope was demonstrated by the effects of absorbed Ba and Cu_2O. The adsorption layer of Cu_2O was oriented with the O atoms pointing outward. The W atoms on the surface were homopolarly bound, their activation energy of mobilization was identical with that observed for the migration of single W atoms over (011). The direct observation of single absorbed mols., viz., of Cu phthalocyanine, on W with a microscopic resolution power of 2.8×10^6 was particularly impressive. The effects of enforce condensation and evapn. rate of crystals was shown for As_2O_3.

1215. SUNDEN, O. AND BOHM, E. **Corrosion resistance of alloy steels to pure and sulfur-containing carbon monoxide.** *Chem.-Ing.-Tech.* **23**, 3-4 (1951).—*C.A.* **45**, 3312*b*.

Comparative corrosion data were presented for six types of alloy steel at initial CO pressures of about 500 atm. All steels were completely resistant to pure CO, but even small amts. of S resulted in considerable attack. Only very high Cr-Ni contents, as, e.g. 18-8 and 26-5, gave protection.

1216. TANAKA, YOSHIO AND SAKAI, MASATOSHI. **Adsorption of gas on the metal blacks.** *Science of Light* (Japan) **1**, No. 2, 93-7 (1951).—*C.A.* **46**, 10774*e*.

The adsorbed gas in metal blacks prepd. by evapn. at a pressure of 1 mm Hg was found to be O_2. The adsorbed gas desorbed if the metal black was heated in vacuum, and the amt. of the desorbing gas was measured at various temps. for Zn, Cd, Pb, and Bi blacks.

1217. TEREM, HALDUN N. **Dry corrosion studies. The oxidation of powdered zinc.** *Rev. faculté sci. univ. Istanbul* **16A**, 226-40 (1951) (in French).—*C.A.* **46**, 11079*c*.

When an increase in the rate of oxidation of Zn is expected because of increasing temps. or favorable media, this increase is very slow or even zero. The initial course of Zn oxidation obeys the parabolic law perfectly. The activation energy of the reaction $Zn + 5\ O_2 \rightarrow ZnO$ is about 23,500 cal per g.

1218. TICHENOR, ROBERT L. **Role of oxide composition in oxidation of nickel and cobalt.** *J. Chem. Phys.* **19**, 796-7 (1951).—*C.A.* **45**, 7416*i*.

It is assumed that only a fraction of the oxide surface is effective in ionizing O. The difference in the no. of cation vacancies is attributed to the higher O-content of Co oxide (Co_3O_4, nearly, although retaining the CoO structure) under equil. conditions, rather than to differences in the rates of ionization of O. This increase in O content leads to higher rates of cation diffusion, in spite of smaller values of the cation diffusion coeff.

1219. Torrisi, A. F. and Kernahan, Jean L. **Modified vacuum fusion apparatus for determination of oxygen, hydrogen, and nitrogen in certain metals.** *Anal. Chem.* **23**, 928-9 (1951).—*C.A.* **45**, 7829*e*.

Assembling, cleaning, and repairing are facilitated by use of ground joints. Two measuring systems are attached to one melting furnace and pumping system which enables one operator to analyze twice as many samples per day as with a single unit system.

1220. Varetto, Mme. J. and Lacombe, L. **Oxygen determination in steel by reduction melting in vacuum and by the Gotta process.** *Rev. universelle mines* **7**, 70-3 (1951).—*C.A.* **45**, 4623*c*.

An investigation of the occasional great differences in results of the detn. of O_2 in steel melts showed that the manner of sampling and the shape of the specimens had a great influence.

1221. Vernon, W. H. J. **Adsorption of water vapor on solid surfaces.** *Nature* **167**, 1037-8 (1951).—*C.A.* **45**, 9334*b*.

The adsorption of water vapor by metal surfaces is negligible provided that both metal surface and the atm. are free from contamination. Fe was particularly susceptible to the presence of disperse solid particles, e.g., traces of $(NH_4)_2SO_4$. Ni provided an extreme case of susceptibility to gaseous pollution, e.g., traces of SO_2.

1222. Wagener, S. **Efficiency and mechanism of barium getters at low pressures.** *Brit. J. Applied Phys.* **2**, 132-8 (1951).—*C.A.* **45**, 7406*i*.

The gettering rates of Ba getters for O_2, N_2, H_2, CO, CO_2, and water vapor were measured in the pressure range 5×10^{-8} to 5×10^{-5} mm of Hg. The gettering effect at these low pressures was due almost entirely to the take-up of atoms or metastable mols. produced by the impact of electrons on the stable gas mols. Ions played a very small part in the gettering process. All the gases contg. O (CO, CO_2, H_2O) were found to belong to the same class as O. Their gettering rates were high ($\geq$700 cc./sec), were almost independent of pressure, and remained fairly const. over several min.

1223. Weber, J. and Laidler, Keith J. **Microwave spectroscopic investigation of the kinetics of the heterogeneous ammonia-deuterium exchange.** *J. Chem. Phys.* **19**, 1089-96 (1951).—*C.A.* **46**, 828*f*.

The technique was applied to detg. the mole fraction of NH_3 in mixts. of deuteriated ammonias, and to a study of the kinetics of the NH_3-D_2 isotopic-exchange reaction on a singly promoted Fe catalyst. Rates of desorption of mols. from surfaces were markedly increased on adsorption of other mols. The rate of the exchange reaction was proportional to the square root of the D_2 pressure. With increasing NH_3 pressure the rate passed through a max., showing that the mechanism involved reaction between adsorbed NH_3 and adsorbed D atoms. The activation energy diminished significantly with increasing NH_3 pressure, providing additional evidence for the existence of strong interactions between adsorbed mols.

1224. Weck, H. I.; Meyerson, S., and Seelig, H. S. **Hydrocarbon synthesis catalyst studies. Use of deuteriochloric acid.** *J. Am. Chem. Soc.* **73**, 2331-3 (1951).—*C.A.* **45**, 7333*i*.

Fe catalysts that had been used in hydrocarbon-synthesis studies liberate H_2 and hydrocarbons when dissolved in HCl soln. By the use of DCl instead of HCl, it was proved that these hydrocarbons were derived from iron carbide and the acid and were not adsorbed synthesis products that were liberated when the catalyst dissolved. No exchange was observed between the H in a sample of n-C_5H_{12} adsorbed on metallic Fe and the D in the DCl used to dissolve the Fe.

1225. Wilkinson, P. G. **The properties of evaporated gold and tungsten oxides.** *J. Applied Phys.* **22**, 226-32 (1951).—*C.A.* **45**, 3676*h*.

Au blacks, prepd. by evapg. Au from a tungsten filament in tank N at several mm pressure, contained W oxides which greatly affected the optical and elec. properties. Deposits contg. more than 0.5 mole % of W oxides were black and showed resistivities 10^3 to 10^8 times that of bulk Au. The resistivities of Au blacks increased on exposure to O_2. On the other hand, oxide-free deposits were yellow and possessed a low stable resistivity, unaffected by exposure to O. So-called Au blacks were black because of the presence of W oxides, since Au evapd. in pressures of several mm of O-free N_2 formed bright reflecting films rather than black absorbing deposits.

1226. Winfield, M. E. **Adsorption and hydrogenation of gases on transition metals.** *Australian J. Sci. Research* **A4**, 385-405 (1951).—*C.A.* **46**, 1939*c*.

The behavior of gases chemisorbed at the surface of face-centered cubic crystals of transition metals is discussed by considering simple models of the surface and the possible arrangements of the gas mols. on them. Models are suggested for the structures of the adsorbates of O_2, H_2, C_2H_4, C_2H_2, and CO on Cu, Ni, and Fischer-Tropsch catalysts. From the properties of these models, mechanisms are suggested for the hydrogenation of C_2H_4 on Ni and for the Fischer-Tropsch hydrocarbon synthesis.

1227. Yanagisawa, Masaaki. **Orientation of products on rolled metal surface.** *Bull. Inst. Chem. Research, Kyoto Univ.* **24**, 75-6 (1951) (in English).—*C.A.* **47**, 1019*c*.

The orientations of several compds. produced on the surface of Cu and Ag foils were studied. The Cu foils were reduced from 2.5 mm to 27-30 μ in thickness and had a fiber structure whose axis [111] was parallel to the direction of rolling. The Ag foils, reduced from 1 mm to 30μ, had also a fiber structure whose [112] was parallel to the direction of rolling. A CuI film produced by making I_2 contact with the Cu foil avoiding sublimation and by heating at 70° for 1 hr showed continuous Debye ring (111) indicating absence of special orientation.

1228. Zwicker, Ulrich. **The system Mn-N.** *Z. Metallkunde* 42, 277-8 (1951).—*C.A.* **46**, 393*c*.

Electrolytic Mn is nitrided with NH_3, N_2, and air Microscopic, röntgenographic, and magnetic investigations are reported and the phase diagram of the system Mn-N_2 from 400 to 1400° is developed. The quenched γ-Mn phase is a solid soln. appearing in the concn. range of the ductile tetragonal form.

1229. Antropoff, A. V.; Propfe, H. A.; Weil, K.; Steinberg, F.; Schaeben, L.; Kalthoff, F.; Schroder, H. J.; Schmitz, L.; Junger, R., and Jungerich, W. **Adsorption of gases at very small to very high pressures.** *Kolloid-Z.* **125**, 40-3 (1952).—*C.A.* **46**, 10774*d*.

Differential adsorption (A_d) of N_2 and A, measured at −76°, −25°, 0°, and 20°C at pressures up to 384 atms., gives isotherms which are like theoritical curves based on the equation $A_d = [qVd/(1 + B(q-1)d)] - Vd$, where q is the distribution coeff., V the adsorption vol., d the molar d. of gas in the gas space, and B of vol. of the gas mols. A_d increases with pressure and then falls off. Some irregularities exist in the adsorption isotherm for N_2 at −25° and −76°.

1230. Arkharov, V. I. and Luchkin, G. P. **Participation of nitrogen in the high-temperature oxidation of titanium in air.** *Doklady Akad. Nauk S.S.S.R.* **83**, 837-9 (1952).—*C.A.* **46**, 8559*h*.

In air, Ti is oxidized less than in O_2 in the range 700-1000°C but from 840°C up, the rate of oxidation in air rises with the temp. faster than in O_2. At still higher temps., Ti is oxidized in air more strongly than in pure O_2. The scale formed by oxidation is in all cases rutile, TiO_2, with some TiO in the thin inner layer close to the metal. In the scale formed by oxidation in air at 1100-1200°C, there is also some Ti_2O_3 in the middle layer. On oxidation in air, or on heating in N_2, some N_2 enters the lattice of rutile, most probably in the form of N^{---} ions which replace O^{--} ions in the ratio 2:3.

1231. Balluffi, R. W. and Alexander, B. H. **Dimensional changes normal to the direction of diffusion.** *J. Applied Phys.* **23**, 953-6 (1952).—*C.A.* **46**, 10749*i*.

Ag from the vapor phase was diffused into thin Au wires and foils at 940°C. Measurements were made of the resulting dimensional changes which occurred normal and parallel to the direction of diffusion. The linear percentage expansion normal to the diffusion direction was slightly less than the corresponding expansion parallel to the diffusion stream.

1232. Barteld, Klaus and Hofmann, Wilhelm. **Oxygen determination in lead.** *Z. Erzbergbau u. Metallhüttenw.* **5**, 102-5 (1952).—*C.A.* **46**, 6033*f*.

A very low O-content was obtained in crude Pb. Only after removal of Sn and Sb was a large quantity of O_2 taken up. The soly. of O_2 in Pb rose from about 1 g per ton at 350°C to about 51 g per ton at 800°C.

1233. Beatty, S. **Note on the effect of oxygen and nitrogen [addition] on the hardness and lattice parameter of high-purity vanadium.** *J. Metals* 4, *Trans.* 987-8 (1952).—*C.A.* **46**, 9042*e*.

Small addns. of O_2 and N_2 result in a sharp increase in the lattice parameter and hardness of V. Progressive line broadening is observed with increasing impurities content.

1234. Becker, W. M. and Lark-Horovitz, K. **Semiconducting films.** *Proc. Natl. Electronics Conf.* **8**, 506-9 (1952).—*C.A.* **47**, 3689*g*.

By thermal dissocn. of GeH_4 at 600° Ge films were produced from less than 0.1μ to 1.5μ thick depending on temp. At room temp. all the films had p-type conduction, caused by lattice defects, as observed already with polished layers on n-type Ge. The carrier mobility was lower than in bulk Ge and only 20-140 cm^2/sec volt. The contacts were made with aquadag. By addn. of the hydrides of As, Sb, and Bi to GeH_4, films with n-type conduction could be made.

1235. Bouillon, F. **The dry oxidation of copper and its alloys. II. The isothermal oxidation of pure copper.** *Bull. soc. chim. belges* **60**, 451-8 (1952) (English summary).—*C.A.* **46**, 7498*a*.

CuO is formed only from Cu_2O and not from pure Cu directly. The Cu_2O layer must reach a crit. thickness before CuO can form. This thickness was detd. as 2600 A. Calcns. from parabolic kinetic constants at 173 and at 247° show that the activation energy is 19,000 cal/mole.

1236. Brace, A. W. **Gas removal from molten aluminum alloys.** *Metal Ind.* (London) **80**, 502-4 (1952).—*C.A.* **46**, 9494b.

In order to minimize gas porosity in Al alloys a trial heat was melted and raised to 880-900°. Pure Cl_2 was bubbled through this Al for 4 min. The metal was then allowed to cool and poured. Radiographs run on these castings showed a substantial decrease in porosity. Cl_2 evolved by the decompn. of org. chlorides exerted a coarsening effect on the grain structure, which could be corrected through use of a grain-refining element, such as B.

1237. Brasunas, Anton deS. and Grant, Nicholas J. **Accelerated oxidation of metals at high temperatures.** *Trans. Am. Soc. Metals* Preprint No. 3W, 30 pp. (1952).—*C.A.* **46**, 326*a*.

Six Mo-bearing and 3 V-bearing alloys were heated up to 1170° in O_2. At the metal-oxide interface, the concn. of the metal having a volatile or low-melting oxide was abnormally high; this is essential to high oxidation rate. Moving atms. that increased the rate of vaporization of volatile oxides retarded the oxidation rate of alloys that formed these oxides. The rate of reaction was frequently so rapid that the liberation of heat raised the temp. of the specimen.

1238. Breckenridge, R. G. and Hosler, W. R. **Titanium dioxide rectifiers.** *J. Research Natl. Bur. Standards* 49, 65-72 (1952) (Research Paper No. 2344).—*C.A.* **47**, 2062*e*.

Pure polished Ti metal when coated with TiO_2, which had been partially reduced, formed an elec. rectifier. Two processes used to form the semiconducting oxide layer were (1) oxidation of the metal by dry O_2 at 800°C for 9 hrs followed by reduction in H_2 at 500°C for 15 min. and (2) oxidation in H_2O at 600°C for 3 hrs. Process (2) carried out at 1 atm. was more easily controlled. It eliminated both O_2 and H_2 embrittlement of Ti, and produced a greater uniformity of surface oxide layer. Semiconducting films of 0.0003 in. thickness with an av. formula $TiO_{1.95}$ gave good rectification.

1239. BUMPS, E. S.; KESSLER, H. D., AND HANSEN, M. **The titanium-oxygen system.** *Trans. Am. Soc. Metals* Preprint No. 32, 18 pp. (1952).--*C.A.* 46, 9495*i*.

Micrographic analysis of arc-melted alloys contg. up to 56 at. % O_2 showed: (1) 2 peritectic reactions: melt $+ \alpha \rightleftarrows \beta$ at 1740° and melt $+ \alpha \rightleftarrows TiO$ at 1770°C; a peritectoid reaction $\alpha + TiO \rightleftarrows \delta$ at approx. 925°C; (3) max. m.p. of α-Ti + 10 at. % O_2 at 1990°C; (4) max. soly. of 1.8% O_2 in β-Ti at 1740° and of approx. 14.5% O_2 in α-Ti between 700° and 1600°C.

1240. BURSHTEĬN, R. KH. AND SHUMILOVA, N. A. **Interaction between iron and ozone.** *Doklady Akad. Nauk S.S.S.R.* 83, 251-2 (1952).—*C.A.* 46, 8478*d*.

Iron plates of 90 cm² true surface area were exposed, at 190°, 290°, 385°, and 430°K, to O_2 or to $O_2 + O_3$, and the thicknesses of the oxide layer formed were detd. by the amt. of H_2 necessary to reduce them. At each temp., the thicknesses of oxide layers formed in O_2 and in $O_2 + O_3$ were very close; the latter was only slightly thicker.

1241. BUTTNER, F. H.; FUNK, E. R., AND UDIN, H. **Adsorption of oxygen on silver.** *J. Phys. Chem.* 56, 657-60 (1952).—*C.A.* 46, 7396*e*.

The surface tension of solid Ag, measured by the weighted-wire method, was 1140 ± 90 dynes/cm in the range 870-945°C. The surface tension decreased linearly with the log of the O_2 partial pressure. Use of the data with the Gibbs adsorption isotherm indicated that O_2 was chemisorbed on Ag and that at 932°C there were approx. 1.4 atoms of O adsorbed per Ag atom at the surface.

1242. CIMINO, A. AND PARRAVANO, G. **Nickel carbide by decomposition of *n*-hexane on metallic nickel.** *J. Phys. Chem.* 56, 706-7 (1952).—*C.A.* 46, 8941e.

n-C_6H_{14} was passed in a stream of N_2 over powd., active Ni (obtained from $Ni(NO_3)_2$) at 250-327°C. Gravimetric detns., hydrogenation of the products, and x-ray analysis indicated that n-C_6H_{14} was decompd. and Ni_3C (stable up to at least 300°) and C were formed. The amt. of carbide formed as detd. by hydrogenation was about equal to the first rapid stage of the process and amounted to 95% of the total C deposited. The reaction proceeded by dissociative adsorption of n-C_6H_{14} on Ni, production of at. C, and diffusion through the Ni_3C formed.

1243. CLASING, M. AND SAUERWALD, F. **Effect of surface layers, especially oxides, on the sintering of metals.** *Z. anorg. u. allgem. Chem.* 271, 88-92 (1952).--*C.A.* 47, 5854*f*.

The powders were first reduced and then artificially oxidized. After sintering Cu in vacuo, a definite strength max. was found for an oxide layer of 400-600 A. When heavier oxide films surrounded the particles they could not be absorbed during sintering and interfered with bonding. When sintering Cu in H_2, highest tensile strength was found for approx. the same oxide film thickness. The drop in strengths for higher O_2 contents was attributed, in this case, to an excess amt. of loosening of the surface structure or too much H_2O vapor as a result of the reduction.

1244. CUBICCIOTTI, DANIEL. **The oxidation of calcium at elevated temperatures.** *J. Am. Chem. Soc.* 74, 557-8 (1952).—*C.A.* 47, 2077*g*.

Ca was oxidized 100 min. at 200 mm O_2 and 330-475°C. Oxidations below 435°C obeyed the parabolic law for at least 100 min. At 435°C the curve was not parabolic beyond the 1st 5 min. The oxidations had an induction period followed by a rapid rise to an approx. linear shape after about 50 min.

1245. CUBICCIOTTI, DANIEL. **The reaction between uranium and oxygen.** *J. Am. Chem. Soc.* 74, 1079-81 (1952).—*C.A.* 47, 4175*i*.

U oxidizes according to the parabolic law at 90-165°C, and according to the linear law at 165-215°C. At still higher temps. the oxidation curve was lower than 1st degree in the wt of C_2 consumed. The temp. of the parabolic to linear transition for U was lower than that for Th. In a long oxidation at 170°C, the initially parabolic oxidation became more rapid than parabolic after 100 min.

1246. CUBICCIOTTI, DANIEL. **The reaction of cerium with oxygen.** *J. Am. Chem. Soc.* 74, 1200-1 (1952).—*C.A.* 46, 6472g.

The oxidation of Ce obeys the parabolic law from 30 to 125°C. Above 125°C the reaction starts parabolically, but subsequently becomes linear. The parabolic portion becomes shorter as the temp. is increased. The oxidation of Ce is the most rapid of the known parabolic metal oxidations. The energy of activation of the parabolic reaction (12 kcal./mole) is the smallest yet observed.

1247. CULLELL, JOSE AGUILERA. **Degassing of light alloys by hexachloro-ethane.** *Inst. hierro y acero* 5, Spec. No. Feb. 209-14 (1952).—*C.A.* 46, 6573*i*.

The mean tensile strength for over 167 tensile test specimens was 19.25 kg² and 20.65 kg², resp., and elongation of 0.52% and 0.81%. The addn. consisted of 3 treatments of 140 g of C_2Cl_6 each for 100 kg of alloy at 800°C and below and then casting at 760°C.

1248. DANKOV, P. D. **The theory of oxidation of alloys.** *Zhur. Fiz. Khim.* 26, 753-8 (1952).—*C.A.* 47, 5224*a*.

The oxidation of a 80% Ni + 20% Cr alloy is discussed. The oxidation of this alloy ought to be characterized by 3 different successive steps. In the beginning, the outermost layer is NiO, the subjacent layer being $NiO.Cr_2O_3$ plus an excess of NiO. At later stages, a two-phase layer is formed with $NiO.Cr_2O_3$ plus an excess of Cr_2O_3. Finally, the outermost layer consists of α-Cr_2O_3, the subjacent layer being again $NiO.Cr_2O_3$ plus an excess of Cr_2O_3.

1249. Dawson, J. K. **The sublimation technique for the preparation of thin films of plutonium.** *Ministry of Supply, Harwell, Berks. (Eng.) At. Energy Research Estab., Unclassified* C/R 861, 26-9 (1952).—*C.A.* 46, 10991*i*.

Since a temp. of 2500°C at 10^{-6} mm Hg is necessary for the sublimation of U (from oxide produced from nitrate soln.), W is the only usable filament material. Ta filaments employed with Pu nitrate soln. give no stains on the collecting trays unless the soln. contains impurities such as Fe.

1250. Devienne, Marcel. **Condensation of molecular jets of antimony on a surface.** *Compt. rend.* 234, 80-1 (1952).—*C.A.* 46, 3359*b*.

At 25°C for the condensation plate and for a deposit of about 40 A., the condensation factor of Sb on Cu is very close to 0.74 (temp. of the furnace 320°C, pressure less than 10^{-4} mm of Hg.) The "condensation factor" increases with thickness; for a deposit of 14A., it is about 0.55 and for a deposit about 100A. thick, the factor is about 0.76.

1251. Dietrich, Isolde. **Measurement of the resistance of thin insulating layers between gold contacts in the region of the tunnel effect.** *Z. Physik* 132, 231-8 (1952).—*C.A.* 46, 9369*c*.

Known quantities of TiO_2 were evapd. on clean Au surfaces, and the thickness of the condensed layers was detd. from the change in wt and interferometrically. The sp resistance of TiO_2 layers was detd. from independent measurements. For thicknesses below 1000 A. the values found at room temp. were between 10^9 and 10^{10} ohm-cm. Up to TiO_2 thicknesses of 100 A. between Au contacts the resistance of the assembly was temp.-independent and detd. only by the tunnel effect and not by the resistance of the layer.

1252. Doring, H. and Moliere, K. **Dissociation of zirconium iodide on hot metal surfaces.** *Z. Elektrochem.* 56, 403-8 (1952) (in German) *C.A.* 46, 9390*e*.

The evacuated tube containing excess Zr was heated in an elec. oven between 150° and 550°C. Wire was heated by an elec. current to 1000° to 1500°C. The ZrI_4 vapor decompd. on the hot wire to Zr, which was deposited on the wire, and I_2, which recombined with the excess Zr powder. The rate of growth of the wire radius was independent of the time, and of the surface area of the wire, showing that the I_2 was absorbed by the Zr before returning to the wire. This was true only when the expts. were not continued too long, or the wire temp. was not too high.

1253. Dunnington, B. W.; Beck, F. H., and Fontana, M. G. **The mechanism of scale formation on iron at high temperature.** *Corrosion* 8, 2-13 (1952).—*C.A.* 46, 1419*d*.

Diffusion of lattice vacancies in the metal influences the type of oxide formed on Fe at high temp. An adherent layer forms on one side of thin specimens, and on the opposite side a loose, more highly oxidized layer forms. The oxide layer on a large specimen is uniform over the entire surface but of a different character from the layers formed on a thin specimen.

1254. Eggleton, A. E. J. and Tompkins, F. C. **Thermal accommodation coefficient of gases and their adsorption on iron.** *Trans. Faraday Soc.* 48, 738-49 (1952).—*C.A.* 47, 2567*f*.

Use was made of the large difference in the thermal accommodation coeff. (α) of Ne at the surface of a pure Fe wire in an investigation of the methods of producing a surface free of contaminants. Reduction in H_2 followed by flashing *in vacuo* at 1200°C proved ineffective, but Ne-ion bombardment was successful if this was preceded by a preliminary treatment with N ions. Values of α for Ne at surfaces covered with adsorbed gases were: 0.0995 at 3×10^{-4} mm H_2; 0.111 at 1.5×10^{-2} mm H_2; max. of 0.268 for O_2; max. of 0.438 for N_2. The value of $\alpha = 0.053$ is given for a clean Fe surface. O_2 can displace both H_2 and N_2 from the surface, and this emphasizes the importance of removing small traces of O_2 when using H_2 or N_2 as adsorbate.

1255. Eggleton, A. E. J.; Tompkins, F. C., and Wanford, D. W. B. **Measurements of the thermal accommodation coefficients of gases.** *Proc. Roy. Soc.* (London) A213, 266-73 (1952).—*C.A.* 46, 10732*i*.

The exptl. value for the accommodation coeff. for Ne at a W surface is discussed. App. is described and new results are reported. The continuous circulation of the inert gas through charcoal traps cooled with liquid N_2 is an essential precaution.

1256. Eischens, R. P. **Isotopic exchange rates as criteria of surface heterogeneity.** *J. Am. Chem. Soc.* 74, 6167-71 (1952).—*C. A.* 47, 3668*g*.

The exchange between chemisorbed and gaseous CO over unpromoted Fe was followed by introducing $C^{14}O$ as the chemisorbed phase and measuring the rate of its appearance in the gaseous phase. The most weakly bonded CO exchanges the fastest. The exchange data show that the Fe is heterogeneous. There is no difference in the chem. properties of $C^{14}O$ and CO within the limit of exptl. accuracy (1%).

1257. Eischens, R. P. and Webb, A. N. **Carbon-oxygen exchange in chemisorbed carbon monoxide.** *J. Chem. Phys.* 20, 1048-9 (1952).—*C.A.* 46, 10775*e*.

A mixt. of $C^{13}O$ and CO^{18} was chemisorbed on Fe and then progressively desorbed at temps. from –78 to 160°C. The desorbed gas was analyzed for $C^{13}O^{18}$ with a mass spectrometer. A significant intermol. O exchange occurred as low as –33°C (the detn. at –78° failed); at 120-160°C equil. was almost attained within a pumping time of 52 hrs. The desorbed gas collected at 120-160°C contained almost 50% CO_2; this gas was in isotopic equil. with the CO.

1258. Engell, H. J. and Hauffe, K. **Influence of of adsorption phenomena on the oxidation of metals at high temperatures.** *Metall* 6, 285-91 (1952).—*C.A.* 46, 8585*b*.

The nature of the oxide layer formed (porosity, diffusion of ions or electrons through this layer, or layer of scale, d. of the oxide layer), the lattice structure of the metal and the mode of entry of O_2 into the lattice, the influence of skin formation on the formation of a thick oxide layer, and various other factors are considered.

1259. Fedorchenko, I. M. **Heats of activation for surface self-diffusion of metals.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk* **1952**, 560-71.—*C.A.* **47**, 6842*i*.

Powd. Fe, stainless steel, Cu, Ni, and Al were heated to 300-1200°C, and the decrease in specific surface was detd. The diffusion coeff. D was calcd. by means of an equation relating D to the specific surface. The heat of activation for surface diffusion, Q, was calcd. from the equation $D = Ae^{-Q/RT}$, A being a const. for each type of material.

1260. Feldman, Charles. **The protection of thin deposits of molybdenum by a layer of SiO obtained by evaporation in vacuo.** *Compt. rend.* **235**, 706-7 (1952).—*C.A.* **47**, 3073*g*.

The rate of oxidation was followed by measuring the elec. resistance. Thin layers of SiO offered moderate protection, whereas layers of the order of $1\ \mu$ in thickness offered very good protection. Oxidation is attributed to diffusion across the layer of SiO, either of the metal or of O_2.

1261. Fischer, W. A. and Ende, H. vom. **The solubility of oxygen in iron melts under ferrous oxide, silicic-acid- and lime-saturated ferrous oxide slags for temperatures from 1530° to 1700°C.** *Arch. Eisenhüttenw.* **23**, 21-33 (1952).—*C.A.* **46**, 5502*i*.

Crucibles were made of pure lime. Under FeO slags contg. FeO 85-90, Fe_2O_3 8-10, and MgO 2-5%, O_2 contents of 0.18-0.33% in the Fe were detd. in a magnesite crucible. Under SiO_2-satd. slags contg. 40-8% SiO_2 and the remainder essentially FeO, O-contents of 0.09-0.13% in the Fe in the sand crucible, and O-contents of 0.08-0.12% were found under lime-satd. slags contg. CaO 32-8, SiO_2 2-4, MgO 1, Al_2O_3 1, and total Fe 40-6% in the lime crucible.

1262. Fontana, C. M.; Gorin, Everett, and Meredith, C. S. **Chlorination of methane with copper chloride melts. Kinetics of oxygen absorption by the melt.** *Ind. Eng. Chem.* **44**, 373-8 (1952).—*C.A.* **46**, 4333*d*.

In the chlorination of light hydrocarbons by means of $CuCl_2$ melts, the rates of O_2 absorption were detd. by the decrease in pressure with time in reactors contg. melts of known compn. and known surface area. Extensive data illustrated the decrease in rate with increasing Cu-content the increase in rate with increasing KCl-content, the specific effects on the rate resulting from the replacement of KCl with NaCl or $CaCl_2$, and the unusually low values of the apparent activation energy (9-14 kcal./mole).

1263. Forestier, Hubert and Maurer, Joseph. **The influence of absorption of gas on the surface hardness of quenched and age-hardened beryllium copper.** *Compt. rend.* **234**, 2196-8 (1952).—*C.A.* **46**, 7973*i*.

Quenched specimens of Be-Cu (2.5% Be) were aged at 250° to 500°C in purified CO_2,A, and H_2, and *in vacuo*. Max. hardness varied slightly and occurred at 365° in CO_2, 375° in A, 400° in H_2, and 410°C *in vacuo* because of absorbed gas in the surface layers of the alloy to depths of approx. 0.1 mm. Rate of hardening was fastest in H_2 and slowest in CO_2.

1264. Fukuroi, Tadao.; Tanuma, Seiichi, and Tobisawa, Shotaro. **Electrical properties of antimony-doped tellurium crystals.** *Science Repts. Research Inst., Tohoku Univ., Ser. A.*, **4**, 283-97 (1952).—*C.A.* **47**, 5201*g*.

Sb-doped Te crystals (0.002-5 at. % Sb) were studied between −190 to 300°C and the Hall coeffs. detd. at −190°C and at room temp. Both resistivity and Hall coeff. of the purer samples showed the characteristics of the intrinsic cond. in the high-temp. range, whereas resistivity decreased from 4.2×10^{-1} to 1.7×10^{-3} ohm-cm at room temp. and from 2.4 to 8.2×10^{-4} ohm-cm at liquid-air temp. and the Hall coeff. changed from -3.6×10^3 to $+3.3$ electromagnetic units at room temp. and from $+3.9 \times 10^4$ to $+2.7$ at liquid-air temp. as the Sb content increased by 5.2%. The Hall coeff. of alloys contg. more than 1% Sb increased with rising temp. The thermoelec. power showed a complicated but systematic temp. variation with sign.

1265. Gemant, Andrew. **Film formations on metals in hydrocarbons.** *J. Electrochem. Soc.* **99**, 279-84 (1952).—*C.A.* **46**, 11063*h*.

Cu, Pb, and Zn were subjected to corrosion tests in oxidized transformer hydrocarbon oils and in fresh oils whose conductivities were increased by small addns. of tridecanoic acid (labelled with C-14), tributyl amine, and o-cresol. The radioactivity of the deposits served as a measure of the corrosion rate. The rates on all 3 metals were several fold higher in the mixt. than minus the amine. Pb was often attached as much as 50 times faster than Cu, and Cu was more rapidly attached than Zn. Visible deposits were observed. Electrochem. film formation was possible in addn. to chem. formation. The oxidized oils often dissolved corrosion products, especially those from Cu.

1266. Ghosh, J. C.; Sastri, M. V. C., and Kini, K. A. **Adsorption of hydrogen and carbon monoxide and their mixtures by cobalt Fischer-Tropsch catalysts.** *Ind. Eng. Chem.* **44**, 2463-70 (1952).—*C.A.* **47**, 7195*b*.

The adsorption of CO and H_2, as pure gases and in mixts. of 1-to-1 and 1-to-2, were studied at varying temps. on two Co catalysts. Catalyst A consists of 34.22% Co, 4.05% Cu, 2.33% thorium oxide, 0.24% cerium oxide, and the balance kieselguhr. Catalyst B was the same as A plus 4.6% chromium oxide. Catalyst B chemisorbed much more of either pure gas or mixts. than A. Rates of adsorption were higher with B than A.

1267. Gobrecht, H. and Barsch, G. **Radiation from freshly evaporated metal and salt layers.** *Z. Physik* **132**, 129-39 (1952).—*C.A.* **46**, 9971*a*.

Fe, Ni, Al, and Sb, or of salts such as NaCl and K_2SO_4, produced a blackening of a photographic plate held close to, but not necessarily in contact with them. The radiation was not related to the formation of the metal, but was one of slow electrons produced by oxidation or adsorption on the surface. Sharp edges, scratches, different layer thicknesses, different supports, and centers of metal formation affected the reaction rate.

1268. GRUNBERG, L. AND WRIGHT, K. H. R. **Russell effect on evaporated metal films.** *Nature* 170, 456-7 (1952).—*C.A.* 47, 2563*i*.

Evapd. films of metals, when exposed to the action of O_2 and water vapor, were found capable of producing an image on photographic plates. At a given ratio of water/O_2, the optical d. increased at first with increase in air pressure. At higher air pressures the d. became independent of the pressure.

1269. HACKERMAN, NORMAN AND COOK, E. L. **Dual adsorption of polar organic compounds on steel.** *J. Phys. Chem.* 56, 524-6 (1952).—*C.A.* 46, 7018*h*.

Portions of the surface of steel powder are apparently specific to the irreversible adsorption of alkyl carboxy acids, amines, alcs., and esters. Alcs. and esters are not irreversibly adsorbed by steel powder on which an acid has already been irreversibly adsorbed. The max. amt. of irreversible adsorption observed with the org. solutes is not sufficient to form a closed packed monolayer over the surface of the steel powder available for Kr adsorption.

1270. HALL, W. KEITH; TARN, WM. H., AND ANDERSON, ROBERT B. **Fischer-Tropsch synthesis. XIII. Structural changes of a reduced iron catalyst on reoxidation and on formation of interstitial phases.** *J. Phys. Chem.* 56, 688-91 (1952).—*C.A.* 46, 10582*g*.

Upon complete reduction at 450° or 550°C, a fused Fe synthetic NH_3 catalyst develops an extensive pore structure corresponding to about 45% porosity. On reoxidation, the vols. of the individual particles remain const., while the surface areas and pore vols. decrease. Formation of the interstitial nitrides and carbides causes the catalyst particles to expand and the pore vol. and av. pore diam. to increase.

1271. HARRIS, LOUIS AND BEASLEY, JOHN K. **The infrared properties of gold-smoke deposits.** *J. Optical Soc. Am.* 42, 134-40 (1952).—*C.A.* 46, 4365*g*.

Au-smoke deposits are very porous structures of colloidal Au particles prepd. by evaporating Au in an inert atm., such as N_2, at a pressure of about 2-3 mm Hg. The evaporated Au atoms condense to form particles about 100 A. in diam., which adhere to one another to form chains and aggregates.

1272. HARRISON, E. R. **A simple method of purifying hydrogen, nitrogen, and the inert gases.** *J. Sci. Instr.* 29, 295 (1952).—*C.A.* 47, 3529*g*.

Water vapor and O_2 are removed from com. H_2,N_2, and A by passing through a trap contg. a Na-K alloy. The trap consists of a large glass U-tube contg. a 25% Na-75% K liquid alloy. As a drying means the Na-K alloy trap compares favorably with silica gel and $CaCl_2$, but is slightly less efficient than Mg perchlorate.

1273. HART, R. K. **The thermal oxidation of tin.** *Proc. Phys. Soc.* (London) 65B, 955 (1952).—*C.A.* 47, 3669*i*.

Electron-diffraction expts. show that when Sn foil is thermally oxidized in air, an amorphous oxide layer is formed up to 130°C. Above 130° only cryst. SnO and SnO_2 are formed. The formation of a protective amorphous oxide with rising temp. precedes the growth of the cryst. oxide.

1274. HAUFFE, K. AND PFEIFFER, H. **The participation of phase-boundary reactions in the oxidation of metals and alloys at higher temperatures.** *Z. Elektrochem.* 56, 390-8 (1952).—*C.A.* 46, 9391*a*.

The rate-detg. step was the entrance of Fe into the FeO phase as Fe^{1+} ions and electrons. The lattice defect concn. in the FeO phase was calcd. as a function of the CO/CO_2 ratio. The Zn expts. made under N_2-O_2 mixts., also led to the conclusion that phase-boundary reactions played a part. In the NiS reaction, the NiS layer was porous and allowed the direct attack of metal by S_2 vapor, the dissocn. and adsorption of S_2 being rate-detg. MoO_3 or WO_3 catalyzed the oxidation of Ni, whereas Li_2O inhibited it; the reverse was true with Ti.

1275. HEAVENS, O. S. **The contamination in evaporated films by the material of the source.** *Proc. Phys. Soc.* (London) 65B, 788-93 (1952).—*C.A.* 46, 11028*h*.

Contamination was detected both by microchem. test and by radioactive-tracer method for Ag and Ge evapd. from Mo or W filaments. The limit of sensitivity of detection of the W and Mo was discussed. Evapn. from Ta filaments was also studied. Evapd. film thickness was detd. by multiple-beam interferometry.

1276. HEDVALL, J. ARVID; BRISI, CESARE, AND LINDNER, ROLAND. **Self diffusion in monocalcium ferrite.** *Arkiv Kemi* 4, 377-80 (1952).—*C.A.* 47, 3072*c*.

The self diffusion of Ca and Fe in tablets of $CaO.Fe_2O_3$ is detd. by use of Ca^{45} and Fe^{59} as the radioactive indicators. Equimolar amts. of $CaCO_3$ and Fe_2O_3 are heated first to 950°C and then to 1150°C, then powd., hand-pressed into tablets, and heated for 20 hrs at 1150-80°C. Measured amts. of the indicator in paste form are placed in intimate contact with the tablets, and the temp. functions of the diffusion consts. detd.

1277. HELWIG, G. **Electrical conductivity and structure of sputtered cadmium oxide layers.** *Z. Physik* 132, 621-42 (1952).--*C.A.* 46, 10745*c*.

By cathodic supttering of Cd with pure O_2 in a carefully controlled app. (water-cooled electrodes) CdO layers of great mech. strength high light transparency, and good elec. cond. were prepd. under reproducible conditions. Lattice defects and gas inclusions were shown present by electron interference studies.

1278. HENISCH, H. K. AND SAKER, E. W. **The effect of mercury on selenium.** *Proc. Phys. Soc.* (London) 65B, 149-54 (1952).—*C.A.* 46, 10994*i*.

Mercuric selenide formed when Hg liquid or vapor interacts with cryst. Se. Vol. and surface diffusion were measured by means of radioactive Hg. If Hg was added to Se before crystn., there resulted a high resistivity due to reduction in positive-hole mobility. The effect of Hg was not merely a surface effect but concerns thick layers.

1279. HEROLD, ALBERT; MULLER, PIERRE, AND ALBRECHT, PIERRE. **Permeability of steel by lithium.** *Compt. rend.* **235**, 658-9 (1952).—*C.A.* **47**, 2005*i*.

Pieces of Li were placed in 0.1% C steel tubes with 1-mm walls which were welded tight at the ends. They were heated in H_2, and the presence of Li on the outside was detd. spectroscopically. The element did not permeate steel in the gamma state or pure iron. Quenched steels remained impermeable to Li on heating at 600°C in H_2 on account of their fine distribution of carbides.

1280. HILL, TERRELL L. AND KEMBALL, CHARLES. **Thermodynamic functions of adsorbed molecules from surface-tension measurements: toluene, benzene, and heptane on mercury.** *J. Am. Chem. Soc.* **74**, 3946-8 (1952).—*C.A.* **47**, 9742*b*.

Calcd. adsorption isotherms for toluene, C_6H_6, and C_7H_{16} were of the conventional form; toluene and C_6H_6 showed some indications at the beginning of multilayer adsorption at the lighest pressures. At low coverages the order of decreasing energy of binding was toluene, C_6H_6, and C_7H_{16}; the energies of vaporization were 8.7, 7.5, and 8.3 kcal./mole, resp., at av. T = 310.1°K. There was little variation in the energy of adsorption over the range investigated.

1281. HOFFMAN, R. E. AND TURNBULL, D. **Effect of impurities on the self-diffusion of silver.** *J. Appl. Phys.* **23**, 1409-10 (1952).—*C.A.* **47**, 3645*e*.

The effect of Pb in dil. Ag-Pb alloys on diffusion of Ag is expressed by $D = D° + xD'$, where $D°$ is the self-diffusion coeff. in pure Ag, x is the mole fraction of Pb, and $D' = 7.6 \exp(-40{,}500/RT)$ cm^2sec^{-1}.

1282. HUDSWELL, F. **Methods available for the preparation of thin films.** *Ministry of Supply, Harwell, Berks. (Engl.) At. Energy Research Estab., Unclassified* **C/R 861**, 10-21 (1952).—*C.A.* **46**, 11078*i*.

Foils in the form of hollow Ta cylinders are heated by high-frequency induction. Ti and I_2 are enclosed in the same vessel, which is evacuated. Ti iodide is prepd. gradually by heating to 200°C. When the foil is heated to 1400°C the iodide is decompd. at its surface. Thus, the reservoir of metal is gradually combined with I_2 to build up a Ti film on the Ta foil.

1283. HUFF, G. F.; BAILEY, G. R., AND RICHARDS, J. H. **Sampling of liquid steel for dissolved oxygen (with discussion).** *J. Metals* **4**, *Trans.* 1162-1228 (1952).—*C.A.* **47**, 1004*g*.

An improved bomb-sampling technique is described for obtaining samples for O_2 analysis from liquid steel.

1284. HUGHES, R. C.; COPPOLA, P. P., AND EVANS, H. T. **Chemical reactions in barium oxide on tungsten emitters.** *J. Applied Phys.* **23**, 635-41 (1952).—*C.A.* **46**, 8510*e*.

When $BaCO_3$ is heated *in vacuo* in contact with W, the following reactions may occur in sequence as progressively higher temps. are reached: (1) $WO_3 + BaCO_3 \rightleftarrows BaWO_4 + CO_2$; (2) $3BaCO_3 + W \rightleftarrows Ba_3WO_6 + 3CO$; (3) $BaCO_3 \rightleftarrows BaO + CO_2$; (4) $6BaO + W \rightleftarrows Ba_3WO_6 + 3Ba$. At approx. 600° reaction (2) begins to occur with appreciable speed. Reaction (3) proceeds at 800-900°.

1285. HUGHES, R. C. AND COPPOLA, P. P. **Bariated tungsten emitters.** *J. Appl. Phys.* **23**, 1261-2 (1952).—*C.A.* **47**, 1483*a*.

Thermionic emitters consisting of Ba oxide dispersed throughout a body of porous W can be successfully made if suitable compds. of Ba are employed as the source of the oxide. Compds. such as the carbonate, are unsuitable. If by various means, BaO is dispersed in W, reaction occurs at the operating temp. of the cathode to generate free Ba slowly. $6BaO + W \rightarrow Ba_3WO_6 + 3Ba$, which diffuses to the surface and lowers the work function.

1286. INGRAHAM, T. R. AND PIDGEON, L. M. **Reactions of titanium tetraiodide on heated titanium and tungsten surfaces.** *Can. J. Chem.* **30**, 694-7 (1952).—*C.A.* **47**, 952*i*.

When TiI_4 is passed over a hot bar of Ti metal, the reactions depend on whether the temp. of the bar is above or below 1100°C. If the temp. is below 1100°, Ti is rapidly etched from the bar to form TiI_2. The activation energy for this reaction over the temp. range 800-1000° is 19.8 ± 0.5 kcal. At bar temps. above 1100°C TiI_4 is decompd. to Ti and I_2. The activation energy for the deposition of Ti on a W bar is 92.0 ± 2 kcal.

1287. ITTERBEEK, A. VAN; GREVE, L. DE, AND HEREMANS, F. **Measurements of the formation of thin tin films.** *Applied Sci. Research* **B2**, 352-60 (1952).—*C.A.* **46**, 8448*i*.

Sn films were sputtered in H_2, Ne, He, and A. The films formed in H_2 exhibited infinite resistance, but those formed in Ne, He, and A exhibited a finite resistance if they were not too thin. The sp resistance of the films sputtered in He was approx. ten times that of the films sputtered in Ne. The rate of oxidation was followed by measuring the change in resistance with time after admission of O_2 to a sputtered film.

1288. JENKENS, A. E. AND WORNER, H. W. **The structure and some properties of titanium oxygen alloys containing 0-5 atomic per cent oxygen.** *J. Inst. Metals* **80**, 157-66 (1951) (Paper No. 1337).—*C.A.* **46**, 2468*a*.

The limits of the $\alpha + \beta$ region up to 5 at.% O_2 were established by quenching expts. and thermoelec. measurements at various temps. Impurities in com. Ti caused a marked broadening of $\alpha \rightleftarrows \beta$ transformation range. Forging, cold working, and annealing procedures were given for alloys contg. 3.5 at. % O_2.

1289. JOSEFSSON, AKE AND KULA, ERIC. **Determination of nitrogen and carbon dissolved in α-iron by internal friction measurements on soft steel of commercial purity.** *Jernkontorets Ann.* **136**, 63-73 (1952).—*C.A.* **46**, 7487*g*.

Presence of impurities such as Mn and P changed the position of the internal friction curve for N_2 and broadened it. Fixation of N_2 by Al was illustrated, also the inclination of N_2 to stay in supersaturated solid solution, even at rather slow cooling rates.

1290. Kaiser, Wolfgang. **New light absorption in silver halides.** *Z. Physik* 132, 497-507 (1952).—*C.A.* 46, 9996*c*.

AgCl and Ag are condensed simultaneously to obtain thin films. New absorption bands at 375 and 530 mμ are found, of which the former is removable by irradiation. The corresponding bands for AgBr plus Ag occur at 400 and 570 mμ. The low-wave bands are probably caused by inclusion of dispersed at. Ag or by its surface adsorption.

1291. Kefeli, L. M. and Lel'chuk, S. L. **Pyrophoricity of the nickel skeleton catalyst.** *Doklady Akad. Nauk S.S.S.R.* 83, 697-9 (1952).—*C.A.* 46, 6916*g*.

It is not possible to desorb the H_2 dissolved in the catalyst by mere evacuation. Removal of the H_2 by oxidation under H_2O (through the O_2 dissolved in H_2O) is extremely slow; thus, after 2 months standing under H_2O, at room temp., the catalyst was still pyrophoric. Catalytic activity is contingent on occlusion of H_2 at the stage of formation of the catalyst. Likewise, films of Pt, Ni, Fe, or W, evapd. in strict absence of a gas, are inactive, and cannot be reactivated by subsequent treatment with a gas.

1292. Keier, N. P. **Role of the different adsorption centers in the hydrogenation of acetylene or metallic nickel. I. Investigation of the active surface of nickel with the aid of the differential isotopic method.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* 1952, 616-26.—*C.A.* 46, 10820*g*.

Desorption and catalytic reactions of C_2H_2 on Ni were investigated by following the C_2H_2 by portions, one of which was tagged with radioactive C^{14}; the desorbed gas or the gaseous reaction products were analyzed for C^{14} by radioactivity measurements. This catalyst did not adsorb C_2H_4 or C_2H_6, but did adsorb C_2H_2 in significant amts. even at room temp. On desorption at 150°C of C_2H_2 adsorbed at room temp. CH_4 and H_2 were found, along with C_2H_2, which were not evolved in the course of the adsorption. 3 kinds of active centers were inferred: centers from which C_2H_2 was desorbed reversibly, centers of hydrogenation, and centers of decompn. of C_2H_2.

1293. Kemball, C. **Reaction of ammonia and deuterium on evaporated nickel catalysts.** *Trans. Faraday Soc.* 48, 254-8 (1952).—*C.A.* 46, 8489*c*.

The exchange reaction was followed between 33° and 115°C by means of a mass spectrometer. The initial product was NH_2D and the other deuterioammonias were formed by successive reactions. The energy of activation for the initial reaction was 8.7 kcal./mole, and the rate of reaction was proportional to $p_{D_2}^{1/2}$ and to a slightly greater power of p_{NH_3}. The adsorption of NH_3 on a freshly prepd. Ni film was measured at 0°. The adsorption was complete in less than a min., and the amt. adsorbed corresponded to 6.2×10^{18} mols. per 100 mg of Ni at 0.07 mm. The adsorption of NH_3 was only slightly less than the adsorption of D_2 under the same conditions.

1294. Kemball, C. **Catalysis on evaporated films. I. The efficiency of different metals for the reaction between ammonia and deuterium.** *Proc. Roy. Soc.* (London) A214, 413-26 (1952).—*C.A.* 46, 10820*f*.

The exchange reaction between NH_3 and D_2 was studied on evapd. films of Pt, Rh, Pd, Ni, W, Fe, Cu, and Ag by use of a mass spectrometer. The initial product was always NH_2D, the other deuterio compds. forming successively. The energies of activation were correlated with the work functions of the metals. Catalysis of the reaction by films of oxidized Cu, W, Ni, and Zn and by ZnO is studied.

1295. Kitchener, J. A.; Bockris, J. O'M., and Spratt, D. A. **Solutions in liquid iron. II. Influence of sulfur on the solubility and activity coefficient of carbon.** *Trans. Faraday Soc.* 48, 608-17 (1952).—*C.A.* 47, 462*i*.

The soly. of graphite in liquid Fe was detd. between 1200 and 1700°C with the addn. of 0 to 1.4% S. To avoid an apparent supersatn. effect arising from the stabilization of Fe_3C by S it was necessary always to approach satn. with a slightly rising temp. S redued the soly. of graphite approx. proportional to its concn. The study of solute interactions by the change of soly. of a pure solid was preferable to gas-liquid equil. methods at high temps. because it avoided the uncertainties assocd. with thermal segregation in gas mixts.

1296. Kitchener, J. A.; Bockris, J. O'M.; Gleiser, Molly, and Evans, J. W. **Note on the solubility of oxygen in γ-iron.** *Trans. Faraday Soc.* 48, 995-7 (1952).—*C.A.* 47, 5334*g*.

1297. Kolomiets, B. T. **Mechanism of photoconduction and conduction in lead sulfide layers.** *Izvest. Akad. Nauk S.S.S.R., Ser. Fiz.* 16, 70-80 (1952).—*C.A.* 46, 9414*i*.

PbS layers were evapd. onto Au electrodes and treated with O_2. Dark cond. measurements in air show that at 40-60°C the semicond. changes into metallic. Variations in cond. and photocond. are due to dissolved O_2, since layers cooled after degassing in Ne or H_2 did not show any increase in cond. Thermoelec. measurements indicate that the carriers of dark cond. are pos., but surprisingly measurements of photocond. with the condenser method show that the carriers in this case are electrons. The original electronic cond. of evapd. PbS changes to hole cond. after oxidation and the thermoelec. force changes from 60 to 400 microvolts per degree. Degassed samples have better frequency response.

1298. Lander, J. J.; Kern, H. E., and Beach, A. L. **Solubility and diffusion coefficient of carbon in nickel: reaction rates of nickel-carbon alloys with barium oxide.** *J. Appl. Phys.* 23, 1305-9 (1952).—*C.A.* 47, 2581*i*.

Between 700° to 1300°C, $\ln S = 2.480 - 4{,}880/T$, where S was the soly. in g of C per 100 g of Ni. Values obtained for the diffusion coeff. in the same range fitted the equation $\ln D=0.909-20{,}200/T$, where D is in sq cm per sec. Rates of reaction between diffused C and BaO coatings on Ni were measured. The rates are diffusion-limited over a wide range of conditions of interest.

1299. LEVINA, S. D. AND BURSHTEIN, R. KH. **Oxide layers on highly alloyed steels.** *Zhur. Fiz. Khim.* **26**, 555-9 (1952).—*C.A.* 47, 5336*d*.

The surface of a 18-8 Cr-Ni steel was reduced. Adsorption of O_2 at 20°C was used as a criterion of complete reduction. Thus, after heating at 800°C during 5 hrs in H_2, subsequent reduction or reduction at higher temps. did not increase the amt. of O_2 adsorbed on the reduced sample. Oxygen adsorption measurements on a reduced powder were: (mols. $10^{-15} O_2$ per cm^2 of true (BET) surface at temp. *t*°): 1.29 at 20°, 1.38 at 100°, 1.73 at 200°, 2.23 at 300°, 4.35 at 400°, 5.66 at 500°C.

1300. LI WANG, HUNG AND HACKERMAN, NORMAN. **Sorption of gases on metal powders and subsequent change in metal reactivity at room temperature.** *J. Phys. Chem.* **56**, 771-4 (1952).--*C.A.* 47, 378*b*.

Curves were given for the sorption of Cl_2, NO_2, O_2, and CO on unreduced and reduced stainless steel, Ni, and Mo powder at room temp. The quantities of gases sorbed on unreduced stainless steel and Ni powders could be arranged in the order: $Cl_2 > NO_2 > O_2 > CO$. For unreduced Mo powder the order was: $O_2 > NO_2 > CO$; the data for Cl_2 were very erratic. The uptake of O_2 on reduced powders was greater in all cases than with CO.

1301. MANTLE, E. C. **Nitrogen degassing and metal mold reaction in the production of gunmetal castings.** *Foundry Trade J.* **93**, 95-100 (1952).—*C.A.* 47, 2669*a*.

Phosphor-bronze shows the effects of gas pick-up. When the bronzes and gunmetals contain more than a certain amt. of P, they absorb gas by reacting with the steam produced when the hot metal is poured into a sand mold. The amt. of gas absorbed in this way can be regulated by adjusting the P content of the alloy and the pouring temp. A certain small amt. of gas is helpful, because it produces a more uniform distribution of unsoundness. A simple technique of gas-scavenging with N_2 is described.

1302. MCMASTER, J. G. **Oxygen determination in lead.** *Z. Erzbergbau u. Metallhüttenw.* **5**, 363-4 (1952).—*C.A.* 47, 69*h*.

The soly. of O_2 in the vicinity of the f.p. is less than 0.001%, but at higher temps. much more O_2 is dissolved. The surface layers contain considerable O_2 but the center contains much less. As much as 0.05% can be present at 800°C, but 0.0001% is found in the inner parts after cooling.

1303. MENZEL, ERICH. **Self-diffusion on the copper surface.** *Z. Physik* **132**, 508-28 (1952).—*C.A.* 46, 9925*d*.

The changes on the surface of a chemically etched Cu monocrystal were observed as a function of temp. The time required for a definite change to occur was a measure of the surface migration of Cu atoms on their own lattice. The surrounding atm. profoundly affected the results. For air pressures near 1 μ the surface migration in the region of 700°-1050° followed a Boltzmann law with an activation energy of 13 ± 2 kcal./mole.

1304. MICHEL, PIERRE. **The formation of thin layers of alloys by evaporating pure constituents in a vacuum.** *Compt. rend.* **235**, 377-9 (1952).—*C.A.* 47, 2105*i*.

Thin layers, deposited by simultaneous evapn. from pure Ag and Sn filaments, formed the following phases: face-centered cubic, *a* 4.15 A.; orthorhombic, *a* 2.99 A., *b* 5.15 A., *c* 4.77 A.; tetragonal Sn, *a* 5.82 A., *c* 3.17 A. Simultaneous evapn. of Au and Cu gave face-centered cubic solid soln. having parameters varying continuously with the compn. Successive evapn. of Ag-Mg and Au-Cu did not form any alloys. In the system Ag-Sn, successive evapn. always produced alloys in consequence of the high diffusion const. of Sn.

1305. MIYAZAWA, HISAO; NOGA, KINICHI; CHIKAZUMI, SOSHIN, AND KOBAYASHI, AKIO. **Composition of the antimony-cesium photocathode.** *J. Phys. Soc. Japan* **7**, 647-9 (1952).—*C.A.* 47, 6772*h*.

The cond. of the Sb decreased rapidly as soon as a small quantity of Cs is introduced. The metallic appearance of the Sb layer was lost and the deposit became fairly transparent. The cond. passed through a min. where Cs/Sb = 1.0 and the transmitted color of the layer was pale yellow. As the Cs/Sb ratio increased the layers became more and more deep red and the cond. showed subsequent min. at a ratio of 1.5 and 3.0. The photoelec. emission increased gradually with *R*, and saturated approx. as *R* approached 3. These intermetallic compds. CsSb and Cs_3Sb showed the properties of semiconductors.

1306. MOORE, WALTER J. AND LEE, JAMES K. **Kinetics of the formation of oxide films on nickel foil.** *Trans. Faraday Soc.* **48**, 916-20 (1952).—*C.A.* 47, 4710*d*.

The rate of growth of the layer of NiO on Ni was detd. from 400 to 900°C at 10 cm O_2 pressure. The film thickness *y* increased according to the parabolic law $dy/dt = k/y$, the rate const. *k* being, in theory, equal to 2*D*, where *D* was the self-diffusion coeff. of Ni in NiO. The heat of activation was 34.7 ± 0.8 kcal., and the entropy of activation −17.3 ± 0.9 cal/degree.

1307. MORTON, P. H. AND BALDWIN, W. M. JR. **The scaling of titanium in air.** *Trans. Am. Soc. Metals* **44**, 1004-29 (1952).--*C.A.* 46, 6570*g*.

Scaling in air of com. Ti strip from 3 sources was detd. at 930 to 2370°F for 0.1 to 600 hrs. Ti from one source showed parabolic scaling below 1290°F; deviations between 1380 and 1560°F; an isothermal transformation between 1560 and 1830°F with resulting higher rate of scaling, and a new form of scale which was affected markedly by O_2 partial pressure; and more complex conditions above 1830°F. The Ti from two other sources showed no transition.

1308. MORTON, P. H. AND BALDWIN, W. M. JR. **Scaling of titanium at high temperatures.** *Iron Age* **169**, No. 18, 133-8 (1952).—*C.A.* 46, 7015*b*.

At 850 to 1000°C, a transition from a primary light scale to a black scale was observed. This oxidation product was composed of 5 layers and was accompanied by a change from a low scaling rate to a much higher one. The black scale nucleated at relatively few points. It wells up from the interior of the primary scale, ultimately replacing it entirely. Below 850°C in air the exterior never became black. The outer scale was shown by x-rays to have the structure of TiO_2. Beneath this outer scale was a bronze-colored metallic layer, which proved to be TiO.

1309. Moss, T. S. **Properties of films of nonmetallic antimony.** *Proc. Phys. Soc.* **65A**, 147-8 (1952).—*C.A.* **46**, 10776*g*.

Semiconducting layers were obtained by evapn. *in vacuo* on substrates at 90°K. These changed irreversibly to the metallic form at 0°C. Resistance-temp. measurements were reported. Resistance decreased on irradiation.

1310. Müser, Helmut and Schilling, Helmut. **Measurements of thermoelectric forces of cuprous oxide at high temperatures.** *Z. Naturforsch.* **7a**, 211-12 (1952).—*C.A.* **46**, 8914*c*.

Samples of thin Cu foil of 20 μ thickness were suspended between 2 thermocouples of Pt/Pt-Rh and oxidized in com. N_2 with O_2 impurity or in purified CO_2 or N_2 with a low content of O_2. In the atm. with high O_2 impurity the thermoelec. force rose rapidly from 20 for Cu-Pt to 700 microvolts/degree and could be regarded as a consequence of p-conduction. With very low O_2 partial pressure initially on n-type conduction occurred with a max. of 150 microvolts/degree after which p-carriers were formed.

1311. Myers, H. P. **The secondary emission from copper and silver films obtained with primary electron energies below 10 e.v.** *Proc. Roy. Soc.* **215A**, 329-45 (1952).—*C.A.* **47**, 4188*f*.

The values for freshly evapd. Cu and Ag films of the secondary emission ratio are lower than those hitherto recorded, both Ag and Cu possessing a secondary emission ratio less than 0.1 in the primary energy range 1-5 e.v. Discrepancies with earlier work are attributed to the improved vacuum conditions used here.

1312. Nielsen, Anders and Bohlbro, Hans. **Investigation on surface properties of reduced iron catalysts for the synthesis of ammonia and correlation with crystal sizes and high-pressure conversion activities.** *J. Am. Chem. Soc.* **74**, 963-6 (1952).—*C.A.* **46**, 5414*d*.

K_2O-CaO-Al_2O_3-Fe catalysts were examd. by adsorption measurements, and the adsorption data were correlated with x-ray data and high-pressure conversion measurements. Crystal sizes detd. from line broadening in x-ray patterns and surface areas derived from low-temp. A and N_2 adsorption were in satisfactory agreement. The more active catalyst had the smaller surface area and the smaller CO chemisorption at −78°. A first-order phase transition of adsorbed N_2 at liquid N_2 and liquid O_2 temps. was found, and isosteric heats of adsorption were detd.

1313. Nury, Georges. **Influence of the disappearance of antiferromagnetism of nickel oxide on the chemical activity of this oxide.** *Compt. rend.* **234**, 946-8 (1952).—*C.A.* **46**, 10723*c*.

The amt. of reduction of NiO in 2 hrs in H_2 at temps. from 200° to 425°C shows max. at 265 and 350°C and is essentially zero in the ranges 300-340° and 355-400°C. The metallic Ni formed is estd. by a magnetic method.

1314. Oding, I. A. **Thermodiffusion in metals.** *Doklady Akad. Nauk S.S.S.R.* **86**, 67-70 (1952).—*C.A.* **47**, 2006*f*.

In the original absence of a concn. gradient a strain gradient will give a rise to a diffusion that will set up a concn. gradient and thus give rise to back diffusion counteracting the ascending diffusion. Dehydrogenation of steel could be made more efficient by cyclic heating and cooling. The soly. of H_2 in steel being, roughly, 8-10 times as high at 1300° as at 500°C, cooling of the outer parts ought to give rise to diffusion of H_2 into the hotter (more centrally located) parts of the metal; if there is a hollow, the H_2, on cooling, will be eliminated. On subsequent heating, the H_2 will diffuse to the outer surface and escape. Repetition of that cycle between 400 and 1100° should shorten the time needed for dehydrogenation.

1315. Ogawa, Iwao; Dôke, Tadayoshi, and Nakada, Ichirô. **Surface potentials of adsorbed gas films on evaporated metal deposits.** *Ôyô Butsuri* (J. Applied Phys.) **21**, 223-4 (1952).—*C.A.* **46**, 10776*i*.

Surface potentials of O_2 and H_2 films chemisorbed on Ni, Ag, Zn, and Cd evapd.-deposits were measured by the vibrating-condenser method in a vacuum. The observed values were: Ni-O_2 −550 mv., Ni-H_2 −400 mv., Ag-O_2 −600 mv., and Ag-H_2 −490 mv. Zn and Cd show complicated variations when the amt. of the gas changes.

1316. Olney, M. J. **Thermal etching of iron and steel.** *Metal Treatment* **19**, 347-54 (1952).—*C.A.* **46**, 9490*h*.

Eutectoid steels contg. 0.8% C show one clearly defined network after heating in the austenite range and cooling *in vacuo*, A, or H_2. Another network, consisting of broad diffuse boundaries related to the previous system of boundaries, is due to old austenite boundaries which once occupied these positions, when grain growth was for some reason temporarily halted. When hypoeutectoid steels are heated and slowly cooled *in vacuo*, A, or H_2, 3 networks are normally seen. Two of these are due to austenite.

1317. Paproth, H.; Rathje, W., and Stranski, I. N. **Electron emission of a silver surface acted upon by iodine vapor.** *Z. Elektrochem.* **56**, 409-14 (1952).—*C.A.* **47**, 398*c*..

Sublimed I_2 is directed against a high-purity Ag block. A Mo plate is used as the collecting electrode with the Ag cathode placed immediately opposite in a vacuum system. The emitted charge carriers are identified as pure electron emission by using magnetic deflection techniques.

1318. Perrot, Marcel and Tortosa, Jean. **Conductance of silicon.** *Compt. rend.* **235**, 143-5 (1952).—*C.A.* **47**, 18*a*.

Thin films deposited on glass in an atm. of N_2 by thermal evapn. of Si of 98.75% purity were used. About 10 films of thickness 0 to 300 mμ, estd. by reflection of monochromatic light were measured. The thinnest films had the most coloration; the thickest were red-brown by transmitted light with a slight metallic luster. The resistance increased with time. The current-voltage curves digressed from Ohm's law in the case of very thin films.

1319. PFEIFFER, HARALD AND HAUFFE, KARL. **Affecting the oxidation rate of nickel and titanium by alloying and treatment with metal oxide vapor.** *Z. Metallkunde* **43**, 364-9 (1952).—*C.A.* **47**, 1019*f*.

Addn. of Cr increased the oxidation rate of pure Ni but Ag had no noticeable influence which is ascribed to the difference of ionic radii of Ag_2O and NiO, hence the low soly. of Ag_2O in NiO. An improvement in the reduction of oxidation rate was found if Ni was treated with Li_2O vapor, or Ti with WO_3 vapor at 1000°C.

1320. PROBST, R. E.; MEYERSON, SEYMOUR, AND SEELIG, HERMAN S. **Adsorption and reaction of carbon monoxide on promoted iron catalysts.** *J. Am. Chem. Soc.* **74**, 2115-16 (1952).—*C.A.* **47**, 6747*h*.

During the course of studies at 0-108°C on the adsorption of CO on K_2CO_3-promoted Fe catalysts, chem. reactions occur that produce $Fe(CO)_5$ and CO_2. At temps. as low as 25°C, CO reacts with reduced Fe to form $Fe(CO)_5$. The interpretation of CO-adsorption expts. at temps. above 25°C is subject to question unless gas analyses are made to confirm the absence of chem. reactions.

1321. RANC, GASTON. **Thin metallic layers.** *Le Vide* **7**, 1211-19 (1952).—*C.A.* **47**, 2033*e*.

Thin layers were made by evapn. *in vacuo* where the mean free path of the mols. was 10 times the distance from the evaporator to the object. The resistivity of Au deposited on Plexiglas and left in air goes through a min. and increased without reaching a stable value in 1000 hrs. The min. was more pronounced in thin deposits and absent beyond a thickness of 300 A. Below a thickness of 50 A., the resistance tended to become infinite; above this thickness it diminished asymptotically to the value for massive Au. Deposits of Au on NaCl had a smaller resistance at the same thickness than on Plexiglas; the crit. thickness was 35 A. Deposits on glass and Rhodoid were similar to deposits on Plexiglas and deposits on KCl, KBr, and $NaNO_3$ to deposits on NaCl. Cu deposits were similar to Au.

1322. RAUSCH, W. **Adsorption of pentane, propl chloride, and other vapors on zinc and thin zinc phosphate layers.** *Z. physik. Chem.* **201**, 32-54 (1952).—*C.A.* **47**, 7286*e*.

The adsorption of PrCl, pentane, Et_2O, and CCl_4 vapors below satn. pressure was studied on Zn and on Zn that was covered with a thin layer of $Zn_3(PO_4)_2$. The evaluation of the adsorption isotherms showed that by covering Zn with a thin layer of $Zn_3(PO_4)_2$ the surface was increased by a factor of 5-6.

1323. REYNOLDS, F. W. AND STILWELL, G. R. **Mean free paths of electrons in evaporated metal films.** *Phys. Rev.* **88**, 418-19 (1952).—*C.A.* **47**, 1451*i*.

The prepn. of thin films of Cu and Ag was examd. Optimum cond. was obtained by using high rates of evapn. (500-1000 A./sec) and low residual gas pressure (~0.00001 mm). Films evapd. at slower rates, at higher residual pressures, or deposited by chem. or electrolytic processes departed from calcd. values. The resistivity and resistance-temp. coeffs. were reported at 25° fo films of Cu and Ag 100-1500 A. thick.

1324. RIENACKER, G.; BREMER, H., AND UNGER, S. **Catalytic activity and surface of silver powder.** *Naturwissenschaften* **39**, 259-60 (1952).—*C.A.* **47**, 6233*g*.

The catalytic activity of Ag powder in the HCO_2H reaction at 140°C was studied. For the range 300° to 900°C of H_2 pretreatment, the difference in activity (log k) was not outstanding. The B.E.T. surface decreased steadily with treatment temp.; the time of treatment had little effect. The activity per unit surface increased with temp. of treatment.

1325. ROBINSON, CHARLES F. **Effect of various gases on potassium-ion emission from hot platinum.** *J. Chem. Phys.* **20**, 1329 (1952).—*C.A.* **46**, 10857*e*.

The efficiencies of the 2 ionization processes (direct emission of K^+ from the Pt surface, and ionization by electron impact with the vapor phase) are widely different. While the 2 ionization processes have different probabilities, they also may have different efficiencies of measurement in the mass spectrometer.

1326. SAKURAI, TAKEMARO AND MUNESUE, SEIJI. **Resistivity of evaporated tellurium films.** *Phys. Rev.* **85**, 921 (1952).—*C.A.* **46**, 5922*h*.

Te was deposited in films 200-5000 A. thick by vacuum evapn. on Si plates. The resistivity R obeyed the equation $\log (R-r) = U/2kT +$ const., where U was the activation energy of a bulk specimen (0.34 e.v.), and r was a const. sensitive to the thermal history and thickness of the film.

1327. SASAKI, NOBUJI AND YUASA, TOSHIYOSHI. **Chemical studies on ion emission. I. The effect of beryllia on the electrical emission from alumina-coated tungsten filament.** *J. Chem. Soc. Japan*, Pure Chem. Sec., **73**, 273-5 (1952).—*C.A.* **46**, 6928*b*.

The W filament was stretched along the axis of a cylindrical diode bulb. The pos.-ion (alkali metal) current from the filament at 900° decreased exponentially from about 7×10^{-10} to 1.3×10^{-11} amp./cm within 1.5 hrs. Previous washing of the filament with water diminished the values to about one half. If the filament was coated with beryllia (about 0.1 mg per cm of the filament), both the pos.- and the neg.-ion currents remained almost unchanged at about 1×10^{-11} amp.

1328. SAVORNIN, JEAN AND COUCHET, GEORGES. **The thermoelectric force of aluminum in very thin layers.** *Compt. rend.* **234**, 1608-10 (1952).—*C.A.* **46**, 7838*c*.

The thermoelec. force was detd. between 15 and 300°C for thermocouples consisting of an Al layer evapd. onto glass at 10^{-5} mm Hg pressure and a Cu wire. Two samples of Al were applied and gave no difference (99.5 and 99.995%). The thermoelec. force was independent of thickness of the Al film.

1329. Schäfer, Klaus. **Energy-transfer mechanism and reaction rate on metallic surfaces.** *Z. Elektrochem.* **56**, 398-403 (1952).—*C.A.* **46**, 8944*e*.

The accommodation coeff. α for C_2H_6 on a series of Pt-Cu alloys was detd. between 0 and 105°C. In the same app., the initial rate of the reaction $C_2H_6 \rightarrow C_2H_4 + H_2$ was measured at 600°C. The temp. coeff. of α was much higher on pure Pt than on the alloys; this shows that energy transfer to a vibration transition was favored. There was a correlation between the rate of the decompn. reaction and the partial α of the $\delta'(\sigma,a)$ vibration, which, according to a model, should favor decompn. Pt was the best catalyst for the decompn., because the α for this vibration was high and that for others low.

1330. Schulz, L. G. **Oriented overgrowths of alkali halides on silver substrates.** *Acta Cryst.* **5**, 266-8 (1952).—*C.A.* **46**, 10761*i*.

CsCl, CsBr, LiF, NaCl, NaBr, KCl, RbBr, and KI were deposited from the vapor phase and from soln. on oriented Ag substrates. The orientation of the deposits was detd. by use of electron diffraction. Although the surface of the oriented Ag substrate might be microscopically irregular, a definite orientation was induced in the deposit. The lattice consts. of the substrate and the deposit, the method of growth of the deposit (vapor of soln.), and the elec. conditions at the interface were factors.

1331. Seddig, M. and Haase, G. **The measurement of pressures below 10^{-7} millimeters of mercury by means of an adsorption manometer.** *Z. Angew. Physik* **4**, 105-8 (1952).—*C.A.* **46**, 6439*e*.

A manometer based on the photoelec. principle for use below 10^{-7} mm Hg is described. The time dependence of the work of electron emission from an incandescent W surface is used as a criterion for the estn. of pressure changes.

1332. Shepherd, A. A. **Poisoning of oxide cathode emission by oxygen.** *Nature* **170**, 839-40 (1952).—*C.A.* **47**, 4188*b*.

The emission from mixed BaO and SrO cathodes at 1000-1200°K was reduced 10% of its initial value by liberation of O_2 from a heated W wire coated with BaO_2. The poisoning phenomenon was completely reversible, even after several previous attacks. The emission of ionized O from the cathode increased often by a factor of 10 or more, and gradually decayed to its original intensity as recovery was completed. The results indicated that the main cause of O_2 poisoning was probably the adsorption of thin films of O on both the outer cathode surface and the interior crystallite surfaces.

1333. Slichter, W. P. and Kolb, E. D. **Impurity effects in the thermal conversion of germanium.** *Phys. Rev.* **87**, 527-8 (1952).—*C.A.* **46**, 10758*c*.

The thermal history and exposure to pure water and to air had no effect on the $n \rightarrow p$ type conversion of Ge. Conversion was extensive on heating after contact with dil. $CuSO_4$ solns.

1334. Slifkin, L. M.; Lazarus, D., and Tomizuka, T. **Self-diffusion in pure polyscystalline silver.** *J. Applied Phys.* **23**, 1032-4 (1952).—*C.A.* **46**, 10749*h*.

Self-diffusion was measured with Ag^{110} as a tracer. The results of the high-temp. expts., where vol. diffusion was predominant, were in excellent agreement with those of other investigators. A least-squares calcn. with all available data on vol. diffusion of Ag gave as a value for the diffusion coeff. $D = 0.724 \exp(-45{,}500/RT)$.

1335. Slifkin, L. M.; Lazarus, D., and Tomizuka, T. **The diffusion of antimony in silver single crystals.** *J. Appl. Phys.* **23**, 1405 (1952).—*C.A.* **47**, 3645*d*.

Diffusion of Sb^{124} in Ag single crystals is described by $D = 0.29 \exp(-39{,}400/RT)$ in agreement with results of other radioactive tracer expts., differing considerably from older data.

1336. Suhrmann, R. **The adsorption status of adsorbed molecules at conducting surfaces.** *Z. Elektrochem.* **56**, 351-60 (1952).—*C.A.* **47**, 1457*d*.

The elec. changes at catalyzing metal surfaces of Ni and Pt were investigated during the adsorption or sorption of O_2, H_2, N_2O, and NH_3. Thin layers of these metals showed an increase of cond. when H_2 was adsorbed, because of the dissocn. of the H atoms and their migration in the crystal lattice as protons and electrons. O_2 decreased the cond. of a Ni film 2.6% at 290°K. Furthermore, the photoelec. emission of metal surfaces was very sensitive to adsorption of mols. Adsorption of H_2, H_2O, and NH_3 increased the photoelec. sensitivity by partial compensation of the electron affinity of the metal support. O_2 and N_2O showed the opposite effect.

1337. Takeuchi, Sakae and Igaki, Kenzô. **Statistico-thermodynamical studies on fundamental reactions concerning steelmaking. II. Oxidation and reduction equilibrium of wüstite ferrous oxide with gas phases.** *Science Repts. Research Insts., Tohoku Univ.*, Ser. A, 4, No. 2, 164-75 (1952).—*C.A.* **47**, 2102*i*.

The excess O_2 over the stoichiometric compn. FeO in wüstite is due to the fact that the crystal is ionic contg. a certain no. of lattice imperfections such as the vacant lattice points and the electron deficits of the form of the Fe^{+++} on the Fe^{++} lattice. The equil. condition between wüstite and the gas mixt. $CO\text{-}CO_2$ surrounding the crystal is deduced by making min. the total sum of the free energies of the crystal and the gas phase.

1338. Tödt, F. **The electrical measurement of small amounts of oxygen on metallic surfaces.** *Glass u. Hochvakuum-Tech.* **1952**, 109-10.—*C.A.* **47**, 3723*c*.

O_2, 10^{-12} γ or less than 0.0001 part of an at. layer, on the surface of noble metals can be measured by electrochem. means. The principle of the measurement depends on the condition that the current produced by a metal surface covered with O_2

is detd. against a practically unpolarizable anode. A smooth Pt surface exposed to air absorbs about 10 at. layers of O, based on the surface geometry.

1339. TRAMM, HEINRICH. **Technique of carbon monoxide hydrogenation.** *Erdöl u. Kohle* 5, 10-17 (1952).—*C.A.* 46, 4193f.

A study of the kinetics of reaction over Fe catalysts led to equations: $n_{CO}=k_1(P_{H_2})^2/P_{CO}$); $n_{CO_2}=k_3P_{H_2}/[P_{CO}(1+k_4(CO_2+H_2O)^7)]$ for the velocity of CO_2 formation; $n_{H_2O}=kP^2_{H_2}/[P_{CO}(1+k_2(CO_2+H_2O)^5)]$ for the synthesis reaction under H_2O formation; and $n_k=k_5P_{H_2O}$ for the conversion reaction (k stands for hydrocarbons). A qual. explanation of the kinetics was given by the behavior of catalyst adsorption at the reaction temp. At 250°C N_2 alone was physically adsorbed, while H_2, CO, CO_2 were all chemisorbed. Exptl. data for the derivation of the kinetic equations were given.

1340. TRAPNELL, B. M. W. **Nitrogen and ethylene adsorption on evaporated tungsten films.** *Trans. Faraday Soc.* 48, 160-5 (1952).—*C.A.* 46, 7858*h*.

The chemisorption of N_2 and C_2H_4 by clean evapd. W films was detd. together with the chemisorption of H_2 into adsorbed layers of these gases and of O_2. The poisoning of the catalytic para-H_2 conversion by C_2H_4 and O_2 layers was due to simple blockage of surface sites. The action of N_2 was to decrease the condensation coeff. of the incoming H_2.

1341. TRECO, R. M. **Some properties of high-purity zirconium and dilute alloys with oxygen.** *Trans. Am. Soc. Metals* Preprint No. 38, 19 pp. (1952).—*C.A.* 46, 9496*d*.

Mech. and phys. properties of alloys of high purity, I_2-refined Zr contg. up to 2.5% O_2 were increased greatly by O_2 with only slight decreases in ductility and resistivity which did not affect working properties.

1342. TRISCHKA, J. W.; MARPLE, D. T. F., AND WHITE, A. **The production of halogen negative ions at the surface of a thoriated tungsten filament.** *Phys. Rev.* 85, 136-7 (1952).—*C.A.* 46, 4356*d*.

By directing mol. beams of Cs halides at a thoriated W wire (at 1200-1500°K) large yields of halogen neg. ions were obtained. There were no mol. ions. The yield from pure W surfaces was much lower.

1343. VARETTO, J. AND LACOMBLE, L. **Determination of the oxygen and inclusions in steels.** *Rev. universelle mines* 8, 270-4 (1952).—*C.A.* 46, 9489*b*.

By combining reducing fusion *in vacuo* and anodic soln. the detn. of total O_2 was more exact and gave an approx. value of the content of inclusions of FeO + MnO.

1344. WABER, J. T. **The cubic law of oxidation.** *J. Chem. Phys.* 20, 734-5 (1952).—*C.A.* 46, 10710*a*.

Exptl. and theoretical studies were reviewed to indicate that a cubic law of oxidation occurred at low temps. Data for Ta and Ti were presented.

1345. WINEGARD, W. C. AND CHALMERS, B. **Self diffusion at silver surfaces.** *Can. J. Phys.* 30, 422-9 (1952).—*C.A.* 47, 4160*d*.

The surface self diffusion of radioactive Ag^{110} on electropolished, electroetched, and chemically etched polycryst. Ag and the (100), (110), and (111) planes of a Ag single crystal was investigated. Surface diffusion was accelerated during changes of surface shape. An abnormally high concn. of lattice vacancies was considered necessary for changes of surface shape to occur.

1346. YING, CHUNG FU AND FARNSWORTH, H. E. **Changes in work functions of vacuum-distilled gold films.** *Phys. Rev.* 85, 485-6 (1952).—*C.A.* 46, 5427*h*.

Au was deposited onto outgassed polycryst. Au at room temp. The effect of the thickness and of the thermal history on ψ was examd. It was improbable that gases adsorbed on, or absorbed by, a film were the only cause of its lower ψ. These results indicated that the Au film deposited on a surface at room temp. possessed some structure characteristics different from that of polycryst. bulk Au and that the structure of the film approached that of the bulk when the temp. of the film was raised.

1347. ANSBACHER, F. AND JASON, A. C. **Effects of water vapor on the electrical properties of anodized aluminum,** *Nature*, 171, 177-8 (1953).—*C.A.* 47, 6725*b*.

The capacity of a condenser made from anodized com. Al wire, 1/16 in. in diam., was measured at 25, 30, 40, 50, 60, and 70°C in the presence of various amts. of water vapor. Max. capacity was obtained when the vapor pressure reached satn. The leakage resistance of the Al_2O_3 at 50°, 60°, and 70°C decreased exponentially with increasing water vapor pressure.

1348. BECKER, J. A. AND HARTMAN, C. D. **Field-emission microscope and flash-filament techniques for the study of structure and adsorption on metal surfaces.** *J. Phys. Chem.* 57, 153-9 (1953).—*C.A.* 47, 6761*e*.

The properties of single-crystal W points are described as a function of temp. (0-2500°C) and field potentials (up to 50 million v. per cm). The conditions for surface mobility of Ba atoms adsorbed on W are given. Flash-filament techniques are used to det. rate of N_2 adsorption on W at low pressures, the sticking probability of N_2 as a function of the fraction of surface covered, and the activation energy for the conversion of a mol. to 2 adsorbed atoms.

1349. BOWERS, RAYMOND. **Thickness of the saturated helium II film.** *Phys. Rev.* 91, 1016-17 (1953).—*C.A.* 47, 11859*h*.

The satd. He II film on Al was investigated by a gravimetric method. The film was not affected by temp., 1.2-2.1°K. The 99.92% satd. film was 20 atoms thick. The satd. film was 55-175 atoms thick, depending on the height of the bulk liquid He.

1350. DREYFUS-ALAIN, BERTRAND. **Radiocrystallographic study of the adsorption of deuterium by lanthanum.** *Compt. rend.* 236, 1265-6 (1953).—*C.A.* 47, 7286*d*.

Two face-centered cubic structures were formed by the deuteride of La in which the parameter was either 5.60 or 5.67 A.

1351. Hauffe, Karl and Pfeiffer, Harold. **Kinetics of wüstite formation in the oxidation of iron.** *Z. Metallkunde* 44, 27-36 (1953).—*C.A.* 47, 3669*h*.

Linear oxidation rates for Fe → FeO were confirmed for the range 900-1000°C. The rate dependence was measured as function of the partial pressure of O_2, CO_2, and CO, and the effect of disorder loci is discussed.

1352. Healey, F. H.; Chessick, J. J., and Zettlemoyer, A. C. **Adsorption studies on metals. I. Physical and chemical adsorption of gases on molybdenum.** *J. Phys. Chem.* 57, 178-82 (1953).—*C.A.* 47, 7287*a*.

The adsorption of O_2, CO, N_2, and A was studied on unreduced, partly reduced, and reduced Mo powder at −195°C. The surface area increased by a factor of at least 2 during reduction. The reduced Mo was capable of chemisorbing O at −195°C equiv. to 10-20% of the surface; at 25°C the O pickup approached a complete monolayer. The value of the mol. of gas in a monolayer, for the unreduced oxide, was the same for O_2, A, and N_2. Continued reduction at 550-600°C caused the surface to decrease to about that of the original oxide. No chemisorption of either CO or N_2 at −195°C occurred.

1353. Holden, F. C.; Ogden, H. R., and Jaffee, R. I. **Microstructure and mechanical properties of iodide titanium.** *J. Metals* 5, *Trans.* 238-42 (1953).—*C.A.* 47, 2659*a*.

There is a fine structure in iodide Ti, which is attributed to the formation of Ti hydride whose soly. is very low at room temp. The degree of dispersion of the Ti hydride apparently has an important effect on impact-energy values. Variation of the grain size of equiaxed α Ti from 0.01 to 0.25 mm, in the A-cooled condition, produces relatively small changes in the tensile and impact properties.

1354. Keier, N. P. **Role of the different adsorption centers in the hydrogenation of acetylene on metallic nickel. II. Kinetics of hydrogenation and of activated adsorption of acetylene on a nickel catalyst.** *Izvest. Akad. Nauk. S.S.S.R., Otdel. Khim. Nauk* **1953**, 48-57.—*C.A.* 47, 5780*b*.

In consecutive expts. with the same sample of Ni, regenerated by prolonged outgassing in 300-500°C under 10^{-5} mm Hg), the C_2H_2 adsorbed at about 25° decreased; on the fresh catalyst the amt. adsorbed was 2.5 times as great. To obtain reproducible data, the pretreatment was: 1 hr at 130-50°C in N_2, 2 hrs at 300° under 10^{-4} mm with a liquid N_2-cooled trap, reduction with H_2, and 1 hr in vacuo at 500°C. Not all the centers that adsorbed C_2H_2 reversibly were useful for hydrogenation. The adsorption of H_2 was enhanced by adsorbed C_2H_2. Only a fraction of centers, occupying some 4-6% of the surface, were active in hydrogenation. On Ni catalysts CH_4 was formed only above 150°C, both in the presence and in the absence of H_2.

1355. Kitchener, J. A.; Bockris, J. O'M; Gleiser, Molly, and Evans, J. W. **Solubility of oxygen in γ-iron.** *Acta Met.* 1, No. 1, 93-101 (1953).—*C.A.* 47, 3775*g*.

The O_2 absorbed by high-purity Fe foil was detd. by deoxidation with pure H_2 at 1275°C, the H_2O formed being frozen out, vaporized, and measured manometrically in a small vol. High-purity irons from 3 different sources led to a result of 0.003 ± 0.003% by wt for the max. O-content of γ-Fe in equil. with FeO. Traces of Mn, Si, Cr, Al, and other impurities may lead to O-pickup by formation of oxidation products at grain boundaries.

1356. Morrison, John L. and Grummitt, W. E. **The accommodation-coefficient technique applied to a study of molecular oxygen film on tungsten.** *J. Chem. Phys.* 21, 654-8 (1953).—*C.A.* 47, 6734*d*.

Adsorption isotherms of the upper mol. O_2 film on W at 25 and 100°C and at pressures from 9×10^{-9} to 1×10^{-4} mm were measured by the accommodation-coeff. method. The entropy of adsorption was calcd. to be approx. 4 entropy units at low film concns. and less than 1 at high film concns. The large discrepancy between calcd. and theoretical entropies suggested either or both irreversible effects and nonlinearity of the relation between accommodation coeffs. and surface coverage.

1357. Rhodin, T. N., Jr. **Physical adsorption of single-crystal zinc surfaces.** *J. Phys. Chem.* 57, 143-8 (1953).—*C.A.* 47, 7286*i*.

By use of a modified quartz vacuum microbalance, the phys. adsorption of N_2 and A was measured at 78° to 90°K on the surface of single crystals of Cu and Zn. The adsorption data obeyed B.E.T. plots and indicated surface areas corresponding to roughness factors in the range 1.1 to 1.2. Calcd. heats of adsorption appeared to pass through max. at about monolayer coverage.

1358. Seybolt, A. U. and Sumsion, H. T. **Vanadium-oxygen solid solutions.** *J. Metals* 5, *Trans.* 292-9 (1953).—*C.A.* 47, 2660*b*.

The results of an investigation of V-rich V-O solid solns. are presented, indicating the structure and lattice parameters of 2 solns., α and β, and their approx. temp.-compn. existence. The α soln. is the terminal body-centered cubic one, and contains up to 3.2 at. % O. The β soln. has an ordered body-centered tetragonal structure, is formed at 1270°C, and exists from about 15 to 22 at. % O.

1359. Treco, R. M. **Effect of small additions of oxygen on lattice constants and hardness of zirconium.** *J. Metals* 5, *Trans.* 344-8 (1953).—*C.A.* 47, 2660*d*.

The effect of small addns. of O_2 on the hardness, d., and lattice parameters of high purity Zr has been investigated. Precision parameter values and d. of O-free Zr are given as: $a_0 = 3.2258$ kX units, $C_0 = 5.1373$ kX units, $d_{25} = 6.507$ g/cc.

1360. Turkdogan, E. T. and Leake, L. E. **An oxygen detector.** *J. Sci. Inst.* 30, 27 (1953).—*C.A.* 47, 3624*b*.

A strip of pure Fe 9 × 0.1 × 0.003 in. is connected and heated to about 600°C. If the gas passed through contains O_2 the Fe strip quickly changes to different hues of blue, brown, gray. If the temp. is raised the original bright color is restored. The app. will detect O_2 in inert gases if its partial pressure is not less than 10^{-6} atm. Before using, the strip should be reduced by passing through pure H_2 at 600-700°C.

1361. Vernon, W. H. J.; Calnan, E. A.; Clews, C. J. B., and Nurse, T. J. **The oxidation of iron around 200°.** *Proc. Roy. Soc.* (London) **216A**, 375-97 (1953).—*C.A.* **47**, 6229*d*.

There is predominant metal-ion diffusion above, and predominant O-ion diffusion below, 200°C, in the oxide film. An outer layer of rhombohedral α-Fe_2O_3 overlies a layer of cubic oxide which, initially nearer γ-Fe_2O_3, tends towards Fe_3O_4, rapidly and completely above 200°C, slowly and incompletely below 200°. Above 200°C the rate of oxidation is controlled by the diffusion of ions across the film. Thickening of the film and progression of colors may be long delayed during the period of O_2 uptake within the substrate.

1362. Weissler, G. L. and Wilson, T. N. **Work functions of gas-coated tungsten and silver surfaces.** *J. Appl. Phys.* 24, 472-5 (1953).—*C.A.* 47, 6760*b*.

The av. electronic work functions of W and Ag surfaces, subjected to glow discharges in various gases (He, A, H_2, N_2, O_2, freon-12) and to water vapor, were detd. Oxygen and freon-12 produced increases in work functions in excess of 1 e.v., whereas N_2 and particularly H_2 caused decreases of the order of 0.5 e.v. The inert gases and water vapor produced relatively few changes.

I-8. Gases on Inorganic Crystals

1363. Alimarin, I. P. **The preparation of anhydrous magnesium perchlorate ("anhydrone") and its use as a drying agent.** *Zavodskaya Lab.* **9**, 915-16 (1940).—*C.A.* **37**, 4315^7.

Add an excess of MgO to a 30% $HClO_4$ soln. (in small portions), filter, neutralize the filtrate with $HClO_4$ to a weakly-acid reaction, evap. and cool. Filter the crystals obtained on a Buchner funnel, dissolve in a small amt. of hot water, evap. and crystallize (twice). $Mg(ClO_4)_2.6H_2O$ melts 145-7°C in its crystn. water; on removal of water, it solidifies to porous $Mg(ClO_4)_2.3H_2O$. Heat the trihydrate with mixing to 170-200°C (melts) for 1-2 hrs, cool, grind and heat *in vacuo* first at 170°C, then at 220-40°C (for 3 hrs). The "anhydrone" obtained is a white porous mass contg. approx. 0.1% of H_2O and absorbs 60% of its wt.

1364. Cooper, J. A. and Garner, W. E. **Dehydration of crystals of chrome alum.** *Proc. Roy. Soc.* (London) **A174**, 487-503 (1940).—*C.A.* **34**, 3149^4.

The rate of growth of the dehydration nuclei over the 111 surfaces of $K_2SO_4.Cr_2(SO_4)_3.24H_2O$ was detd. from 0° to 40°C. The dehydration came to a stanstill when 12.1-12.3 moles of water of crystn. were lost, i.e., corresponding to a formula $K_2SO_4.Cr_2(SO_4)_3.12H_2O$.

1365. Pogodaev, K. N. **Diffusion of nickel in rock salt.** *Trudy Vostochno-Sibirskogo Gosudarst. Univ.* 2, No. 1, 65-86 (1940).—*C.A.* **37**, 4608^5.

The fundamental physical laws of diffusion could be studied under the simplest conditions when the diffusion took place in rock salt. The temp. dependence of Ni ions was studied in the interval 627-780°C. The relation between the coeff. of diffusion and the temp. was given by $D = 0.42 \exp(-132{,}220/T)\,cm^2/sec$. By means of the Born cycle it was shown, on the example of Ni and Cu ions in rock salt, that the occurrence of diffusion can be detd. by the energy ratio.

1366. Uyeda, Ryozi; Takagi, Satio, and Hagihara, Hitosi. **Cathode-ray investigation of the surface oxidation of zinc blende.** *Proc. Imp. Acad.* (Tokyo) **16**, 389-90 (1940).—*C.A.* **35**, 2762^2.

The orientation of ZnO crystals on the cleavage and natural faces of zinc blende was studied with artifically prepd. surfaces. The type of orientation was confirmed to be distinctly different on each tetrahedral surface.

1367. Pitzer, E. C. and Frazer, J. C. W. **The physical chemistry of hopcalite catalysts.** *J. Phys. Chem.* **45**, 761-76 (1941).—*C.A.* **35**, 5776^5.

X-ray data showed that active hopcalite catalysts were for the most part amorphous. Only the active metallic oxides Co_3O_4, MnO_2, Ni_2O_3 and Co_2O_3 had a metal to oxygen distance in the range 1.75 to 1.85 A. Poisoning expts. and a consideration of catalyst geometry suggested that the catalytic oxidation involved the adsorption of each mol. of CO on two points of the catalyst.

1368. Shirai, Shunji. **Orientation of molybdenum crystals deposited on sodium chloride crystals.** *Proc. Phys. Math. Soc. Japan* **23**, 914-18 (1941).—*C.A.* **41**, 6100*i*.

The structure of thin Mo films was examd. by the method of cathode-ray transmission. Mo films were prepd by evapn, in vacuo on the cleavage faces of rock salt heated to a high temp. A (110) axis of the Mo crystal was parallel to a (100) axis of the rock salt crystal. Mo films were mainly composed of oriented crystals when the temp. was higher than a certain crit. temp., whereas they were randomly oriented at a lower temp.

1369. Shirai, Shunji. **Orientation of molybdenum crystals deposited on sodium chloride crystal.** *Proc. Phys.-Math. Soc. Japan* **23**, 12-18 (1941).—*C.A.* **35**, 4652^3.

Thin films of Mo were evapd. on a heat-treated cleavage plane of NaCl. The latter was dissolved in water, the Mo was transferred to a collodion film and the crystal structure studied with cathode rays of 25-30 kv. The orientation of the Mo crystals depended on the heat-treatment given the NaCl.

1370. UYEDA, RYOZI; TAKAGI, SATIO, AND HAGIHARA, HITOSI. **Cathode-ray investigation of the surface oxidation of zinc blende.** *Proc. Phys. Math. Soc. Japan* **23**, 1049-58 (1941).—*C.A.* **41**, 6101*d*.

The orientation of ZnO crystals in the thin oxide layers formed on various faces of ZnS upon heating in air was investigated by means of cathode-ray diffraction. The surfaces investigated were the (111), $(\overline{111})$, (110), and (100) faces in the natural and etched states and also the cleaved (110) surface. The observed orientations of the oxide as a whole had the tetrahedral symmetry of zinc blende crystals, if etched with the same agent. Simple rules that det. the orientation were pointed out.

1371. WEISER, HARRY B.; MILLIGAN, W. O., AND BATES, J. B. **Isothermal dehydration of heavy-metal iron cyanides.** *J. Phys. Chem.* **45**, 701-6 (1941).—*C.A.* **35**, 3874^9.

Continuous dehydration isotherms for the gels of $Cu_2Fe(CN)_6$, $Cu_3[Fe(CN)_6]_2$, Prussian blue and Turnbull's blue indicated that these materials were not definite hydrates. The electron-diffraction pattern obtained in a high vacuum which removed all the water was identical with the x-ray diffraction pattern of the moist gel.

1372. HAGIHARA, HITOSI. **Cathode-ray investigation of the surface oxidation of galena. I.** *Proc. Phys. Math. Soc. Japan* **24**, 762-8 (1942).—*C.A.* **41**, 6101*c*.

For the very thin layer produced on the cleavage surface of galena upon heating in air, reproducible cathode-ray diffraction patterns were obtained for the oxidation at about 200°C. The oxidized layer was composed only of $PbSO_4$ crystallites.

1373. MORITA, NORIYOSHI. **The catalytic exchange reactions of oxygen atoms between gaseous oxygen and water vapor by iron oxide catalyst. I. Experimental. II. Theoretical.** *J. Chem. Soc. Japan* **63**, 659-64, 665-7 (1942).—*C.A.* **41**, 2974*h*, 2974*i*.

Four catalysts: (1) $\alpha-Fe_2O_3$, (2) $\gamma-Fe_2O_3$, (3) $Fe_2O_3+Bi_2O_3$ (2:1 by wt), (4) Bi_2O_3 were prepd. Their catalytic activity was detd. in the exchange reactions of O atoms in O_2 and water vapor. The first three catalysts showed about the same activity. The activity of the first two decreased with repeated use. All 4 catalysts lost their catalytic activity when heated above 800°C. The temp. of the exchange reaction was 300-700°C.

1374. OSUMI, YOSHIO AND MORITA, NORIYOSHI. **The catalytic exchange of isotopes of gaseous oxygen. XI. The exchange reaction of oxygen atoms between oxygen and steam on the surface of sodium and potassium hydroxides.** *Bull Chem. Soc. Japan* **17**, 217-20 (1942).—*C.A.* **41**, 4365*e*.

Steam of heavy water and the light oxygen gas obtained electrolytically were passed together over a mixt. of asbestos and alkali. The effluent steam, after being condensed, was weighed, and from the decrease in wt. the exchange percentage of the oxygen atoms was calcd. The activation energy for the exchange reaction was found to be 47 kcal. with NaOH as catalyst and 21 kcal. with KOH. Some peroxide was first formed on the alkali surface and the exchange was completed through its decompn.

1375. OSUMI, YOSHIO; MORITA, NORIYOSHI, AND CHITANI, TOSHIZO. **The catalytic exchange of isotopes of gaseous oxygen. XII. The exchange reaction of oxygen atoms between oxygen and steam on the surface of sodium and potassium carbonates.** *Bull. Chem. Soc. Japan* **17**, 189-96 (1942).--*C.A.* **41**, 4365*f*.

Steam of heavy water, together with electrolytic light oxygen was passed through finely granulated NaCl, Na_2SO_4, Na_3PO_4, Na_2CO_3, or K_2CO_3. The effluent condensate was weighed. Catalytic exchange reaction took place with carbonates only. The activation energy of the exchange reaction was 23 kcal for Na_2CO_3 and 27 kcal for K_2CO_3. Further expts. showed that the exchange reaction took place between O atoms of solid Na_2CO_3 and steam of heavy water. Anomalously large values shown in the beginning of the expts. were attributed to the indirect exchange between carbonate and steam.

1376. ZEIMENS, K. E. **Surface determination and diffusion measurements by radioactive noble gases. (Practice and quantitative method.) I. The practical procedure of measuring.** *Z. physik. Chem.* **A191**, 1-53 (1942).—*C.A.* **37**, 5648^5.

Temp. considerations with respect to various kinds of emanations as thoron, actinon, radon, etc., are graphically shown from 0° to 1200°C. A study of Xe from I with AgI shows the existence of two emanations, one of half life of 10 min. which is weak compared with the other of 9.4 hrs. The activity of the latter is compared with time to the iodide of half life of 6.6 hrs from which it is obtained.

1377. FEIGL, FRITZ; MIRANDA, LUIZ INÁCIO, AND SUTER, HANS ALBERTO. **Reactions in the solid state.** *Anais acad. brasil. cienc.* **15**, 151-86 (1943).--*C.A.* **38**, 910^2.

Reactions between solids do not occur if the reaction product remains in situ. Temp., contact area and time are necessary, but not always sufficient. *Type A* (reactions analogous to those in soln): (1) When $CuSO_4$ or $Fe_2(SO_4)_3$ is heated with MgO, the color changes from white to gray (CuO) or brown (Fe_2O_3). (2) When $MnSO_4$, $NiSO_4$ or $CoSO_4$ is heated with MgO in air, darker higher oxides of the heavy metals result. *Type B:* reactions not obtained in soln., usually because of insoly. of one or more reagents. Such reactions are mainly addns. of acidic and basic oxides, etc.

1378. HASEGAWA, SHIGEO. **Formation of the reaction nuclei in the reduction of cupric oxide by hydrogen.** *Proc. Imp. Acad. (Tokyo)* **19**, 393-7 (1943) (in English).—*C.A.* **41**, 5777*h*.

The reduction of CuO by H_2 is explained by 3 assumptions: (1) a reaction between adsorbed H_2 and CuO at the interface of reduced Cu, creating a reaction nucleus; (2) the nuclei on CuO are small in no. and are not in contact with one another in the beginning; (3) the reaction progresses in proportion to the velocity of the growth of the nuclei which increase also in no.

1379. Hedvall, J. A. and Hedin, R. **The importance of surface structure for the velocity of oxidation processes and the thermal decomposition processes of solid substances.** *Die Chemie* **56**, 45-7 (1943).—*C.A.* **37**, 3999^4.

The dissocn. of calcite and pyrites was detd. for various temps. and times of reaction. Individual crystals or crystal particles were used. The reactions were performed in N_2. The data showed small but definite differences in reactivity for different surface types.

1380. Shirai, Shunji. **Structure of a thin silver film deposited on some alkali halide crystals.** *Proc. Phys. Math. Soc. Japan* **25**, 633-6 (1943).—*C.A.* **41**, 6100g.

The structure of a Ag film on crystals with NaCl structure was investigated by the transmission of cathode rays. The dependence on temp. of the substrate was different from that of a Au film, though Au and Ag had almost the same lattice const. It resembled that of a Ni film.

1381. Wooten, L. A. and Brown, Callaway. **Surface area of oxide-coated cathodes by adsorption of gas at low pressures.** *J. Am. Chem. Soc.* **65**, 113-18 (1943).—*C.A.* **37**, 1317^4.

Adsorption isotherms for ethylene at −183° and −196°C and butane at −116°C on oxide-coated cathodes were used to deduce the surface area of the oxide coating. Areas of approx. 10 cm^2/mg of oxide were obtained. The method was capable of detg. surface areas as small as 10 cm^2. Ethylene adsorption at −183°C on alk. earth oxides showed an abrupt adsorption rise in the pressure region 0.25 to 0.30 p_0, where p_0 was the vapor pressure of the gas at the temp. of the isotherm.

1382. Barrer, R. M. and Ibbitson, D. A. **Occlusion of hydrocarbons by chabazite and analcite.** *Trans. Faraday Soc.* **40**, 195-206 (1944).—*C.A.* **38**, 5445^9.

Sorption rates or equil. were studied for gases: O_2, NH_3, HCl, CH_4, C_2H_6, C_3H_8, n-C_4H_{10}, iso-C_4H_{10}, n-C_5H_{12}, iso-C_5H_{12}, n-C_7H_{16}, and iso-octane. When the minerals were suitably outgassed the sorption of He, A, N_2, O_2, CH_4 and C_2H_6 occurred in chabazites and in "active" analcite at very great velocity. C_3H_8, n-C_4H_{10}, n-C_5H_{12} and n-C_7H_{16} were sorbed fairly rapidly at temps. of 100-300°. Hydrocarbons with side chains were totally excluded under all conditions. The sorption was reversible and could be approached from the adsorption or desorption side. The affinity of solutes for the lattice increased in the order $He < H_2 < O_2$, or $A < N_2$, or $CH_4 < C_2H_6 < C_3H_8 <$ n-C_4H_{10}.

1383. Barrer, R. M. and Ibbitson, D. A. **Kinetics of formation of zeolite solid solutions.** *Trans. Faraday Soc.* **40**, 206-16 (1944).—*C.A.* **38**, 5451^9.

Mols. with a cross-sectional diam. not more than 4.0 A. (He, H_2, O_2, N_2, CH_4, C_2H_6) are taker up by dehydrated chabazite or active analcite. Mols. with a cross-sectional diam. = 4.89 A. (paraffins) are occluded by a slow process of diffusion, in which an energy of activation is needed to move the mol. along the interstices from one position of max. sorption potential to another. Mols. with a cross-sectional diam. not less than 5.58 A. (isoparaffins and aromatic hydrocarbons) are totally excluded. There is a limiting pressure above which no further significant increase in sorption rate is possible. The kinetics of sorption are those of a pure diffusion process. The rate of sorption was greatly modified by the conditions of dehydration of the original mineral.

1384. Barrer, R. M. **Thermodynamics and statistics of zeolitic solid solutions.** *Trans. Faraday Soc.* **40**, 374-84 (1944).—*C.A.* **39**, 1096^1.

The existing data for the soln. of gases and vapors in zeolites and of H_2 in Pd, V, Zr, Th and Ti are used to calc. the free energy and the entropy changes. The solute mols. are assumed to possess various degrees of mobility within the crystal lattice, and isotherms are then calcd. and compared with quantities derived from exptl. data. Good agreement was obtained when the solute mols. or atoms were treated as possessing a mobility corresponding to 3 vibrational degrees of freedom in the interstitial vol. and with free rotation. No large fraction of the solute mols. can possess even one-dimensional translational freedom within the zeolite.

1385. Barrer, R. M. **Sorption by gmelinite and mordenite.** *Trans. Faraday Soc.* **40**, 555-64 (1944).—*C.A.* **39**, 2442^3.

Gmelinite resembled chabazite; dehydrated samples occluded CH_4, C_2H_6, and C_3H_8 as typical solutes, but not isoparaffins and aromatic hydrocarbons. Mordenite occluded O_2, N_2, A, CH_4, C_2H_6, HCl, CS_2, NH_3, MeCN, $MeNH_2$, MeOH, but not normal paraffins, isoparaffins, or aromatic hydrocarbons. Ba and Ca base-exchange mordenites were prepd. by heating the powd. mineral with strong aq. $Ba(NO_3)_2$ and $Ca(NO_3)_2$ between 265° and 225°C and were identified by x-ray data. The minerals were dehydrated for periods up to 30 hrs at 300-350°C; they appeared to be quite stable. The mordenite modified by base exchange could not occlude CH_4, C_2H_6, MeOH, or MeCn, but was still able to occlude O_2, N_2, A, NH_3, and HCl. The occlusion and heats of occlusion of O_2 and N_2 increased in the order: natural mordenite, Ba mordenite, Ca mordenite.

1386. Bower, John H. **Revised results obtained with certain dehydrating agents used for drying gases.** *J. Research Natl. Bur. Standards* **33**, 199-200 (1944) (Research Paper 1603).—*C.A.* **39**, 1350^3.

New values were obtained for silica gel and Al_2O_3. The materials studied (with amt. of residual H_2O in mg per liter for air dried), in order of increasing efficiency at 30°C, were: $CuSO_4$ (anhyd.) (2.8); $CaCl_2$ (granular) (1.5); $CaCl_2$ (tech. anhyd.) (1.25); $ZnCl_2$ (sticks) (0.98); $Ba(ClO_4)_2$ (anhyd.) (0.82); NaOH (sticks) (0.80); $CaCl_2$ (anhyd.) (0.36); $Mg(ClO_4)_2$.3-H_2O (0.031); KOH (sticks) (0.014); silica gel (0.006); $CaSO_4$ (anhyd.) (0.005); CaO (0.003); $Mg(ClO_4)_2$ (anhyd.) (0.002); Al_2O_3(0.001); BaO (0.00065).

1387. Briner, E. and Knodel, Ch. **The thermal decomposition of $CaSO_4$ in the presence of water vapor.** *Helv. Chim. Acta* **27**, 1406-14 (1944) (in French).—*C.A.* **39**, 2923[7].

At 1300°C the rate of decompn. of $CaSO_4$ into CaO, SO_2 and O_2 is increased 5-fold if water vapor is circulated over the salt in place of air. After 4 hrs pure $CaSO_4$ is 84% decompd., whereas if water is absent the same extent of decompn. is attained only at 1450°C. Under the same conditions anhydrite is 93.5% decompd.

1388. Kleber, W. **Nonstructural enantiomorphism of crystals.** *Naturwissenschaften* **32**, 77-8 (1944).—*C.A.* **42**, 4015*e*.

Enantiomorphism in solid substances without the crystal structure, e.g., with Cu_2O, can be explained by supposing that there is selective adsorption of some optically active substances from the soln., melt, or vapor. The selective adsorption of foreign mols. may alter the relative rates of growth of different crystal faces. Asymmetric mols. can be differently adsorbed on d- and l-faces, and it is possible that at a certain stage of growth one of the faces disappears.

1389. Barrer, R. M. **Separation of mixtures using zeolites as molecular sieves. I. Three classes of molecular-sieve zeolite.** *J. Soc. Chem. Ind.* **64**, 130-1 (1945).—*C.A.* **39**, 4789[8].

Three different classes are defined. At room temp. class-1 minerals, such as chabazite, active analcite, gmelinite, and a synthetic mineral, exclude isoparaffins, occlude normal paraffins, such as propane, slowly, and occlude methane, ethane, and mols. of smaller cross-section rapidly. Class-2 minerals, such as mordenite, exclude both normal paraffins and isoparaffins, occlude methane and ethane slowly, and smaller mols. rapidly. Class-3 minerals such as Ca and Ba base-exchanged mordenites prepd. hydrothermally at high temps., show negligible occlusion of methane, ethane, and higher normal paraffins and isoparaffins, but occlude O_2, N_2, and smaller mols.

1390. Prilezhaeva, N. A. **Absorption spectra and electronic state of molecules in interaction processes.** *Bull. acad. sci. U.R.S.S., Ser. phys.* **9**, 211-13 (1945) (in Russian).—*C.A.* **40**, 1093[4].

The absorption spectrum of I_2 adsorbed on CaF_2 and also on NH_4Cl aerosol was enhanced over the vapor, owing to the lengthening of the path of the light through repeated reflections on the crystals of the disperse phase; a second max. was found coinciding with the max. shown by solns. in solvents. The absorption increased in the direction of shorter waves, in analogy with solid I_2. NH_3 adsorbed on NH_4Cl aerosol showed absorption between 3100 and 2400 A., in which region also lay the max. of its photochem. decompn. on various other adsorbents ($CuSO_4$, CdI_2, MgO, Cu, glass). Preliminary expts. showed that CO_2 adsorbed on solid benzene plates acquired absorption in the region of 3000 A.

1391. Boer, J. H. de. **The determination of surface areas by adsorption methods.** *Rec. trav. chim.* **65**, 576-9 (1946) (in English).—*C.A.* **41**, 1908*a*.

Adsorption isotherms for I_2 on $BaCl_2$ or CaF_2 layers sublimed on glass walls had the sigmoid shape assocd. with the B.E.T. adsorption theory. The data agreed with the theory at relative pressures from 0.05 to 0.35, but surface areas calcd. from the theory were lower than the true surface areas by a factor of 2 to 4. The true areas were detd. by the surface action of alizarin or by measuring the chemisorption of H_2O. The adsorption of I_2 on salt layers formed unimol. layers only.

1392. Boer, J. H. de. **The formation of two-dimensional nuclei by ionic molecules.** *Proc. Koninkl. Nederland. Akad. Wetenschap.* **49**, 1103-10 (1946) (in English).—*C.A.* **41**, 5360*b*.

Condensation of ionic mols. from the vapor phase on a cool surface in a high vacuum under conditions avoiding collisions of the salt mol. gave rise to two-dimensional nuclei which grew two-dimensionally. Energies for the formation of agglomerates of 2, 3, and 4 mols. of NaCl (with interionic distance of 2.5A) showed that the two-dimensional structure was favored. At. mols. such as Al_2O_3, ZrO_2, SiO_2, and AgCl, for which van der Waals' forces prevail, condensed to compact layers only.

1393. D'Eustachio, D. **Surface layers on quartz and topaz.** *Phys. Rev.* **70**, 522-8 (1946).—*C.A.* **41**, 1522[b].

X-ray studies of single crystals of quartz and topaz showed that there existed on the surfaces of these crystals disturbed layers that were not removed by etching, and that they exerted an effect on etched surfaces to a depth of 5 μ or more. The disturbance was not caused by plastic flow. Good, single-crystal quartz wafers, 35 μ thick, changed when they were etched to 15 μ. The thin plates no longer appeared to be single-cryst. This "poly-cryst." state was stable at room temp. Thin crystals underwent further changes when flexed. Similar results were observed with topaz.

1394. Gregg, S. J. **An electrical sorption balance.** *J. Chem. Soc.*, July, **1946**, 561-2.—*C.A.* **40**, 6302[3].

A balance suitable for adsorption measurements consisted of a glass beam and sample supports, with steel needle and glass-cup bearings, enclosed in a glass tube vessel which may be evacuated. The construction permitted out-gassing the sample conveniently. The sensitivity was 0.3 mg, independent of the total load, which may be 10-20 g.

1395. Gregg, S. J. and Wintle, M. F. **An automatically recording electrical sorption balance.** *J. Sci. Instruments* **23**, 259-64 (1946).—*C.A.* **41**, 2282*h*.

A continuous plot is made of time vs change in mass of a solid adsorbent. As the mass changes, the balance beam is automatically brought to its null position by alteration of the current flowing through a control solenoid. Photoelectrically operated relays adjust the position of a wiper moving along a potentiometer which is uniformly wound and carries a stabilized voltage. The voltage picked up on the wiper is used to control the balance. The max. mass change which can be recorded is 300 mg, and the sensitivity is given as 1.44 mg per mm. A typical curve for the decompn. of pptd. lead carbonate at 420°C and *in vacuo* is given.

1396. Hintenberger, Heinrich. **The effect of gases especially of traces of oxygen, on the electrical properties of "evaporated" lead sulfide films.** *Z. Naturforsch.* **1**, 13-17 (1946).—*C.A.* **41**, 4987*i*.

Although N_2 and A had no effect on the elec. properties of PbS, air and especially O_2 even in slight traces, had a marked effect. Treatment with O_2 had an effect similar to treatment with S. The first traces of O_2 fitted into vacant positions and could be removed again only at 350°C. This filling in of vacant lattice positions took place in an analogous manner for S and for O^{--}. As a result, the Pb^+ ions in the neighborhood of the vacant S positions were converted into Pb^{++} ions and were no longer available to furnish electrons for excess conduction. At lower temps. (below 150°) the O_2 can become incorporated in the PbS in another manner. Tempering in H_2 increased the cond. of the "over-leaded" films.

1397. Kondrat'eva, H. and Kondrat'ev, V. **Detection and measurement of the concentration of hydrogen atoms in a hydrogen flame.** *Acta Physicochim. U.R.S.S.* **21**, 1-12 (1946).—*C.A.* **40**, 5613^9.

The concn. of H atoms in a H_2 flame can be measured by a thermoelec. method based on the temp. increase of a thermocouple coated with $ZnO.Cr_2O_3$ which catalyzes the recombination of atomic H.

1398. Ruess, G. L. **Binding of water in halloysite.** *Monatsh* **76**, 168-73 (1946).—*C.A.* **41**, 1181^e.

The structure proposed by Hendricks for hydrated halloysite of alternating layers of neutral $[(OH)_4Al_2Si_2O_5]_n$ and $[(H_2O)_2]_n$ was confirmed by x-ray and available water-content studies. The so-called metahalloysite formed at 50°C by the removal of water from hydrated halloysite corresponds to a kaolinite of low-ordered arrangement. Thus, hydrated halloysite can be regarded as the forerunner of kaolinite.

1399. Agliardi, N. **Adsorption of sulfur dioxide and oxygen on silver vanadate catalyst.** *Atti accad. nazl. Lincei, Classe sci. fis., mat. e nat.* **2**, 617-22 (1947).—*C.A.* **42**, 2734*c*.

Ag vanadate is found to adsorb SO_2 at about the same rate as does V_2O_5, while O_2 is adsorbed at a lower rate. The rate of adsorption does not drop with increased amt. adsorbed, as is the case with V_2O_5. Adsorption data alone do not give any clue to the reason for the superiority of Ag vanadate over V_2O_5 in the manuf. of SO_3 and H_2SO_4.

1400. Barrer, R. M. **Molecular-sieve action at low temperatures.** *Nature* **159**, 508 (1947).—*C.A.* **41**, 5772*b*.

Mol.-sieve behavior could be extended considerably by sorbing at −183° to −195°C those gases that had a small energy of activation for diffusion. By using a suitable mol.-sieve sorbent, differences in the sorption rates of O_2, N_2, and A were found which permitted quant. or semiquant. resolution of their mixts. The relative amts. of these gases sorbed by 1 g of dehydrated levynite at −184°C at various times were given.

1401. Bering, B. P. and Serpinskiĭ, V. V. **Adsorption of methanol vapor on barium sulfate.** *Doklady Akad. Nauk S.S.S.R.* **58**, 1061-4 (1947).—*C.A.* **46**, 4318*b*.

The adsorption isotherm at 20°C has S-shape, with apparent unimol. adsorption up to 0.3, followed by multilayer adsorption, with 2nd layer completed at 0.98 and 3rd at 0.99. The isotherm equation is $\log(a/h) = A'a^2 + B = (A/s^2)a^2 + B$, which in this instance gives $A' = 9.88 \times 10^{-4} g^2/\mu M^2$ and $B = -6.16$.

1402. Berthillier, J. **Manufacture of photoelectric cells.** *Electricite* **31**, No. 126, 69-74; *Engrs. Digest, Am. Ed.* **4**, No. 11, 500-3 (1947).—*C.A.* **45**, 4149*d*.

In the prepn. of Cs_2O cathodes, Cs is deposited on the walls of the ampul contg. the cup in which pellets of mixed Cs salts and a reducing metal (Zr, Si, or Al) are heated to 700-800°C by induced eddy currents. The cathode of the Cs_2O cell is Ag (or electrodeposited Cu covered with electrodeposited Ag) with a layer of Ag_2O, plus a layer of Cs_2O, and finally one of Cs. The anode is usually Ni.

1403. Billings, Bruce H. and Hyman, Mark, Jr. **Infrared refractive index and dispersion of evaporated stibnite films.** *J. Optical Soc. Am.* **37**, 119-21 (1947).—*C.A.* **43**, 2062*a*.

The n at 10 μ of evapd. Sb_2S_3 films on AgCl was detd. by comparison of the transmission curves, from 1 to 13 μ, of coated and uncoated AgCl. After making a correction for the adsorption of the Sb_2S_3, detd. by comparison of the max. transmission of the 2 plates, n of Sb_2S_3 was calcd. A second detn. was obtained from a dispersion curve which was extrapolated to 632 mμ, where a single value of n was measured.

1404. Dunn, R. C. and Pomeroy, H. H. **A vapor-phase sorption study of iodine and active magnesium oxide utilizing the McBain-Bakr sorption balance.** *J. Phys. & Colloid Chem.* **51**, 981-4 (1947).—*C.A.* **41**, 6791*d*.

Rapid, irreversible sorption of I_2 vapor occurred on MgO at 82°. MgO had a B.E.T. surface area of 126 ± 10 m2/g. The area calcd. from the flat portion of the I_2 sorption isotherm (a unimol. layer being assumed) was 122 m2/g. The I_2 sorption method is more direct and definitive than sorption from soln. and easier to carry out than low-temp. N_2 sorption.

1405. Gol'danskiĭ, V. I. and Chirkov, N. M. **Multimolecular adsorption on mica.** *Doklady Akad. Nauk S.S.S.R.* **58**, 1065-7 (1947).—*C.A.* **46**, 4317*h*.

Adsorption on mica of vapors of H_2O, EtOH, AcOH, EtOAc, and aq. HCl was studied by the method of residual pressure. EtOAc gave most pronounced adsorption, with layer thickness reaching 3×10^{-6} cm; in descending order were: EtOH, H_2O, AcOH, and 20% aq. HCl. All curves had similar shapes in accord with Polanyi theory.

1406. Jolibois, Pierre and Berges, Marthe. **The preparation of oxides by electrolysis.** *Compt. rend.* **224**, 78-9 (1947).—*C.A.* **41**, 2340*b*.

Dehydration of $Mg(OH)_2$ and $Be(OH)_2$, was followed by continuous weighing with a thermobalance. $Mg(OH)_2$ began to lose water at 340°C and was totally dehydrated at 800°C. For $Be(OH)_2$ the corresponding figures were 230° and 900°C, resp.

1407. Kawai, Heiji. **Effect of humidity on the surface electric resistance of Rochelle salt.** *Proc. Phys. Soc. Japan* **2**, 193-5 (1947).—*C.A.* **44**, 10421*g*.

When Rochelle salt was brought from the dry state (relative humidity less than 60%) into the wet state (more than 70%), or vice versa, the surface elec. resistance of (001) plane varied to some extent until it became const.

1408. Lemmlein, G. G. **Rendering a very fine surface structure on crystals visible by a dew method.** *Doklady Akad. Nauk S.S.S.R.* **58**, 1939-42 (1947).—*C.A.* **44**, 8726*i*.

A step-like or even a spiral secondary structure can frequently be observed on SiC crystals that have grown undisturbed and that have smooth, well formed (0001) faces. The thickness of this layer is about 0.5 μ. Photographs of such a (0001) face made by a "dew method" were obtained by the condensation of water vapor on crystals that had been carefully cleaned with $CHCl_3$ and then slightly cooled or breathed upon. The droplet pictures so obtained were reproducible and indicated a surface structure of the order of magnitude of 10 A.

1409. Powers, T. C. and Brownyard, T. L. **The physical properties of hardened portland cement paste. IV. The thermodynamics of adsorption of water on hardened paste.** *J. Am. Concrete Inst.* **18**, 549-602 (1947).—*C.A.* **41**, 3271*f*.

A discussion is given of the energy changes of adsorption of water in hardened paste and their relations to swelling, capillary flow, and moisture diffusion.

1410. Powers, T. C. and Brownyard, T. L. **The physical properties of hardened portland cement paste. V. Studies of the hardened paste by means of specific-volume measurements.** *J. Am. Concrete Inst.* **18**, 669-712 (1947).—*C.A.* **41**, 3272*g*.

The total H_2O in a satd. specimen of hardened paste is divided into a part with a sp. vol. less than 1.0, termed compressed H_2O and a part with a sp. vol. of 1.0. The mean sp.vol. of the H_2O is calcd. from the vol. of the satd. granular samples and vols. and wts of ingredients.

1411. Schwab, Geo. Maria. **Crystallite orientation in coating films. III. Orientation of silver iodide upon silver bromide.** *Trans. Faraday Soc.* **43**, 715-23 (1947), *Kolloid-Z* **101**, 204 (1942).—*C.A.* **42**, 5294*c*.

"Coating films" were discussed, e.g. AgBr films formed by reaction of (a) Ag surfaces with Br_2 or (b) AgCl surfaces with KBr solns. AgI films formed by exchange coating of AgBr in I^- solns. were examd. by x-rays to obtain their lattice orientation. As long as they did not undergo recrystn. or polymorphous change, they grew upon the lattice of the basic Br^- crystals such that the hexagonal basis (001) coincided with the octahedral plane (111) of the Br^-. Both planes had the same closest hexagonal arrangement of atom and contained ions of one sign only. Because of this, the phenomena differed from the formation of the other Ag halides on each other or on Ag.

1412. Schwob, Yvan. **Thermal dissociation of dolomite. The effect of small amounts of flux.** *Compt. rend.* **224**, 47-9 (1947).—*C.A.* **41**, 2306*d*.

The dolomite structure was stable up to 770°C. Near 780°C it underwent violent nonreversible decompn.: $CaCO_3.MgCO_3 \rightarrow CaCO_3 + MgO + CO_2$, as if it were in unstable equil. above the dissocn. temp. of magnesite (630°C). Near 900°C a second dissocn., reversible, occurred: $CaCO_3 \rightleftharpoons CaO + CO_2$. Addn. of 1 to 5% Na_2CO_3 or K_2CO_3 to the powd. dolomite completely upset the decompn. process. The first reaction then began at about 630°C and is completed before 800°C. The second dissocn. proceeded normally. 1% NaCl or NaF induces fusion without release of CO_2 at about 680°C.

1413. Vonnegut, B. **Nucleation of ice formation by silver iodide.** *J. Applied Phys.* **18**, 593-5 (1947).—*C.A.* **41**, 5360*e*.

AgI particles serve as nuclei for the formation of ice crystals in supercooled water and in water vapor supersatd. with respect to ice, probably because it very closely resembles ice in crystal structure. The dimensions of the unit cell of ice and of AgI are the same to within approx. 1%. The max temp. at which AgI particles serve as nuclei is approx. −4° for particles 1 μ in diam., and −8° for particles 100 A. in diam. Mixts. of I_2 and Ag vapors are also effective in producing ice nuclei.

1414. Aldrich, L. T. and Nier, Alfred O. **Argon 40 in potassium minerals.** *Phys. Rev.* **74**, 876-7 (1948).—*C.A.* **43**, 485*e*.

The isotopic compn. of A from orthoclase, microcline, sylvite, and langbeinite was detd. In each of these K minerals the ratio A^{40}/A^{36} was high compared to that of atms. A; K^{40} decayed to both Ca^{40} and A^{40}.

1415. Barrer, R. M. **Synthesis of a zeolitic mineral with chabazite like sorptive properties.** *J. Chem. Soc.* **1948**, 127-32.—*C.A.* **42**, 4422*i*.

A new group of minerals was synthesized from analcite, leucite, and pptd. aluminosilicates by autoclaving a mixt. of the aluminosilicate, an equal vol. of $BaCl_2$, KCl, or KBr, and H_2O equal to the apparent vol. of the solids in a stainless steel autoclave at 180-220°C for 2-6 days. With $BaCl_2$, the compd. has the compn. corresponding to $(Na_2O, BaO). Al_2O_3.4SiO_2.-xBaCl_2.yH_2O$, with x equal to about 0.66. X-ray diffraction patterns were detd.

1416. Barrer, R. M. and Riley, D. W. **Sorptive and molecular-sieve properties of a new zeolitic mineral.** *J. Chem. Soc.* **1948**, 133-43.—*C.A.* **42**, 4423*c*.

Outgassing of the new synthetic zeolite at 300-360°C for 24 hrs after extn. of $BaCl_2$ yielded a microporous sorbent which retained sorptive properties indefinitely. It did not occlude iso-C_4H_{10} or C_6H_6, sorbed n-C_4H_{10} and C_3H_8 slowly at room temp. by a process of activated adsorption, and sorbed CH_4, C_2H_6, and other small mols. rapidly at all temps. Sepns. of n-C_4H_{10} from iso-C_4H_{10}, iso-C_5H_{12}, C_6H_6, and other mixts. were made at 160°C. Isotherms with O_2, N_2, A, He, Kr, Xe, CH_4, C_2H_6 and NH_3 were detd. from −194° to 300°C. The new xeolite showed a better selectivity at −194°C for the rare gases than did charcoal.

1417. Barrer, R. M. and Woodhead, M. **The mercury-chabazite system.** *Trans. Faraday Soc.* **44**, 1001-7 (1948).—*C.A.* **43**, 7288g.
Sorption of Hg by chabazite up to 400°C under high-vacuum conditions was measured by a modified McBain-Baker silica-spring balance. In the absence of O_2, Hg was not sorbed significantly at room temp. or below and it was suitable as a manometric liquid in studies with chabazite. Max. sorptions possible per 100 g chabazite were: less than 0.1 g at 100°C, 0.8 at 200°C, 1.9 at 250°C, 3.9 at 300°C, 7.0 at 350°C, 11.6 at 400°C, 19.0 at 450°C. The sorption heat was 5800 cal/g atom of Hg, which was less than the initial sorption heat of N_2 and about the same as that of A.

1418. Bering, B. P. and Serpinskiĭ, V. V. **Adsorption of vapors by crystalline adsorbents.** *Zhur. Fiz. Khim. (J. Phys. Chem.)* **22**, 1058-71 (1948).—*C.A.* **43**, 461*f*.
The app. contained 3 adsorbents, *A*, *B*, and *C*. *A* and *B* were birchwood charcoal and were suspended on spring balances of two different sensitivites. They were satd. with the vapor at, e.g., −60°C. *C* was $BaSO_4$ crystals with the most frequent radius of 0.06 μ and the geometrical area of 7 m^2/g. By heating *A* or *B* some vapor was released and then equilibrated with *C*; the vapor remaining in the gas phase was readsorbed by *A* or *B* on cooling, and the amt. adsorbed by *C* was calcd. from the wt of *A* or *B* before and after the expt. Adsorption isotherms on $BaSO_4$ were given for MeOH at 20° and 50°C. They were reversible. Up to the relative pressure $h = 0.5$ they can be represented by the equation $\ln (a/h) = k_1 - k_2a^2$; a was the adsorbed amt., and k_1 and k_2 were consts. At higher h, the adsorption seemed to be multimol. The heat of adsorption calcd. from the temp. coeff. of a was 12,000 to 16,000 cal/mol.

1419. Briner, E.; Pamm, G., and Palliard, H. **The dissociation equilibria of calcium sulfate, potassium sulfate, and sodium sulfate alone or in the presence of additional compounds.** *Helv. Chim. Acta* **31**, 2220-35 (1948).—*C.A.* **43**, 2493*i*.
In the presence of SiO_2 or metakaolin, Na_2SO_4 melted before the dissocn. pressure was large enough to be measured with precision. The results with $CaSO_4$ alone agreed reasonably well with the values calcd. thermodynamically, but those with addn. of SiO_2 did not agree, presumably because of the formation of polysilicates. Kaolin markedly increased the dissocn. pressures of $CaSO_4$ and K_2SO_4 because of its decompn. to SiO_2 and Al_2O_3.

1420. Cole, James W.; Salsbury, Melvin, and Yoe, John H. **Photoelectric detection and estimation of carbon monoxide with granules coated with palladous silicomolybdate.** *Anal. Chim. Acta* **2**, 115-26 (1948).—*C.A.* **42**, 8710*d*.
The continuous detection of CO in air was based on the color change from yellow to green and blue of translucent granules of silica gel coated with $Pd_4[Si(Mo_2O_7)_6]$. Measurements were made of the decrease in photoelec. current when the incident light touched the treated gel during the passage of air contg. CO. The scale of the instrument was calibrated in terms of the vol. % of CO. Concns. down to about 0.001% can be estd. with an accuracy within about 10% in 1 min.

1421. Crawford, V. A. and Tompkins, F. C. **Adsorption of gases sulfur dioxide, ammonia, carbon dioxide, and nitrous oxide on barium fluoride crystals.** *Trans. Faraday Soc.* **44**, 698-708 (1948).—*C.A.* **43**, 2485*b*.
The adsorption between −78 and 119°C was reversible and complete within 5 min. of gas admission. The B.E.T. plots were linear except at low pressures where departures were anticipated. The vol. adsorbed tended to be too small at high pressure, in keeping with the decrease in the heat of adsorption. The latter were detd. by use of the Clausius-Clapeyron and the B.E.T. equations.

1422. Dilke, M. H.; Eley, D. D., and Maxted, E. B. **Catalytic poisons and magnetic susceptibility.** *Nature* **161**, 804 (1948).—*C.A.* **42**, 6184*h*.
The change in magnetic susceptibility of Pd due to adsorption of Me_2S (a catalytic poison) were detd. to study the nature of the adsorption link. Only the chemisorbed layer affected the susceptibility. A chemisorbed mol. transferred an electron to a vacant surface *d* orbital, and thus the susceptibility of the surface Pd atoms was reduced to zero.

1423. Fok, N. V.; Gol'danskiĭ, V. I., and Chirkov, N. M. **Adsorption of water vapor and of aqueous solutions of hydrogen chloride on mica.** *Doklady Akad. Nauk S.S.S.R.* **61**, 673-6 (1948).—*C.A.* **43**, 462*g*.
The adsorptive capacity of muscovite (2.1 m^2) was improved considerably by preliminary adsorption of HCl (from HCl + H_2O vapor), resulting in a strongly adherent film of 2.5×10^{15} mols. HCl/cm^2. Adsorption of H_2O on this film gave a typical Langmuir curve with a level portion extending from $p/p_s = 0.02$ to 0.1. Above $p/p_s > 0.1$, the adsorbed films were multimol., the adsorption isotherms rising very nearly exponentially. Adsorption of H_2O from HCl + H_2O, and its adsorption from pure H_2O, but on a surface with an adsorbed monolayer of HCl, involved marked hysteresis; it was absent in adsorption from pure H_2O on a HCl-free surface.

1424. Gray, T. J. **Application of measurements of semiconductivity to heterogeneous reactions.** *Nature* **162**, 260-1 (1948).—*C.A.* **43**, 474*h*.
The effect of adsorption of O_2, N_2, H_2, and CO on the resistance of semiconducting films composed of Cu_2O-CuO were studied. O_2 and N_2 decreased the resistance, whereas H_2 and CO increased the resistance of the film on adsorption. On desorption the films treated with O_2, N_2, H_2, returned to their initial value, whereas that for CO did not.

1425. Gruner, E. **The osmotic and zeolitic binding of the volatile phase.** *Kolloid-Z.* **111**, 31-46 (1948).—*C.A.* **43**, 4537*a*.
Water may be held in the solid phase by chem. binding, sorption, capillary binding, or osmotic-zeolitic binding. Osmotically-bound H_2O was not in any sense chemically bound. The vapor pressure

on thermal decompn. followed Raoult's law. Zeolitically-bound H_2O was wholly or partly chemically bound or affected by the solid phase. The systems studied were: H_2O and zeolite, S and ultramarines, NH_3 and zeolites, CO_2 and limestones, and SO_2 and zeolites.

1426. Gyulai, Z. **Crystal growth processes.** *Z. Physik* **125**, 1-17 (1948).—*C.A.* **43**, 8787*g*.

The various forms in which NaCl crystals grow from the vapor phase are described and illustrated by photographs. In some cases there is evidence of surface diffusion.

1427. Harris, Louis; McGinnies, Rosemary T., and Siegel, Benjamin M. **The preparation and optical properties of gold black.** *J. Optical Soc. Am.* **38**, 582-9 (1948).—*C.A.* 42, 6603*i*.

The optical properties of gold smokes deposited on cellulose nitrate films under different exptl. conditions were studied. The conditions of pressure of the inert atm., purity of the gas, rate of evapn., and the distance between source and deposition surface giving the highest infrared absorption per unit mass were found. The thermal mass required for high infrared absorption was small compared with the thermal masses of other receivers used for infrared measurements. The gold "blacks" turned yellow and had lower infrared absorption when heated above 110°C.

1428. Huttig, Gustav F. and Heinz, Helga. **The rate of decomposition of calcium carbonate and the effect of foreign gases on it.** *Z. anorg. Chem.* **255**, 223-37 (1948).—*C.A.* **43**, 2078*e*.

Decompn. of $CaCO_3$ depended on the rate of heating, and hence varied with the size of the sample and the size and rate of rotation of the oven. Decompn. was slowest in a vacuum. In the presence of He, A, N_2, air or CO_2 the evolution increased inversely with the mol. wt of the gas. H_2 had a much greater effect, probably because of catalytic action. NH_3 and H_2O also strongly increased the decompn. rate, and here also a chem. action probably occurred. Mixts of NH_3 and H_2O had less effect than the pure gases.

1429. Katz, Morris and Katzman, John. **Rapid determination of low concentrations of carbon monoxide in air.** *Can. J. Research* **26F**, 318-30 (1948).—*C.A.* **43**, 1686*e*.

Granular $AgMnO_4$ deposited on ZnO carrier was effective for the oxidation of CO at room temps. Results accurate to 5 p.p.m., in the range of 10-200 p.p.m., have been obtained. The heat of the reaction was detd. by means of the potential generated in a thermocouple cell. A linear relationship between concn. and e.m.f. was found to exist. The presence of H_2 in excess of the CO content, caused no appreciable error.

1430. Khan, G. A. **Adsorption of air on minerals.** *Gornyi Zhur.* **122**, No. 9, 34-7 (1948).—*C.A.* **43**, 3325*f*.

The conditions necessary for an air bubble to form on the surface of a mineral particle were $W = 2\pi\sigma(2R^2 - p^2)$ where W was the energy spent to form the bubble, σ was the surface tension at the liquid gas interface, R was the radius of the bubble, and p was the radius of curvature of the contour of bubble adhesion. Sulfidic minerals prepd. by dry method or prepd. by wet method and subsequently dried adhered strongly to air bubbles. The same minerals left wet after prepn. did not adhere to bubbles unless a surface-active substance (collector) was added.

1431. Morrison, J. A. and Szasz, G. J. **The heat capacity of nitrogen adsorbed on titanium dioxide between 20°K and 80°K.** *J. Chem. Phys.* **16**, 280-6 (1948).—*C.A.* **42**, 4041*f*.

A low-temp. adiabatic calorimeter suitable for thermal measurements on adsorbed gases was described. Heat-capacity values for 0.00996 and 0.01974 mole N_2 adsorbed on 96.8 g TiO_2 (rutile) were presented. Although the measurements were complicated by the appearance of warm drifts in the calorimeter over part of the temp. range when N_2 was present, at these concns. and temps. the adsorbate was present as a condensed phase.

1432. Plyler, Earle K. and Ball, Joseph, J. **Infrared absorption of deposited blacks.** *J. Optical Soc. Am.* **38**, 988 (1948).—*C.A.* **43**, 944*b*.

Infrared-absorption measurements of gold blacks recently reported to 15 μ have been extended to 39 μ with films deposited on windows of thallium bromide-iodide. Transmission curves of carbon, bismuth, zinc, and gold blacks from 1 to 39 μ show that (unlike carbon, bismuth and zinc blacks) gold blacks do not change appreciably in transmission throughout this range of spectrum.

1433. Stranski, I. N. and Moliere, K. **Structural deviations in the surface of ionic crystals.** *Z. Physik* **124**, 421-8, 429-40 (1948).—*C.A.* **43**, 4072*d*.

The surface of a NaCl crystal was discussed in terms of an incipient formation of NaCl mols. with crevices between them. The effect of these crevices on the tensile strength and rate of flow of the crystal was considered. Partial soln. of a crystal increased the tensile strength by rounding off the cube corners and removing the crevices. If the mean ionic polarizability was above a certain value (approx. that of NaCl) the tangentially distorted form of the surface was favored.

1434. Voevodskii, V. V. and Lavrovskaya, G. K. **Recombination of atoms on solid surfaces.** *Doklady Akad. Nauk S.S.S.R.* **63**, 151-4 (1948).—*C.A.* **43**, 1635*d*.

Recombination of O atoms produced in a discharge under 300 v., 350 milliamp., and detd. by the rise of the temp. on the wall of a side capillary connected with the discharge tube, proved to be weak on glass and quartz, covered or not with KCl, LiCl, or $K_2B_4O_7$, fairly intense on surfaces coated with sputtered Pt, $ZnO.Cr_2O_3$, or $AgNO_3$.

1435. Zawadzki, J. and Szamborska, W. **Kinetics of the decomposition of zinc carbonate.** *Bull. intern. acad. polon. sci., Classe sci. math. nat., Ser. A*, **1940-46**, 27-31 (1948) (in English).—*C.A.* **43**, 7306*d*.

The decompn. in vacuum of $ZnCO_3$ into ZnO and CO_2 was detd. Between 400° and 420°C a noticeable speeding-up of decompn. and the appearance of 2 velocity max. were observed. Similar effects were absent at 440°C. ZnO bound on the surface a part of the CO_2 from the decompn. of $ZnCO_3$, and the velocity of this tendency increased with increased temp. At 440°C this tendency predominated; at lower temp. it did not. Decompn. was not complete in any of the expts., and never exceeded 91%. X-ray analyses indicated no $ZnCO_3$ above 90% decompn., but only ZnO and adsorbed CO_2. Below 90% decompn. $ZnCO_3$ was present.

1436. Zawadzki, J. and Bretsznajder, S. **Kinetics of reaction in which solid phases take part.** *Bull. intern. acad. polon. sci., Classe sci. math. nat., Ser. A*, **1940-46**, 60-4 (1948) (in English).—*C.A.* **43**, 7307*f*.

The decompn. of $CaCO_3$ in vacuum and in the presence of CO_2 was studied to det. the velocity of decompn. of crystals of the same size and compn. Numerous difficulties were encountered and the results were erratic. Likewise, a study of the system $4CaSO_3 \rightleftharpoons CaS + 3CaSO_4$ showed that the transformation was accompanied by increasing mobility of the structural elements, which almost reached the passage through the liquid phase. At 500° and several months no $CaSO_3$ resulted from CaS and $CaSO_4$.

1437. Arnold, James R. **Adsorption of gas mixtures. Nitrogen-oxygen on anatase.** *J. Am. Chem. Soc.* **71**, 104-10 (1949).—*C.A.* **43**, 3263*h*.

Adsorption isotherms at const. gas compn. were detd. at 78.2°K, for five N_2-O_2 mixts. on Harkins' anatase. Isotherms for the two pure gases were also detd. The isotherms showed selective adsorption of N_2 by this surface at low coverage. There was evidence against at least one of the assumptions of the B.E.T. theory. Use of a "liquid entropy" model gave semiquant. agreement with expt.

1438. Badger, E. H. M.; Griffith, R. H., and Newling, W. B. S. **The catalytic decomposition of simple heterocyclic compounds. I. Preparation and properties of molybdenum sulfide and nickel sulfide catalysts.** *Proc. Roy. Soc.* (London) **A197**, 184-93 (1949).—*C.A.* **44**, 2357*e*.

The decompn. of thiophene, furan, and pyrrole on MoS_2 catalysts occurred by 2-point adsorption, which lead to a half-hydrogenated state from which the hetero-atom was then broken off. Retardation was caused by mols. also capable of giving 2-point adsorption. These changes arose from any reactant that could compete for Ni atoms, or that could cover the subsulfide surface and prevent its conversion to metal.

1439. Barrer, R. M. **Preparation of some crystalline hydrogen zeolites.** *Nature* **164**, 112-13 (1949).—*C.A.* **43**, 9296*e*.

Cryst. H-zeolites were made by heating the corresponding NH_4 zeolites in O_2. H-mordenite and H-chabazite were excellent sorbents and gave x-ray powder photographs characteristic of the parent minerals. Propane was sorbed more rapidly by H-chabazite than by natural chabazite. Propane was excluded by natural mordenite, and was occluded, though slowly, by H-mordenite.

1440. Bischoff, F. **Catalytic effects through gas phases in calcining gypsum, limestone, and magnesite.** *Radex-Rundschau* **1949**, 8-13.—*C.A.* **43**, 8621*i*.

Air and O_2 influence the equil. in mixts of $CaSO_4$ and SiO_2 markedly, while N_2 and A are completely inert. Water vapor acts with increasing partial pressure, catalytically promoting the reaction. The thermal dissocn. of $CaCO_3$ is particularly promoted by H_2, H_2O, NH_3, and N_2O. The decompn. of magnesite is promoted not only by H_2O and NH_3, but also to a very high degree by moisture in the atm.

1441. Boissonnas, Charles G. **Latent images on the surface of a macro-crystal of silver bromide.** *Science et. inds. phot.* **20**, 361-3 (1949).—*C.A.* **44**, 57*f*.

Molten AgBr was crystd. under red light and cut into disks 2-3 cm in diameter and few mm thick. Development in an alk. hydroquinone soln., sometimes contg. Na_2SO_3, was observed under the microscope. Ag grains appeared on the polished surface of unexposed AgBr a few sec after contact with the developer. If the AgBr was exposed to a pencil of white light, an image of the pencil developed. If polished AgBr was used, the Ag grains were much less numerous in the exposed than in the unexposed regions. If the AgBr surface had been roughened with emery it behaved like a photographic emulsion and a negative was obtained on development.

1442. Briner, E.; Pamm, G., and Paillard, H. **The velocity of thermal dissociation of the sulfates of calcium, potassium, and sodium in the presence of added materials reaction strongly accelerated by water vapor.** *Helv. Chim. Acta* **32**, 635-46 (1949)((in French).—*C.A.* **43**, 6895*g*.

The reaction, $CaSO_4 \rightleftharpoons CaO + SO_2 + 1/2\ O_2$, was studied from 400° to 900°C in pure N_2, H_2O, and N_2-H_2 mixts. The accelerating actions of metakaolin ($2SiO_2.Al_2O_3$), SiO_2, and 3 types of bauxite were investigated. In all cases the addn. of H_2O vapor, metakaolin, SiO_2, or bauxite increased the percentage reacted and the rate of the reaction.

1443. Chufarov, G. I. and Averbukh, B. D. **Oxidation of iron sulfide by oxygen.** *Zhur. Obshchei Khim. (J. Gen. Chem.)* **19**, 857-62 (1949).—*C.A.* **43**, 7854*g*.

FeS (area about 0.1 m^2/g) was oxidized by dry O_2 at 50° or 100°C and at initial pressure of 0.1 mm. Under these conditions, the reaction stopped very soon. Up to 250°C, the oxidation took place without evolution of gas; consequently, the product was $FeSO_4$. The early stoppage of the reaction was due to the dense structure of this product. If the oxidized sample was heated to 600°C or higher, the $FeSO_4$ was partly dissocd. to a less dense oxide, and the sample became susceptible to renewed low-temp. oxidation.

1444. Clark, L. M. **The effect of gases on the sintering of lime.** *Rec. trav. chim.* **68**, 969-82 (1949).—*C.A.* **44**, 3221*d*.

Rates of sintering of lime at 1000°-1250°C were detd. from the decrease in surface area as measured by adsorption of the dye hydroxyazobenzene-2-carboxylic acid (0.08 g in 20 ml of 98% $CHCl_3$-2% alc. for 0.5 g sample). When lime was heated in vacuo or in A, rates of loss of surface were the same. Rates increased with N_2, O_2, or air, H_2O vapor, CO_2, and SO_2 atms. and in this order.

1445. Cremer, E. and Gatt, F. **The position of the equilibrium $MgCO_3 \rightleftharpoons MgO + CO_2$ at different firing temperatures.** *Radex Rundschau* **4**, 144-9 (1949).—*C.A.* **44**, 3339*d*.

The entropy and enthalpy values were calcd. for the 3 components and the equil. for the range 300-1200°K also detd. at 100° intervals. The theoretical temp. of dissocn. at a CO_2 pressure of 1 atm. was 350°C. However, calcns. showed that equil. was reached very slowly, and could not be attained in expts.

1446. Cremer, E. and Gatt, F. **Kinetics of the thermal decomposition of magnesite.** *Radex Rundschau* **4**, 257-61 (1949).—*C.A.* **44**, 4317*i*.

Expts. were made at various temps. on natural $MgCO_3$ with grain sizes from 0.75 to 0.01 mm. Although the surface area calcd. on the basis of grain size varied greatly, no difference in the speed of decompn. in excess of exptl. error was apparent. The process detg. the velocity was a diffusion process that takes place in the primary particles, the size of which was assumed to be about 10^{-5} cm. The dependence on temp. of the diffusion const. corresponded to a diffusion heat $Q = 50$ kcal., and a proportionality factor $A = 10^{-3}$ cm² per sec.

1447. Croatto, Ugo. **Chemical manometers.** *Ricerca sci.* **19**, 1160-3 (1949).—*C.A.* **45**, 6435*b*.

Chem. systems in equil. with a gas have been studied as chem. manometers. The systems CdO_x, CoO_x, and Ag_2S_x at 600-500°, 1000-950°, and 400-350°C, resp., were studied for gas pressures of 2-760 mm, 10^{-7}-10 mm O_2, and 10^{-6}-5 mm S, resp. The materials were prepd. in small cylinders with Pt contacts, and the elec. cond. was measured at various gas pressures. All 3 gave good reproducibility and constancy with time at a fixed temp.

1448. Dell, H. A. **The physical properties of thin films used in the reduction of surface reflection.** *Proc. Phys. Soc.* (London) **62B**, 81-93 (1949).—*C.A.* **44**, 893*g*.

Evidence is given suggesting that polished or aged cryolite films behave as if they consisted of a lower stratum of cryolite surmounted by a secondary layer of higher n. Some of the properties of this layer are described. The self-stripped specimens suggest that the high-index layer may sometimes penetrate some distance into the original cryolite film.

1449. Duval, Clément. **Pyrolysis of asbestos.** *Anal. Chim. Acta* **3**, 163-4 (1949 in French).—*C.A.* **43**, 8310*b*.

The asbestos in a Gooch crucible loses wt gradually above 283°C, when studied by means of a thermobalance. Accordingly, it should only be used below this temp.

1450. Esin, O. A.; Gel'd, P. V., and Popel, S. I. **Redistribution of ions in the thermal dissociation of double salts.** *Zhur. Priklad. Khim.* (J. Applied Chem.) **22**, 354-60 (1949).—*C.A.* **43**, 7306*g*.

The initial process is the dissocn. of $CO_3^{--} \rightarrow CO_2 + O^{--}$, at the surface which results in a loosening of the lattice. Decompn. is easier where CO_3^{--} is surrounded by Mg^{++} than in the neighborhood of the larger Ca^{++}. The rates of decompn. increase in the order dolomite, $MgCO_3$, $CaCO_3$ since the diffusion of ions that follows the decompn. of CO_3^{--} is easier the higher the temp. The accelerating effect of NaCl consists in the redistribution of Mg^{++}, Ca^{++}, O^{--}, and CO_3^{--} ions. $NaNO_3$, NaF, KCl, $Na_2C_2O_4$, and to a lesser degree Na_2CO_3, have an effect similar to that of NaCl.

1451. Frenkel, Ya. I. **Diffusion and spontaneous diffusion in substances that are complicated chemically.** *Zhur. Eksptl. Teoret. Fiz.* **19**, 814-18 (1949).—*C.A.* **46**, 10758*d*.

Beginning with considerations of the mechanism of diffusion into NaCl crystals on the basis of the pore theory, the considerations of diffusion without essential heat exchange are extended to more complicated binary systems and to polymers.

1452. Furst, Otto; Glocker, Richard, and Richter, Hans. **The atomic arrangement in amorphous germanium.** *Z. Naturforsch.* **4a**, 540-2 (1949).—*C.A.* **44**, 4745*b*.

Evapd. films of Ge were built up on a rock-salt surface, and monochromatized x-rays of 1.54 A. wave length were used to det. the angular dependence of scattering intensity. There were 4 atoms at a distance of 2.40 A. and 12 at 3.95 A. Tetrahedra of atoms could be arranged so that the atom at the peak of one tetrahedron was at the center of the next. These tetrahedra were free to turn relatively to one another, with the result that long-range order was destroyed, but short-range order was preserved.

1453. Giauque, W. F. **An example of the difficulty in obtaining equilibrium corresponding to a macrocrystalline nonvolatile phase in the reaction.** *J. Am. Chem. Soc.* **71**, 3192-4 (1949).—*C.A.* **43**, 8823*a*.

It was shown that the true dissocn. pressure in the reaction $Mg\text{-}(OH)_2$ (cryst.) = MgO (cryst.) + H_2O (g), as detd. from the 3rd law of thermodynamics, was some 130% higher than accurately measured values which were reproducible to 0.1%. This result was attributed to the colloidal nature of the MgO produced under equil. conditions. The colloidal particles approached essentially zero entropy at very low temp. and evidently approximated a perfect cryst. structure. Many equil. measurements involving gases and finely divided dry solid phases, produced by the evolution of gases, or formed by reaction with gases, did not correspond to the properties of macroscopic materials.

1454. Gray, T. J. **The application of semi-conductivity measurements in the study of catalysis on copper oxide.** *Proc. Roy. Soc.* **A197**, 314-20 (1949).—*C.A.* **44**, 2355*f*.

An app. was constructed to measure the elec. cond. of thin films of oxides. Semi-cond. of the Cu_2O-CuO system was used to obtain a qual. picture of the processes of adsorption and catalytic reaction while these processes were being quant. followed by alternative methods.

1455. Gregg, S. J. and Razouk, R. I. **The kinetics of the thermal decomposition of magnesium hydroxide.** *J. Chem. Soc.* **1949**, S36-44.—*C.A.* **43**, 8816*c*.

The dehydration of pptd. $Mg(OH)_2$ and naturally occurring brucite was studied between 300° and 370°C in a vacuum. The decompn. curves were of the usual sigmoid type. The reaction came practically to a standstill at some 3-5% short of complete dehydration, and it was necessary to heat to 500°C for a short time to expel the last traces of H_2O. The rate of dehydration of brucite was not generally affected by its state of subdivision, and at a given temp. was of the same order as for the pptd. $Mg(OH)_2$.

1456. HARRIS, B. L. **Surface area of vermiculite.** *J. Am. Chem. Soc.* **71**, 353 (1949).--*C.A.* **43**, 4826*i*.

The B.E.T. surface area of unexfoliated vermiculite was found to be 0.52 m^2/g. Exfoliation by 5 min. exposure at 950°C increased the area to 10.35 m^2/g. The loss in weight on exfoliation was 19.6%. The area changes corroborated previous observations that the structure collapses above 750°C.

1457. HEILAND, GERHARD AND KELTING, HEINKE. **Absorption of light by potassium chloride crystals with excess potassium and added calcium chloride.** *Z. Physik* **126**, 689-96 (1949).--*C.A.* **44**, 2817*a*.

KCl crystals contg. Ca ions were grown from melts, heated in the presence of K vapor, tempered at elevated temps. until the absorption spectrum was const., and rapidly cooled to room temp. These crystals had a red color produced by a broad absorption band with a max. at 540 mμ. This band was not changed by lowering the temp. to -183°C. Holding the crystals at 500-600°C developed the band due to F centers at 563 mμ at the expense of the Ca band.

1458. HOPKINS, D. W. **A reaction between solids: the formation of zinc ferrite from zinc oxide and ferric oxide.** *J. Electrochem. Soc.* **96**, 195-203 (1949).--*C.A.* **43**, 8933*h*.

The formation of Zn ferrite from a stoichiometric mixt. of ZnO and Fe_2O_3 was investigated from 600 to 1150°C. There was a sharp decrease in the reactivity of the ferric oxide if the temp. of prepn. exceeded about 675°C. The reaction was controlled by the diffusion of Fe_2O_3 through the ferrite layer. The activation energies for the low-and high-temp. Fe_2O_3 were 110,000 and 57,000 cal/mole, resp.

1459. INGRAM, G. **The use of silver vanadates as absorbents for sulfur dioxide.** *Anal. Cnim. Acta* **3**, 137-43 (1949) (in English).—*C.A.* **43**, 8308*g*.

A new solid absorbent for SO_2 was described, which was effective at room temp., and which did not absorb CO_2. Exhaustion of the material was indicated by a color change from green to brown. The reagent was made by heating mol. quantities of Ag_2O and $AgVO_3$ together at 150°C. The product had the same empirical compn. as orthovanadate, but very different properties from that produced by the usual pptn. method.

1460. JAMES, HUBERT M. **Conduction in photoconductive lead sulfide films.** *Science* **110**, 254-6 (1949).--*C.A.* **43**, 8848*e*.

Photoconductive PbS films with Pb and O impurities lead to n- and p-type semiconductors, resp. High photosensitivity of PbS films might result from closely-balanced fairly-high contents of n- and p-impurity atoms in homogeneous films about 1μ thick. The required potential fluctuations in the film arise from the random impurity distribution.

1461. JURA, GEORGE. **Thermodynamic properties of the surface of magnesium oxide.** *J. Chem. Phys.* **17**, 1335 (1949).—*C.A.* **44**, 4749*e*.

From a comparison of published values for the heat capacity of large crystals of MgO and a very fine cryst. prepn. (50 m^2/g), an approximation of the surface thermodynamic properties was made. These included the free surface energy, entropy, and total surface energy.

1462. KALLWEIT, HERBERT. **Mix crystals of calcium carbonate-strontium carbonate studied by the "emanation" method.** *Z. Naturforsch.* **4a**, 140-9 (1949) (in German).--*C.A.* **43**, 8271*f*.

Mix crystals of $CaCO_3$-$SrCO_3$ in varying proportions were mixed with small amt. of Th X nitrate. The crystals were heated at a rate of 10-12° per min. to temps. of 1300°C. A stream of CO_2 over the crystals gave an electroscope reading proportional to the amt. of emanation. Maxima in the curves as a function of temp. corresponded to changes in the crystal structure. The temp. of the rhombic-hexagonal transition was a linear function of compn. of the crystal. The rhombic-hexagonal transition for mixts. ranging from pure $CaCO_3$ to 50% $CaCO_3$, 50% $SrCO_3$ was not reversible but mixts. from pure $SrCO_3$ to 30% $CaCO_3$, 70% $SrCO_3$ were reversible.

1463. KEENAN, A. G. AND HOLMES, J. M. **The adsorption of nitrogen, argon, and oxygen on potassium cloride at 78-90°K.** *J. Phys. & Colloid Chem.* **53**, 1309-20 (1949).—*C.A.* **44**, 4747*c*.

The adsorption of N_2, A, and O_2 on KCl (area about 3 m^2/g) was measured between 78 and 90°K at relative pressures between 0.01 to 0.9. The B.E.T. surface-area values calcd. from the N_2 isotherms were about 25% smaller than those calcd. from the isotherms for A and O_2. Plots yielded smooth curves for O_2 and A and 2 straight lines intersecting at about 0.25 relative pressure for N_2.

1464. KELTING, HEINKE AND WITT, HORST. **Potassium chloride crystals with additions of alkaline earth chlorides.** *Z. Physik* **126**, 697-710 (1949).—*C.A.* **44**, 2817*c*.

As the crystal grows from the melt, successive layers had increasing concns. of bivalent ions and the slower the growth the higher the concn. Concns. in the crystal decreased in the order Sr, Ba, Ca for equal rates of growth and concns. in the melt. Although the bound alk. earth ions had zero mobility in an elec. field they caused an addnl. sp cond. in the crystal that was approx. proportional to their concn. and independent of the chem. species.

1465. KOSKI, W. S. **Diffusion of oxygen in potassium chloride.** *J. Chem. Phys.* **17**, 582 (1949).—*C.A.* **43**, 8863*f*.

By bombarding KCl with slow neutrons, S is formed. If appropriate care is taken to exclude oxidizing agents the bulk of the S^{35} is in the form of either elementary sulfur or more probably sulfide ion. Radio-sulfur is thus randomly distributed through the KCl crystal. If O_2 is permitted to diffuse into such a crystal the sulfide ions will be oxidized to SO_3. The position of the oxidation boundary in any one crystal can be detd. by permitting the crystal to dissolve slowly in an appropriate solvent, and analyzing the resulting soln. for sulfide and sulfate activity from time to time.

1466. LOCKEMANN, GEORG. **Formation of basic calcium carbonate by ignition of the carbonate.** *Z. anal. Chem.* **129**, 213-17 (1949).—*C.A.* **44**, 74*e*.

When a dried CaC_2O_4 ppt. is heated in a porcelain crucible which is inside a somewhat larger one, a basic carbonate is obtained which corresponds almost exactly to the formula $CaO.CaCO_3$. $CaCO_3$ is stable up to 600°C but the basic carbonate is stable at 700°C.

1467. LONGUET-ESCARD, J. **Reaction in the solid state at low temperatures, in the presence of water.** *Bull. soc. chim. France* **1949**, D153-6.—*C.A.* **43**, 6531*f*.

The formation of ferrites, chromites, sulfides, silicates, and aluminates was studied between room temp. and 100°C in the presence of H_2O. Several of the products formed were similar to those found in nature, notably franklinite, chalcopyrite, and antigorites. The hydroxides of Ni, Co, Zn, and Mg crystallized in the hexagonal system, type CdI_2.

1468. MAXTED, E. B. **The nature of chemisorptive bonds. I. Some observed regularities.** *J. Chem. Soc.* **1949**, 1987-91.—*C.A.* **44**, 3777*g*.

Deficiencies in the d-bond of the metal play a crit. part in hydrogenation catalysis and adsorption. Three types of strongly-held adsorbates are discussed as to toxicity: (a) nonmetals of Groups Vb and VIb: S, P, or N compds., which have free electron pairs in the valency shell. (b) Metallic ions: The adsorption complex probably resembles an intermetallic compd. (c) Compds. with unsatd. bonds.

1469. REISS, HOWARD. **An approximate solution of certain diffusion problems.** *Trans. N. Y. Acad. Sci.* **11**, 236-9 (1949).—*C.A.* **44**, 2823*e*.

The method is used to investigate problems of the growth of aerosols and of S-hydrosols. In a napthalene-like aerosol system, growing by the diffusion of vapor toward sinks which cannot support supersatn., spontaneous nucleation will not occur if the no. d. of nuclei exceeds 100 per cc. The growth of S-hydrosols can be explained on the basis of a simple diffusion mechanism.

1470. SCHULZ, L. G. **Structure and growth of evaporation lithium fluoride and sodium chloride films on amorphous substrates.** *J. Chem. Phys.* **17**, 1153-62 (1949).—*C.A.* **44**, 2317*c*.

Thin films of LiF and NaCl were prepd. by evapn. in a vacuum. On amorphous substrates the films possessed a crystal orientation that varied with the film thickness. For both LiF and NaCl deposits thinner than 100 A. showed almost completely random structure, but with a small amt. of (100) preferred orientation. As the thickness was increased, there was a change, first to completely random, and then to a very definite and strong preferred orientation which was (111) for LiF and (110) for NaCl. A less extensive study of five other substances showed the following orientation: CaF_2 (111); KCl (110); MgF_2 (302); NaBr and KBr random or a vague (211).

1471. SCHWOB, YVAN. **The simple and complex rhombohedral carbonates of calcium, magnesium, and iron. Their thermal dissociation.** *Rev. Materiaux construction trav. publ., Ed. C.* No. **411**, 409-20 (1949).—*C.A.* **44**, 3339*f*.

The dissocn. and recarbonation of $CaCO_3$ from various sources was detd., the rate of heating being 5° per min. The thermal-analysis curves showed that thermal dissocn. took place around 900°C and that recarbonation started at 880°C, but that recarbonation was not complete under the conditions of the expt. The decarbonated CaO particles had the same dimensions as the original calcite crystals, but they were completely isotropic. Calcite, pptd. $CaCO_3$, chalk, and marble showed decreasing degrees of recarbonation in the order listed. The addn. of water vapor to the CO_2 increased the extent of recarbonation; also, increasing the rate of flow increased recarbonation.

1472. SELWOOD, P. W.; MOORE, T. E.; ELLIS, MARYLINN, AND WEITHINGTON, KATHRYN. **Supported oxides of manganese.** *J. Am. Chem. Soc.* **71**, 693-7 (1949).—*C.A.* **43**, 5654*b*.

The susceptibility isotherm method was extended to supported oxides of Mn. It was found that supported transition group oxides may imitate the crystal structure of the support even to the extent of changing oxidation state.

1473. SHUTTLEWORTH, R. **The surface energies of inert-gas and ionic crystals.** *Proc. Phys. Soc.* (London) **62A**, 167-79 (1949).—*C.A.* **44**, 894*f*.

The surface energies of inert-gas crystals were proportional to their sublimation energies. The const. of proportionality was evaluated for the (111), (100), and (110) faces for different assumed forms of the interat. repulsive forces. To within 15% it was independent of the face, and of the form of the repulsive force. The contribution of van der Waals-type forces to the surface energy of a (100) face was almost half the total. Elementary methods were given for the evaluation of lattice sums. Contributions of electrostatic, dipole-dipole, dipole-quadrupole, and repulsive forces to energies were calcd.

1474. SPANGENBERG, K. **New measurements of the vapor pressures and decomposition temperatures of alums.** *Neues Jahrb. Mineral., Geol., Monatsh.* **1949A**, 113-38.—*C.A.* **43**, 8785*h*.

Vapor-pressure measurements at 5 to 70°C were given for 41 alums, and detns. of temps. of sintering and melting for 43 alums, $A^IB^{III}(XO_4)_2.12H_2O$ The vapor pressures of the alums of Tl, NH_3Me, and NH_3OH were higher than would be expected from the ionic radii, which was ascribed to the non-noble gas character of the ions. For alums with the same A^I, the vapor pressures increased in the order Al, Cr, V, Fe, Co.

1475. SPANGENBERG, K. **The binding of water in the alums.** *Neues Jahrb. Mineral., Geol., Monatsh.* **1949A**, 99-112.—*C.A.* **43**, 8936*g*.

The measurements of vapor pressure and decompn. temp. are not in accord with the assumption that 6 H_2O are coordinated with A^I and 6 H_2O with B^{III}, nor are the distances calcd. for neighboring atoms in good agreement with theory. A structure is proposed in which all the H_2O is coordinated in double mols. around B^{III}, these mols. forming zigzag chains along the (110) direction. In this structure, the size and nature of the B^{III} ion has the greatest effect on the vapor pressure and stability.

1476. Spooner, Robert B. and Selwood, P. W. **Nuclear induction and the structure of catalytically active solids.** *J. Am. Chem. Soc.* **71**, 2184-7 (1949).—*C.A.* **43**, 8831*i*.
The chief application is the promise of making *in situ* observations while the catalyst is promoting a chem. reaction. Relaxation times for Fe and Nd oxides, each supported on γ-alumina, and for MnO_2 on rutile, detd. *in situ*, are in agreement with theory.

1477. Stranski, I. N. and Wolff, G. **The forced condensation of arsenic oxide. A theory for the rate of vaporization from crystals.** *Z. Elektrochem.* **53**, 1-4 (1949).—*C.A.* **43**, 5250*b*.
A theoretical discussion of the vaporization and condensation of As oxides.

1478. Walker, G. F. **Water layers in vermiculite.** *Nature* **163**, 726-7 (1949).—*C.A.* **43**, 6949*d*.
A powd. specimen and single flake of vermiculite were heated at 110°C and sealed in a thin glass tube. The basal reflection of this material was 11.8 A. as against 14.2 A. for vermiculite. The H_2O-layer thickness of the dehydrated material was 2.54 A., approx. half the original value. The removal of half the H_2O was accompanied by replacement of an original double H_2O layer by a single layer. The rapid and spontaneous rehydration which took place on contact with atm. moisture appeared to be related with the very high cation-exchange capacity of this mineral.

1479. Wieninger, L. and Adler, N. **Formation of microscopic crystals on crystal surfaces exposed to α-rays.** *Nature* **163**, 989 (1949).—*C.A.* **43**, 7769*g*.
The surface of rock salt exposed to α-rays from Po became dull. Examn. under a microscope showed that the surface was covered by minute birefringent crystals. The crystals were identified as $NaNO_3$, and were formed by the action of NO_2 produced by the α-rays in air. Crystals of KNO_3 were formed also on KCl, but on KBr, isotropic triangular crystals were formed. Anisotropic crystals were found also on fluorite and calcite.

1480. Zvorykin, A. Ya. and Timokhina, N. I. **Sintering of salts and oxides.** *Zhur. Priklad. Khim.* (J. Applied Chem.) **22**, 1063-7 (1949).—*C.A.* **44**, 892*g*.
The ratio of the temps. of beginning sintering to their temp. of fusion (t_s/t_f) was 0.44 for salts, and 0.8 for oxides and silicates. Powders sintered at temps. above t_s were tested for mech. strength, *s*, by detn. of the min. wt necessary to crush a specimen. For NaF, NaCl, NaBr, KCl, KBr, and KI, $t_s = 285$, 204, 181, 216, 190, and 137°C, heated at 500°C, $s = 25.0$, 47.5, 92.4, 65.6, 87.1, and 371.7 g/0.95 cm^2. CaF_2 heated at 400-700°C, reached only small *s* of 9.2-56.4. Heating of $Ca_3(PO_4)_2$ at 700-1000°C resulted in $s = 2.7$-11. With $CaHPO_4$ *s* increased sharply with the temp. from 800° upwards, reaching 782.5 g at 1000°C. SiO_2 began to sinter only at 1000°C. For Fe_2O_3, the rise of *s* with the temp. of heating reflected the transitions of that oxide. $CaCO_3$ showed a very slow rise of *s* up to 800°, followed by very fast increase above 800°C.

1481. Barrer, R. M. **Intracrystalline sorption.** *J. Chim. Phys.* 47, 82-94 (1950).—*C.A.* **44**, 6701*a*.
The sorption of gases in silicate and ionic crystals increase in relative accessibilities of the interstitial adsorption sites in the order: beryl < silicate glasses < silica glass < harmotome < levynite < mordenite < gmelinite, chabazite, and synthetic cryst. zeolite $BaAlSi_2O_6.2\text{-}3H_2O$. The last six of the zeolites listed above are discussed from the point of view of sieve action in adsorption, thermodynamics of adsorption, and kinetics of adsorption.

1482. Bielański, A. **Sorption of water vapor by dehydrated potassium alum.** *Bull. intern. acad. polon. sci. Classe sci. math. et nat.*, Ser. A, **1950**, 35-72 (in English).—*C.A.* **46**, 2872*h*.
Potassium alum was dehydrated to $K_2SO_4.Al_2(SO_4)_3.(2.65 \pm 0.25)H_2O$ *in vacuo* at 55°C and rehydration studied at 45°, 55°, and 62°C with p_{H_2O} of 4 to 94 mm. Primary hydration up to a max. of 7.7 moles H_2O per mole alum showed a linear relation between wt increase and the sq root of the time. If p_{H_2O} exceeded 50-60% satn., secondary hydration occurred, which caused the crystal to become translucent and finally opaque owing to dendritic growths.

1483. Bielański, A. and Tompkins, F. C. **Sorption of water by dehydrated alum crystals.** *Trans. Faraday Soc.* 46, 1072-81 (1950).—*C.A.* **45**, 4996*b*.
Single crystals of potash alum dehydrated for 18 hrs at 55°C were investigated between 45 and 62°C at relative vapor pressure between 0.04 and 0.95. First-layer adsorption on the easily accessible surface was reversible and complete at a relative pressure of 0.04. Second (and higher) layer adsorption proceeded at higher pressures and largely controlled the rate of diffusion of water into the dehydrated alum. The heat of "desorption" was 11 kcal./mole water, and the activation energy assocd. with the diffusion process was less than 500 cal/mole.

1484. Clancey, V. J. **Evaporation and mobility of naphthalene molecules.** *Nature* **166**, 275 (1950).—*C.A.* **44**, 10425*g*.
The rates of evaporation of solid naphthalene into a vacuum from different crystal faces were measured by masking two crystals so that only portions of the faces to be studied were exposed and mounting these crystals so that the evaporation produced a torque which was measured with a quartz suspension fiber. It was found that both the abs. rate of evapn. and its temp. coeff. were different for different crystal faces; this indicated variations in condensation coeffs. and energies. Anomalies appeared in the results which suggested possible mobility of the mols. over the solid phase and the glass support. Measurements were made with mica, tin (foil), graphite, and glass as the substratum.

1485. Crawford, V. A. and Tompkins, F. C. **Adsorption of gases on calcium fluoride.** *Trans. Faraday Soc.* **46**, 504-14 (1950).—*C.A.* **44**, 9768d.

Adsorption isotherms were detd. on CaF_2 crystals for SO_2 at 0°, 19.1°, 32.9°, 55.9°, 74.9°, and 98.5°C; CO_2 at -22.8°, 0°, 19.7°, 32.4°, and 55.9°C; N_2O at -22.8°, 19.4°, and 35.5°C. The adsorption was reversible and complete within 3-4 min. Heats of adsorption were calcd. in the various temp. intervals from the Clausius-Clapeyron equation and decreased with increase of vol. adsorbed for all gases but were sensibly independent of temp.

1486. Forestier, Hubert and Kiehl, Jean Pierre. **Influence of the adsorption of gas on polymorphic transformations.** *Compt. rend.* **230**, 2288-90 (1950).—*C.A.* **44**, 10412*g*.

The following transformations were studied in He, H_2, Ne, N_2 air, O_2, and CO_2 at a no. of different temps.: Tl $\alpha\rightarrow\beta$, SnO_2 $\alpha\rightarrow\beta$, KNO_3 ortho→rhombic, $AgNO_3$ ortho→hexagonal, Fe $\alpha\rightarrow\gamma$, and steel (0.8%C) $\alpha\rightarrow\gamma$. The temp. of transformation of different substances examd. varied according to the nature of the adsorbed gas. The importance of the lowering of the temp. of transformation varied with the material studied; it was negligible for the steel eutectic which was in accord with the considerable weakening of the phys. adsorption of gases at this temp.

1487. Forst, P. von der; Ruter, Fr., and Schenck, Rudolf. **Surface chemistry: the system zinc sulfide-silver sulfide.** *Z. anorg. Chem.* **262**, 100-8 (1950).—*C.A.* **44**, 7618*h*.

ZnS, freshly prepd. at 400°C, prevents the reduction of Ag_2S by H_2. Pretreatment of ZnS affects the quantity of irreducible Ag_2S. The greatest effect is obtained at 650°C whereas upon heating to 1000°C no appreciable effect is observed. The phenomenon is attributed to adsorption of solid Ag_2S on surface-rich ZnS. In contrast to pure Ag_2S, adsorbed Ag_2S and Cu_2S can be partially sulfurized, probably owing to the formation of AgS or Ag_2S_3 in the surface layer.

1488. Frank, F. C. **The structure of a crystal surface.** *Phil. Mag.* **41**, 200-5 (1950).—*C.A.* **44**, 6225*f*.

Dislocations play an essential role in the growth of crystals. The crystal structure of beryl is discussed in terms of growth from screw dislocations. The dependence of the 2-dimensional crystal growth rate on the orientation of the step line imposes a characteristic distortion of the growth spirals and loops, exhibiting the symmetry of the crystal face. A fairly simple theory can be given to account for the shape assumed by each growth layer as it expands.

1489. Frauenfelder, Hans. **Radioactive investigation of surface processes.** *Helv. Phys. Acta* **23**, 347-80 (1950).—*C.A.* **44**, 10531*i*.

Adsorption of thin gas layers at low pressure can be studied by means of recoil atoms from K-capture. Exptl. results with Ag, Cu, Cd, and Hg on mica and on surface diffusion of Cu and Cd are compared with earlier results, obtained by nonradioactive methods. These techniques can be applied to the rapid sepn. of radioactive mixts. and to the prepn. of very thin sources.

1490. Funaki, Koemon and Asada, Kazuo. **Fundamental research on the metallurgy of tungsten. I. The heterogeneous equilibrium among tungsten, its oxides, hydrogen, and water vapor.** *J. Electrochem. Soc. Japan* **18**, 250-3 (1950).—*C.A.* **45**, 8423*b*.

The reduction process on heating WO_3 in a stream of H_2 was studied by measuring the weight of WO_3 by a thermobalance and the following 7 stages of reduction were found: $WO_3\rightarrow W_4O_{11}\rightarrow W_2O_5\rightarrow W_4O_9\rightarrow WO_2\rightarrow W_2O_3\rightarrow WO\rightarrow W$. The exptl. results for the H_2 reduction of WO_3 were satisfactorily explained.

1491. Garner, W. E.; Gray, T. J., and Stone, F. S. **Reactions on the surface of copper oxide.** *Disc. Faraday Soc.* **1950**, No. 8, 246-50.

The nature of the various stages occurring in the interaction of CO and O_2 on the surface of CuO was studied. For this purpose two techniques had been combined, one based on measurements of changes of surface conductivity due to the adsorption of gases, and the other on measurements of heats of adsorption.

1492. Gray, T. J. and Savage, S. D. **Reactions on the surface of copper oxide. I. Semiconductivity measurements.** *Disc. Faraday Soc.* **1950**, No. 8, 250-4.

The adsorption of O_2 increased the semiconductivity of the Cu_2O-CuO system, giving a surface-energy of 4.96 kcal. The rate of development of cond. on the adsorption of O_2 at 140-200°C over the low-pressure range indicated that the rate-detg. step was first order. It was uncertain whether this related to the dissocn. of O_2 or to the formation of O^- from O atoms. At room temp. 50% of the adsorbed O_2 reacted with CO to give CO_2, whereas there was no significant reaction with an evacuated film. A similar reaction occurred between CO_2 and adsorbed O_2 to give CO_3 comples. The rate of adsorption on porous oxide was controlled by the activated diffusion of O atoms. These results indicated that in the dissocn. of O_2, one atom entered the lattice and the other was free to move over the surface.

1493. Gray, T. J. **Semiconductivity and catalysis.** *Discussions Faraday Soc.* **8**, 331-7 (1950).

The adsorption and interaction of gases on semiconductors led to a variation in semiconductivity which could be successfully applied to the study of adsorption catalysis. Fundamental information was simultaneously furnished regarding the semiconductivity process. An experimental technique was described for a study of the adsorption of gases by variation in semiconductivity.

1494. Griffin, L. J. **Observation of unimolecular growth steps on crystal surfaces.** *Phil. Mag.* **41**, 196-9 (1950).—*C.A.* **44**, 6225*d*.

Surface line markings on natural surfaces of beryl crystals were the height of only one unit cell. These lines followed contour lines of the surface topography. The lines were widely spaced where the surface was relatively flat, and crowded together where there was a steep gradient. The only evident departure from contouring was that occasionally a single line terminated at a point in the face, instead of forming a closed loop.

1495. Grillot, Edmond and Bancie-Grillot, Marguerite. **Influence of oxidation state of fluorescence centers on the luminescent color of zinc sulfide activated with copper.** *Compt. rend.* **231**, 966-8 (1950).—*C.A.* 45, 3718*e*.

If ZnS contg. trace amts. of Cu is prepd. in the total absence of O_2, the luminescence is blue-violet and not at all persistent; if O_2 is present during prepn. the luminescence is either nonpersistent blue with a persistent green afterglow, or clear persistent blue, or green with a bit of blue at the start, depending upon the amt. of O_2 introduced. The amt. of O_2 necessary to change from blue to green luminescence is of the same order of magnitude as the amt. of Cu present.

1496. Hass, Georg. **Preparation, structure, and applications of thin films of silicon monoxide and titanium dioxide.** *J. Am. Ceram. Soc.* **33**, 353-60 (1950).—*C.A.* **45**, 1403*d*.

A material whose compn. satisfied the formula SiO was prepd. by heating a mixt. of finely divided Si and SiO_2 in the closed end of a SiO_2 tube. The SiO evolved from the heated mixt. condensed at a temp. above 800°C, forming a light-brown, loose material; at lower temps. the condensate was dark brown to black, massive, and glassy. The SiO was structurally different from Si or SiO_2, and existed only in amorphous form. These vacuum-deposited films of SiO decompd. to Si and SiO_2 when heated for several hrs at temps. above 600°C in an inert atm., and oxidized to SiO_2 when heated in air. Films of TiO_2 were prepd. by evapg. Ti and oxidizing it in air at 400-450°. These films had a rutile structure.

1497. Johnson, Gerald W. **Some observations of the epitaxy of sodium chloride on silver.** *J. Chem. Phys.* **18**, 154-5 (1950).—*C.A.* **44**, 5175*b*.

Ag film, grown on NaCl was removed and dipped into a satd. soln. of NaCl. Almost complete orientation of the NaCl crystals resulted, with the cube edges of the crystallites parallel to the (110) direction of Ag. A lightly etched polycryst. sheet of Ag also exhibited orienting effects. Crystn. was much more profuse on the grains that showed the greatest epitaxy. When a mica sheet was treated similarly, the (111) planes of NaCl were in the plane of the surface.

1498. Johnson, W. T. M. and Krieger, K. A. **Use of carbon^{14} in a study of the mechanism of the heterogeneous oxidation of acetylene over silver nitrate.** *Brookhaven Conf. Rept.*, Chem. Conf. No. 4, 16-38 (Jan., 1950).—*C.A.* **45**, 1857*a*.

Small amts. of C_2H_2 were removed from an air stream, using $AgNO_3$ supported on alumina as a catalyst. $C^{14}O_2$ resulting from the oxidation of labeled C_2H_2 was measured radiometrically. C_2H_2 removal was due to 2 distinct and successive processes: adsorption and oxidation (combustion), the $AgNO_3$ being reduced to Ag. The start of the combustion process, characterized by both evolution of CO_2 and rise in temp. of the catalyst bed, depended on the temp. of the reaction. Oxidation did not occur at temps. much below 140°; it was delayed for a period of about 50 min. at 149°. A definite "population density" of C_2H_2 was required on the $AgNO_3$ surface, either as adsorbed mols. or as a definite surface compd., before reaction began.

1499. Kawamura, Hajimu and Shinohara, Akira. **Resistance of interface of oxide-coated cathode.** *J. Phys. Soc. Japan* **5**, 90-5 (1950).—*C.A.* **45**, 5539*g*.

When the impurity forms an interstitial compd. such as Ba_2SiO_4 at the interface, a double rectifying layer in series is formed. A bad vacuum can cause double rectifying. It is best to use core materials which do not contain impurities such as Mg, Ca, or Ba.

1500. Krasnovskii, A. A. and Gurevich, T. N. **Relation between atmospheric stability of pigmented paint films and the pigment-photosensitized formation of peroxide compounds.** *Doklady Akad. Nauk S.S.S.R.* **74**, 569-72 (1950).—*C.A.* **46**, 755*c*.

In case of TiO_2, peroxides were detd. by a colorimetric method based on measuring intensity of coloration from reaction of Fe^{+++} and CNS^-; accelerated atm.-stability tests were made under a C arc of 2000 w. In case of ZnO, measurements were made of the fading of methylene in an aq. suspension of ZnO instead of direct detn. of peroxide. TiO_2 with the structure of anatase was photochemically more active than rutile. Muffle ZnO had bright yellow fluorescence and ZnO obtained by calcination of carbonates had dark brown fluorescence.

1501. Laporte, Francois. **The surface of pulverulent solids.** *Pubs. sci. et tech. ministère air* (France), *Notes tech.* No. **39**, 1-38 (1950).—*C.A.* **45**, 2744*a*.

The enthalpy of immersion of anatase, TiO_2 (surface area 10.6 m^2/g) varied from 48 $ergs/cm^2$ before treatment to 490 after heating for 16 hrs at 500°C and 10^{-2} mm pressure.

1502. Lauterbach, Kenneth E.; Laskin, Sidney, and Leach, Leonard. **Specific-surface determinations of uranium dusts by low temperature adsorption of ethane.** *J. Franklin Inst.* **250**, 13-24 (1950).—*C.A.* **44**, 9211*b*.

The adsorption of C_2H_6 on the sample was detd. and the surface area for the micropulverized dusts was: 0.38 m^2/g for UO_3, 0.43 for UO_2, and 0.69 for $UO_2(NO_3)_2 \cdot 6H_2O$. Microscopic measurements were 0.36, 0.24, and 0.37 m^2/g, resp., indicating relatively nonporous materials. Values of 0.71 and 0.19 for adsorption and microscopic measurements indicated surface irregularity in the UF_4. However, for the peroxide the values were 5.74 m^2/g by adsorption and 0.49 by microscopic examn. indicating considerable porosity. The UO_2 sample of "fine suspensions" showed a surface (4.23 m^2/g) ten times that of "coarse suspensions" (0.47).

1503. Lihl, F. **Pyrophoric iron oxide.** *Monatsh.* **81**, 632-46 (1950).—*C.A.* **45**, 3276*i*.

The thermal decompn. of iron formate or iron oxalate results in a carbon-bearing FeO. This γ-FeO has the same structure and nearly the same lattice const., $a = 8.375$, as has Fe_3O_4. The oxide is pyrophoric; it burns to Fe_2O_3 on exposure to air, but retains its spinel structure. The

γ-Fe_2O_3 thus formed is ferromagnetic, and has the lattice const. $a = 8.330$. The structure of the γ-FeO is stabilized only if a definite min. no. of carbon atoms are present in the lattice; carbon-free γ-FeO cannot exist.

1504. Loeser, Edward H. and Harkins, W. D. **Surfaces of solids. XXI. Areas of nonporous solids from adsorption isotherms of heptane or hexane.** *J. Am. Chem. Soc.* **72**, 3427-31 (1950).--*C.A.* **44**, 10443*f*.

The areas of the following nonporous solids calcd. from n-C_7H_{16} adsorption isotherms at 25°C by the Harkins-Jura relative method and by the B.E.T. method were in satisfactory agreement: Fe_2O_3, rutile, graphite, SnO_2, PbS, CuO, CuS, Fe_3O_4, Ag, Ag_2S, Cr, PbO, Sn, Fe, Pb. The value of k in the H.J. relative method was 16.9 (or 18.2 more rarely) for heptane at 25°C. The effective cross-sectional area of heptane at 25°C used in the calcn. of areas by the B.E.T. method was 64 A². Similar agreement for a smaller no. of solids was obtained by use of the isotherms of hexane at 0°C. The value of k for hexane was 14.3, and the hexane area was 58.9 A². The values for the areas were in satisfactory agreement with those calcd. from the adsorption isotherms of N_2.

1505. Long, Earl A. and Meyer, Lothar. **Superfluidity and thermomechanical effect in the adsorbed helium II film.** *Phys. Rev.* **79**, 1031-2 (1950).--*C.A.* **44**, 10419*i*.

Superfluidity occurred in films of He II adsorbed on Fe_2O_3. The temp. was a function of the no. of adsorbed layers and of the pressure difference across the superleak. Superfluidity occurred at the temp. of the bulk liquid, and was independent of the no. of adsorbed layers. The transition He II → He I became first order in adsorbed layers. The normal rate of flow from the adsorbent system to the collection can be greatly increased or even reversed by changes of few ten-thousandths of a degree in the bath temp.

1506. Mapother, Dillon; Crooks, H. Nelson, and Maurer, Robert. **Self-diffusion of sodium in sodium chloride and sodium bromide.** *J. Chem. Phys.* **18**, 1231-6 (1950).—*C.A.* **45**, 2739*e*.

The self-diffusion coeff. of Na in NaCl and NaBr was measured as a function of temp. A comparison of the self-diffusion coeff. with the electrolyte cond. revealed that the Einstein relation was satisfied at high but not as low temps. A possible explanation for the failure of the Einstein relation in terms of assocn. between multivalent foreign ions and vacancies was suggested.

1507. Miyahara, Yutaka. **Adsorption of water vapor by zinc oxide. III.** *J. Chem. Soc. Japan*, Pure Chem. Section, **71**, 153-6 (1950).—*C.A.* **45**, 4522*d*.

The adsorption of water vapor by ZnO was measured by a const.-vol. method, and adsorption velocity and adsorption isotherms at the temps. ranging from 200° to 350°C were observed. The chem. adsorption was fairly rapid and reversible below 200°C. The max. values of the adsorption were obtained at about 200°C. The surface area of ZnO was calcd. from these values by use of the lattice consts. of ZnO crystal. The surface area thus obtained agreed well with that obtained from the phys. adsorption of benzene vapor.

1508. Ordonneau, Jacques. **Hygroscopicity of salts. Potassium chloride.** *Ann. Mines* **139**, 35-63 (1950).--*C.A.* **44**, 6587*b*.

The wt of H_2O absorbed was proportional to time and surface, although the method of prepn. of the KCl, e.g. cryst. ground, or fused, had some effect. Various coating materials applied from water and nonaq. solvents were found to reduce water absorption. Paraffin waxes and high-boiling petroleum fractions (350°C) were particularly effective. The caking tendency was detd. by forming test bars from 100 g KCl and 25 ml satd. KCl soln. plus the coating material or other additive, drying at 80°, and measuring the breaking strength.

1509. Pahl, M.; Hiby, J.; Smits, F., and Gentner, W. **Mass spectrographic determination of argon in potassium salts.** *Z. Naturforsch.* **5a**, 404-5 (1950).--*C.A.* **45**, 1924*c*.

The geol. age of K salt deposits is derived from measurement of the A^{40} content. The abs. amt. of A is measured, and the ratio of A^{40}, formed by the decay of K^{40}, to A^{36} is measured to correct for atm. contamination.

1510. Pashley, D. W. **Oriented growth of silver in silver halide crystallites.** *Acta Cryst.* **3**, 163-4 (1950) Fundamental Mechanisms of Photo. Sensitivity **1951**, 39-45.--*C.A.* **44**, 6696*b*.

Completely oriented layers of AgBr and AgCl were found to change gradually to Ag until only a very small amt. of the halide remained. The Ag from AgCl at first grew parallel to the AgCl crystal and later developed twinning about the (111) axes. The Ag from AgBr showed similar behavior at first but later developed other orientations.

1511. Podgurski, H. H.; Kummer, J. T.; DeWitt, T. W., and Emmett, P. H. **Preparation, stability, and adsorptive properties of the carbides of iron.** *J. Am. Chem. Soc.* **72**, 5382-8 (1950).—*C.A.* **45**, 2835*e*.

A hexagonal form of Fe_2C can be produced by carefully carbiding an Fe synthetic NH_3 catalyst at about 215°C with CO. This carbide appears to be stabilized by the presence of Cu. The formation of carbide appeared to take place through nuclei, as evidenced by the fact that there is still considerable free Fe on the surface of the sample after most of the Fe has been converted to Fe_2C. The completely carbided sample does not chemisorb appreciable amts. of CO at either 100 or 200°C. It does, however, still adsorb a considerable amt. of H_2 at 100°C. Even a small amt. of carbide formation eliminates completely the chemisorption of H_2 at -78° to 0°C.

1512. Preston, J. S. **Constitution and mechanism of the selenium rectifier photocell.** *Proc. Roy. Soc.* (London) **A202**, 449-66 (1950).—*C.A.* **45**, 5045*e*.

Expts. were made to elucidate the structure of the Se rectifier photocell, especially that of the thin surface film. A technique was described for sputtering films of Cd oxide which, though transparent in the thickness required for a cell, have an elec. cond. exceeding that of graphite. The thickness of the films can be closely controlled. With such films, on pure cryst. Se, cells were produced with white-light sensitivities of over 700 microamp. per lumen. Expts. with single films of Au, and double films of Zn oxide and Au, illustrated the behavior of these, in intimate contact with Se. The metal-Se contact yielded a poor photocell.

1513. Reiss, Howard. **Time lag in the nucleation of supercooled water clouds by silver iodide smokes.** *J. Chem. Phys.* **18**, 529-33 (1950).—*C.A.* **44**, 9211*f*.

A mechanism was proposed by means of which the time lag in phase transitions initiated by foreign bodies may be calcd. The half-lives of AgI particles in supercooled water clouds were calcd. There was extremely sharp dependence on both radius and temp. The decrease from 253° to 248°C transformed the half-life of particles of radius 0.8×10^{-6} cm from what was almost an infinity to a virtual zero. This meant that a fraction of a degree change in this interval, transformed the AgI particle from essentially a non-nucleus to a nucleus. At 253°C increasing the radius from 0.8×10^{-6} cm to 10^{-6} cm also reduced the half-life from an infinity to zero.

1514. Schulz, L. G. **Polymorphism of cesium and thallium halides.** *J. Chem. Phys.* **18**, 996 (1950) Acta Cryst. **4**, 487-9 (1951).—*C.A.* **44**, 7612*f*.

Salts having the CsCl-type structure (CsCl, CsBr, CsI, TlCl, TlBr, TlI) were deposited by evapn. onto cleavage surfaces of mica, LiF, NaCl, KBr, CI, and CaCO. Electron-diffraction examn. showed that the crystals touching the substrate often had the NaCl-type structure (CsCl and CsBr on all, TlI only on LiF). Lattice parameters, a_0, for the new structures of the above salts, in order, were: 6.94, 7.23, 7.66, 6.30, 6.58, and 6.94 A.; the interat. distances were lower than in the CsCl-type structure by 0.09 to 0.17 A.

1515. Seitz, Frederick. **Influence of plastic flow on the electrical and photographic properties of the alkali halide crystals.** *Phys. Rev.* **80**, 239-43 (1950).—*C.A.* **45**, 411*i*.

The effect of plastic flow on the ionic cond. and darkenability of the alkali halides is discussed on the assumption that vacant lattice sites are generated during lattice flow and subsequently condense to form clusters. These assumptions lead to a reasonable interpretation of the available expts.

1516. Selwood, P. W.; Ellis, Marylinn, and Davis, Charles F. Jr. **The disperse structure of paramagnetic oxides and hydroxides.** *J. Am. Chem. Soc.* **72**, 3549-57 (1950).—*C.A.* **45**, 1828*h*.

Paramagnetic oxides of the transition-group elements may exist in either a gel-like disperse state or in a cryst., massive state. The magnetic properties of the disperse state differed greatly from those of the massive state. The magnetic moments derived from the several chromia gels were consistent with the spin-only formulas for Cr^{3+}. Slow isobaral dehydration results in a moderate decrease of attenuation, accompanied in some cases by a moderate increased in surface area. But at the glow point the area and susceptibility both decreased precipitously as the x-ray pattern developed.

1517. Smits, F. and Gentner, W. **Argon determinations in tertiary potassium salts.** *Geochim. et Cosmochim. Acta* **1**, 22-7 (1950) (in German).—*C.A.* **45**, 5083*b*.

The direct detn. of A from Tertiary (Oligocene) sylvite of Buggingen (Upper Rhine) was important for the calcn. of the K:A ratio and of the abs. age. In air, the ratio A^{40} to A^{36} was 296:1, and A^{36}: $A^{38} = 5.4$; from the deviations of the observed isotope ratio the contamination was measurable. The He content of the A was less than 0.05 mm^3/100 g salt, in contrast with the considerably higher contents previously detd. The A evolved from sylvite varied from 3.4 to 7.1 mm^3/100 g K; the coarsely cryst. sylvite layer which was richest in A was situated between layers with a markedly lower A content; evidently A was lost from these, either by diffusion, or by geol. processes.

1518. Stone, T. S. and Tiley, T. F. **Reactions on the surface of copper oxide. II. Surface processes and heats of adsorption.** *Disc. Faraday Soc.* **1950**, No. 8, 254-8.

The heat of adsorption of O_2 was 54, of CO 20, and of CO_2 23 kcal/mol. The adsorption of CO between 20-200°C reduced the conductivity due to adsorbed oxygen, probably by the formation of a CO_3 complex. At the higher temperature the formation of CO_2 was a three-stage process.

1519. Taylor, H. F. W. **Hydrated calcium silicates. I. Compound formation at ordinary temperatures.** *J. Chem. Soc.* **1950**, 3682-90.—*C.A.* **45**, 3569*g*.

Ca silicate hydrate was prepd. by action of H_2O on tricalcium silicate, double decompn. of $Ca(NO_3)_2$ and Na silicate, and from $Ca(OH)_2$-silica gel reaction. Compn. varied from $CaO.SiO_2$ aq. to $3CaO.2SiO_2$ aq. without change in x-ray pattern.

1520. Tseft, A. L. and Salibaev, T. O. **The effect of ore components on the kinetics of the dissociation of sodium sulfate and carbonate.** *Zhur. Priklad. Khim.* **23**, 1047-50 (1950); *J. Applied Chem. U.S.S.R.* **23**, 1113-16 (Engl. translation).—*C.A.* **46**, 7857*h*.

Na_2SO_4 and Na_2CO_3, either alone or in the presence of SiO_2, Al_2O_3, Fe_2O_3, or V_2O_5, were heated in a Pt boat in a tube furnace at 10° per min. with air passing over at the rate of 1 liter per hr. The beginning of dissocn. was detd. by means of adsorption flasks. Dissocn. of Na_2SO_4 began at 1070°C, in presence of Al_2O_3 1045°, Fe_2O_3 1045°, SiO_2 1030°, V_2O_5 740°. Dissocn. of Na_2CO_3 in the presence of Al_2O_3 began at 670°, Fe_2O_3 670°, SiO_2 560°, V_2O_5 450°C.

1521. Vedeneeva, N. E. **Luminescence of clay minerals as an indication of their secondary structure.** *Kolloid. Zhur.* **12**, 88-94 (1950).—*C.A.* **44**, 5711*b*.

Halloysite, chrysotil, silica gel, and permutite luminesced in long-wave ultraviolet. The luminescence disappeared after heating to 250°, 150°, 150°, 300°C, resp. The intensity of emitted light generally decreased from 405 to 560 mμ, but there was indication of broad luminescence bands different for different minerals. The luminescence of fibers stained with eosin was similar. Plate-shaped crystals of montmorillonite were colored by benzidine and did not fluoresce, while its needle-shaped crystals fluoresced and took up benzidine.

1522. Wieninger, Lepold and Adler, Norbert. **Formation of microcrystals on crystal surfaces exposed to polonium α-rays.** *Acta Phys. Austriaca* 4, 81-4 (1950).—*C.A.* 45, 4110*i*.

Crystals of $NaNO_3$ could be identified on exposed rock salt surfaces. Apparently NO_2, produced from atm. N_2 by the α-rays, and a little moisture were responsible, as the same crystals were found on salt exposed to moist NO_2. Similarly, irradiated KCl crystals formed anisotropic KNO_3 microcrystals which could be identified by their crystal form and m.p., and also small isotropic triangular pyramids of m.p. > 500°.

1523. Yagi, Hisao. **Photoconduction of alkali halide crystals which adsorb dyes.** *Mem. Coll. Sci., Univ. Kyoto Ser.* **A**, **26**, 75-84 (1950).—*C.A.* **47**, 6770*i*.

Dicyanine-A, kryptocyanine, and phenosafranine dyes were adsorbed by means of vacuum sublimation to a thickness of one micron on artificial single crystals of rock salt. The adsorption spectra of these dyes in water, MeOH and adsorbed on rock-salt crystals were measured by using a grating monochromator and a Mazda PG-65-G photocell in connection with an amplifier. Observations of the photoelec. effect in rock-salt crystals revealed a difference of energy between the ground state and *F*-centers of 4.9-4.4 e.v. in agreement with previous measurements. Crystals upon which these dyes were absorbed became photosensitive at 1.8 e.v., while the pure crystal was photosensitive at 9 e.v. and one contg. *F*-centers at 2.7 e.v.

1524. Zhuravlev, V. F. and Zhitomirskaya, V. I. **Binding properties of crystal hydrates of the sulfate type.** *J. Applied Chem. U.S.S.R.* **23**, 115-19 (1950) (Engl. translation); *Zhur. Priklad. Khim.* **23**, 113-17.—*C.A.* **45**, 3141c.

The dehydration of $MgSO_4$ was studied with thermal analysis by use of the Kurnakov pyrometer; dissocn. began above 900°C. Binding tests on powd. partially dehydrated $MgSO_4$ showed it commenced to set in 3 min. and setting was complete in 6 min. After storage in air for one year, samples retained hardness, strength, and color.

1525. Amelinckx, S. **An interferometric study of cleavage surfaces of artificially grown crystals of sodium chloride.** *Phil. Mag.* **42**, 324-7 (1951).—*C.A.* **46**, 1328*i*.

Cleavage surfaces of an artificially grown crystal of NaCl were examd. by multiple-beam interferometry. Two main features were noted, namely long, narrow, more or less parallel strips, and superposed on this a secondary fine-grain structure. Ag films on NaCl were unstable and apparently photosensitive. Main and secondary cleavage structures were revealed and discussed in terms of crystal blocks.

1526. Anous, M. M. T.; Bradley, R. S., and Colvin, J. **The rate of dehydration of chrome alum.** *J. Chem. Soc.* **1951**, 3348-54;—*C.A.* **46**, 3837*b*.

The rate of dehydration *in vacuo* of large crystals of chrome alum of mass about 1 g was studied at thermostate temps. of 15-35°C. The activation energy was about 23 kcals. per mole, and the kinetics of dehydration agreed roughly with the Polanyi-Wigner expression. The dehydration was also studied at -1.7 to -12°C, at which temps. self-cooling was negligible. At the low temp. the activation energy was about 30 kcal. per mole.

1527. Arizumi, Tetsuya and Narita, Shin-ichiro. **Activation of the oxide-coated cathode.** *J. Phys. Soc. Japan* **6**, 15-20 (1951) (in English).—*C.A.* **45**, 5511*d*.

A Ni cathode activated with BaO was studied. The surface was poisoned by momentary exposure to O_2 and the recovery of activity was measured. The diffusion energy of free Ba atoms was estd. to be 0.75 e.v. A cathode exposed to O_2 for a relatively long time (not given) recovered its activity linearly with time at low temp. The activation energy for transferring a Ba atom from the normal lattice site to an impurity center was 3.9 e.v. Exposure of the cathode to O_2 for 30 min. increased greatly the work function.

1528. Aurelio, Burdese. **Adsorption of water vapor by magnesium oxide.** *Atti accad. sci. Torino. Classe sci. fis. mat. e nat.* **86**, 107-12 (1951-52).—*C.A.* **47**, 3079*g*.

The adsorption of water vapor by MgO was studied at 20°C. The behavior of the adsorption isotherms can be referred to type IV of Brunauer's classification.

1529. Barrer, R. M. and Grove, D. M. **Flow of gases and vapors in a porous medium and its bearing on adsorption problems. I. Steady state of flow.** *Trans. Faraday Soc.* **47**, 826-37 (1951).—*C.A.* **46**, 1818*d*.

The flow of He, Ne, A, Kr, H_2, O_2, N_2, NH_3, CCl_4, and SO_2 through a bed of small nearly spherical synthetic analcite crystals was studied. Flow rates, permeabilities, Knudsen and Poiseuille contributions to permeability, and permeability consts. were detd. and significant deviations were observed, especially for vapors.

1530. Barrer, R. M. and Grove, D. M. **Flow of gases and vapors in a porous medium and its bearing on adsorption problems. II. Transient flow.** *Trans. Faraday Soc.* **47**, 837-44 (1951).—*C.A.* **46**, 1818*d*.

By measuring the time-lag in setting up the steady state of flow, the diffusion coeffs. of gases in porous media could be detd. and a mean pore radius and an internal surface obtained of the porous medium independently of all steady state methods. In the beds of analcite crystals the inert gases, permanent gases, and CCl_4 behaved as though they were not adsorbed appreciably at low pressures, while NH_3 and SO_2 showed strong adsorption effects. The lifetimes (τ) in the adsorbed states were: NH_3 $\tau = 3.1 \times 10^{-11}$ exp (4300/RT) sec; SO_2 $\tau = 6.6 \times 10^{-11}$ exp (3010/RT) sec.

1531. BAYLEY, S. T. **Dielectric properties of adsorbed water layers on inorganic crystals.** *Trans. Faraday Soc.* **47**, 518-22 (1951).—*C.A.* **45**, 9953*g*.

Small amts., probably unimol. layers, of adsorbed water gave rise to sharp peaks at about -30° in the temp. variation of dielec. const. and power factor of powd. crystals of inorg. salts. The effect, not confined to H-bonded materials, was found in $NaHCO_3$, $NaHSO_4$, Na_2SO_4, NaCl, $KHCO_3$, $KHSO_4$, NH_4Cl, and $(NH_4)_2SO_4$. The observations were made *in vacuo* at a frequency of 3000 cycles/sec with a Schering bridge.

1532. BLANCHIN, LOUIS; IMELIK, BORIS, AND PRETTRE, MARCEL. **Modification of the texture and structure of gibbsite during dehydration.** *Compt. rend.* **233**, 1029-31 (1951).--*C.A.* **46**, 7395*f*.

The detn. of the equil. at each stage of the dehydration was made at each temp. The decompn. was arrested in an interval of 100 degrees, when the solid attained the approximate compn. $2Al_2O_3.H_2O$. This single phase had the boehmite structure.

1533. BLANCHIN, LOUIS; IMELIK, BORIS, AND PRETTRE, MARCEL. **Modifications of texture and structure of a boehmite gel during dehydration.** *Compt. rend.* **233**, 1106-8 (1951).--*C.A.* **46**, 7395*h*.

Boehmite gel was prepd. by treating a soln. of Na aluminate with warm acid. By thermo-gravimetry at pressures of 0.001 mm and 750 mm, it was found that the compn. after removal of adsorbed water was $2Al_2O_3.3H_2O$, which contained more water than boehmite but had the same x-ray pattern. The dehydration proper was complete at 400 or 500°C and the porous structure was maintained to the end of the dehydration.

1534. BÖHM, WOLFGANG. **Colloids and color centers in additively colored rock salt.** *Österr. Akad. Wiss., Math.-naturw. Kl. Sitzber. Abt. IIa* **160**, 70-97 (1951).—*C.A.* **47**, 3084*b*.

The reversible coloring of rock salt between yellow and violet-blue by suitable thermal treatment in the presence of Na, is paralleled by a transition of Na atoms between color centers and colloids. The no. of Na atoms involved in color centers and in formation of colloids remains const. during the color change; i.e. there is quant. passage of Na from centers into colloids.

1535. BOSE, BENOY B. AND KHUNDKAR, M. H. **Dehydration of dihydrates of bivalent iron, nickel, cobalt, and manganese chlorides.** *J. Indian Chem. Soc., Ind. & News Ed.* **14**, 45-9 (1951).—*C.A.* **46**, 4943*h*.

Attempts were made to obtain anhyd. $FeCl_2$, $NiCl_2$, $CoCl_2$, and $MnCl_2$ from the dihydrates by heating in air and in HCl vapor. In the first method there was a tendency toward hydrolysis, decreasing in the order in which the compds. were listed. The second method was successful in all cases. The min. temps. for complete dehydration over a 4-hr period were 150-175°C.

1536. BOSE, BENOY B. AND KHUNDKAR, M. H. **Dehydration of magnesium chloride hexahydrate.** *J. Indian Chem. Soc., Ind. & News Ed.* **14**, 171-4 (1951).--*C.A.* **46**, 8561*c*.

Loss of HCl was not observed during the release of the first three mols. of H_2O, but it occurred later. A slow stream of HCl vapor checked the hydrolysis entirely, and complete dehydration was obtained at 250°C.

1537. BOWDEN, F. P. AND THROSSELL, W. R. **Adsorption of water vapor on solid surfaces.** *Nature* **167**, 1038 (1951).--*C.A.* **45**, 9334*c*.

If clean metal surfaces are washed with tap water and dried, there is a large increase in wt when they are exposed to water vapor well below its satn. pressure. With surfaces that have been cleaned by heating in vacuo, this is not observed. The adsorption, however, is appreciable and is measurable by direct weighing and by the use of polarized light.

1538. BRADLEY, R. S. **Rate of growth of nuclei in dehydration of hydrates.** *Trans. Faraday Soc.* **47**, 630-3 (1951).--*C.A.* **45**, 10017*c*.

The relatively slow rate of growth of small nuclei formed on the surface of hydrates in vacuo may be due to the effect of the dehydrated phase on the activation energy necessary for the escape of water mols. The nuclei are assumed to be hemispheres on the surface of the crystal, and a theoretical treatment shows that log(da/dt), where a is the radius of a nucleus, is a linear function of $1/a$.

1539. BURSTEIN, E.; OBERLY, J. J.; HENVIS, B. W., AND DAVISSON, J. W. **The distribution of impurities in alkali halides.** *Phys. Rev.* **81**, 459-60 (1951).—*C.A.* **45**, 3713*b*.

The formation if impurity aggregates in NaCl crystals contg. Pb^{++} is shown from optical data. Transmission curves are given for NaCl with 0.0005-0.01% Pb, for KCl with 0.01% Pb, and for crystals heat-treated at 100°, 200°, and 750°C.

1540. CHEMLA, MARIUS. **Diffusion of phosphorus^{32} and sulfur^{35} in sodium chloride.** *Compt. rend.* **232**, 1553-5 (1951).—*C.A.* **45**, 8314*i*.

The diffusion of the products of the reactions $Cl^{35}(n,p)S^{35}$ and $Cl^{35}(n,\alpha)P^{32}$ was observed in NaCl heated to 660°C during 4 or 7 hrs. Monocryst. NaCl plates ($0.25 \times 1.2 \times 1.2$ cm) were cut by a biologist's microtome to various depths after irradiation and subsequent heating. The activity of the powder removed by the microtome at each depth was measured, and curves were drawn for the ratios (sample activity)/(activity of unheated crystal) *vs.* depth. Each curve had a max. at the crystal center and sharp rises near each face.

1541. CLUSIUS, KLAUS AND MEYER, HORST. **Formation of precipitates from gas currents by thermal diffusion.** *Z. Naturforsch.* **6a**, 401-2 (1951).—*C.A.* **46**, 6898*g*.

The pptn. of NaCl on a cold surface from an aerosol prepd. by vaporizing NaCl in a H_2 flame is uniform at pressures near atm. Below 100 mm the deposit takes the form of 2 unrolling whirls. Since the velocity of convection is proportional to the pressure, convection prevents the formation of whirls at high pressures.

1542. Colombani, Antoine and Ranc, Gaston. **Crystallization of very thin layers of gold.** *Compt. rend.* **232**, 1344-6 (1951).—*C.A.* **46**, 2868*h*.

Thin layers of Au were deposited by thermal evapn. *in vacuo*. Rate of crystn. of the layers was studied by change of resistance with time. Films deposited on amorphous Plexiglas showed spontaneous crystn. only if they were thicker than 50 A. The corresponding min. thickness for spontaneous crystn. was 35 A., for films deposited on NaCl.

1543. Colombani, Antoine and Ranc, Gaston. **Effect of the support on crystallization of very thin gold films.** *Compt. rend.* **233**, 46-8 (1951).—*C.A.* **46**, 2868*g*.

Au films were crystd. on KCl, KBr, $NaNO_3$, NaCl, Rhodoid, Plexiglas, and glass. The thickness at which crystal development began was always lower on oriented bases than on amorphous ones. At equal thicknesses the resistivity was always lower on cubic (NaCl) or rhombohedral ($NaNO_3$) than on the amorphous materials, and was comparable for all crystal bases.

1544. Ehrenberg, W. and Hirsch, J. **The conductivity-temperature characteristics of lead sulfide. The influence of oxygen and of the rate of heating.** *Proc. Phys. Soc.* (London) **64B**, 700-6 (1951).—*C.A.* **46**, 9963*h*.

Tests made on PbS films in O_2 led to conclusions about the stages of oxidation. To obtain a high rate of heating, the semicond. was deposited as a narrow strip on one side of a thin mica lamella next to a Pt strip (Pt thermometer) whose resistance as a function of temp. was known. The back of the mica lamella was platinized (heater). The range between 100° and 600°K could be covered in slightly more than 0.1 sec.

1545. Forestier, Hubert and Maurer, J. **Effect of adsorbed gas on the fusion temperature of crystals.** *Compt. rend.* **232**, 1664-6 (1951).—*C.A.* **45**, 7402*e*.

The solid was pulverized, degassed slightly below the m.p. in vacuo, the gas was introduced, and after a short interval to allow adsorption to occur the m.p. was detd. For high-melting solids such as LiCl the amt. of gas adsorbed was so small that no effect can be detected. The m.p. of KNO_3, Pb, Bi, and Sn, in He, H_2, Ne, A, CO_2 and N_2 were given.

1546. Frost, G. B.; Moon, K. A., and Tompkins, E. H. **The role of amorphous intermediate products in the dehydration of certain hydrated salts.** *Can. J. Chem.* **29**, 604-32 (1951).—*C.A.* **45**, 8868*f*.

$CuSO_4.5H_2O$ and $ZnSO_4.7H_2O$ were dehydrated at 0.8 mm Hg and at several temps., and some time after admitting dry air heat evolution was observed. X-ray pictures taken before and after the heat evolution confirmed the transformation from amorphous to cryst. material. No heat effect was observed when the dehydration pressure was 1.85 mm Hg. No heat effect was observed with $MnSO_4.4H_2O$ and $FeSO_4.7H_2O$ and a slight but reproducible heat effect with $CoCl_2.6H_2O$. $CuSO_4.5H_2O$ and $ZnSO_4.6H_2O$ were dehydrated at a series of water vapor pressures between 0.02 and 2.21 mm Hg, and the heat of soln. in water and the x-ray diagram of the products was detd. The products of the dehydration of $CuSO_4.5H_2O$ probably contained only the pentahydrate and the cryst. and amorphous monohydrate.

1547. Fuller, A. A. **Epitaxis of rubidium iodide on a barium stearate substrate deposited on mica.** *Nature* **168**, 471 (1951).—*C.A.* **46**, 2868*d*.

RbI crystd. from aq. solns. on glass or on Ba stearate layers on glass forms cubic crystals, whereas on mica the crystal outline is mostly an equilateral triangle with sides parallel to the traces of the (010), (110), and $(1\bar{1}0)$ planes of mica; the (111) plane of RbI being parallel to the (001) plane of mica. If the crystn. is effected on Ba stearate layers deposited on mica, the proportion of unoriented cubic crystals increases with the thickness of the Ba stearate layer.

1548. Gallo, G. and Del Guerra, M. **The reaction of hydrogen with metallic oxides and sulfides.** *Ann. Chim. (Rome)* **41**, 51-60 (1951).—*C.A.* **45**, 8395*e*.

The oxides and sulfides of the following metals were treated with H_2. The temp. at which initial reduction of oxides with H_2 was observed: Co: 80°, Ni: 95°, Cd: 95°, Cu: 102°, Bi: 150°, Pb: 160°, Sn: 175°, Fe: 180°, Mn: 260°, Zn: 340°. In general the affinity of these metals for S was greater than for O_2.

1549. Gregg, S. J. and Sing, K. S. W. **The effect of heat-treatment on the surface properties of gibbsite. I. Adsorption isotherms of nitrogen and oxygen at -182.7°.** *J. Phys. & Colloid Chem.* **55**, 592-7 (1951).—*C.A.* **45**, 6005*g*.

The surface activity of gibbsite increased sharply with increasing temp. of heat-treatment up to approximately 410°C. Samples treated at higher temps. showed a decrease in activity. Gibbsite treated above 1000°C exhibited negligible N_2 adsorption. The O_2 isotherms that extended to relative pressures close to unity exhibited hysteresis loops at the high-pressure end.

1550. Gregg, S. J. and Sing, K. S. W. **The effect of heat-treatment on the surface properties of gibbsite. II. Isotherms of carbon tetrachloride vapor at 25°A.** *J. Phys. & Colloid Chem.* **55**, 597-604 (1951).—*C.A.* **45**, 6005*h*.

The CCl_4 isotherms on successive samples prepd. by heating portions of gibbsite at temps. between 300 and 1000°C fall into 2 classes corresponding to the ranges 300-450°C and 480-1000°C. The main distinction between the two is the presence of an addnl. point of inflection in the latter case and a much greater length of the steep portion of the desorption branch. All isotherms exhibited permanent hysteresis loops.

1551. Gregg, S. J. and Willing, E. G. J. **The dehydration of gypsum. I. A study of the thermal decomposition of gypsum by the adsorption of oxygen and nitrogen at -183°.** *J. Chem. Soc.* **1951**, 2373-7.—*C.A.* **46**, 370*i*.

The surface area of gypsum dehydrated at a succession of temps. between 100° and 700°C was detd. by adsorption of N_2 and O_2. Maximum areas were found in samples which have been heated to approx. 180° and 280°C. In the region 150° to 350°C the area calcd. from O_2 adsorption was significantly greater than that calcd. from N_2 adsorption. Above 400°C the O_2 and N_2 areas agreed closely.

1552. Gregg, S. J. and Willing, E. G. J. **The dehydration of gypsum. II. A study of the thermal dehydration of gypsum by means of adsorption of carbon tetrachloride vapor at 25°.** *J. Chem. Soc.* **1951**, 2378-80.—*C.A.* **46**, 371*a*.

The adsorption isotherms are of the B.E.T. type II, with a small value of the parameter *c*, so that the surface area cannot be detd. by the usual B.E.T. procedure. Since, however, all the isotherms can be superposed by adjustment of the adsorption ordinates, the relative area values can be obtained from adsorption at a given pressure. These are consistently less than the previously obtained values, on account of the larger CCl_4 mol.

1553. Gregg, S. J. and Willing, E. G. J. **Dehydration of gypsum. III. Dehydration and rehydration of gypsum by adsorption methods. IV. Heat of immersion, heat of hydration, specific gravity, sedimentation volume, and bulk density of the dehydration products.** *J. Chem. Soc.* **1951**, 2916-20, 2921-4.—*C.A.* **46**, 2872i.

Samples of gypsum were dehydrated between 110 and 700°C, and the surface area of the product was estd. by CCl_4 adsorption, both before and after detg. the water adsorption isotherm at 25°. The surface area generally diminished by the H_2O treatment. The maxima found in the surface area-temp. curves at 180-190° and 300°C originate in the reactions: gypsum → hemihydrate + water, and hemihydrate → anhydrite + water.

1554. Haul, R. A. W.; Stein, L. H., and Louw, J. D. **Exchange of carbon^{13} dioxide between solid carbonates and gaseous carbon dioxide.** *Nature* **167**, 241-2, 727 (1951).—*C.A.* **45**, 7855*e*.

Exchange of C^{13} dioxide was measured over dolomite and calcite under pressure of 400 mm CO_2 at 700°C. Exchange occurred in the surface layer, as indicated by decreasing content of C^{13} dioxide in the CO_2 with successive decompn. of the dolomite after initial exchange. The result could be explained by the hypothesis that dolomite decompd. to CaO and MgO followed by the reaction of CaO to $CaCO_3$.

1555. Hayashi, Toyozo and Satō, Shigeo. **Dehydrating properties of gypsum.** *Gypsum* **1**, 137-41 (1951) (English summary).—*C.A.* **46**, 10574*h*.

The dehydration velocity of 6 samples of com. gypsum (differing in microscopic cryst. structures) in an elec. furnace (a) kept at 150°C or (b) heated up to 300°C at 1°/min. was plotted against the temps. of the samples. From the curves, 3 samples formed 1 group calcined at lower temps., the rest another calcined at higher temps. Those having finer cryst. structures tended to be calcined more rapidly. The dehydrating properties, besides the chem. purity, distinguished the quality of gypsum samples.

1556. Hüttig, G. F.; Theimer, O., and Mehlo, W. **The theory of adsorption. III. The isotherms of the barium sulfate-water system and their evaluation.** *Kolloid-Z.* **121**, 50-4 (1951).—*C.A.* **45**, 8319*i*.

Adsorption isotherms are measured at 0°, 10°, 20°C for the system water vapor/$BaSO_4$ in the pressure range of 0.025 mm up to the vapor pressures of water (4.58 mm, 9.21 mm, 17.64 mm). No disturbing effects are observed. The differential heats of adsorption were calcd. and found to be about 14,400 cal at small surface coverings and to approach slowly, with increasing d. of the adsorbate, the molar latent heat of evapn. of water (10,630 cal). The exptl. isotherm is in fairly good agreement with the B.E.T. theory.

1557. Kane, Evan O. **Optical absorption of barium oxide with excess barium.** *J. Applied Phys.* **22**, 1214-15 (1951).—*C.A.* **46**, 1867*b*.

Small crystals of BaO grown from soln. in molten Ba are deep red in color. The absorption may be due to interstitial Ba atoms or to O_2 vacancies.

1558. Kitchener, J. A. and Ignatowicz, S. **Reduction equilibria of zinc oxide and zinc silicate with hydrogen.** *Trans. Faraday Soc.* **47**, 1278-86 (1951).—*C.A.* **46**, 6472f.

A known vol. of H_2, dild. with N_2, was passed through a bed of Zn_2SiO_4 or ZnO. The quantity of Zn vapor carried off by the gases drawn through a sampling capillary tube from the center of the bed was detd. The partial pressure of H_2 in the ingoing gas detd. the compn. of the equil. mixt. in the bed according to reactions: $Zn_2SiO_4(s) + 2H_2(g) \rightleftarrows 2Zn(g) + 2H_2O(g) + SiO_2$; $ZnO(s) + H_2(g) = Zn(g) + H_2O(g)$.

1559. Lawson, W. D. **A method of growing single crystals of lead telluride and lead selenide.** *J. Applied Phys.* **22**, 1444-7 (1951).—*C.A.* **46**, 4305*g*.

Single crystals measuring up to 1 1/4 cm diam. and 6 cm long were grown in sealed SiO_2 crucibles. Extreme purity of the materials and cleanliness of the crucible were essential. Attempts to introduce excess of one of the constituents, Pb or Te, into the crystal lattice during growth were not successful so far.

1560. Macaulay, James M. **Adsorption of water vapor on solid surfaces.** *Nature* **167**, 1038 (1951).—*C.A.* **45**, 9334*b*.

A fresh, clean, mica surface in an atm. of clean unsatd. water vapor took on a measurable layer of moisture only with the greatest difficulty.

1561. Margolis, L. Ya. **Sorption of oxygen on magnesium chromite.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* **1951**, 262-7.—*C.A.* **45**, 9333*a*.

Rates of adsorption of O_2 under low pressures (up to 2 mm Hg) on $MgCr_2O_4$, at 185, 230, 260, 300, and 340°C, are given in the form of plots of the amt. adsorbed q (cc./g) as a function of the time τ (min.). Linearity of the plots of log q as a function of log τ proves the applicability of the equation $q = A\tau^{1/n}$, where $1/n = aRT$; $A = H/a\tau_0{}^{1/n}$, where H and a are consts.; $\tau_0 = 1/K_0p^3$, where K_0 = a factor of the rate const., p = pressure. The exptl. values of $1/n$ at 185, 230, and 260°, are 0.476, 0.626, and 0.680, resp. (initial pressures p_0 = 0.545, 0.575, and 0.582 mm, resp). Addn. of Na_2SiO_3 to the $MgCr_2O_4$ results in a lowering of the adsorption.

1562. Mastrangelo, S. V. R. and Aston, J. G. **Thermodynamic data and some notes on the nature of adsorbed helium.** *J. Chem. Phys.* **19**, 1370-5 (1951).—*C.A.* **46**, 2372*f*.

The adsorption isotherms and heat capacities of He on TiO_2 in the rutile cryst. form were obtained. On the basis of the observed shift in λ-point with coverage, the behavior of the adsorbed phase was correlated with the behavior of the bulk liquid and solid under pressure.

1563. Neuhaus, A. **Partial isomorphous systems. XI. Oriented crystal precipitation on activated carrier surfaces.** *Fortschr. Mineral.* **29-30**, 18-23 (1951).—*C.A.* **46**, 7838*g*.

KBr, KCl, NaBr, and NaCl were sublimed onto orthoclase at high vacuum and at temps. of 340 to 500°C. Several different oriented overgrowths were noted.

1564. Nikol'shii, G. P.; Bagdasar'yan, Z. A., and Kazarnovskii, I. A. **Ozonides of sodium, rubidium, and cesium.** *Doklady Akad. Nauk S.S.S.R.* **77**, 69-72 (1951).—*C.A.* **45**, 5554*h*.

Reaction between finely ground anhyd. NaOH (98.2%) and ozonized O_2 (8-9% O_3) at temps. between -50 and -60°C produced an intensely yellow color. Extn. with liquid NH_3 (at the same low temp.) and evapn. left a finely cryst. dark-red powder, which analyzes about 90% NaO_3, some 2-3% NaOH, and 4-6% H_2O. With RbOH (99%), at -30°C, an orange finely cryst. product was obtained contg. from 40 to 67% RbO_3, the rest RbOH (no H_2O). From CsOH (98.9%), the red-brown product obtained by the same method contained 64-7% CsO_3, the rest CsOH (no H_2O).

1565. Saito, Hirotaro. **The manganese oxide catalysts. I. The sorption velocity of oxygen by manganese sesquioxide.** *J. Chem. Soc. Japan*, Pure Chem. Sect., **72**, 262-4 (1951).—*C.A.* **46**, 812*g*.

The sorption of O_2 by Mn_2O_3 consisted of rapid surface adsorption and a slow sorption that followed. The former was instantaneous and reversible and turned into pure chemisorption above 110°C. This was due to the combination of O_2 with the surface Mn atoms that had been exposed as a result of the evapn. of O_2 caused by preliminary high-temp. evacuation.

1566. Schreiner, H. **The character of the porous condition of various sintered natural magnesites.** *Radex Rundschau* **1951**, 149-57.—*C.A.* **46**, 2767*a*.

Samples of high-Fe raw magnesite and of very pure natural Zillertal magnesite were sintered for 1 hr at 1300, 1400, 1500, 1600, and 1700°C. The sinters were crushed and sieved. Only particles finer than 100 μ were used. Porosity and bulk porosity were calcd. During sintering at 1300-1500°C porosity decreased considerably, especially in the high-Fe magnesite. At 1500-1600° porosity increased slightly, but at 1600-1700° a further decrease took place. Absorption isotherms were calcd. by using Hüttig's isotherm equation. The surface area decreased at 1300-1400°. It decreased to min. values at 1400° and 1600°C for pure and high-Fe magnesite, resp.

1567. Schreiner, H. **The influence of manner of deposition of solid powdered adsorbents on the adsorption of gas.** *Kolloid-Z.* **123**, 113-16 (1951).—*C.A.* **46**, 8928*c*.

Tests were run with electrolytic Cu powder, $BaSO_4$ and Al_2O_3 powders to adsorb MeOH vapors, 3 exptl. variations being followed: (1) loose deposition of the powder at low depth on a flat bottom, (2) deposition of the powder in a 4.8 mm glass tube in a deep layer without, however, obtaining highest possible d., (3) steady restratification of the powder during the test. Adsorption isotherms were taken for each powder with the same adjustment time of 10 min. in each case. In a layer of great depth the adsorption kinetics was detd. by diffusion of the gas to the lower strata. Even after longer time the adsorption was somewhat lower. Even a small variation in deposition, such as by weighing operation, affects the adsorption.

1568. Schulz, L. G. **Growth of alkali halide crystals from the vapor phase and from solution onto substrates of mica.** *Acta Cryst.* **4**, 483-6 (1951) (in English).—*C.A.* **46**, 4875*c*.

KF, NaCl, NaBr, KCl, NaI, KBr, KI, NH_4I, and RbI were oriented to the larger at. network in muscovite mica. LiCl with a mismatch of 30% and NaF showed a [111] fiber structure; the latter showed considerable diln. with crystals having random orientation. LiF was unique in orienting to the smaller hexagonal mica network. Crystal growth from soln. was studied by exposing the salt deposited on the mica to moist air and evapg. H_2O after returning it to the camera. The growth of salts with a_0 less than 6.5 A. supported the oriented nucleus hypothesis, whereas the growth of salts with a_0 greater than 6.5 A. supported the monolayer hypothesis.

1569. Sproull, R. L.; Dash, W. C.; Tyler, W. W., and Moore, A. R. **Growth and manipulation of barium oxide crystals.** *Rev. Sci. Instruments* **22**, 410-14 (1951).—*C.A.* **46**, 1326*b*.

Seeds of BaO crystals were placed in an enclosure of compressed BaO powder in a vacuum furnace and heated to 1400°C whereby crystals were grown from the vapor. Crystals 1 × 10 × 10 mm were grown.

1570. Stitt, Fred and Tomimatsu, Yoshio. **Sensitized paper for estimation of mercury vapor.** *Anal. Chem.* **23**, 1098-1101 (1951).—*C.A.* **45**, 10127*h*.

Impregnate filter paper with red Se by soaking it in KSeCN soln., drain, and expose to an atm. contg. HCl. The paper reacted with Hg in the air at 65°C or higher; the length of blackening was directly proportional to the concn. of Hg at 65-200°C.

1571. Stitt, Fred; Tjensvold, A. H., and Tomimatsu, Yoshio. **Rapid estimation of small amounts of ethylene in air.** *Anal. Chem.* **23**, 1138-41 (1951).—*C.A.* **46**, 63*g*.

Air and the C_2H_4 were passed over red HgO at 285°C; the Hg released was detected by Se sulfide paper at 125°C. The low practical limit was 5 p.p.m. Possible interfering substances such as EtOH, MeCHO, esters of fatty acids, geraniol, and limonene were removed by 95% H_2SO_4 pumice traps.

1572. Stone, F. S. and Tiley, P. F. **Influence of a chemisorbed film on subsequent physical adsorption processes on solids.** *Nature* **167**, 654-5 (1951).—*C.A.* **45**, 7406*f*.

The adsorption of Kr by a Cu oxide catalyst at 90°K is given as a function of pressure. Isotherms are given for a clean surface, for a surface that has absorbed CO, and for a surface contg. CO that has been converted to a CO_3-surface complex by the addn. of O_2. The curves are discussed qualitatively with reference to the B.E.T. theory.

1573. Tompkins, F. C. and Young, D. M. **Adsorption of gases on cesium iodide.** *Trans. Faraday Soc.* **47**, 77-87 (1951).—*C.A.* **45**, 6454*d*.

The adsorption of CO, N_2, A, and O_2 by CsI between 65.5 and 91.6°K was measured. Heats of adsorption were calcd. from the Clausius-Clapeyron equation and, within ± 100 cal in the range 0.2 to 0.8 coverage, they showed no definite trend with temp. Over the initial region of decreasing heat with coverage, the log p against log x plots were accurately linear for A, O_2, and N_2. The initial decrease in the heat of adsorption of A, O_2, and N_2 with coverage was attributed to the nonuniformity of the surface.

1574. Tompkins, F. C. and Young, D. M. **Adsorption of gas mixtures.** *Trans. Faraday Soc.* **47**, 88-96 (1951).—*C.A.* **45**, 6454*f*.

The adsorptions of two binary gas mixts. (N_2+ CO at 83.6°K and A+ O_2 at 77.5°K) by CsI were detd. by using a const.-vol. method. The total amts. of the two gases for each compn. originally admitted were in a fixed ratio. N_2 and CO mixts. followed a "mixed" Langmuir equation and O_2 and A followed the Freundlich equation. This was due to the much lower net heats of adsorption of O_2 and A which allowed multilayer adsorption to occur well before the monolayer was complete. In the lower-pressure range the amts. of these two gases adsorbed were smaller and deviations from the Langmuir equation due to heterogeneity were more marked.

1575. Tourneux, C. and Devin, C. **Adsorbing properties of ammonium phosphomolybdate.** *Compt. rend.* **232**, 2430-2 (1951).—*C.A.* **45**, 8846*h*.

$(NH_4)_3PO_4(MoO_3)_{12}$ adsorbed gases and vapors reproducibly and reversibly. Prepns. of smallest crystal size adsorbed 8 mols. H_2O per mol. adsorbent, those of largest crystal size adsorbed 4 mols. from humid air at 20°C. For homologous series the adsorption decreased with increasing no. of C atoms. HCOOH and AcOH were adsorbed less than were the corresponding alcs., and CO_2 and CS_2 less than was HCOOH. The primary butanols were equally adsorbed but more so than the secondary and tertiary isomers. C_6H_6 was adsorbed much more than cyclohexane and the latter a little more than hexane.

1576. Tourneux, C. and Devin, C. **Adsorbing properties of ammonium phosphomolybdate.** *Compt. rend.* **233**, 43-5 (1951).—*C.A.* **45**, 8846*i*.

The adsorbing power of prepns. differing in crystal size is not a matter of specific surface but one of homogeneity of the crystals. The small, highly adsorbing crystals are made by very rapid crystn.; the large, less adsorbing crystals are made by very slow crystn. from only slightly supersatd. soln., and their crystn. is more nearly perfect. The adsorption is intracryst., therefore a matter of voids. A peculiarity of the adsorption of most org. compds. by phosphomolybdate is a change in color from yellow to more or less deep green either during or some time after completion of adsorption. The color change indicates reduction of the Mo and oxidation of the adsorbate but there is no change in weight.

1577. Trillat, Jean J. **The conversion of silver bromide to silver.** *Compt. rend.* **233**, 1188-9 (1951).—*C.A.* **46**, 2868*f*.

Thin films of AgBr prepd. by vacuum evapn. are microcryst. when deposited on an amorphous surface (gelatin) and monocryst. when deposited on a freshly cleaved NaCl crystal (200). *Bombardment* of such films by *electrons* produces very small crystals of Ag randomly oriented.

1578. Uno, Tatsuji. **Reaction of hydrogen sulfide on calcium oxide.** *Tetsu-to-Hagane* **37**, No. 1, 14-17 (1951).--*C.A.* **46**, 2382*a*.

H_2S gas mixed with H_2 was passed over CaO at 900° to 1100°C, and the equil. const. of the reaction $CaO + H_2S = CaS + H_2O$ was detd. from the analysis of H_2S to be $\log K = \log\text{-}(P_{H_2O}/P_{H_2S}) = 3231.83/T - 0.060$.

1579. Villaseca, L. Bru and Gharpurey, K. G. **Orientation of silver on the (110) and (111) faces of rock salt.** *Anales real soc. españ. fis. y. quim.* **47A**, 101-10 (1951).—*C.A.* **45**, 7842*i*.

Ag was sublimed gently on polished faces of NaCl (111) and (110). X-ray diffraction showed that the Ag grows on NaCl faces in parallel orientation in spite of the 30% difference in lattice consts. The NaCl structure continued through the interface. Rotational slip around the (110) axis was observed.

1580. Watanabe, Yasuyoshi and Kimoto, Shizuo. **Orientation between silver and sodium chloride crystal.** *Science of Light* (Japan) **1**, No. 1, 37-41 (1951).--*C.A.* **47**, 4680*g*.

In the electron-diffraction pattern of Ag film evapd. on a cleavage surface of synthetic NaCl single crystal and exposed to moist air, the pattern was found to correspond to the NaCl crystal oriented as if the substrate NaCl crystal was rotated by $\pi/4$ about the axis normal to the surface. When NaCl was evapd. on the fresh Ag film prepd. so that its (001) plane is parallel to the surface, the (111) or (001) plane of evapd. NaCl was oriented parallel to the surface.

1581. Weaver, E. R. **Electrical measurement of water vapor with a hygroscopic film.** *Anal. Chem.* **23**, 1076-80 (1951).—*C.A.* **45**, 10136*h*.

Very sensitive films of H_2SO_4 and H_3PO_4 can be used rapidly but require calibration at the time of use. The procedure is based on the measurement of the elec. cond. of the film. The method has been used for detg. H_2O in cylinders contg. O_2, for measuring the water vapor pressure of liquids, and is applicable to detg. water in butter, soaps, lubricants, bituminous materials, and emulsions of various kinds.

1582. WEBER, HEINRICH. **Discoloration of magnesium oxide crystals by lattice materials.** *Z. Physik* **130**, 392-402 (1951).—*C.A.* **46**, 823*g*.

Heating in O_2 at about 1500°K under pressure discolors the crystals so that they show adsorption bands at 285 and 216 mμ (half widths 0.63 and 1.28 e.v.) at 293°K which are only slightly temp.-sensitive. Mg vapor also penetrates the crystals, causing them to absorb over a wide wave length region. Both discolorations disappear completely on heating the crystals in a high vacuum.

1583. WHALEY, THOMAS P. AND KLEINBERG, JACOB. **A contribution to the chemistry of the alkali metal "ozonates."** *J. Am. Chem. Soc.* **73**, 79-82 (1951).—*C.A.* **45**, 4591*i*.

O_3-treated NaOH decomp. in H_2O with evolution of O_2, but does not liberate I_2 from acidified KI soln. Ozonated KOH and CsOH also evolve O_2 upon decompn. in H_2O but liberate I_2 from acidified I^- soln. Analyses of the gross products of ozonization of NaOH and CsOH agree with the formulas NaO_3 and CsO_3 for the colored, paramagnetic materials.

1584. YOUNG, D. M. **Calculation of the adsorption behavior of argon on octahedral potassium chloride.** *Trans. Faraday Soc.* **47**, 1228-33 (1951).—*C.A.* **46**, 4318*d*.

The (111) plane of KCl was composed of equilateral triangular arrays of ions, so that an A atom might be adsorbed over 2 distinct types of array. Including adsorption above an ion, 6 adsorption sites were considered, namely, 3 including K^+ in surface and 3 including Cl^-. The potential energy of an isolated A atom as a function of distance above the (111) plane was calcd. at 6 different positions on the crystal surface, and heats of adsorption were evaluated.

1585. AIGRAIN, P. R. AND DUGAS, C. R. **Adsorption on semiconductors.** *Z. Elektrochem.* **56**, 363-6 (1952).—*C.A.* **47**, 1458*i*.

The electrostatic changes during the adsorption at surfaces of semiconductors as consequence of the exchange of electrons between adsorber and adsorbed mol. are considered. The elec. and energetic conditions are calcd. for the adsorption, if the adsorbed mols. have no chem. affinity to the adsorber. The no. of adsorbed mols. is detd. by the concn. of impurity centers. With 2% impurities only 10% of the surface is covered.

1586. BUTYAGIN, P. YU. AND ELOVICH, S. YU. **Adsorption studies of platinum-supported catalysts.** *Zhur. Fiz. Khim.* **26**, 692-700 (1952).—*C.A.* 47, 5233*e*.

Adsorption isotherms at low temp. of propylene and oxygen were obtained on the following adsorbents: $BaSO_4$, $BaSO_4$+ 5 wt % Pt, $BaSO_4$+ 8 wt % Pt. Special attention was devoted to a comparison of the isotherms obtained on $BaSO_4$ and on the other two adsorbents: Pt modified the spectrum of heats of adsorption. A new method was proposed to det. the relative surface areas of catalyst and support. The method was based on the irreversibility of the adsorption of O_2 or C_3H_6 at low temp. on Pt. The adsorption on Pt corresponded to the difference between 2 adsorption isotherms obtained with O_2, at −183°C, on the catalyst: the first one was obtained after preliminary evacuation of the catalyst at high temp. (320°); the 2nd one was obtained after pumping at −183°C.

1587. CLARKE, EDWARD N. AND FARNSWORTH, H. E. **The photoelectric work functions and low-speed electron diffraction from thin films of silver on the (100) face of a silver single crystal.** *Phys. Rev.* **85**, 484-5 (1952).—*C.A.* **46**, 5427*e*.

The lattice structure and orientation of the deposited film are the same as those of the supporting crystal. Deposition of Ag produces a decrease of work function, ψ, only if the crystal temp. is less than approx. 65°C. Deposition of doubly distd. Ag in a high vacuum may result in a more gas-free surface as detd. by electron diffraction, i.e., a Ag-crystal surface producing no diffraction beams or weak beams can be made to produce strong beams by proper deposition of Ag onto the surface.

1588. COLOMBANI, ANTOINE AND RANC, GASTON. **Copper crystallization in thin layers.** *Compt. rend.* **234**, 78-80 (1952).—*C.A.* **46**, 3359*f*.

A technique used to deposit a thin layer of Au was extended to Cu, Pb, and Bi. Results similar to those with Au were obtained, Cu being deposited on an amorphous support (Plexiglas) and on an oriented crystal of NaCl. For deposits of less than 110A. on Plexiglas the evolution of the resistivity was an increasing function of time. Above 110A. it decreased with time. The same observations were made with NaCl, but the transition point was at 65A. For the same thickness, the resistivity of the Cu layer on an oriented crystal was always inferior to one made on amorphous support.

1589. COULTER, L. V. AND CANDELA, G. A. **Adsorption of water vapor by silver iodide.** *Z. Elektrochem.* **56**, 449-52 (1952).—*C.A.* **46**, 10774*b*.

Adsorption isotherms were detd. volumetrically at 16.0°, 34.0°, and 50.0°C. Normal surface adsorption was accompanied by a phase transition which appeared to be the formation of a chem. hydrate by a surface impurity. After correcting for this effect, a type-**111** isotherm was obtained. The isosteric heat of adsorption was found to be approx. 1 kcal. less than the heat of liquefaction of water at the same temp.

1590. CRAIG, A. AND McINTOSH, R. **The preparation of sodium chloride of large specific surface.** *Can. J. Chem.* **30**, 448-53 (1952).—*C.A.* **46**, 10780*f*.

NaCl was evapd. at 750-850°C and collection of the smoke particles made in an electrostatic precipitator at 20,000 v. The prepns. had areas varying from 7.1 to 54.4 m2 per g, measured by CO_2 adsorption at −78.5°C. The areas were checked by estg. from electron micrographs. One sample having a specific area of 40 m2 by CO_2 adsorption showed a specific area of 60 m2 by N_2 adsorption.

1591. DRAIN, L. E. AND MORRISON, J. A. **Interpretation of the thermodynamic properties of adsorbed argon at low surface coverages.** *Trans. Faraday Soc.* **48**, 316-26 (1952).—*C.A.* **46**, 9931*c*.

Measurements of A adsorbed on TiO_2 (rutile) at low surface coverages could be interpreted satisfactorily on a model of localized adsorption on a heterogeneous surface without interactions. The distribution function for the energy of the adsorption sites was obtained from the heat of adsorption data and used to calc. entropies and heat capacities of the adsorbed phase. It was unlikely that a single distribution function could be used to fit the thermodynamic data for all systems, particularly at low temps.

1592. Drain, L. E. and Morrison, J. A. **Thermodynamic properties of argon adsorbed on rutile.** *Trans. Faraday Soc.* **48**, 840-7 (1952).--*C.A.* 47, 3079*e*.

The heat capacity of A adsorbed on rutile was detd. at 4 different surface coverages in the region of the monolayer over the range 13° to 95°K. Also, the integral and isosteric heats of adsorption were detd. at 85°K up to a vol. adsorbed of 4.6 V_m. Approx. 40 heat-capacity detns. were made for each of 4 surface coverages, and smoothed molar-heat-capacity values of 5° intervals were tabulated. The adsorption isotherm at 85°K was detd. with 41 points. Inflection points occurred in the integral and isosteric heats of adsorption at 85°K as a function of the vol. adsorbed.

1593. Engel, Olive G. **Model for epitaxy in metal-rock salt pairs.** *J. Chem. Phys.* **20**, 1174 (1952).—*C.A.* **46**, 10772*g*.

The ionization process on the surface consists of the steps $M - ne \rightarrow M^{n+}$ and $nS + ne \rightarrow nF$, where M is the metal in question, S is a vacant anion site on the surface which serves as an electron trap, and F is a color center. Calcns. show that the model is energetically feasible for, e.g., Ag and Pd on rock salt. For the cleavage face of rock salt, distances between deposit-metal ions and Cl ions in the substrate (which det. the bonding energy) must be as small as possible, and distances between deposit-metal ions and Na ions (which det. the antibonding energy) must be as large as possible.

1594. Ewles, J. and Heap, C. N. **Luminescence and adsorption phenomena in some oxides and halides.** *Trans. Faraday Soc.* **48**, 331-8 (1952).—*C.A.* **46**, 9990*b*.

Solids, in which the luminescence assocd. with adsorption had been removed by long heating in dry air or pure dry O_2, lose to a considerable extent their power of adsorption. Reheating *in vacuo* or in reducing gases introduced new luminescent effects and restored in appreciable measure the power of adsorption and the luminescence assocd. with it. The luminescent effects described arose in mols. adsorbed at active sites provided by anion defects in the crystal lattice of the adsorbent.

1595. Flood, H.; Førland, T., and Motzfeldt, K. **The oxygen electrode in molten salts.** *Acta Chem. Scand.* **6**, 257-69 (1952) (in English).—*C.A.* **46**, 8544*f*.

The electrode behaved as a reversible O_2-O^{2-} electrode. Na_2SO_4 and Na_2CO_3 formed an ideal soln., and the junction potential was negligible. In order to find if the electrode worked also at higher acidites, the sýstem K_2CrO_4-$K_2Cr_2O_7$ was studied in a similar cell. The observed e.m.f. was 15% lower than calcd.

1596. Garner, W. E.; Stone, F. S., and Tiley, P. F. **The reaction between carbon monoxide and oxygen on cuprous oxide at room temperature.** *Proc. Roy. Soc.* **A211**, 472-89 (1952).

The differential heat of adsorption of oxygen during the formation of the first few layers of Cu_2O on Cu were detd. A constant value of 55 kcal. was obtained after the first few layers. The adsorbed O_2 reacted with CO and CO_2, giving a CO_3 complex as an intermediate stage in the reactions. The complex was unstable in the presence of CO. The reactivity of the adsorbed O decreased with time, due to the diffusion of Cu^+ ions to the surface, which partially built the oxygen ions into the lattice. The reaction mechanism of the catalytic reaction involved CO, O_2, and CO_3 complex in the stationary state on the surface, the last two species being present in small amount.

1597. Gregg, S. J. and Sing, K. S. W. **The effect of heat-treatment on the surface properties of gibbsite. III. The chemical nature of the products formed.** *J. Phys. Chem.* **56**, 388-91 (1952).—*C.A.* **47**, 28*d*.

Samples of gibbsite were heated for 5 hrs at a succession of fixed temps. and the products examd. by x-rays and by measurements of volatile matter, sp.gr., and bulk d. Below 200°C practically no chem. change was observed. Heating between approx. 300° and 500°C resulted in a product that was a mixt. of boehmite and γ-Al_2O_3. From 500 to 1000°C the γ-Al_2O_3 of crystallite size progressively diminished with increasing temp.

1598. Gritton, H. T. S.; Gregg, S. J., and Winsor, G. W. **Calcination of dolomite. I. Kinetics of the thermal decomposition of calcite and of magnesite.** *Trans. Faraday Soc.* **48**, 63-9 (1952).—*C.A.* **46**, 6909*i*.

The kinetics were detd. *in vacuo* with an automatically recording sorption balance at 720-780°C for calcite and 540-600°C for magnesite. The decompn. was represented by $(w/w_0)^n = -kt + a$, where w/w_0 = the fraction still undecompd. at time t; k, a, and n were const. The decompn. probably occurred at an interface advancing from the outside to the interior, requiring $(1 - n) = 0.67$ in the ideal case. Deviations were due to self-cooling, to impedance in the escape of CO_2, and to a somewhat slow rate of formation of decompn. nuclei.

1599. Gritton, H. T. S.; Gregg, S. J., and Winsor, G. W. **Calcination of dolomite. II. Thermal decomposition of dolomite.** *Trans. Faraday Soc.* **48**, 70-5 (1952).—*C.A.* **46**, 6910*b*.

Four specimens of dolomite were studied *in vacuo* between 640° and 720°C. The decompn. advanced from an interface at the exterior of the sample to the interior. The initial product was a solid soln. of (Ca, Mg) O which quickly broke up into crystallites of CaO and of MgO. If the escape of CO_2 was hindered, quantities of $CaCO_3$ only would be formed behind the interface. When vacuum-decompd. dolomite was exposed to CO_2 at 800°C, the gas was rapidly taken up to an extent smaller than that corresponding to the total Ca content.

1600. Grossweiner, Leonard I. and Seifert, Ralph L. **The reaction of beryllium oxide with water vapor.** *J. Am. Chem. Soc.* **74**, 2701-4 (1952).—*C.A.* **46**, 9390*d*.

At high temps. the volatility of BeO is greatly increased by the presence of water vapor. Measurements of the effect of temp. (1199-600°C), flow rate, and partial pressure of water (76-750 mm) on the rate of volatilization of BeO indicate that the increased volatility results from the reaction $BeO(s) + H_2O(g) \rightarrow Be(OH)_2(g)$.

1601. Higuchi, Izumi and Utsugi, Hiroshi. **Capillary condensation in contact zones between nonporous particles of a powder.** *J. Chem. Phys.* **20**, 1180-1 (1952) Science Repts. Tohoku Univ. **36**, 27-36 (1952).—*C.A.* **46**, 10701*h*.

Adsorption isotherms were obtained at 0°C for EtOH on anatase (particle radius 0.05μ). The steep slope of the adsorption curve was attributed to capillary condensation in the contact zones of the particles. Formulas were derived for the vol. of the interstices corresponding to closest packing, planar close packing, and linear packing of the particles.

1602. Higuchi, Izumi and Utsugi, Hiroshi. **The differential molar entropy of adsorbate and the mobility of molecules adsorbed on a solid surface.** *Science Repts. Tohoku Univ.* **36**, 37-9 (1952).—*C.A.* **47**, 5759*i*.

The differential molar entropy of C_2H_5OH and *n*-butane at 0°C was calcd. as a function of surface coverage. Adsorptions in the initial parts of the curves for ethanol on anatase and for C_4H_{10} on glass beads and carbolac indicated that the adsorbates were essentially two-dimensional gases. In the case of butane on SiO_2 gel there was an entropy decrease. For the adsorption of EtOH on $3TiO_2.3Fe_2O_3$ gel, steep falls in the differential molar entropy at low coverage indicated partial fixing of adsorbate mol.

1603. Holm, Else. **Theory of the silicon carbide contact.** *J. Applied Phys.* **23**, 509-17 (1952).—*C.A.* **46**, 7911*e*.

Practically clean SiC possessed a superficial layer which functioned as a potential hill for the electrons. Because of its thinness the hill was penetrable for the elec. current by means of the tunnel effect. The tunnel resistance per unit area was investigated with terminal areas of the order of 2 mm^3. Being const. at small voltages, it dropped down through some orders of magnitude within the voltage range of 0.5 to 5 v. The thickness of the potential hill was of the order of 10 to 20 A.

1604. Holzman, G. R. and Moore, K. H. **Electron-diffraction study of the reorientation of certain alkali halides deposited on mica and on mica surfaces covered by organic films.** *J. Colloid Sci.* **7**, 396-406 (1952).—*C.A.* **46**, 10762*c*.

Electron diffraction patterns of NH_4I sublimed in air on mica showed a partial tetrahedral orientation that becomes complete on exposure to limited amts. of H_2O vapor. Sublimation of NH_4I on an org. film (cellulose acetate) produced no orientation, even after exposure to H_2O vapor. NH_4I sublimed in air on mica coated with films 100-200A. thick of cellulose acetate, Formvar, or chlorinated rubber showed no initial orientation, but complete tetrahedral orientation occurred on exposure to H_2O vapor.

1605. Honig, Jurgen M. **Adsorption of NO_2-N_2O_4 on rutile surfaces.** *Univ. Microfilms, Pub.* No. **4356**, 104 pp. *Dissertation Abstracts* **12**, 810-11 (1952).—*C.A.* **47**, 3079*g*.

1606. Honig, J. M. and Reyerson, L. H. **Adsorption of nitrogen, oxygen, and argon on rutile at low temperatures; applicability of the concept of surface heterogeneity.** *J. Phys. Chem.* **56**, 140-4 (1952).—*C.A.* **46**, 8458*h*.

The adsorption of N_2, O_2, and A on rutile was measured in the region of low relative pressures at temps. between 77 and 91°K. The data obeyed B.E.T. plots over the relative pressure range 0.05 to 0.3 for O_2 and A; for N_2 they fitted from the lowest relative pressures up to 0.2. N_2 was adsorbed extensively at much lower relative pressures than O_2 or A. At 77°K for $p/p_0 = 0.001$ the surface was 66% covered by N_2 but only 13 and 10% by O_2 and A, resp.

1607. Jury, Stanley H. and Licht, William Jr. **Static sorption isotherm for β-soluble anhydrite and humid air.** *Ind. Eng. Chem.* **44**, 591-4 (1952).—*C.A.* **46**, 4882*c*.

The equil. characteristics of the system β-sol. anhydrite and moist air, particularly in the low-humidity range, were studied from both the adsorption and desorption sides. Some hysteresis was observed. The effects of repeated regeneration and of varying the regeneration cycle were also studied.

1608. Kern, Raymond. **The effect of the rate of evaporation of aqueous solutions of alkali halides on the faces of crystalline precipitates.** *Compt. rend.* **234**, 970-1 (1952).—*C.A.* **46**, 9372*h*.

Crystals were obtained by evapn. from a microscope slide of glass or of Pt and observed with a microscope. Salts studied were LiF, NaF, NaCl, KCl, KBr, and KI. Slow evapn. gave only the 100 faces. A crit. rate was found above which octahedra form and were in the order given above.

1609. Kiehl, Jean Pierre. **Influence of heat of transformation of solids on the displacement of their transformation temperature by adsorbed gases.** *Compt. rend.* **234**, 943-5 (1952).—*C.A.* **46**, 10837*f*.

Transformations were studied by thermal analyses after admitting the vapors under study to the evacuated powder. Hexagonal AgI changed to cubic at 143.6°C in He, at 139.0°C in CO_2. Change of Na_2MoO_4 from γ to δ at 440° was not influenced by adsorbed gas. The heat of transformation detd. the magnitude of lowering of transformation temp. for a given gas.

1610. Lawson, W. D. **Oxygen-free single crystals of lead telluride, selenide, and sulfide.** *J. Applied Phys.* **23**, 495-6 (1952).—*C.A.* **46**, 6455*i*.

Anomalies in the type of cond. of artificially prepd. crystals of lead selenide and lead telluride were the result of the presence of O_2. A method was developed for eliminating O_2 from the specimens by melting the elements into the crucible in H_2. Single crystals of lead sulfide were grown when O_2 was eliminated from the specimen in this way.

1611. Lindner, Roland. **Diffusion of radioactive iron in iron (III) oxide and zinc-iron spinel.** *Arkiv Kemi* 4, 381-4 (1952) (in German).—*C.A.* **47**, 3072*a*.

The diffusion of Fe^{59} as an indicator into Fe_2O_3 at 930-1270°C and into Zn-Fe spinel at 750-1300°C was detd. Pressed tablets of Fe_2O_3 and the spinel were prepd., and Fe^{59} indicator applied in the contact method. The temp. function of the diffusion const. for Zn-Fe spinel was $D = 8.5 \times 10^2 \exp(-82{,}000/RT)$ cm^2/sec and for Fe_2O_3 $D = 4 \times 10^4 \exp(-112{,}000/RT)$ cm^2/sec.

1612. Lindner, Roland. **Self diffusion in lead oxide.** *Arkiv Kemi* 4, 385-8 (1952) (in German).—*C.A.* **47**, 3072*b*.

Th B (Pb^{212}) was used as an indicator in the study of the self diffusion of Pb in PbO. The indicator, prepd. in the form of a natural soln., was applied to pressed tablets of PbO and the tablets heated. The diffusion const. $D = 10^5 \exp(-66{,}000/RT)$ cm^2/sec. No difference in the value of D was found for various crystallographic directions.

1613. Lindner, Roland; Austrümdal, St., and Åkerström, A. **The kinetics in calcium oxide.** *Acta Chem. Scand.* **6**, 468-74 (1952) (in German).—*C.A.* **47**, 30*c*.

Study of the diffusion of Ca in CaO by the contact method gave the following value for the diffusion const.: $D = 0.4 \exp(-81{,}000/RT)$ cm^2 sec^{-1}. The self-diffusion consts., detd. from partial ionic mobilities, agreed fairly well with those detd. by radioactivity measurements and indicated exclusively Ca-ion diffusion in CaO.

1614. Lucas, L. N. D. **Oriented chemical growth on single crystals of zinc and cadmium.** *Proc. Roy. Soc.* (London) **215A**, 162-74 (1952).—*C.A.* **47**, 4160*h*.

The oriented chem. growths of the oxides were studied on different surfaces of single crystals of Zn and Cd and also of Cd sulfide. The orientation depended on the surface topography of the substrate which could be detd. in favorable cases. The clean surfaces of the metallic crystals used were prepd. by electrolytic methods. The inner potentials of Zn and ZnO were measured. Very thin layers of ZnO on a cleavage face of Zn did not have the pseudomorphic structure but had the normal bulk structure. ZnO grew on Zn in a parallel or pseudoparallel orientation, for all substrate surfaces used. CdO grew on Cd such that the oxide contact planes were (111) for (100), (101), and (001) Cd contact planes.

1615. Lyashenko, V. I. **Adsorption of molecules and the photoconductivity of cuprous oxide.** *Doklady Akad. Nauk S.S.S.R.* **87**, 33-5 (1952).—*C.A.* **47**, 3686*f*.

If adsorption of a mol. at the surface lowered the work function, the cond. of a pos.-type semiconductor was decreased, and that of an electronic semiconductor was increased; if the adsorption raised the work function, the cond. of a pos. semiconductor would be increased, and that of an electronic conductor decreased. Thus, adsorption of substances which did not themselves absorb light of the wave length exciting photocond., should alter the photocond. of a semiconductor. This was confirmed by oscillography of the photocond. of samples of $Cu_2O \sim 1\mu$ thick, excited by II-shaped light impulses of 3 millisec. duration, with dark pauses of 115 millisec., *in vacuo* ($\sim 10^{-4}$ mm Hg) and in the presence of vapors of Me_2CO or EtOH. All the observed effects of adsorption were completely reversible.

1616. Mitsuki, Chikara. **Dehydration of gypsum.** *J. Ceram. Assoc. Japan* **60**, 92-5 (1952).—*C.A.* **46**, 6805*a*.

After gypsum began dehydration at about 100°C, it continued even when the temp. was lowered, e.g. below 87°C. No differences were found in crystal structure and hardness between the plaster of Paris prepd. from hemihydrate by dehydration and that prepd. from anhydrite by hydration. By dehydration gypsum changed into directly sol. anhydrite.

1617. Monier, Jean C. **Regular orientation of dimethylglyoxime on different supports.** *Compt. rend.* **234**, 1185-6 (1952).—*C.A.* **46**, 8448*h*.

Dimethylglyoxime was sublimed and oriented on fresh cleavage faces of crystals placed in the vapor of dimethylglyoxime. When dimethylglyoxime was deposited on KCl, NaCl, CaF_2, $BaSO_4$ $NaNO_3$, mica, and calcite, it was oriented preponderantly about its *b* axis.

1618. Monier, Jean C. **Epitaxy of *p*-aminophenol on different supports.** *Compt. rend.* **234**, 2375-7 (1952).—*C.A.* **46**, 8448*h*.

p Aminophenol was sublimed, at atm. pressure, onto crystals of NaCl, KCl, $NaNO_3$, calcite, barite, and celestite. Although many orientations were found, crystals of p-$NH_2C_6H_4OH$ always had their 100 planes attached to the supporting crystal.

1619. Monier, Jean C. **Epitaxes of organic crystals by sublimation on blende.** *Compt. rend.* **234**, 2456-8 (1952).—*C.A.* **46**, 9922*d*.

The epitaxes of *o*-aminophenol, *p*-aminophenol, and dimethylglyoxime obtained by sublimation on blende are described. A study of twin crystal of dimethylglyoxime confirms former studies showing that the blende has a peculiar effect on this compd. not present with other compds.

1620. Mukhlenov, I. P. **Mechanism of the arsenic poisoning of vanadium catalysts in the production of sulfuric acid.** *Zhur. Priklad. Khim.* **25**, 793-6 (1952).—*C.A.* 47, 4714*i*.

The catalyst consists of an aluminosilicate and $BaSO_4$ carrier, with an alkali polyvanadate as the catalytically active substance. A side reaction, $m\text{As}_2\text{O}_5 + \text{M}_2\text{S}_2\text{O}_7 \rightleftarrows \text{M}_2\text{O}.m\text{As}_2\text{O}_5 + 2\text{SO}_3$, favors the poisoning by diminishing the amt. of solvent for the alkali polyvanadate. In the beginning of the poisoning, the main reaction proceeds rapidly, and its limiting stage is sorption. A sharp acceleration of the fall of activity occurs when all the excess alkali metal has been bound and V_2O_5 begins to crystallize. Sorption of greater amts. of As is easily reversed and results in no permanent poisoning. Only the chemically bound As poisons irreversibly. This poisoning is due to the alkali metal contents of the com. catalysts. Pure V_2O_5 is not poisoned by As.

1621. Mutô, Tokio; Fukase, Masahiko; Sekine, Eiiji, and Waku, Shigeru. **Gas evolution of artificial mica.** *Ôyô Butsuri* (J. Applied Phys.) **21**, 164-8 (1952).—*C.A.* **46**, 10854*e*.

Gas evolution and dielec. const. are measured of an artificial mica $F_2KMgAlSi_3O_{10}$ for electron tubes. The mica prepd. in a carbon-black crucible evolves more gas, which is mainly adsorbed air and some H_2S, than that prepd. in a Pt crucible.

1622. Neuhaus, A. **Nucleus formation and orientation of precipitated materials on alien crystalline surfaces.** *Z. Elektrochem.* **56**, 453-8 (1952).—*C.A.* **47**, 2564*e*.

Material in the gaseous phase was deposited on cryst. surfaces at a very slow and controllable rate. For a thickness of deposit less than 100 A. there was almost random distribution, after which a quasi-two-dimensional orientation took place. Special emphasis was given to the effect of the deposit on hardness. The orientation of alizarin on alkali halides and the lattice periodicity and the misfit of deposit and substrate plane was shown.

1623. Neven, P. and Tiggelen, A. van. **A reaction involving the quantitative absorption of hydrogen.** *Bull. soc. chim. Belges* **61**, 328-9 (1952).—*C.A.* **47**, 5291*a*.

H_2 is absorbed quantitatively by either Ag_3PO_4 or $Ag_2B_4O_7$, forming metallic Ag, and either H_3PO_4 or $H_2B_4O_7$. The activation energies are 16 kcal. for the phosphate and 17 for the borate.

1624. Pace, E. L.; Sasmor, D. J., and Heric, E. L. **Heat capacity of methane adsorbed on titanium dioxide between 55 and 90°K.** *J. Am. Chem. Soc.* **74**, 4413-15 (1952).—*C.A.* **47**, 32*e*.

A low-temp. adiabatic calorimeter was used to det. the heat capacity of CH_4 adsorbed on TiO_2 between 50 and 90°K at coverages of approx. 0.2, 0.4, 0.8, and 1.0 monolayer. The heat capacity of the adsorbed CH_4 at all coverages was greater than that of solid CH_4, and at 89°K it exceeded the value for liquid CH_4. The heat capacity-temp. curves pointed to the absence of any 1st-order phase transitions under the exptl. conditions used.

1625. Pagel, H. Armin and Oita, Itsumi Jack. **Air adsorption error in the micro-Dumas method for nitrogen.** *Anal. Chem.* **24**, 756-8 (1952).—*C.A.* **46**, 11034*b*.

Expts. are described indicating that the adsorbed air on CuO in the micro-Dumas detn. is less than 0.001 ml. High N-values are caused mainly by incomplete combustion.

1626. Papée, Denis. **Relation between the adsorption velocity and isotherms.** *Compt. rend.* **234**, 437-9 (1952).—*C.A.* **46**, 5928*b*.

Adsorption curves of water vapor on boehmite and bayerite show that the rapid attainment of equil. at a partial pressure of 0.96 in the case of boehmite is due to the isotherm turning towards the abscissa. In the case of bayerite the slow attainment of equil. is explained by the asymptotic form of the isotherm at satn.

1627. Pashley, D. W. **Oriented deposits on crystalline surfaces.** *Proc. Phys. Soc.* (London) **65A**, 33-8 (1952).—*C.A.* **46**, 10762*b*.

Layers of Ag and Th halides were evapd. onto cleavages or rock salt, KBr, MgO, and mica, and the films were studied by electron diffraction. Both high and low interat. misfits were observed between the substrate and oriented overgrowths. In AgCl on KBr a reaction occurred. ThCl crystallized in a rock-salt-type structure on KBr, but was normal on other substrates. AgCl oriented on mica with a misfit of -24%.

1628. Pashley, D. W. **Oriented chemical overgrowths and surface topography.** *Proc. Roy. Soc.* (London) **A210**, 354-76 (1952).—*C.A.* **46**, 10778*d*.

The growth of thin halide tarnish layers on silver crystals was studied. Contact planes between Ag and halide were often not parallel to the macroscopic surface. Halide orientation on Ag facets was independent of the position of those facets with respect to the macroscopic surface. The orientations depended considerably on the topography of the substrate. A small percentage misfit was not an essential condition for the appearance of oriented overgrowths.

1629. Pashley, D. W. **Orientation of silver formed during electron bombardment of silver halides.** *Acta Cryst.* **5**, 850 (1952) (in English).—*C.A.* **47**, 3107*a*.

Electron bombardment of AgBr deposited on KI cleavage faces caused growth of Ag oriented parallel to the AgBr. Thus, the substrate was not responsible for the Ag orientation. Expts. with detached AgBr or AgCl films showed some parallel oriented Ag formed. Formation of parallel oriented Ag was the effect of decompn. of AgBr or AgCl.

1630. Patterson, D. **Surface stability of alkali halide crystals.** *Trans. Faraday Soc.* **48**, 877-87 (1952).—*C.A.* **47**, 4681*a*.

The instability of the surface layer could be regarded as brought about by stretching the 2-dimensional lattice from its equil. spacing so that it fitted the substrate. The repulsive forces between ions were lowered, which, with the electrostatic forces of the substrate, maintained the regular spacing on the surface. The equil. spacing of the two-dimensional lattice was detd. using the point-charge model but including van der Waals forces and without assuming equal polarizabilities of the ions.

1631. Pickering, H. L. and Eckstrom, H. C. **Physical adsorption of gases on anatase.** *J. Am. Chem. Soc.* **74**, 4775-7 (1952).—*C.A.* **47**, 1456*h*.

Adsorption data at -195° and -183°C and for CO_2 at -78°C were detd. by the abs. method of Harkins and Jura. The calcd. mol. cross-sectional area values in general agreed poorly with those obtained from liquid adsorbate d. data. A simple relation was obtained between the B.E.T. cross-sectional area values (σ) and the Harkins and Jura const. (k) for adsorption on anatase: $k = 0.251\sigma$ (for vols. in ml at S. T. P.).

1632. Pieri, Mario. **The absorption of moisture by raw calcium cyanamide.** *Chimica* (Milan) 7, 158-60 (1952).—*C.A.* **46**, 8335*i*.

During the pulverization and ventilation (with atm. air), $CaCN_2$ absorbs about 0.75% H_2O, which is partially absorbed by CaO and CaC_2 and partially by graphitic carbon. The presence of H_2O may cause explosions, when $CaCN_2$ is stored in the silos. This danger can be avoided by using a pure CaO in the prepn. of $CaCN_2$, by ventilating with dried air, and by oiling the powder.

1633. Reynolds, S. E.; Hume, William II, and McWhirter, Max. **Effects of sunlight and ammonia on the action of silver iodide particles as sublimation nuclei.** *Bull. Am. Meteorol. Soc.* **33**, 26-31 (1952).—*C.A.* **46**, 6461*a*.

AgI smoke from a hot Pt filament produces 100 times as many ice crystals in a supercooled cloud in a lab. cold chamber at -13°C if a little NH_3 vapor is added to the cloud. An air sample contg. deactivated AgI produces large nos. of ice particles in a supercooled cloud when NH_3 vapor is added to the cloud, but if NH_3 vapor is added to the air sample before exposure to sunlight the rate of decay is increased and nucleating effects are not enhanced by adding NH_3 to the supercooled cloud.

1634. Salmanov, G. D. **Zeolitic water of hydrated calcium silicate.** *Tsement* **18**, No. 5, 16 (1952).—*C.A.* **47**, 1353*e*.

Synthetic β-$2CaO.SiO_2$, contg. no free CaO, was ground to -60, mixed with 30% of H_2O, and made into 20 x 20 x 20-mm test pieces. After 21 days the loss of H_2O upon heating was detd. Loss of H_2O began at 100-200°C, became slower at 200-350°C, was nearly complete at 350-800°C, and complete at 800-1000°C.

1635. Schulz, L. G. **Growth of alkali halides from the vapor on single-crystal substrates of alkali halides.** *Acta Cryst.* 5, 130-2 (1952).—*C.A.* **46**, 4305*d*.

Alkali halides of the NaCl-type structure (LiF, NaF, LiCl, KF, NaCl, NaBr, KCl, KBr, KI, and RbI) were deposited from the vapor phase by evapn. in a vacuum onto cleavage surfaces of LiF, NaCl, KCl, and KBr. Crystals of the initial deposit were oriented with their crystallographic axes parallel to those of the substrate for all deposit-substrate combinations.

1636. Schulz, L. G. **Overgrowths of alkali halides on calcium carbonate and sodium nitrate.** *Acta Cryst.* **5**, 264-5 (1952) (in English).—*C.A.* **47**, 937*c*.

Crystals of NaCl, KCl, KBr, CsCl, CsBr, RbI, KI, NaF, LiF, and CsF were grown from the vapor and from soln. on cleavage faces of $CaCO_3$ and $NaNO_3$. The orientations were detd. by electron diffraction. A deposit 10A. thick usually showed a well-defined pattern, but with thicknesses greater than about 150A., random orientation occurred.

1637. Siat, Albert and Hocart, Raymond. **Statistical nature of the epitaxy of molybdic anhydride on molybdenite.** *Compt. rend.* **234**, 2377-9 (1952).—*C.A.* **46**, 8448*f*.

Crystals of MoO_3 were slowly sublimed onto a cleavage face of MoS_2. The deposit showed rectangular crystals of MoO_3 having their 010 planes in contact with 0001 of MoS_2. The largest group of crystals (60 to 70%) had their long axis inclined at 12.5° to the trace of the $01\bar{1}0$ plane of MoS_2. A second group (15 to 20%) had the long axis of MoO_3 inclined at 30° to the trace of $01\bar{1}0$ of MoS_2.

1638. Smith, G. Frederick; Bernhart, D. N., and Wiederkehr, V. R. **Desiccator data.** *Anal. Chim. Acta* **6**, 42-6 (1952) (in English).—*C.A.* **46**, 7253*b*.

The time rate of dehydration of air in lab. desiccators had been detd. by direct measurement of residual moisture at given time intervals. By using $Mg(ClO_4)_2$, BaO, and $CaSO_4.\frac{1}{2}H_2O$, a 3000-ml desiccator produced a bone dry atm. within 7.5-15 min. Anhyd. $CaCl_2$ was found to be rapid in reaction, but not quite 100% efficient. In large desiccators the time rate of dehydration was but slightly reduced.

1639. Young, D. M. **Adsorption of argon on octahedral potassium chloride.** *Trans. Faraday Soc.* **48**, 548-61 (1952).—*C.A.* 46, 10773*b*.

Two samples of octahedral KCl were obtained by crystn. in the presence of Pb^{2+} and the dye Amaranth, resp. The adsorptive properties at liquid-air temps. of the two prens. were similar. Theoretical calcns. for the variation in the heat of adsorption of A on (111) KCl with the amt. adsorbed gave results which agreed with expt. Exptl. and theoretical evidence showed that the adsorption behavior of A on the (111) differed considerably from that on the (100) plane.

1640. Ballou, E. V. and Ross, Sydney. **Adsorption of benzene and water vapor by molybdenum disulfide.** *J. Phys. Chem.* 57, 653-57 (1953).

Adsorption isotherms of N_2, C_6H_6 and H_2O on molybdenum sulfide were detd. A hydrophilic layer of molybdenum trioxide was found on sulfide surfaces that had been heated to 110°C. The oxide layer was largely removed by treatment with NH_4OH at room temp., or by this treatment followed by H_2S at 125°C. The oxide-free surface was hydrophobic and the amt. of H_2O adsorbed proportional to the extent of surface oxidation.

1641. Frost, G. B. and Campbell, R. A. **The rate of dehydration of copper sulfate pentahydrate at low pressures of water vapor.** *Can. J. Chem.* 31, 107-19 (1953).—*C.A.* 47, 5772*f*.

The rate of dehydration of $CuSO_4 \cdot 5H_2O$ was detd. in the presence of water vapor; the water vapor pressures were very low, in the range of 0.002 to 4.57 mm Hg. As the pressure was increased, the rate dropped very rapidly, but at about 0.3 mm Hg the rate rapidly increased until at about 2 mm Hg the rate slowly declined. $CuSO_4 \cdot 5H_2O$ was similar in this respect to $MnC_2O_4 \cdot 2H_2O$ which was formerly considered unique in its behavior.

1642. Healey, F. H.; Fetsko, J. M., and Zettlemoyer, A. C. **Physical adsorption on cadmium oxide.** *J. Phys. Chem.* 57, 186-8 (1953).—*C.A.* 47, 7286*c*.

Relative values for the vol. of adsorbate in a monolayer, on crystals of CdO, were found from adsorption isotherms to be 96 and 89, resp., for N_2 at -195 and -183°C; 106 and 103 for O_2; 102 and 97 for CO; and 100 and 107 for A. The absence of adsorption in preferred positions, such as previously observed for MgO, was explained on the basis of the weak potential field of the Cd^{++} ion as compared to the strong field of the small Mg^{++} ion.

1643. Smakula, Alexander and Klein, Myron W. **Investigation of crystal growth by thermal etching and oriented overgrowth.** *J. Chem. Phys.* **21**, 100-4 (1953).—*C.A.* **47**, 4160*f*.

Thermal etching of Tl bromide iodide single crystals in vacuum takes place preferentially at points where the crystal is distorted. The etching proceeds in regular steps with the formation of pits always bounded by (110) planes. High temp. produces a disordered etching and marked surface striation. Deposition of vapor on single crystals of the bromide iodide leads to the formation of isolated hillocks whose sides are bounded by (110) planes.

1644. Taylor, H. F. W. **Hydrated calcium silicates. V. Water content of calcium silicate hydrate I.** *J. Chem. Soc.* **1953**, 163-71.—*C.A.* **47**, 5209*a*.

Ca silicate hydrate I prepd. at room temp. had a typical layer structure, with some analogies to clay minerals; the compn. was 1 to 1.5 $CaO.SiO_2.xH_2O$, with $x = 2$ to 2.5 at room temp., $x = 1.0$ over CaO, or if heated to 100-150°C, or after NH_3 extn. Riversideite was a natural regular intergrowth of an apatite-like mineral (wilkeite), with hydrate I. Isobaric dehydration curves, combined with x-ray powder diagrams, were detd., which confirmed that 1 mol. H_2O remained above 100°C, or after standing over CaO at room temp., fixed in the structure. The isobaric dehydrations all showed an inflection at about 220°C which possibly indicated the existence of a hemihydrate. As long as the dehydration did not remove the fixed 1 mol. H_2O, the samples could be rehydrated, but with a typical hysteresis of the rehydration curve which was the more pronounced, the higher was the temp. of dehydration.

1645. Walker, W. C. and Zettlemoyer, A. C. **Active magnesia. V. Adsorption in preferred positions.** *J. Phys. Chem.* **57**, 182-6 (1953).—*C.A.* **47**, 7285*i*.

Adsorption-isotherm data for N_2 and A at −195°C; N_2, A, and O_2 at −183°C; CO_2 at −78°C; CH_3OH at 0°C; C_2H_2 at −80°C; I_2 at 25°C; and CO_2 (chemisorption) at 25°C were obtained on samples of pure MgO having an area of about 200 m² per g. When 16.2 A² was used for the area occupied by a N_2 mol. at −195°C, the areas by all other adsorbates (except I_2 and CO_2 at 25°C) averaged 14.3% too low. If the area per N_2 mol. was taken as 14.0 A², these same adsorbates showed areas for the MgO differing by an av. of 2% from that obtained with N_2.

I-9. Gases on Glass and Quartz

1646. Itterbeek, A. van and Vereycken, W. **The adsorption of vapors of water and of deuterium oxide on glass.** *Meded. Kon. Vlaamsche Acad. Wetensch., Letteren Schoone Kunsten België, Klass Wettensch.* **1940**, No. 9, 3-15.—*C.A.* **37**, 3989^8.

From the adsorption isotherms at 0°, 18° and 42°C, water vapor was adsorbed more strongly than D_2O. Measurements at const. vol. at 18° to 350°C showed that the adsoprtion decreased sharply with rising temp. and became zero for water at 180°C and for D_2O at 160°C. The heat of adsorption of H_2O was about 4000 cal greater than that of D_2O. The adsorption isotherms were explained by the B.E.T. theory. The adsorption surface corresponded closely with that calcd. from the adsorption isotherms if for each mol. a square was assumed having a length of side equal to the diam. of the mol.

1647. Smith, Paul L. and Taylor, Nelson W. **Diffusion of helium through several glasses.** *J. Am. Ceram. Soc.* **23**, 139-46 (1940).—*C.A.* **34**, 4871^4.

The diffusion at 300-500°C through 4 different glasses showed that the heat-treatment of the glass had a marked effect. He appeared to pass through holes of at. size in the network of atoms which constituted the glass structure. As the glass became more basic so that pos. ions, such as Pb or Na, could occupy some of these holes the freedom of movement of He became less. Glasses high in SiO_2 or B_2O_3 or both showed the greatest permeability. A silicate glass of high alkali content, and no B_2O_3, showed the lowest permeability.

1648. Chapek, M. V. **Study of the "disjoining action" under conditions of the sorption of water vapors.** *Compt. rend. acad. sci. U.R.S.S.* **31**, 588-90 (1941) (in English).—*C.A.* **37**, 815^2.

Small cylinders of monodispersed quartz and kaolin were placed between metal disks, of which the upper one was connected to a mirror and thence to a registering device. The cylinders were subjected to a pressure of 0.01 mm Hg and then exposed to vapor. The expansion of cylinders due to sorption was transmitted through the mirror onto a screen. Sorption occurred even at very low partial pressures of the vapor.

1649. Keesom, W.H. and Schweers, J. **Measurements of hydrogen adsorption on glass.** *Physica* **8**, 1007-19 (1941) (in English).—*C.A.* **37**, 1637^4.

The adsorption isotherms for H_2 on glass were detd. at 20.31°, 19.96°, 17.07°, 14.20°, 8.70° and 8.62°K for equil. pressures up to 9 dynes/cm². From 20° to 14°K the isotherms were given by: $\log (X/p) = (226.54/T) - \log T - 15.328 - [(5.8050/T) + 0.1108] \times 10^{10}$, where X was the quantity absorbed in mols./cm² and p was the pressure in dynes/cm². Within the accuracy limits of the expts., the adsorption energy between 14° and 20°K was independent of the temp. It decreased linearly with increasing X.

1650. KEESOM, W. H. AND SCHWEERS, J. **Measurements of helium and neon adsorption on glass.** *Physica* 8, 1020-31 (1941) (in English).—*C.A.* 37, 1637^6.

The adsorption isotherms of He at 9°-1.2°, and for Ne at 20°-11°K were detd. at max. equil. pressures of approx. 20 dynes per cm^2. It was likely that more than 1 layer of absorbed mols. was formed. The adsorption energies, within the limits of exptl. accuracy, were independent of the temp. and depended strongly on the surface coverage.

1651. KEESOM, W. H. AND SCHWEERS, J. **Measurements of the adsorption of helium on solidified layers of some gases.** *Physica* 8, 1032-43 (1941) (in English).—*C.A.* 37, 1637^7.

The adsorption of He at 4°-1°K and max. equil. pressure, approx. 10 dynes per cm^2, was detd. on solidified layers of H_2, Ne, N_2, and O_2 on glass. At the same pressure and temp. (4.2°, 3.2° and 2.2°K) the amt. of He adsorbed on H_2 was $\frac{1}{70}$-$\frac{1}{35}$ the amt. adsorbed on glass; at 1.33°K it was $\frac{1}{4}$-$\frac{1}{3}$ the amt. adsorbed on glass. The adsorption of He on Ne was $\frac{1}{3}$-$\frac{1}{2}$ the adsorption on glass. The adsorption of He on N_2 and O_2 was approx. the same as on glass and more than one layer of He mols. were adsorbed.

1652. HEDVALL, J. ARVID; ALFREDSSON, S.; OHLSON, KNUT; RUNEHAGEN, O.; WALDENSTRÖM, S., AND ÅKERSTRÖM, S. **Reactivity and the effects of lattice distortion in important glass-technical and ceramic systems.** *Glastech. Ber.* 20, No. 2, 34-42 (1942).—*C.A.* 37, 4866^9.

The characteristics of oxides were considerably influenced by treatment with "neutral" gases. The physicochem. as well as the mech. properties of oxides and their products varied to a considerable degree, depending on the kind and amt. of dissolved and adsorbed gas. The effects of O_2-, N_2-, SO_2- and SO_3- treated prepns. of various modifications of SiO_2, Al_2O_3 and "Jena Supremaxglass" on their reactivity with CaO in the solid state were reported.

1653. HEDVALL, J. A.; ALFREDSSON, S.; RUNEHAGEN, O., AND ÅKERSTRÖM, P. **The effect of normally inactive gases on the chemical activity of solids.** *Iva* 1942, 48-64.—*C.A.* 37, 5641^3.

Various modifications of SiO_2 quartz, tridymite, cristobalite and SiO_2 glass were treated with O_2, N_2, SO_2 or SO_3 at various temps., and the reactivity of the resulting material toward CaO was detd. Al_2O_3 and α-Al_2O_3 were treated similarly. O_2, N_2 and SO_2 activated and SO_3 deactivated the SiO_2 and Al_2O_3. The activating and deactivating effects held for all modifications of SiO_2; the effects increased with increasing time of treatment and also with increasing temp. to a max. of 1000°C. The effect of SO_3 was attributed to a change in the surface tension produced by this gas. Extensive expts. with quartz that was treated with O_2 at temps. from 400° to 1325°C and then reacted with CaO at temps. from 800° to 1000°C showed that activation occurred only when the preliminary treatment was at temps. above 400°C. The optimal temp. for the gas treatment was 800-1200°C and the upper limit of activation was 1400°C.

1654. EMMETT, P. H. AND DEWITT, THOMAS W. **The low-temperature adsorption of nitrogen, oxygen, argon, hydrogen, butane and carbon dioxide on porous glass and on partially dehydrated chabazite.** *J. Am. Chem. Soc.* 65, 1253-62 (1943).—*C.A.* 37, 4950^1.

The adsorption of N_2, O_2, H_2, A, CO_2 and butane on porous glass and on partially dehydrated chabazite indicated that the surface area of porous glass could apparently be measured satisfactorily by the low-temp. gas-adsorption method. Chabazite, when only 50% dehydrated, adsorbed no N_2 at -195°C, but would adsorb considerable H_2 at -195°C and CO_2 at -78°C. The occurrence of reproducible hysteresis loops in the adsorption-desorption curves on porous glass was discussed. The largest pores were about 60 A. in radius as calcd. by the Kelvin equation from the low-temp. isotherms for A, O_2, N_2 or butane.

1655. SMAKULA, A. **Reflection on glass surfaces and its elimination.** *Sprechsaal* 76, 237-40 (1943).—*C.A.* 42, 5184*e*.

The types of layers that may be applied to glass surfaces to reduce reflection and the refractive properties of these layers are discussed.

1656. SAWAI, IKUTARO; TASHIRO, MEGUMI, AND UMEYA, KAORU. **Fundamental studies on the chemical resistance of optical glasses. III.** *J. Japan. Ceram. Assoc.* 52, 198-200, 200-202, 258-62 (1944).—*C.A.* 45, 7320*b*.

The corrosion of a glass surface by the alternating action of hot water and air was observed under the microscope. The glass used was Na_2O-$2SiO_2$, and the temp. was 80°C. Shivering was formed by water in the thin film on the glass surface, and this film was removed by cragging formed by drying. The activation energy of dissoln. of the thin film on the glass surface was calcd. Borosilicate soda glass separated on heating into two phases, SiO_2-rich glass and alkali- and H_3BO_3-rich glass. The glassy phases were less resistant to corrosion than was the original glass.

1657. SCHWARZ, HELMUT. **Gas absorption and change in the measurement of lowest pressures by the ionization gage. A critical investigation in H_2, N_2, and A.** *Z. Physik* 122, 437-50 (1944).—*C.A.* 39, 2681^1.

Because of gas take-up by metal and glass surfaces the use of ionization gages for very low gas pressures was critized. The more the ionization was increased by improved construction, the poorer the tube was as a manometer.

1658. VEITH, H. **Simple arrangement for determination of the thickness of water films adhering to glass.** *Z. physik. Chem.* 193, 378-85 (1944).—*C.A.* 41, 1908*f*.

Two cylindrical vessels of the same height but of different diams., a vacuum system contg. a supply of water and a manometer were used. The procedure involved pressure measurements and condensation of the water in dry ice. If the adsorbed liquid film had the same d. as liquid water, its thickness (at room temp. and between pressures of 5 and 15 mm) varied between 5° and 800°A. for several varieties of soft and hard glass.

1659. VASICEK, ANTONIN. **Chemistry of the preparation of unimolecular layers on glass.** *Chem. Listy* 39, 63-5 (1945).—*C.A.* 44, 9648*c*.

If the H_2SO_4 used for etching glass contained some Pb, the *n* of the layer increased, e.g., from 1.48 to 1.525. The surface layer contracted when exposed to air, and it was necessary to make the layer accordingly thicker.

1660. BAKER, T. C. AND PRESTON, F. W. **Effect of water on the strength of glass.** *J. Applied Phys.* 17, 179-88 (1946).—*C.A.* 40, 3241^6.

Measurements were made in dry air, vacuum, autoclave at steam pressures from 600 to 800 p.s.i. and in solns. contg. CO_2, $Ca(OH)_2$, and NaOH. In high vacuum, thoroughly baked glass had a strength fairly independent of duration of load, up to 10 sec. Glass exposed to moisture rapidly lost its strength under stress. In 10 sec. the strength could decay to 50 or 40% of the vacuum strength, and might decay to 33% in 24 hrs. For long durations the chem. compn. was so important as to be the controlling factor in strength.

1661. ELEY, D. D. **Structure of catalytic metal films.** *Nature* **158**, 449 (1946).—*C.A.* **41**, 1537*a*.

The evapn. of metals onto glass at room temp. often yields films of high catalytic activity. These data are best explained by a microcryst. film, in accordance with electron-diffraction evidence. If equal spheres are assumed, the diams. of W and Ni films are 0.0043 - 0.007 μ. These dimensions are profoundly affected by chemisorbed gases; H_2 at 10^{-6} mm will lower the surface tension of W by 500 dynes/cm.

1662. HODGINS, J. W.; FLOOD, E. A., AND DACEY, J. R. **The flow of gases and vapors through media.** *Can. J. Research* **24B**, 167-77 (1946).—*C.A.* **40**, 6932^5.

The flow of He, H_2, N_2, Et_2O, and EtBr through a sintered glass plug was studied. The permanent gases were transferred by a combination of Knudsen and Poiseuille flow, whereas the flow of condensable vapors diverged from these equations in such a fashion as to suggest surface transfer. The flow rates of the condensable vapors began to fall off at about 50% of the satn. pressures. Hysteresis effects were also observed in this region.

1663. HUBBARD, DONALD. **Hygroscopicity of optical glasses as an indicator of serviceability.** *J. Research Natl. Bur. Standards* 36, 365-75 (1946) (Research Paper No. 1706).—*C.A.* 40, 6768^2.

The hygroscopicities of a no. of powd. glasses (optical and chem. glasses, window glass, and Corning 015 (used for making glass electrodes) and other special glasses) were detd. Typical optical glasses in common use were much less hygroscopic than the av. commercial sheet and container glasses. The pH response of a glass was primarily a function of its hygroscopicity. Tests made on a binary series Na_2O-SiO_2, K_2O-SiO_2, Li_2O-SiO_2, and PbO-B_2O_3 reflected some of the crit. compns. of the respective phase equil. diagrams.

1664. KONDRAT'EVA, E. I. AND KONDRAT'EV, V. N. **Catalytic recombination of active centers and its application for determining their concentration in the reaction zone.** *J. Phys. Chem. (U.S.S.R.)* **20**, (1946) 1239-47 (in Russian).—*C.A.* **41**, 2972*d*.

The temp. increase of a thermocouple coated with $ZnO.Cr_2O_3$ and kept in a H_2-O_2 flame shows that the rate of adsorption of H atoms by the walls is almost independent of temp. between 800° and 900°K.

1665. TSUCHIHASHI, SHOJI. **The surface-chemical study of the solid-water interface.** *Rev. Phys. Chem. Japan, Shinkichi Horiba Commem. Vol.* **1946**, 31-4.—*C.A.* **44**, 4306*i*.

Contact angles were measured (by a photographic method) of small H_2O droplets on glass coated with films of various resins. On polystyrene the contact angle was larger than 90°C; with "Kurulugamu," vinyl acetate, ethyl- and benzylcellulose the contact angles were between 60 and 70°C, and with polyvinyl alc. about 36°C, presumably because this film adsorbed H_2O readily. In this case visibility should be least hindered.

1666. VOEVODSKII, V. V. **The role of the hydroxyl adsorption in the chain mechanism of the combustion of hydrogen.** *J. Phys. Chem. (U.S.S.R.)* **20**, 779-88 (1946) (in Russian), *Acta Physicochim. U.R.S.S.* **22**, 45-60 (1947) (in English).—*C.A.* **41**, 2310*g*.

The theory attributing the termination of chain reactions to recombination of H atoms at the walls was not applicable to gas mixts. contg. much O_2 and little H_2. In these mists. recombination of OH radicals at the walls could be more important. The probabilities P_H and P_{OH} of a recombination on contact with the wall could be correlated with the concn. limits of ignition. At 500-530°C on glass, P_H was 1.5×10^{-3} to 2.4×10^{-5}, and P_{OH} was 8×10^{-2} to 2.5×10^{-3}.

1667. WEYL, W. A. **Some aspects of the surface chemistry of glass.** *Bull. inst. verre* **1946**, No. 3, 1-10.—*C.A.* 40, 7543^9.

On the surface of glass valence forces are not satd. which results either in increased adsorption of water or in a repelling by Si to the surface of weaker-bound particles such as alkali or B. The alkali can be neutralized by SO_2 from furnace gases. In glass treated with acids or with hydrosilicates such as clay, H ions replace surface cations and increase chem. resistence. A change in refraction causes the appearance of a colored film on the surface. Treatment of glass with chlorinated Si org. compds. (Drifilm) sats. the surface with org. radicals and makes them water-repellent.

1668. BANGHAM, D. H. **Physical processes involved in sintering.** *J. Soc. Glass Technol.* 31, 264-6 (1947).—*C.A.* **42**, 8062*f*.

The shrinkage occurring when presses powders are fired is a manifestation of the tendency of the material to reduce its surface energy to a min. The surface forces act locally at the contacts between particles and tend to broaden these areas. The elastic forces resident in the particles resist such deformation, but become relatively (as well as absolutely) less powerful as the temp. is raised.

1669. BATESON, S. **The application of magnesium fluoride antireflection films to glass surfaces.** *J. Soc. Glass Technol.* **31**, 170-93 (1947).—*C.A.* **42**, 2067*g*.

The vacuum equipment and the process by which MgF_2 films are produced are described in some detail. In order to realize max. hardness and durability the work must be thoroughly heat-conditioned and the glass held at a temp. not lower than 250 °C during film deposition. Adhesion between the film and the glass is further influenced by the kinetic energy of the incident mols. By selecting a source which produces a high-velocity mol. beam, harder films can be secured.

1670. DERYAGIN, B. V.; GOL'DANSKII, V. I., AND KARASEV, B. V. **Multimolecular adsorption and condensation of vapor on glass as studied by optical methods.** *Doklady Akad. Nauk S.S.S.R.* **57**, 697-700 (1947).—*C.A.* **46**, 4881*a*.

The adsorbed films were examd. by detn. of the parallel and perpendicular components of reflected polarized light on the surface in question, with the green Hg line as light source. Adsorption isotherms for EtOH, AcOH, H_2O, and EtOAc on glass were given graphically. Near the site of condensation of vapor adsorbed layers about 5×10^{-6} cm thick were observed.

1671. DURÁN MIRANDA, ARMANDO AND SÁNCHEZ DEL RIO y SIERRA, CARLOS. **Theory of absorbent, antireflection, optical coatings.** *Anales fís. y quím. (Madrid)* **43**, 671-8 (1947).—*C.A.* 42, 1097*c*.

When light strikes an air-glass surface, an antireflection layer of adequate thickness and refractive index can be used to avoid loss by reflection. If this layer consists of an absorbent material, the most suitable index is given by $(M + n^{1/2} + M^2)$ M being a term dependent on the absorption. Cases of homogeneous and nonhomogeneous absorption are considered.

1672. EMMETT, P. H. AND CINES, MARTIN. **Adsorption of argon, nitrogen, and butane on porous glass.** *J. Phys. & Colloid Chem.* **51**, 1248-62 (1947).—*C.A.* **42**, 1100*h*.

Low temp. adsorption and desorption isotherms were detd. for N_2 and A at - 195°C and for n-C_4H_{10} at 0°C on five different samples of porous glass. The pores of each glass seemed to be rather uniform in size as judged by the large desorption that occurs at an approx. const. relative pressure. The av. pore size as calcd. by the ratio of pore vol. to pore area agreed within an av. of about 2 A. with that calcd. by applying the Kelvin equation to the desorption isotherms. On one glass five sets of scanning curves were taken with A at -195°C. The surface-area values of one glass (m^2 per g) were 232, 217, 156, 159, 207, 128, and 164, for N_2, A, C_4H_{10}, CO_2, NH_3, H_2O, and C_2H_2, resp.

1673. GIGUERE, PAUL A. **Thermal decomposition of hydrogen peroxide vapor. II.** *Can. J. Research* **25B**, 135-50 (1947).—*C.A.* 41, 4364*g*.

The decompn. of H_2O_2 vapor was studied at low pressures in the temp. range 50-420 °C in round one-liter flasks made of soft glass, Pyrex, quartz, or metallized glass. In most cases the decompn. was found to be of the first order, but the rates varied from one vessel to another. On a quartz surface, the reaction at low temps. was preceded by an induction period. A superficial fusion of the surface reduced the speed and seemed to increase the activation energy. This fusion effect was removed by washing with acid. The marked surface effects pointed strongly to a heterogeneity in the reaction, which was further shown by a range of values for the energy of activation from 8 to 20 kcal.

1674. KISTMAKER, J. **Anomalous adsorption of helium gas on glass, between 3 and 1.7°K.** *Physica* 13, 81-7 (1947).—*C.A.* 41, 6106*f*.

Adsorption was measured with x-ray shadowgraphs between 1.7° and 3°K over a pressure range of 4 to 16 mm Hg (corresponding to 9 to 99% of the vapor pressure). The no. of adsorbed layers varied from about 5 to 31; this indicated the probable preformation of the liquid He film.

1675. WEYL, W. A. **Some practical aspects of the surface chemistry of glass. II.** *Glass Ind.* **28**, 300-2, 324-6 (1947).—*C.A.* 42, 2411*h*.

Structural changes of glass surfaces are discussed under their mol. rearrangements due to surface and interfacial tensions, the volatility of glass constituents, base-exchange reactions of dry glass surface, and the dealkalization of the glass surface such as with a clay treatment at 400 °C.

1676. WEYL, W. A. **Some practical aspects of the surface chemistry of glass. III.** *Glass Ind.* **28**, 349-53, 370, 372, 374, 376, 382. (1947).—*C.A.* **42**, 2411*i*.

Methods of superficially reducing metals in glass and the deposition of metals and compds. on glass are presented. The hydrolysis and wettability of glass surfaces and the reactions of the silica gel with aq. solns. and vapors and org. compds. are discussed.

1677. BADIN, ELMER J. **The reaction between atomic hydrogen and molecular oxygen at low pressures. Surface effects.** *J. Am. Chem. Soc.* **70**, 3651-5 (1948).—*C.A.* **43**, 2079*i*.

In the low-temp. reaction (-196°C), the rate of peroxide and water formation was proportional to O_2. At temps. slightly above -196°C, water formation increased at the expense of a decrease in peroxide formation. The effect of Pyrex, phosphoric acid, and KCl surfaces at higher temps. was studied. The effects were attributed to the relative amts. of water present on the 3 surfaces. Surfaces of LiCl, NaCl, and KCl gave essentially similar results. The decrease in peroxide and water had been attributed to destruction of OH (or possibly HO_2) in addn. to H recombination to give H_2 and O_2.

1678. BANNON, J. AND CURNOW, C. E. **Structure of calcium fluoride films evaporated on polished glass surfaces.** *Nature* **161**, 136-7 (1948).—*C.A.* **42**, 3235*f*.

The films were deposited on crown glass over a range of surface temps. X-ray measurements were made of the films. At 25 °C the (111) planes of the crystallites were not appreciably oriented. There was considerable orientation of the (111) planes at 75 °C with a random arrangement of the (110) planes. At 105 °C the (111) planes were completely oriented. A max. was reached at 100 °C after which the double refraction weakened as the temp. was increased to 300°C. The films were of a fibrous structure and the oriented (111) planes were perpendicular to the axis of the fibers and parallel to the glass surface.

1679. Canneri, G. and Cozzi, D. **New method for the determination of fluorine by means of the alteration of glass surface.** *Anal. Chim. Acta.* 2, 321-7 (1948).—*C.A.* 43, 4599*e*.

The wettability of glass was reduced when it was dipped into CrO_3 cleaning-mixt. contg. HF. Measurement of the contact angle was made of a captive air bubble which appeared at the bottom of a glass capillary tube previously dipped into the test soln. These angles varied from 30° for 0.003 g NaF per liter to 82° for 1.5 g NaF per liter. As little as 0.5γ could be detd. in a drop of soln. Boric acid and silicic acid interfered.

1680. Cohn, Gunther and Kolthoff, I. M. **Thermal aging of silica.** *Festskr. J. Arvid Hedvall* 1948, 97-116.—*C.A.* 42, 6196*e*.

Relative sp. surface, bulk and apparent d., microscopic examn., x-ray data, and the compressive strength of pellets (pressed from loose SiO_2 powder) were detd. The bulk d. decreased, whereas the apparent d. increased with an increase in the water content of the SiO_2. When SiO_2 was heated in air at 865°C for 1-5 hrs. there occurred a decrease in sp. surface, an increase in apparent d., whereas the bulk d. approached the value of amorphous SiO_2 (2.20). When the SiO_2 was treated in water vapor at 865°C the bulk d. reached 2.23. The sp. surface (detd. by adsorption of methyl red) decreased gradually from 47.5 mg of adsorbed methyl red at room temp., up to 600°C, then remained const. at about $\frac{1}{5}$ its original value to about 900°C, after which it dropped to extremely low values.

1681. Coles, Harold W.; Schulz, Walter F.; Levy, Sylvia, and Wheatley, Thomas A. **Optical lens coatings.** *Modern Plastics* 25, No. 11, 123-6, 167-70, 172, 174, 176-81 (1948).—*C.A.* 44, 9648*d*.

Spun coating on glass optical lenses had been made with a no. of polymers and the coatings examd. Allymer CR-39 (an allyl diglycol carbonate polyer) was most resistant to marring, but had to be used in an inert atm. An alkyd-modified melamine resin was second best and did not need such special care. Diallyl phthalate was also good against marring. A silicone, a trimethylcyclohexyl methacrylate, and Kotol coatings were most resistant to roof exposure and H_2O.

1682. Davis, R.T., Jr. and DeWitt, T.W. **The adsorption of butane on glass spheres.** *J. Am. Chem. Soc.* 70, 1135-41 (1948).—*C.A.* 42, 4422*h*.

Data were presented for a relative pressure range from below 0.0001 to near satn. at -78°, -46°, and 0°C. Heats of adsorption, calcd. from the Clausius-Clapeyron equation, remained const. at approx. 2,500 cals/mole up to several % surface coverage. It then decreased approx. logarithmically with increasing adsorption. Exptl. heats and entropies of adsorption were compared with the corresponding quantities calcd. from the B.E.T. equation.

1683. Dietzel, A. **Gases in glass.** *Glashutte* 75, 125-27 (1948).—*C.A.* 44, 9646*i*.

Examples of chem. gas reactions were the soln. of water in the glass melt by the formation of OH^- ions, the oxidation of FeO by O_2. The phys. problem of gas evolution was one of the formation of a new surface in the interior of the melt, for which high energies must be made available. At the end of fining with 1% CeO_2 pronounced gas under-pressure was observed and explained by the resorption of O_2 by Ce_2O_3 at a lower temp. (800°C) than that of max. fining (900°C). Phenomena observed in this borax glass-CeO_2 system were also valid if sulfate or As were used as the fining agent. Two gases (SO_2 and O_2) were formed, however, with sulfate which could lead to a persistance of bubbles.

1684. Dietzel, A. **Glass structure and glass properties. II.** *Glas-tech. Ber.* 22, 81-6 (1948).—*C.A.* 45, 7317*c*.

The free space of 17% present in vitreous SiO_2 compared with quartz was discussed in the light of gas diffusion and soly. The soly. of He or H_2 of 0.0045 cc./g SiO_2 at 445°C was considered to be caused by the flaws rather than the pores of the random network, which were closed to the gas mols. on the basis of the dimensions. Gas diffusion at increased temps. was attributed to the breaking of bonds isolating neighboring pores, thus depending on mobility of the lattice which explained the temp. dependence of the diffusion.

1685. Dufour, Ch. **Technique of evaporation of multiple thin layers.** *Le Vide* 3, 480-6 (1948).—*C.A.* 43, 1621*e*.

Lenses coated with fluorides (cryolite, MgF_2) of low *n* have better reflective properties if the layers of fluorides are combined with layers of a material of high *n* (ZnS, TiO_2, Sb_2S_3) at a detd. thickness. A method and the equipment necessary to obtain such composite layers are completely described.

1686. Green, Robert L. and Blodgett, Katherine. **Electrically conducting glasses.** *J. Am. Ceram. Soc.* 31, 89-100 (1948).—*C.A.* 42, 3921*a*.

Samples were lightly sandblasted, placed in an asbestos boat at spaced intervals, and reduced by H_2 in an elec. furnace at 250-600°C. The glass batches were mostly silicate (some borate) glasses, contg. Pb, Bi, or Sb oxides, or combinations of these. Results indicated that electronic conduction was maintained in a reduced surface layer less than 0.0001 in. thick. This surface conduction increased with increase in reducible oxide.

1687. Markevich, A. M. **The role of the surface in the thermal reaction of chlorine and hydrogen.** *J. Phys. Chem.* 22, 941-52 (1948).—*C.A.* 43, 474*c*.

To decide whether the combination of H_2 and Cl_2 (a stoichiometric mixt.) in glass was a vol. or a surface reaction, the temp. difference in a reaction vessel and on the reaction wall was carefully detd. The process was a chain reaction and the chains started from the wall and, in the absence of O_2, extended over the whole vol. They were broken by O_2, and in the presence of O_2 the reaction took place in a thin (e.g. 0.8mm) layer adjacent to the walls.

1688. RAZOUK, RASHAD I. AND SALEM, AHMED S. **The adsorption of water vapor on glass surfaces.** *J. Phys. & Colloid Chem.* **52**, 1208-27 (1948).—*C.A.* 43, 1623*f*.

Adsorption isotherms of water vapor were detd. on a glass of known compn. in the form of fibers, powder, and microspheres. The real surface was about 2 to 3 times the geometric surface in the case of water-washed glass and 10 to 20 times in the case of acid-treated glass. The adsorption of water vapor on glass surfaces was due in part to a chemisorbed monolayer and partly to a physically adsorbed film.

1689. SCHULZ, L. G. **Preparation of aspherical refracting optical surfaces by an evaporation technique.** *J. Opt. Soc. Am.* **38**, 432 (1948).

By selective depostition of evaporated dielectrics it was found possible to form aspherical surfaces on plane glass plates which, when used with a lens, made the combination free from spherical aberration. LiF was used as the dielectric because of its low melting point and the success with which it had been used in the construction of interference filters. MgF_2, the only other dielectric tested, was used to give a final thin, insoluble coating over the somewhat more soluble LiF.

1690. TSINZERLING, E. V. **Investigation of the hardness and fragility of quartz.** *Doklady Akad. Nauk S.S.S.R.* **60**, 1033-6 (1948).—*C.A.* 43, 976*e*.

The hardness data were always lower for colored parts than they are for the colorless ones. HF etched the colored crystal parts much easier than the colorless ones, e.g., on (0001) and $(11\bar{2}0)$ of quartz crystals with a pronounced zonal structure or with sector subdivision. The fragility or brittleness of colored parts was also greater than in colorless fields. Many local defects in the disturbed lattice structure of the colored quartz in comparison with the more regular structure of the colorless explained the observed differences.

1691. WEYL, W. A. **The surface properties of glasses as effected by heavy metal ions.** *J. Soc. Glass Technol.* **32**, 247-59 (T) (1948).—*C.A.* 43, 2386*e*.

Most glass-forming ions have 8 outer electrons and the stability of this arrangement in the elec. fields of neighboring ions of opposite charge makes it possible to treat some ions as rigid spheres. Large ions, such as Ba^{2+}, or ions having an electronic structure that differs from that of the noble-gas atoms (Zn^{2+} Cd^{2+}, Pb^{2+}) cannot be treated as rigid spheres, but their deformation has to be taken into consideration. The deformed Pb^{++} ion explains why some PbO-contg. glasses have a pos. temp. coeff. of surface tension.

1692. ABELÈS, FLORIN. **Determination of refractive index and thickness of thin layers.** *Compt. rend.* **228**, 553-5 (1949).—*C.A.* 45, 8315*a*.

When linearly polarized light is reflected from a glass plate, half of which is covered by a thin layer, the angle of incidence (θ) at which the 2 halves reflect equally is given by: $\tan\theta = n_1/n_0$, where n_0 refers to the first medium, usually air, and n_1 to the thin layer. Equations are also given for the simultaneous detn. of n_1 and the layer thickness when the latter is $>\lambda/4$.

1693. ALLERTON, JOSEPH; BROWNELL, LLOYD E., AND KATZ, DONALD L. **Through-drying of porous media.** *Chem. Eng. Progress* 45, 619-35 (1949).—*C.A.* 44, 6*h*.

Drying by passing air through porous media and by vaporizing water contained in the media was termed through-drying. Through-drying expts. under adiabatic conditions were performed on porous beds composed of uniform glass balls, crushed quartz, and a binary mixt. of glass balls. During max. rate drying, the air left the bed virtually satd. with water and picked up moisture in the bed so quickly that drying might be considered to take place in a narrow zone. When the bottom of the narrow zone reached the bottom of the bed, the drying rate began to decrease rapidly. It had been correlated with the vaporization efficiency, with the max. drying rate, the moisture content, and a drying factor.

1694. BAILEY, DONALD A. **A note on the conversion of amorphous silica to quartz.** *Am. Mineral.* 34, 601-5 (1949).—*C.A.* 45, 1835*b*.

Amorphous silica with 5 to 10% CaO or $CaCO_3$ was converted to quartz when heated between 1070° and 1100°C. MgO in place of CaO was inactive. Decrease in grain size increased the rate of conversion.

1695. CALHOUN, JOHN C., JR.; LEWIS, MAURICE, JR., AND NEWMAN, R. C. **Experiments on the capillary properties of porous solids.** *Am. Inst. Mining Met. Engrs., Tech. Pub. No.* **2640**, J. Petroleum Technol. **1**, 189-96 (1949).—*C.A.* 44, 1248*h*.

Exptl. work was performed on the capillary retention of H_2O within porous solid systems consisting of consolidated quartz, the displacement being made with air and toluene, benzene, cyclohexane, tetradecane, and oleic acid. Theoretically, there was no "irreducible min." and zero H_2O satn. was reached at some finite value of capillary pressure.

1696. CHMUTOV, K. V. **Sorption phenomena in capillary systems. II.** *Kolloid. Zhur.* **11**, 44-9 (1949).—*C.A.* 43, 6882*d*.

The dimensions of liquid drops condensed from vapor between 2 quartz lenses were detd. for different vapor pressures at 20°C. Visible drops appeared when the relative vapor pressure p/p_0 was greater than 0.7, but persevered at lower p/p_0 (e.g., 0.2). The curvatures of the menisci calcd. from the Kelvin equation were several times that calcd. from the distance between the lenses for benzene, H_2O, and EtOH. The Kelvin equation could not be used for computing the pore radius of adsorbents.

1697. DOUGLAS, R. W. AND ISARD, J. O. **The action of water and of sulfur dioxide on glass surfaces.** *J. Soc. Glass Technol.* **33**, T 289-330, discussion, 331-5 (1949).—*C.A.* 44, 6592*e*.

The reaction with water involved the exchange of Na^+ by H^+ and was limited by the rate of diffusion of Na^+ to the surface. The reaction with SO_2 at 20-100°C in gas satd. with water vapor involved the same process and proceeded at the same speed as the reaction with water. The SO_2 reaction at 100-600°C was limited by the rate of diffusion of Na through a compacted layer of glass at the surface which arose from a secondary dehydration process, and with anhyd. reagents Na and O ions diffused on the glass surface.

1698. Franke, Emmanuel and Longchamp, Marthe Hout De. **Production of artificial quartz crystals in large sizes.** *Compt. rend.* **228,** 1136-7 (1949).—*C.A.* 43, 6026*h*.

Single crystals of quartz, (3 × 2 × 0.5 cm and weighting 8-10 g) were grown in alk. soln. (NaOH, LiOH, $NaHCO_3$, Na_2CO_3, $Na_2B_4O_7$, etc.) at 200-300 °C and a pressure of 60 atms. in 3-4 weeks. Best results were obtained when the seed crystal exposed the pyramid faces; the growth occurred very slowly on the prism faces, and very rapidly and irregularly on the basal faces. The crystals were identical with natural quartz.

1699. Harris, B. L. and Emmett, P. H. **Adsorption studies. Physical adsorption of nitrogen, toluene, benzene, ethyl iodide, hydrogen sulfide, water vapor, carbon disulfide, and pentane on various porous and nonporous solids.** *J. Phys. & Colloid Chem.* **53,** 811-25 (1949).—*C.A.* 43, 7288*d*.

The adsorbents were Pyrex glass spheres, ground Pyrex glass, porous glass, reduced-iron synthetic-ammonia catalysts, and Ag. Areas calcd. from the data for the various adsorbates by the B.E.T. method had to be multiplied by factors ranging from 1.03, for C_2H_5I on glass spheres, to 3.7 for CS_2 on ground Pyrex glass, to obtain values agreeing with those calcd. from N_2 isotherms.

1700. Jones, W. H. **Electrostatically charged particles in the detection of minute surface defects in porcelain enamel.** *J. Can. Ceram. Soc.* **18,** 29 (1949).—*C.A.* 43, 6802*e*.

A method to use electrically charged particles was developed to disclose minute surface-discontinuities in nonconducting materials.

1701. Kitaĭgorodskiĭ, I. I. **Preparation of high-silica porous bodies at low temperatures.** *Doklady Akad. Nauk S.S.S.R.* **64,** 219-21 (1949).—*C.A.* 44, 11047*i*.

Finely ground quartz glass (99.9% SiO_2) and a special low-melting boro-silicate glass were thoroughly mixed in various ratios, moistened, shaped into 20 × 3-5 mm disks, by using pressure of 60 kg/cm², and fired at around 750 °C. The disks were treated in boiling 0.5 *N* HCl and the remaining porous bodies contained 96 to 98% SiO_2. Water absorption was 30% regardless of initial compn., apparent porosity was 37%, and true porosity was 45%.

1702. Newkirk, Terry F. and Tooley, F. V. **Study of effect of cation concentration and size on helium permeability of alkali-silica glasses.** *J. Am. Ceram. Soc.* **32,** 272-8 (1949).—*C.A.* 43, 9401*c*.

Permeability detns. were made at 300 °C on fused SiO_2, Pyrex chem. glass, Na_2O-SiO_2 glasses contg. 20, 25, and 30 mol. % Na_2O, a K_2O-SiO_2 glass contg. 30 mol. % K_2O, and a Li_2O-Na_2O-SiO_2 glass contg. 5 mol. % Li_2O and 25 mol. % Na_2. The addns. of Na_2O caused a rapid decrease in permeability; it decreased exponentially over the range 0-30 mol. % Na_2O. The comparative packing index was a potentially valuable guide to permeability only for glasses contg. the same atoms, because new atoms introduced a new polarizing factor.

1703. Rood, Joseph L. **Some properties of thin evaporated films on glass.** *J. Optical Soc. Am.* **39,** 854-9 (1949).—*C.A.* 44, 14*a*.

Properties of thin evapd. films of MgF_2 and of $CaSiO_3$ on glass were studied. Thicknesses of the films were detd. from measurements of reflected intensity as a function of wave length, and *n*s were computed. Density was measured for MgF_2 films. All these properties differed from those of the corresponding bulk materials, and moreover, changed with time.

1704. Seddig, Max and Haase, Günter. **Experimental investigations of the critical condensation temperature.** *Kolloid-Z.* **114,** 169-74 (1949).—*C.A.* 44, 4306*g*.

In a vacuum (10^{-6} mm) a stream of vapor from Hg at 20 °C did not condense on chemically-cleaned glass at temps. above -140 °C, and vapor from Cd at 220-90° not above -80 °C. But on cleaned glass baked for 2 days at 350-450 °C condensation in a 10^{-8} mm vacuum occurred at temps. up almost to the temp. of the metal. On the specially clean glass, a thin layer of metal was first adsorbed, as shown by an increase in the surface cond. of the glass, and then vapor condensed visibly on this layer.

1705. Weyl, W. A. **Surface structure and surface properties of crystals and glasses.** *J. Am. Ceram. Soc.* **32,** 367-74 (1949).—*C.A.* 44, 808*i*.

The difference between the surface structure and the interior of a crystal depends on the polarization properties of the ions. A similarity is shown between the surface of crystals and the structure of glasses. The devitrification of a glass surface, the effect of imperfections on the transformation of crystals, the sintering of highly refractory oxides, the dielec. const. of polycryst. materials, and the elec. absorption of stratified dielectrics are discussed.

1706. Zhdanov, S. P. **Irreversible hysteresis of water vapor adsorption isotherms on porous glass and on silica gel.** *Doklady Akad. Nauk S.S.S.R.* **68,** 99-102 (1949).—*C.A.* 43, 8790*h*.

Porous glass at 15 °C showed an adsorption-desorption hysteresis loop limited to a narrow medium range of p/p_s. After the glass was heated to 300 °C, a larger hysteresis loop was formed, and after heating to 650 °C the loop extended over the whole range from $p/p_s = 0$ to 1. Silica gel, when heated to 650 °C, showed a complete hysteresis loop at 15 °C. When the adsorption-desorption expt. was repeated after evacuation at room temp., without heating, the loops shrank to their normal width and extension. Adsorption of H_2O took place mainly at the OH groups. The O-bridges produced by dehydration were again hydrated by adsorbed H_2O to OH groups.

1707. Aron, Ya. B. **Behavior of liquid drops at the boundary of two solid phases.** *Zhur. Fiz. Khim.* **24,** 82-4 (1950).—*C.A.* 44, 4748*f*.

H_2O drops (0.034 g) were placed on a surface partly of glass and partly of mica. The contact angle between glass, H_2O, and air was 50°, and between mica, H_2O, and air was 26°. When the drop was partly on glass and partly on mica, both angles depended on the ratio of the glass to mica surfaces covered by the drop.

1708. Blackmer, L. L. and Farnsworth, H. E. **Effect of the type of support on the photo-electric work function of silver films.** *Phys. Rev.* 77, 826-9 (1950).—*C.A.* 44, 6257*b*.

Ag was doubly and fractionally distd. with the middle fraction deposited on previously outgassed bulk Ag, on smooth fused quartz, and on outgassed Mo sheet in a sealed-off, gettered tube. A film of Ag on bulk Ag caused the work function, ϕ, to decrease by amts. of 0.25 e.v. to 4.50 ± 0.02 e.v. Subsequent heating below 100°C caused ϕ to increase to the original value. For a Ag film on smooth fused quartz and on outgassed Mo sheet ϕ was 4.41 e.v. The variations in the observed values was due to a dependence of the sizes of the microcrystals on the structure of the support.

1709. Blau, H. and Johnson, J. R. **Radioactive tracer methods for the study of glass constitution.** *Glastech. Ber.* **23**, 180-2 (1950).—*C.A.* 44, 10274*i*.

Abs. reaction rates opened a way for an understanding of the activation energies for at. mobility in glass frameworks. As a first approximation to an exptl. realization of such ideas, the study of the diffusion process in glass as a function of temp. was made possible by radioactive tracer methods. The diffusion coeff. -1/T curve showed a typical inflection range between the limits of log $n = 8$ and 15 which correspond to an at. mobility change in the transformation range of the glass.

1710. Boettcher, A. **Production and structure of aluminum-silver and aluminum-magnesium films.** *Z. angew. Physik* **2**, 193-203 (1950).—*C.A.* 46, 9921*g*.

An analysis of the change in compn. of the melt together with the known phase diagram showed that an Al-Ag alloy contg. 10% by wt of Al deposited first in the form of crystals of the α-modification, followed by thinner layers of β', γ and δ-crystals, with the latter phase in a very thin layer. On heating an Al-Ag mixt. of 6% Al, the elec. resistance rose steeply at about 150°C, owing to a rapid increase of the β'-phase which had the smallest cond. of all the phases in question. The situation was completely altered in a condensate contg. 19% Al. On heating to room temp., a marked decrease of the resistance set in, which was completed at 200°C. With increasing Al content, the decrease in resistance became less pronounced because of the smaller concn. of the β crystallites.

1711. Borzyak, P. G. **Study of oxygen-cesium films.** *Zhur. Tekh. Fiz.* **20**, 928-36 (1950).—*C.A.* **45**, 438*f*.

Wedge-shaped films of Cs on glass were produced by condensation from a mol. beam. Oxidation of this Cs film with O_2 at the temp. of liquid air produced a colorless transparent film, undetectable in transmittance, but noticeable by interference figures in reflection. By microweighing, the oxidized film had the compn. CsO_2, remaining unchanged on heating to room temp. and above; the same film, but whitish, was obtained by oxidation at room temp. When a CsO_2 film was treated with Cs vapor at 150-180°C, an external photoelec. effect began to appear even while the film was still colorless; the effect increased with the progress of incorporation of Cs, with the color veering progressively to yellow.

1712. Dunoyer, Jean Michel. **The electric properties of thin layers of germanium.** *Compt. rend.* **230**, 1664-5 (1950).—*C.A.* 44, 10423*g*.

Thin layers of Ge were vaporized onto a quartz support and then the resistance was measured at room temp. With the support above 370°C the resistance was always of the order of 0.025 ohm/cm; held at 270-370°C the resistance increased rapidly, and results were difficult to reproduce; below 270°C the resistance was of the order of 10^5 ohms/cm. When the Ge was vaporized onto a cold support, then heated, the transformation occurred a little below 400°C. A slight rectifying effect could be observed which was considerably increased by utilization of alternate cryst. and amorphous layers.

1713. Faust, R. C. **An interferometric study of some optical properties of evaporated silver films.** *Phil. Mag.* 41, 1238-54 (1950).—*C.A.* 45, 2738*b*.

Thermally evapd. Ag films were studied in the reflectivity range of 4 to 95%. The air-Ag and glass-Ag reflection and transmission coeffs., the corresponding reflection phase changes and the apparent film thickness were measured and compared with those of sputtered Ag films.

1714. Franke, I. **Action of pure water below its critical point on α-quartz and fused silica.** *Bull. soc. franc. mineral. et. crist.* 73, 503-10 (1950).—*C.A.* 45, 3689*f*.

The soly. of α-quartz in pure H_2O at 350°C, measured by the loss in wt of the quartz originally used, was 0.67 mg = 10%/g of H_2O used. The soly. was independent of the degree of pressure applied. Fused silica was tested in H_2O at 370°C and the results showed that the loss in silica was a function of the amt. of pressure applied. The fused silica was transformed into cristobalite in the satd. vapor.

1715. Gibson, George and Vogel, Richard C. **Migration of lithium and several multicharged ions through quartz plates in an electric field. II.** *J. Chem. Phys.* **18**, 1094-7 (1950).—*C.A.* 45, 411*g*.

The migration was induced by an elec. field and probably took place through tunnels inherent in the crystal structure and parallel to the principal axis of the quartz. The rate-detg. step was assocd. with the passage of the Li ions into or out of the quartz plate because the rate of diffusion was independent of plate thickness. The activation energy of diffusion of Li ions at 190 varied from 17.8 to 21.5 kcals./mol. Neither Mg, Zn, Cd, nor Bi ions would migrate through quartz plates under these exptl. conditions. Cu ions migrated through the quartz plates but caused the plate to crack in each expt.

1716. Haase, G. **Wetting of glass surfaces.** *Glastech. Ber.* **22**, 262 (1949) *Ceram. Abstracts* **1950**, 220.—*C.A.* **45**, 7320*a*.

The wetting properties of glasses are strongly influenced by adsorbed layers of other materials. The wetting of glasses by Hg after treatment in a very high vacuum is considered as being due to the formation of an invisible adsorbed Hg film.

1717. Heavens, O. S. **Adhesion of (metal) films produced by vacuum evaporation.** *J. phys. radium* **11**, 355-9 (1950).—*C.A.* **46**, 4447*a*.

The load on a Cr steel point drawn across the surface at a known rate so as to remove the film is measured. Films prepd. at pressures of $<10^{-8}$ mm Hg in all-glass vacuum systems show much greater adherence and coherence than do those deposited at 10^{-5} mm Hg. Al films are particularly sensitive to Hg contamination. Adhesion of films to plates subjected to glow discharge is better than that to plates which have been preheated only. The adhesion of Cr to glass is much better than that of Ag or Al. No improvement in adhesion of Al films results from previous deposition of a Cr film 1 mol. thick. Cr films approx. 300 A. thick are required to improve the adhesion of Al and Ag films.

1718. Hedvall, J. Arvid; Jagitsch, Robert, and Olsen, Gillis. **Coating glass surfaces with protective films.** *Z. physik. Chem.* **196**, 23-34 (1950).—*C.A.* **45**, 8730*f*.

Various possible coatings were studied to det. their suitability for protecting glass museum pieces. Most suitable was a soln., as concd. as possible, of methacrylate resin in high-boiling "lacquer benzine."

1719. Iberall, Arthur S. **Permeability of glass wool and other highly porous media.** *J. Research Natl. Bur. Standards* **45**, 398-406 (1950).—(Research Paper No. 2150).

An elementary treatment was developed for the permeability of fibrous materials of high porosities, based on the drag of the individual filaments. The fluid inertia resulted in a permeability that varied with flow even at low Reynolds number. The permeability to gaseous flow was also shown to vary with the absolute gas pressure. Data suitable for the design of linear flowmeters utilizing fibrous materials of high porosity were given, including data on the useful porosity range of fibrous media.

1720. Itterbeek, A. van; Greve, L. de, and Francois, M. **Measurements of the oxidation of thin metallic films (nickel, iron, and lead).** *Mededel. Koninkl. Vlaam. Acad. Wetenschap., Belg., Klasse Wetenschap.* **12**, No. 16, 3-17 (1950) (in English).—*C.A.* **45**, 7840*b*.

Metallic films, 30-400 $m\mu$ in thickness, were sputtered on Pyrex strips and the change in elec. resistivity was followed as a function of time at 75°, 20°, -23°C, and at the temp. of liquid air. Oxidation was carried on for 2 hrs in 5 cm of O_2. No pronounced difference was observed in the oxidation characteristics of films sputtered in Ne, H_2, or N_2. Electron micrographs of the films indicated that they had a granular structure. Oxidation was greatest for the Pb films. No oxidation was observed at liquid air temps. At 75°C for the thinnest films an S-shaped curve was observed. The curves for Fe and Ni at room temp. were very similar to typical Langmuir adsorption isotherms.

1721. Jebsen-Marwedel, H. and Dinger, K. **Comparative effect of various stabilizing treatments on the extractability of fresh glass surfaces.** *Glastech. Ber.* **22**, 57-62 (1948).—*C.A.* **45**, 5811*c*.

The pretreatment of glass plates in cold water gave a slight but observable decrease in extractability in the standard stability test. The treatment with an $SO_2 + O_2$ gas mixt. at 500° to 600°C for only a few min. gave an effect which was around 16 times that of cold water on the initial untreated glass. A gas treatment of 5 min. at 550°C had twice the effect of a 1-hr treatment in hot aq. HCl in improving extractability. By examg. the Na_2SO_4 layer on variously treated samples, the percentage improvement in stability was shown to be directly proportional to the thickness of the sulfate layer formed.

1722. Kinumaki, Jo. **Glass surfaces. I. Migration of alkali ions through the surface layer.** *Science Repts. Research Insts., Tohoku Univ.* **2**, 405-11 (1950).—*C.A.* **45**, 4418*i*.

The surface alky. and the elec. vol. cond. of com. soda lime-silica glass were measured as functions of pretreatment, time, and temp. A parabolic rate law derived for the diffusion of alkali to the surface (detd. by measuring surface alky. as a function of time), and the activation energy of this process was 12 kcal./mol. in the range 350-450°C.

1723. Nagaeda, Shumpei. **Changes of glass surface by acidic gases.** *J. Japan. Ceram. Assoc.* **50**, 648-50 (1942) *Ceram. Abstracts* **1950**, 4.—*C.A.* **45**, 5379*e*.

Eight samples of optical glass were heated to 300°C for 4 hrs in CO_2 or SO_2. The glass surfaces were subjected to the stain test after cooling to room temp. Dry SO_2 and CO_2 reacted with glass surfaces equally and attached the edges of the 5 × 10 × 10-mm test pieces. Moist gases formed thin films of hydrated silica on the surfaces.

1724. Rouard, P. **Optical properties of thin platinum films and their comparison with those of other metals.** *J. phys. radium* **11**, 390-3 (1950).—*C.A.* **46**, 4876*e*.

A distinct min. of the reflection factor (R) characterized a film of Pt approx. 25 A. thick deposited on glass, whatever the wave length (λ) of light used. Thin films of Cu and Fe produced by thermal evapn. and of Au and Ag produced by cathode sputtering were characterized by a min. value of R, but with all these metals this min. corresponded to a different thickness of film for different λ of the incident light. Al, Be, Zn, and Mg films behave like a Pt film.

1725. Saksena, B. D. and Pant, L. M. **The development and the surface energy of the planes of the primary rhombohedron in a-quartz.** *J. Chem. Phys.* **18**, 1304-5 (1950).—*C.A.* **45**, 17*b*.

The Si-O bonds in quartz lay very close to the planes of the primary rhombohedron; this caused the large development of those planes. The surface energy of the primary rhombohedral face was calcd. to be 1895 ergs/cm^2; this was reduced to 1340 if the angle with the Si-O bond was considered. The energy of the inverse rhombohedral faces was 3790, and of the hexagonal-prism faces, 2368 ergs/cm^2. The surface energies of the (111) and (100) planes of crystobalite were 1420 and 2460 ergs/cm^2, resp.

1726. Tamres, Milton and Frost, Arthur A. **Adsorption effects in the decomposition of hydrogen peroxide vapor.** *J. Am. Chem. Soc.* 72, 5340 (1950).—*C.A.* 45., 2294*h*.

At room temp. and at 45°C the pressure increase was greater than 50%, the expected increase for a homogeneous reaction. Addn. of glass wool to the system clearly showed the adsorption of H_2O_2, but coating the surface with Cerese wax AA or Dri-Film 9987 had little effect on the rate.

1727. Terent'ev, A. P.; Klabunovskii, E. I., and Patrikeev, V. V. **Asymmetric synthesis with the aid of catalysts: deposited on right and left quartz.** *Doklady Akad. Nauk S.S.S.R.* 74, 947-50 (1950).—*C.A.* 45, 3798*c*.

The reactions were carried out on metals deposited by either reduction or evapn. on either left (*l*) or right (*r*) quartz powder. The metals included Cu, Ag, Ni, Pb, Pd. Syntheses of optically active compds. from compds. without an asym. C atom were given.

1728. Tsinzerling, E. V. **Residual tensions in glass and quartz.** *Zapiski Vsesoyuz. Mineral. Obshchestva* (Mém. soc. russe minéral.) 79, 223-4 (1950).—*C.A.* 45, 833*h*.

A rapid heating of glass and quartz plates to 300°C, or the application of a diamond point under load, brings about fine cracks which show under crossed nicols at distinct spots the characteristic fanlike "torches" of anomalous birefringence. The changes observed in the light-interference "brushes" by rotating the microscope stage are described; they often resemble conoscopic interference figures of biaxial crystals, and indicate in quartz the trace of $(11\bar{2}0)$ by the symmetry plane of the figure.

1729. Blanc-Lapierre, Andre; Perrot, Marcel, and Nifontoff, Nicolas. **The conductivity of thin carbon deposits.** *Compt. rend.* 233, 141-3 (1951).—*C.A.* 46, 1892*h*.

The deviation from Ohm's law of the conductivities of thin layers of carbon deposited on glass was investigated. Resistances of the specimens were lower than 500,000 ohms, and the applied potentials varied from 0.1 to 40 v. The various curves of R vs. I were sepd. by sharp bends into two distinct regions, interpolative formulas for which, along with a table of the consts. involved, were given.

1730. Blodgett, Katherine B. **Surface conductivity of lead silicate glass after hydrogen treatment.** *J. Am. Ceram. Soc.* 34, 14-27 (1951).—*C.A.* 45, 2642*g*.

An x-ray shield glass contg. PbO 61, BaO 8, SiO_2 31% was used. The surface was ground with 150-mesh SiC and treated with dil. HCl or dil. HNO_3 to produce a surface film of SiO_2 which gave protection to the conducting layer beneath it. The conducting layer was only 50-100 A. thick and lay immediately under the SiO_2 film. Its specific resistance was 800 ohm-cm or more, depending upon the H_2 treatment. The best method of developing a specified resistance was to continue the H_2 treatment until the resistance was considerably less than that desired and then to bring it up to the specified value by treatment in hot H_2O or in hot damp air.

1731. Bockris, J.O'M.; Kitchener, J. A., and Davis, A. E. **Ionic transport in liquid silicates.** *Chem. Phys.* 19, 255 (1951).—*C.A.* 45, 3692*e*.

The silicate (Li_2O-SiO_2 system) was heated *in vacuo* at 800°C in a Mo cell with a C anode and an Al_2O_3 anode compartment. The O_2 liberated attacks the C and the resulting CO and CO_2 were adsorbed on charcoal at liquid-air temp. and subsequently analyzed. Within the exptl. error of ±5% the conduction was completely ionic.

1732. Carman, P. C. and Raal, F. A. **Role of capillary condensation in physical adsorption.** *Nature* 167, 112-13 (1951).—*C.A.* 45, 4522*f*.

The adsorption of CF_2Cl_2 on Linde silica as a loose powder and a compressed plug was studied at -33.1°C. Below 250 mm both the powder and the plug yielded identical results. At higher pressures the plug exhibited greater adsorption, and a marked hysteresis loop was noted upon desorption. No hysteresis was found with the loose powder. The results indicated the contribution of capillary condensation to phys. adsorption.

1733. Dartnell, R. C.; Fairbanks, H. V., and Koehler, W. **Investigation of the adherence of glass to metals and alloys.** *J. Am. Ceram. Soc.* 34, 357-60 (1951).—*C.A.* 46, 225*b*.

The adherence temps. of W, Ni, and Monel were above 1000°F. In a C-Fe series the adherence temp. decreased with increase in C, the highest being 920°F at 0.05% C. A sample of electrode-grade C had an adherence temp. of 1145°F. A sample of brass used for glass molds had a nodular structure and its adherence temp. was 900°F while a mold of the same compn. showed, after service, a dendritic structure and its adherence temp. was lowered to 850°F.

1734. Dietzel, A. **Reactions and adhesion between glass and metal sealings.** *Glastech. Ber.* 24, 263-8 (1951).—*C.A.* 46, 1726*i*.

(1) The melt was adherent on a highly roughened metal surface by mech. indentation. This was the typical adhesion-oxide phenomenon in enamels on Fe (steel). (2) The glass (enamel) may adhere on the metal surface over an intermediate oxide layer, by chem. valence forces. (3) The glass (enamel) may in other cases (e.g. on Cu, Ag, etc.) adhere without any intermediate oxide layer, if O (as oxide) was dissolved in the metal, and diffuse with a considerable speed in it. At all events, the presence of O_2 was indispensable for every adhesion phenomenon.

1735. Ewles, J. and Youell, R. F. **Luminescence effects associated with the production of silicon monoxide and with oxygen deficit in silica.** *Trans. Faraday Soc.* 47, 1060-4 (1951).—*C.A.* 46, 3860*e*.

The production of O-deficits in SiO_2 by heating *in vacuo* or H_2 caused luminescent properties, and the products of condensed SiO were luminescent. SiO_2 heated in H_2 at 750°C for 2 hrs had 0.05% O-deficit; when heated *in vacuo* at 1250°C for 4 hrs it had 0.01% O-deficit; and when heated in air at 1000° for 24 hrs it had no deficit. SiO_2 was reduced with Si and with C. SiO could exist at least for a few hrs in the solid state and might be able to exist for a long time in solid soln. with SiO_2.

1736. FLINT, D. AND LINDSAY A. W. **Catalytic oxidation of sulfur dioxide on heated quartz surfaces.** *Fuel* **30**, 288 (1951).—*C.A.* **46**, 707*h*.

Catalytic oxidation of SO_2 in flue gas could not take place in a quartz tube with flue gas at 1300°C and elec. heating of the quartz tube to 300°C. Only a very short portion of the tube would reach a max. surface temp. of 600°C and the time of contact in this zone would be of the order of 0.05 sec.

1737. GEFFCKEN, W. **Thin layers on glass.** *Glastech. Ber.* **24**, 143-51 (1951).—*C.A.* **45**, 8730*h*.

The application of interference in multiple-layer complexes was discussed for the production of light filters of highly specified characters. This method could be extended to the application of chalcogenides on glass surfaces to produce light filters with particularly sharp and steep absorption characteristics.

1738. HEAVENS, O. S. **Measurement of the thickness of thin films by multiple-beam interferometry.** *Proc. Phys. Soc.* (London) **64B**, 419-25 (1951).—*C.A.* **46**, 9378*g*.

The small-scale irregularities on the surfaces of optical flats and other optically worked glass were studied. Thickness measurements were made on films of Ag and of LiF with several different metals as reflecting layers. The measurements covered the range 120 A. to 1400 A. With Ag as the reflecting layer an accuracy of ±10 A. could be expected.

1739. KLABUNOVSKIĬ, E. I. AND PATRIKEEV, V. V. **Mechanism of the asymmetrizing effect of metal catalysts deposited on right and left quartz.** *Doklady Akad. Nauk S.S.S.R.* **78**, 485-7 (1951).—*C.A.* **45**, 7860*a*.

The outstanding facts are (1) the necessity of a well-developed metal-quartz, phase boundary, (2) the identity of the sign of the rotation of the catalyzate and of the quartz in the case of destructive asym. synthesis, (3) the opposition of the signs of the rotations of the catalyzate and of the quartz in the case of asym. hydrogenation, and (4) the occurrence of low-temp. catalysis with amorphous catalysts deposited on quartz. Owing to the selective adsorption, the concn. of the (+) antipode at the surface is greater than that of the (-) antipode, and the rate of its reaction at the active centers (at the Cu/quartz boundaries) is greater; as a result, the catalyzate shows (-) rotation. Chromatographic sepn. of the antipodes of 2-butanol through asym. adsorption on left quartz powder of 0.5-0.75 mm grain size, in a column 130 cm long, 2.5 cm in diam., moving downward against a rising stream of the vapor, gave, in 30 cycles, a rotation of 0.05°C, corresponding to 0.22% sepn.

1740. KUBOTA, HIROSHI. **Interference color of a thin film viewed from the theory of colorimetry. II.** *Repts. Sci. Research Inst.* (Japan) **27**, 125-31 (1951).—*C.A.* **46**, 9368*b*.

The interference color of a thin nonmetallic film on glass when the angle of incidence of light is less than 90° was theoretically discussed mainly in reference to the parallel component of the reflected rays. From this and the manipulation of 4 characteristic angles of incidence, a film can possibly be made to any precise thickness for sensitive polarizers, filters, and semitransparent mirrors.

1741. LAING, K. M.; EMHISER, D. E.; FITZGERALD, J. V., AND JONES, R. E. **The location of sodium by nuclear activation in glass-corroded tank block refractories.** *J. Am. Ceram. Soc.* **34**, 380-3 (1951).—*C.A.* **46**, 2256*i*

Clay-grog and fused-cast refractories were subjected to corrosion by molten plate glass at 2650°F, either in Pt crucibles or in a small glass-melting tank. Activation and isotope tracing were used to study the location and concn. of Na. All of the clay-grog samples showed the same distribution of Na. The fused-cast samples all showed greater resistance to corrosion than did the clay-grog samples, but varied considerably in the extent to which Na had penetrated.

1742. NICOL, D. L. **Drying granular solids by high-frequency heating.** *Ind. Chemist* **27**, 339-44 (1951).—*C.A.* **46**, 8905*h*.

The high-frequency heating of water, salt solns., and glass beads (0.19 and 0.49 mm in diam.) wetted with these was studied in an arrangement with a tray between horizontal condenser plates. The frequency was 16-18 Mc. and expts. were run at const. "output power." With decreasing H_2O content the drying rate of glass beads, in g H_2O removed/min., increased rapidly, then more slowly, to a max. at 5-10% H_2O, and then decreased sharply. Heat input decreased in a similar manner. The temp. of the drying bed rose to 100°C and remained const. until most of the H_2O was evapd. when it fell rapidly. The explanation lay in the fact that heat was developed only in the water.

1743. RICE, F. O. AND HERZFELD, K. F. **The mechanism of some chain reactions.** *J. Phys. & Colloid Chem.* **55**, 975-85, discussion 986-7 (1951).—*C.A.* **45**, 26*c*.

A mechanism was proposed in which the chain-starting step was a loss of a H atom to the wall: wall + substrate = adsorbed $H + R_2$. The chain-breaking mechanism may occur in one of two ways according as the large-chain radical R_2 was unstable and decomp. readily into a small radical R_1 and a mol. or whether the large-chain radical was comparatively stable and was present in relatively large concn. in the gas. The two endings were: adsorbed $H + R_1 = R_1H +$ free wall; or adsorbed $H + R_2 = H +$ free wall.

1744. Rood, Joseph K. **Evaporated zinc sulfide films.** *J. Optical Soc. Am.* **41**, 201-2 (1951).—*C.A.* **45**, 4511*c*.

Evapd. ZnS films on glass were studies, including method of prepn., optical properties, and aging effects. The influence of rate of evapn. and pressure during evapn. was noted. Thicknesses and *ns* of the films were detd. from measurements of reflected intensity as a function of wave length. ZnS films were soft just after prepn. but became harder if aged in a dry atm.

1745. Slavyanskiĭ, V. T. **Fused glass on platinum in various gas atmospheres.** *Zhur. Fiz. Khim.* **25**, 1059-63 (1951).—*C.A.* **46**, 2766*d*.

Glass was fused on Pt *in vacuo* (10^{-4}mm) or in a controlled gas atm. and the behavior observed visually. Two different samples of glass were used of compn. Na_2O-$2SiO_2$ and 2.7% Na_2O-97.3% B_2O_3. *In vacuo*, N_2, H_2, CO_2, and H_2O fused glass did not wet the Pt surface. Upon introduction of traces of O_2, fused glass flowed slowly over the whole Pt surface. Thus, wetting of Pt by glass was attributed to an oxide film on the Pt surface.

1746. Stahl, Paul. **Influence of adsorbed gas on the polymorphic transformation of quartz, $\alpha \rightleftarrows \beta$.** *Compt. rend.* **232**, 1669-70 (1951).—*C.A.* **45**, 7422*a*.

The polymorphic transformation of α quartz to β quartz at temps. near 570°C varied according to the nature of the gas used. The liquefaction temps., °K, and the transition temps., °C, were He 4, 578.0; H 20, 577.5; Ne 27, 576.5; air 81, 575.5; A 87, 574.0; CO_2 195, 573.0; H_2O 373, 572.0. The effect was attributed to a diminution of the stability of the surface cryst. system by adsorption of gas.

1747. Amberg, C. H. and McIntosh, R. **Adsorption hysteresis by length changes of a rod of porous glass.** *Can. J. Chem.* **30**, 1012-32 (1952).—*C.A.* **47**, 4686*h*.

As adsorption occurs with increasing P/P_0 up to 0.6 (inflection point in the isotherm), a regular extension of a porous glass (Vycor) rod occurs. From $P/P_0 = 0.6$ to $P/P_0 = 0.87$, the adsorption isotherm rises steeply but the rod length remains virtually const. This is interpreted as resulting from a compensation of forces: a further reduction of surface free energy due to capillary filling and formation of concave menisci compensated by the neg. pressure created under the menisci. Thus no net change in length occurs as larger and larger pores are filled. The rod begins to lengthen again with adsorption at P/P_0 above 0.87. When water is desorbed in the region below $P/P_0 = 0.87$, although very little is removed, marked shortening of the rod occurs (reversibly) down to $P/P_0 = 0.70$. The no. of pores/g is about 10^{17}, the surface area about 129 m^2/g.

1748. Antal, John J. and Weber, A. H. **Tracer method for the thickness measurement of thin bismuth films.** *Rev. Sci. Instr.* **23**, 424-6 (1952).—*C.A.* **47**, 2610*f*.

A direct method for the detn. of Bi film thickness was based on the counts/min. produced by a Bi film and those produced by a standard film of known thickness. The films are made by evapn. from a furnace of Bi contg. Bi^{210} (as tracer). The standard was calibrated by evapn. and condensation of the Bi onto glass and weighing the relatively thick (about 300 A.) film.

1749. Barrer, R. M. and Barrie, J. A. **Sorption and diffusion in porous glass.** *Proc. Roy. Soc.* (London) **A213**, 250-65 (1952).—*C.A.* **46**, 10772*i*.

Sorption, gas-phase diffusion in mol. streaming, and surface diffusion were studied using O_2, N_2, A, SO_2, and NH_3. Porosity, surface area, and mean pore radius were evaluated. The Henry's law sorption coeffs. were derived for O_2, N_2, A, K, methane, and ethane. The microstructure was so fine that nonsorbed gases diffused only by mol. streaming at a pressure of half an atm.

1750. Bishop, F. L. and Mowrey, F. W. **Deterioration of the surface of sheet glass.** *Am. Ceram. Soc. Bull.* **31**, 13-15 (1952).—*C.A.* **46**, 2253*b*.

The accelerated test appeared to be a dependable guide to the breakdown of the surface during com. storage. To det. surface breakdown samples 2 × 2 in. cut from the sheets were boiled under reflux in 400 ml of distd. H_2O, and the cond. of the solns. was detd.; detns. of pH were of less value. Surface breakdown was increased greatly by dusting with wood flour during packing, but was decreased somewhat by coating the glass with SO_2 in the lehr during drawing.

1751. Blanc-Lapierre, Andre; Perrot, Marcel, and David, Jean P. **Electric properties of very thin layers of silver, aluminum, and silicon.** *Compt. rend.* **234**, 1133-5 (1952).—*C.A.* **46**, 8446*f*.

Films of the above metals, approx. 0.01 μ thick, were deposited on glass plates provided with Ag electrodes. The elec. resistivity of the films increased with time, very rapidly at first and subsequently at a much slower rate. In the case of Ag, stabilization occurred much sooner than with Al or Si. With Al and Si films, a "drag" phenomenon was described characterized by deviation of the current-voltage curves for increasing and decreasing voltage changes.

1752. Boer, J. H. de and Steenis, J. van. **The behavior of hydrogen atoms on surfaces. I. Adsorption, reflection, and reaction on the surfaces of glass and of inorganic salts.** *Proc. Koninkl. Ned. Akad. Wetenschap.* **55B**, 572-7 (1952).—*C.A.* **47**, 5759*f*.

H atoms on the surfaces of glass, rock salt, LiF, and CaF_2 were strongly adsorbed on these surfaces to form a nearly completed unimol. layer at room temp. A small fraction of H atoms impinging on the 1st layer reacted with adsorbed atoms to form H_2, whereas other H atoms were reflected or adsorbed only for a short time. The 1st layer of H atoms on a cleavage face of LiF formed a two-dimensional pattern of the regularity and dimensions of the surface F ions. At liquid-air temp. a 2nd layer of H atoms may be adsorbed and formed the "nonrecondensable gas" described by Langmuir.

1753. Boettcher, A. **Glass surfaces in a high vacuum.** *Glastech. Ber.* **25**, 347-53 (1952).—*C.A.* **47**, 1347*f*.

Sorption phenomena as functions of the chem. compn. of glass are reviewed with applications to the production of electron tubes and to deposition of metallic films by evapn. *in vacuo*.

1754. BRIEGLEB, G.; SCHOLZE, H., AND STROHMEIER, W. **Is hydrazine associated in the gaseous state? Vapor density and adsorption measurements.** *Z. physik. Chem.* **199**, 15-21 (1952).—*C.A.* **46**, 8918*d*.

Vapor-d. measurements on N_2H_4 at 30-60 °C in the range of relative pressures greater than 0.5 showed a steady increase in f, $f = p_0v_0/pv$, with increase in p/p_0 at const. temp. This increase in f was due to adsorption on the glass walls and not to an assocn. of N_2H_4 mol. This adsorption was of the same order of magnitude as for H_2O. MeNH-NHMe, Me_2N-NH_2, and $(NH_2$-$CH_2)_2$ were less strongly adsorbed, to an extent about 0.1 as much.

1755. COLOMBANI, ANTOINE AND RANC, GASTON. **The thermal evolution of thin gold layers and the transformation points of Fery.** *Compt. rend.* **234**, 1757-9 (1952).—*C.A.* **46**, 9403*h*.

The resistance of Au layers 2000-10,000 A. thick, evapd. onto a polished sheet of SiO_2, was investigated during heating to elevated temps. Between 20 and 140 °C the resistance decreased because of a crystn. effect. Beyond 140 °C the resistance increased, and a reversible curve was obtained on alternating cooling and reheating for layers more than 5000 A. thick.

1756. GURNEY, C. **The effect of surface condition on the strength of brittle materials.** *Symposium on Properties of Metallic Surfaces* (Inst. Metals, London) **1952**, 145-60.—*C.A.* **47**, 2564*b*.

The strength of plastics and of glass, except when drawn into fine fibers, is not nearly so dependent on the mech. perfection of the surface. In the case of glass, the kind of damage that occurs during normal handling results in a strength about half that of glass with a perfect surface. Deliberate scratching of the surface with a diamond reduces the strength by a further factor of 2.

1757. HOLLAND, L.; MOUTON, C., AND HACKING, K. **Optical properties of layers of iron oxide obtained by evaporation.** *Rev. optique* **31**, 209-17 (1952).—*C.A.* **46**, 8968*h*.

Iron oxide was evapd. on glass in vacuum to form light-absorbing layers. The reduction could be minimized by (1) evapg. at higher residual gas pressures (about 1 μ), (2) subsequent baking of the film in air, or (3) evapg. mixts. of Fe_2O_3 and transparent oxides. The reflectivity could be further reduced by deposition of an antireflection film of MgF_2.

1758. KAISER, RUDOLF. **Disturbance centers of high concentration in alkali halides.** *Z. Physik* **132**, 482-96 (1952).—*C.A.* **46**, 9995*i*.

By evaporating *in vacuo* both alkali halides and free alkali metal and condensing the vapor on a quartz plate kept at low temp. (20-90° K) thin layers ($<1\mu$) of very high color-center concn. can be produced. In the system KCl + K a concn. of 1.1% can be obtained. An excess of a foreign alkali or alk. earth metal but not of a heavy metal can also serve as electron donor for the occupation of perturbation centers. However, in cryst. KCl plus 2% AgCl as base and 2% K as electron donor at. Ag can be identified with a new absorption band at 285 mμ. It is produced by the combination of Ag^+ ions with electrons migrated from the place of condensation of the K atom.

1759. LEGER, M. **Adsorption of gases by glass.** *Silicates ind.* **17**, 121-5 (1952).—*C.A.* **47**, 1347*f*.

Volumetric and gravimetric detns. showed SO_2 to be adsorbed more rapidly than CO_2. After the first (more rapid) sorption was completed, the const. rates of (slower) sorption decreased in the order H_2O, SO_2, CO_2.

1760. LYASHENKO, V. I. AND STEPKO, I. I. **Influence of adsorption on surface charges and conductivity of a semiconductor.** *Izvest. Akad. Nauk S.S.S.R., Ser. Fiz.* **16**, 211-17 (1952).—*C. A.* **46**, 10018*d*.

Cu_2O samples were made by vacuum deposition of Cu on quartz, heating for 30-45 min. at 1030 °C, and quenching with H_2O. The samples were aged by exposure to air for 1 month. The layer thickness was 1×10^{-5} cm, and the Hall const. was 12-18 sq. cm v.$^{-1}$ sec^{-1}; this indicated smaller mobility than in thick samples. CuO, ZnO, and CdO samples were obtained by vacuum deposition of the metal and oxidation. MnO_2 samples were obtained by decompn. of $Mn(NO_3)_2$. In CdO the work function was increased by adsorption. The "screening" length was measured by measuring the cond. of the semiconducting plate forming 1 electrode of a condenser while applying a field to the other electrode.

1761. MORITA, NOBUYOSHI. **Evaporated magnesium fluoride films.** *J. Sci. Research Inst.* (Tokyo) **46**, 127-30 (1952).—*C.A.* **47**, 4159*h*.

The ratio of transmissivity of glass coated with a ¼-wave film in vacuum to that of plain glass was measured. The highest calcd. n was $1.39_1 \pm 0.007$ where the temp. of the glass was 20 °C during the deposition. Max. transmissivity was at 4900 A. The lowest n was $1.36_0 \pm 0.003$ where the temp. was 350 °C.

1762. NORTON, FRANCIS J. **Diffusion of gases through solids.** *Gen. Elec. Rev.* **55**, No. 5, 28-9 (1952).—*C.A.* **46**, 10743*e*.

The rate of permeation of He through various glass walls was measured by noting evapn. rates of liquid N_2 out of Dewar flasks made of the glasses under test, and the outside surfaces of which were exposed to He to diffuse it into the vacuum space, thereby affecting the quality of the Dewar flask.

1763. OVERBEEK, J. TH. G. AND SPARNAAY, M. J. **Long-range attractive forces between macroscopic objects.** *J. Colloid Sci.* **7**, 343-5 (1952).—*C.A.* **46**, 10717*f*.

The attractive forces between flat, highly polished glass and quartz plates were measured in a dry system evacuated to 0.04 mm Hg pressure and in the presence of an ionizing source to prevent electrostatic effects. The force F, measured by the bending of a spring on which one of the plates was mounted, increased as the distance D between the plates decreased from 15,000 to 5000 A., following an equation: $F = (\text{const.})/D^n$, where n had a value of approx. 3.

1764. PIPER, WM. W. **Growth of zinc sulfide single crystals.** *J. Chem. Phys.* **20**, 1343 (1952).—*C.A.* **46**, 10765*c*.

ZnS crystals (wurtzite structure) up to 5 mm long and 3 mm² cross section were grown on a quartz wall by condensation from the vapor phase. Pure ZnS was evapd. at 1170-1200°C and condensed at 1070-1120°C. Small amts. of Cu or Ag could be incorporated by adding $Cu(NO_3)_2$ or $AgNO_3$ to the vaporization chamber.

1765. SARAKHOV, A. I. **High-sensitivity adsorption balance.** *Doklady Akad. Nauk S.S.S.R.* **86**, 989-92 (1952).—*C.A.* 47, 5729*c*.

A quartz-thread torsional balance, permited an accuracy of 8×10^{-8}g per 1 g, and measurement of a total change of wt of 2.3-2.5g. The use of the balance was illustrated by an adsorption isotherm of C_6H_6 vapor on highly dispersed quartz at 20°C.

1766. SATOR, ABDELHAK. **A reversible cell in which the electrolyte is a crystal deposited in a thin layer by evaporation.** *Compt. rend.* **234**, 2283-5 (1952).—*C.A.* 46, 9453*e*.

The $PbCl_2$ electrolyte was deposited as a thin layer (approx. 1 μ) over a thin layer of Ag on glass and then covered by another layer of Ag. Prolonged charging at 0.5 microamp. formed AgCl on one Ag electrode and Pb on the other. The e.m.f. of the cell at 22°C was 0.460 v. and the temp. coeff. between 21° and 26°C was -3×10^{-4} v./degree.

1767. THOMPSON, JOHN B.; WASHBURN, E. ROGER, AND GUILDNER, L. A. **Adsorption of carbon dioxide by glass.** *J. Phys. Chem.* 56, 979-81 (1952).—*C.A.* 47, 2010*i*.

"Scotchlite" brand glass beads yielded a surface area of 0.158 m² per g by the application of the B.E.T. equation to the adsorption of CO_2 at about -77°C. The area calcd. from observations of the particle-size distribution was 0.151 m² per g. Type 120 beads yielded an area 1.7 times the geometric area if sample was degassed at 180°C; however, the surface area was up to 3 times as large with incomplete degassing to remove water vapor as with degassing at 180°C. Roughness factors increased by factors of 21 and 12 for types 520 and 120, resp., on soaking the beads in water at room temp. for 33 days. Measurements on glass wool yielded a type-III isotherm.

1768. TOLSTOĬ, D. M. **Slip of mercury on glass.** *Doklady Akad. Nauk S.S.S.R.* **85**, 1329-32 (1952).—*C.A.* 47, 1450*g*.

The velocity v of rise of the meniscus of Hg was detd. as a function of the pressure, in extremely fine glass capillaries obtained by drawing out a thermometer capillary to a thread. The effective capillary radius r was detd. by calibration with H_2O and checked with C_6H_6. Measurements with Hg at 21.3 ± 0.1°C, in capillaries of $r = 13.3$ and 3.48 μ, gave an apparent $\eta = 1.45$ and 1.21, resp. (as against the normal $\eta_0 = 1.547$).

1769. YAROSLAVSKIĬ, N. G. AND KARYAKIN, A. V. **Changes of the infrared OH absorption band of microporous glass on low-temperature adsorption of oxygen and nitrogen.** *Doklady Akad. Nauk S.S.S.R.* **85**, 1103-6 (1952).—*C.A.* 47, 967*g*.

Microporous glass evacuated at +550°C and then cooled to -180°C showed a narrow absorption band with a sharp max. at 1.365 μ (7326 cm^{-1}) corresponding to the 1st harmonic of the valence vibration in the O—H bond, and a low secondary max. at 1.380 μ (724.5 cm^{-1}). Upon admission of N_2, the 1st peak decreased gradually and disappeared completely after 20-30 min. Heating up to room temp. restored the original spectrum, as a result of desorption of the N_2. On admission of O_2, at -180°C, the OH peak disappeared instantaneously, and a secondary max. appeared, more diffuse than with N_2. O_2 is held at the glass surface more firmly than N_2.

1770. LIANG, S. CHU. **Physical adsorption at low coverages.** *J. Phys. Chem.* 57, 84-7 (1953).—*C.A.* 47, 5211*a*.

The adsorption of Kr and A on 3-mm glass spheres shows the glass surface to be heterogeneous. Isotherm data for low surface coverages show that repeated treatment at 300°C *in vacuo* progressively increases the no. of highly active sites but leaves the total no. of adsorption sites unchanged. Addnl. adsorption on the monolayer is similar to that on a uniform surface, even though the glass surface is heterogeneous.

1771. NORTON, FRANCIS J. **Helium diffusion through glass.** *J. Am. Ceram. Soc.* 36, 90-6 (1953).—*C.A.* 47, 4567*i*.

A mass spectrometer was used both as an analytic tool and to det. the rate of diffusion of He, at -80 to 600°C, through 9 types of glass, including fused SiO_2, borosilicate, phosphate, soda lime, combustion tubing, x-ray shield, Pb borate, and chem. glassware. The highest rates of diffusion were for fused SiO_2 and Corning Vicor glass (SiO_2 96, B_2O_3 3, Al_2O_3 1%); the lowest were for x-ray shield and Pb borate glasses. The rate of diffusion decreased enormously with decrease in the percentage of SiO_2, B_2O_3, P_2O_5 in the glass.

1772. SCHULZE, A. AND EICKE, H. **Electric behavior of thin metal layers.** *Metall* 7, 171-82 (1953).—*C.A.* 47, 6725*h*.

Thin layers were obtained by cathode sputtering in a vacuum. For Au and Ir the temp. coeff. of resistance was zero at resistance values of 10^6 ohms, yet here the required layer thickness was still so thin that the loose structure had no definite value of resistance. With Ni the temp. coeff. was pos. at low magnitudes of resistance and neg. at high magnitudes of resistance. No conducting Fe layer was established, although upon the base a visible metal layer could be perceived. With Sb the measured temp. coeff. was neg. and the same linear relation as found with other metals existed. In the case of Cu, Ag, and Mn the detn. of the temp. coeffs. was not possible.

I-10. Gases on Silica Gel

1773. ZEL'DOVICH, A. G. **Drying oxygen as a means for combating the corrosion of oxygen cylinders.** *Avtogennoe Delo* 11, No. 8-9, 25-7 (1940).—*C.A.* 37, 2893[2].

To avoid corrosive attacks upon O_2 cylinders, the moist O_2 must be well dried by means of silica gel.

1774. GROTH, W. AND HARTECK, P. **Study of adsorbent surfaces by means of xenon isotopes.** *Naturwissenschaften* 29, 535-6 (1941).—*C.A.* 37, 2634[9].

With 25 g of silica gel, 6.8 cc. of a heavy Xe mixture was adsorbed at -125°C. The adsorbent was then treated with 8 cc. of a light Xe mixture, ½ hour at -125 °C. Upon desorption by slow temperature rise in 3 fractions no difference in composition was found. The same experiment was conducted with 14 g of activated carbon. The desorption temperatures for activated carbon were higher and the lighter isotopes appeared at higher concentrations in the first fractions. The heavier isotopes, first adsorbed, were found in the last fractions.

1775. LADKA, F. AND PROKOP, V. **Preparation of granular active silicic acid on a laboratory scale.** *Chem. Listy* 35, 218-19 (1941).—*C.A.* 37, 4288[4].

A water glass soln. (7.49% Na_2O, 25.08% SiO_2, dild. 1:1 with H_2O) was poured with stirring into HCl (30 cc. concd. HCl, 200 cc. H_2O, methyl orange) until the resulting soln. was weakly acidic. When evapd. on a water bath until 80% H_2O, a gel formed which was cut into small pieces and washed with H_2O by decantation until absence of Cl^-. The gel was dried above 180°C and the final form of the product depended upon the method of drying.

1776. WACHTER, H. **The adsorption capacity of silica gels for water vapor (drying in vacuum apparatus).** *Chem. Fabrik* 14, 376-8 (1941).—*C.A.* 37, 2242[6].

Seven products with various pore sizes were investigated at vapor tensions between 3.6 and 30.9 mm Hg. Comparison of small-, medium- and wide-pore gels showed that small-pore gels were best for drying gases. When drying in chambers evacuated with the usual lab. app., it was not possible to reduce the pressure much below 0.1 mm Hg with silica gel as the drier, and under high vacuum (10^{-3} mm or less) the use of these materials was of no value.

1777. BÉKÉSY, NIKOLAUS v. **A drying tube in which a high vacuum is obtained by adsorption.** *Biochem. Z.* 312, 107 (1942).—*C.A.* 37, 6500[8].

A vacuum drying tube of the Abderhalden type was provided with moistened silica gel. The tube was evacuated with a water pump (20-35 mm Hg) and a slow stream of air introduced at the opposite end, to displace the air with water vapor from the moistened silica gel. The evacuation was continued until the gel temp. was 270-280°C. The system was then closed and allowed to cool. Pressures of 0.05 mm were always obtained. Benzene or alc. could be substituted for water to moisten the gel.

1778. DUNTZE, RICHARD. **Scientific basis and technical progress in the use of silica gel.** *Chem.-Ztg.* 66, 196-9 (1942).—*C.A.* 38, 1931[9].

The prepn. of SiO_2 gel, its structure and properties are reviewed historically. The principal use is for the drying of gases. Static and dynamic considerations of drying are discussed.

1779. ISHIGAKI, YOKA. **Silica gel from iron ore tailings. I, II.** *J. Soc. Chem. Ind. Japan* 45, 73-8 (1942).—*C.A.* 43, 1925*i*.

SiO_2 gel was prepd. from the Fe ore tailings which contained 75% of SiO_2. About 70% (or 52.5% of the ore) was recovered as SiO_2 gel when the material was fused with 3 times its wt of Na_2CO_3. The SiO_2 gel contained a small amt. of Fe_2O_3. The max. adsorption for C_6H_6 was 65% of the wt of SiO_2 gel with very small amt. of residual C_6H_6 found upon desorption.

1780. MAGNUS, A. **Adsorption capacity of silica gels.** *Z. ver. deut. Ing., Verfahrenstech.* 1942, No. 4, 102.—*C.A.* 38, 4490[4].

Adsorption isotherms of seven com. sample of silica gel were obtained and the results shown graphically. The adsorption isotherms all indicated capillary condensation.

1781. RANDS, M. B. **Moisture problem in transformer insulation.** *New Zealand J. Sci. Tech.* 23B, 217-23 (1942).—*C.A.* 38, 1584[2].

Large transformers were shipped to New Zealand with the oil removed and with the case either sealed or fitted with a breather contg. silica gel. In spite of such precautions the paper or pressboard insulation frequently acquired some moisture and this should be removed before the transformer is put into service. $CaCl_2$ was formerly used as the desiccant in the breather tubes in shipment, but this was generally now replaced by silica gel. The use of $CoCl_2$ as an indicator for moisture in the silica gel had not proved satisfactory.

1782. REYERSON, L. H. AND CINES, MARTIN R. **Adsorption of propane and propylene by silica gel and metallized silica gel.** *J. Phys. Chem.* 46, 1060-8 (1942).—*C.A.* 37, 2977[2].

Sorptions of propane and propylene on silica gel and on silica gel metallized with Pd were measured at -25°, 0° and 35°C. The olefin was more strongly sorbed by the metallized surface than by the untreated gel, and it was more strongly sorbed than the paraffin. The results were in reasonably good agreement with the B.E.T. theory.

1783. WHITE, J. F. **Manufacture of silica aerogel-description of process and heat transfer problems.** *Am. Inst. of Chem. Engrs.* 38, 435 (1942).

The method of preparing aerogels with particular emphasis on autoclaving a silica alcogel was described. The major portion of heat transfer was accomplished by convection, the amount being transferred by radiation and conduction being negligible in the pilot plant autoclave described. The advantages of diphenyl vapor as a heat transfer medium was described.

1784. ANON. **Production of silica aerogel.** *Chem. & Met. Eng.* 50, 144-47 (February) 1943.

The large scale production of silica aerogel at the Boston plant of the Monsanto Chemical Co. was described and illustrated by photographs. The process depended upon the heating of a silica gel system satd. with EtOH to temps. and pressures above the critical state for the liquid phase present in the gel. The heating was done at 550°F and the pressure maintained at 1150 lb.

1785. BRINER, E. AND LACHMANN, A. **Oxidation of SO_2 by O_2 or O_2-O_3 mixtures in presence of silical gel. Adsorption of O_3 on silica gel, alumina gel and cotton.** *Helv. Chim. Acta* 26, 346-57 (1943).—*C.A.* 37, 6532^2.

SO_2-O_2 mixts. at 0°, 100°, 200° and 400°C in contact with partially dehydrated silica gel formed very little SO_3. The use of O_3 together with silica gel had little value for H_2SO_4 manuf. The reaction probably proceeded through formation of H_2SO_3 on the gel and subsequent oxidation (accelerated by O_3) to H_2SO_4. Adsorption of O_3 on silica gel increased greatly as the temp. decreased from 0° to -80°C; at the same time the proportion of O_3 decompd. decreased. Alumina gel gave nearly the same magnitude of O_3 adsorption and decompn.

1786. CRALLEY, LESTER V.; SHEA, THOMAS E., AND CRALLEY, LEWIS J. **Modification of the silica gel method for the determination of atmospheric organic solvent vapors.** *J. Ind. Hyg. Toxicol.* 25, 172-3 (1943).—*C.A.* 37, 5926^9.

CCl_4 was adsorbed by silica gel, then removed by EtOH, and the gel decompd. by alc. KOH. Between 90 and 99% of CCl_4 was recovered as Cl^- by this method.

1787. DOBROWSKY, ALFRED. **Diffusion equations, preparation of their models, and diffusion experiments in silica gel. I. Theory of the model and application in unlimited space. II.** *Kolloid-Z* 104, 87-96 (1943); 105, 56-70 (1943).—*C.A.* 38, 2254^6, 2545^2.

A hydraulic diffusion model was described consisting essentially of a no. of vertical glass tubes connected in series by means of capillary tubes and supplied with liquid by means of a const.-level device. The results of some expts. on diffusion in silica gel were used to illustrate the math. methods.

1788. CAPELL, R. G.; HAMMERSCHMIDT, E. G., AND DESCHNER, W. W. **Dehydration of commercial gases by solid adsorbents.** *Ind. Eng. Chem.* 36, 779-84 (1944).—*C.A.* 38, 6520^2.

Silica gel, activated alumina grade A, florite (a natural bauxite), and Hi-florite (florite impregnated with 12-14% manganous chloride) were tested in units 7 3/8 in. inside diam. with adsorbent beds 34 1/2 in. deep. Tests were run on dehydrating natural gas, and reactivation gas supplied by the com. plant heater at about 350°F. All 4 adsorbents showed initial increases in capacity followed by slow declines in 29 runs on each material. Oil vapors in humid gas seemed to cause the most pronounced decline. H_2S, expecially along with O_2, and nonvolatile compds., also caused decline in capacity. Data were presented for the pressure drop through adsorbent beds for various screen analyses between 2 and 8 mesh and varying gas velocities.

1789. HIGUCHI, IZUMI. **Sorption isotherms for benzene on silica gels with special reference to the condition of their preparation.** *Bull. Inst. Phys. Chem. Research (Tokyo), Chem. Ed.* 23, 40-6 (1944).—*C.A.* 43, 7774*b*.

An excellent SiO_2 gel was prepd. as follows: dil. 200 cc. water glass (d. 1.26) 17 times by vol. and gradually add 400 cc. 2 *N* $FeCl_3$ to pH 4. Let stand 11 days at room temp. and dry 44 hrs at 50°C. Filter the product and wash with hot water 2 hrs, then with 6 N HCl, finally wash by decantation and dry.

1790. HIGUCHI, IZUMI. **Dielectric properties of substances in the sorbed condition. III. Coagulation of nitrobenzene sorbed on silica gel.** *Bull. Inst. Phys. Chem. Research (Tokyo), Chem. Ed.* 23, 359-66 (1944).—*C.A.* 42, 6593*e*.

The dielec. polarization of nitrobenzene sorbed on silica gel at -75 to 75°C was detd. The value for the liquid increased with increase in capillary diam. From the change in dielec. polarization, it appeared that a condensed liquid coagulated below the m.p., and ΔT was greater the smaller the capillary diam. Since there was no lowering of the m.p. when adsorbed, the lowering of dielec. polarization at low temps. was attributed to abnormal dispersion arising from the adsorbing forces.

1791. KATSURAI, TOMINOSUKE AND NAKAHIRA, MITSUOKI. **The change in silica sol caused by autoclaving.** *Bull. Inst. Phys. Chem. Research Chem. Ed.* 23, 345-6 (1944).—*C.A.* 42, 5304*g*.

By dialyzing a soln. of Na_2SiO_3 against dil. HCl, a stable silica sol was obtained. the sol was acidic and showed no cataphoresis. By autoclaving at 200°C, the sol was transformed into a gel, which turned to a sol by shaking. This transformation could be repeated. The sol did not transform into a gel simply by standing.

1792. KUBELKA, PAUL AND PROSCHKA, RUDOLF. **The super cooling of water in a silica gel.** *Kolloid-Z.* 109, 19 (1944).—*C.A.* 41, 4995*c*.

The water enclosed within the capillaries of a silica gel tended to undergo supercooling. The supercooling temp. was sharply reproducible and independent of the rate of cooling. The solidification of the water in the gel was followed by thermal analysis in a bulb filled with Hg.

1793. PERNELL, CARROLL. **Collection and analysis of halogenated hydrocarbon vapors employing silica gel as an adsorbing agent.** *J. Ind. Hyg. Toxicol.* 26, 331-3 (1944).—*C.A.* 39, 886^1.

Silica gel was an efficient adsorbent of halogenated hydrocarbons under normal sampling rates (1-2 liter/min.) and with concns. normally encountered in industry. The adsorbed compds. were completely decompd. by digesting with alc. KOH or by burning an alc. soln. of them. A desiccating agent was unnecessary for air 40-60% satd. with water vapor.

1794. FOSTER, A. G. **Low-pressure isothermals and heats of sorption.** *J. Chem. Soc.* 1945, 360-6.—*C.A.* 39, 4785^7.

Sorption isothermals of water, EtOH, toluene, dioxane, *n*-octane, and CCl_4 were detd. at 25°C on silica and Fe_2O_3 gels. All gave the linear plot of p/c against p. Heats of sorption were calcd. by means of the Clapeyron equation and compared with the values calcd. by statistical theory from the const. of Langmuir's equation. The entropy changes accompanying the sorption process were shown to be consistent with the view that the adsorbed mols. behaved as three-dimensional oscillators.

1795. FREIDLǏN, L. KH.; BALANDIN, A. A.; FRIDMAN, G. A., AND LEBEDEVA, A. I. **Mechanism of vapor-phase catalytic substitution by hydroxyl of halogen attached to aryl group.** *Bull. acad. sci. U.R.S.S., Classe sci. chim.* **1945**, No. 2, 154-61 (in English, 162).—*C.A.* **39**, 4792¹.

A theory of the vapor-phase hydrolysis of aryl halides, catalyzed in the liquid phase by Cu and in the vapor phase by SiO_2 gel, was advanced.

1796. GYANI, B. P. AND GANGULY, P. B. **Adsorption in relation to constitution. IV. Adsorption of hydrocarbons by silica gel.** *Bull. Patna Sc. Coll. Phil. Soc. No.* **15**, 29-39 (1945).—*C.A.* **42**, 1101*h*.

The adsorptions of pentane, heptane, octane, cyclohexane, benzene, tolune, and xylenes were measured on silica gel at 35°C. Silica gel adsorbed about one-third its own weight of the various org. vapors near max. adsorption. The orientation of adsorbed paraffins was analogous to the orientation obtained for the adsorption of dibasic acids at low concn. With aromatic hydrocarbons, the mols. stood on their edges with the plane of the ring perpendicular to the surface. The behavior of benzene and its homologs was explained by an orientation brought into play by substitution in different positions in the ring. Cyclohexane mols. laid flat on the surface at low relative pressures, but at higher relative pressures, a tilting of the plane occurred owing to the closer packing, the mols. tending to stand on edge.

1797. TAYLOR, ROGER K. **Water-adsorption measurements on silica gel.** *Ind. Eng. Chem.* **37**, 649-52 (1945).—*C.A.* **39**, 3989⁸.

Adsorption of H_2O on silica gel was independent of temp. over a limited range at const. relative humidity. The measurements were extended to higher temp. in a special static-method app. permitting the detn. of adsorption in the absence of air, the use of measured amts. of air-free water, and activation and deaeration of the SiO_2 gel of known water content. In the activation treatment, it was noted that the last portions of adsorbate removed from the gel contained more air than the first portions. The isosteres, plotting relative humidity vs. temp., were straight lines for percentages of adsorbed water from 1 to 30%, for relative humidities to 75% and temp. to 230°. Isosteres at 5% and 30% added water did not show hysteresis in the presence of air added at 10 mm partial pressure.

1798. RODE, T. V. AND BALANDIN, A. A. **A physicochemical study of silica-gel catalysts.** *Acta Physicochim. U.R.S.S.* **21**, 853-68 (1946) (in English).—*C.A.* **41**. 1920*c*.

The best unmixed catalysts for the vapor hydrolysis of chlorobenzene were silica gels. Differential heating curves were given for 2 samples, an imported one and one prepd. by the method of Okatov. Compn.-temp. diagrams (x-t) plotted up to 1125°C were obtained for both samples and there were breaks in the curves in the intervals 185-270°C and 380-430°C corresponding to the decompn. of 2 hydrates of a definite compn. The thermal irreversible inactivation of the catalyst, which started at 480-550°C, was due not to any change in their inner structure, but chiefly to other factors, probably to the elimination of a definite amt. of chemically bound H_2O.

1799. CASTRO Y RAMOS, R. DE. **Highly adsorbent silica gels. II. Gels made from copper silicate.** *Anales fís. y quím. (Madrid)* **43**, 245-60 (1947).—*C.A.* **41**, 6376*b*.

Activity of the gel increased with cold HCl and diminished with boiling HCl. Adsorbent capacity varied inversely with HCl and Na-silicate concn. and increased with temp. of soln. and quantity of $CuSO_4$. Time of washing the gel was inversely proportional to HCl concn. used to produce the gel. The adsorbing surface was calcd. from the heat of moistening and varied between 733 and 1713 m^2/g.

1800. KISELEV, A. V.; AVGUL, N. N. MIKOS; ROMANCHUK, M. A., AND SHCHERBAKOVA, K. D. **Thermodynamic properties of adsorption films on silica gel.** *J. Phys. Chem. (U.S.R.R.)* **21**, 1223-36 (1947) (in Russian).—*C.A.* **42**, 2489*a*.

The adsorption and desorption isotherms at 14-20°C were detd. for a silica gel for H_2O, MeOH, and n-heptane. The heat of wetting by the evacuated gel was 15.7, 16.7 and 6.5 cal/g for H_2O, MeOH, and heptane, resp. The area of the gel was 180-330 m^2/g according to the B.E.T. method and assuming the adsorbed film to have the usual surface tension at the start of the hysteresis loop. The most frequent radius of the pores was calcd. to be 40-60A.

1801. KRISHNAPPA, T.; RAO, K. SUBBA, AND RAO, B. SANJIVA. **Hysteresis in sorption. XI. Permanence of sorption-desorption hysteresis.** *Proc. Indian Acad. Sci.* **25A**, 162-73 (1947).—*C.A.* **41**, 5358*d*.

Silica gels were pptd. by interaction of Na silicate soln. and AcOH at 25° and 100°C by preheating the solns. and by autoclaving for 3 hrs at 120°C; TiO_2 gels pptd. from a soln. 0.5 *N* in $TiCl_4$ and 0.2 *N* in HCl by a 2% excess of 0.7 *N* NH_4OH at 25°C and boiling; Al_2O_3 gels pptd. from 0.5 *N* $Al_2(SO_4)_3$ soln. with excess of 0.5 *N* NH_4OH at 25°C and boiling. The sorption-desorption cycles for H_2O at 30°C were detd. after degassing to 0.001 mm pressure. Equil. was reached in 6 hrs for silica gel, 4 hrs for TiO_2, and 3 days for Al_2O_3. The hysteresis loops were smaller in area for the gels pptd. at the b.p.

1802. KRISHNAPPA, T.; RAO, K. SUBBA, AND RAO, B. SANJIVA. **Hysteresis in sorption. XII. Influence of the temperature of activation of silica gel on the hysteresis effect.** *Proc. Indian Acad. Sci.* **25A**, 174-80 (1947).—*C.A.* **41**, 5358*g*.

Silica gel pptd. at 25°C was activated by heating in a stream of dry air at 35°, 70°, 140°, 300°, 500°, 750°, and 1000°C. From 35° to 140°C there was a decrease in sorptive capacity with H_2O from 84.2 g to 63.1 g per 100 g of gel at satn. pressure, with a small decrease in the area of the hysteresis loop. Above 500°C there was a marked decrease in sorption and at 1000°C the capillary vol. had decreased to ⅓ the vol. at 500°C.

1803. Krishnappa, T.; Rao, K. Subba, and Rao, B. Sanjiva. **Hysteresis in sorption. XIII. Mode of preparation of silica gel and its influence on hysteresis.** *Proc. Indian Acad. Sci.* **25A**, 181-5 (1947).—*C.A.* **41**, 5358*h*.

Transparent and opaque silica gels were activated at 450°C for 4 hrs, after which the residual H_2O was 5.2% and 5.57%, resp. Sorption-desorption cycles on H_2O at 30°C requiring 1 month per cycle, were detd. after degassing. At low vapor pressures, the gels showed about the same sorption. The hysteresis loops were permanent and reproducible, but the method of prepn. of the gel had a profound effect on their shape and size.

1804. Milligan, W. O. and Rachford, Henry H., Jr. **The effect of heat-treatment on the sorption-desorption hysteresis characteristics of silica gel.** *J. Phys. & Colloid Chem.* **51**, 333-59 (1947).—*C.A.* **41**, 2625*d*.

Com. silica-gel samples, conditioned 6 weeks in air satd. with water vapor attained a const. wt. The samples were heated for 2 hrs to temps. of 30° to 930°C and allowed to come to equil. with water vapor at 12°C. The samples were thoroughly evacuated and the sorption and desorption isotherms were taken for each temp. From a no. of pore-distribution curves for silica gel taken at different temps. it is concluded that the heat-treatment of the original gel did not appreciably modify the distribution or size of the pores, but appeared to diminish their no.

1805. Neĭmark, I. E. and Khatset, F. I. **Effect of the surface tension of the coagulant on the formation of the internal structure of silica gels.** *Kolloid. Zhur.* **9**, 289-96 (1947).—*C.A.* **47**, 947*g*.

Acids having different surface tensions γ were added to a Na silicate soln., d. 1.12. The pore vol. V of the silica gels obtained was, for example, 0.618 for $\gamma = 77$ and 0.726 for $\gamma = 47$ dynes/cm. The max. (liquid) vol. v of adsorbed C_6H_6 vapor was 0.53 and 0.75 for $\gamma = 77$ and 47, resp. The max. adsorption of AcOH (from CCl_4) was 3.59 and 3.00 millimol./g; the calcd. surface was 522 and 436 m^2/g for $\gamma = 77$ and 47, resp. The most frequent pore radius was 25 μ and 35 μ for $\gamma = 77$ and 60, resp.

1806. Plank, C. J. and Drake, L. C. **Differences between silica and silica-alumina gels. I. Factors affecting the porous structure of these gels.** *J. Colloid Sci.* **2**, 399-412 (1947).—*C.A.* **42**, 436*i*.

The particle d. by Hg displacement and surface area by N_2 adsorption were detd. for a series of gels made by different methods. For silica gels, surface area and particle d. decreased with increasing pH of the hydrosol, solids content of the hydrosol, and pH of the base-exchange medium used to remove Na ions from the gel. In the case of SiO_2-Al_2O_3 gels, particle d. decreased but surface area increased with increasing pH and solids content.

1807. Plank, C. J. and Drake, L. C. **Differences between silica and silica-alumina gels. II. A proposed mechanism for the gelation and syneresis of these gels.** *J. Colloid Sci.* **2**, 413-27 (1947).—*C.A.* **42**, 437*b*.

The extremely rapid gelation of SiO_2 and SiO_2-Al_2O_3 hydrosols under certain conditions and the sensitivity of gelation time to pH was demonstrated experimentally. It was proposed that the intermicellar bonds were H-bonds, whose rupture in acid media led to the formation of smaller particles of higher d. and higher surface area. In SiO_2-Al_2O_3 gels, the H-bonds joining silica and alumina groups were most important. Alumina groups must occupy a terminal position on the silica chain.

1808. Rosenblum, A. A. **Silica aerogels.** *Australia, Dept. Munitions, Inform. Circ.* **8**, 14 pp (1947).—*C.A.* **43**, 4789*g*.

Silica hydrogel is a light-wt microporous material, slightly hygroscopic, but capable of being made hydrophobic by coating with a mol. film of H_2O-repellent silicone. It is an effective, non-shattering, blast-proof material, its air spaces being sufficient to pick up a shock-wave, but small enough to provide a large solid interspace to deflect and cancel the shock.

1809. Rushmore, Donald. **Drying instrument air with silica gel.** *Chem. Eng.* **54**, No. 6, 120 (1947).—*C.A.* **41**, 6083*c*.

Two tanks were used alternately; each was equipped with steam coils for drying the silica gel.

1810. Shepard, Martin. **Rapid determination of small amounts of carbon monoxide. Preliminary report on the NBS colorimetric indicating gel.** *Anal. Chem.* **19**, 77-81 (1947).—*C.A.* **41**, 1952*d*.

The min. information necessary for prepg. silica gel was given. As little as 0.001% CO by vol. could be detected and detd. in 1 min. The procedure would detect less than 0.022 p.p.m. The purified silica gel was about 4 times as sensitive as gel used before 1941 in England.

1811. Balandin, A. A. and Rode, T. V. **Application of thermal analysis to the study of catalysts.** *Problemy Kinetiki i Kataliza* **5**, 135-44 (1948).—*C.A.* **46**, 10821*i*.

Thermograms were detd. for 2 samples of silica gel. Sorbed H_2O in one sample was progressively eliminated up to 115°C until a compn. $6SiO_2.H_2O$ was reached. Between 115° and 185°C, practically no H_2O was eliminated. It was decompd. between 185° and 270°C to a hydrate $9SiO_2.H_2O$ which was stable up to 380°C and loses H_2O progressively between 380° and 1125°C. The thermograms confirmed the view that part of the H_2O in silica gels was bound, not by adsorption, but by chem. forces. Further thermograms showed distinct differences between different samples of Cr_2O_3 catalysts.

1812. BORESKOV, G. K.; BORISOVA, M. S.; DZHIGIT, O. M.; DZIS'KO, V. A.; DREVING, V. P.; KISELEV, A. V., AND LIKHACHEVA, O. A. **Effect of the conditions of preparation on the structure of silica gels.** *J. Phys. Chem. (U.S.S.R.)* **22**, 603-16 (1948).—*C.A.* **42**, 7132*d*.

Glassy silica gels (prepd. by adding a K silicate soln. to acid, ripening the gel formed, washing, and drying) were relatively unidispersed; e.g., a gel whose most frequent pore radius was 15-20 A. had almost no pores wider than 30 A. The total pore vol. varied between 0.28 and 0.83 cc/g. Chalk-like silica gels (prepd. by adding $FeCl_3$ to a K silicate soln., filtering, and treating the ppt. with H_2SO_4) were polydispersed. The surface area of the glassy gels was 360 to 600, and of the chalk-like gels about 500 m^2/g as detd. from adsorption of MeOH and H_2O vapors. Adsorption of BuOH, lauric acid, and stearic acid from solns. in CCl_4 were also detd.

1813. BORESKOV, G. K.; BORISOVA, M. S.; DZIS'KO, V. A.; KISELEV, A. V.; LIKHACHEVA, O. A., AND MOROKHOVETS, T. N. **Effect of the temperature of firing on the structure of various types of silica gels.** *Doklady Akad. Nauk S.S.S.R.* **62**, 649-52 (1948).—*C.A.* **43**, 1628*d*.

Three samples were investigated in adsorption and desorption of MeOH vapor, after heating 12 hrs between 115-1000°C. I was a vitreous fine-pore gel, pore radius, r, under 20 A.; II mainly coarse-pore, $r = 35$-40 A.; III of mixed pore size, r from 15 to 80 A. The adsorption isotherm of I heated to 300°C, was typical of fine-pore adsorbents, leveling off to const. adsorption at p/p_s (relative pressure) 0.6. The isotherm for II (300°C) rose steeply at high p/p_s and showed marked hysteresis. The isotherm of III rose rapidly at high p/p_s. The B.E.T. surface area remained approx. const. up to about 400°C for II, then fell rapidly, to about 70 m^2/g at 900°C; in the case of III, it decreased regularly to about 150 m^2/g at 100°C.

1814. BURTT, BENJAMIN P. AND KURBATOV, J. D. **Mixed adsorption of radon and argon on silica gel.** *J. Am. Chem. Soc.* **70**, 2278-82 (1948).—*C.A.* **42**, 6603*b*.

Adsorption isotherms were obtained for air, A, and CO_2 on silica gel at 25°C. Adsorption isotherm for radon in air followed Henry's law and substantiated the Langmuir theory of mixed adsorption as applied to low concns. The adsorption of radon was slightly suppressed in CO_2. The isotherms of radon in A showed that the adsorption of radon was enhanced in the presence of A even though a very small fraction of the total surface of silica gel was covered by the radon. The heats of adsorption of radon in air and in A were estimated from the data obtained to be of the order of magnitude of 9000 cal per mole.

1815. FLAGG, JOHN F. AND LOBENE, RALPH. **A rapid method for the determination of nitrogen oxides in air.** *J. Ind. Hyg. Toxicol.* **30**, 370-2 (1948).—*C.A.* **43**, 1686*g*.

NO_2 was adsorbed on silica gel, treated with diphenylamine, and the color compared with standards, The method was suitable for air-gas mixts. contg. 1-50 p.p.m. NO_2. The advantages included sensitivity, speed, and simple app. and reagents; the disadvantage was its limited accuracy. It was assumed that in air NO was converted to NO_2.

1816. KIRSHENBAUM, ISIDOR AND GROVER, RICHARD K. **Low-temperature nitrogen adsorption studies of silica gel.** *J. Am. Chem. Soc.* **70**, 1282-3 (1948).—*C.A.* **42**, 4019*h*.

A Davison silica gel, activated at 650°C and having a surface area of 655 m^2/g, on grinding from 80 +μ to a powder contg. about 40% 0-80-μ particles had an area of 599 m^2/g (8.6% decrease). A gel contg. 64% H_2O showed a decrease in surface area of 6.7% on grinding. Little or no effect was observed on the av. Kelvin pore radius on grinding.

1817. KURBATOV, L. N. **Dielectric properties of adsorbed vapors.** *Doklady Akad. Nauk S.S.S.R.* **63**, 557-60 (1948).—*C.A.* **43**, 2831*g*.

The dielec. consts. of adsorbates were detd. as a function of the vol. (v) of the vapor adsorbed on 1 g of silica aerogel using resonance measurements of the capacities (C) of a cylindrical condenser filled with the aerogel. Simultaneous weighings were made on an adsorption balance. The capacity of the condenser was calibrated with C_6H_6 after removal of the aerogel with alkali. Exptl. plots of ΔC against v, for Me_2CO vapor, at 30.0°, 51.5°, and 72°C, coincided and consisted of 2 linear portions of different slopes. The breaking point corresponded to the vol. v_m of a unimol. layer.

1818. MILLIGAN, W. O. AND RACHFORD, HENRY, H. JR. **Sorption-desorption hysteresis characteristics of the system SiO_2-H_2O below the bulk freezing point of water.** *J. Am. Chem. Soc.* **70**, 2922-4 (1948).—*C.A.* **43**, 1237*f*.

Sorption-desorption isotherms for H_2O vapor on several silica gels were measured at -5°C. The sorption characteristics of the same samples previously detd. at 12°C permitted a comparison showing the effect of freezing. When the sorption was plotted against the relative satn., the isotherms at the two temps. coincided only if the satn. pressure was taken to be the experimentally detd. value for supercooled water at that temp.

1819. NEĬMARK, I. E.; KHATSET, F. I., AND SHEĬNFAĬN, R. YU. **Sorption properties and structure of silica gels.** *Doklady Akad. Nauk S.S.S.R.* **61**, 1057-60 (1948).—*C.A.* **43**, 824*h*.

Samples of silica gels of different microporosities had different adsorption isotherms for MeOH vapor. With micropore vol., the adsorption equil. was reversible, the sorption and desorption branches coincided, indicating absence of capillary condensation. Medium porous and large pore vol. showed hysteresis. The B.E.T. equation was not applicable to micropore vol., but did apply to medium porous and large pore vol. up to relative pressures $p/p_s = 0.35$-0.40.

1820. OHTA, NOBUTO. **Effect on aging on the dehydration activity and proton-donating intensity on silica-gel catalysts.** *J. Chem. Soc. Japan, Ind. Chem. Sect.*, **51**, 17-18 (1948).—*C.A.* **44**, 9224*i*.

The activity of silica gel, hitherto regarded as a weak catalyst of proton-donor type, can be increased, if during its prepn. precautions are taken to prevent aging of the gel. This may be done by shortening the period of contact of undried gel with electrolytes and by drying under 500°C.

1821. OHTA, NOBUTO. **A table of proton-donating intensities of solid catalysts of the proton-donating type and effect of added substance on activity (particularly PD-intensity) of catalysts.** *J. Chem. Soc. Japan, Ind. Chem. Sect.*, **51**, 139-41 (1948).—*C.A.* 44, 9226*a*.

The addn. of alkalies decreased the activity values, especially in silica gel as contrasted to Al_2O_3 gel, because cations on the catalysts removed the active protons. The stronger the alky., the more effective was the poisoning. Addn. of acids slightly decreased the activity, because of the formation of compds. with the active centers (OH radicals).

1822. REUTHER, HELLMUT. **Stability of aerosols.** *Kolloid-Z.* **110**, 221-40 (1948).—*C.A.* 43, 5255*g*.

The stability of an aerosol depended on the size and size distribution of the particles as well as on the changes of these characteristics with age of the sol. Sedimentation, particle growth, isothermal distn., elec., magnetic and other forces effected changes in aerosol systems. Non-hygroscopic materials (naphthalene, anthracene, phenanthrene and 2-naphthol) had a strong coagulational effect on certain org. (bituminous or wax) aerosols. The coagulation was caused by the chain-forming properties of these additive substances.

1823. SHAPIRO, I. AND KOLTHOFF, M. **Aging of precipitates and coprecipitation XLI. The bulkiness and porosity of silica powder.** *J. Phys. & Colloid Chem.* **52**, 1020-33 (1948).—*C.A.* 42, 6607*i*.

Particle size, true and apparent d. of individual gel particles, and bulk d. of gel powder were detd. The internal surface area of 300 m^2 per g (B.E.T.) and the external surface area of 0.1 m^2 per g were detd. Below a critical particle diam., d. interparticle void vol. increased rapidly with decreasing diam. Above d. the void vol. was const. The percent porosity, 34.5% for particles greater than d. was fairly close to the theoretical value of 26% for spheres; hence, particles had a low degree of irregularity.

1824. SHULL, C. G.; ELKIN, P. B., AND ROESS, L. C. **Physical studies of gel microstructure.** *J. Am. Chem. Soc.* **70**, 1410-14 (1948).—*C.A.* 42, 6603*a*.

Ten amorphous silica and silica-alumina gels were studied for adsorption of N_2 at low temps., porosity, and small-angle x-ray scattering. Good correlations were found between (1) the mean pore diam. calcd. from specific micropore vol. and specific surface and that calcd. according to the capillary condensation theory of isotherm analysis (2) av. particle size and specific surface, and (3) pore: particle-size ratio and porosity factor.

1825. VELDHEER, P. A. **A new method for the determination of acetylene in liquid oxygen.** *Chem. Weekblad* 44, 499-501 (1948).—*C.A.* 43, 2894*i*.

Silica gel adsorbed C_2H_2 quantitatively at a low temp. Evap. 500 cc. liquid O_2 in an insulated conical flask leading the gas through an adsorption tube filled with silica gel placed in Dewar vessel contg. liquid air. After complete evapn. of the O_2 rinse the entire app. with N_2, remove the adsorption tube from the liquid air. Drive out the C_2H_2 adsorbed by the silica gel with N_2, converting it into actylene-copper. This method dets. C_2H_2 contents of 1-5 p.p.m.

1826. BRUSSET, H. **X-ray study of particle size in silica gels.** *Bull. soc. chim. France* **1949**, 319-23.—*C.A.* 43, 6335*i*.

From low-angle scattering measurements av. radii were detd. in a com. silica gel desiccant, a com. aerogel, and gels made in the lab. The radius observed in the com. gel changed little during adsorption of H_2O but the intensity of scattering decreased markedly. The scattering elements were small pores in relatively large particles. Aerogel contained clusters of nearly identical small particles.

1827. CRESPI, S. **Dynamic adsorption and desorption of water vapor on silica gel.** *Chaleur & ind.* **30**, 53-8, 93-102 (1949).—*C.A.* 43, 6034*d*.

Dynamic adsorption and desorption studies were made with water vapor and a microporous SiO_2 gel of d. about 0.7. The efficiency of adsorption was defined as the ratio of the quantity of H_2O adsorbed to that supplied, and the adsorptive power as the weight of water adsorbed per unit weight of dry gel. Dry gel was defined as gel heated to const. weight in an oil bath at 210-220°C. With increasing velocity of the stream (within limits) at const. humidity, the break point concn. of the gel increased. The efficiency of adsorption remained at 100% up to a limiting velocity, after which the efficiency fell rapidly to about 35%. The desorption curves were similar to the adsorption curves, but had two inflection points at low moisture concns.

1828. DICKEY, FRANK H. **Preparation of specific adsorbents.** *Proc. Natl. Acad. Sci. U. S.* **35**, 227-9 (1949).—*C.A.* 43, 6489*c*.

Silica gel formed in the presence of methyl, ethyl, propyl, and butyl orange was 4 to 20 times as effective in adsorbing the particular dye as a control gel. The adsorbent was prepd. by the addn. of 30 ml of aq. Na silicate ($d_{20} = 1.401$), 275 ml of H_2O, and 30 ml of glacial AcOH to 0.4 g of finely divided dye. After the mixt. had been dried at room temp., ground and sieved, the fraction between 48- and 200-mesh was extd. with MeOH.

1829. DOBAY, DONALD G. **Adsorption of aliphatic amine vapors by silica gel.** *Univ. Microfilms Pub. No.* **1138**, 139 pp (microfilm $1.74, paper enlargements $13.90); Microfilm Abstracts **9**, No. 1, 22-3 (1949).—*C.A.* **43**, 4922*h*.

1830. DUBININ, M. M. AND ZUEV, A. G. **Adsorptive properties and structure of silica gels and alumina gels.** *Doklady Akad. Nauk S.S.S.R.* **69**, 209-12 (1949).—*C.A.* 44, 2324*a*.

Finely porous gels gave a reversible adsorption isotherm for C_6H_6 vapor at 20°C, showing practically completed adsorption at the relative pressure of 0.4. The coarse gel showed a broad hysteresis loop, and completed adsorption at about $p/p_s = 0.8$. With the mixed-type gel the hysteresis loop was considerably narrower. B.E.T. surface areas (265-670 m^2/g for the silica gels, 100-205 for the Al_2O_3 gels) gave a mean thickness of the adsorbed film of 3.8 A. for silica and 5.9 for the Al_2O_3 gels. A general increase of the pore size due to development of intermediate porosity resulted also in an increase of the dimensions of micropores. Comparisons were made with finely-porous active carbons, the finely-porous silica and the Al_2O_3 gels.

1831. Fogo, James K. and Popowsky, Milton. **Conversion of sulfur compounds to hydrogen sulfide in air, fuel gas, or mixtures.** *Anal. Chem.* 21, 734-7 (1949).—*C.A.* 43, 6112*f*.

Org. compds. contg. S can be removed by adsorption on silica gel at about 25 °C, desorbed at 500 °C, and hydrogenated over a quartz catalyst. The H_2S formed was preferably detd. by the methylene blue method.

1832. Gyani, B. P. **Adsorption of vapors on silica gel at low pressures.** *J. Indian Chem. Soc.* 26, 307-12 (1949).—*C.A.* 44, 3332*c*.

The adsorption of EtOH and CCl_4 at 25 °C on silica gel was detd. at low pressures with a sensitive manometer. The slopes of the log (x/m)-log p curves showed that CCl_4 in the adsorbed state was confined to a 2-dimensional space. Langmuir's adsorption isotherm at low pressures was discussed to show that Henry's law need not apply in these circumstances.

1833. Harle, G. A. **An accurate determination of the adsorption-relative humidity relations of silica gel and alumina.** *Australian J. Sci.* 11, 172-4 (1949).—*C.A.* 43, 6881*i*.

The water vapor pressure in equil. with a solid desiccant was detd. at const. temp. over a complete range of adsorptions. The adsorption-relative humidity curves for silica gel and alumina were similar in form. At low humidities the water content of alumina was higher; at high humidities that of silica gel was higher.

1834. Karyakin, A. V. **Quenching by oxygen of the fluorescence of anthraquinone derivatives. I. In the vapor state. II. In the adsorbed state.** *Zhur. Fiz. Khim.* 23, 1332-44, 1345-56 (1949).—*C.A.* 44, 2853*cf*.

The maxima of absorption in 10^{-4} M alc. solns. and of fluorescense in the vapor state were detd. for some anthraquinone derivs. The max. of fluorescence of vapors adsorbed by SiO_2 was also detd. Compds. where the latter was less than 500 mμ showed fluorescence reversibly quenched by O_2 and also afterglow, while the fluorescence of the other compds. was not quenched by O_2 and ceased when irradiation ceased. The lifetime of excited adsorbed mols. was $1\text{-}8 \times 10^{-8}$ sec.

1835. Karyakin, A. V. and Galanin, M. D. **Life of the excited state in molecules of anthraquinone derivatives in the vapor state and in adsorbates.** *Doklady Akad. Nauk S.S.S.R.* 66, 37-40 (1949).—*C.A.* 43, 6085*d*.

The life of the excited state, detd. by quenching of the fluorescence by O_2, was of the order of 10^{-8} sec for the substances adsorbed on silica gel and sealed in glass tubes, but of the order of the 10^{-9} sec when measured in the vapor state.

1836. Karyakin, A. V. and Kalenichenko, Ya. I. **Infrared luminescence of adsorbates of anthraquinone derivatives.** *Doklady Akad. Nauk S.S.S.R.* 66, 191-3 (1949).—*C.A.* 43, 6085*h*.

In adsorption on silica gel covered with paramagnetic Cu^{++} ions and at the temp. of liquid air an intense emission band (excitation by Hg 360 mμ, with the infrared radiation filtered out), with a max. around 880 mμ was observed with α- and β-aminoanthraquinone, 1,5- and 1,4-diaminoanthraquinone, and 1,2,5,8-tetrahydroxyanthraquinone, but not with anthraquinone itself.

1837. Karyakin, A. V. and Terenin, A. N. **The extinction of luminescence and metastable triplet states.** *Izvest. Akad. Nauk S.S.S.R., Ser. Fiz.* 13, 9-17 (1949).—*C.A.* 43, 7829*h*.

Quenching of fluorescence by O_2 was studied in 24 compds. derived from anthraquinone. Fourteen of these compds. were listed with the max. of the emission spectra of their vapors, the quenching of vapors and adsorbed material (on silica gel) and the calcd. duration of the excited state.

1838. Karyakin, A. V.; Terenin, A. N., and Kalenichenko, Ya. I. **Quenching of the fluorescence of vapors and adsorbates of anthraquinone derivatives by nitric oxide.** *Doklady Akad. Nauk S.S.S.R.* 67, 305-8 (1949).—*C.A.* 43, 7828*c*.

Strong quenching by NO both in the vapor phase and in the adsorbed state on silica gel was observed for anthraquinone and 4 derivs. which were likewise quenched by O_2. A substantial difference between the actions of NO and O_2 was in the efficiency of quenching. This was very nearly 1 at low pressures of NO, both in the vapor phase and in the adsorbed state, and fell with increasing pressure, the variation being reproducible upon reversal.

1839. Konchar-Durdević, Slobodan. **Adsorption under fixed hydrodynamic conditions.** *Bull. soc. chem. Belgrade* 14, 233-47 (1949). (English summary).—*C.A.* 46, 4317*i*.

A mixt. of 0.4 g SiO_2 gel, 7.5 ml acetone and 2.5 ml 10% cellulose nitrate in acetone was repeatedly sprayed on Al plates to form a 0.1-mm film. By exposing the coated plates to a stream of 0.00025% aq. methylene blue soln. of varying conditions of flow, different colored patterns were obtained, from which qual. conclusions as to dynamic adsorption, diffusion, and fluid flow could be drawn. The film could be detached from the plate and kept for record.

1840. Kurbatov, L. N. and Neuimin, G. G. **Infrared absorption spectra of vapors adsorbed on silica aerogels.** *Doklady Akad. Nauk S.S.S.R.* 68, 341-4 (1949).—*C.A.* 44, 435*f*.

Silica aerogel (600 m^2/g) in the form of plates 10 × 15 × 2 mm (outgassed in vacuo 3-4 hrs at 400 °C) showed an intense narrow absorption band at 1.37 μ. On gradual adsorption of $CHCl_3$ vapor, its intensity decreased, and a new band, 0.02 μ farther in the long-wave direction appeared. Another band, at 1.69 μ, increased in intensity regularly as the vapor pressure increased. With Me_2CO and PhOH, the 1.37 μ band showed a sharp drop of intensity even at the lowest vapor pressures; bands of the adsorbed substances appeared only at very much higher pressures. The 1.37 μ also disappeared without adsorption, after heating for 12 hrs *in vacuo* at 900 °C.

1841. Meissner, H. P. and Mickley, H. S. **Removal of mists and dusts from air by beds of fluidized solids.** *Ind. Eng. Chem.* 41, 1238-42 (1949).—*C.A.* 43, 6471*b*.

Mists composed of H_2SO_4 droplets were filtered from air at atm. temp. and pressure by passing the air up through a fluidized solid bed. Porous materials like com. microspheres, silica gel, and Al_2O_3 picked up over 5% by wt of acid before sticking destroyed fluidization. Nonporous materials showed impractically short lives.

1842. Munro, L. A.; McNab, J. G., and Ott, W. L. **Elastic properties of silica gels.** *Can. J. Research* 27B, 781-90 (1949).—*C.A.* 44, 6237*a*.

The elastic properties of acid and alk. silica gels were examd. In the range of concns. studied (3.3-6.6%), Young's modulus for acid (pH 3.6) and alk. (pH 8.2) gels was not independent of load, and it increased with the age of the gel as well as concn. Increased temp. increased the modulus of acid gels (pH 5.6) but decreased the modulus of alk. gels (pH 8.2) at the same silica concn.; the alk. gels, however, showed a higher modulus at room temp. and a lower elastic recovery.

1843. Reyerson, L. H. and Wertz, John E. **Adsorption of the oxides of nitrogen. I. The adsorption of nitrogen dioxide-nitrogen tetroxide by rutile and silica gel; preliminary magnetic susceptibility measurements of the adsorbed layers.** *J. Phys. and Colloid Chem.* 53, 234-51 (1949).—*C.A.* 43, 6034*h*.

The adsorption of a NO_2-N_2O_4 mixt. was studied for silica gel at 30.05° and 49.16 °C and for rutile at -15°, 10.39°, 30.42°, and 49.21 °C. Reversible adsorption was obtained for both adsorbents. The adsorption of N_2O_4 on silica gel appeared to form a multilayer; for rutile, a monolayer satn. value existed extending up to 0.97 or 0.98 relative pressure. The isosteric heat of adsorption appeared to be 11,000 cals per mol. on silica, and had a value that increased from 5,000 to 9,000 cals with increased adsorption on rutile.

1844. Slyusareva, R. L. and Tesner, P. A. **Measurement of the moisture content of a gas.** *Zavodskaya Lab.* 15, 647-9 (1949).—*C.A.* 44, 483*f*.

A 5% soln. of $CoCl_2$ adsorbed on Al_2O_3 or silica gel and dried at 180-200 °C was a convenient indicator of moisture. Silica-gel changed color at 3 g/m^3 of H_2O in air, while the Al_2O_3-type changed at 1 g/m^3; these corresponded to dew points of -4° and -15 °C, resp. The use of reactive gases, such as SO_2 or Cl_2, was contra-indicated.

1845. White, Locke Jr. and Schneider, Charles H. **Physical adsorption from mixtures of gases. II. Oxygen-argon on silica gel at 0 °C.** *J. Am. Chem. Soc.* 71, 2945-6 (1949).—*C.A.* 44, 7615*g*.

The vol. of either O_2 or A adsorbed was a linear function of its partial pressure, and was independent of the presence or absence of the other component. With forced circulation of O_2-A mixts. through the sample used, the compn. of the adsorbed phase was not greatly affected by the order in which the 2 gases reach the gel surface.

1846. Yoroslavskii, N. G. and Terenin, A. N. **Infrared absorption spectra of adsorbed molecules.** *Doklady Akad. Nauk S.S.S.R.* 66, 885-8 (1949).—*C.A.* 43, 7343*i*.

The adsorption of C_6H_6 and $PhCH_3$ vapors at room temp., on vitreous silica gel, showed (initially only O-H bands) peaks corresponding to the C-H frequencies of the ring, and (in the case of $PhCH_3$) to CH_3 in positions identical to those found with CCl_4 soln.; at the same time, the narrow O-H peak became increasingly weaker. In the adsorption of $PhNH_2$ the gradual disappearance of the O-H peak set in long before the appearance of the C-H and N-H peaks of the adsorbed mols. At the stage of greater surface coverage, th N-H peak at 1.52 μ shifted 0.01 μ to longer wave lengths relative to the peak of assocd. NH groups. The effects observed with $PhNH_2$ were even more pronounced in C_5H_5N. In the adsorption of PhOH, the O-H peak of the adsorbent remained narrow and disappeared much more slowly than with $PhNH_2$. In the range of capillary condensation, there appeared broad maxima characteristic of assocd. OH groups.

1847. Bartell, F. E. and Dobay, Donald G. **The adsorption of aliphatic amine vapors by silica gel.** *J. Am. Chem. Soc.* 72, 4388-93 (1950).—*C.A.* 45, 3681*f*.

The adsorption isotherms (relative pressures of 0.002 to satn.) for Et_2NH, $BuNH_2$, and Bu_2NH on silica gel were detd. at 25 °C. The completion of the monolayers occurred at the very low relative pressure of about 0.01 The three-const. B.E.T. equation was applicable in the approx. relative pressure range of 0.002-0.4. The const. n was less than 3 in all cases. Highly concordant values for the capillary radius of the gel were obtained by the application of the Kelvin equation.

1848. Běhounek, F. and Ĵech, Č. **Emanating power and the age of complex silica gels.** *Nature* 166, 792-4 (1950).—*C.A.* 45, 4148*b*.

Silica gels prepd. in 1934 included various electrolytes and some Ra. The activity of these samples was measured by means of the Rn escaping. The intensity of this emanation varied depending on the treatment of the gel. Those samples kept dry showed only a slight decrease in emanating power, but those heated to dryness showed a marked decrease.

1849. Dumanskiĭ, A. V. and Kurilenko, O. D. **Relation between the dielectric constant of disperse systems and surface phenomena.** *Kolloid. Zhur.* 12, 326-30 (1950).—*C.A.* 45, 937*g*.

Silica gel was ground, passed through a sieve having 10,000 openings/cm^2, heated, and suspended in 50 parts H_2O. The dielec. consts. ϵ of the suspensions, for the wave length λ 800 m were 85, 99, 86, and 88 after 300°, 550°, 1000°, and 1200 °C resp. The ϵ of similar suspensions in a picric acid soln. in C_6H_6 also had a max. after 550 °C. The ϵ of the "bound" H_2O could not be very low. The ϵ of disperse systems was affected by adsorption and by deformation of the elec. double layer and could not be expressed as a function of the ϵ of the components.

1850. Dzhigit, O. M.; Kiselev, A. V.; Avgul, N. N. Mikos, and Shcherbakova, K. D. **Poisoning and regeneration of the surface of silica gel in the adsorption of vapors.** *Doklady Akad. Nauk S.S.S.R.* 70, 441-4 (1950).—*C.A.* 44, 4304*i*.

Adsorption-desorption isotherms at 20°C and differential heats *Q* in adsorption and desorption were detd. for MeOH vapor on a homogeneously finely porous silica gel heated 12 hrs at 450°C. *Q* in adsorption and desorption were identical only in the range of capillary condensation. To eliminate the last amts. of MeOH, pumping was done over active charcoal, cooled in liquid N_2, with the gel heated to 65°C; this left a residue of 0.5 milli-mole MeOH/g adsorbed. On repeated adsorption, after heating to 400°C, the *Q* evolved in adsorption were smaller than in the 1st run, and the isotherm lay lower. A further lowering of *Q* and of the amt. adsorbed occurred in a 3rd run.

1851. Dzis'ko, V. A.; Vishnevskaya, A. A., and Chesalova, V. S. **Effect of heating on the catalytic activity of silica gel.** *Zhur. Fiz. Khim.* 24, 1416-19 (1950).—*C.A.* 45, 4123*f*.

Three silica gel catalysts were prepd. with the following pore vols., area (m^2/g) and mean pore diam.: (*A*) 0.24, 400, 10; (*B*) 0.85, 450, 27; (*C*) 1.05, 540, 20. The effect of heating on the H_2O content of the gels was studied between 115° and 1000°C. Assuming that the structural H_2O was held as OH groups on the surface (15×10^{-16} cm^2/OH), the fraction of surface, θ, covered by OH was detd. at all temps. The H_2O content followed the decrease in surface area. The decrease in surface area due to heating corresponded to the evolution structural H_2O, and as a consequence θ remained approx. const. The hydrolysis dropped only slightly in the case of *A* which was not temp. resistant, but in the case of *B* and *C*, it increased between 600° and 1000°C.

1852. Ewles, J. **Luminescence of silica.** *Nature* 165, 812-13 (1950).—*C.A.* 44, 7151*h*.

Finely divided silica became luminescent after being wetted by water and MeOH or EtOH or by being exposed to H_2. This luminescence exhibited an intense spectral band from about 2400 to 2900 A. with a max. at about 2650 A. The luminescence was attributed to OH carriers and active sites of Si monoxide in the SiO_2. A mixt. of Si and SiO_2 heated in vacuo to 1250°C produced luminescent material.

1853. Freĭdlin, L. Kh.; Neĭmark, I. E.; Fridman, G. A.; Sheinfaĭn, R. Yu., and Khatset, F. I. **Relation between the type of the porosity of a silica gel and its catalytic properties.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* **1950**, 521-30.—*C.A.* 45, 3238*b*.

Only nondehydrated silica gel was active; consequently, the active centers lay at the OH groups of the silica gel. However, the catalytic activity was governed not only by the d. of these centers but by the vol. if the micropores, which detd. the surface area, and the amt. of intermediate pores necessary for the transport of reactants and products. Yields of PhOH and of HCl, from PhCl and H_2O under controlled conditions were detd. for 6 types of silica gel catalysts of B.E.T. area (m^2/g): 390; 450; 560; 490; 420; 325.

1854. Gyani, B. P. **Adsorption of alcohol on silica gel.** *J. Indian Chem. Soc.* 27, 577-85 (1950).—*C.A.* 45, 7844*i*.

Isotherms of EtOH on various silica gels were detd. gravimetrically at 35°C. Evacuation above a certain temp. (300-350°C) increased adsorption at all pressures. Aging of a gel increased adsorption at higher pressures but decreased it at lower pressures. Hysteresis occurred, if in its prepn. gel was evacuated above a certain temp., usually well over 300°C. About 2% of adsorbed EtOH was irreversibly retained at highest temp. and vacuum used.

1855. Haul, R. **Measurement of the surface diffusion of adsorbed molecules.** *Angew. Chem.* 62, 10-16 (1950).—*C.A.* 44, 3766*b*.

The diffusion of MeOH, C_5H_{12}, C_7H_{16}, and toluene in silica gel and active carbon was studied at low temps. A direct-weighing method was developed to measure the diffusion.

1856. Higuchi, Izumi. **Dielectric properties of substances in the sorbed state. II. The freezing phenomenon of nitrobenzene sorbed on silica gel.** *Science Repts. Tohoku Univ.* 33, 174-81 (1950).—*C.A.* 45, 12*i*.

Nitrobenzene (1.82 g) was held at satn. by 1 g of gel, the apparent d. of the powd. gel being 0.27 g/cc. The dielec. polarization was detd. with frequencies of 3.0, 1.5, 0.870, and 0.373 *Mc.* over a temp. range from 70 to -75°C. The sorbed substance showed a f.p. depression, and the temp. at which the sorbate froze tended to the normal m.p. with increasing amt. of the sorbate. The dielec. consts. for nitrobenzene were larger, the larger the pore size in which the sorbate was held.

1857. Higuchi, Izumi. **A supplement to the previous paper on the freezing phenomena of highly dispersed substances.** *J. Chem. Soc. Japan, Pure Chem. Sect.*, 71, 141-2 (1950).—*C.A.* 45, 4526*f*.

The values of liquid d. and the heat of condensation ought to be those at the temp. of condensation to adsorb liquid. The correction for this point was applied based on the first law of thermodynamics. The theoretical formula agreed with the exptl. values on nitrobenzene in the whole temp. range down to -60°C.

1858. Hubbard, Byron R. and Silverman, Leslie. **Rapid method for the determination of aromatic hydrocarbons in air.** *Arch. Ind. Hyg. Occupational Med.* 2, 49-55 (1950).—*C.A.* 44, 8285*e*.

C_6H_6 and homologs in air can be detd. in the field by passing the air through tubes contg. silica gel impregnated with a H_2SO_4-HCHO reagent, assembled in a hand-size sampling unit. Concns. of 20-200 p.p.m. are indicated with an accuracy of 15% by the length of the reddish brown stain produced in the treated gel.

1859. Imelik, Boris and Carteret, Yvette. **Diffusion of the x-ray beam by silica gel.** *Compt. rend.* 231, 280-2 (1950).—*C.A.* 45, 1866*g*.

Porosity of silica gel and absorption of dense vapors by it can be followed by measuring the diffusion of x-rays. The effect of pore size is not easily interpreted quantitatively.

1860. Johnson, Marvin F. L. and Ries, Herman E. Jr. **Effect of wetting on the nitrogen adsorption-desorption isotherm of silica aerogel.** *J. Am. Chem. Soc.* 72, 4289 (1950).—*C.A.* 45, 2285*f*.

Large-pore SiO_2 aerogel contracted on treatment with H_2O to form a small-pore xerogel structure with an insignificant change in surface area. N_2 adsorption-desorption isotherms nearly coincided in the lower-pressure region ($p/p_0 = 0.05$ to 0.45) indicating similar B.E.T. areas, 796 and 813 sq m/g, and the pore vols. obtained were 3.90 and 0.66 cc./g for the aerogel and xerogel, resp.

1861. Juza, Robert and Tentschert, Hans. **Magnetochemical investigation of the sorption of nitrogen dioxide on active silica and charcoal.** *Z. anorg. Chem.* **262**, 165-74 (1950).—*C.A.* 44, 7616*i*.

The sorption and magnetic susceptibility of NO_2 on silica and charcoal were measured. The partial susceptibility of NO_2 was detd. for various amts. sorbed. The susceptibility of NO_2 was taken as 39×10^{-6} e.m.u. and of N_2O_4 as -0.28×10^{-6} e.m.u., and the degree of dissocn. of N_2O_4 on the adsorbents was calcd. On SiO_2 the degree of dissocn. varied from 0.7% at a concn. of 0.02 g N_2O_4 per g SiO_2 to 0% at 0.65 g per g. On charcoal, NO_2 was found to be chemisorbed up to a concn. of 0.025 g per g. Above this concn. it was physically sorbed largely as N_2O_4, the degree of dissocn. varying from 1.2 to 7.0%.

1862. Kurbatov, L. N. **Oxyluminescence and cathodic luminescence of silica gels.** *Zhur. Fiz. Khim.* 24, 913-23 (1950).—*C.A.* **45**, 1426*d*.

In the oxyluminescence arising during the catalytic oxidation of MeOH, EtOH, AcH, and Et_2O over silica gel, the luminescence carrier was believed to be excited mols. of HCHO. The catalyst did not participate in the luminescence. Cathodic luminescence of silica gel was observed in the presence of adsorbed H_2O.

1863. Mills, F. A. and Hindin, S. G. **Chemical characterization of catalysts. II. Oxygen exchange between water and cracking catalysts.** *J. Am. Chem. Soc.* 72, 5549-54 (1950).—*C.A.* 45, 5394*h*.

Water contg. O^{18} was used to detn. the rate by which this compd. exchanged O with solid oxides such as silica gel, active silica-alumina cracking catalyst, kaolin, bentonite, and acid-activated bentonite, at temps. of 100°C, and in a few cases, at 565°C. These solids having high specific surfaces exchanged rapidly 10 to 25% of all their oxide oxygens, followed by a slow further exchange that led, at 105°C, to exchange of an addnl. 10 to 60% of the oxide oxygens over a period of one month. No exchange could be observed with natural kaolin or bentonite. During contact with water, all the oxides other than the clays showed substantial changes of specific surface area, pore-size distribution, moisture content, and x-ray diffraction patterns.

1864. Mizuno, Shigeru; Toshima, Shinobu, and Shiratori, Hajime. **Anomalous dispersion and absorption of electromagnetic waves in microheterogeneous systems. II. The factors affecting anomalous dispersion. III.** *J. Electrochem. Soc. Japan* **18**, 301-2, 334-5 (1950).—*C.A.* 45, 8310*h*.

Dielec. const. and tan δ of various dispersed systems were measured at 500-10,000 cycles. The effect of strength of elec. field, temp., grain size, and concn. on anomalous dispersion and absorption were very small. A remarkable anomalous dispersion was observed in the case of silica gel, contg. considerable water, dispersed in liquid paraffin, and in the case of strongly active carbon dispersed in liquid paraffin.

1865. Neimark, I. E. and Khatset, F. I. **The phase state of a substance in the adsorbed layer.** *Doklady Akad. Nauk S.S.S.R.* 74, 751-4 (1950).—*C.A.* 45, 1838*c*.

Three types of silica gel, (I) finely porous, (II) medium-porosity, and (III) coarsely porous, preliminarily heated to 400°C, were exposed to mixed vapors of $C_6H_6 + CCl_4$; the substance adsorbed was desorbed at 400°C until const. wt, and its compn. was detd. On type I, the compn. (at high surface coverage) was found to correspond to that of the vapor, on III mainly to the liquid phase, whereas on II it is intermediate between the two. At low surface coverages, the adsorbed substance was gaseous in all cases. C_6H_6 was selectively adsorbed on silica gels of type I from a mixt. $C_6H_6 + C_7H_{16}$, i.e. a mixt. of mols. of distinctly different sizes. The view ascribing all phys. adsorption to capillary condensation was erroneous.

1866. Shapiro, I. and Kolthoff, I. M. **Aging of precipitates and coprecipitation XLIII. Thermal aging of precipitated silica gel.** *J. Am. Chem. Soc.* 72, 776-82 (1950).—*C.A.* 44, 4305*h*.

Silica gel was subjected to different thermal treatments up to 1050°C and the moisture, dye adsorption, and apparent d. (Hg displacement) were detd. Some doubt was cast on the usefulness of the 2 adsorption methods for following the aging process. A surface differential aging process below 700°C resulted in a perfection in arrangement of elementary units; in this region, the porosity decreased slightly, but the surface area decreased considerably. A bulk differential process at higher temp. involved sintering and increased particle-to-particle contacts.

1867. Srivastava, Arvind M. **Ultrasonic investigation of gels.** *Z. Physik* **128**, 614-16 (1950).—*C.A.* **45**, 5489*g*.

An ultrasonic pulse method was used to measure wave speed in Fe silicate gels as a function of frequency in the range $0.6\text{-}2.5 \times 10^6$ cycles/sec, gel age, and temp. With increasing gel age the shear wave speed and the shear modulus increased and approached a const. value.

1868. Voorthuijsen, J.J.B. van Eijk van and Franzen, P. **The influence of silicon dioxide on the activity of nickel catalysts.** *Rec. trav. chim.* 69, 666-7 (1950).—*C.A.* 44, 10473*f*.

Under appropriate conditions $Ni(OH)_2$ and silica gel can form two compds.: $Ni_3(OH)_4Si_2O_5$ (nickel antigorite) and $Ni_3(OH)_2(Si_2O_5)_2$ (nickel montmorillonite). These two compds. together with $Ni(OH)_2$ were present in the pre-reduction stage of

Ni-on-silica catalysts depending on the Ni/Si ratio. Their properties were a determining factor for the activity of the catalysts prepared from them by reduction.

1869. Yaroslavskiĭ, N. G. **Infrared absorption spectrum of microporous adsorbents of the silica gel type.** *Zhur. Fiz. Khim.* 24, 68-81 (1950).—*C.A.* 44, 4786*g*.

The spectrum (between 1 and 2.4 μ) of porous glass (porosity = 27%) was detd. after different treatment of the glass. A very sharp line 1.356 μ was given by glass heated in a vacuum at 300 °C which disappeared at 1000 °C and on keeping the glass in moist air. A line at 1.39-1.40 μ appeared when the glass was stored in air and disappeared on heating. The line 1.46 μ was present in moist glass. A line 1.90 μ behaved like 1.39-1.40 μ and also was attributed to adsorbed H_2O. The state of H_2O in the glass could thus be detd. by optical means.

1870. Avgul, N. N. Mikos; Dzhigit, O. M.; Kamakin, N. M.; Kiselev, A. V.; Luk'yanovich, V. M.; Neĭmark, I. E., and Sheĭnfaĭn, R. Yu. **Investigation of the structure of an adsorbent by independent methods.** *Doklady Akad. Nauk S.S.S.R.* 76, 855-8 (1951).—*C.A.* 45, 4995*f*.

A silica gel of the homogeneous coarse-pore type was prepd. by dehydration of the hydrogel. Adsorption-desorption isotherms of C_6H_6, C_7H_{16}, and MeOH, showed that some 90% of the vapor sorbed was accompanied by a broad, exactly reproducible hysteresis loop. The surface area of the skeleton and of the adsorption film were 330 and 320 m²/g, resp.; the vol. of liquid sorbed at satn. was found = 1.72 cc./g, equal for all 3 substances. The dimensions of 645 pores on an electron-microscope picture of a sample ground under water, and shaded with Au (8-10 A), gave a distribution curve very close to that obtained from the desorption isotherms.

1871. Avgul, N. N. Mikos; Dzhigit, O. M.; Dreving, V. P.; Gur'ev, M. V.; Kiselev, A. V., and Likhacheva, O. A. **Absolute adsorption isotherms of vapors on quartz and on silica gels of different structures.** *Doklady Akad. Nauk S.S.S.R.* 77, 77-80 (1951).—*C.A.* 45, 5483*g*.

Adsorption isotherms were referred to unit surface area using previous exptl. data for finely ground cryst. quartz, coarse-pore (200 A.) silica gel "E", and coarse-pore (90 A.) silica gel "K". The surface area for the quartz was 5.7 m²/g by the B.E.T. method and 6.6 by the Harkins method. The area of silica gel E was detd. by adsorption of C_7H_{16}, C_6H_6, and MeOH vapors at 20 °C and the results were 330, 330, and 300, av. 320 m²/g. Silica gel K was 440 m²/g (B.E.T.) and 430 m²/g (Harkins), by adsorption of C_7H_{16} at 20 °C, 390 m²/g, and by adsorption of H_2O vapor at 18.2 °C, 410; mean 420 m²/g. Referred to unit surface area, adsorption isotherms of MeOH vapor coincided very exactly for the three adsorbents up to the beginning of the hysteresis loop (relative pressure $p/p_s \sim 0.6$).

1872. Buckley, R. A. and Altpeter, R. J. **Vapor-phase catalytic esterification rates.** *Chem. Eng. Progress* 47, 243-50 (1951).—*C.A.* 45, 5461*f*.

Rates for the vapor-phase esterification of AcOH and EtOH with a silica gel catalyst were limited by the rate at which AcOH was activatedly adsorbed when the mole fraction of AcOH in the feed was less than 0.7 at temps. between 200° and 260 °C and under total pressures of 1 to 2.33 atm. The rate of adsorption of AcOH was found to be dependent on the water content of the silica gel. A rate equation was based on a function having the form of an adsorption isotherm relating the partial pressure of water vapor in the reacting stream to the total no. of active available sites.

1873. Cremer, E. and Müller, R. **Separation and determination of substances by chromatography in the gas phase.** *Z. Elektrochem.* 55, 217-20 (1951).—*C.A.* 45, 9335*a*.

A quant. sepn. of acetylene and ethylene, of CO_2 and acetylene, and of ethylene and propylene, was achieved. Detection of a gaseous component without complete sepn. was possible by observing the breakthrough time characteristic of a substance. This was possible only if the breakthrough time was independent of concn., which was true, e.g., for acetylene and ethylene on finely divided silica gel, but not for the same substances on coarse silica gel.

1874. Dreving, V. P.; Kiselev, A. V., and Likhacheva, O. A. **Adsorption of nitrogen vapors on silica gel at low temperature.** *Zhur. Fiz. Khim.* 25, 710-18 (1951).—*C.A.* 47, 4164*d*.

A silica-gel adsorbent, prepd. by hydrolysis of $SiCl_4$, evacuated at 300 °C and of homogeneous porosity as detd. by desorption of H_2O in the region of capillary condensation, was used in 8 series of adsorption and desorption runs at −195.7 °C with N_2 at relative pressures between 10^{-6} and 0.5. The B.E.T. equation was obeyed for $0.035 < x < 0.33$; that of Harkins and Jura for $0.075 < x < 0.58$. The surface area (m²/g) of the adsorbent was 440 (B.E.T.) or 430 (H.J.). The monolayer part of the isotherm was not fitted by the equations of Langmuir, Williams, or Freundlich.

1875. Fialkovskaya, O. V. and Terenin, A. N. **Photoreaction of pyridine in the adsorbed state.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Khim, Nauk* 1951, 226-41.—*C.A.* 45, 9374*g*.

Pyridine adsorbed from the vapor *in vacuo* on dry outgassed granular silica gel, in an amt. well below complete coverage exposed 2 hrs, to a Zn spark (ultraviolet 3000-2000 A.) showed no visible changes. On a plate of vitreous silica aerogel, exposure of 2 hrs of the pyridine adsorbate produced a light-brown spot, which did not disappear on heating to 500 °C *in vacuo*. A different colored product was formed when pyridine was illuminated while adsorbed on silica gel contg. Tl^+ ions. There was no photoreaction with pyridine adsorbed on sublimed films of TlCl, not supported on silica gel; consequently, the reaction hinged on the presence of Tl^+ *ions* distributed in the silica gel. Adsorbates of pyridine on films of $ZnCl_2$ and $SnCl_2$ on quartz gave no photoreaction, nor was a reaction observed with KCl, CsCl, $BiCl_3$, and $AlCl_3$.

1876. Foster, A. Graham. **Sorption hysteresis. I. Some factors determining the size of the hysteresis loop.** *J. Phys. & Colloid Chem.* **55**, 638-43 (1951).—*C.A.* **45**, 6894*h*.

The adsorption isotherms were detd. for propylamine, tert-butylamine, and amylamine on a sample of silica gel. The size of the hysteresis loop decreased with increasing temp. and with increasing mol. diam. of the adsorbate. The observed facts could not be readily explained by the "ink-bottle theory," whereas they were explained by the open-pore theory.

1877. Foster, E. Gordon and Daniels, Farrington. **Recovery of nitrogen oxides by silica gel.** *Ind. Eng. Chem.* **43**, 986-92 (1951).—*C.A.* **45**, 6353*f*.

Basic data were presented for the dehydration and adsorption of 1 to 1.5% NO produced in fixation of atm. N_2. The feasibility of the process was discussed. Silica gel had practically no adsorption capacity for NO. Although dry silica gel contg. adsorbed NO_2 catalyzed the oxidation of NO to NO_2, silica gel satd. with water vapor did not catalyze the oxidation. Silica gel had a much higher adsorption capacity for water vapor than for NO_2, and the rate of adsorption was much greater than for NO_2. The different silica gels examd. were not similar in their behavior in the various steps of the process, some being better for the dehumidification and others better for the adsorption and catalysis.

1878. Freymann, Marie and Freymann, Rene. **Microwave absorption and hydroxyl bond; water of crystallization and water of adsorption.** *Compt. rend.* **232**, 401-3 (1951).—*C.A.* **45**, 6013*g*.

Ice at or below 0°C does not absorb at 3.15 cm, whereas the presence of 10% or more of liquid water produces absorption. Water adsorbed on alumina or silica gel is partially "liquid," but the absorption is less than for the same amt. of water added to sucrose and NaCl. Water in hydrated alumina is "solid," but if dehydrated and rehydrated becomes "liquid."

1879. Hauser, Ernst A.; LeBeau, D. S., and Pevear, P. P. **Surface structure and composition of colloidal siliceous matter.** *J. Phys. & Colloid Chem.* **55**, 68-79 (1951).—*C.A.* **45**, 2745*c*.

Since the surface of siliceous matter is found by infrared absorption and by differential thermal analysis to be composed primarily of OH ions, the internal crystal structure does not govern its reactivity or colloidal behavior. Evidence of the release of O from newly exposed surfaces of many types of silicate, as indicated by the use of α,α-bis (*p*-dimethylaminophenyl) toluene, indicates the type and extent of alteration of the internal structures to form the surface structure.

1880. Higuchi, Izumi and Shimizu, Michie. **Dielectric properties of substances in the sorbed state. IV. Freezing phenomenon of *o*-nitrophenol sorbed on silica gel.** *J. Chem. Soc. Japan*, Pure Chem. Sect., **72**, 536-9 (1951); *J. Phys. Chem.* **56**, 198-201 (1952).—*C.A.* **46**, 5384*c*.

The dielec. polarization of *o*-nitrophenol on silica gel was detd. in the range 0-110°C. The dielec. consts. of the sorbate were detd. as a function of temp. The f.p. depression was detd. as a function of the capillary core.

1881. Imelik, Boris and Carteret, Yvette. **Silica gels.** *Bull. soc. chim. France* **1951**, 864-7.—*C.A.* **46**, 4325*e*.

Gels prepd. by the action of HCHO on Na silicate were studied with respect to the mechanism of formation, scattering of x-rays, and structure alteration by heat-treatment. Gels formed most rapidly with 50 cc. of 30% HCHO, 30 cc. Na silicate (d. 1.39, 360 g SiO_2 per liter) and 20 cc. H_2O at 100°C. CH_3CHO gave similar results. The greater the amount of Na silicate in the gel, the less the scattering of x-rays and the less linear the relation $\log I = f(\epsilon)^2$. When 5 cc. Na silicate and 45 cc. H_2O were added to 50 cc. of 30% HCHO, the gel which formed gave a linear scattering effect.

1882. Imelik, B.; Teichner, S., and Carteret, Y. **Comparative study of the texture of silica gel by small-angle x-ray diffraction and low-temperature nitrogen adsorption.** *J. chim. phys.* **48**, 438-46 (1951).—*C.A.* **46**, 4325*b*.

Two gels, *A* and *F*, were used in this study. The B.E.T. area of *A* was 385 m²/g, that of *B*, 386 m²/g. *A* was a compact rigid mass full of pores of uniform shape. *F* was composed of a mass of uniform spherical particles about 0.0001 mm in diam. The particles did not form a homogeneous mass but contained cavities of variable shape and size. Evidence points to the existence of two main types of gels, the classical type typified by *A* and the silica gels called aerogels consisting of small uniform spherical particles 50 to 100 A. in diam. surrounding large empty spaces. Gel *F* is intermediate between the two main types.

1883. Iwakami, Yoshimoto. **The melting point of benzene in the sorbed state.** *J. Chem. Soc. Japan, Pure Chem. Sect.*, **72**, 259-62 (1951).—*C.A.* **46**, 802*h*.

The capillary size distribution was computed for active charcoal and silica gel by detg. the adsorption isothermal of C_6H_6 at 0°C. From the detn. of the heat capacity, the silica gels plus adsorbed C_6H_6 showed abnormal sp. heat. This was attributed to the m.p. lowering of adsorbed C_6H_6.

1884. Iwakami, Yoshimoto. **Freezing-point depression of carbon tetrachloride in the sorbed state.** *J. Chem. Soc. Japan*, Pure Chem. Sect., **72**, 707-10 (1951).—*C.A.* **46**, 1329*i*.

The heat capacity of CCl_4 sorbed in various amts. on silica gel with the known distribution of pore sizes was measured from − 190 to − 20°C. An abnormally large heat capacity was found at a certain temp. below the normal m.p., T_o. The radii of capillary pores, in which the sorbate melts at T_m, was computed from the distribution of capillary pores. The observed f.-p. depression, of the sorbate in the capillary pore of radius r agreed with that calcd.: $\Delta T/T_0 = 2\gamma M/\rho r\Delta H$, where γ was the surface tension, ρ the d. of liquid, M mol. wt, and ΔH the heat of melting.

1885. Kiselev, A. V. and Kamakin, N. M. **Absolute adsorption isotherms of vapors on silica and alumina-silica gels of different structures.** *Doklady Akad. Nauk S.S.S.R.* **80**, 393-6 (1951).—*C.A.* **46**, 316*i*.

Adsorption isotherms of MeOH vapor were detd. on 5 hydrated SiO_2-Al_2O_3 gels of different porosity types. The surface areas of the skeleton, and of the adsorption film in m^2/g, were (I) 520, 0; (II) 425, 40; (III) 255, 110; (IV) 415, 220; (V) 425, 355. The adsorption referred to unit surface area (detd. from the same adsorption isotherms of MeOH) coincided for all 5 samples between $p/p_s = 0$ and 0.3. Phys. adsorption of MeOH was little sensitive to the nature of the atoms lying underneath the OH groups; in particular it was indifferent whether these atoms were Si or Al.

1886. Le Bot, Jean and Le Montagner, Serge. **The dielectric properties in the centimeter-wave region of water fixed on silica gel.** *Compt. rend.* **233**, 862-3 (1951).—*C.A.* **46**, 1829*d*.

The variation of ϵ' and ϵ'' of hydrated silica gel at frequencies between 2800 and 26,000 megacycles was measured at 20°C. The gel lost part (18%) of its hydrated H_2O in a reversible fashion when heated to 100-110°C. The remainder (10%) was eliminated in an irreversible manner by heating above 600°C. The dielec. const. of samples heated to 110° showed a max. at 17,000 megacycles which was attributed to the H_2O removed at 600°C.

1887. McIntosh, R.; Rideal, E. K., and Snelgrove, J. A. **The dielectric behavior of vapors adsorbed on activated silica gel.** *Proc. Roy. Soc.* (London) **A208**, 292-301 (1951).—*C.A.* **46**, 5384*g*.

The increase in capacity of a test cell contg. a porous activated silica on the admission of adsorbates such as water, Et chloride, and butane was measured. Two types of film were established for the adsorbates butane and Et chloride. The computation of dielec. consts. of adsorbed matter in such systems was discussed. The d. of the adsorbed state may be detd. through dielec. studies. In the case of butane, the procedure gave a value of the d. of the adsorbed state in agreement with that which might be expected if He were used. The arrangement of the adsorbed mols. remained unaltered with increasing satn. of the surface, until a crit. satn. was reached, at which point a more dil. type of film began to form and persisted until no further adsorption.

1888. Nakagaki, Masayuki. **The mechanism of evaporation in vacuum. I. Evaporation of silica gel.** *Bull. Chem. Soc. Japan* **24**, 206-9 (1951) (in English).—*C.A.* **46**, 8931*a*.

Silica gel prepd. by tenfold diln. of water glass, followed by addn. of an excess of *N* HCl, drop by drop, filtration and washing, then shaping into rods, 4 mm in diam., was used to prep. replicas for electron micrographs. Films 200 and 250 A. thick were used. Preheating prior to evapn. of SiO_2 served to complete the dehydration. Comparison of silica gel and quartz indicated that the gel evapd. with greater ease than did quartz. The results were compared with data for Pt, Au, Cr, and Al.

1889. Neimark, I. E.; Freidlin, L. Kh.; Sheinfain, R. Yu., and Fridman, G. A. **Poisoning of the silica-gel catalyst by inorganic impurities and by the reactants.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* **1951**, 311-16.—*C.A.* **45**, 9350*b*.

Poisoning of com. Silica gel with 1% HCO_2Li caused a decrease of the micropore vol. from 0.21 to 0.11 ml/g, and of the surface area from 398 to 161 m^2/g. In another sample, the same addn. caused a decrease of the total pore vol. from 0.46 to 0.40 ml/g, of the micropore vol. from 0.26 to 0.19 ml/g, and of the surface from 450 to 309 m^2/g. There was also a decrease of the catalytic activity in the gas-phase hydrolysis $PhCl + H_2O \rightarrow PhOH + HCl$. The poisoning was reversible. Adsorption of H_2O vapor on the SiO_2 gels was not detected at either 300° or 450°. At 450°, PhCl was adsorbed without decompn., but PhBr and PhI underwent decompn.

1890. Osawa, Fumio and Satô, Hisanao. **Adsorption of mixture of gases** *Busseiron Kenkyû (Researches on Chem. Phys.)* No. **36**, 35-40 (1951).—*C.A.* **46**, 6896*a*.

Statistical thermodynamics for multicomponent systems (McMillan and Mayer) was applied to the adsorption of mixed gases. The adsorbed amt. of one gas was increased by the presence of another if the intermol. potential of force was greater in the first gas than that in the second. This conclusion agreed for mixed adsorption of CO and CO_2 on silica at 100°C. An application of the theory to adsorption in solns. was suggested.

1891. Rolland, Marie Thérèse and Bernard, Raoul. **Absorption in the range of kilometer wave lengths by adsorbed water.** *Compt. rend.* 232, 1098-9 (1951).—*C.A.* 45, 6491*d*.

Water adsorbed on silica gel showed a variation of adsorption as a function of temp. There was a strong absorption at 0°C, displaced from +12° to −40°C depending on the concn. of adsorbate, and a 2nd absorption at −100°C, which was relatively independent of temp. The former was attributed to assocd. water, the latter to water dissocd. by adsorption.

1892. Ross, W. L. and McLaughlin, E. R. **Dynamic characteristics of a solid adsorbent.** *Refrig. Eng.* 59, 167-73 (1951).—*C.A.* 45, 7725*e*.

An equil. chart was given for silica gel and water vapor at temperatures between 0 and 250°F. The factors investigated were: ambient dry-bulb temp. 40, 70, 100°F; ambient relative humidity, 20, 35, 55, and 90%; desiccant bed thickness 2, 4, 8 in.; adsorption air flow desorption heater power and desorption air flow. Type and grain size of silica gel, shape of bed, and dry wt of desiccants were controlled.

1893. TERENIN, A. N. AND KARYAKIN, A. V. **Effect of adsorption of water on the quenching of the fluorescence of adsorbates.** *Zhur. Eksptl. Teoret. Fiz.* 21, 107-13 (1951).—*C.A.* 45, 7882*g*.

Anthraquinone adsorbed on purified silica gel from the vapor at about 240°C was held firmly. Fluorescence was investigated in excitation with ultraviolet. Quenching by O_2, as a function of its pressure p, followed the linear law $I_0/I_p = 1 + kp$, where k contained the probability of quenching on collision between adsorbate and O_2. At −180°C the quenching became exceedingly strong; thus, under $p = 1$ mm, the intensity of the fluorescence fell to 50%, and was suppressed altogether on further slight increase of p, whereas at −70°C, 60 mm O_2 was needed to decrease the intensity by 50%. At −180°C, the original intensity was restored only upon prolonged evacuation of the O_2. The fluorescence spectrum of the H_2O-treated adsorbate remained unchanged, but quenching by O_2 was enhanced.

1894. UTSUGI, HIROSHI. **Adsorption of vapors in the low-pressure region.** *J. Chem. Soc. Japan*, Pure Chem. Sect., 72, 812-15 (1951).—*C.A.* 46, 1306*d*.

The adsorption isotherms of EtOH on a number of silica gels were measured at 10°, 15°, 20°, and 25°C. No discontinuous increase of the amt. adsorbed was found in the whole range examd. The B.E.T. plots of exptl. results showed a number of straight portions. The differential heat of adsorption first decreased rapidly with increasing amt. of the adsorbate.

1895. VAN NORDSTRAND, ROBERT A.; KREGER, WM. E., AND RIES, HERMAN E. JR. **Adsorption studies of two silica gels and a gel-type catalyst.** *J. Phys. & Colloid Chem.* 55, 621-38 (1951).— *C.A.* 45, 9992*g*.

Changes in structure caused by sintering and grinding were followed by low-temp. N_2 adsorption isotherms for a silica aerogel, a silica xerogel, and a silica-alumina bead-type cracking catalyst. Sintering *in vacuo* caused a proportionate decrease in adsorption at all pressures for the silica xerogel and the catalyst. NH_3 adsorption on the catalyst was similar to N_2 adsorption.

1896. AVGUL, N. N. MIKOS; DZHIGIT, O. M.; KISELEV, A. V., AND SHCHERBAKOVA, K. D. **Adsorption of various vapors on silica gel.** *Zhur. Fiz. Khim.* 26, 977-85 (1952).—*C.A.* 47, 3079*c*.

The adsorption of pentane, MeOH, and water was measured on a silica gel adsorbent. Whereas the isotherms showed a reproducible hysteresis at high values of relative pressure for all 3 vapors, an irreversible hysteresis was observed at low relative pressures for MeOH and water. The loop of the latter was more marked if adsorption had been carried out to higher pressures. The B.E.T. area of the gel was 435 m^2/g from N_2 adsorption. The B.E.T. area from pentane and MeOH were, resp., 440 and 430, assuming 64 and 25 A^2. as area per mol.

1897. BARTELL, F. E. AND BOWER, JOHN E. **Adsorption of vapors by selica gel of different structures.** *J. Colloid Sci.* 7, 80-93 (1952).—*C.A.* 46, 6896*b*.

The free surface energy changes were detd. during adsorption of vapors on silica gels. Surface areas of the gels were detd. with MeOH, EtOH, PrOH, C_6H_6, C_6H_{14}, CCl_4, H_2O, and N_2 as adsorbates. Similar values were obtained with the different adsorbates, and the results agreed with those obtained by the B.E.T. method.

1898. BARTELL, F. E. AND DONAHUE, DANIEL JOSEPH. **Preferential capillary adsorption of water from solutions of alcohols by silica gel.** *J. Phys. Chem.* 56, 665-70 (1952).—*C.A.* 46, 7397*d*.

The adsorption of water from *n*-butyl, *n*-amyl, *n*-hexyl, and heptyl alcs. at 0°, 25°, and 45°C were detd. and the amts. adsorbed were plotted against the reduced concns. The B.E.T. equations was applied to the adsorption data, and the phys. significance of the consts. examd. A process analogous to capillary condensation in gases must have occurred, causing an apparently large increase in the amt. adsorbed, resulting from the sepn. of a water-rich phase in the capillaries.

1899. BORESKOV, G. K. AND KARNAUKHOV, A. P. **The adsorption method of measurement of the surface of platinum in platinized silica gels.** *Zhur. Fiz. Khim.* 26, 1814-23 (1952).—*C.A.* 47, 5758*g*.

A glassy silica gel was platinized with 0.2% or 0.5% Pt. The adsorption isobar of H_2 was detd. on the original gel between 0° and 450°C; the min. adsorption occurred at 250°C. From the MeOH isotherm and from adsorption isotherms of A. and N_2 at −183°C, the surface area was 340-400 m^2/g. The platinized gels at 250°C adsorbed 2-6 times more H_2. Adsorption of H_2 by a Pt sponge (0.17 m^2/g) also was detd. at 250°C. From adsorption isotherms of A at −183°C and of MeOH at 20°C the areas of platinized gels were: 300-310 m^2/g for 0.2% Pt and 280-290 m^2/g for 0.5% Pt.

1900. BOWER, JOHN E. **Adsorption of vapors by silica gels of different structures. Free-surface-energy changes which occur during adsorption by porous adsorbents.** *Univ. Microfilms* (Ann Arbor, Mich.), *Pub.* No. 3720, 220 pp. (microfilm $2.75, paper enlargements $22.00).—*C.A.* 47, 1457*a*.

1901. BROWN, MARJORIE J. AND FOSTER, A. GRAHAM. **Melting point of adsorbed liquids.** *Nature* 169, 37 (1952).—*C.A.* 46, 5929*a*.

The vapor pressure-temp. curve of ethylenediamine adsorbed on silica gel at an equil. pressure of 5.41 mm at 25°C corresponding to a relative pressure of 0.403 and a pore radius of 25 A., showed a discontinuity at 3.2°. Similar curves for pure ethylenediamine or for silica gel satd. with an excess of ethylenediamine showed a discontinuity at 10°C; this fact indicated a lowering of the m.p. of 6.8°C.

1902. BROWN, MARJORIE J. AND FOSTER, A. GRAHAM. **The sorption of amines by silica gels.** *J. Phys. Chem.* 56, 733-7 (1952).—*C.A.* 46, 8459*c*.

Sorption isotherms were detd. at 25°C of ethyl-, propyl-, butyl-, tert-butyl-, hexyl-, heptyl-, and cyclohexylamines, ethylenediamine, and pyridine on 2 silica gels. One gel showed no hysteresis with the lower amines, whereas higher amines and the other gel with all amines, showed typical hysteresis loops. The point of hysteresis inception corresponded to a pore radius of 2 to 3 times the mol. diam. The satn. vols. were essentially const.

1903. Chesalova, V. S. and Boreskov, G. K. **Specific catalytic activity of metallic platinum.** *Doklady Akad. Nauk S.S.S.R.* **85**, 377-9 (1952).—*C.A.* **46**, 9961*a*.

Six catalyst prepns. were made: (1) silica gel, (original surface area 350 m^2/g, most frequent pore diam. 80 A.) with 0.2% Pt; (2) ditto with 0.5% Pt; (3) spongy Pt, made by sintering Pt black in vacuo; (4) Pt wire of 0.2 mm diam.; (5) Pt net from a 0.09 mm wire; (6) Pt foil 0.2 mm thick. The sp surface areas of (1) and (2) (by activated adsorption of H_2) were 30 and 73 m^2/g, resp. The sp area of (3), measured by adsorption of A, was 0.17 m^2/g, (4), (5), and (6) had surface area of $(0.5\text{-}2) \times 10^{-3}$ m^2/g. The catalytic activity was detd. in the flow-system oxidation of SO_2 in a mixt. of 3% SO_4 – 97% air between 360° and 515°C.

1904. Donahue, Daniel Joseph. **Preferential capillary adsorption of water from solutions of alcohols by silica gel.** *Univ. Microfilms* (Ann Arbor, Mich.), *Pub.* No. **3740**, 138 pp. (microfilm $1.73, paper enlargements $13.80).—*C.A.* 47, 1457*b*.

1905. Dreving, V. P.; Kiselev, A. V., and El'tekov, Yu. A. **Dependence of the adsorption of isopentane vapor on the pore dimensions of silica gels.** *Doklady Akad. Nauk S.S.S.R.* **86**, 349-52 (1952).—*C.A.* 47, 2011*b*.

Adsorption isotherms were detd. by the method of evapn. of liquid from a calibrated capillary, permitting an accuracy of 0.5 micromoles with a 1-mm capillary (better by a factor of 10-100 than the McBain balance method). Silica gels were characterized by the effective pore diam. (*D*), pore vol. and surface area. With decreasing *D*, the range of capillary-condensation hysteresis decreased; on the fine-pore gel the pores were filled in the primary adsorption process and there was no capillary condensation at all.

1906. Dzis'ko, V. A. and Krasnopol'skaya, V. N. **Effect of the chemical nature of adsorbent on the adsorption of methyl alcohol.** *Zhur. Fiz. Khim.* **26**, 1841-3 (1952).—*C.A.* 47, 5758*i*.

Assuming that the adsorption of N_2 at -183°C gave the true surface area, the area per mol. of MeOH was (from adsorption at 20°) 25-28 $A.^2$ on silica gels, 16-19 $A.^2$ on Al_2O_3 gels, 16-17 $A.^2$ on MgO, and 15 $A.^2$ on Ni. Before MeOH could be used for detg. surface areas of adsorbents, its mol. cross section for each adsorbent material had to be detd.

1907. Gyani, B. P. **Adsorption of organic vapors on silica gel and heats of adsorption.** *J. Indian Chem. Soc.* **29**, 83-91 (1952).—*C.A.* 47, 20*g*.

The adsorption of acetal, HCOOH, AcOH, propionic acid, $CHCl_3$, CCl_4, CS_2, H_2O, and EtOH on silica gel was measured at 35°C. Hysteresis was observed in some of the isotherms. Anomalies were observed in detg. the specific area of the adsorbing surface by the B.E.T. method. The heats of adsorption and the entropy changes accompanying desorption were detd. in some cases.

1908. Gyani, B. P. **Adsorption of alkyl halides on silica gel.** *J. Indian Chem. Soc.* **29**, 317-22 (1952).—*C.A.* 47, 5759*d*.

Adsorption of CCl_4, PrBr, PrI, BuCl, and BuBr was measured at 35°C on freshly prepd. silica gel evacuated for 2 hrs. at 320°C. The isotherms were roughly parabolic to a relative pressure of 0.25 and reach satn. at 0.35 except for PrBr. There was a hysteresis region in a limited pressure range towards satn. pressures. CCl_4 was not retained by the gel at low pressures.

1909. Harvey, Edmund N. Jr. **Sorption studies on silica aerogel.** *Univ. Microfilms* (Ann Arbor, Mich.), *Pub.* No. **2963**, 138 pp. (microfilm $1.73, paper enlargements $13.80).—*C.A.* 46, 8928*f*.

1910. Kurosaki, Shigehiko. **Dielectric properties of sorbed water. IV. Sorbed water in silica gel.** *J. Chem. Soc. Japan*, Pure Chem. Sect. **73**, 606-10 (1952).—*C.A.* 47, 3652*b*.

Sorption of water by silica gel was studied by measuring wt increase, dielec. const. and dielec. loss. For relative humidity less than 40% the sorption isotherm obeyed the B.E.T. formula, the effective area of the gel was approx. 143 m^2/g. The sorption of water took place in three steps, decreasing in the heat of condensation, increasing in specific polarization and increasing in dielec. loss.

1911. Milligan, W. O. and Whitehurst, Harry B. **Magnetic properties of adsorbed vapors.** *J. Phys. Chem.* **56**, 1073-7 (1952).—*C.A.* 47, 3635*h*.

Water, propanol, acetic acid, salicylaldehyde, and heptane were used as adsorbates on silica gel. Adsorption isotherms at 25°C were given for each of the adsorbates, and plots of x/m vs. (1) apparent magnetic susceptibility (χ), and (2) F/m, where x = wt of adsorbed vapor, m = sample wt, and F = force exerted by magnetic field on the sample. The variations in χ observed for less than monolayer coverage was due to the disruption of H-bonds which were present in the bulk liquids and which exert appreciable effect on magnetic susceptibility.

1912. Papee, Denis. **Adsorption of water vapor by alumina and silica.** *Compt. rend.* **234**, 952-4 (1952).—*C.A.* 46, 10773*h*.

The first adsorption isotherm on a silica or alumina gel consists of chem. and phys. adsorption. After evacuation at room temp. subsequent adsorption and desorption isotherms are reproducible and consist only of phys. adsorption. These later isotherms serve to measure surface area of the gels.

1913. Patterson, Gordon D. Jr. and Mellon, M. G. **Determination of sulfur dioxide by color-changing gels.** *Anal. Chem.* **24**, 1586-90 (1952).—*C.A.* 47, 71*e*.

Place the gel containing NH_4VO_3 in a glass tube and draw air through it. As little as 10 p.p.m. of SO_2 can be detd. H_2S and HCl also produce color effects which interfere, and NH_3 has a bleaching effect.

1914. Robert, Louis. **The determination of the covolume of molecules adsorbed on silica gel.** *Compt. rend.* 234, 2066-7 (1952).—*C.A.* 46, 9369*h*.

From a detn. of the surface area of a silica gel column and of the amt. of material adsorbed from a heptane or cyclohexane solvent, the area occupied per mol. was detd. EtOH and Me_2CO show the usual 18-23 $A.^2$ cross section of a perpendicularly adsorbed mol. The value of 26-27 $A.^2$ for aniline and nitrobenzene was considered to be the cross sectional area of a vertical benzene mol., whereas the value of 50 sq A. for benzene represents the horizontal area.

1915. Sabatier, G. **Crystallization of mixtures of amorphous silica and oxides of magnesium, zinc, and copper by heating.** *Bull. soc. franc. minéral. et crist.* 75, 506-26 (1952).—*C.A.* 47, 5643*i*.

Mixts. of SiO_2 with MgO, ZnO, and CuO are prepd. by the copptn. of SiO_2. Solidification takes place after the NaCl is removed at 110°C. Differential thermal analysis up to 1000°C is used to det. the crystn. temps., which vary depending upon the % of metal salt added.

1916. Utsugi, Hiroshi. **Adsorption of vapors in the low-pressure region. IV. Differential molar entropy of adsorption.** *J. Chem. Soc. Japan, Pure Chem. Sect.* 73, 917-20 (1952).—*C.A.* 47, 3651*f*.

Differential entropy of adsorption was calcd. from the expts. on the adsorption of n-butane, EtOH, and N_2 on various adsorbents. For *n*-butane adsorbed on glass powder, carbolac, and silica gel, the agreement between theory and expt. was good. In the case of EtOH and N_2 the exptl. differential entropy did not agree with the theoretical value.

1917. Waarden, M. van der and Scheffer, F. E. C. **The adsorption of nitrogen, hydrogen, and their mixtures on silica gel.** *Rec. trav. chim.* 71, 689-98 (1952) (in English).—*C.A.* 46, 10773*e*.

Adsorption isotherms were detd. for H_2 and N_2 between 300° and −195°C and at pressures up to slightly above 1 atm. The adsorption of mixts. of the 2 under a pressure of 1 atm. was detd. at 0, −78, and −183°C. At 0° and −78°C N_2 increased the adsorption of H_2, and H_2 decreased the adsorption of N_2. At −183°C N_2 greatly decreased the adsorption of H_2, but H_2 had almost no effect on the adsorption of N_2. The higher-temp. isotherms were linear.

1918. White, David; Chou, Chien, and Johnston, H. L. **Heat conduction and isotherms of adsorbed helium on silica gel.** *J. Chem. Phys.* 20, 1819-20 (1952).—*C.A.* 47, 4685*c*.

Temp. drops were measured, as a function of heat input, at various points along a silica-gel-filled tube (2 mm diam. x 12 cm long) for different amts. of adsorbed He at a series of temps. below the λ-point. The data for the isotherms of He adsorbed on silica gel above and below the λ-point fell on the same curve; the isotherms did not show the S-shape characteristic of multilayer adsorption on silica gel.

1919. Haul, R. A. W. **Measurement of activated diffusion of adsorbed molecules.** *Nature* 171, 519 (1953).—*C.A.* 47, 7287*c*.

Rates of adsorption of butane in porous SiO_2 plugs were measured by a gravimetric method over a temp. range of −14° to −80°C, a porosity range of 0.72 to 0.53, and a surface coverage range of 0.37 to 6.9 statistical layers. At −14.4°, −44.2°, and −79.5°C, 70, 80, and 94%, resp., of the total transport was due to the mobility of adsorbed mols. on the surface. The activation energy for surface diffusion was 3 kcal/mol.

1920. Pimentel, Geo. C.; Garland, Carl W., and Jura, Geo. **Infrared spectra of heavy water adsorbed on silica gel.** *J. Am. Chem. Soc.* 75, 803-5 (1953).—*C.A.* 47, 5253*a*.

A technique was developed for the detn. of the infrared absorption spectrum of D_2O adsorbed on silica gel. In the 1900-3400-cm-region, the spectra of samples with surface coverages from 0.35 to 1.8 monolayers were similar to the spectrum of D_2O in the liquid phase. Exchange of the adsorbed D_2O with the H_2O in the gel was observed.

1921. Snelgrove, J. A.; Greenspan, H., and McIntosh, R. **The dielectric behavior of vapors adsorbed on silica gel.** *Can. J. Chem.* 31, 72-83 (1953).—*C.A.* 47, 5746*g*.

The sudden change of the dielec. const. of adsorbed butane, EtCl, and H_2O on activated silica gel was detd. to 3.7 Mc. per sec. No Debye-type dispersion was observed for the polar adsorbates down to −30°C. Mixts. of EtCl-H_2O and C_4H_{10}-H_2O were measured at 0.1 , the quantity of H_2O being varied up to 250 cc. at N.T.P.

1922. Stitt, Fred and Tomimatsu, Yoshio. **Removal and recovery of traces of ethylene in air by silica gel.** *Anal. Chem.* 25, 181-3 (1953).—*C.A.* 47, 3184*f*.

Ethylene was detd. with HgO as an oxidizing agent and Se-sensitized paper strips. Expts. with com. silica gel (14-20 mesh) and a sample contg. 5 p.p.m. C_2H_4 in com. tank O_2 showed that all C_2H_4 was adsorbed by the gel at −78°C and released at 150°C; oxidizable impurities in the O_2 were adsorbed at −78°C and were not completely released at 150°C.

I-11. Gases on Other Porous Oxides

1923. Strese, H. and Hofmann, U. **Synthesis of magnesium silicate gels with two-dimensional regular structure.** *Z. anorg. allgem. Chem.* **247**, 65-95 (1941).—*C.A.* **36**, 5074^1.

Mg silicate gels, obtained by boiling together solns. of $MgCl_2$ and hydrated SiO_2 with KOH and $Ca(OH)_2$, showed Rontgen interferences, and all those that were characteristic for the Si layers of the clay minerals (in contradiction to analogously pptd. Al silicates). It was possible to get gels of the compn. of montmorillonite, $Mg_3(OH)Si_4O_{10} + nH_2O$. These gels consisted of single Mg silicate layers. The detn. of d., n, base exchange, thermal decompn. and water absorption affirmed the structure detn.

1924. Suzuki, Shin-ichi. **Titanium compounds. XVII. Titania gel.** *J. Japan Ceram. Assoc.* **49**, 409-15 (1941).—*C.A.* **44**, 10282*d*.

Titania gels were prepd. by heating sols which were made by hydrolyzing $TiCl_4$ contg. chlorides of Ca, Mg, Al, Fe, or Mn. The decreases in wt caused by heating the gels from room temp. to 1000°C were detd. Dehydration took place rapidly at 350°-500°C and then slowly from 500° to 700°C.

1925. Abe, Shiro. **Study of the alumina gels. IV.** *Bull. Inst. Phys. Chem. Research (Tokyo)* **21**, 424-6 (1942).—*C.A.* **43**, 2080*d*.

Active Al_2O_3 gel was prepared from solns. of $Al(NO_3)_3.9H_2O$ and NH_4OH of concns. between 5-45 and 4-35% resp. The hydrogel of $Al(OH)_3$ was decanted and centrifuged. The gel was then filled in molds, dried by air at 70°C, and heated in an elec. furnace at not above 400°C. Glassy active Al_2O_3 gel, each particle having a vol. of 0.0726 cc., was produced.

1926. Besson, Jean. **Action of carbon tetrachlorida vapors on beryllium oxide.** *Compt. rend.* **214**, 861-3 (1942).—*C.A.* **38**, 3559^9.

The rate of the reaction of CCl_4 vapors with BeO was studied. In general, the activity of BeO was reduced by previous heating to high temps. The reaction velocity (measured by detg. the percentage of BeO changed to $BeCl_2$ upon heating the CCl_4 at a definite temp. for a definite time) increased between 300° and 400°C, remained practically const. between 400° and 500°C, and then increased rapidly up to 900°C. Up to 500°C, $COCl_2$ was formed; above 500°C, the $COCl_2$ reacted with the BeO giving $CO_2 + 2BeCl_2$.

1927. Funaki, Koemon. **The properties of aluminum hydroxide and alumina I.** *J. Electrochem. Assoc. Japan* **10**, 103-11 (1942).—*C.A.* **44**, 9844*i*.

Dehydration curves up to 800°C were given for various samples of $Al(OH)_3$ obtained (1) by treating Na aluminate with H_2O, or (2) with CO_2 gas, (3) by treating solid $Al_2(SO_4)_3$ in soln. with NH_4OH, or (4) by treating $Al_2(SO_4)_3$ in soln. with NH_4OH. Two types of Al $(OH)_3$ prepd. below 80°C were very unstable and gradually became similar to bayerite, while that prepd. above 80°C was of the boehmite type, and that obtained at 150-200°C had the exact compn. $Al_2O_3.H_2O$.

1928. Higuchi, Izumi. **The dielectric properties of substances in the sorbed state. II. Anomalous dispersion of isoamyl alcohol sorbed on titania gel.** *Bull. Inst. Phys. Chem. Research* **21**, 1138-46 (1942).—*C.A.* **42**, 8556*b*.

The change of capacitance due to the isoamyl alc. sorbed on titania gel packed in a cylindrical Ni condenser was detd. between 70° and 80°C. There were 2 types of contribution to the capacitance; one was due to the surface sorption, that is, to the electronic and at. polarization of the sorbate, and the other to the capillary condensation of the sorbate. The dielec. const. of the condensed liquid increased with the quantity sorbed.

1929. Katsurai, Tominosuke. **Preparation of superheated aluminum hydroxide sol.** *J. Soc. Chem. Ind., Japan* **45**, Suppl. binding, 217 (1942) (in English).—*C.A.* **45**, 1842*i*.

A very stable $Al(OH)_3$ sol. was prepd. by heating $Al(OH)_3$ contg. a small amt. of Cl at 190°C in an autoclave for 1 hr. The sol. thus obtained is designated as superheated $Al(OH)_3$ sol. This sol. *adsorbs pure diastase* as well as the *Shigadysentery toxin* to a great extent.

1930. Luyckx, A.; Rens, G., and Bodart, J. **Adsorption of hydrogen activated by mercury resonance radiation.** *J. chim. phys.* **39**, 139-51 (1942).—*C.A.* **38**, 4516^9.

H_2 irradiated with the Hg resonance line was adsorbed on ThO_2 at ordinary temp. in about the same vol. as in thermal adsorption. By continued irradiation for several hrs one can produce a complete vacuum. At. H formed in the gas phase was held on the surface. There was a crit. pressure of a few mm Hg above which there was no photo-activation. Above this threshold, which varied with the adsorbent, a protective layer of H_2 was formed.

1931. Briner, E. and Lowy, E. **The adsorption of nitrogenous gases by alumina gel and by beryllium and calcium hydroxides.** *Helv. Chim. Acta* **26**, 1054-64 (1943).—*C.A.* **38**, 2253^4.

Air contg. 2% by vol. of NO was passed over Al_2O_3 at -70°, -15°, 0° and 100°C. Gels satd. at -15° and -70°C gave up, resp., 30 and 76% of the adsorbed gas after desorption for 1 hr at 0°C. In all cases the desorbed gas was entirely N_2O_4. The behavior of Al_2O_3 gel was similar to that of silica gel, but the recovery of N_2O_4 from the former was not so efficient. With $Ca(OH)_2$ no significant adsorption was found below 300°C. With $Be(OH)_2$ gel a small amt. of gas was retained by reversible adsorption, but most was absorbed by chem. union with water on the hydroxide.

1932. Capell, R. G.; Amero, R. C., and Moore, J. W. **New data on activated bauxite desiccants.** *Chem. & Met. Eng.* **50**, No. 7, 107-10 (1943).—*C.A.* **37**, 5802^5.

Dehydration of org. gases and liquids with an activated bauxite desiccant, Florite, was described. Equil. dryness obtainable, H_2O-adsorption capacity, regeneration and effects of pressure drop and fluid velocity were discussed.

1933. Chowdhury, J. K. and Datta, R. M. **Recovery of elementary sulfur from gases containing hydrogen sulfide.** *J. Indian Chem. Soc.* **20**, 253-60 (1943).—*C.A.* **38**, 2457⁶.

Fe_2O_3 showed an increase in wt of 25.54% due to adsorption of H_2S and pure Al_2O_3 only 0.36%, but a mixed adsorbent contg. 25.11% Al_2O_3 showed 56.98% increase in wt. MnO_2 also increased the activity of the adsorbent. The recovery of S and revivification of the adsorbent were satisfactory.

1934. Hedvall, J. A. and Günther, T. **The influence of the gas atmosphere on the surface structure and the adsorptivity of ferric oxide.** *Z. anorg. allgem. Chem.* **251**, 305-14 (1943).—*C.A.* **37**, 6515⁸.

Fe_2O_3 was prepd. by decompn. of dehydrated $Fe_2(SO_4)_3.(NH_4)_2SO_4.24H_2O$ in a N_2 and O_2 stream, resp. The surface area in cm^2/g was calcd. on the assumption of cubes with smooth surfaces. The ratios of the areas of the N_2-treated to the O_2-treated samples were 0.79, 0.88, 0.80 for the 3 temps., resp. The adsorptivities for fast red H, di-Na salt of 7-(4 sulfo-1-naphthylazo)-1-naphthol-4-sulfonic acid, were detd. and the ratios for the 2 samples were 0.53, 0.83, 0.31 for the 3 temps., resp.

1935. Hedvall, J. A. and Lundberg, A. **The effect of the gaseous atmosphere on the preparation, the chemical activity and the surface formation of powdered substances.** *Kolloid-Z.* **104**, 198-203 (1943).—*C.A.* **38**, 1419⁴:

Pure Fe_2O_3 was prepd. from $Fe(NH_4)(SO_4)_2.12\ H_2O$ *in vacuo* and in CO_2-free air and CaO from pure $Ca(OH)_2$ *in vacuo* and in CO_2-free air. The CaO reacted with SiO_2 (ratio 2:1) and with Fe_2O_3 (ratio 1:1) at 600°C for 1 hr both *in vacuo*, and in air. The amt. of CaO that had reacted was invariably greater *in vacuo* than in air. The effects observed were ascribed to the soln. of the gases.

1936. Ku, Chen Chun; Huntington, R. L., and Reid, L. S. **Selective adsorption of hydrocarbon and water vapor on alumina at atmospheric pressure.** *Am. Inst. Mining Met. Engr., Tech. Pub.* No. **1628**, 13 pp. (1943).—*C.A.* **38**, 1345⁶.

The simultaneous adsorption of H_2O and hydrocarbon vapor from natural gas by 3 grades of Al_2O_3 was studied at atm. pressure and temp. The presence of H_2O vapor in the gas inhibits the adsorption of hydrocarbon vapor, although the presence of the latter has no pronounced effect on the adsorption of H_2O vapor. Both theory and exptl. data can be applied to design and operation of com. dehydration plants.

1937. Mignolet, J. **Investigations on adsorption at present in progress.** *Rev. universelle mines* **19**, 111-13 (1943).—*C.A.* **38**, 5719¹.

The adsorption of H_2 on catalysts of MoO_2 base was investigated. This oxide was not stable in the presence of H_2. A slow reduction of the MoO_2 was observed and the reduced form stable under conditions suitable for the technical use of MoO_2 was sought. The app. used in the expts. was described.

1938. Montoro, Vincenzo. **The water of constitution of hydrated aluminas.** *Gazz. chim. ital.* 73, 43-8 (1943).—*C.A.* **40**, 3067⁹.

Distinguishing between hydroxides and hydrated oxides of Al, which sometimes is not possible by x-ray examn., can be effected by detns. of d., porosity, and contraction on calcination, and by comparison with the d. values calcd. from the mol. wt. In the freshly prepd. hydrated alumina, H_2O was in the mol. state, and Al_2O_3 in the γ-form.

1939. Morita, Noriyoshi. **The catalytic exchange of isotopes of gaseous oxygen. XIII. The exchange reaction of oxygen atoms between oxygen and water vapor on the surface of various catalyzers of iron oxides.** *Bull. Chem. Soc. Japan* **18**, 242-7 (1943).—*C.A.* 41, 4366*a*.

Light O_2 and heavy water vapor were passed together over α-Fe_2O_3, γ-Fe_2O_3, $2Fe_2O_3 + Bi_2O_3$, and Bi_2O_3, resp., at various temps. From the decrease of the vapor density, the exchange percentage of O-isotopes was calcd. The 3 kinds of iron oxides have nearly the same catalytic activity, but Bi_2O_3 is far less active. The activity of pure iron oxides was reduced to a const. value through repeated use, whereas that of $2Fe_2O_3 + Bi_2O_3$ showed a const. value from the beginning. The activity decreased remarkably when the oxides were heated beforehand to 800°C for 24 hrs.

1940. Sakai, Wataru; Kurimura, Rokuro, and Okuno, Toshiro. **Catalytic powers of manganese oxides. IV-V. Adsorption equilibrium of oxygen by manganese oxides.** *J. Soc. Chem. Ind. Japan* **46**, 1011-16 (1943).—*C.A.* **43**, 1624*a*.

To Mn oxide, previously heated *in vacuo* to 175-80°C, a definite quantity of O_2 was introduced at 0-70°C and the quantity adsorbed by the oxides is calcd. The equil. condition was expressed by the formula $a = kp^m$, where a was the quantity of O_2 adsorbed, p the pressure, and k and m const., m being always greater than 1.

1941. Schneider, W. G. and Thorvaldson, T. **The hydration of the aluminates of calcium. III. The hydration of the 5:3, 1:1 and 3:5 calcium aluminates.** *Can. J. Research* **21B**, 34-42 (1943).—*C.A.* **37**, 3997².

The hydration of the aluminates of Ca in satd. steam at 150° and 105°C was studied. At 150°C when conditions favoring rapid hydrolysis were avoided, the 1:1 and 3:5 Ca aluminates were apparently transformed almost quantitatively to the cubic hexahydrate of tricalcium aluminate and hydrated alumina approaching the compn. of the monohydrate. The steam-treated 5:3 Ca aluminate gave lower water absorption and higher content of combined alumina than called for by the above end products.

1942. Brauer, Peter and Muller, F. Horst. **Gas adsorption on cuprous oxide and its electrical properties.** *Kolloid-Z.* **107**, 129-31 (1944).—*C.A.* **31**, 10⁶.

The elec. properties of the electron-semiconducting Cu_2O were changed reversibly through the action of active gases, such as H_2O and NH_3. The very small quantity of H_2O taken up by the Cu_2O crystals and measured quantitatively at room temp. corresponded to a unimol. adsorption layer.

1943. Faivre, René and Chaudron, Georges. **The zeolitic nature of the water in calcium sulfate hemihydrate and the effect of its removal upon the transformation of soluble anhydrite into insoluble anhydrite.** *Compt. rend.* **219**, 29-30 (1944).—*C.A.* **40**, 4942^9.

By almost complete dehydration of the hemihydrate below 200°C, the sol. anhydrite was obtained. This had the same x-ray spectrum as the hemihydrate. The contraction when sol. anhydrite was transformed into the insol. was obtained by dilatometric thermal analysis. The transformation was not complete below 400°C and until the last traces of water were removed.

1944. Kohata, Katricko. **The sorption of water vapor by slaked lime.** *Bull. Inst. Phys. Chem. Research, (Tokyo) Chem. Ed.* **23**, 274-80 (1944).—*C.A.* **42**, 5300*a*.

A static study was made on the sorption equil. at 15°, 25°, 35°C at just below the satn. pressure of steam. Freundlich's equation held both at higher and lower pressures. An exptl. formula was given for the sorption equil. at const. temp.: in the lower region, $\log a = (0.65108 + 0.2003 \log P) + (0.02174 - 0.01329 \log P)t$, where a = amt. of sorption (mg); in the higher region, $\log P = [9.23987 - (2441.1/T)] - [0.34932 - (168.4/T)] \log a$. From these, the differential heat of sorption was calcd.

1945. Tachiki, Kenkichi. **Adsorption of chlorine by magnesium oxide I.** *J. Chem. Soc. Japan* **65**, 50-2 (1944).—*C.A.* **41**, 3342*g*.

The adsorption equil. of Cl_2 by porous MgO was studied at 25°, 35°, and 45°C in the pressure range 20-700 mm. The results are summarized.

1946. Borgstrom, L. H. **Sintering of iron ore upon reduction with carbon.** *Finska Kemistsamfundets Medd.* **54**, 39-52 (1945).—*C.A.* **41**, 3411*e*.

Mixts. of magnetite or hematite with coke, lampblack, or graphite were heated. The greatest sintering (up to 40% linear shrinkage) occurred with the most finely powd. ore mixed with less than the equiv. amt. of carbon. With a 2-5% excess of carbon, the product was loose and powdery. Below 1000°C sintering rarely occurred. It increased from 1000° to 1300°C. There was an appreciable increase of sintering upon addn. of 3-13% quartz or limestone.

1947. Bradley, W. F. **Diagnostic criteria for clay minerals.** *Am. Mineral.* **30**, 704-13 (1945).—*C.A.* **40**, 2089^8..

The advantages of utilizing the glycol-complexes of clay minerals for characterization are emphasized, esp. for montmorillonite and halloysite. Mixed layer minerals that involve intergrowths of montmorillonite and illite can be studied anew, as the illite does not undergo structural changes when treated with glycol. The characteristic 17 A. glycol complex was also obtained with most beidellites and nontronites.

1948. Burbo, P. Z. **Drying air with inorganic adsorbents.** *Khimicheskaya Prom.* **1945**, No. 11, 11-14.—*C.A.* **40**, 3028^9.

The efficiency of removing H_2O from air in the production of liquid air, liquid O_2, or liquid rare gases was compared by freezing the H_2O out or by adsorption. $CaCl_2$, anhyd. $CaSO_4$, NaOH, KOH, silica gel, activated Al_2O_3, and BaO were compared. While BaO was most effective, the use of silica gel or Al_2O_3 was more advisable.

1949. Fricke, R. and Weitbrecht, G. **The effect of small amounts of silica on the primary particle size and lattice distortion of γ-alumina.** *Z. anorg. Chem.* **253**, 30-6 (1945).—*C.A.* **43**, 3685*d*.

More than 2% SiO_2 hindered the crystn. of γ-Al_2O_3 below 800°C. At 900°C 0.5% SiO_2 aided the crystn. It is probable that the SiO_2 was between the primary particles.

1950. Raychaudhuri, S. P. and Datta, N. B. **Comparison of the properties of freshly precipitated and heated aluminosilicates and alumina and silica gels and of clay minerals.** *J. Phys. Chem.* **49**, 21-32 (1945).—*C.A.* **39**, 1584^5.

Nine kinds of aluminosilicates were prepd. by mixing silicic acid and $Al(OH)_3$ sols in the respective proportions 2:1, 3:1, 4:1 and in 3 different ways: by slow addn. of the hydroxide to an excess of the acid sol., by reversing the procedure, and by mixing the 2 components dropwise. Chem. compn., electroösmotic charge, capacity of combination with bases, moisture contents at 50% humidity and buffer curves were detd. The gels were electrodialyzed. The third method of mixing favors the formation of mineral structures.

1951. Weitbrecht, G. and Fricke, R. **Particle size, lattice distortion, and secondary structure of γ-alumina and its starting material.** *Z. anorg. Chem.* **253**, 9-29 (1945).—*C.A.* **43**, 3685*b*.

γ-AlOOH was prepd. by pptn. and by autoclaving boehmite with H_2O above 370°C. γ-Al_2O_3 was prepd. by heating either species of γ-AlOOH. The various prepns. were examd. by x-ray diffraction and under the electron microscope for particle size, lattice distortion, and shape.

1952. Belcher, Ronald. **Efficiency of desiccants.** *Analyst* **71**, 236-7 (1946).—*C.A.* **40**, 3943^7.

The efficiency of desiccants was concerned chiefly in their use in drying trains. For the purposes of gravimetric analysis, it was more important to keep the crucible covered and to weigh promptly. Then reignition to const. wt was important.

1953. Broad, D. N. and Foster, A. G. **Sorption of vapors by ferric oxide gel. II.** *J. Chem. Soc.* **1946**, 446-50.—*C.A.* **40**, 6931^6.

Adsorption-desorption data were detd. for a Fe_2O_3 gel with the adsorbates CCl_4, $CHCl_3$, EtI, cyclohexane, dioxane, hexane, morpholine, octane, diisopropyl ether, toluene, and triethylamine. All gave isotherms with a large hysteresis area. The capillary radii calcd. by means of the Kelvin equation from the point of inflection of the desorption curves and corrected for primary adsorption were in agreement, at 31-32°A.

1954. Emmett, P. H. and Cines, Martin R. **Adsorption of hydrogen and nitrogen on chromium oxide gel.** *J. Am. Chem. Soc.* **68**, 2535-6 (1946).—*C.A.* **41**, 1139*i*.

The chemisorption of 3.57 cc. of H_2 per g of Cr_2O_3 gel had substantially no effect on the phys. adsorption of H_2 at -195° and -78°C, and of N_2 at 0°C. The difference between these results and the marked inhibition of phys. sorption previously reported was attributed to differences in the pore sizes.

1955. Fichter, R. **Infrared absorption of aluminum oxide layer.** *Helv. Phys. Acta* **19**, 21-40 (1946).—*C.A.* **40**, 3682^9.

The spectral region extended from 0.90 to 12.0μ. Part of the observed bands could be attributed to H_2O and others to Al_2O_3. Presence of the deformation vibration of H_2O indicated that the latter was present as such in the oxide layer and not in the form of a true hydroxide.

1956. Forestier, Hubert and Perbet, Noel. **The effect of adsorbed water on the velocity of reaction between ferric oxide and nickel oxide.** *Compt. rend.* **223**, 575-6 (1946).—*C.A.* **41**, 6458*a*.

The rate of the reaction $Fe_2O_3 + NiO \rightarrow Ni(FeO_2)_2$ was studied magnetically. The reactants were prepd. by pptn., dried, and heated to 415° for 15 min. under various conditions. The velocity of the reaction was least for material heated in a vacuum, intermediate for heating in air, and greatest for heating in the presence of water vapor.

1957. Hée, Arlette. **Comparison of results obtained by the method of emanation power and by the thermomagnetic method upon the modifications in structure of iron sesoxide.** *Compt. rend.* **223**, 749-51 (1946).—*C.A.* **41**, 5770*i*.

Near the Curie point of Fe_2O_3 and Fe_3O_4, diffusion of adsorbed radioactive atoms increased notably. The increased emanation power of Fe_3O_4 and Fe_2O_3 near the Curie point either was directly connected with a mol. field, or was related to contractions and deformations due to disappearance of orientation in the Weiss elementary regions.

1958. Jura, George; Loeser, Edward H.; Basford, Paul R., and Harkins, Wm. D. **Surfaces of solids. XV. First-order phase changes of adsorbed films on the surfaces of solids: the film of heptane on ferric oxide.** *J. Chem. Phys.* **14**, 117-23 (1946).—*C.A.* **40**, 3323^2.

Two-dimensional first-order changes, in which a gaseous film of heptane was transformed into another phase of lower mol. area with evolution of heat, were discovered on subphases of Fe_2O_3, Ag, and graphite. All of the crit. phenomena observed in 3-dimensional systems were duplicated. For heptane on Fe_2O_3 the crit. consts. are: σ_c (area) 900 A.^{2} per mol.; π (film pressure) 0.45 dyne per cm; and T_c, 29°C. The crit. consts. depend on the nature of the solid as well as on that of the vapor.

1959. Murata, Kiku and Kakudo, Akiyo. **Preparation of adsorbent, active alumina and a method for its recovery.** *Rept. Osaka Minicipal Research Inst. Domestic Sci.* **17**, No. 1, 199-201 (1946).—*C.A.* **41**, 4897*i*.

Into 1 kg of concn. H_2SO_4 was sprayed 500 g of Al_2O_3 at 80-5°C, while the acid was being slowly stirred until it became a pasty mass. It was left alone for 2.5 hrs. Into the mass was dropped 17 g of $K_2Cr_2O_7$, dissolved in 260 cc. of water. After continuously stirring for 5 hrs at 80-5°C, 2 liters of water were added, and after stirring, it was left alone overnight, washed in water, dried, and finally calcined to become adsorbent, active alumina. The degree of adsorption was detd. colorimetrically with the standard solns. made from the coloring matter formed by adding Prebulda's reagent to 60γ vitamin B_1, the color appearing in 2 cc. of the 5 cc. xylene fraction of the matter being rated as 10.

1960. Powers, T. C. and Brownyard, T. L. **Studies of the physical properties of hardened portland cement paste. II. Studies of water fixation.** *J. Am. Concrete Inst.* **18**, 249-336 (1946).—*C.A.* **41**, 843^h.

Exptl. methods and app. used in water-vapor sorption measurements of cement pastes and mortars were described. Age and original water-cement ratio influenced the shape of isotherms only above a relative humidity of about 0.40.

1961. Puri, Amar Nath; Rai, Balwant, and Rahman, M. A. **Relative vapor pressures and moisture contents of activated alumina and silica.** *J. Indian Chem. Soc.* **23**, 85-98 (1946).—*C.A.* **40**, 6931^9.

The moisture-adsorption capacities of a no. of activated Al_2O_3, SiO_2, and Fe_2O_3 samples prepd. in a variety of ways were studied. Data for various org. vapors on activated Al_2O_3 were also obtained. The mechanism of moisture adsorption by Al_2O_3 and SiO_2, and by soils in general, was briefly discussed. Various silica samples were also compared as to activity in bleaching crude vegetable oils.

1962. Thibon, Honore; Maillard, Albert, and Savon, Louis. **Activated alumina: prepatation, properties, nature.** *Chimie & industrie* **57**, 117-25 (1946).—*C.A.* **41**, 6030*a*.

For dynamic adsorption of water vapor from air, activation by heating hydrated Al_2O_3 for 30 min. at 310°C gave better adsorption than heating for 30 min. at 360°C. A micro- or ultramicroporous silica gel adsorbed more water vapor than an equal wt of activated Al_2O_3; equal vols. of the 2 adsorbents and approx. the same adsorbing power. Reactivation could be accomplished at 155°C, unless there had been prolonged contact (several weeks) with water vapor, in which case heating to 300°C was required for reactivation. In dynamic adsorption of $C_2H_2Cl_4$, C_2HCl_3, and $C_2H_2Cl_2$ from air, the satn. capacity of activated Al_2O_3 on a vol. basis approached SiO_2. Max. adsorptive capacity was obtained by heating for a time which decreased with increase in activating temp. In the adsorption of As_2O_3 from alk. aq. sol., the max. adsorptive capacity was the same for all activating temps. Adsorption of I_2 dissolved in aq.

KI soln. was extremely slow (0.5% I_2 on the wt of Al_2O_3 at the end of 14 hrs). Adsorption of Congo red, As_2O_3, or I_2 cannot be a quick reliable test to control the adsorptive capacity of activated Al_2O_3.

1963. WHALLEY, H. K. **The preparation of an active absorbent of hydrogen sulfide from waste oxide of iron.** *J. Soc. Chem. Ind.* **65**, 217-24 (1946).—*C.A.* **41**, 837*g*.

Impure Fe oxide, which was a by-product in the extn. of Al_2O_3 from bauxite, was valueless as an absorbent for H_2S. Partial reduction in coal gas, followed by oxidation with air gave 3 groups of oxides which showed good absorbing properties. Group I oxides were prepd. by reduction at 550°C and oxidation at 250-300°C in air and steam. Group II oxides were prepd. by reduction at 550°C for 4-6 hrs and oxidation in air alone at or above 400°C. Group III oxides were prepd. by reduction at 550°C for 4-6 hrs and oxidation in air alone below 400°C. Group I was shown to be better than all of a no. of com. absorbents, except for bog ore admixed with peat.

1964. BRINTZINGER, HERBERT AND MOLLERS, ANNEMARIE. **Preparation of active oxides and oxide hydrates by decomposition of metal salts with superheated steam.** *Z. Anorg. Chem.* **254**, 343-6 (1947).—*C.A.* **43**, 2533*i*.

The following were prepd.: BeO, La_2O_3, $La_2O_3.3H_2O$, $3La_2O_3.4H_2O$, Al_2O_3, $3Al_2O_3.H_2O$, ThO_2, and $ThO_2.H_2O$. BeO and La_2O_3 are dehydration catalysts. Al_2O_3/La_2O_3 (10:1) gives 100% conversion of 1,4-butanediol to tetrahydrofuran without side reactions at 400°C; Al_2O_3/ZrO_2 (10:1) gives a 90% conversion. Al_2O_3/ThO_2 (10:1) gives a 95% conversion.

1965. COOKE, P. W. AND HARESNAPE, J. N. **Effect of steam on some alumina transitions.** *Trans. Faraday Soc.* **43**, 395-8 (1947).—*C.A.* **42**, 1481*g*.

Rates of transformation of γ-Al_2O_3 and of boehmite to α-Al_2O_3, and the rate of crystal growth of γ-Al_2O_3 increased on increasing the H_2O pressure at a fixed temp. Below 450°C and pressures below 240 lb/in², none of these reactions were appreciable. After 14 hrs at 500°C and a H_2O pressure of 600 lb/in², crystal growth of γ-Al_2O_3 was extensive, but formation of α-Al_2O_3 was inappreciable. Steam behaved as a catalyst with regard to these transformations by providing a medium in which the phases could dissolve and transform.

1966. DANIL'CHENKO, P. T. **Determination of stoichiometrically combined water in hydrogels and other finely dispersed systems by a method of third component.** *Zhur. Anal. Khim.* **2**, 299-308 (1947).—*C.A.* **43**, 6943*c*.

Chemically bound H_2O in hydrogels and similar systems was detd. by a method referred to as a third-component method. The third-component content was detd. in its own equil. soln. and in a mixt. of such soln. with the investigated material (gel or finely dispersed substance).

1967. DEKKER, A. J. AND GEEL, W. C. VAN. **The amorphous and crystalline oxide layers of aluminum.** *Philips Research Repts.* **2**, 313-20 (1947).—*C.A.* **42**, 438*b*.

By anodic oxidation, Al could be covered with either an amorphous or a cryst. oxide layer. The amorphous layer, which was porous, was obtained in aq. solns. of a borate, succinate, or citrate, and had pronounced *insulating properties*. When a cryst. layer was formed on a surface that had been coated with an amorphous layer, the cryst. layer formed in the pores of the amorphous layer until these were filled.

1968. DONGES, E. **The oxidation of carbon monoxide by oxygen-containing cobalt or nickel sulfide and by atmospheric oxygen in the presence of cobalt sulfide.** *Z. anorg. Chem.* **254**, 133-6 (1947).—*C.A.* **43**, 2076*i*.

Damp pptd. Co(III) and Ni(III) sulfides were able to oxidize CO slowly to CO_2 at room temp.; the CO:sulfide ratio was approx. 1:1. This was owing to the existence of basic CoS(OH) and NiS(OH). If these sulfides were dried over P_2O_5 or cooled to 0°C no oxidation of CO occurred.

1969. EISCHENS, ROBERT P. AND SELWOOD, P. W. **Structure studies of chromium-aluminum oxide and related catalyst systems.** *J. Am. Chem. Soc.* **69**, 2698-702 (1947).—*C.A.* **42**, 1793*d*.

Magnetic susceptibility isotherms, x-ray diffraction, and surface-area studies were made of catalysts prepd. by impregnation, pptn., and copptn. and contg. Cr, Mo, W, and U, generally supported on γ-Al_2O_3, but in certain cases on α-Al_2O_3, silica gel, TiO_2, and ThO_2.

1970. EUCKEN, A. **A model for the hindered chemical adsorption of hydroxyl compounds on γ-alumina.** *Naturwissenschaften* **34**, 374 (1947).—*C.A.* **44**, 2357*d*.

Dehydration of OH compds. on γ-Al_2O_3 required the presence of chemically adsorbed H atoms. It was significant that in γ-Al_2O_3 1/9 of the lattice locations for metal were unoccupied; hence, these "faults" had abnormal neg. fields and could readily hold H atoms. A heat of activation of up to 10 kcal. was required to lift a H atom sufficiently out of the fault location to permit OH to approach it. This was followed by dehydration.

1971. GARNER, W. E. **The reduction of oxides by hydrogen and carbon monoxide.** *J. Chem. Soc.* **1947**, 1239-44.—*C.A.* **42**, 1110*i*.

The reduction of metallic oxides by H_2 and CO proceeded through a no. of intermediate stages to yield hydroxides and carbonates which decomp. to produce the lower oxide or metal. There was considerable mobility of ions in the oxide lattice at the temp. of reduction. Reversible chemisorption of CO occurred in metal-rich oxides with neg. holes, and irreversible chemisorption on oxides with pos. holes. The two types of chemisorption were not readily interconvertible. The reversible adsorption of CO on ZnO and the adsorption of CO_2 on the oxides of the transition elements occurred without appreciable activation energy.

1972. KONDRAT'EVA, E. I. AND KONDRAT'EV, V. **Active centers in the acetylene flame.** *J. Phys. Chem. (U.S.S.R.)* **21**, 761-8 (1947) (in Russian).—*C.A.* **42**, 2162*c*.

A thermocouple coated with ZnO, and Cr_2O_3 and introduced into an C_2H_2-O_2 flame showed a temp. higher by ΔT than that of an uncoated thermocouple. When the ratio $O_2 = C_2H_2$ was less than 2.5, the introduction of a coated couple extinguished the flame and ΔT was zero. The max. ΔT observed was about 45°C. The main reaction products were CO and H_2O.

1973. KONDRAT'EVA, E. I. AND KONDRAT'EV, V. **Active centers in the combustion of carbon monoxide.** *J. Phys. Chem. (U.S.S.R.)* **21**, 769-76 (1947) (in Russian).—*C.A.* **42**, 2162*e*.

The coated thermocouple was hotter than an uncoated couple in burning moist $CO + O_2$ mixts. ΔT was proportional to the rate of combustion when the temp. varied between 610° and 717°C, the pressure between 12 and 23 mm Hg, and the rate of gas flow between 0.55 and 3.55 cc/sec. The highest ΔT was 60°C.

1974. KRATKY, O. **The structure of amorphous bodies.** *Monatsh.* **76**, 311-18 (1947).—*C.A.* 41, 6111*d*.

The two types of Al_2O_3 gels previously proposed can be explained as weak hexagonal and cubic packing.

1975. MAKAROV, S. K. AND KALIKO, M. A. **Poisoning of alumina-silica catalyst by water vapor.** *Neftyanoe Khoz.* **25**, No. 2, 42-6 (1947).—*C.A.* **41**, 6697*d*.

A Houdry-type alumina-silica catalyst normally capable of producing a 40% yield of gasoline, gave only a 35% yield after storage in open air. The deactivation was due partly to adsorption and capillary condensation of water vapor from the air. At 500-600°C enough absorbed moisture remained in the catalyst to cause subsequent deactivation at higher temps. Exothermic effects exhibited in the absorption and desorption isotherms at 400-600°C were apparently due to catalytic action of moisture on the process of recrystn. of the catalyst.

1976. MOISEEV, P. S. **Fibrous alumina.** *Kollid. Zhur.* **9**, No. 1, 53-6 (1947).—*C.A.* **41**, 4729*e*.

Heating curves and x-ray pictures were obtained for fibrous Al_2O_3, obtained by the action of a 1% $HgCl_2$ soln. on Al. The product, of d. 1.77, on heating at 80-100°C crystallized to either bauxite dihydrate $(Al_2O_3.H_2O).2H_2O$ (d. 1.89) or hydragillite (d. 2.24), depending on the treatment of the original material. Further heating (4 hrs at 500°C) drove off H_2O of crystn., and gave an amorphous product of d. 2.03.

1977. OWEN, J. R. **Correlation of surface area and dehydrogenation activity for a chromia-alumina catalysts.** *J. Am. Chem. Soc.* **69**, 2559-60 (1947).—*C.A.* **42**, 442*b*.

In the dehydrogenation of butane, the data showed that there was a definite correlation between surface area and dehydrogenation activity for the CrO_3-Al_2O_3 catalyst.

1978. RIES, H. E. JR.; VAN NORSTRAND, R. A., AND KREGER, W. E. **Adsorption-desorption isotherm studies of catalysts. II. Comparisons of low-temperature isotherms of ammonia and nitrogen.** *J. Am. Chem. Soc.* **69**, 35-40 (1947).—*C.A.* **42**, 807*a*.

Adsorption isotherms were measured with NH_3 as the adsorbate on a pelleted supported Co catalyst at liquid-NH_3 temp. The isotherms were compared with N_2 isotherms obtained for the same adsorbent at liquid-N_2 temp. Contrary to that of N_2, the NH_3 adsorption was not instantaneous but required at least 24 hrs before stationary values were reached. Furthermore, the desorption branch of the NH_3 isotherm did not completely join the adsorption branch. In spite of the slowness of adsorption, reproducible isotherms were obtained by a standardized procedure. The B.E.T. area of the adsorbent was 217 m^2/g and if calcd. from the NH_3 isotherms 238 m^2/g.

1979. ROGINSKIĬ, S. Z. AND TSELLINSKAYA, T. F. **Effect of the free energy of the process of preparing pyrolytic nickelous oxide on activated adsorption.** *J. Phys. Chem. (U.S.S.R.)* **21**, 919-26 (1947) (in Russian).—*C.A.* **42**, 2500*i*.

$NiCO_3$ was heated at a CO_2 pressure of either 3×10^{-3} mm or 2-10 mm Hg until NiO was obtained. The adsorption isotherms of CO_2 at 23°C on both types of NiO were similar, and the surface areas were about 5×10^5 and 4×10^5 cm^2/g. However, the rate of activated adsorption of CO was greater for the 1st sample than for the 2nd. The ratio of these rates increased with the amt. (q) adsorbed, but was smaller the higher the temp. (23-160°C). NiO took up O_2 also; q increased between 60° and 180°C and the rate of adsorption was greater for the 1st than for the 2nd type.

1980. RUSSELL, ALLEN S. AND STOKES, JOHN J. **Sorption of hydrogen on alumina.** *J. Am. Chem. Soc.* **69**, 1315-19 (1947).—*C.A.* **41**, 5771*d*.

Between 400° to 900°C and 9 to 620 mm Hg, the adsorption of H_2 on alumina increased with a decrease in temp. and increased as the one-fourth power of the H_2 pressure. The adsorption was slow, difficult to reproduce, and covered no more than a few % of the total surface of the alumina.

1981. SINGER, FELIX AND THURNAUER, HANS. **Sinter alumina.** *Metallurgia* **36**, 237-42, 313-15 (1947).—*C.A.* **42**, 727*h*.

The temp. of sintering was about 0.8 to 0.9 that of melting. Crystallites in sintered alumina were not completely homogeneous. They contained gas bubbles which were definitely within the crystals and not at the junctures between sep. crystallites. As the gas bubbles were completely enclosed, there was no effect on the apparent porosity of the material. Sintered alumina was characterized by its extreme chem. inertness. It was resistant to solns. and melts of alkalies, HF, and nearly every acid. It was not attacked by steam at high pressure, or Cl_2 and CO_2 at high temp.

1982. STALEY, H. R. AND GREENFELD, S. H. **Surface areas of high-calcium quicklimes and hydrates.** *Am. Soc. Testing Materials, Proc.* **47**, 953-64, discussion, 965-6 (1947).—*C.A.* **42**, 6508*d*.

When slaked with excess water, lime hydrates produced from hard burned quicklimes had higher surface areas than those made from soft burned quicklimes. The surface area of lime hydrates made from either type quicklime increased with slight excess water of slaking but with increasing amts. of excess water the surface areas dropped rapidly to const. values. Quicklimes made in the presence of NaCl under relatively low-temp. conditions were similar to hard burned quicklimes but gave a low surface area upon hydration. Ethanol and sucrose solns. produced high surface area wet hydrates but had no appreciable effect on the dry-hydrating properties.

1983. TRAVERS, A. AND CLAUSE, F. **The nature of precipitated alumina.** *Bull. Soc. Chim. France* **1947**, 209-10.--*C.A.* **41**, 6125*b*.

The Baeyer process was discussed as a two-step time reaction: (1) pptn. of bohmite and (2) hydration of bohmite to baeyerite. Phenol added to sodium aluminate soln. gave instantly a fine easily filterable ppt. yielding $Al_2O_3.2.2H_2O$ after vacuum drying.

1984. WALKENHORST, W. **Structureless carrier films of aluminum oxide.** *Naturwissenschaften* **34**, 373 (1947).—*C.A.* **44**, 2317*f*.

Carrier films of Al_2O_3 were prepd.: Aluminum foil of 10 μ thickness was cleaned in hot dil. HNO_3 at 80°C, washed with water, and anodically oxidized in 3% ammonium citrate soln. This oxide layer grew to a max. thickness, it was then cleaned in distd. water and the metallic Al dissolved away by allowing the film to float on a 0.25% $HgCl_2$ soln. The thickness of the oxide film varied linearly, with the potential used, it was 275 mμ for 200 v. Films of Al oxide so prepd. showed no structure in the electron microscope and can be heated in vacuum ovens to 600°C without structural change.

1985. WICKE, E. **The separation of gas mixtures by flow through adsorbents.** *Angew. Chem.* **B19**, 15-21 (1947).--*C.A.* **41**, 4349*e*.

Several sets of exptl. data were reported. With a 57.5 cm high column of ignited German bauxite (grain size 5 to 1.2 mm) contained in a U glass tube of 0.56 cm² cross section, and after proper pretreatment of the adsorbent, 60 cc. of 50-50 propane-propylene mixt. could be sepd. into the pure components in a single pass.

1986. ANDERSON, J. S. **Primary reactions in roasting and reduction processes.** *Discussions Faraday Soc.* **1948**, No. 4, 163-73.--*C.A.* **43**, 4988*f*.

The cond. of simple oxides (ZnO, Fe_2O_3, Cr_2O_3) and spinel-type double oxides ($ZnFe_2O_4$, $ZnCr_2O_4$) were measured up to 1000°C and pressures between 1 atm. and 10^{-4} mm. The reduction to the metal took place in 3 stages: (1) chemisorption of the reducing gas whereby lattice defects were created at the surface; (2) migration of the lattice defects from the surface; and (3) satn. of the crystal lattice with the defect with consequent appearance of a new phase (metal, or lower oxide).

1987. BORK, A. KH. AND MARKOVA, O. A. **Dependence of relative adsorption coefficients on temperature and the extent and nature of the catalyst surface.** *Zhur. Fiz. Khim.* **22**, 1381-4 (1948).—*C.A.* **43**, 2498*c*.

Water-EtOH mixts. were passed over Al_2O_3 or ThO_2, and the yield C_2H_4 was detd. From the relation between the yield and the H_2O content, the relative adsorption coeff. H_2O:EtOH was calcd. to be 0.66 for 2 samples of Al_2O_3 and 2 samples of ThO_2 between 330 and 398°C.

1988. BORK, A. KH. **Properties of catalytically active surfaces on the basis of the kinetics of unimolecular reactions.** *Zhur. Fiz. Khim.* **22**, 1385-9 (1948).—*C.A.* **43**, 2498*d*.

The relative adsorption coeff. α was 0.66 for H_2O:EtOH on Al_2O_3 and ThO_2 and 0.4 on Cu and for xylene:dimethycyclohexane I.0 on Ni+Al_2O_3 independently of temp., the relative concns. of the components, and the amt. of the catalyst. The heats of adsorption of the two components on the active surface were equal.

1989. CARTER, P. T. **Physical chemistry of sulfur removal in steelmaking.** *Discussions Faraday Soc.* **1948**, No. 4, 307-16.--*C.A.* **43**, 4936*a*.

The data showed that CaO, MgO, MnO, and FeO could all desulfurize molten Fe with about equal power. When these oxides combined with acidic oxides to form compds., the desulfurizing power was diminished. Probably combination states are $2MO.SiO_2$, which was either undissocd. or slightly dissocd., $3MO.P_2O_5$, $MO.Al_2O_3$, and $MO.Fe_2O_3$.

1990. EISCHENS, ROBERT P. AND SELWOOD, P. W. **Structure and activity of the chromium-aluminum oxide catalyst system.** *J. Am. Chem. Soc.* **70**, 2271-3 (1948).—*C.A.* **42**, 8598*b*.

Surface areas of catalysts with a Cr content of 1.9% to 34.5% Cr, made by the impregnation of γ-Al_2O_3 and bohemite, decreased linearly with increase in Cr concn. At the "λ" point of the magnetic susceptibility curve corresponding to the inflection point from a low to a high rate of change of the susceptibility with Cr diln., only 1/9 of the Al_2O_3 surface was covered with Cr_2O_3 and the av. Cr atom was in a crystallite 3 atom layers thick.

1991. GONCHAROV, V. V. **Effect of some admixtures on the hydration of magnesium oxide and magnesite.** *Ogneupory* **13**, 266-73 (1948).--*C.A.* **43**, 5919*h*.

Cylindrical samples of (1) calcined magnesite and Fe_2O_3 and (2) MgO and CaO, SiO_2, Al_2O_3, and Fe_2O_3 individually and in combinations were used to study the effects of various admixts. on the hydration of pure MgO and magnesite. The samples were fired at 1400, 1500, and 1600°C. The hydration was increased by increasing CaO from 1 to 3%; with addn. of 2% SiO_2, the hydration tendency dropped sharply while an increase of SiO_2, to 5% caused a less rapid drop in hydration. Addn. of Al_2O_3 reduced the hydration considerably less than SiO_2. In the presence of 1% Fe_2O_3 the hydration of MgO dropped sharply but with increasing content of Fe_2O_3 the reduction became less.

1992. HAASSER, CHARLES AND FORESTIER, HUBERT. **Effect of adsorbed water vapor and compression on reactions in the solid state.** *Compt. rend* **227**, 123-5 (1948).—*C.A.* **42**, 8586*f*.

Fe_2O_3+NiO mixts. pptd. separately, dried at 100°C in vacuum of 10^{-5} mm Hg and mixed for an hr in a pulverizer vibrator, were studied at 300-700°C. The reaction to form ferrite started slowly at 100°C, increased rapidly after 450°C, diminished towards 600°C. Water vapor increased the speed of reaction decidedly between 350° and 625°C. Anologous results were obtained with ferrites of Mg and Pb. Water vapor affects the reaction itself rather than the diffusion phenomena.

1993. Hüttig, Gustav F. and Dreithaler, Herbert. **The dehydration of gypsum and chromium oxide hydrate gel in the presence of inert gases.** *Festskr. J. Arvid Hedvall* **1948**, 285-90.—*C.A.* 42, 6216*c*.

$CaSO_4.2H_2O$ contg. 20.91% H_2O was ground to 800 mesh before use. $Cr_2O_3.xH_2O$ was prepd. and sifted through an 800 mesh screen. Tank N_2, O_2, CO_2, SO_2, NH_3, CH_4, and acetone-free CH_3OH were passed individually over 1.000 g of sample in a small boat at a rate of 4 liters/hr, and the loss of H_2O was measured by direct weighing. The results were very reproducible in the case of $CaSO_4$ but less so with Cr_2O_3. The dehydration of $CaSO_4.2H_2O$ at 100°C occurred most rapidly in H_2, and only slightly less rapidly in O_2, N_2, CO_2, SO_2, and C_2H_4; 85-90% of the H_2O being removed in 3 hrs. After 4 hrs, NH_3 had removed only approx. 5% of the H_2O and CH_3OH approx. 15%. The rate of dehydration with NH_3 increased very rapidly in the range 100°-150°C, more than 90% of the water being removed at 150°C in 1 hr.

1994. Hüttig, Gustav F. and Pietzka, G. **The adsorptive binding of methanol and ethanol on the oxides of silicon, titanium, zirconium, and thorium.** *Monatsh.* **78**, 185-92 (1948).—*C.A.* 42, 7598*c*.

Adsorption isotherms for MeOH, EtOH, and CCl_4 were detd. on SiO_2, TiO_2, ZrO_2, and ThO_2. The data were plotted according to the Huttig equation for multilayer adsorption. For a given adsorbent, the vol. of gas required to form a monolayer was independent of the temp. of the adsorbent. The vol. of MeOH required to form a monolayer was always larger than the vol. of EtOH.

1995. Hüttig, Gustav F. and Zagar, L. **The activated state of desorbed gas molecules.** *Monatsh* **79**, 581-5 (1948).—*C.A.* 43, 4088*a*.

O_2 and CO were mixed after passing through concentric tubes in a furnace at 280°C. No CO_2 was formed in the absence of a catalyst. With Al_2O_3 or platinized asbestos in both tubes, much CO_2 was formed even though the gases travel 1.5 cm beyond the catalyst before mixing. If only the O_2 passed over the catalyst, scarcely less reaction occurred; but if only the CO passed over the catalyst, no CO_2 formed.

1996. König, Hans. **The lattice constants of γ-alumina.** *Naturwissenschaften* **35**, 92-3 (1948).—*C.A.* 44, 2320*e*.

All Al_2O_3 films that were in contact with Al at 800°C gave a lattice const. of 7.89 A. ±0.01 regardless of their previous history. On the other hand, films that were heated at 800°C in air or O_2 without Al support had consts. of more than 8.00 A.; the highest value of 8.06 was obtained by heating in O_2 at 800°C. High consts. can be lowered by heating at 800°C *in vacuo* for several hrs or by vaporizing Al onto them.

1997. Milligan, W. O.; Whitehurst, Harry B., and Bushey, G. L. **Sorption-desorption characteristics of hydrous oxide pigments.** *Official Digest Federation Paint & Varnish Production Clubs* No. **283**, 601-9 (1948).—*C.A.* 42, 8491*c*.

Red iron oxide pigments consisted essentially of crystals of Fe_2O_3. Surface areas varied from 10 to 21 m^2/g. Black iron oxide pigments consisted essentially of Fe_3O_4 crystals, together with a possible trace of Fe_2O_3. The surface areas from 57 to 105 m^2/g paralleled the relative size of the primary particles. The brown iron oxide possessed the relatively large surface area of 620 m^2/g. The 2 yellow iron oxide pigments (Fe_2O_3-H_2O) examd. formed a pair of pigments covering a wide range of properties. One had a low surface area of 24 m^2/g whereas the second had a large surface of 425 m^2/g.

1998. Miyahara, Yutaka and Sano, Isamu. **Adsorption of water vapor by zinc oxide.** *J. Chem. Soc. Japan, Pure Chem. Sect.* **69**, 90-1 (1948).—*C.A.* 44, 9223*d*.

The adsorption of water vapor at 4.6 mm Hg at 30-400°C was detd. gravimetrically. There were 2 types of adsorption, phys. adsorption ending at about 200°C and activated adsorption beginning at 200°C. The mechanism of catalytic action was discussed.

1999. Norton, F. H. **Fundamental study of clay. VIII. A new theory for the plasticity of clay-water masses.** *J. Am. Ceram. Soc.* **31**, 236-41 (1948).—*C.A.* 42, 7949*i*.

A new mechanism of plasticity was suggested, called the "stretched-membrane theory," in which it was postulated that the particles in the plastic mass were always acted on by two forces in equil.; one, the repulsion between the particles; the other, a compressing together of the particles by the capillary force of the water film, or membrane, on the surface of the mass. This capillary force was calcd. as being 75-2400 lb/in^2 with variations in particle size 8.0-0.25μ.

2000. Rotinyan, A. L. **Velocity of the reaction between hydrogen sulfide and certain metal oxides** *Zhur. Priklad. Khim. (J. Applied Chem.)* **21**, 807-9 (1948).—*C.A.* 43, 8817*i*.

The kinetics of the reaction between gaseous H_2S and solid HgO, MnO_2, or PbO_2 (in grains of 1.5-2.0 mm) were derived from published exptl. data. A 1st-order chem. reaction, of rate const. k, was assumed at the surface of the grains, followed by further reaction between the H_2S diffusion with a diffusion coeff. D, through a sulfide rind of growing thickness, and the progressively shrinking oxide core of the grain. The rate of consumption of gaseous H_2S from the space was calculated.

2001. Schröder, Wilhelm. **Investigations of the changes in the thermal transformation series γ-AlOOH → γ-Al_2O_3 → α-Al_2O_3 by Otto Hahn's emanation method and X-rays.** *Z. Ekektrochem.* **52**, 133-9 (1948).—*C.A.* 43, 5300*d*.

γ-AlOOH upon heating at low and high temp. was subject to chem. and allotropic transformations as well as changes of active states of the surface area. The results were supported by both analytical and X-ray investigations. The crystal type and the av. size of the primary particles were detd.

2002. Schröder, Wilhelm. **The influence of the Tammann exchange temperature and loss of adsorption water on emission-power curves, obtained by the Otto Hahn method, for variously prealtered oxides.** *Z. Elektrochem.* **52**, 166-9 (1948).—*C.A.* **43**, 8822*c*.

The Tammann exchange temp. (0.52 × m.p. °K) coincided with pronounced min. in plots of percentage emission power *vs.* T in the Hahn emission method. The minima in the hydroxide curves, corresponding to the loss of water, formation of the oxide, and the Tammann exchange temp. were as follows: For $Be(OH)_2 \rightarrow BeO$, 1185°C, for γ-$FeOOH \rightarrow \alpha$-Fe_2O_3, 685°C, for titanic acid $\rightarrow TiO_2$, 792°C. For α-$AlOOH \rightarrow \alpha$-Al_2O_3 there appeared no influence of the exchange temp. (932°C) on the emission power.

2003. Sweep, W. R. **Determination of the activity of fresh iron oxide.** *Het Gas* **68**, 72-3 (1948).—*C.A.* **42**, 6515*h*.

The Seil method for detn. of activity of gas-purification oxide was described with slight variations.

2004. Zawadzki, J. **The action of gaseous acidic oxides on solid metal oxides. The decomposition of carbonates, sulfates and sulfites.** *Festskr., J. Arvid Hedvall* **1948**, 611-34.—*C.A.* **42**, 7648*g*.

The extent of decompn. of calcite contained in a narrow tube decreased with increasing distance below the surface. This was a result of the fact that CO_2 formed in the deeper layers cannot diffuse away fast enough so that its pressure approached the equil. pressure (p_o) more closely than at the surface. With a layer of $ZnCO_3$ so thin that slow diffusion of CO_2 through the solid was not a complication, the velocity was related to the decompd. part of the carbonate. At 440°C CO_2 was adsorbed by ZnO after its evolution from the $ZnCO_3$, an effect which increased with increase in temp. The final product at 440°C contained 9% CO_2 and, when examd. by x-rays, showed the faintly marked cryst. lattice of the oxide but no evidence of $ZnCO_3$.

2005. Zomosa, R. Abdon. **Determination of critical humidities in drying.** *Rev. ing. quim., Univ. Conception* **7**, 121-8 (1948).—*C.A.* **43**, 3246*c*.

In the drying of spheres of Fe_2O_3 (10 mm diam.) in a circulating air drier with const. heat input, the material was weighed every 10 min. until drying was very slow, and then at 15-, 25-, and 30-min. intervals. Results were plotted as wt loss vs. time. The point at which the initial straight line started to curve was the crit. humidity.

2006. Abe, Ryûji; Yoshioka, Ei, and Uyeda, Ryozi. **Mechanism of iron-rust formation.** *Science* (Japan) **19**, 472 (1949).—*C.A.* **45**, 5496*d*.

Several kinds of iron rusts were examd. by electron diffraction. Green rust of Fe has the formula $2FeO.Fe_2O_3.H_2O$ and decompd. into FeO and Fe_3O_4 (magnetite) when heated *in vacuo*. Although the crystal of $Fe(OH)_3$ was not recognized, the substance β-$Fe_2O_3.H_2O$ was probably present.

2007. Allen, J. A. and Lauder, I. **Oxygen exchange with oxides.** *Nature* **164**, 142-3 (1949).—*C.A.* **43**, 8821*i*.

Preliminary results were reported for the exchange between O_2 and CuO, Co_3O_4, CoO, and NiO, obtained by the use of O_2 contg. 1.4% O^{18}. The temp.-percentage exchange relation at 4 hrs reaction time was investigated between 400-1000°C for each of the 4 oxides. The rate of the exchange, and the effect of pressure, were investigated at 700° and 800°C for Co_3O_4 only.

2008. Brey, Wallace S. Jr. and Krieger, K. A. **The surface area and catalytic activity of aluminum oxide.** *J. Am. Chem. Soc.* **71**, 3637-41 (1949).—*C.A.* **44**, 2709*i*.

Al_2O_3 prepd. by heating in vacuum and in H_2O vapor at 500° to 1000°C were measured for the dehydration of EtOH at reaction temps. of 350° and 400°C. Both total activity and specific activity decreased as the prepn. temp. increased above 600°C. Heating with H_2O vapor induced an addnl. loss of area and activity as compared with heating in vacuum, but the specific activity of the surface was nearly independent of the presence of H_2O. Changes of activity with use were the result of changes in the H_2O content of the surface, rather than in surface area.

2009. Danil'chenko, P. T. **Application of physicochemical analysis to the study of amorphous hydrated oxides (dehydration on the solid-liquid interphase).** *Izvest. Sektora Fiz.-Khim. Anal., Inst. Obshchei i Neorg. Khim., Akad. Nauk S.S.S.R.* **19**, 227-34 (1949).—*C.A.* **45**, 427*i*.

The hydrogels were dehydrated under solns. of various pressure under such condition that formation of a meniscus for capillary adsorption was precluded. The chemically bound H_2O was differentiated from the other kinds of H_2O by detg. it through the 3rd-component method. The curves x, p and x, t obtained under these circumstances were steplike, as were the curves for cryst. hydroxides, where x = compn., $p = H_2O$ pressure, t = temp.

2010. Dent, F. J. and Moignard, L. A. **The purification of town gas by means of iron oxide. I. The hardening of oxide in purifiers. II. Preliminary experiments on the extraction of sulfur from spent oxide.** *Gas Research Board copyright Pub.* No. **GRB 52**, 39 pp. (1949); *Gas World* **130**, 1932-7 (1949); **131**, 119-25 (1950).—*C.A.* **44**, 3237*a*.

Hardening of oxide depended upon the migration of Fe oxide and S, in the presence of moisture, towards the points of contact between the particles. Next, a continuous, cellular structure developed, covered with a dense skin of Fe sulfide assuming a high activity, but the subsequent formation of the dense skin gave rise to hardening. Hardening can be prevented or delayed by maintaining H_2O in the oxide, by controlling the use of revivification air, and by avoiding over-heating in the boxes.

2011. Di Giulio, Giacomo. **Active alumina.** *Chimica e industria* (Milan) **31**, 360-2 (1949).—*C.A.* **46**, 662*e*.

Different types of active Al_2O_3 were prepd., and their dehydrating action was studied by a dynamic method. The satn. point is defined as the point at which total dehydration of air ends. Silica gel can adsorb much more water than Al_2O_3 but its satn. point is lower than that of Al_2O_3.

2012. Dominé-Bergès, Marthe. **The oxide CrO_2.** *Compt. rend.* **228**, 1435-7 (1949).—*C.A.* **43**, 7363*c*.

The thermal decompn. of hydrated Cr_2O_3 in air results in simultaneous dehydration and oxidation to CrO_2, which was stable in the temp. interval 320-400°C, but not at higher temps. The heating of hydrated Cr_2O_3 in a P_2O_5 vacuum resulted in a continuous wt loss with increasing temp., even in the interval 320-400°C, whereas heating in air produced a product of const. wt thought to be CrO_2.

2013. Forestier, Hubert; Haasser, Charles, and Longuet-Escard, J. **Reaction in the solid state at low temperature. Influence of the state of the surface and of the water vapor adsorbed.** *Bull. soc. chim. France* **1949**, Mises au point D146-521.—*C.A.* **43**, 6059*h*.

Magnetic detection of ferrites was used to study the rate of reaction between solid Fe_2O_3 and oxides of Ni, Pb, and Mg at temps. low enough for diffusion to be neglected. For Ni and Pb, reaction can be detected at 200°C; for Mg, only above 400°C. Starting mixts. were prepd. in 3 ways: (A) copptn. followed by drying at 100°C *in vacuo*; (B) sep. pptn. and drying followed by mixing, (C) sep. pptn. and drying at 750°C followed by grinding. The rate and extent of reaction at a given temp. (up to 700°C) are $A>B>C$. The presence of water vapor even in trace amts. considerably increased the rate of reaction for A and B and had a small effect for C.

2014. Forestier, Hubert and Kiehl, Jean Pierre. **Effect of gaseous adsorption on the velocity of reaction of metallic oxides.** *Compt. rend.* **229**, 47-9 (1949).—*C.A.* **44**, 403*g*.

Yields of ferrite from powd. Fe_2O_3 and NiO heated in H_2O, CO_2, O_2, air, N_2, Ne, A, and He at 600°, 650°, and 700°C plotted as isotherms against abs. temp. of liquefaction of the gases gave smooth curves except for N_2. Yields decreased with particle size. The gases were most readily-adsorbed in the order named and adsorption swelled the particles till they shattered.

2015. Forestier, Hubert and Kiehl, Jean Pierre. **The reactions between solid oxides in vacuo.** *Compt. rend.* **229**, 197-9 (1949).—*C.A.* **43**, 8930*f*.

The velocity of the reaction $NiO + Fe_2O_3 \rightarrow NiO.Fe_2O_3$ was a linear function of the log of the pressure, and approached zero as the pressure approached zero. Samples of the oxides copptd. to minimize diffusion showed that adsorbed gases had a marked effect on the rate of reaction. At low temp. with a gas present the reaction occurred between small amts. of the solids dissolved in the layer of gas adsorbed on the solid surface.

2016. Frederikse, H. P. R. **The specific heat of adsorbed helium.** *Physica* **15**, 860-2 (1949).—*C.A.* **44**, 3322*g*.

Sp heats of He adsorbed on jeweller's rouge, measured from 1.0 to 2.5°K, were strongly dependent on the thickness of the films. With decreasing film thickness from approx. 12 to 3 layers the max. of the sp-heat curve was flattened and shifted towards lower temps. Above 1.6°K the sp heats were smaller, but at 1.0°K larger than those of liquid He.

2017. Fricke, R. and Kubach, J. **Investigation of conversion processes in the reaction series $Cu(OH)_2 \rightarrow CuO \rightarrow Cu \rightarrow CuO$ with pure substances and on kieselguhr as a carrier with the emanation method of Otto Hahn, with a few notes on the "copper tower."** *Z. Elektrochem.* **53**, 76-82 (1949).—*C.A.* **43**, 6063*g*.

Thermal decompn. of pure $Cu(OH)_2$ was followed by wt loss and by the emanation method at 150-160°C. Since all the H_2O was not lost, a Cu hydroxide contg. less than one H_2O per mol. was indicated. The reduction of CuO and CuO on kieselguhr with H_2 gave pyrophoric Cu in both cases, but the Cu from CuO recrystallized whereas that on kieselguhr did not. Kieselguhr suppressed the tendency for cryst. rearrangements in these compds.

2018. Gard, C. D. **Utilization of carbon monoxide extracted from natural gas in the production of Dry Ice. I. Extraction of hydrogen sulfide and carbon dioxide from natural gas. II. The manufacture of Dry Ice.** *Gas* **25**, No. 2, 30-6 (1949).—*C.A.* **43**, 2711*g*.

A 20% soln. of ethanolamine in water was used to remove the CO_2 with a min. amt. of H_2S. The natural gas was further purified by scrubbing with a suspension of iron oxide in Na_2CO_3 soln. to remove H_2S. This soln. was reactivated by air agitation in long troughs, and the iron oxide returned to the system, any losses being made up with $FeCl_3$. The gas leaving this scrubber had a H_2S content of 3.4 grains, readily removed by dry purifier boxes; about 1100 lb of S was recovered per day. Before liquefaction, H_2O was removed with activated Al_2O_3.

2019. Givaudon, Jean; Nagelstein, Ernest, and Leygonie, Robert. **Formation of chromic anhydride from chromic oxide at 520°.** *Compt. rend.* **228**, 1868-9 (1949).—*C.A.* **43**, 8296*f*.

Cr_2O_3 deposited on Al_2O_3 and submitted to the action of a current of air at 520°C formed CrO_3; this can be reduced to Cr_2O_3 by H_2.

2020. Higuchi, Izumi. **Dielectric properties of substances in the sorbed state.** *Science Repts., Tôhoku Univ.* **33**, 99-107 (1949).—*C.A.* **44**, 7105*e*.

The apparent dielec. const. of substances sorbed on titania gel increased with successive addn. of propyl alc. and isoamyl alc. over a range from 60 to 70°C. In a lower range of concn. the polarization of the sorbed substance showed very different behavior from the ordinary liquid. At higher concn. the sorbed substance showed behavior analogous to that of the free liquid in respect to the dielec. polarization.

2021. Hutchison, Clyde A. and Malm, John G. **The volatilization of beryllium oxide in the presence of water.** *J. Am. Chem. Soc.* 71, 1338-9 (1949).—*C.A.* 43, 5431*h*.

BeO reacted with water vapor at 1250°C or greater to form an unidentified volatile substance. This substance condensed with decompn. to BeO.

2022. Jayaraman, A. and Srikantan, B. S. **System [Al_2O_3-H_2O] in relation to the dehydrating properties of alumina.** *J. Indian Chem. Soc.* 26, 63-6 (1949).—*C.A.* 43, 8833*h*.

Dehydration of $Al(OH)_3$ from 100° to 400°C showed that the prepn. (I) from Na_3AlO_3 by pptn. with CO_2 exhibited a transition at 220°C between systems having the limiting compns. $Al_2O_3.3H_2O$ and Al_2O_3-H_2O. Prepns. (II) from $Al(NO_3)_3$, $Al(OAc)_3$, or ammonium alum by pptn. with NH_4OH give continuous desorption curves. The ability of Al_2O_3 to hold H_2O in zeolitic condition gave a more active catalyst than either chem. or lattice-type binding.

2023. Kiselev, A. V. and Smirnova, I. V. **Peculiarities of the sorption of water by active alumina.** *Zhur. Fiz. Khim.* 23, 1018-24 (1949).—*C.A.* 44, 899*h*.

Adsorption and desorption isotherms of MeOH and EtOH vapors on Al_2O_3 ignited at 550°C were reproducible; there was hysteresis above the relative vapor pressure $p/p_s = 0.5$, whereas at p/p_s less than 0.5 both isotherms coincided. Adsorption of H_2O by these Al_2O_3 specimens increased after every adsorption-desorption cycle until 1 g of the sorbent contained 5-7 millimol. H_2O; then ad- and desorption became reproducible with hysteresis above $p/p_s = 0.5$. The (liquid) vol. of H_2O adsorbed was, at small p/p_s, 2-3 times that of MeOH or EtOH. A mixt. of SiO_2 and Al_2O_3 behaved like Al_2O_3.

2024. Kolarow, Nikola. **Reduction of some oxides with hydrogen. II.** *Compt. rend. acad. bulgare sci., math. et natur.* 2, 45-8 (1949). (in German).—*C.A.* 44, 1353*a*.

For CuO, MnO_2 and, PbO_2, the temp. of initiation of H_2 reduction was raised 10-25°C by previous heating in O_2, N_2, or CO_2, or by treatment with 20-30% H_2O_2.

2025. Lecuir, René. **Sintering of pure oxides.** *Bull. soc. chim. France* 1949, D227-30.—*C.A.* 43, 7205*e*.

MgO particles were heated to 150°C in a mech. mixer in the presence of urea and after being cooled the mass was passed through a 100-mesh sieve. It was sintered at a min. pressure of 200 kg/cm^2 by raising the temp. to 1420°C at a rate of 74° per hr and maintaining it for 8 hrs. Satisfactory results were obtained by this general method with MgO, BeO, and Al_2O_3. Al_2O_3 compacts prepd. in the presence of urea had much higher strengths than those prepd. in the absence of org. material.

2026. Mansfield, R. **The electrical properties of bismuth oxide.** *Proc. Phys. Soc. (London)* 62B, 476-83 (1949).—*C.A.* 44, 1299*f*.

The cond. and thermoelec. power of Bi_2O_3 was detd. from 680° to 150°C, and at O_2 pressures from 76 to 10^{-4} cm Hg. The variations with O_2 pressure were less than 10%, except at pressures less than 10^{-3} cm Hg when the sign changes above 550°C. Bi_2O_3 becomes an excess or intrinsic semiconductor. The cond. in Bi_2O_3 is due to an excess of O_2 or lattice defects produced by the absence of Bi^{+++} ion, and cond. is by pos. holes.

2027. Miyahara, Yutaka and Sano, Isamu. **Adsorption of water vapor by zinc oxide. II.** *J. Chem. Soc. Japan, Pure Chem. Sect.* 70, 3-4 (1949).—*C.A.* 45, 2741*f*.

The adsorption isotherm of water vapor on ZnO was measured at 234°C. The isotherm belongs to the Langmuir type. The heat of adsorption was calcd. to be 10 kcal. from the previous isobar data and the present data, and calcd. to be 27 kcal. from the data from the chem. const. of water.

2028. Pappas, Alexis C. **Use of porous materials to store dissolved acetylene in bottles.** *Chimie & Industrie* 61, 25-8 (1949).—*C.A.* 43, 7212*c*.

For the transportation of C_2H_2 dissolved in Me_2CO, porous absorbent masses were used, such as (1) ceramic materials (e.g. pumice, kieselguhr, asbestos) with binders, (2) powd. or granulated materials without binder, and (3) fibrous materials. Ceramic masses gave the best results.

2029. Selwood, P. W. **The structure of solid catalysts and the phenomenon of valence induction.** *Bull. soc. chim. France* 1949, D167-9.—*C.A.* 43, 6897*e*.

The magnetic properties of the oxides of transition metals, adsorbed in small concn. on inert supports, are approx. those of paramagnetic ions that have been magnetically dild. This effect is utilized to study the state of dispersion and oxidation of catalysts with promoting action, such as Cr_2O_3-Al_2O_3 mixts. Mn on a γ-Al_2O_3 support assumes a trivalent state, but on finely divided TiO_2 the Mn assumes the tetravalent state.

2030. Selwood, P. W.; Ellis, Marylinn, and Wethington, Kathryn. **Supported oxides of iron.** *J. Am. Chem. Soc.* 71, 2181-4 (1949).—*C.A.* 43, 8831*g*.

Susceptibility isotherms for iron oxides contg. up to 7.1% Fe, supported on high-area γ-alumina and on rutile at -171°, -87°, and 25°C are of the same general shape as those reported for other transition-group oxides. Partial covalent bonds between adjacent atoms causes Fe(III) on γ-alumina to be almost midway between slight diminution of moment as found for Cr and the almost complete loss noted in Mo and Rh.

2031. Staley, H. R. and Greenfeld, S. H. **Surface areas of quicklimes.** *Ind. Eng. Chem.* 41, 520-2 (1949).—*C.A.* 43, 3988*g*.

The calcining characteristics of a high-calcium limestone were studied in the residual atm. of a muffle furnace and the surface areas detd. by the adsorption of liquid N_2. In general, once CO_2 had been liberated completely the surface area decreased from 2.01 m^2/g for 1 hr of burning at 1800°F to 0.15 m^2/g for 16 hrs of burning at 2400°F.

2032. STANLEY, ALAN AND MEAD, JOSEPH C. **Sintering characteristics of minus sixty-five and twenty mesh magnetite.** *J. Metals* 1, No. 7, Trans. 435-40 (1949).—*C.A.* 43, 6553*e*.

The best quality and quantity of sinter were obtained with the following mix: 4.0% coal, 25.0% return fines (-10-mesh +0) (at least 18.75% -10-mesh plus 35-mesh); 70.3% magnetite (-65-mesh size), 0.7% slaked lime. The av. production with the above "mix" was 246 lb/hr/ft^2 of grate area. A more accurate metallurgical control on overall operation will be necessary for sintering -65-mesh magnetite than is needed in present plant operation for sintering -20-mesh magnetite.

2033. STEPHANOU, S. E.; SCHECHTER, WILLIAM H.; ARGERSINGER, W. J. JR., AND KLEINBERG, JACOB. **Absorption of oxygen by sodium peroxide; preparation and magnetic properties of sodium superoxide.** *J. Am. Chem. Soc.* 71, 1819-21 (1949).—*C.A.* 43, 7363*f*.

Sodium superoxide (NaO_2) was prepd. from O_2 and Na_2O_2 at elevated temps. and pressures; a max. yield of 92% was obtained in 100 hrs at 490°C and 298 atm. NaO_2 was a yellow, hygroscopic powder, decompg. quantitatively to O_2 and Na_2O_2 when treated with 20% HOAc in CCl_4. It was paramagnetic.

2034. VARGA, JÓZSEF AND POLINSZKY, KÁROLY. **Dehydration of Hungarian bauxites.** *Magyar Kém. Lapja* 4, 589-92 (1949).—*C.A.* 45, 993*h*.

Six bauxite samples were treated at 5-350 atm. pressure in gas-heated rotating autoclaves. Hydrargillite begins to change into böhmite at about 240°C as the first step in the loss of water. The second step occurs at about 470°C when böhmite changes into corundum and another portion of water evaps. The effect of dehydration on the decompn. of bauxite by means of alkalies was also investigated. Dehydration at 20 atm. pressure for 30 min. had no adverse effects. Dehydrated bauxite did not contain more than 1.5-3.0% hygroscopic H_2O after storing for 1 month.

2035. WHITE, LOCKE, JR. AND SCHNEIDER, CHARLES H. **Physical adsorption from mixtures of gases. I. Oxygen-nitrogen and Oxygen-argon at -185.6°.** *J. Am. Chem. Soc.* 71, 2593-600 (1949).—*C.A.* 44, 2819*b*.

Cr_2O_3 gel was activated at 150°C to 0.001 mm Hg. Adsorption pressures were attained in 30 to 45 min. independent of which gas was adsorbed first. The total gas adsorbed from a mixt. at any set of conditions tends to agree with Hill's equation. With allowance for capillary condensation, the theoretical and exptl. isotherms agree semi-quantitatively.

2036. WICKE, E. **Oxide contacts and their behavior in dehydrogenation and dehydration.** *Z. Elektrochem.* 53, 279-85 (1949).—*C.A.* 44, 2356*i*.

The chemisorption of H_2 and H_2O on ZnO and γ-Al_2O_3 and the catalytic decompn. of alcs. on these oxides take place on regular crystallographic surface points and not on accidental lattice defects or other irregularities. With ZnO H-bonding takes place on faces carrying Zn ions at the outside resulting in hydride-like adsorption compds., or in dehydrogenation reactions, whereas crystal faces carrying O ions at the outside yield hydroxide-like adsorption compds. and dehydration reactions by means of H-exchange. With γ-Al_2O_3 the active centers are normally vacant Al sites, at which surface OH groups are formed, and at which dehydration of alcs. occurs.

2037. WILLIAMS, A. E. **Activated alumina.** *Can. Chem. Process Inds.* 33, No. 1, 41-3 (1949).—*C.A.* 43, 2379*i*.

Activated Al_2O_3 is being used increasingly in a variety of industries, including gas drying, liquid drying, dehydration of solids, and as a catalyst. Its regenerative property permits repeated use.

2038. ANTIPINA, T. V. AND FROST, A. V. **Connection between the kinetics of a heterogeneous reaction and adsorption on catalysts.** *Zhur. Fiz. Khim.* 24, 860-70 (1950).—*C.A.* 45, 937*d*.

The kinetics of the catalytic dehydration of EtOH and also the adsorption of H_2O and EtOH vapors on Al_2O_3 were expressed by equations that assume a uniformity in both catalyzing and adsorption surfaces. The adsorption coeffs. of the products of the dehydration of EtOH were detd. by studying the rate of the heterogeneous catalytic reaction from the absorption data. The adsorption and catalyzing centers are different.

2039. ANTIPINA, T. V. AND FROST, A. V. **Relation between the kinetics of heterogeneous reactions and the adsorption on catalysts. I. Determination of the adsorption coefficient of water on aluminum oxide from kinetic data.** *Vestnik Moskov. Univ.* 5, No. 3, *Ser. Fiz.-Mat. i Estest. Nauk* No. 2, 81-6 (1950).—*C.A.* 45, 4540*i*.

The rate of the dehydration $EtOH \rightarrow C_2H_4 + H_2O$ in a flow system was detd. at 380°C on (alkali and alkaline-earth metal free) Al_2O_3. These data were used to det. b_i (adsorption coeff. multiplied by the total pressure and the stoichiometric coeff.) of H_2O, on the basis of the Langmuir isotherm.

2040. CIRILLI, VITTORIO. **Solid solutions of γ-Fe_2O_3 and γ-Al_2O_3.** *Gazz. chim. ital.* 80, 347-51 (1950).—*C.A.* 45, 1828*c*.

By treatment of a solid soln. of Al_2O_3-Fe_2O_3 (50:50) with hot aq. NaOH, most of the Al_2O_3 can be removed. After treatment with NaOH, the products were washed thoroughly, dried at 110-20°C, and examd. With increase in Fe_2O_3, the magnetic susceptibility increased to a max. at a content of Fe_2O_3 of 90.4%, then decreased abruptly for higher Fe_2O_3 contents. The expts. show that Fe_2O_3 and Al_2O_3 were mutually sol. in all proportions, even close to room temp. The magnetic susceptibility of the solid soln. contg. 90.4% Fe_2O_3 was high compared with that of normal Fe_2O_3, but low compared with that of γ-Fe_2O_3, because of the size of the microcrystals. Solid solns. of Fe_2O_3-Al_2O_3 are catalysts of the thermal decompn. of N_2O above 300°C.

2041. DEMIDOVA, L. D. AND GONCHAROV, V. V. **"Active oxides" in dead-burned magnesite.** *Ogneupory* 15, No. 2, 66-9 (1950).—*C.A.* 44, 6587*h*.

The concept of active oxides in dead-burned magnesite was without significance because it was impossible to differentiate or to sep. one portion of the total MgO and CaO from another in the hydration process of magnesite. The magnitude of hydration (loss during calcination) of dead-burned magnesite increased continuously with extent of aging. Although the hydration proceeded faster during the first than in the subsequent periods of aging, this was more plausibly explained by the development, during the second period of hydration, of the protective action of $Mg(OH)_2$ which envelops the grains of MgO (periclase).

2042. Dunoyer, J. M. **A kinetic study of the reaction between a gas and a pulverized solid substance.** *J. chim. phys.* 47, 290-302, discussion 302-3 (1950).—*C.A.* 44, 7631*a*.

The importance of diffusion of the gas into a granular solid was treated mathematically. The reduction of MoO_3 to MoO_2 by flowing H_2 was studied at 365, 372, 383, 394, 405, and 445°C by a gravimetric method. The raction was unimol. and first-order, and the energy of activation was 46,000 cal/mole.

2043. Forestier, Hubert and Kiehl, Jean P. **Effect of adsorbed gases on the rate of reaction between metallic oxides.** *J. Chim. phys.* 47, 165-73 (1950).—*C.A.* 44, 7128*c*.

The rate of formation of ferrite from Fe_2O_3 and NiO increased logarithmically with the partial pressure of H_2O over the pressure range 10^{-5} to 760 mm at 500 to 700°C. Extrapolation indicated zero reaction rate at 10^{-9} mm. The order of decreasing efficiency of gases in speeding up the reaction in the temp. range 600° to 700°C was H_2O, CO_2, A and O_2, air, N_2, Ne and He.

2044. Frederikse, H. P. R. and Gorter, C. J. **Investigations on the adsorption of helium at very low temperatures.** *Physica* 16, 402-18 (1950) (in English).—*C.A.* 45, 1837*f*.

Adsorption isotherms of He were measured on jewelers rouge and steel between 1.3 and 2.3°K. The isotherms were sigmoid shaped. N_2, O_2, and A were also adsorbed at higher temp. for comparison purposes. The no. of He mols. adsorbed in the 1st layer on the adsorbents was about 4 times the no. of N_2, O_2, or A mols. The adsorption potentials were not independent of the temp. for He. At $T = 2.182$°K and when the amt. of gas adsorbed in the 1st layer $= 40 \times 10^{-10}$ mol./cm^2, the entropy was 3.5 cal/mol. degree when the total amt. of gas adsorbed was 26.54×10^{-10} mol./cm^2, 7.0 at 25.63×10^{-10}, and 11.4 at 22.56×10^{-10}, resp.

2045. Gachkovskii, V. F. **Fluorescence of magnesium phthalocyanine and of chlorophyll in different states. Effect of oxygen on the fluorescence of magnesium phthalocyanine and of chlorophyll in the adsorbed state.** *Doklady Akad. Nauk S.S.S.R.* 70, 51-4 (1950).—*C.A.* 45, 3720*c*.

Absorption and fluorescence spectra of Mg phthalocyanine adsorbed on MgO (from EtOH soln., and outgassed *in vacuo*) showed, as in soln., mirror-like disposition of the bands. In the adsorbed state, the whole band system was shifted to shorter waves as compared with the soln. Desorption of O_2 at 20°C resulted in an increase of the intensity of the fluorescence up to the max., but on further desorption the intensity remained at the max., unless the O_2 was removed by outgassing at the previous outgassing temp. The intensity-increasing effect of O_2 (and the org. compds. mentioned) might be explained by a dedimerization of the adsorbed mols.

2046. Ghosh, J. C.; Sastri, M. V. C., and Vedaraman, S. **Adsorption studies on methanol-synthesis catalysts. I. Adsorption of carbon monoxide and hydrogen on zinc oxide-chromium oxide mixture.** *Current Sci. (India)* 19, 342 (1950).—*C.A.* 45, 7406*g*.

The range studied was 50° to 200°C for CO and up to 250°C for H_2. The adsorption isobars of CO at pressures below 1 atm. showed 2 max., one at 52°C and the other at 178°C. The activation energy was 5 to 8.5 kcal, and the heat was 6 kcal. for 0.9 cc. adsorption/g. Activated adsorption was observed for H_2 at the lowest temp.; the heat was 10 kcal. for 1.30 cc. adsorption/g and the energy of activation was 8.5 kcal for 1.19 cc. adsorption/g at 37 cm pressure.

2047. Johnson, P. D. **Behavior of refractory oxides and metals, alone and in combination, in vacuo at high temperatures.** *J. Am. Ceram. Soc.* 33, 168-71 (1950).—*C.A.* 44, 6092*b*.

Changes in bulk d., shrinkage, and wt were detd. for carbon and for dry-pressed specimens of BeO, MgO, ZrO_2, ThO_2, Mo, and W after firing for 2, 4, and 8 min. in vacuo, at 100° intervals from 1500° to 2300°C. The limiting factor for many refractories was not the m.p., but stability when in contact with other substances, and the rate of volatilization. BeO was the most stable in contact with carbon, ZrO_2 most stable in contact with Mo, and ThO_2 most stable in contact with W. The most stable oxide mixts. were ZrO_2 with ThO_2 and MgO with ThO_2.

2048. Kuczyński, W. and Zagórski, Z. **Adsorption of benzene on several kinds of activated alumina.** *Roczniki Chem.* 24, 211-17 (1950) (English summary).—*C.A.* 46, 5398*e*.

The adsorption of C_6H_6 vapor at 25°C at relative pressures up to 0.4 was investigated. $Al(OH)_3$ was pptd. from the soln. of $Al_2(SO_4)_3$ by means of variable amts. of NH_4OH. The ppts. obtained were subjected to heat-treatment at the max. temp. of 400°C. For the concns. of C_6H_6 vapor investigated the acid gel showed the smallest adsorption; the two other kinds adsorbed almost equally in those circumstances, but the basic gel was somewhat superior in this respect.

2049. Lomer, P. D. **Electric strength of alumina films.** *Nature* 166, 191 (1950).—*C.A.* 44, 10423*i*.

Thin films of amorphous Al_2O_3 increased in elec. strength if the film thickness was less than 10^{-5} cm. The oxide was formed by "anodic oxidation" of Al evapd. in a vacuum on a glass optical flat.

2050. Lomer, P. D. **The dielectric strength of aluminum oxide films.** *Proc. Phys. Soc. (London)* 63B, 818-20 (1950).—*C.A.* 45, 5992*b*.

Dielec. strength was reported for films of thickness up to 1500 A measured interferometrically.

2051. Mesnard, Guy and Uzan, Roger. **Optical emissivity of thorium dioxide.** *Le Vide* 5, 844-52 (1950).—*C.A.* 45, 31*h*.

ThO_2 was deposited by cataphoresis on 0.10-mm W wire. The emissivity at 0.65 μ was obtained by comparing the brightness temps. of the coated and uncoated W wires. Emissivity increased with temp.

in nonactivated cathodes and decreased with temp. in activated cathodes. The thickness of the deposit and the time had a considerable influence on the emissivity, whereas the nature of the base material does not seem important.

2052. Miyahara, Yutaka. **Adsorption of water vapor by zinc oxide. IV.** *J. Chem. Soc. Japan, Pure Chem, Sect.*, 71, 536-8 (1950).--*C.A.* 45, 6454*g*.

The adsorption isotherm was detd. for the adsorption of water vapor by ZnO at 200-400°C. An equation was proposed that represented the exptl. data fairly well.

2053. Rijnders, G. W. A. and Schuit, G. C. A. **Adsorption of ammonia on surfaces of oxides.** *Rec. trav. chim.* **69**, 668-70 (1950).—*C.A.* **44**, 10444*a*.

The adsorption of NH_3 as a function of temp. and pressure on some oxides and oxide mixts. was studied. All observed adsorptions were within the monolayer, and NH_3 was not adsorbed by van der Waals forces but by chemisorption. The packing of the NH_3 mol. was strongly dependent on the nature of the surface.

2054. Roĭter, V. A.; Korneĭchuk, G. P.; Leperson, G.; Stukanovskaya, N. A., and Tolchina, B. I. **Experimental study of macrokinetic phenomena on porous catalysts.** *Zhur. Fiz. Khim.* **24**, 459-67 (1950).—*C.A.* **44**, 8214*g*.

A tube was sepd. in two by a membrane, about 1 cm thick, made of MnO_2 and asbestos. Through one half of the tube air contg. 0.002-0.008 ml/ml C_2H_2, and through the other half pure air was circulated. The C_2H_2 which diffused through the membrane was pptd. as Ag_2C_2 and detd. as Ag, and the CO_2 formed by oxidation of C_2H_2 was absorbed in $Ba(OH)_2$ and detd. The effective diffustion coeff. of C_2H_2 was 0.10 for the most porous and 0.01 cm^2/sec for the densest membrane used and was const. between 0° and 70°C.

2055. Schulek, Elemér and Pungor, Erno. **Titrimetric gas analysis. I. Determination of oxygen.** *Magyar Kém. Folyóirat* **56**, 250-5 (1950).—*C.A.* **46**, 378*g*.

For detg. O_2 content in gas samples contg. above 0.1 vol. %, the method was based on the absorption of O_2 by MnO at 200-50°C. This reagent was produced by heating $MnCO_3.2H_2O$ in N_2 to 300°C. The temp. was decreased to 200-50°, the gas sample passed through the app., the granulated glass (contg. Mn oxide) washed with HCl contg. KI and starch, and then titrated with 0.1 *N* $Na_2S_2O_3$. When analyzing gas samples with O_2 below 0.1 vol. %, the freshly pptd. $Mn(OH)_2$ was suitable for absorbing traces of O_2 in the gas sample.

2056. Schweckendiek, Otto E. **The behavior of iron oxide aerosols.** *Z. Naturforsch.* **5a**, 397-9 (1950).—*C.A.* **45**, 1840*h*.

$Fe(CO)_5$ was burned in air. Samples of aerosols taken after 120 min. and observed with the electron microscope showed considerable flocculation. The flocculates were primarily of a long-chain type. Under the influence of a slow, weak alternating elec. field, the chains were observed to twist in an S-shape in response to the field. The chains were primarily Fe_2O_3.

2057. Selwood, P. W. and Lyon, Lorraine. **Structure of oxide catalyst systems.** *Discussion Faraday Soc.* **1950**, No. 8, 222-9.—*C.A.* **45**, 9988*h*.

Magnetic-susceptibility isotherms were detd. for: vanadia + alumina; vanadia + rutile; chromia + rutile; copper oxide + magnesia; copper oxide + rutile; ruthenia + alumina; and Cu, Ni, Cr, and Fe oxides supported silica. Catalyst activity might be predicted in some cases from susceptibility measurements, especially when these were considered together with surface-area measurements.

2058. Shekhter, A. B. and Moshkovskii, Yu. Sh. **Physical structure and catalytic properties of zinc oxide.** *Doklady Akad. Nauk S.S.S.R.* **72**, 339-42 (1950).—*C.A.* **44**, 7132*i*.

ZnO was prepd. by decompn. of $ZnCO_3$ in vacuo at 350°C (samples *K*) or by oxidation of Zn dust in an elec. arc (samples *D*). By X-ray examn., heating from 350° up to 1000°C caused no change of either the deviation from lattice perfection or the grain size *S* with the *D* samples, whereas the *K* samples showed uniform increase of *S* and decrease of the degree of lattice perturbation with increasing temp. The surface area of $K_{(350°)}$ (80 m^2/g) fell to less than 4 for $K_{(700°)}$; for the *D* samples, it remained unchanged, 13-14 m^2/g between 350° and 1000°C. The catalytic activity in the decompn. of MeOH showed no connection with either the color of the luminescence or the X-ray structure.

2059. Tamele, M. W. **Chemistry of the surface and the activity of alumina-silica cracking catalyst.** *Discussions Faraday Soc.* **1950**, No. 8, 270-9.—*C.A.* **45**, 9989*i*.

The catalyst owed its activity primarily to a no. of acid sites located in the catalyst surface, which were formed in the prepn. by the condensation of the surface OH groups of the incompletely polymerized silica hydrogel with the OH of the hydrolyzed Al ions. The formation of acid was due to the tendency of the Al atom to acquire a pair of electrons, enhanced by the displacement of electrons in the Al-O-Si bonds toward the Si atom carrying 4+ charges. The electron pair was donated by H_2O, the OH became part of the structure, and the H^+ was held by electrostatic attraction.

2060. Tatievskaya, E. P.; Chufarov, G. I., and Antonov, V. K. **The rates of reduction of iron oxides.** *Zhur. Fiz. Khim.* **24**, 385-93 (1950).—*C.A.* **44**, 8209*d*.

Fe_2O_3, Fe_3O_4, and FeO were reduced by H_2 at similar rates. The surface areas (from N_2 adsorption at -195°C) were 0.85, 0.86, and 0.60 m^2/g, resp. The oxides were heated in H_2, the H_2O formed was frozen out, and the rate v of reaction was calcd. from the decrease in pressure p. At reductions below 10%, v was proportional to p_0^n, and the const. n was at 400° and 450°C, 0.68, and 0.83 for Fe_2O_3, 0.68 and 0.76 for Fe_3O_4, and 0.5 and 0.65 for FeO.

2061. Topchieva, K. V. and Ballod, A. P. **Poisoning and regeneration of the surface of adsorbents.** *Doklady Akad. Nauk S.S.S.R.* **75**, 247-50 (1950).—*C.A.* **45**, 2760*c*.

On an aluminosilicate catalyst (Al_2O_3 30%, SiO_2 70%), part of the vapor-phase-adsorbed MeOH was found to be adsorbed irreversibly, i.e. not to be desorbed on prolonged pumping without heating.

The fraction of MeOH adsorbed irreversibly increased by 30% with the relative pressure p/p_s increasing from 0.1 to 1. With a medium-porosity Al_2O_3 gel, of surface area 255 m^2/g, the original wt was restored after a few hrs at 400°C, whereas the wt of a coarse silica gel, of surface area 530 m^2/g, was not restored even after 3 days. With regard to stability of the bond of MeOH with the solid surface, the aluminosilicate catalyst evidently is intermediate between the Al_2O_3 and silica gels.

2062. WHALLEY, E. AND WINTER, E. R. S. **The exchange reactions of solid oxides. II. The exchange of oxygen between water vapor and certain metallic oxides.** *J. Chem. Soc.* **1950**, 1175-7.—*C.A.* **44**, 9220*c*.

Preliminary results were reported on the exchange of O^{18} between O_2-D_2O vapor and γ-Al_2O_3, ThO_2, and TiO_2. As in the exchange of O_2 with these substances there was an initial rapid reaction followed by a slow exchange. The rapid step may be due to exchange with surface oxide ions and part or all of the water contained in the Al_2O_3; the slow process may be due to exchange with O ions in the second layer of the lattice.

2063. WINTER, E. R. S. **The exchange reactions of solid oxides. I. The exchange of oxygen isotopes between gaseous oxygen and certain metallic oxides.** *J. Chem. Soc.* **1950**, 1170-5.—*C.A.* **44**, 9220*a*.

The exchange of O^{18} between O_2 and γ-Al_2O_3, ZnO, ThO_2, and TiO_2 was investigated at 360-600°C. The initial rapid reaction was followed by a slow reaction. For γ-Al_2O_3 the rapid exchange was first order and independent of O_2 pressure. The rate-detg. step of the initial rapid reaction was the exchange of adsorbed O^{18}-enriched gas and surface O ions, although it may be either adsorption or desorption. The subsequent very slow exchange may be due to (a) reaction with less active parts of the surface or (b) slow diffusion of O ions from the second layer to the surface.

2064. WINTER, E. R. S. **The use of O^{18} in studies of the reactivity of solid oxides.** *Discussions Faraday Soc.* **1950**, No. 8, 231-4, discussion 234-7.—*C.A.* **45**, 9981*i*.

O^{18} exchange between solid oxides and O_2 was followed continuously with a mass spectrometer. The apparent E for exchange was 27 ± 0.5 kcal for thorium oxide between 440° and 540°C. With Cr_2O_3 two processes were operative: (1) below 410°C, $E = 29.5 \pm 0.5$ kcal, (2) above 410°C, $E = 1 \pm 4$ kcal. The high value of E was ascribed tentatively to a limiting process governed by the rate of desorption of O_2 from the oxide surface.

2065. ANTIPINA, T. V. AND FROST, A. V. **Relation between the kinetics of heterogeneous reactions and the adsorption on catalysts. III. Temperature dependence of the adsorption coefficient of water on aluminum oxide.** *Vestnik Moskov. Univ.* 6, No. 10, *Ser. Fiz.-Mat. i Estestven. Nauk* No. 6, 79-87 (1951).—*C.A.* **46**, 8487*i*.

Flow expts. of dehydration of EtOH on Al_2O_3 were evaluated with the aid of the equation $v_0 \ln [1/(1-y)] = \alpha + \beta v_0 y$, where v_0 = space velocity in millimoles/min./cc. catalyst, y = degree of conversion, and α and β were functions of the temp. only, independent of v_0 and of y. The expts. were made in the presence of H_2O or of argon as diluent. The adsorption coeffs. b ($atm.^{-1}$) were detd. from the slopes of the linear graphs of $1/\alpha$ as a function of δ with H_2O and with argon; the values of b for H_2O, at 380, 415, and 350°C were 17.2, 14.5, and 12.2, and for C_2H_4, 16.0, 12.2, and 11.5.

2066. BLUE, R. W. AND ENGLE, C. J. **Hydrogen transfer over silica-alumina catalysts.** *Ind. Eng. Chem.* **43**, 494-501 (1951).—*C.A.* **45**, 2759*d*.

The transfer of H from *cis*-decahydronaphthalene, *trans*-decahydronaphthalene, and tetrahydronaphthalene to 1-butene and isobutene was studied. The reaction was of 1st order and occurred most rapidly over a catalyst compn. of 60-90% SiO_2. As a H donor, the *cis* compd. was about 10 times as active as the *trans*, and tetrahydronaphthalene more active than the *cis* compd. Isobutene was more active as H acceptor than 1-butene. The cause of catalyst deposit was studied by using 1-butene-$4C^{14}$, and largely attributed to the H-donor.

2067. BRAUER, G. AND HOLTSCHMIDT, U. **Cerium oxides. I.** *Z. anorg. u. allgem. Chem.* **265**, 105-16 (1951).—*C.A.* **46**, 7920*i*.

With com. pure CeO_2, measurable reduction by H_2 occurred at 500°C. The slightest impurity of Pr (0.005% Pr_2O_3) increased the reducibility.

2068. BREWER, LEO AND SEARCY, ALAN W. **The gaseous species of the aluminum-alumina system.** *J. Am. Chem. Soc.* 73, 5308-14 (1951).—*C.A.* **46**, 1855*g*.

The vapor pressures of Al (1383-1468°K) and of Al_2O_3 (2309-2605°K) were measured by the Knudsen effusion method. Al-Al_2O_3 mixts. were heated in Al_2O_3 containers, and changes in volatility of Al_2O_3 in the presence of Al were detd. in expts. from 1466 to 1853°K. The results indicated the importance of 2 gaseous oxides of Al. Al_2O gas was evolved when Al_2O_3 was heated with Al or another reducing metal. AlO appeared to be the principal Al species when Al_2O_3 was volatilized alone.

2069. CREMER, E. AND GRUNER, R. **Measurement of the adsorption of ammonia on ferric oxide from the thinnest coating to a multimolecular layer.** *Z. physik. Chem.* **196**, 319-28 (1951).—*C.A.* **45**, 8846*f*.

Adsorption isotherms of NH_3 were detd. on Fe_2O_3 prepd. in various ways; the pressure range was 0.001 to 700 mm Hg. Between 293° and 333° K the isotherms were consistent over the entire concn. range with the equation developed previously. At 253° K and high pressures there were deviations in the direction of thicker layers. An adsorption formula contained, in addn. to the usual factors, a const. characteristic of the system and having the dimensions of a temp. The value of this const. in the present case (approx. 1250) was almost independent of the temp. at which the adsorbent was prepd.

2070. GLAESER, RACHEL. **Organic-montmorillonite complexes in vapor phase. Desorption isotherms of acetone-montmorillonite and 2-propanol-montmorillonite.** *Mem. services chim. etat* 36, No. 1, 69-76 (1951).—*C.A.* 46, 11054*f*.

Ca montmorillonite and Na montmorillonite were treated with either anhyd. acetone or 2-propanol until no more H_2O was extd. The montmorillonite, covered with the org. compd., was placed over a soln. of the org. compd. in castor oil and allowed to come to equil. in vacuo (about 15 days), and then desorbed in vacuo over P_2O_5 at 40 °C or 20 °C. Both formed bimol.-layer complexes which, on desorption, changed to unimol.-layer complexes.

2071. GREGORY, J. N. AND MOORBATH, S. **Diffusion of thoron in solids. I. Investigations on hydrated and anhydrous alumina at elevated temperatures by means of the Hahn emanation technique.** *Trans. Faraday Soc.* 47, 844-59 (1951).—*C.A.* 46, 2367*b*.

Phase changes and recrystn. processes were clearly indicated in the heating of hydrated γ-Al_2O_3 in the range 100° to 1200 °C. Variation of O_2 partial pressure above α-Al_2O_3 showed how the diffusion of the inert gas depends on lattice defect equilibria. The diffusion consts. of Th in Al_2O_3 were calcd. by means of simple relations together with an approximation for mean particle size.

2072. HAUFFE, KARL AND PETERS, HORST. **Mechanism of reduction of cerium dioxide.** *Z. anorg. u. allgem. Chem.* 266, 345-8 (1951).—*C.A.* 46, 7854*g*.

The reduction proceeds by the migration of O atoms to the surface leaving unoccupied O sites in the lattice and quasifree electrons. The addn. of Pr_2O_3 to the CeO_2 lattice creates O vacancies, and should increase the ease of reduction, whereas the addn. of ThO_2 does not create defects and should not affect the reduction. Application of the mass-action law indicates that the elec. cond. should be proportional to $(p_{H_2}/p_{H_2O})^{1/3}$. The concn. of O vacancies is calcd. to be about 10^{-4} in the pure CeO_2 phase at 1000 °C.

2073. HINDIN, S. G.; MILLS, G. A., AND OBLAD, A. G. **Hydrogen exchange between cracking catalyst and the butanes.** *J. Am. Chem. Soc.* 73, 278-81 (1951).—*C.A.* 45, 6371*i*.

The procedure was either to bring the paraffin into contact with a silica-alumina cracking catalyst that had been enriched with D or to bring the silica-alumina cracking catalyst contg. H_2 into contact with the monodeuteriated hydrocarbon. The reaction time and temp. was 1 hr at 150 °C. At 150 °C extensive H_2 exchange occurred between catalyst and isobutane, while under the same conditions the exchange with n-C_4H_{10} was lower by more than an order of magnitude. The addn. of air or of olefin to the iso-C_4H_{10}-catalyst system accelerated the exchange reaction only to a relatively minor extent. The effect of the H_2O content of the catalyst was critical. By drying to higher temp. the ability of the catalyst to catalyze exchange was almost eliminated.

2074. HOLM, V. C. F. AND BLUE, R. W. **Hydrogen-deuterium exchange activity of silica-alumina catalysts.** *Ind. Eng. Chem.* 43, 501-5 (1951).—*C.A.* 45, 2759*e*.

Catalysts in the range 0 to 7.5% SiO_2 were most active. The H-D exchange and H transfer involve different mechanisms and require different characteristics in a catalyst. Catalysts pretreated at 800° instead of 400 °F were 1000 times more active in the H-D exchange.

2075. HOYOS, ANGEL DE CASTRO AND RODRIGUEZ, JULIO. **Surface changes of an acid bentonite on thermal treatment.** *Anales real soc. espan. fis. y quim.* 47B, 504-14 (1951).—*C.A.* 46, 5747*b*.

After being heated to 300 °C, bentonite could be rehydrated; the higher it was heated above this temp., the less able it was to be rehydrated. The specimens heated to 600° or 700 °C were able to recover partly the loss of reticular water, but this recovered water was lost at 300° and 400 °C. This was not associated with the loss of OH groups. The decrease of hydrating capacity and the change of hydrating surface were proportionally greater for the first reticular water losses.

2076. IMELIK, BORIS. **The rehydration of alumina and its significance in interpretation of the isothermal absorption of water.** *Compt. rend.* 233, 1284-6 (1951).—*C.A.* 46, 4318*i*.

Samples of Al_2O_3 prepd. by heating a gel with the boehmite structure between 400 and 900 °C were exposed to air satd. with H_2O vapor at 37 °C. After one week the sample ignited at the lowest temp. showed x-ray evidence for the presence of boehmite and hydrargillite. With exposure up to 5 weeks all samples showed this change in compn. This change in Al_2O_3 structure explains the irreversible character of the isothermal adsorption of H_2O.

2077. JURA, GEORGE AND POWELL, RICHARD E. **Kinetics of gas adsorption as a method of area determination.** *J. Chem. Phys.* 19, 251-2 (1951).—*C.A.* 45, 3681*b*.

If there is a significant change in the rate of adsorption when a monolayer is completed, a detn. of gas-adsorption kinetics gives a value for the area of a solid. This is the case for NH_3 adsorbed on a SiO_2-Al_2O_3 cracking catalyst at 0° and for H_2O on anatase at 25 °C; the area of the former is 290 and of the latter 8.6 m^2/g.

2078. MILLIGAN, W. O., SIMPSON, WARREN C.; BUSHEY, GORDON L.; RACHFORD, HENRY H. JR., AND DRAPER, ARTHUR L. **Precision multiple sorption-desorption apparatus.** *Anal. Chem.* 23, 739-41 (1951).—*C.A.* 45, 8320*h*.

A precision multiple sorption-desorption app., based on wt changes on SiO_2-spring balances, was constructed capable of 15 isotherms or isobars simultaneously. Equil. points were obtained in the temp. range -20° to 60 °C and at pressures from 10^{-6} to 400 mm of Hg. The app. is especially designed for the examn. of *hydrous oxide-water systems*.

2079. Milligan, W. O. and Weiser, Harry B. **Orientation effects in alumina films.** *J. Phys. & Colloid Chem.* **55**, 490-6 (1951).—*C.A.* **45**, 5995*h*.

Transparent films of alumina (γ-$Al_2O_3.H_2O$ or γ-AlOOH) were prepd. by evapg. a highly thixotropic alumina sol to dryness at room temp. A film of γ-AlOOH remained transparent after being transformed into γ-Al_2O_3 by heating to 600-800 °C. Films of either on various surfaces show a behavior which suggests that the orientation process is closely connected with the strain which results when the gel is dried.

2080. Moshkovskiĭ, Yu. Sh. **Influence of the method of preparation of zinc oxide on its sintering.** *Doklady Akad. Nauk S.S.S.R.* **80**, 215-16 (1951).—*C.A.* **46**, 3822*c*.

ZnO prepd. by decompn. of $ZnCO_3$ at 350 °C begins to sinter at 500 °C, whereas ZnO obtained by oxidation of Zn evapd. in an elec. arc sinters only at 1000 °C. Deep defects with energy levels of the order of 1.4 e.v. will hold electrons firmly, and their caputre by the holes left vacant by evapd. O atoms will be difficult; under these conditions, the transfer of matter necessary for sintering, must be inhibited. In the presence of only slight defects, with energy levels no deeper than 0.4-0.6 e.v., the electron can remain at the points vacated by O atoms, and diffusion and sintering should be easier. The effect of promoters, such as Cr_2O_3, on ZnO, may consist in the creation of energy levels deep enough to inhibit sintering.

2081. Rienäcker, G. and Birckenstaedt, M. **The reduction of cerium dioxide, especially at 250-350 °C.** *Z. anorg. u. allgem. Chem.* **265**, 99-104 (1951).—*C.A.* **46**, 7922*a*.

CeO_2 was reduced about 12% by H_2 at 250-350 °C. Reduction was accompanied by a color change from yellowish white to gray-blue. With increasing temp. the percentage of reduction increased (with various color changes) until at 1250 °C, Ce_2O_3 was the product.

2082. Rodier, Georges. **The study of catalysts by the determination of nuclear reaction times.** *Compt. rend.* **232**, 513-15 (1951).—*C.A.* **45**, 5472*b*.

The magnetic susceptibility of Al_2O_3 was detd. by nuclear resonant techniques. Two distinct curves of relaxation time *vs.* Fe concn. were reported for the 2 samples.

2083. Roiter, V. A.; Yuza, V. A., and Kuznetsov, A. N. **Mechanism of reduction of iron oxides by hydrogen, carbon monoxide, and their mixtures.** *Zhur. Fiz. Khim.* **25**, 960-70 (1951).—*C.A.* **46**, 9391*d*.

The kinetics of the reduction of pure pelletized Fe_2O_3 (from Fe_2O_3 gel) was investigated in a circulating system with removal of reduction products between 200° and 300 °C. H_2 was a much slower reducing agent than CO. In all cases, the rate curves consisted of two parts: the 1st corresponding to the practically quant. reduction of Fe_2O_3 into Fe_3O_4 was nonautocatalytic; the 2nd was autocatalytic and relative to the reduction of Fe_3O_4 to Fe. All curves for H_2-CO mixts. lay between the curves for pure H_2 and CO but showed a striking nonadditive action of the reducing gases.

2084. Romwalter, A. and Hauer, A. **New possibilities for the application of activated aluminum.** *Acta Tech. Acad. Sci. Hung.* **2**, No. 1, 43-58 (1951).—*C.A.* **46**, 10711*h*.

Active Al is Al amalgam. Its reaction rate with liquid H_2O varied irregularly, owing to a scablike oxide layer, causing Hg losses, and resulting first in an increase, then in a decrease, of activity until finally Hg-free Al remains Activated Al is suitable for the *desiccation* of gases, org. liquids, and for the careful *dehydration* of adsorbing gels (SiO_2 or Al_2O_3).

2085. Selwood, P. W.; Lyon, Lorraine, and Ellis Marylinn. **Magnetic susceptibilities of Cr_2O_3-Al_2O_3 and of Fe_2O_3-Al_2O_3 solid solutions.** *J. Am. Chem. Soc.* **73**, 2310-11 (1951).—*C.A.* **45**, 9943*i*.

Magnetic-susceptibility measurements from 90 to 300 °K were made for the solid solns. Cr_2O_3-Al_2O_3 and Fe_2O_3-Al_2O_3. At infinite magnetic diln. the Cr^{3+} ion has a magnetic moment of 3.8 Bohr magnetons. The Weiss const. is 0. The Fe^{3+} ion under similar conditions has a moment of 5.9 and a Weiss const. of 0. The moment of the Fe^{3+} ions decreases rapidly with increasing magnetic concn.

2086. Thibon, Honoré; Charrier, Jacques, and Tertian, Robert. **Thermal decomposition of alumina hydrates.** *Bull. soc. chim. France* **1951**, 384-92.—*C.A.* **45**, 10023*g*.

The anhyd. aluminas showed a continuity of crystal lattice throughout the calcination process. Calcination of hydrargillite (20-30 μ monocrystals) to 1400 °C produced, successively, boehmite, κ'-, κ-, and α-Al_2O_3. Hydrargillite of very high sp surface underwent changes to χ-, η, and θ-Al_2O_3. Up to 5% CaF_2, AlF_3, or NaF in the calcining mixt. resulted in increased crystal sizes and lowered temp. at which the hydrargillite underwent the above changes.

2087. Wartenberg, H. v. **Water absorption by melting oxides.** *Z. anorg. u. allgem. Chem.* **264**, 226-9 (1951); *Z. Elektrochem.* **55**, 445-6 (1951).—*C.A.* **46**, 3358*i*.

BeO, Al_2O_3, and La_2O_3 absorb H_2O when melted and release it with eruption upon solidification. The technique for the manuf. of artificial rubies prevents H_2O from interfering with the process in this manner. The same phenomenon occurs slightly with ZrO_2, but not at all with a mixt. of Pr_2O_3, Nd_2O_3, and Yb_2O_3 or with CaO, MgO, or ThO_2. Al_2O_3 is more volatile in the presence of H_2O vapor than in dry air, so gaseous $Al(OH)_3$ is also stable.

2088. Zabor, Robert C. and Emmett, Paul H. **The adsorption of normal paraffins on cracking catalysts.** *J. Am. Chem. Soc.* **73**, 5639-43 (1951).—*C.A.* **46**, 2786*i*.

Adsorption of butane, heptane, and octane on a silica-alumina cracking catalyst (Houdry S-46) at temps. from 40° to 531 °C was detd. by volumetric and gravimetric methods. The adsorption appeared to be phys. in nature up to about 150 °C. Above this temp., and even at cracking temps., the adsorption was very small, about 0.005 millimole per g of catalyst.

2089. Antipina, T. V. and Frost, A. V. **A new form of the pressure dependence of adsorption.** *Doklady Akad. Nauk S.S.S.R.* **84**, 985-7 (1952).—*C.A.* **46**, 9377*d*.

Adsorption isotherms for EtOH vapor were detd. at 108°, 150°, and 188°C, and for Et_2O vapor at 188°C, on Al_2O_3 (prepd. by gas-phase hydrolysis of pure $AlCl_3$). Plots of the reciprocal $1/x$ of the amt. adsorbed as a function of the reciprocal pressure $1/p$ show, at higher p, a portion parallel to the $1/x$ axis. The same is found in the sorption of H_2O vapor at 310°C.

2090. Antipina, T. V. and Frost, A. V. **Relation between the kinetics of heterogeneous reactions and adsorption on catalysts. IV. Determination of the adsorption coefficient of water on aluminum oxide from adsorption measurements.** *Vestnik. Moskov. Univ.* **7**, No. 8, 111-16 (1952).—*C.A.* **47**, 2026*a*.

One portion of Al_2O_3 was heated 4 hrs at 550°C and used directly for the adsorption measurements; another portion, after the same treatment, was used repeatedly in dehydrogenation of EtOH, until it reached a const. max. catalytic activity. Both had the same surface area but different pore distributions. Adsorption isotherms of H_2O vapor at 340°, 380°, and 415°C on both up to 16-10 mm Hg, showed the typical leveling off. Plots of the reciprocal adsorbed amt. $1/a$ as a function of the reciprocal pressure were linear at all 3 temps., with different slopes for both; i.e. the adsorption obeyed Langmuir's law.

2091. Boreskov, G. K.; Dzis'ko, V. A.; Borisova, M. S., and Krasnopol'skaya, V. N. **Effect of heat on the structure and catalytic activity of alumina.** *Zhur. Fiz. Khim.* **26**, 492-9 (1952).—*C.A.* **47**, 957*h*.

Three Al_2O_3 catalysts were heated at 450°, 600°, 800°, 1000°, and 1200°C. Pore structure, surface area, activity for decompn. of EtOH and x-ray pattern were detd. after each heat-treatment. All powders consisted of γ-Al_2O_3 except that treated at 1200°C which showed the α-form. Heating at 600°C during 24 hrs did not modify the surface area nor the pore structure of samples previously treated at 450°C. After a heating period at 1200°, the pore vol. decreased by a factor of 2 but the surface area by a factor of 60. After a heat-treatment at 1200°, the sp activity decreased markedly and the catalysts became mainly dehydrogenating.

2092. Brown, Marjorie J. and Foster, A. Graham. **Sorption of vapors by ferric oxide gel. III. Aliphatic amines.** *J. Chem. Soc.* **1952**, 1139-44.—*C.A.* **46**, 10775*b*.

Isothermals of sorption on a ferric oxide gel included Et, Pr, Bu, Am, hexyl heptyl, tert-Bu, cyclohexyl amines and ethylenediamine and pyridine. Volumes adsorbed at satn. were const. for all vapors. For normal amines the amt. required for a monolayer was proportional to mol. wt; this indicated an oriented monolayer with area per mol. of 31 A^2.

2093. Calvet, Édouard. **Thermokinetic study of adsorption. Soluble bodies and macromolecular substances.** *J. Polymer Sci.* **8**, 163-71 (1952) (in French).—*C.A.* **46**, 9931*f*.

A microcalorimeter of the Tian-Calvet type can be used for detn. of the surface area and the approx. rate of expansion of the surface film, and for the study of the activated fraction of the surface of insol. powders. The amts. of H_2O adsorbed by different samples of Al_2O_3 at the point of formation of a unimol. film are: hydrargillite 0.3%, boehmite 0.20%, and activated Al_2O_3 4.9%.

2094. Dumbrowski, Henry S. **Residual equilibrium saturation of porous media.** *Univ. Microfilms* (Ann Arbor, Mich.), *Pub.* No. **3581**, 171 pp. (microfilm $2.14, paper enlargements $17.10).—*C.A.* **46**, 8931*b*.

2095. Glemser, Oskar; Hauschild, Ulrich, and Lutz, Gertrud. **Preparation of hydroxides by the action of atomic hydrogen on oxides.** *Z. anorg. u. allgem. Chem.* **269**, 93-8 (1952).—*C.A.* **47**, 438*b*.

Atomic H, generated by elec. discharge, was allowed to react directly with powd. metallic oxides. An intermediate, MnOOH, is formed in the reduction of MnO_2 to $Mn(OH)_2$. Prolonged reaction results in the formation of MnO. Atomic H reduces Na_2O_2 to NaOH. Reaction with WO_3 gives $H_{0.1}$ WO_3 and $H_{0.33}$ WO_3. Reaction with MoO_3 gives $Mo_4O_{10}(OH)_2$, which can be reduced further to $Mo_2O_4(OH)_2$, and to $Mo_5O_7(OH)_8$ by prolonged exposure.

2096. Gyani, B. P. and Sinha, A. P. B. **Sorption of water vapor by alumina gel.** *J. Indian Chem. Soc.* **29**, 582-8 (1952).—*C.A.* **47**, 2567*i*.

Adsorption of H_2O vapor on Al_2O_3 gel was measured at -3.5°, 0°, 10°, and 25°C. Hysteresis extended over the entire temp. range. There was a tendency to show fictitious satn. much before the true value. The anomalies persisted after numerous flushings with H_2O vapor and evacuations to remove gaseous impurities. The curves for the isosteric heats of adsorption and desorption are flat W curves and approach 10,500 cal per mole with increase in the amt. of adsorption.

2097. Harwood, J. H. **Recent technological applications of activated alumina.** *Ind. Chemist* **28**, 16-23 (1952).—*C.A.* **46**, 4145*f*.

2098. Iwase, Eiichi and Nishiyama, Seijiro. **Cramer's alkalinity of activated alumina.** *J. Sci. Research Inst.* (Tokyo) **46**, 181-4 (1952).—*C.A.* **47**, 4246*c*.

Cramer's test is more precise if the end point is indigo. Max. inner surface and max. alky. were obtained when $Al_2O_3.3H_2O$ was heated to $Al_2O_3.H_2O$ at 300-350°C.

2099. Kamakin, N. M. and Kiselev, A. V. **Hysteresis in the pressing of mercury into porous substances.** *Doklady Akad. Nauk S.S.S.R.* **83**, 589-92 (1952).—*C.A.* **46**, 10744*c*.

Detns. of the vol. of Hg taken up by porous aluminosilica gel as a function of the pressure P (up to 1500 kg/cm^2) gave results very close to those derived from adsorption-desorption isotherms of MeOH. On 2 different samples, the Hg "porometer" gave, under $P = 1500$, pore vols. of 67 and 43%, as against 63 and 43% by the adsorption isotherms. Hysteresis was observed on gradual relaxing of the pressure, with 25-50% of the Hg retained in the pores. A possible factor could be a mol. penetration of Hg into the skeleton of the sample.

2100. Milligan, W. O. and Whitehurst, Harry B. **Apparatus for the simultaneous determination of adsorption isotherms and magnetic susceptibility.** *Rev. Sci. Instr.* 23, 618-20 (1952).—*C.A.* 47, 3046*c*.

An app. for the simultaneous detn. of adsorption isotherms and magnetic susceptibility is similar in many respects to a previously fabricated app. for detg. adsorption only. The amt. of adsorption is measured by means of a fused silica spring (50 turns; 1 cm in diam.; sensitivity 3 mm/mg; max. load, about 100 mg).

2101. Papée, Denis. **Relation between the speed of adsorption and the isotherm.** *Compt. rend.* 234, 437-9 (1952).—*C.A.* 46, 6896*e*.

Adsorption expts. with H_2O vapor on 2 types of Al_2O_3 and 2 types of SiO_2 gel show that each substance has a specific adsorption curve whether such expts. are done statically or dynamically, whether the adsorbant is in pellets or in powder form in the static expts., and also throughout a variation in flow rate of 7-25 liter/hr in the dynamic expts.

2102. Papée, Denis. **The retention of water vapor by alumiua and silica.** *Compt. rend.* 234, 2536-8 (1952).—*C.A.* 46, 10773*i*.

The permanent adsorption of H_2O vapor by alumina and silica samples was that quantity, *m*, of water which was not desorbed at 25 °C after a cycle of adsorption-desorption. By heating of silica to elevated temps. both *in vacuo* and at atm. pressure, it was shown that permanent adsorption varied with structural changes as well as with the surface area. For boehmite, *m* increased from 100 to 400 °C; this showed that its decompn. increased with temp. Silica lost residual water at about 250 °C, but gave the same values of *m* when remoistened.

2103. Puri, Balwant Rai and Bhushan, Vidya. **Hygroscopic properties of metallic oxides prepared by different methods.** *J. Sci. Ind. Research* (India) 11B, 504-5 (1952).—*C.A.* 47, 4686*f*.

Co(II) oxide prepd. by heating the (1) carbonate, (2) nitrate, (3) oxalate, and (4) acetate; and Zn (II), Ni(II), and Cr(III) oxides prepd. by heating the (*a*) carbonate, and (*b*) nitrate, and by pptn. of hydroxides from the (*c*) sulfate, and (*d*) nitrate, were placed in humidistats contg. H_2SO_4 of various concns. The increase in wt at various relative humidities was noted. The hygroscopicity appears to depend on the acid radical, the carbonates giving the most hygroscopic oxides and the nitrates the least.

2104. Rubinshtein, A. M.; Vasserberg, V. E., and Pribytkova, N. A. **Effect of the dimensions of the elementary crystallites on the porosity and the activity of alumina catalysts in the dehydration reaction.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* 1952, 323-33.—*C.A.* 46, 9961*e*.

Three Al_2O_3 prepns. of different grain sizes were made by fractional sedimentation of a ppt. from a boiling soln. of a 50 g $Al(NO_3)_3.9H_2O$ in 3 liters H_2O with 5% NH_4OH. Catalytic activities were detd. in dehydration of 77.5% HCO_2H and of 96% EtOH. The absence of AlOOH lines in x-ray patterns proved that the residual H_2O in the catalyst was not constitutive, but that the H_2O was adsorbed on the surface, preferentially in micropores, and thus blocked active centers or inhibited diffusion thereto. The surface areas, detd. by the B.E.T. method by adsorption of MeOH vapor at 25°C were the same for all 3 catalysts, 286 m^2/g. The surface area detd. by adsorption of C_5H_{12} were 182, 179, 264 m^2/g resp.

2105. Tran, Huu-The and Prettre, Marcel. **The thermicity of the dehydration reactions of gibbsite.** *Compt. rend.* 234, 1366-8 (1952).—*C.A.* 46, 6553*d*.

The dehydration of $Al_2O_3.3H_2O$ was followed by thermogravimetry and differential thermal analysis. Thermal analysis showed that the 1st reaction, giving the boehmite phase, was endothermic, but the 2nd, leading to γ-Al_2O_3, was exothermic.

2106. Utsugi, Hiroshi. **Adsorption of vapor in the low-pressure range.** *J. Chem. Soc. Japan,* Pure Chem. Sect. 73, 232-4 (1952).—*C.A.* 47, 377*i*.

The adsorption isotherms of EtOH on the gel of $3Ti_2O_2.2Fe_2O_3$ activated at 150°, 250°, 350°, and 450°C, resp., were studied at 0-90°C. The quantity adsorbed increased discontinuously for the gels activated at 250° and 350°C. A point of inflection was observed in the isotherms above 60° for the gel activated at 450°C at 2×10^{-3}-1.5×10^{-2} mm Hg.

2107. Utsugi, Hiroshi. **Adsorption of vapors in the low-pressure region. III. Influence of solid surface on the discontinuity of isotherms.** *J. Chem. Soc. Japan*, Pure Chem. Sect. 73, 450-3 (1952).—*C.A.* 47, 3651*d*.

The isotherm for the adsorption of EtOH on the mixed gel $3TiO_2$-$2Fe_2O_3$ showed a discontinuity in the low-pressure range. If the two-dimensional pressure of the adsorbed phase was plotted against the area per mol., which was calcd. from the amt. adsorbed and the B.E.T. area, isotherms very similar to those for the condensation of imperfect gas are obtained. Hence the discontinuity can be regarded as a phase change of 2-dimensional adsorbed phase.

2108. Deisler, Paul F., Jr. and Wilhelm, Richard H. **Diffusion in beds of porous solids. Measurement by frequency response techniques.** *Ind. Eng. Chem.* 45, No. 6, 1219-27 (1953).—*C.A.* 47, 9125*b*.

Diffusion within the pores of catalytic particles and diffusion between particles were measured simultaneously. The results of expts. led to individual diffusion consts. and adsorption capacitances. The H-N, C_2H_4-N, and C_2H_6-N systems were studied with porous spherical pellets and spherical glass beads. Exptl. variables were total gas flow rate and changes in phase angle and amplitude of varying gaseous compn. waves sent through the bed.

2109. EAGLETON, L. C. AND BLISS, HARDING. **Drying of air in fixed beds.** *Chem. Eng. Progress* **49**, 543-8 (1953).—*C.A.* **48**, 5*b*.

The rate of drying of air in fixed beds of activated alumina, Florite, and silica gel was studied. Effluent concn. as a function of time was measured at several values of inlet concn., bed length, flow rate, and temp. It was found that the rate was governed by diffusion, both through the air film and within the particles.

2110. HAUL, R. A. W. **Measurement of activated diffusion of adsorbed molecules.** *Nature* **171**, 519 (1953).—*C.A.* 47, 7287*c*.

Rates of adsorption of butane in porous SiO_2 plugs were measured by a gravimetric method over a temp. range of -14° to -80°C, a porosity range of 0.72 to 0.53, and a surface coverage range of 0.37 to 6.9 statistical layers. At -14.4, -44.2, and -79.5°C it was calcd. that 70, 80, and 94%, resp., of the total transport was due to the mobility of adsorbed mols. on the surface. The activation energy for surface diffusion was 3 kcal/mol.

2111. SUTHERLAND, K. L. AND WINFIELD, M. E. **Transient rates of gas sorption. III. Pore structure, adsorption isotherms, and calculated rates at constant volume.** *Australian J. Chem.* **6**, 244-56 (1953).—*C.A.* **48**, 21*i*.

Pore structure of Al_2O_3 and thoria and Henry's law consts. for adsorption of H_2O vapor were detd. Exptl. rates of gas uptake by Al_2O_3 can be accounted for by Knudsen flow accompanied by rapid adsorption on the pore walls. None of the equations can account for the dependence of the rate of uptake by thoria on the 2nd (or higher) power of mass of the bed. Dependence of rate on mass or total surface area (*S*) at const. bed cross-section was a useful criterion of limiting step in gas uptake.

2112. WINFIELD, M. E. **Transient rates of gas sorption. I. Measurement of rapid gas uptake by oxide catalysts.** *Australian J. Chem.* **6**, 221-33 (1953).—*C.A.* **48**, 21*f*.

App. for admitting gas within about 0.001 sec to a porous solid and following subsequent rapid changes in rate of gas uptake in a const.-vol. system was described. The app. may be used up to 210°C and at pressure up to 20 mm. The sensitivity of pressure measurement was 0.001 mm. At 1.5-4 mm initial pressure, times for half-adsorption varied from 0.002 to 70 sec. Rates of sorption of H_2O and alcs. by Al_2O_3 and thoria at 110-200°C were 1st order with respect to initial pressure and had neg. temp. coeff.

2113. YOUNG, D. M.; BEEBE, R. A., AND BIENES, H. **Adsorption of heptane on solids at low pressure.** *Trans. Faraday Soc.* **49**, 1086-9 (1953).—*C.A.* **48**, 5595*b*.

Isotherms were detd. on graphite, Fe_2O_3, and on reduced Ag at low pressures. The first increment of heptane required approx. 2 hrs to attain equil. at both 25° and 30°C. Subsequent doses came to equil. within 15 min. or less. On Fe_2O_3 at 15°C, the 1st increment of vapor required 4 hrs 15 min. to come to equil., and the 2nd required 2 hrs 45 min., subsequent doses decreasing until only 10 min. was required at the 15th dose.

I-12. Gases on Clays and Soils

2114. YAROSHEVSKII, A. V. **The theory of drying ceramic products.** *Ogneupory* **8**, 451-6 (1940)—*C.A.* **37**, 4214⁵.

The theory that the drying process represented a series of sharply defined steps was discussed. The decrease in moisture followed a curve which rose regularly and later fell. An exptl. formula was offered for such a curve.

2115. ALTEN, F., AND LOOFMANN, M. **The adsorption of air by soils and soil constitutents and its influence upon the determination of the pore space and the specific gravity of cultivated soils with the pressure-air pycnometer.** *Bodenkunde u. Pflanzenernahr* **26**, 1-13 (1941).—*C.A.* **37**, 2859⁹.

The adsorption of air was detd. by mixtures of practically pure German bentonite and quartz sand (0.3-0.2 mm particle size) in the ratio of 1:3, 1:1, 3:1; upon quartz flour (0.1-0.06 mm); kaolin from Selb, Bavaria; micalike clay from Saraspatok; and silica gel. Adsorption was proportional to the pressure and to the amount of soil component in the colloidal state. Adsorption of air was 0.0014 moles per 100g of bentonite at 1 atm.

2116. BUSWELL, A. M. AND DUDENBOSTEL, B. F. **Spectroscopic studies of base-exchange materials.** *J. Am. Chem. Soc.* **63**, 2554-8 (1941).—*C.A.* **35**, 7829⁹.

Films of H^+, Li^+, K^+, NH_4^+, Ca^{++}, Mg^{++} and Ba^{++} montmorillonites were prepd. by evapn. of a suspension on microscope cover slips floating on Hg. Infrared absorption was detd. on films hydrated for various time periods over distd. H_2O. The montmorillonites satd. with various cations (Ca^{++}, Mg^{++}, Li^+, K^+, Ba^{++}, H^+, Na^+ and NH_4^+) could be placed in 4 classes with respect to water uptake. The first class, one of extreme absorption, consisted of the Ca^{++} and Mg^{++} montmorillonites. The second, of appreciable absorption, consisted of the Li^+, K^+ and Ba^{++} montmorillonites; and the third class, H^+ and Na^+ montmorillonites, was one of slight absorption. The fourth, consisting of NH_4^+ montmorillonite, showed almost no change on attempted hydration.

2117. DITTLER, EMIL. **The nature of clay.** *Tonind.-Ztg.* **65**, 515, 528 (1941).—*C.A.* 42, 5381*g*.

The electron microscope and a new ultramicroscope showed that the constituents of clays were not amorphous but possessed a cryst. character and that the clay mineral allophane was for the most part halloysite. Adsorption and base exchange were important properties of clay; the former was largely dependent on the latter.

2118. DITTLER, EMIL. **The nature of clays.** *Keram. Rundschau* **49**, 307-9 327-9 (1941).—*C.A.* 42, 5381*h*.

Research on clays was reviewed: the different clay minerals and their idenification by the electron microscope, base exchange and adsorption, and the synthesis of the clay minerals in the lab. and in nature.

2119. ISHIMURA, KOSHIRO. **The catalytic action of Japanese acid earth. XI. The isomerization of aldehydes to ketones and the explanation of the migration of the radicals from the standpoint of the electronic theory.** *Bull. Chem. Soc. Japan* 16, 196-209, 252-62 (1941). —*C.A.* 36, 4487[4].

When a mol. of a disubstituted acetaldehyde approached the surface of the acid earth, an unshared electron pair of the carbonyl O was attracted by the earth, enhancing the single bond character of the C-O link and leaving the C atom with an open sextet of electrons; an anion from the adjacent α-C atom moved toward the C atom with the open sextet of electrons, and a proton split from the carbonyl C and united with the O atom, forming the enolic form of a ketone. If the protons and anions pass outside the force field of the rearranging mol., they may combine to form hydrocarbons (benzene and toluene have been found in the reaction products from some of the isomerization expts.).

2120. ISHIMURA, KOSHIRO. **The catalytic action of Japanese earth. XII. The relation between the catalytic activity and adsorption. II. The adsorption isotherms of water and acetonitrile for the earth.** *Bull. Chem. Soc. Japan* 16, 349-55 (1941).—*C.A.* 41, 4368*b*.

In adsorption of water and acetonitrile by Japanese acid earth, studied by McBain's sorption balance, a marked hysteresis was observed.

2121. CHAPEK, M. V. **Thin water layers.** *Kolloid-Z.* 101, 209-13 (1942).—*C.A.* 38, 4491[7].

Swelling and splitting apart of small prisms of quartz and kaolin were investigated by evapg. suspensions of quartz with an av. diam of 5×10^{-4} cm and of kaolin with an av. diam of 5 to 7×10^{-5} cm. Particles were not in contact, but were sepd. by adsorbed water interlayers. These layers occurred at relative vapor pressures of 0.32-0.55 at which capillary condensation was unlikely. Degree of swelling and adsorbed vapor were detd. simultaneously at relative pressures of 0 to 1.0. Results for clay and kaolin corresponded to each other. Splitting apart was caused by adsorption layers, the thickness of which amounted to a few A units.

2122. JOHNSON, A. L. AND NORTON, F. H. **Fundamental study of clay. III. Casting as a base-exchange phenomenon.** *J. Am. Ceram. Soc.* 25, 336-44 (1942).—*C.A.* 36, 5623[5].

Specimens of com. casting slip were cast in plaster molds, porous bisque molds, and porous bisque molds treated with either $CaCl_2$ or $AlCl_3$. Detection of the ion serving in the exchange position was possible by the evaluation of the yield value of the cast specimen. Casting may be carried out by mech. water removal by the porous mold, by an exchange reaction between the ions of the slip and those of the mold, or by a combination of the two.

2123. JOHNSON, A. L. AND LAWRENCE, W. G. **Fundamental study of clay. IV. Surface area and its effect on exchange capacity of kaolinite.** *J. Am. Ceram. Soc.* 25, 344-6(1942).—*C.A.* 36, 5623[6]

Six monodisperse fractions of kaolinite (mean particle size 10.0, 4.4, 2.5, 0.95, 0.52, 0.28 μ, by calcn.) were prepd. and the exchange capacity was detd. from the viscosity relations on addns. of NaOH to the electrodialyzed fractions. A linear relationship was found between surface area and base-exchange capacity.

2124. YAMAMOTO, KENICHI. **Contact action of aluminum silicate catalysts.** *Waseda Applied Chem. Soc. Bull.* 19, 17-32 (1942).—*C.A.* 44, 8754*e*.

Acid clay contained noncryst. $mSiO_2.nH_2O$ mixed variously with cryst. $Al_2O_3.4SiO_2.H_2O$ covered by a colloidal film of noncryst. hydrous Al silicate gel whose quality and quantity detd. the activity. An increase of the silicate gel means greater activation. The activity of various natural and synthetic active clays varied generally in parallel to the adsorption considered as a function of the capacity factor, i.e., surface area and intensity.

2125. BERKELHAMER, LOUIS H. **Rehydration study of clays.** *J. Am. Ceram. Soc.* 26, 120-6 (1943).—*C.A.* 37, 2898[3].

At 30 °C, 20 different clays in a water-satd. atmosphere, (first dehydrated at 300 °C to const. wt) were studied. Montmorillonite-type clays were distinctly different from other types. One halloysite acted like the montmorillonites for the first 50 hrs, then the rehydrating slowed down and satn. was complete at about 1000 hrs. All other clays tested still adsorbed water at the end of over 1500 hrs in some instances. A rapid dehydration-rehydration test was developed. Duplicate samples were dehydrated at 300 °C for 2 hrs; one was rehydrated for 2 hrs at 65 °C, and the other dehydrated for 2 hrs more at 600 °C. The test could be made in 5 hrs.

2126. CHISHOLM, R. D. AND KOBLITSKY, L. **Sorption of methylbromide by soil in a fumigation chamber.** *J. Econ. Entomol.* 36, 549-51 (1943).—*C.A.* 38, 447[6].

The effect of excess moisture and type of soil on the concn. of MeBr in the atm. of a fumigation chamber was studied. MeBr in an empty chamber contg. an excess of moisture decreased at the same as the rate of decrease in an empty dry chamber. Dry sand, clay and peat soils sorbed more MeBr than the resp. wet soils; sorption for the peat soil was 4.5 times and for the clay soil 2.75 times as much as sand.

2127. CORNET, I. **Sorption of ammonia on montmorillonitic clay.** *J. Chem. Phys.* 11, 217-26 (1943).—*C.A.* 37, 3990[1].

When the pressures of NH_3 were plotted against the quantity of NH_3 sorbed, typically parabolic or hyperbolic sorption isotherms were obtained with ammonium bentonite, potassium bentonite and finely ground hydrogen bentonite. Sorbed NH_3 occupied base-exchange-reactive spots; phys. trapping of NH_3 mols. in the interplanes would not account for the lattice expansion. Both lattice OH ions and polarization of H_2O mols. may give rise to base-exchange capacity on grinding some clay minerals.

2128. Kulkarni, B. S. and Jatkar, S. K. Kulkarni. **The activation and clarifying properties of fuller's earth. VII. Activation of fuller's earth.** *Proc. Natl. Inst. Sci. India,* **9,** 111-16 (1943).—*C.A.* **42,** 7945*h*.

A thick paste was formed by grinding fuller's earth with 100 g of concd. H_2SO_4 per 100 g earth. This was heated 2 hrs at 150 °C, powd., and washed free of acid. The activity of the earth was raised considerably, at the cost of a 10.6% loss of earth.

2129. Leonida-Zamfirescu, Elisa. **Study of the Rumanian decolorizing earths.** *Inst. geol. Roumaniei, Studii tech. econ. Ser B.,* **22,** 92 pp. (1943).—*C.A.* **42,** 8428*e*.

Decolorizing earths in Rumania, were acceptable to the chem. and oil industries either in their natural form or after activation. Bentonites from Rugi and Talmaciu in Transylvania and Carali in Dobrogea were excellent. Kaolin, bentonite, and infusorial earth samples from various parts of Rumania were evaluated. Chem. analyses indicated that the best decolorizing earths are hydrosilicates, contg. MgO and more than 20% H_2O.

2130. Nutting, P. G. **Some standard thermal dehydration curves of minerals.** *U. S. Geol. Survey, Professional Papers No.* **197E,** 197-216 (1943).—*C.A.* **37,** 5339^1.

From about 250 curves previously obtained, 73 of the more significant were given.

2131. Page, J. B. **Differential thermal analysis of montmorillonite.** *Soil Science* **56,** 273-283, 1943.

The variations in the type of curves given by the different samples were caused by differences in the amount of substitution in the lattices. The characteristics of the curves might be used to indicate the nature and extent of these substitutions and thus aid in arriving at a better understanding of soil colloids.

2132. Zuev, L. A. and Gapon, E. N. **The adsorption of water vapor by Al silicates.** *Pedology (U.S.S.R.)* **1943,** No. 8, 13-18 (in English 19).—*C.A.* **38,** 3528^8.

Bentonite was electrodialyzed to pH 5.5 and then treated with 90 milliequiv. of N and 90 and 45 milliequiv. Ca. The adsorption isotherm of water vapor by H-, Na-and Ca-bentonites was then compared with that of kaolin and humic acid. The bentonite and humic acid gave an S-shaped curve; whereas the kaolin did not and the quantity of adsorption was small. At low vapor pressures the bentonites in their effect on adsorption can be arranged as follows: Na bentonite < H bentonite < Ca bentonite.

2133. Kawashima, Chihiro and Shiraki, Yoichi. **Fundamental studies on Japanese diatomaceous earths and their industrial applications. XIV, XV, XVI, XVII.** *J. Japan, Ceram. Assoc.* **52,** 81-7, 125-9, 174-9, 212-16 (1944).—*C.A.* **45,** 7481*h*.

The particle-size distribution of 13 samples of Japanese earths and 3 samples of American diatomaceous earths was detd. The distributions agreed with those detd. by microscopic observation. The hygroscopicity of 30 specimens of Japanese earths was detd. at 18 °C. The values found were 5.50 to 12.13%. Hygroscopicity decreases on heating at 500° to 600° and tends to zero at 900 °C. Water absorption was detd. by dropping, suction, or immersion method.

2134. LaLande, W. A., Jr.; McCarter, W. S. W., and Sanborn, J. B. **Bauxite as a drying adsorbent.** *Ind. Eng. Chem.* **36,** 99-109 (1944).—*C.A.* **38,** 1612^9.

The mechanism of the thermal decompn. and activation of 2 U.S., 1 French and 1 South American bauxite was discussed on the basis of differential thermal analysis and x-ray diffraction and with particular reference to the production of highly efficient drying adsorbents. The surface area increased with the activation temp. to 650°-700 °F and decreased at higher temps. The total amt. of water which can be removed from a fluid attained a max. value (18-19%) at activation at 850°-900 °F. Activated bauxite may be regenerated by heating at 300°-500 °F and the efficiency remains with 5% of the initial value. The capacity to produce dry gas decreased with decreasing humidity, but not in direct proportion, with increasing gas velocity and with increasing temp. of the adsorbent. Removal of Fe from bauxite contributed to longer life and higher efficiency.

2135. Marsh, C. E. **Beneficiation of alumina clays.** *Light Metal Age* **2,** No. 2, 22-4 (1944).—*C.A.* **38,** 2908^3.

Expts. indicated that a kaolin product contg. 35% Al_2O_3 could be produced from the residual clays of Eastern Washington and Idaho that would compete with transported clays and were lower in Fe. A clean (97 +%) silica sand could be produced from these residual clays for possible use as a filter aid in the alumina-leaching operations or for other uses.

2136. Sandford, Folke. **Effect of inert gases on the changes of ceramic products in moist air.** *Trans. Chalmers Univ. Technol., Gothenburg, Swed. No.* **36,** 3-58 (1944).—*C.A.* **40,** 2278^7.

Ceramic substances γ-Al_2O_3, α-Al_2O_3, quartz, cristobalite, clay, kaolin, and feldspar were heated in a Pt boat in 3 mm layers to 800°, 1000°, and 1200 °C. N_2, O_2, CO_2, 10%CO +90%N_2, and H_2O were passed at a rate of flow of 2 liters/hr for 2 hrs. The samples were then cooled to 100 °C, transferred into a weighing glass, and weighed at room temp. H_2O vapor had a stronger inactivating effect than the other gases, except on γ- and α-Al_2O_3 and feldspar pretreated at 1200 °C and α-Al_2O_3 and quartz pretreated at 1000° and 800 °C.

2137. Areshidze, Kh. I. and Tavartkiladze, E. K. **Georgia bentonite clays as dehydrating catalysts. I. Ascanite as a dehydrating catalyst.** *J. Applied Chem. (U.S.S.R.)* **18,** 271-2 (1945).—(English summary).—*C.A.* **40,** 3239^2.

Bentonite clay from the Ascana district (Georgian S.S.R.) was tried at 300 °C as a dehydrating catalyst on EtOH, PrOH, BuOH, and AmOH and the i-isomers. In all cases the corresponding olefins were obtained in appreciable (but not detd.) yields. The hydrocarbons were not identified.

2138. Broughton, D. B. **The drying of solids. Prediction of critical moisture content.** *Ind. Eng. Chem.* 37, 1184-5 (1945).—*C.A.* 40, 7769.

The crit. av. moisture concn., the drying conditions, and the nature of the material were studied. The derivation was based on the assumption that the water distribution in the slab follows the diffusion equation and that the surface moisture concn. gradient at the crit. point was a function only of the nature of the material. The method was tested by using data on the drying of 3 clays.

2139. Shaaban, M. A. **Investigation of the drying of solid granular materials.** *J. Imp. Coll. Chem. Eng. Soc.* **1**, 32-8 (1945).—*C.A.* **41**. 4973*b*.

Investigation on the air drying of whiting, contg. approx. 30% moisture and classified by particle size, were carried out with great precision, with a balance to record the drying rate. It was discovered that the so-called "constant-rate" period was only approx. const., there being a slight decrease in drying rate with decreasing moisture content of the cake.

2140. Tsitsishvili, G. V. and Arevadze, I. Z. **Investigating the sorption properties of natural adsorbents—Georgian bentonite.** *J. Applied Chem. (U.S.S.R.)* **18**, 572-5 (1945).—*C.A.* 41, 20^{a}.

The adsorptive properties of bentonite (askanite, gumbin, and askangel) were detd. with benzene, toluene, xylene, benzine, ether, acetone, and ethyl alc. For comparison, activated charcoal was also used as an adsorbent. The results indicated a certain adsorption equil. which decreased with increasing concn. Acetone, alc., and ether were adsorbed by bentonite material much better than the other reagents mentioned.

2141. Altinli, E. and Irmak, Lütfiye Rüstü. **Diatomaceous earth from Geyikeçeli-Kayseri Vilâyeti, Turkey.** *Rev. faculté sci. univ. Istanbul. Ser. B,* **11**, No. 2, 131-4 (1946). (in English).— *C.A.* **41**, 2354*h*.

The d. was 0.48 g/cc. by pycnometer. Sp resistance in plate forms was 2-10 megaohm cm for 250-600-v. d.c., and 1.5-6.5 megohm cm for 300-600-v. a.c. Four specimens tested showed a decrease in the coeff. of the water permeability with time from 4.9 to 11.7 × 10^{-3} g/atm.- sec cm to subsequent values of 3.3 to 9.5 × 10^{-3}.

2142. Bezborodov, M. A. **Sintering temperature range for clays as a function of their alumina to silica ratio.** *Compt. rend. acad. sci. U.R.S.S.* 52, 605-7 (1946) (in English),—*C.A.* 41, 2543*i*.

The sintering range (Δt) can be expressed: $\Delta t = 456\,°C - (420°/(1+a))$, where $a = Al_2O_3$ to SiO_2 ratio, which showed that the dependence between Δt and a was expressed by a hyperbolic curve. On passing from the two-component Al_2O_3-SiO_2 to clays, the relation between sintering range and chem. compn. became very complicated.

2143. Brindley, G. W.; Robinson, K., and MacEwan, D. M. C. **The clay minerals halloysite and metahalloysite.** *Nature* **157**, 225-6 (1946).—*C.A.* 40, 3073^{9}.

Halloysite consisted of the same layers which occurred in kaolinite and metahalloysite, with intervening layers of H_2O mols. (or org. compds.). In halloysite (and in its org. compds.) c_o was increased. When metahalloysite was formed from halloysite by low-temp. dehydration, the H_2O layers were expelled with subsequent collapse of the randomly oriented kaolinite layers. Heat-treatment of metahalloysite caused a decrease in its capacity for combining with ethylene glycol: this was probably due to an increase in the no. of effective linkages between the kaolinite sheets.

2144. Fisk, Henry G. **Bentonite: test methods and results of tests of Wyoming bentonites.** *Natural Resources Research Inst., Bull. No.* **2**, 39 pp. (1946).—*C.A.* 42, 733*e*.

The color and values for grit content, colloidally subdivided material, viscosity (Stormer), gel strength (Stormer), wall-building test, green and dry bonding power, and bleaching tests were given for 65 samples of Wyo. bentonites in comparison with Black Hills bentonites.

2145. Heredia, Pedro A. **Physicochemical study of Argentine clays. II.** *Univ. nacl. Tucumán, Pub.* **400**, *Cuadernos min. y geol.* **4**, c. 3, No. 15, 208-10 (1946).—*C.A.* **41**, 1532*i*.

Chem. analyses and phys. properties were tabulated for two kaolin samples, one from Tasna, Yavi department, Jujuy, and the other from Agua de Dionisio, Belén department, Catamarca province, Argentina.

2146. Ledoux, Edward. **Reactivation of adsorbent desiccants.** *Chem. & Met. Eng.* 53, No. 1, 127-8 (1946).—*C.A.* **40**, 1977^{5}.

Rate of reactivation increased with wt rate of gas flow, with efficiencies of vapor and heat transfer, and with vapor-pressure difference between gas and adsorbate. Performance curves were given for removal of water from bauxite.

2147. MacEwan, D. M. C. **The identification and estimation of the montmorillonite group of minerals, with special reference to soil clays.** *J. Soc. Chem. Ind.* **65**, 298-304 (1946).—*C.A.* 41, 7320*i*.

A method for detg. montmorillonite in amts. as low as 1% in mixts. of other clay minerals, including chlorites and vermiculites, was described. This was possible with a single x-ray powder photograph on a clay treated with glycerol. Ethylene glycol was less ideal because of higher volatility and less sepn. of its montmorillonite-complex diffraction line (17.1 A.) from chlorite. Neither the position nor intensity of the line was affected by the degree of base satn. of the clay as was for example the hydrated montmortillonite diffraction line whereby a Ca-satd. complex had to be used to produce a sharp line at 15 A.

2148. Mering Jacques. **The hydration of montmorillonite.** *Trans. Faraday Soc.* **42B**, 205-19 (1946).—*C.A.* 42, 7669*d*.

Detailed analyses of hydration isotherms for Na and Ca montmorillonites were correlated with their x-ray diffraction characteristics. A comparison of the isotherms for raw clays with those of specimens preheated to temps. up to about 550 °C was utilized properly to differentiate between mol. and OH group water. X-ray dimensions were utilized to partition the mol. water into interparticle (crystn.) water and inter-particle surficial water. Surficial water made up from about 1/5 at 30% relative humidity to about 4/5 at satn. mol. water was essentially reversibly regained after mild heating, and partial dehydroxylation was followed by some reconstitution. Reconstitution of OH groups was about 60% around 300 °C and decreased to zero by about 850 °C. From about 550 °C to 800 °C all individual layers were inactivated by dehydroxylation.

2149. Peterson, J. B. **Water stability of bentonite films.** *Soil Sci. Soc. Am., Proc.* **11**, 53-6 (1946) (Pub. 1947).—*C.A.* 42, 1682*d*.

The order of effectiveness of cations in increasing the water stability of bentonite clay on glass slides was H > C > Na. Pectin increased the stability of the Na-clay films, and gelatin showed even a greater favorable effect on water stability than did pectin. The relationships found between water stability of clay films and the structural properties of clay suspensions may be taken as an indication that the same forces which contribute to the water stability of clay films also contribute to structure in suspensions. The effect of pectin and of gelatin may be due to the types of linkages which they can produce in water systems.

2150. Shiraki, Yoichi and Kawashima, Chihiro. **Special porcelains of porous bodies. V. Relation between the texture and water permeability of porous bodies.** *J. Japan. Ceram. Assoc.* 54, 37-41 (1946); *J. Am. Ceram. Soc.* **32**, No. 3, *Ceram. Abstracts Sect.*, **86**, (1949).—*C.A.* 44, 7502*e*.

Water permeability of porous bodies of the system diatomaceous earth-Kibushi clay-cullet, fired at 600°-1300 °C, was measured with a water pressure of 20-100 cm. The test piece was a disk 100 mm in diam. and 7 mm thick. Water permeability of the test piece decreased as the time of immersion increased and reaches a const. value at about 24 hrs. Water permeability of samples high in clay was low and did not change with the firing temp., while the permeability of test pieces high in flux was great; it increased as the firing temp. rose and fell again as the temp. reached 1200°-1300 °C.

2151. Sveshnikova, V. N. and Kuznetsov, V. G. **Structural relations between zeolites and natural kaolin and their transformations on heating.** *Izvest. Akad. Nauk. S.S.R. Otdel Khim. Nauk* **1946**, 25-36.—*C.A.* 42, 6200*d*.

Thermography of cryst. aluminosilicate zeolite showed an endothermal effect of dehydration beginning at 100 °C and ending at 350 °C and 2 exothermal effects at 895° and 960 °C. Amorphous zeolite and electrodialyzed cryst. aluminosilicate gave the same endothermal effect 100-350 °C, max. at 160 °C, and an exothermal effect around 960 °C. Kaolin lost H_2O between 380° and 650 °C, max. at 565 °C, and had 2 exothermal effects at 960° and at 1200 °C. Thus, artificial zeolites gave up H_2O at a considerably lower temp. than kaolin.

2152. Yusupova, S. M. **The characteristics of montmorillonite.** *Compt. rend. acad. sci. U.R.S.S.* **51**, 631-4 (1946) (in English).—*C.A.* 41, 1955*e*.

Montmorillonite subjected to special thermal conditions over a period of 2 yrs showed gradual change in adsorptive properties, swelling capacity, and lattice structure (toward halloysite). Conversion of montmorillonite to halloysite was accompanied by desilicification and crystn. of SiO_2. Changes created above 350 °C were not reversible by any treatment. Weathering conditions affected adsorptive properties of clay minerals in takyrs, loesses, and clays.

2153. Bhola, K. L. **Bentonite in India.** *Quart. J. Geol., Mining Met. Soc. India* **19**, 55-77 (1947).—*C.A.* 42, 6281*g*.

The distribution of bentonite in India and the chem. analyses were given. Physical-chem. properties discussed were: sp gr, exchangeable base at pH 7, base satn. capacity, pH with 2 and 6% suspension, swelling water absorbed, setting time for 6% suspension, and viscosity of drilling mud.

2154. Butterworth, B. **The absorption of water by clay building bricks and related properties. III. The rate of absorption of water by partly saturated bricks.** *Trans. Brit. Ceram. Soc.* **46**, 72-6 (1947).—*C.A.* 41, 6683*b*.

The rate of absorption of water by 5 makes of brick was measured in the dry state and at a no. of different degrees of satn. The times required for the absorption of 1 g/cm² and for penetration to a fixed height were calcd. The former increased while the latter decreased as the degree of satn. of the bricks increased.

2155. Caillère, Simonne and Hénin, Stéphane. **Formation of a phyllite of the kaolinite type by treatment of montmorillonite.** *Compt. rend.* **224**, 53-5 (1947).—*C.A.* 41, 2539*i*.

Samples of kaolin-free, montmorillonite, were treated in the cold for 3-4 days with: 20% $CaCl_2$, 5% Na_3AlO_3, 10% $Al(NO_3)_3$, then pptd. with HCl or NH_4OH. The new curve, in which Δt was plotted against t, was characterized by the development of a peak at 600 °C with a temp. drop of 50-100 °C, and with the shrinkage or suppression of the peak at 750 °C. In contrast, there was often an exothermic inflection near 950 °C. The curve resembled that obtained with a mixt. of kaolinite and montmorillonite.

2156. Caillère, Simonne. **Experimental transformation of montmorillonite to a phyllite with a stable spacing of 14 A.** *Compt. rend.* **224**, 842-3 (1947).—*C.A.* 41, 4990*c*.

Heating curves were given (0-1000 °C) for (1) montmorillonite, (2) montmorillonite treated cold 4 days with 20% $MgCl_2$, then with concd. NH_4OH, and (3) a sheridanite from Comberousse. The treated montmorillonite showed an endothermic region at 550-600 °C, and one near 750 °C followed immediately by an exothermic region. An irregularity near 450 °C showed the presence of brucite. The x-ray diagram indicated an important interlayer distance of 14 A. Treatment with glycerol, water, or drying at 350 °C causes this 14 A. distance to disappear.

2157. Dominikiewicz, Mieczyslaw. **The theory of the building of kaolin nucleus.** *Arch. mineral. soc. sci. Varsovie* **17**, 191-281 (in Eng. 238-81) (1947).—*C.A.* **43**, 1291*c*.

A review of the formation of "kaolinitic" compds. of Na, K, NH_4, and Ag was given.

2158. Edelman, C. H. **Relations between the properties and the structure of several clay minerals.** *Verre Silicates ind.* **12**, No. 6, 3-6 (1947).—*C.A.* **42**, 5631*g*.

Kaolinite was characterized by Al-OH groups, and it properties were similar to those of $Al(OH)_3$. The colloidal-chem. properties of kaolinite and $Al(OH)_3$ were analogous; only the transition pH and the isoelec. point were different. The radical $Si_2O_5^{--}$, which constituted a characteristic part of clay minerals, had very little influence on the phenomena of absorption. Diazomethane, which reacts with hydroxyl ions in a dry medium reacted with montmorillonite and silicic acid, but not with kaolinite, $Al(OH)_3$, or quartz.

2159. Kister, E. G. **The swelling of clays.** *Neftyanoe Khoz.* **25**, No. 12, 23-7 (1947).—*C.A.* **42**, 7512*i*.

The kinetics of the combined process of water absorption and swelling of various clays in distd. water were detd. In kaolin-type clays the process was almost completed within 30-60 sec, the max. absorption being 220-510 vol. % after 24-72 hrs. In bentonite-type clays it ranges from 6 days and a max. of 1220 vol. % for Gilyabi clay to 25 days and 2440 vol. % for Aquagel.

2160. Kuzovlev, A. D. **Identification of clay minerals of the montmorillonite group.** *Razvedka Nedr* **13**, No. 6, 69 (1947).—*C.A.* **43**, 2129*i*.

Minerals of this group (montmorillonite, beidellite, nontronite) were readily identified in the field by their swelling with water. Take a lump of the material, shave clean one or more flat spots until the microstructure is revealed, and place on this spot a few drops of H_2O. If the sample is one of the above minerals, the wetted area will instantly stand out.

2161. Marshall, C. E. and Caldwell, O. G. **The colloid chemistry of the clay mineral attapulgite.** *J. Phys. & Colloid Chem.* **51**, 311-20 (1947).—*C.A.* **41**, 2627*c*.

Hydration and dehydration of attapulgite was compared with zeolites. Its d. was 2.3 and it was extremely sensitive to coagulation. In the electron microscope the particles appeared lath-like, of a size of 0.1 to 0.5 micron. The electrodialyzed attapulgite had a pH of 3 to 4, it was the strongest colloidal acid among the clays. Its structure, stability, and cation exchange properties were discussed and the characteristics of attapulgite films were compared with those of other clay films.

2162. Teichner, Stanislas. **Substitution of ions in montmorillonite.** *Compt. rend.* **225**, 1337-9 (1947).—*C.A.* **42**, 2895*f*.

Retention of adsorbed H_2O and specific surfaces were detd. of natural montmorillonite and of Na-substituted montmorillonite, obtained with dil. acid and neutralized with soda. Both lose adsorbed H_2O with rising temp., all adsorbed H_2O having been given off at 180°C. Up to 280°C no H_2O of crystn. was given off *in vacuo*. The specific surfaces of the 2 substances were detd. by N_2 adsorption. At dehydration temps. of 20° and 180°C, resp., specific surfaces in m^2/g were 48, 52, 13.6 and 88. The H_2O adsorbed on natural montmorillonite appeared not to interfere with N_2 adsorption, while that on Na-substituted montmorillonite prevented adsorption of N_2 at centers where H_2O was located.

2163. Thiessen, Peter A. **Characteristics of various effects at ultramicroscopic boundaries.** *Z. anorg. Chem.* **253**, 161-9 (1947).—*C.A.* **43**, 6489*e*.

Ultramicroscopic observations of crystals of kaolinite and mica treated with pos. or neg. Au sols. showed that edges of crystals exert nonspecific adsorption effects.

2164. Anon. **Methods used in evaluating adsorbent clays.** *U.S. Bur Mines, Inform. Circ., No.* **7475** 29 pp. (1948).—*C.A.* **42**, 9098*h*.

A description of the procedures and app. that were accepted as standard by the industry, and an outline of other methods that had been found particularly suitable for the clay lab.

2165. Barrer, R. M. **Syntheses and reactions of mordenite.** *J. Chem. Soc.* **1948**, 2158-63.—*C.A.* **43**, 5323*d*.

Mordenite ($Na_2O.Al_2O_3.10SiO_2$) identified with the polarizing microscope and by diffraction patterns was crystd. by heating suspensions prepd. by adding $NaAlO_2$ soln. to SiO_2 gel suspension at 265-295°C under pressure. With nitrates or chlorides cation exchange decreased in the order Ca, Ba, K, NH_4, Na, and Li, in accordance with the open molecular-sieve character of mordenite. The products when dehydrated were good sorbents for gas.

2166. Bell, W. C. **Reheat shrinkage characteristics of silica and clay mixtures.** *N. Carolina State Coll. Record* **47**, No. 10. 5-32 (1948).—*C.A.* **43**, 828*i*.

A time-temp. study of refractory mixts. with fine SiO_2 (finer than 100 mesh), coarse SiO_2 (coarser than 100 mesh), and plastic fire clays contg. most of the fusible impurities showed no appreciable vol. change up to 2400°F.

2167. Bichler, Antonin. **A new method for producing bentonite.** *Hutnicke Listy* **3**, 203-5 (1948).—*C.A.* **43**, 3580*i*.

The ability of montmorillonitic raw materials of Czechoslovakia to absorb water depended upon the expansion of the lattice and upon the presence of adsorbed ions. By varying the mixt. of anions and cations the original water-absorbing power was increased to 1 to 3 fold.

2168. Blake, George R. and Page, J. B. **Direct measurement of gaseous diffusion in soils.** *Soil Sci. Soc. Am., Proc.* **13**, 37-42 (1948).—*C.A.* **44**, 2681*i*.

The diffusion of CS_2 through field soils showed a straight-line relation between diffusion rate and porosity. Characteristics of the curve may vary between different soils. Diffusion rates varied with the cropping system being followed and a fair correlation was found between diffusion rates and corn yields.

2169. CHARRIN, VICTOR. **The kieselguhrs of Touraine.** *Génie civil* **125**, 412-13 (1948).—*C.A.* **43**, 1292*i*.

The low Ca-content of these radiolarites gave them a marked superiority in certain fields. Moisture, amounting to 25 to 40%, must be removed before crushing. At the Cavaliers plant, near Chateauroux, the powder was bolted to pass through a 300 sieve or finer.

2170. DETAILLE, HECTOR. **Organic matter in clays.** *Trans. Intern. Ceram. Congr.* **1948**, 111-31 (in French).—*C.A.* **46**, 6346*c*.

The effect of carbonaceous matter upon the behavior of clay during firing was studied by successive quant. analyses of the gases evolved during the firing of pieces of white and gray clay. The relative amts. of gas and its compn. were shown to depend upon the amt. of org. matter present in the clay, whereas the H_2O content varied very little.

2171. ENDELL, K. AND HOFMANN, U. **The adhesion of inorganic binding material and the plasticity of clay.** *Monatsh.* **78**, 258-72 (1948).—*C.A.* **42**, 8432*d*.

Solids adhered together if the distances between mols. in their surfaces approached those in the body of the solid and if sufficiently strong forces between the mols. or atoms were active. These forces differed depending on the nature of the material. An explanation was advanced for the difference between the wet and dry strengths of the materials considered.

2172. FORSLIND, ERIK. **Clay-water system. I. Crystal structure and water adsorption of clay minerals.** *Svenska Forsknings-inst. Cement Betong vid Kgl. Tek. Högskol. Stockholm Medd.* No. **11**, 20 pp. (1948) (in English).—*C.A.* **46**, 5804*e*.

H_2O layers adsorbed on the montmorillonite lattice may be regarded as having the structure of ice, the state of order being disturbed by foreign ions entering the system. The dehydrated state corresponds to an intercryst. distance of about 10.6 A. Electron-microscopical pictures, diffraction photographs, and diagrams of theoretical and observed intensities for different crystals are given.

2173. FRANCIS-BOEUF, C. **Oxygen adsorption of estuary muds.** *Rev. inst. franc. petrole et Amn. combustibles liquides* **3**, 119-33 (1948).—*C.A.* **43**, 916*c*.

Muds taken from river estuaries were equal to proper marine muds in reducing properties, adsorbing O_2 dissolved in the supernatant external water phase. Delta muds could not sat. themselves with O_2 even when exposed to the air, because their surface consisted of a film of several mm thickness of bacteria and algae, which prevented diffusion of O_2.

2174. GLAESER, RACHEL. **Formation of the montmorillonite-acetone complex.** *Compt. rend.* **226**, 935-7 (1948).—*C.A.* **42**, 6261*d*.

The vapor-phase absorption of acetone by montmorillonite was studied as a function of the relative pressure of acetone and of the state of hydration of the mineral. By means of x-ray diagrams the depths of the elementary spaces occupied by org. mols. could be detd. Preliminary hydration was necessary for the formation of a complex with acetone.

2175. GRIM, RALPH E. AND BRADLEY, W. F. **Rehydration and dehydration of the clay minerals.** *Am. Mineral.* **33**, 50-9 (1948).—*C.A.* **42**, 5809*c*.

Samples of montmorillonite, illite, kaolinite, and halloysite were dehydrated at various temps. up to 800 °C, allowed to stand at room temp. for varying periods of time, and were then studied by differential thermal analysis. Montmorillonite and illite slowly regained some water as hydroxyl, in addn. to adsorbed H_2O.

2176. MARSHALL, C. E. AND AYERS, A. D. **The electrochemical properties of mineral membranes. VI. Clay membranes for the determination of calcium.** *J. Am. Chem. Soc.* **70**, 1297-1302 (1948).—*C.A.* **42**, 5301*c*.

Membranes prepd. from H- and Ca-bentonite and H- and Ca-Putnam clay were examd. as to their suitability for the detn. of Ca by the potentiometric method. A comparison of the effect of preheating on the sensitivity showed that at 300-415 °C H-bentonite was satisfactory, but above 450 °C became insensitive; at 300-550 °C, Ca-bentonite was suitable. Membranes of H-Putnam clay were somewhat inferior even at 600 °C compared with 600 °C Ca-bentonite.

2177. MARSHALL, C. E. AND EIME, L. O. **VII. Clay membranes for the determination of magnesium.** *J. Am. Chem. Soc.* **70**, 1302-5 (1948).—*C.A.* **42**, 5301*e*.

Clay membranes prepd. from H- and Ca-bentonite and H- and Ca-Putnam clay were used for the detn. of Mg by a potentiometric method. The effect of preheating the clay over a range of 300-600 °C was studied as related to its sensitivity. For solns. contg. only Mg ions, the 400° H-bentonite and 550° Ca-bentonite membranes could be used with activities from 0.008 to 0.0003, and the 600 °C H-Putnam from 0.004 to 0.0001.

2178. MIZUNO, SHIGERU; KUSABA, IKURO, AND IKEDA, HACHIRO. **Activated earth. I. The change of long-period sorption of water and xylene vapor by activated clay with heat.** *Bull. Tokyo Inst. Technol.* **13**, 77-82 (1948).—*C.A.* **44**, 10442*i*.

The rates of sorption of water vapor by clay activated at 100-700°C were found to be represented by an equation of the form $x = a \log t + b$, where x is the amt. of adsorption, t is time, and a and b were constants which vary with time. Resistance to sorption was greater the higher the activation temp. and increased abruptly above 700 °C.

2179. MIZUNO, SHIGERU; KUSABA, IKURO, AND IKEDA, HACHIRO. **Activated earth. II. The change of the rates of short-period sorption of water and heptane vapor by activated clay with heat.** *Bull. Tokyo Inst. Technol.* **13**, 83-8 (1948).—*C.A.* **44**, 10443*a*.

Rates of short-period sorption of water vapor were studied for clay heat-treated at 100-1000 °C by sorption balance and of heptane by those treated at 450-800 °C by a flow method. The early part of the sorption of water vapor was controlled by the equation $x = kt^n$, where k and n were constants. Rate of sorption of heptane was greater for clays activated at lower temps.

2180. MIZUNO, SHIGERU AND KUSABA, IKURO. **Activated earth. III. The fall in catalytic activity of activated clay with heat and the changes of physico-chemical properties accompanied by it.** *Bull. Tokyo Inst. Technol.* **13**, 89-93 (1948).—*C.A.* 44, 10443*c*.

Exptl. results were given showing the effect of heat-treatment of activated clay catalyst on activity of contact cracking, bulk d., true and apparent sp. gr., porosity, size, and compressive strength. Dehydration curves were given. The dehydration curves showed marked dehydration at 200-300°, 450°, and 600-700°C. The first two were thought to be reversible; the latter was irreversible.

2181. MIZUNO, SHIGERU AND KUSABA, IKURO. **Activated earth. IV. Activation of catalysts of fallen activity with heat by steaming.** *Bull. Tokyo Inst. Technol.* **13**, 94-7 (1948).—*C.A.* 44, 10443*d*.

Catalysts spent by heating below 600°C were activated by steaming. The reactivation was caused by water associating with the clay at 450°C owing to the reversible nature of the sorption at that temp.

2182. MIZUNO, SHIGERU AND KUSABA, IKURO. **Activated earth. V. Selection of activated clay catalysts.** *Bull. Tokyo Inst. Technol.* **13**, 98-101 (1948).—*C.A.* 44, 10443*e*.

Cracking activity, bulk d., and electrophoretic-velocity measurements were made on various screen sizes of clay. Activity was about the same for the different sizes but the smaller sizes lost activity more rapidly with temp. The ratio of SiO_2 to Al_2O_3 of both the activated and original clay was greater for the smaller sizes.

2183. NAGASAWA, MAKOTO. **Sorption of gases with activated bentonite. I. Sorption of sulfur dioxide.** *J. Electrochem. Soc. Japan* **16**, 62-6 (1948).—*C.A.* 44, 9770*a*.

Com. bentonite from Iwanai, Nokkaido, was activated with 20% HCl (3 times the wt of the sample) 4 hrs at 104-5°, and treated 2 hrs at 180°C. Sorption of SO_2 with this bentonite at 40, 25, 0, and -10°C obeyed Freundlich's isotherms at lower pressures.

2184. TEICHNER, STANISLAS. **Effect of thermal treatment on the texture and the structure of a montmorillonite.** *Compt. rend.* **227**, 392-3 (1948).—*C.A.* 43, 463*h*.

Surface measurements on montmorillonites of Ca, Na, and H showed that dehydration of Na and H at 450°C under high vacuum caused a diminution of surface area. Rehydrated Na montmorillonites showed the same surface area as untreated Na even though the former contained 25% less H_2O. The surface area in m^2/g measured by N_2 adsorption at -195°C were between 24-240. The area measured by butane at 0°C was between 27 and 87 m^2/g. All adsorption isotherms had an S-shape corresponding to a multimol. adsorption free of capillary condensation.

2185. TEICHNER, STANISLAS. **Surfaces of montmorillonites activated by acid treatment.** *Compt. rend.* **227**, 427-9 (1948).—*C.A.* 43, 464*c*.

Surface measurements with N_2 and butane on a montmorillonite and on samples of montmorillonite treated with 10% H_2SO_4, for 2 hrs and 4 hrs, resp., showed a marked increase in area for the treated samples. The N_2 isotherms, taken from 20° to 450°C, were all of the type II, whereas some of the butane isotherms showed a second point of inflection characteristic of adsorption with capillary condensation.

2186. DART, J. C.; SAVAGE, R. T., AND KIRKBRIDE, C. G. **Regeneration characteristics of clay cracking catalyst.** *Chem. Eng. Progress* **45**, 102-10 (1949).—*C.A.* 43, 3181*e*.

The primary variables in the regeneration of clay cracking catalysts were instantaneous carbon content, combustion temp., and oxygen partial pressure. The burning rate indicated sec-order dependency on carbon content at carbon contents less than 2 wt % on catalyst and first-order dependency on oxygen partial pressure. A single algebraic equation was developed which involved only the 3 primary variables to obtain the instantaneous C burning rate at any design condition. From the relationship between the fraction of H-burned and the fraction of C-burned the coke-burning rate could be calcd.

2187. FERRANDIS, VICENTE ALEIXANDRE. **Differential thermal analysis of some Spanish clays and kaolins.** *Anales edafol. y fisiol. vegetal (Madrid)* **8**, 33-58 (1949).—*C.A.* 43, 8590*c*.

The data were chem. compn., plots of the curves of dehydration and water absorption, differential thermal analysis, and base exchange. The kaolin had the characteristics of kaolinite. The bentonite of Maaza loses water at 100°C and between 400° and 500°C and the curve of thermal analysis indicated that it was composed of hydrated haloysite and beidellite. The base-exchange capacity and the plasticity were in agreement with this.

2188. GONZALEZ, F. GARCIA. **The effect of heat-treatment on the hydration capacity of montmorillonite.** *Anales real soc. españ. fís. y quím.* **45B**, 1183-1210 (1949).—*C.A.* 44, 9209*i*.

Alkali and alk. earth montmorillonites were heated at 100°, 200°, 300°, 400°, and 800°C, until const. wts were reached. The amt. of water lost by wt was detd., and the samples were rehydrated by exposure to an atm. satd . with water vapor for 8 days. In samples with intense electrostatic fields, the laminas became fixed without the reticular water becoming affected.

2189. GRENALL, ALEXANDER. **Montmorillonite cracking catalyst-demonstration of presence of hydrogen ion in heated Filtrol clay catalysts.** *Ind. Eng. Chem.* **41**, 1485-9 (1949).—*C.A.* 44, 2211*h*.

The presence of H^+ in Filtrol clay catalyst over the entire range of cracking temps. was established by a physico-chem. titration method with a 5% soln. of NaCl. The H-ion content was a linear function of the temp. at which the catalyst was heated in air. The effect of steam treatment of H-ion content of the catalyst was nonlinear. Isothermally, with increasing steam concn., an apparent equil. point dependent upon the isotherm temp. was reached for removal of the H ion. Increasing the temp. at which the catalyst was heated at const. steam concn. resulted in lowered H-ion contents.

2190. HAMMER, A. J. **Factors affecting the determination of soluble salts in ceramic clay. I.** *Ceram. Age* **54**, 140-2, 144 (1949).—*C.A.* **43**, 9404*b*.

In the detn. of sol. salts in clay the following factors exert considerable influence: prepn. and condition of the sample; choice of solvent; clay-water ratio; time and temp. of digestion of the sample; method of filtration; and time and temp. of drying the residue.

2191. ISACHSEN, FRIDTJOV AND ROSENQVIST, IVAN TH. **Weathering loam and fuller's earth from Karmöy.** *Norsk Geol. Tids.* **27**, 175-86 (1949) (in Norwegian).—*C.A.* **43**, 8320*f*.

For mineral-oil bleaching and regeneration a montmorillonite occurrence near Vigsnes (Norway) was of a particular economical importance since previously bleaching earths must be imported. A practical staining test with methylene blue in comparison with many typical bleaching earths, in suspensions with pH = 2 and 7, gave a satisfactory result for the suitability of the Vigsnes material as a fuller's earth for the mineral-oil regeneration.

2192. MISRA, M. L. AND HENRY, E. C. **Nature of some Indian clays.** *Am. Ceram. Soc. Bull.* **28**, 187-92 (1949).—*C.A.* **43**, 5559*f*.

Four typical white clays of India were studied. Judged by the morin dye test, the Kasimbazar clay was least stable, the Rajmahal clay most stable, with the other 2 intermediate. All 4 clays showed little base-exchange capacity.

2193. MURRAY, P. AND WHITE, J. **Kinetics of the thermal dehydration of clays.** *Trans. Brit. Ceram. Soc.* **48**, 187-206 (1949).—*C.A.* **43**, 6799*d*.

More knowledge of the reactions involved in the thermal dehydration of clay was needed. Especially, the endothermic peak on the thermal analysis curve must depend on the rate of reaction.

2194. OLIVER, T. R. AND NEWITT, D. M. **The mechanism of the drying of solids. II. The measurement of suction potentials and moisture distribution in drying granular solids.** *Trans. Inst. Chem. Engrs.* (London) **27**, 9-18 (1949).—*C.A.* **46**, 6871*c*.

Granular solids in which capillary forces are responsible for movement of moisture show drying-rate curves in which there are 3 fairly well-defined periods, the crit. points becoming less clearly marked as the particle size decreases. Solids in which the moisture movement is mainly by vapor diffusion exhibit drying rates showing a gradually increasing gradient as drying proceeds. Wood soap, and some clays have drying-rate curves of this latter type. For other classes of metals, such as vegetable products, clays, and granular metals comprised of porous granules, some modification of the vaporization mechanism may occur owing to changes in the phys. properties of H_2O when occupying very fine capillary spaces.

2195. GUTIÉRREZ RÍOS, E. AND VIVALDI, J. L. MARTIN. **Silicates of laminar structure. I. Hydration.** *Anales real soc. españ. fís. y quím.* **45B**, 291-342 (1949).—*C.A.* **43**, 8233*a*.

Dehydration curves from 20° to 900 °C were reported for 2 samples of bentonite in which the exchangeable cations were replaced by Li, Na, K, Rb, Cs, Mg, Ca, Sr, or Ba and for kaolin with replacement by Li, Na, K, Mg, Ca, or Ba. The hydration water H (in g per g of dry material) was calcd. for samples that had reached equil. at 1.30, 6.50, and 13.15 mm water vapor pressure. There was essentially no difference between the behavior of Li and the other alkali ions. The behavior of kaolin was similar to that of the alk. earth bentonites except for a factor arising from the inaccessibility in kaolinite of the intralaminar layers and the interior cations to hydration.

2196. SCHOFIELD, R. K. **Calculation of surface areas of clays from measurements of negative adsorption.** *Trans. Brit. Ceram. Soc.* **48**, 207-13 (1949).—*C.A.* **43**, 6799*b*.

Gouy's theory of ionic equil. in the diffuse component of the elec. double layer was combined with measurements of neg. adsorption and estimates made of the surface area of a sample of bentonite. The montmorillonite in this bentonite had sepd. almost completely into sep. 10A "leaflets." Preliminary measurements with a sample of kaolin gave an estimate of surface area in close agreement with values previously calcd. from particle size and N_2 adsorption.

2197. TAYLOR, STERLING A. **Oxygen diffusion in porous media as a measure of soil aeration.** *Soil Sci. Soc. Am., Proc.* **14**, 55-61 (1949).—*C.A.* **45**, 1709*f*.

The change in partial pressure of O_2 with time was studied. A new soil parameter λ was proposed which is a relative measure of the rate of diffusion of gases through the soil. It can be interpreted physically as the length of a tube of unit cross section through which free diffusion is allowed to take place which will supply O_2 to a point at the same rate as it is supplied by the soil.

2198. ALONSO, J. I. FERNANDEZ; GASCO, L., AND HIDALGO, A. **Physicochemical study of ceramic clays of Eastern Spain. I. Chemical analyses, cationic exchange, and particle-size analysis.** *Anales real soc. españ. fís. y quím.* **46B**, 187-96 (1950).—*C.A.* **44**, 10279*e*.

Analyses and phys. properties of 12 samples were given. Titration graphs resembled weak dibasic acids. Methods and errors of particle size detn. were discussed.

2199. CAILLÈRE, SIMONNE. **Action of heat on clay minerals.** *Trans. 4th Intern. Congr. Soil Sci., Amsterdam* **3**, 54-63 (1950) (in French).—*C.A.* **47**, 1011*e*.

The wt of a sample was detd. as a function of the temp. at which it was held. Results were compared to the wt of H_2O that was driven off and absorbed in H_2SO_4. The temp. at which a loss of H_2O occurred depended on the rate of heating. Another method of detg. changes of mineral samples with heat was based on dilatometric measurements which were compared to a standard. Generally the curves obtained were inclined from 0° to around 700 °C where abrupt changes occurred.

2200. CORNET, I. **Expansion of the montmorillonite lattice on hydration.** *J. Chem. Phys.* **18**, 623-6 (1950).—*C.A.* **44**, 10438*a*.

When exposed to water vapor, water, or some nonaq. solvents, montmorillonitic clays expand. Based on the assumption that the expansion on hydration was a uni-dimensional swelling phenomenon, a thermodynamic analysis indicated that for lattice expansions of 3 or 4A. from the dehydrated contracted state, the force between montmorillonite lattice layers was substantially const.; but for greater expansions the force diminished in a complex manner.

2201. DOMINGO, W. R. **Irreversibly dried, difficultly wettable soils.** *Landbouwkund. Tijdschr.* **62**, 252-60 (1950); *Soils and Fertilizers* **13**, 261 (1950).—*C.A.* **46**, 4714*h*.

Irreversible drying of some soils is related to low ground-water level, type of org. matter, high Fe content, adsorbed air, and presence of fatty substances. Irreversibly dried soils regain the capacity for swelling after exposure to NH_3 for 24 hrs; NH_3 displaces adsorbed air and thus facilitates absorption of water and swelling.

2202. DYAL, R. S. AND HENDRICKS, S. B. **Total surface of clays in polar liquids as a characteristic index.** *Soil Sci.* **69**, 421-32 (1950).—*C.A.* **44**, 10979*e*.

Total surface, external surface, and, by difference, internal surface of clays were detd. by retention of ethylene glycol in an evacuated system. External surface could be detd. by retention of ethylene glycol by a sample heated to 600°C. The difference between these two detns. divided by 3.10×10^{-4} expressed the approx. extent to which the clay had montmorillonite interlayer swelling.

2203. EAST, WALTER H. **Fundamental study of clay. X. Water films in monodisperse kaolinite fractions.** *J. Am. Ceram. Soc.* **33**, 211-18 (1950).—*C.A.* **44**, 8076*f*.

The influence of Ca, Na, and H exchangeable ions on kaolinite films was studied and solid-liquid interface energy was computed by means of heat of wetting. The H_2O film averaged less than 100 A. at low forming pressures and was continuous from crystal surface to total equil. thickness. Exchangeable ions were believed to be adsorbed on all crystal surfaces and influenced the films both by characteristic ion hydration and by polarization, the latter causing unique particle orientation.

2204. ERIKSSON, ERIK. **The water-pressure relationship in bentonite gels.** *Kgl. Lantbruks. Högskol. Ann.* **17**, 17-23 (1950) (in English).—*C.A.* **45**, 5348*f*.

The water held by montmorillonite can be described mathematically in terms of the pressure by a soln. of the Poisson-Boltzmann differential equation between 0.1 and 1.0 atm. The specific plane surface of montmorillonite was calcd. to be 5.3×10^6 cm^2/g.

2205. ESCARD, J. **Adsorption of nitrogen at low temperatures by montmorillonite; influence of residual water and exchangeable cations.** *Trans. 4th Intern. Congr. Soil Sci., Amsterdam* **3**, 71-4 (1950) (in French).—*C.A.* **46**, 7397*g*.

Na and Ca montmorillonites were prepd. by purification of a natural montmorillonite, transformation to the H-form, and exact satn. with Na or Ca. The B.E.T. surface of a montmorillonite freed from all the H_2O bound there, with the exception of the constitution H_2O (5%) had a value of 82 m^2/g. This stage of dehydration was obtained by heating to 300°C *in vacuo*. Practically complete removal of the adsorption H_2O was obtained in a Ca montmorillonite by very slow, gentle dehydration, e.g., 700 hrs at 20°C, then 300 hrs at 45°C.

2206. FERRANDIS, VICENTE ALEIXANDRE AND VERDUCH, ANTONIO GARCIA. **Relations between some physical, chemical, and technical properties of clays. I.** *Anales edafol. y fisiol. vegetal* (Madrid) **9**, 537-65 (1950).—*C.A.* **45**, 6360*d*.

Based on chem. analyses, detns. of base-exchange capacity, adsorption capacity for methylene blue, mech. analyses, dehydration curves, differential thermal analysis, plasticity, rate of loss of water, rate of loss of water through the mass, and contraction on burning, the clays were classified into kaolins, illites, kaolin-illites, and quartzose. The adsorption capacity for methylene blue followed in a general way the exchange capacity.

2207. GLAESER, RACHEL. **Organic-montmorillonite complexes in vapor phase. Desorption isotherms of acetone-montmorillonite and 2-propanol-montmorillonite.** *Trans. 4th Intern. Congr. Soil Sci., Amsterdam* **3**, 65-71 (1950) (in French). *Mém. services chim. état* **36**, No. 1, 69-76 (1951).—*C.A.* **47**, 806*b*; **46**, 11054*f*.

Ca montmorillonite and Na montmorillonite were treated with either anhyd. acetone or 2-propanol until no more H_2O was extd. The montmorillonite, covered with the org. compd. was placed over a soln. of the org. compd. in castor oil and allowed to come to equil. *in vacuo* (about 15 days) and then desorbed *in vacuo* over P_2O_5 at 40°C for acetone clay, and 20°C for 2-propanol clay. The acetone-clay and 2-propanol-clay formed bimollayer complexes with Ca montmorillonite and Na montmorillonite which, on desorption, changed to unimol.-layer complexes.

2208. GONZALEZ, F. GARCIA. **The influence of heat-treatment on the hydration capacity of montmorillonite. II.** *Anles real soc. españ. fís. y quím.* **46B**, 89-100 (1950).—*C.A.* **44**, 10609*e*.

Samples of montmorillonite satd. with Li or Mg were heat-treated. In contrast to alk. and alk. earth samples, they suffered a strong reduction in hydration capacity before the reticular area was affected. Treatment with distd. water failed to modify the new structural system created by the heat-treatment.

2209. GONZÁLEZ, F. GARCÍA. **The determination of reticular water in silicates of the montmorillonite group.** *Anales real soc. españ. fís. y quím.* **46B**, 151-60 (1950).—*C.A.* **44**, 8830*f*.

The loss in wt of Li, K, Mg, Ca, Sr, and Ba montmorillonites from Spanish Morocco over the temp. range 300-850°C was investigated for untreated samples and samples that had been heated to 100°, 200°, 300°, and 400°C, and then rehydrated. The inflection point at 300°C did not always represent the point at which loss of hydration water balanced loss of OH-group water. Previous thermal treatment below 300°C and subsequent hydration may cause some hydration water to become strongly bonded, appearing as OH-group water in the 300-850°C zone.

2210. Granquist, W. T. **Adsorption of methane on fuller's earth.** *Ind. Eng. Chem.* **42**, 2572-5 (1950).—*C.A.* **45**, 1837*h*.

The adsorption isotherm of CH_4 at 112°K was detd. for both crude and extruded fuller's earth. Adsorption isotherms at other temps. (112°-123°K.) and the *isosteric heat of adsorption* were calcd. by the method of Polanyi.

2211. Hoyos, Angel de Castro and Rodriguez, Julio. **Influence of thermal treatment on some physicochemical properties of bentonite.** *Trans. 4th Intern. Congr. Soil Sci., Amsterdam* **2**, 75-7 (1950).—*C.A.* **46**, 4756*i*.

The bentonite, from Spanish Morocco, first was transformed into acid bentonite with 0.5 *N* AcOH. Exptl. values of the rehydration, obtained from dehydration curves, showed that up to 300°C the adsorbed H_2O was entirely recovered in the rehydration; above 300°C the amt. of adsorbed H_2O diminished with rising temp. There was a small diminution of the exchange capacity in passing from the equil. sample to that at 100°C; as the temp. increased the exchange capacity remained const. until the samples began to lose reticular H_2O (about 400°C) and then a great diminution began.

2212. Hyslop, J. F. and Gworek, J. **Heat treatment and contraction of a fireclay.** *Trans. Brit. Ceram. Soc.* **49**, 80-2 (1950).—*C.A.* **44**, 4214*i*.

Heating a dehydrated, oxidized Scottish fireclay to equil. gave two contraction periods connected with major changes in the constitution of the clay. The first, at 850°C, was due to the formation of γ-Al_2O_3 and the second, at 1000°C, was assocd. with the formation of mullite. The main derived contraction curve was a composite one of the curves for metakaolin, γ Al_2O_3, and mullite.

2213. Jasmund, K. **The siliceous clay minerals.** *Angew Chem.* **62**, 181-2 (1950); *Beiheft No.* **60**, 128 pp.—*C.A.* **44**, 8289*c*.

The phys.-chem. properties and behavior of the clay minerals were summarized extensively. The minerals covered were: (1) kaolinite, (2) montmorillite, (3) pyrophyllite and mica-like minerals, and (4) clay minerals possessing alternating layer structure.

2214. Longuet-Escard, J. (Mme). **The effect of progressive dehydration on the area of the surface of montmorillonites.** *J. chim. phys.* **47**, 113-17 (1950).—*C.A.* **44**, 7617*i*.

A Na-montmorillonite contg. 10.3% H_2O dried at 20°C had a surface area of 14 m^2/g. On being dried at successively higher temps. the area increased to a max. of 90 m^2/g with a water content of 5.2%. The area and content of H_2O then decreased to about zero as the sample was dried at successively higher temps. in the range 300 to 900°C. A Ca montmorillonite with a surface area of 38 m^2/g and a water content of 13% at 20°C increased in area to a max. of 75 m^2/g after drying at 70°C to a 10.8% water content. Desorption isotherms for N_2 at -195°C showed hysteresis and an abrupt decrease at a relative pressure of 0.5.

2215. Longuet-Escard, J. (Mme.); Mering, J., and Perrin-Bonnet, I. **Activation of montmorillonite.** *J. chim. phys.* 47, 234-7 (1950).—*C.A.* 44, 7617*g*.

X-ray and gas-adsorption studies with N_2 were made. When montmorillonite was treated with H_2SO_4, the specific surface tended towards a max. and then decreased as increasing amts. of the Al, Fe, and Mg oxides were removed from this siliceous mineral. The variation of the specific surface was attributed to the formation of an amorphous SiO_2 and division of the silicate particles.

2216. McCarter, W.S.W.; Krieger, K. A., and Heinemann, H. **Thermal activation of Attapulgus clay.** *Ind. Eng. Chem.* **42**, 529-33 (1950).—*C.A.* **44**, 4214*f*.

The main constituent of the fuller's earth found near Attapulgus, Ga. was a hydrous Mg-Al silicate, a distinct clay mineral, the structural scheme of which distinguished it from mica and montmorillonite. Water-adsorption properties were correlated with changes in structure during activation as expressed by differential thermal analysis and x-ray diffraction patterns. The effect of thermal cleavage upon surface area and water adsorption, the importance of cleavage for rates of adsorption and diffusion, and the role of extrusion in maintenance of surface area at high activation temp. were discussed.

2217. Mills, G. A.; Holmes, James, and Cornelius, E. B. **Acid activation of some bentonite clays.** *J. Phys. & Colloid Chem.* **54**, 1170-85. (1950).—*C.A.* **45**, 3221*h*.

Fourteen bentonite clays were acid-treated at 93°C in 5-20% H_2SO_4 at acid to clay ratios of 0.2 to 0.8 for times up to 16 hrs. The chem. compns. were detd. and the phys. and catalytic properties measured after the samples were pelleted and calcined at 565°. Increased severity of acid treatment gave a continuous increase in surface area and porosity and a decrease in the d. of the pellet. Certain clays were apparently incapable of being activated for catalytic cracking, even though their phys. properties were substantially identical to other clays that were "activable." High extrusion pressures on the acid-activated bentonites were found to increase pellet d. at the expense of large pores.

2218. Nagasawa, Shin. **Sorption of gases by active bentonite. V. Sorption velocity of water vapor.** *J. Electrochem. Soc. Japan* **18**, 391-3 (1950).—*C.A.* **45**, 8320*c*.

The sorption velocity of water vapor by the activated bentonite was detd. under the satd. vapor. pressure at 25° and 35°C. During the first 13 hrs, surface adsorption and simple capillary condensation took place. In the next 15 hrs water vapor condensed into smaller capillaries, and from that time onward, water vapor penetrated slowly into extremely fine spaces. The desorption process was also measured.

2219. Ono, Sôzaburo and Watanabe, Takehiko. **Colloidal properties of bentonite. I. Influence of heat-treatment and ultrasonic treatment on the degree of swelling of bentonite.** *J. Chem. Soc. Japan, Pure Chem. Sect.*, **71**, 574-7 (1950).—*C.A.* **45**, 6457*i*.

The degree of swelling of bentonite from Niigata Prefecture was reduced by heat-treatment. It could be restored almost reversibly by irradiation with supersonics as long as the heating temp. was below 450 °C. The restoration could hardly be observed when the heating temp. was greater than 800 °C.

2220. SANDFORD, FOLKE. **Investigations on clay. III.** *Trans. Chalmers Univ. Technol., Gothenburg No.* **93**, 31 pp. (1950).—*C.A.* 44, 11050*i*.

The phys. and chem. properties of clay minerals in particular were discussed. The theory of ceramic firing processes was given with a special discussion of the effects of the furnace atm., and their action on the constitution of the ceramic end product.

2221. SIDOROVA, A. I. **Ionization of aromatic amines in the vacuum adsorption on active clays.** *Doklady Akad. Nauk S.S.S.R.* 72, 327-30 (1950).—*C.A.* 44, 7147*g*.

Spectral absorption curves were recorded for the colored adsorption-complexes of Ph_2NH vapor on bentonite, CeO_2, and $BiCl_3$, as compared with the absorption curve of the Ph_2NH^+ ion obtained by photoxidation in soln. The absorption maxima at 500 and 680 $m\mu$, very marked on bentonite, are faint on CeO_2. The semi -quinone-ion maxima at 500 and 680 $m\mu$, on bentonite, weakened increasingly on exposure to air; after 3 days, the 680 max. disappeared completely, the 500 max. almost completely, and a new max. appeared at 600 $m\mu$. An intense rose color was obtained by vacuum adsorption of $p\text{-}Me_2NC_6H_4NH_2$ on bentonite.

2222. TEICHNER, S. **Comparison of adsorption isotherms for nitrogen and for butane on various adsorbents.** *J. chim. phys.* 47, 118-21 (1950).—*C.A.* 44, 7617*e*.

Both N_2 and C_4H_{10} yielded S-shaped (type II) adsorption isotherms at -195° and 0°C, resp., on a sample of montmorillonite. After acid activation the sample yielded a type-II adsorption isotherm for N_2 but a type-IV isotherm for C_4H_{10}.

2223. TEICHNER, S. **Kieselguhrs of the type utilized as support for catalysts.** *J. chim. phys.* 47, 229-32 (1950).—*C.A.* 44, 7635*c*.

Kieselguhr, kieselguhr treated with HCl and HNO_3, and calcined kieselguhr were studied: loss in wt after etching Na_2CO_3, d., and specific surface as detd. by adsorption of N_2 and CO at -195°C and of butane at 0°C. The kieselguhr treated with acids had approx. 50% greater specific surface than the raw kieselguhr and that of the calcined kieselguhr was only 11% as great. Treatment with 5% Na_2CO_3 reduced slightly the surface area of the raw kieselguhr, but the same treatment decreased by 50% the surface area of the kieselguhr treated with acids.

2224. TEICHNER, S. **Analogies of texture between activated montmorillonites and certain catalysts.** *J. chim. phys.* 47, 244-52 (1950).—*C.A.* 44, 7635*g*.

A large amt. of adsorbed water could be removed from Ca- and Na-montmorillonites by vacuum treatment at 20 °C, and practically all of the water except the combined water was removed by vacuum treatment at 180 °C. The surface area increased for samples dehydrated by vacuum treatment at 180 °C. Vacuum treatment at 450 °C reduced the surface area. Adsorption studies with N_2 and hydrocarbons were made of 6 Fischer-Tropsch catalysts. The difference between the total adsorption of N_2 and CO at -195 °C was utilized to det. the fraction of metal exposed at the surface.

2225. VENTRIGLIA, UGO. **Plasticity of clays.** *Periodico Mineral.* **19**, 51-100 (1950).—*C.A.* **45**, 319*i*.

The different methods for the detn. of plasticity were discussed, and some fundamental phys. and chem. factors described. The results of x-ray studies on the layer structure of the clay minerals on these theoretical deductions were shown by a detailed description of the modern electrostatic theory of adsorption and ionic base exchange on the surface of the clay particles, with particular emphasis given to the Hendricks-Jefferson theory of H bonds in adsorbed water films on the clay minerals.

2226. ZUL'FUGAROV, Z. G. **Transformation of the vapor of the amylene-hexylene fraction of the overhead benzene product by the action of natural Azerbaijan aluminosilicates (cinders and clays).** *Zhur. Priklad Khim.* **23**, 767-74; *J. Applied Chem. U.S.S.R.* **23**, 811-18 (1950).(Engl. translation).—*C.A.* 46, 4206*g*.

Vapors of an unsatd. $C_5\text{-}C_6$ hydrocarbon fraction of benzene light oil are adsorbed in varying amts. by samples of volcanic ash and natural or activated bentonites suspended in a container above the liquid. Activated Khanlar bentonite adsorbs as much as 6.06 g of hydrocarbons per g of the clay in 23 days to form a colored liquid condensate having a higher d. and *n* and a much lower I no. Polymerization takes place during the adsorption process.

2227. BAGCHI, S. N. **Minerals present in H-clays from Indian soils, kaolins, and bentonites. I. X-ray studies. II. Thermal and optical studies.** *Indian Soc. Soil Sci. Bull.* No. **6A**, 19-41, 42-66 (1951).—*C.A.* 47, 6077*f*.

Detailed account was given of the application of the powder diffraction method and of temp.-dehydration studies by intermittent heating in confirming the mineralogical character of the clay minerals of the various H-clay fractions.

2228. BYKOV, V. T. AND KUADZHE, M. I. **Sorption and catalytic properties of some bleaching earths.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* **1951**, 487-99.—*C.A.* **46**, 3841*b*.

A no. of earths from different regions of the U.S.S.R. were studied from the point of view of sp gr., bulk wt, swelling in H_2O, pH of the aq. ext., chem. compn., and by thermography, electron microscopy, and x-ray diffraction. The catalytic properties were investigated in flow runs of redistribution of H in a gasoline fraction b. 100-150 °C, cracking of cumene, and dehydration of EtOH. Some of the native earths show high catalytic activity without any treatment. The bleaching properties are better, the closer the B.E.T. area to the surface area of the adsorption film, i.e. the greater the vol. of intermediate pores.

2229. BYKOV, V. T. **Sorption and bleaching properties of native sorbents.** *Izvest. Akad. Nauk S.S.S.R., Otdel Khim. Nauk* **1951**, 678-85.—*C.A.* 46, 3827*c*.

On various native bleaching clays, the sorption of C_6H_6 vapor at 20°C at the point of beginning hysteresis attained 0.5-0.7 millimole/g, corresponding to a vol. of liquid sorbed of 0.05-0.08 cc/g, as against 0.10-0.15 on coarse, and 0.17-0.35 on fine silica gels, but comparable to Al_2O_3 gels, 0.05-0.09 cc/g. At satn., the liquid vol. sorbed attained 0.10-0.50 cc/g, comparable to the best Al_2O_3 and fine silica gels, and inferior only to coarse silica gels. There was good linear relation between the bleaching factor and the vol. of intermediate pores.

2230. Egawa, Tomiji. **A method of measuring the sorption of water vapor by the soil.** *J. Sci. Soil Manure* **21**, 175-8 (1951).—*C.A.* **45**, 10453*b*.

The adsorption and desorption of H_2O vapor by soil samples were directly detd. From sigmoid curves thus obtained there is no satn. point in the adsorption which increases when the vapor pressure approaches satn.

2231. Glaeser, Rachel. **Retention of organic molecules on montmorillonite.** *Compt. rend.* **232**, 1496-8 (1951).—*C.A.* **45**, 8321*b*.

Some volatile org. compds. were retained indefinitely in a vacuum as unimol. layers on Ca- but not usually on Na- montmorillonite. The thickness and ds. of the layers were discussed.

2232. Gonzalez, F. Garcia. **The influence of thermal treatment on the hydration capacity of montmorillonite. III.** *Anales real soc. espan. fis. y quim.* **47B**, 357-62 (1951).—*C.A.* **46**, 4963*e*.

Montmorillonite from Tidinit was heated to just below the temp. at which the crystn. lattice was destroyed, then rehydrated both in steam and water. When samples satd. with small exchangeable cations (such as Li and Mg) were dehydrated by thermal treatment, fixation occurred and a micalike structure formed. This, however, did not occur in samples satd. with cations Si and Ba. The samples of montmorillonite contg. K and Ca retained their rehydration capacity unchanged upon thermal treatment.

2233. Hauth, W. E. Jr. and Davidson, Donald T. **Clay fraction in engineering soils. I. Identification by thermal analysis.** *Iowa Eng. Expt. Sta., Engr. Rept.* No. **10**, 449-58 (1951-1952).—*C.A.* **46**, 9755*h*.

Special sample prepn. becomes necessary when only a small per cent of the soil is clay or when other materials are present whose reactions tend to mask those of the clay minerals. The clay concn. may be increased by extg. and analyzing either the soil fraction passing a 270-mesh sieve or the particles less than 1 μ in diam. Interfering materials can be eliminated by proper treatment, e.g. the removal of org. material from a soil by the use of H_2O_2.

2234. Holmes, James and Mills, G. A. **Aging of a bentonitic cracking catalyst in air or steam.** *J. Phys. & Colloid Chem.* **55**, 1302-20 (1951).—*C.A.* **46**, 7749*h*.

Changes in the cracking activity, surface area, and pore structure of filtrol, an acid-treated bentonitic clay, were measured in the range 510-1135°C. The 10-hr air treatment produced a thermal deactivation which became noticeable at 775°C. Nearly complete deactivation occurred at 850°C, which was characterized by a loss in surface area and a marked decrease in bulk d. Steam produced a pronounced lowering of activity at 550°C after treatment for several hours at atm. pressure. Nearly complete deactivation occurred at 790°C. No overall correlation was found between cracking activity and surface area for all heat-treated samples.

2235. Hoyos, Angel de Castro and Rodriquez, Julio. **Surface changes of an acid bentonite on thermal treatment.** *Anales real soc. espan. fis. y quim.* **47B**, 504-14 (1951).—*C.A.* **46**, 5747*c*.

After being heated to 300°C, bentonite could be rehydrated. The specimens heated to 600° or 700°C were able to recover partly the loss of reticular water, but this recovered water was lost at 300° and 400°C. This was not associated with the loss of OH groups.

2236. Keenan, A. G.; Mooney, R. W., and Wood, L. A. **The relation between exchangeable ions and water adsorption on kaolinite.** *J. Phys. & Colloid Chem.* **55**, 1462-74 (1951).—*C.A.* **46**, 2874*h*.

Adsorption of H_2O at 20°C was detd. for the alkali and alk.-earth salts of kaolinite. Kaolinite, natural gradation and fractionated by sedimentation (0.5μ), was electrodialyzed and converted to the desired salt by treatment with hydroxide soln. except for Rb for which the carbonate was used. The clay suspensions were dried at 70°C to const. wt. Equilibration was rapid, being 85-90% complete in a few min. The presence of 1 mm of air increased the time to reach equil. three-fold. The adsorption was reversible, though hysteresis was noted with clays dried at 90°C. The B.E.T. theory appeared to be justified, though the significance of the H_2O monolayer is not clear.

2237. Mering, Jacques. **Process of hydration of montmorillonite.** *Mem. services chim etat* **36**, No. 1, 43-64 (1951).—*C.A.* **46**, 11055*a*.

2238. Newitt, D. M. **Drying characteristics of china clay.** *Ind. Chemist* **27**, 555-9 (1951).—*C.A.* **46**, 6801*h*.

To have equal vaporization of moisture at all depths at any instant, $(p-p_a)/R$ must be a const. for any point in the body; p is the vapor pressure of the moisture at any point, $(p-p_a)$ is the difference in vapor pressure between that point and a point in the drying air, and R is the resistance to vapor flow from the point under consideration to the air stream.

2239. Roquet, Juliette. **Isothermal residual magnetism of magnetite in small dispersed particles.** *Compt. rend.* **232**, 946-8 (1951).—*C.A.* **45**, 5472*c*.

The magnetic properties were measured on kaolin samples contg. particles of synthetic magnetite whose mean dimensions were 0.1 micron. Magnetic susceptibility, the variation of the isothermal residual magnetism and the demagnetizing field as a function of the magnetizing field were detd.

2240. Sandford, Folke. **The catalytic effect of kiln atmosphere on adsorption and moisture expansion of fired whiteware bodies.** *J. Am. Ceram. Soc.* **34,** 179-83 (1951).—*C.A.* **45,** 7324*d*.

The compns. of a vitreous china body, an earthenware body, and a calcareous earthenware body were, resp.: china clay 30, 35, 21; ball clay 18, 20, 20; quartz 23, 40, 37; feldspar 29, 15, 12; limestone 0, 0, 10%. The kiln atms. were N_2, O_2, CO_2, CO 10 + N 90%, air, and steam. After firing for 5 hrs at 1000, 1100, and 1200°C, the samples were ground to pass a 120-mesh sieve. The samples were weighed before and after exposure, at 25°C, over H_2SO_4-H_2O solns., at 10 different relative humidities from 9.3 to 94.4%. All data were tabulated and sorption isotherms reproduced. The wide variation in the data emphasized the importance of kiln atm.

2241. Sudô, T.; Minato, H., and Nagasawa, K. **Special kaolinitic clay from Shichinohe, Aomori Prefecture.** *J. Geol. Soc. Japan* **57,** 473-80 (1951).—*C.A.* **46,** 9024*f*.

Shichinohe clay showed an isotropic appearance under the microscope, and its x-ray powder pattern agrees with that of hydrated halloysite. Chem. analysis, differential thermal analysis curve, and electron micrograph showed slight difference from typical hydrated halloysite thus far reported. Specifically the water content, and the ratio of silica to alumina were greater.

2242. Vivaldi, J. L. Martín and Gonzalez, F. Garcia. **Characterization and properties of a bentonite from Almería. II.** *Anales edafol. y fisiol. vegetal* (Madrid) **10,** 561-84 (1951).—*C.A.* **46,** 11054*h*.

Bentonite was sepd. into 2 fractions by dispersion in aq. medium with NH_3 and subsequent sedimentation; 44.2% had an apparent particle diam. of less than 1.12μ. Chem. analyses, cation-exchange capacities, water-absorption capacities, dehydration curves, thixotropies, differential thermal and x-ray analyses, and electron-microscope examns. are reported for both fractions. Fibrous aggregates in the coarse fraction cannot be explained on the basis of chem. analysis. Both fractions show a high replacement of Al^{+++} in octahedral coördination by Fe^{+++} and Mg^{++}.

2243. Williamson, W. O. **The physical relations between clay and water.** *Trans. Brit. Ceram. Soc.* **50,** 10-34 (1951).—*C.A.* **45,** 6814*d*.

The formation of water films is initiated by adsorption processes, but the total film thicknesses are not produced thereby. The clay flakes tend to take up equil. positions in a force network and the intervening spaces are filled by water. Equil. is never obtained throughout the whole system, which thus remains mechanically metastable and produce the shear-hardening and other peculiar properties of plastic clay. The effect that adsorbed cations and anions may have on the structure and d. of water at the clay-water interface is assessed.

2244. Woodruff, C. M. **Water retention by clays.** *Soil Sci. Soc. Am., Proc.* **15,** 54-6 (1950) (Pub. 1951).—*C.A.* **46,** 205*g*.

The dehydration curves of kaolinite, beidellite, and montmorillonite were detd. over the p_F range from 0 to 7. Three different mechanisms retain water in a clay system under a moisture stress: adsorption of water on the clay surface. structural formation in the clay, and surface tension where particles come in contact and shrinkage ceases.

2245. Yagi, Skae; Kunii, Daizo, and Katsuki, Sanae. **Infrared drying characteristics of granular or powdery materials. I and II.** *Chem. Eng. (Japan)* **15,** 108-16; 117-24 (1951).—*C.A.* **45,** 7389*f*.

Sand, porcelain clay, dye, and basic Mg carbonate were dried by an infrared projector (9000 kcal./m²/hr). In the const.-rate period drying states of these materials were almost identical with free water. Humidity and velocity of air had only slight effects on the drying rate.

2246. Balduin, H. and Wieden, P. **Discoloration of active clays by treatment with organic vapors.** *Kolloid-Z.* **125,** 173-4 (1952).—*C.A.* **46,** 6460*e*.

Bleaching earth (acid-activated clays) absorbs xylene vapor at 105°C and takes on a rose to red color in 2-5 weeks. Toluene reacts the same as xylene, and tetralin in a much reduced degree. Under the same conditions no color changes were observed with vapors of C_6H_6, cyclohexane, decalin, aniline, MeOH, EtOH, isoamyl alc., or H_2O. The coloration indicates the presence in the clay of side chains which combine with aromatic hydrocarbons. Desorption of the colored product at 105°C results in deepening the color tone to a dark violet-to-gray.

2247. Bering, B. P.; Dreving, V. P.; Kiselev, A. V.; Serpinskii, V. V.; Surova, M. D., and Shcherbakova, K. D. **Adsorption properties of montmorillonite clays.** *Kolloid. Zhur.* **14,** 399-407 (1952).—*C.A.* **47,** 3080*c*.

The total porosity (detd. from the desorption of MeOH vapor), the heat Q of wetting by H_2O and MeOH, and the limiting adsorption a of palmitic acid from CCl_4 were: 0.41 cc./g, 12.7 cal/g, 11.9 cal/g, and 0.15 millimole/g, resp. On heating the clay at 550°C, the Q (for H_2O) was 5. The surface calcd. from adsorption and desorption of 2-methylbutane and n-octane, was 50 m²/g. MeOH was adsorbed very slowly (days instead of min.), but the max. adsorbed amt. corresponded to a surface of 320 m²/g. An even greater surface (350 m²/g) seemed to be accessible to H_2O vapor. The surface occupied by H_2O at the start of the capillary condensation was approx. 55 m²/g.

2248. Budnikov, P. P.; Khiterovich, M. I., and Blokh, G. S. **Effect of sulfite-alcohol wash water on the rate of drying of clay.** *Doklady Akad. Nauk S.S.S.R.* **82,** 127-9 (1952).—*C.A.* **47,** 4570*g*.

Plastic and semiplastic clays were mixed with 0.05 and 0.2% by wt of sulfite-alc. wash water and dried at 110°C. The admixts. increased the rate of drying during the first 2.5 hrs. The effect was more pronounced on plastic than on semiplastic clay.

2249. Bykov, V. T. **Natural sorbents of the Far East. II. Sorption of benzene vapors by natural sorbents and structure of the sorbents.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* **1952,** 583-91;—*C.A.* 47, 940*g*.

The porosity of 30 natural sorbents of different types, including fresh and weathered tuffs, diatomites, and bleaching earths, was investigated by adsorption-desorption of C_6H_6 vapors. The tabulated data include the point of beginning hysteresis, the vol. of C_6H_6 sorbed (cc./g) at that point and at the relative pressures $p/p_s = 0.25$, 0.50, 0.95, and at satn., and the sp. surface area of the skeleton and of the adsorption film.

2250. Colegrave, E. B. and Rigby, G. R. **The decomposition of kaolinite by heat.** *Trans. Brit. Ceram. Soc.* **51,** 355-67 (1952).—*C.A.* 47, 1351*e*.

Dehydrated kaolin was purely amorphous in character. The exothermic reaction, which occurred at about 960-1000°C, was the sudden crystn. of γ-Al_2O_3 from the amorphous phase, which was prevented at lower temp. by the SiO_2 in intimate contact with it. The SiO_2 in dehydrated kaolin, although insol. directly in aq. Na_2CO_3, had been found to be completely sol. in this reagent after previous removal of the Al_2O_3 by acid extn. The form of the SiO_2 residue after $HClO_4$ treatment of the dehydrated kaolin showed that the Al_2O_3 and SiO_2 were not in chem. combination.

2251. Evans, E. J. and Jackson, M. L. **Chemical determination of sorbed water and structural hydroxyl in colloidal minerals of soils and sediments.** *Soil Sci. Soc. Am., Proc.* **16,** 364-8 (1952).—*C.A.* 47, 5596*e*.

The sorbed water was extd. with methanol. The structural hydroxyl was detd. by heating the sample in a silica tube oven, passing a gas through the tube, and collecting the liberated water in methanol. The water contents of the methanol solns. were detd.

2252. Greene-Kelly, R. **A test for montmorillonite.** *Nature* **170,** 1130-1 (1952).—*C.A.* 47, 5847*i*.

Montmorillonite satd. with small ions, such as Li, and dried at moderate temp., is distinguished from other montmorillonoids by the difficulty of rehydration and marked decrease in exchange capacity. Montmorillonite, as oriented flakes or powder, if satd. by 3 washings with 3*M* LiCl, excess salt being removed with warm 80% alc., retains its structure and remains aggregated. After being dried (at 100°), Li-montmorillonite is treated with glycerol, its x-ray diffraction pattern shows *d*(001) corresponding to 17.7 *kX*.

2253. Hoyos, Angel de Castro and Rodriguez, Julio. **Surface changes of an acid bentonite on thermal treatment. II. Imbibition.** *Anales edafol. y fisiol. vegetal* **11,** 125-40 (1952).—*C.A.* 46, 9231*i*.

2254. Linseis, M. **Critical discussion of tests for clay raw materials.** *La Ceramica* 7, No. 5, 49-52 (1952).—*C.A.* 46, 9817*h*.

For kaolinite the precise chem. analysis gives a good basis for discussion of a clay deposit, but only modern phys.-chem., colloid-phys., and x-ray methods are suitable for the identification of montmorillonite clays. The electron microscope may be an important help, e.g. for the identification of halloysite. Differential thermal analysis is very important in combination with x-ray analysis, although the latter cannot give reliable identification of low feldspar contents of pegmatite clays.

2255. Lopez-Gonzalez, Juan de Dios and Deitz, Victor R. **Surface changes in an original and activated bentonite.** *J. Research Natl. Bur. Standards* **48,** 325-33 (1952)(Research Paper No. 2319).—*C.A.* 46, 10779*i*.

The changes in B.E.T. surface area at different temps. were related to the quantity of adsorbed water and the no. of constitutional hydroxyl groups. The surface area is a measure of only the external boundary (nonswelling surface) of the bentonite, and this is increased significantly by the activation process with HCl. The ratio of surface areas (activated to original) is about 4. A max. in the surface area formed when all of the adsorbed water was eliminated. However, the surface area decreased with the removal of water formed by decompn. of the constitutional hydroxyl groups.

2256. Newitt, D. M. and Coleman, M. **The mechanism of drying of solids. III. Drying characteristics of China clay.** *Trans. Inst. Chem. Engrs.* **30,** 28-42, discussion 42-5 (1952).—*C.A.* 47, 4570*i*.

The mechanism of drying was postulated as resulting from forces other than capillarity. A mechanism in which the clay surface dissoc. to produce diffusible cations which imbibe water osmotically was tested by suction potential detns. with a pressure app. consisting of a permeable thimble through which water from the clay slip was expressed by air pressure. By taking equil. readings of pressure at various amts. of water expressed, the moisture content of the bed at various pressures was detd. Osmotic imbibition was used to explain the effect of Na_2SiO_3 and Na_2CO_3 on the fluidity of clay slips.

2257. Palmer, L. S. **The dielectric constant of the water in wet clay.** *Proc. Phys. Soc.* (London) **65B,** 674-8 (1952).—*C.A.* 46, 10729*a*.

Clay consists of closely packed water-coated clay particles in an air matrix, when the clay is relatively dry. Wet clay consists of clay particles uniformly distributed in a water matrix, the assocd. water having a dielec. const. which varies from that of bound water (3) to that of free water (80) as the water content is increased.

2258. Skempton, A. W. and Northey, R. D. **The sensitivity of clays.** *Geotechnique* **3,** 30-53 (1952).—*C.A.* 47, 1461*g*.

The sensitivity of a clay was the ratio of its undisturbed to its remolded strength. Common values were 2-4, but the range was from about 1 to over 100. Moderate sensitivities had been induced in the lab. by mildly consolidating clays near their liquid limits in 1% salt soln. followed by leaching under the consolidating load for 2 or 3 weeks.

2259. Stone, Robert L. **Differential thermal analysis of kaolin group minerals under controlled partial pressures of water.** *J. Am. Ceram. Soc.* **35**, 90-9 (1952).—*C.A.* **46**, 6350*d*.

American kaolins, one English kaolin, dickite, halloysite, and diaspore were studied under dynamic conditions in atms. contg. H_2O vapor of partial pressures 5-760 mm. First signs of dehydration in all the kaolins appeared at about 400 °C, in halloysite at 320 °C, in dickite at 500 °C, and in diaspore at 465 °C., all in dry air. In steam atms. the starting temps. were 470°, 485°, 585°, and 510 °C,, resp. The results showed that the decompn. reactions of the kaolin group of minerals was reversible at equil. temp.

2260. Tschapek, M. **Influence of high temperatures on the adsorptional properties of clays.** *Comun. inst. nacl. invest. cienc. nat. anexo museo argentino cienc. nat. "Bernardino Rivadavia" Ser.: Cienc. geol.* **1**, No. 7, 1-12 (1952).—*C.A.* **47**, 3764*h*.

Samples with heterogeneous porosity were the most heat-resistant, and the least resistant were vitreous silicates with small pores. At 1000 °C the adsorption capacity of most clays was zero. The loss in adsorption capacity was due as much to a change in the properties of the surface coating as to the decrease in the specific surface. As the crystals were calcined, the OH groups on the surface were the first to decomp., being replaced by metallic cations, and then finally the internal OH groups were replaced. When all OH groups were replaced, the adsorption capacity became zero.

2261. Wieden, P. and Balduin, H. **Gas adsorption on bentonites.** *Kolloid-Z.* **127**, 30-2 (1952).—*C.A.* **46**, 8928*g*.

The adsorptive capacity of bentonite pretreated at 100 °C, for NH_4, SO_2, CO_2, and N_2 decreased in the order given. As the thermal pretreatment increased (6 steps up to 600 °C), the adsorptive capacity for N_2 decreased. As the thermal pretreatment was increased to 850 °C, the adsorptive capacity for CO_2 almost disappeared with the greatest loss between 100° and 150 °C.

2262. Bridger, G. L. and Sinner, R. D. **Adsorption of ammonia on fuller's earth and gas-adsorbent carbon.** *Ind. Eng. Chem.* **45**, 581-2 (1953).—*C.A.* **47**, 5757*i*.

Adsorption isobars for the two adsorbents at atm. pressure and at temps. near the condensation temp. of NH_3 were given. The fuller's earth isobar increased sharply, whereas the isobar for gas-adsorbent charcoal approached a const. value.

I-13. Gases on Organic Materials

2263. Rayleigh, Lord. **The passage of argon through thin films of India rubber.** *Phil. Mag.* 49, 220-1 (1900).

A passed the India rubber film more readily than N_2, but not in such a degree as to render the diffusion process a useful one for concn. of A.

2264. Lester, J. H. **The hygroscopic nature of cotton.** *J. Soc. Chem. Ind.* **21**, 388 (1902).

Absorption of moisture by cotton was not entirely due to cellulose. While the water extract may amount to only about 2%, the matters composing the extract were largely responsible for the hygroscopic nature of cotton.

2265. Masson, Orme. **The wetting of cotton by water and by water vapour.** *Proc. Roy. Soc. (London)* **74A**, 230-54 (1904).

The rise of temp. which cotton underwent when immersed in H_2O and its subsequent slow fall followed the same course as the similar change resulting from its exposure to air satd. with H_2O vapor. Both were affected in the same way by previous moisture and other conditions. The heating was a direct result of the absorption of the vapor by the cotton.

2266. Grunmach, L. **Experiment of the diffusion of CO_2 through rubber.** *Physik. Z.* **6**, 795-800 (1905).

The rate of diffusion of CO_2 through rubber increased with increasing pressure (generally with increase of differences in partial pressure), but proportionality between rate of diffusion and difference in pressure was not consistant. Rate of diffusion decreased with increase in thickness.

2267. Masson, Orme and Richards, E. S. **The hygroscopic action of cotton.** *Proc. Roy. Soc. (London)* **78A**, 412-28 (1906).

The quantity of hygroscopic moisture required to put a given quantity of cotton in equilibrium with a given humidity (below satn. value) was detd. by taking the mean of the apparent equilibrium values reached by absorption and evaporation. Vapor tension of any sample of cotton containing a definite quant. of moisture was, at different temp., the same fraction of that of H_2O.

2268. Trouton, F. T. and Pool, Miss B. **The vapour pressure in equilibrium with substances holding varying amounts of moisture. Measurement of the vapour pressure of water at different temperatures in equilibrium with a fabric wetted with a constant quantity of water.** *Proc. Roy. Soc. (London)* **A77**, 292-314 (1906).

The weight of water absorbed or held by a given fabric (cotton or wool) under different conditions of moisture and temperature of the atmosphere, appeared to depend only on the ratio of actual vapor pressure to the maximum possible. As the atmosphere varied from saturation, the temperature remaining the same, the amount of water held followed some parabolic law giving much greater reduction in weight for a given change in vapor pressure when near saturation than was subsequently obtained.

2269. Masson, Orme and Richards, E. S. **The hygroscopic action of cotton.** *Proc. Roy. Soc. (London)* **A78**, 412-429 (1907).

The amount of H_2O vapor absorbed by a given quantity of cotton in atmospheres of known humidity were detd. True equilibrium values were approached from both sides, by absorption and by evaporation. Neither process became really complete in a practicable time, though each led in a few hours to what might be mistaken for true equilibrium.

2270. Travers, M. W. **The absorption of water by cotton and wool.** *Proc. Roy. Soc. (London)* **A79**, 204-5 (1907).
The absorption of water on cotton and wool was detd. The absorption of vapors by amorphous substs. involved formation of solid solutions or "rigid" solns.

2271. Reychler, A. **The action of sulfur dioxide on wool.** *Bull. soc. belg. chim.* **23**, 471-5 (1909).--*C.A.* **4**, 934.
Description of an app. for measuring the SO_2 absorbed by wool by measuring the pressure under const. vol.

2272. Wright, A. M. **Absorption of moisture from the atmosphere by wools.** *J. Soc. Chem. Ind.* **28**, 1020 (1909).—*C.A.* **4**, 1384.
The amt. of moisture which a wool could absorb from the atm. depended upon: (1) The relative humidity, (2) non-wool constituents (pure wool fiber was not sufficient to account for all of the moisture absorbed by the dry normal wool fiber), (3) natural wool fat present in greasy wool, (4) the wool perspiration present in greasy wools and in slipe wools (about 2% was very hygroscopic and could absorb 60-67% of its own of moisture when exposed to the atm.), (5) fatty matter other than natural wool fat.

2273. Reychler, A. **Adsorption of sulphur dioxide by rubber and by wool.** *J. chim. phys.* **8**, 3-9 (1910).—*C.A.* **4**, 1256.
Para rubber, d. 0.95, was used in the form of a sheet 0.3 mm in thickness. The wool fiber was well washed and dried in air; at 105-110°C it lost 11.4% H_2O. Absorption of SO_2 in rubber was simply a soln. phenomenon. With wool 0.88 mol. of SO_2 was combined chemically and the remaining amt. was dissolved.

2274. Rakovskii, A. V. **Adsorption. I. Chemical hysteresis.** *J. Russ. Phys.-Chem. Soc.* **43**, 170-86 (1911).—*C.A.* **6**, 19.
Wheat starch, St. Vincent arrowroot, and potato starch were gradually dehydrated by keeping them successively in atmospheres of successively diminishing H_2O vapor tension until the wts remained const. under a given vapor tension. The completely dehydrated samples were then hydrated. The magnitude of hysteresis was considerably less than for inorganic colloids.

2275. Rakovskii, A. V. **Study of adsorption. IV. Thermodynamics of irreversible processes and chemical hysteresis.** *J. Russ. Phys.-Chem. Soc.* **43**, 1762-84 (1911).—*C.A.* **6**, 1246.
Potato starch contg. 36.98% H_2O was alternately placed in 2 desiccators in which the vapor tensions were 9 and 11 mm, resp. The transfer from one desiccator to the other was made every 24 hrs, and the starch was weighed before each transfer. When the H_2O content reached 19.6% the loss during 24 hrs became very small, but the amt. of H_2O was always higher at the higher tension.

2276. Austerweil, M. G. **Passage of hydrogen through the rubber walls of balloons.** *Compt. rend.* **154**, 196 (1912).—*C.A.* **6**, 1234.
The loss of H_2 from the envelope was not due to simple diffusion but to "colloidal" diffusion accompanied by the phenomenon of H_2 adsorption. The % of H_2 adsorbed increased during the period of inflation.

2277. Bancroft, W. D. **The action of water vapor on gelatin.** *J. Physic. Chem.* **16**, 395-406 (1912).—*C.A.* **6**, 2874.
When gelatin which had been soaked in water was exposed to satd. vapor it lost water, because the vapor pressure of the water inside the walls of the gelatin cells was greater (because of the curved surface) than the v.p. from the plane surface of the water. Dry gelatin exposed to satd. vapor adsorbed water in the cell walls, but the interior of the cell did not fill with water.

2278. Steinitzer, F. **The behavior of rubber towards carbon dioxide.** *Gummi-Ztg.* **26**, 1626-8 (1912).—*C.A.* **6**, 2693.
The absorptive power was found by exposing the material to be tested for 8 days to pure dry CO_2 at a pressure of 1.5 kg/cm^2. Under these conditions rubber can absorb more than its own vol. of CO_2; the less mineral matter present the more CO_2 was absorbed.

2279. Bryant, E. G. **Moisture in cloth.** *Chem. News* **108**, 85 (1913).—*C.A.* **7**, 3666.
The moisture contents of tweed cloths were detd. by drying samples to const. wt at 70°C, with the following % losses: control sample, 13.37; exposed sample, outside of roll, 12.55; middle of roll, 13.44; innermost layer, 13.37.

2280. Leprince-Ringuet, F. **Adsorption of gas by coal.** *Compt. rend.* **158**, 573-6 (1914).—*C.A.* **8**, 1864.
Fire-damp, CO_2, air, O_2 and CH_4 at pressures from 0.25 to 80 atms. were adsorbed by coal to a much less extent than by charcoal. The adsorption in both cases was similar; a state of equil. existed for each temp. and pressure, and the adsorption decreased considerably as the temp. rose. Adsorption increased rapidly at first with increase of pressure but gradually tended to a limit.

2281. Rakovskii, A. V. **Adsorption. XI. Hysteresis of the degree of hydration of cellulose.** *J. Russ. Phys.-Chem. Soc.* **47**, 18 (1915).—*C.A.* **9**, 1567.
The water retained *in vacuo* by cotton, paper, flax, and hemp showed that the max. of hysteresis for cellulose (1.8% H_2O) was slightly lower than for starches.

2282. Dewar, James. **Diffusion of gases through india rubber.** *Proc. Roy. Inst.* **21**, 813-26 (1918); *J. Chem. Soc.* **114**, II, 186-7 (1918).—*C.A.* **12**, 2275.
The relative rates of diffusion through Para rubber membranes 0.01 mm thick at 1 atm. pressure, and 15°C were: air, 1.0; N_2, 0.69; CO, 0.94; He, 1.75; A, 1.28; O_2, 2.0; H_2, 5.6; CO_2, 14.0. The abs. rate for air was 2.0 cc. per cm^2 per day. The relative rate varied with temp. The order of diffusibility was not associated with any chem. or

physical property. The diffusion of H_2O through a membrane, one side of which was immersed in H_2O, showed that the vol. rate at 15°C of the diffusion of H_2O vapor was 163 times that of air.

2283. ODDO, B. **Cellulose and nitrocellulose. Absorbing power for gases and constitution.** *Gazz. chim. ital.* **49**, II, 127-39 (1919).--*C.A.* **14**, 1529.

Cellulose was capable of fixing acid gaseous products like dry HCl in such proportions as correspond to 1 mol. for the quadruple mol., i.e., C_{24}. Of the other gases only NH_3 showed this relation approx. All the gases were absorbed by cellulose in the same relation in which they were dissolved by H_2O. Of the gases tested the order of decreasing absorption by vol. by cellulose was as follows: NH_3, HCl, SO_2, CO_2, O_2, H_2.

2284. DAYNES, H. A. **The process of diffusion through a rubber membrane.** *Proc. Roy. Soc. (London)* **97A**, 286-307 (1920).—*C.A.* **14**, 2573.

The diffusion of H_2 through rubber membranes depended upon both diffusion and absorption phenomena. The mean value for the diffusion const. for the 3 films considered was 11.4×10^{-6} cm/sec at 20°C. The mean value of the absorption coeff. was 0.035 at 20°C and normal pressure. The absorption coeff. had a low temp. coeff. 0.5%/1°C (approx.).

2285. NELSON, O. A. AND HULETT, G. A. **Moisture content of cereals.** *J. Ind. Eng. Chem.* **12**, 40-5 (1920).--*C.A.* **14**, 578.

A description of a method of detg. the H_2O content of cereals and other colloidal org. substances by heating the material in a high vacuum for definite periods of time. The H_2O liberated was condensed in a tube surrounded by solid CO_2, and weighed.

2286. BOIJA, J. **Drying cellulose and determining its water content.** *Svensk Pappers Tid.* **24**, 298-9 (1921).—*C.A.* **16**, 644.

Six curves showed the % of H_2O in the pulp at each set of rolls in the drying machine, the drop in the H_2O content as cellulose was dried at 105°C, the absorption of H_2O by absolutely dry cellulose, the loss of H_2O by cellulose at 15°C, the comparison of the actual with the detd. H_2O content, and the H_2O content of cellulose at varying amts. of moisture in air. The H_2O content of cellulose was about 0.7% higher than tests usually showed.

2287. MUNRO, A. D. **The occlusion of gases in coal.** *J. Soc. Chem. Ind.* **41**, 129T-132T (1922)

Two hypotheses were considered: (1) mechanical holding of the gases and (2) solution of the gases in the coal matter. Only the second could explain reversible nature of the phenomena.

2288. VENABLE, C. S. AND FUWA, TYLER. **The solubility of gases in rubber and rubber stock and effect of solubility on penetrability.** *J. Ind. Eng. Chem.* **14**, 139-42 (1922).—*C.A.* **16**, 1164.

The soly. of He, H_2, N_2, CO, O_2, CH_4, CO_2, C_2H_4, H_2S, NH_3 and SO_2 was detd. When rubber absorbed a gas, true soln. took place, not merely adsorption. The soly. decreased rapidly with increase in temp. The relative solubilities of the gases showed a general relation between soly., d. and rate of penetration.

2289. WILSON, ROBT. E. AND FUWA, TYLER. **Humidity equilibria of various common substances.** *J. Ind. Eng. Chem.* **14**, 913-8 (1922).—*C.A.* **16**, 3803.

The % H_2O content on a dry basis for 50% and 90% relative humidity, resp., for a group of substances were given.

2290. DE VRIES, O. **Investigations on the rate of drying of rubber.** *Arch. Rubber-cultuur* **7**, 95-123 (1923).—*C.A.* **17**, 2796.

The rate of drying may be increased by keeping the freshly rolled sheet in alc. or dil. formalin (1:10 or 1:100). Keeping in 10% AcOH or 5% alum soln. slightly decreased the time of drying but this may be ascribed to a loss of wt by contraction. The rate of drying was decreased by keeping in water.

2291. FARROW, F. D. AND SWAN, ENOCH. **Absorption of water by dried films of boiled starch.** *J. Textile Inst.* **14**, 465-74T (1923).—*C.A.* **18**, 907.

The absorption was estd. by weighing the specimens from time to time. In other expts. a known amt. of H_2O was permitted to evap. on to a starch film contained in an evacuated vessel. Wet starch persistently retained more H_2O than it would have absorbed if introduced dry into the same atm. Prolonged heat treatment reduced the capacity which starch possessed of absorbing water.

2292. FISHER, E. A. **Moisture relations of colloids. I. Comparative study of the rates of evaporation of water from wool, sand and clay.** *Proc. Roy. Soc. (London)* **103A**, 139-61 (1923).—*C.A.* **17**, 2528.

The rates of evapn. of H_2O from wool fabric, quartz sand, silty soil, and heavy clay subsoil, and the factors affecting the rates were studied. The shrinkage of clay had a characteristic effect on the curve, which might have been allowed for in the equation of rate. This effect was absent in wool, sand and silt; hence the so-called *shrinkage of wool* on drying was really a deformation and not a vol. shrinkage. The absorption of H_2O by wool was attributed to a filling up of fine pores of various shapes and sizes.

2293. FUWA, TYLER AND GODBOUT, A. P. **Equilibrium moisture of cotton.** *Textile World* **64**, 3023-5 (1923).—*C.A.* **18**, 331.

The equil. moisture of Arizona, Egyptian and Peeler cotton yarns and Arizona and Egyptian cotton yarns baked for 5 days at 160°C was studied. The equil. points were obtained by progressive dehydration of the satd. cotton to dryness, and then by hydration to the original point of satn. The equil. moisture for cotton was not a single curve but was best expressed by a narrow hysteresis loop.

2294. KUJIRAI, T.; KOBAYASHI, Y., AND TORIYAMA, Y. **Studies on insulating materials. I. Absorption of moisture by fibrous insulating materials.** *Rikwagaku Kenkyujo Iho* **2**, 105-27 (1923); *Sci. Papers Inst. Phys. Chem. Res.* **1**, 79-93 (1923).—*C.A.* **17**, 2758.

Nine fibrous insulating materials were suspended from a beam of a chem. balance by Pt wire and put in a hydrostat containing H_2SO_4 of desired concn. at 30°C. A considerable difference was observed in the quantity of moisture absorbed, whether the humidity varied from dry to wet or wet to dry.

2295. Masucci, Peter and Moffat, Margaret I. **The diffusion of phenol and tricresol through rubber.** *J. Am. Pharm. Assoc.* **12**, 117-20 (1923).—*C.A.* **17**, 3906.
Aging expts. covering 18 months showed that rubber-capped biological products contg. 0.3% tricresol or 0.5% C_6H_5OH lost a part of their preservative by diffusion through the rubber. The loss was 50-70% for tricresol and 20-40% for C_6H_5OH.

2296. Meunier, L. and Latreille, H. **Commercial chlorination of wool.** *Chimie et industrie* **10**, 636-42 (1923).—*C.A.* **18**, 331.
Treatment with Cl_2 of wool contg. moisture caused damage in proportion to the amt. of H_2O, which was not due to the formation of chloramines but to the oxidation of the protein matter in the presence of H_2O. Dry chlorination decreased the contact surface tension between wool and H_2O, so that capillary phenomena took place more rapidly. On the other hand, the swelling power of the chlorinated fiber was reduced.

2297. Rector, T. M. **The absorption of war gases by rubber and rubberized fabric.** *Ind. Eng. Chem.* **15**, 1132-4 (1923).—*C.A.* **18**, 482.
Small amts. of chloropicrin and $COCl_2$ in air were absorbed rapidly by a relatively large surface area of rubber. Absorption of $COCl_2$ was less rapid initially than that of chloropicrin, but subsequently became greater and, unlike that of chloropicrin, was almost complete after some hrs.

2298. Shorter, S. A. **The moisture content of wool—its relation to scientific theory and commercial practice.** *J. Soc. Dyers Colourists* **39**, 270-6; *Am. Dyestuff Rep.* **12**, 797-803 (1923).—*C.A.* **18**, 473.
The low vapor pres. of the H_2O in wool of low regain indicated that the H_2O was distributed in mol. With higher conditions, the vapor pres. increased, not merely absolutely but also relatively to the amt. of H_2O present, and at a condition far removed from satn. the vapor pres. became nearly equal to that of pure H_2O. From this point onwards the vapor pres. increased more and more slowly as satn. was approached.

2299. Andrews, D. H. and Johnston, John. **The rate of absorption of water by rubber.** *J. Am. Chem. Soc.* **46**, 640-50 (1924).—*C.A.* **18**, 1403.
The wt increased rapidly at first and then more and more slowly as it approached a value corresponding to a satn. concn. The general low of diffusion was thus followed. This ultimate concn. was independent of the thickness, though the fractional satn. of the mass as a whole after a definite time of immersion t was a function of t/a^2, where a was 0.5 the thickness of the mass.

2300. Brimley, R. C. **Absorption of vapors of various liquids by cotton.** *Nature* **114**, 432 (1924).—*C.A.* **19**, 757.
The percentage gain in wt of dry cotton at equil. with the satd. vapor at room temp. was: H_2O, 19; glacial AcOH, anhyd. alc., 3; CS_2, 2; C_6H_6, 2; Et_2O, 7; $PhNO_2$, 2 and Me_2CO, 2.

2301. Coles, G. and Graham, J. I. **The influence of preheating on oxidized and partially oxidized coal upon its rate of adsorption of oxygen.** *Fuels in Science and Practice* **3**, 384-90 (1924).—*C.A.* **19**, 5699.
Preheating influenced the reactions of the later stages of oxidation more than those of the initial rapid adsorption, and decreased the rate of O_2 adsorption. Repeated oxidation increased the rate of O_2 adsorption; the effect of H_2O on the adsorption of O_2 was not so marked as with oxidation of fresh coal.

2302. Costa, Domenico. **The absorbing power of starch for gases and its action on magnesyl derivatives.** *Gazz. chim. ital.* **54**, 207-11 (1924).—*C.A.* **18**, 3175.
Under the same conditions starch absorbed nearly 2 times as much HCl gas as cellulose. With cellulose, absorption ceased when the product corresponded to $C_6H_9O_5 + HCl$. Starch continued to absorb HCl slowly beyond this point and gave a black substance easily sol. in H_2O. SO_2 and NH_3 were absorbed in proportions that corresponded closely to 1 mol. for a simple mol. of starch.

2303. Shorter, S. A. and Hall, W. J. **Hygroscopic capacity of wool in different forms and its dependence on atmospheric humidity and other factors.** *J. Textile Inst.* **15**, 305-27T (1924).—*C.A.* **18**, 2813.
Different forms of the same material showed small but unmistakable differences. Yarns and tops gave the same results. Noils were found to be less hygroscopic because of the presence of foreign matter. Oil was found to diminish the regain of wool.

2304. Shorter, S. A. **Thermodynamics of water absorption by textile materials.** *J. Textile Inst.* **15**, 328-36T (1924).—*C.A.* **18**, 2813.
An equation connecting the heat of diln. with vapor pres. data was adapted to a textile material, and the heat of absorption under different conditions of temp. and humidity was calcd. It was detd. for cotton that for the same humidity the first powers of the regain at different temps. were to each other inversely as the first powers of the corresponding temps.

2305. Trotman, S. R. and Wyche, C. R. **The amino-nitrogen content of wool in relation to chlorination.** *J. Soc. Chem. Ind.* **43**, 193T-195T (1924).—*C.A.* **19**, 402.
Ordinary and deaminated wool had the same shrinkage, elasticity and tensile strength and absorbed practically the same amt. of Cl_2. Cl_2 was both adsorbed and entered into chem. combination. The prolonged action of Cl_2 gave rise to H_2SO_4 and sol. N compds.

2306. Urquhart, A. R. and Williams, A. M. **Moisture relations of cotton. The taking up of water by raw and soda-boiled cotton at 20°.** *J. Textile Inst.* **15**, 138-48T (1924).—*C.A.* **18**, 1754.
There were at least 2 possible values for the moisture regain for a sample of cotton exposed to an atm. of given temp. and humidity, a higher value if the cotton had been initially wetter than the atm., and a lower value if it had been drier.

If cotton was heated to 110°C it was less able to absorb water vapor.

2307. Urquhart, A. R. and Williams, A. M. **Moisture relations of cotton. II. Absorption and desorption of water by soda-boiled cotton at 25°C.** *J. Text. Inst.* **15**, 433-42T (1924).—*C.A.* **19**, 1631.

Curves plotted showed that the absorption curve was higher than the desorption curve, but, contrary to previous statements, these curves did not meet at zero humidity, but at a point corresponding with 1.18% relative humidity. The curves did not meet at 100% relative humidity. At 100% relative humidity the moisture content of soda-boiled cotton was 22.6%.

2308. Urquhart, A. R. and Williams, A. M. **Moisture relations of cotton. Effect of temperature on the absorption of water by soda-boiled cotton.** *J. Textile Inst.* **15**, 550-72T (1924).—*C.A.* **19**, 898.

The absorption of water by cotton at all humidities and up to 110°C was studied. The increase of moisture content which began at about 60°C was due to swelling of the material and the consequent exposure of new surface. Any process which depended for its success on the swollen state of the cotton would consequently become easier above 60°C at high humidities.

2309. Costa, Domenico. **The absorbing power of nitrocellulose for gases.** *Gazz. chim. ital.* **55**, 540-8 (1925).—*C.A.* **20**, 583.

The nitric esters of cellulose, $C_{24}H_{18}O_8(ONO_2)_{10}(OH)_2$, fixed NH_3 at first in proportions corresponding to 1 mol. of NH_3 or each ONO_2 group present. The NH_3 absorbed combined with the ONO_2 groups, forming the true salt of NH_4 with consequent denitration and dehydrogenation and decompn. of the cellulose complex. Dry HCl displaced the ONO_2 groups in nitrocellulose completely.

2310. Leblanc, M.; Kroger, M., and Kloz, D. **The adsorption properties and particle size of several lamp-blacks in organic liquids and in crude rubber mixtures as well as the effect of these lamp-blacks on the properties of vulcanized products.** *Kolloidchem. Beihefte* **20**, 356-411 (1925).—*C.A.* **19**, 3398.

The sorptive capacity for water vapor showed irregularities which may be traced back to the ash content and the content of extractives. A high degree of dispersion was necessary, but not sufficient, for the development of great adsorptive power.

2311. Urquhart, A. R. and Williams, A. M. **Moisture relations of cotton. The absorption of water by cotton mercerized without tension.** *J. Textile Inst.* **16**, 155-66T (1925).—*C.A.* **19**, 2749.

The variations in water-fixing power of mercerized cotton with the concn. of the mercerizing soln. employed were strikingly similar to the variations in dimensions of the unit hairs. Mercerization increased the accessible surface of the cotton in proportion to the mercerization ratio, which, therefore, might have been used as a measure of the absorptive capacity of the material for dyes as well as water.

2312. Swan, Enoch. **Absorption of water by dried films of boiled starch—absorption and desorption between 20° and 90°C.** *J. Textile Inst.* **17**, 527-36T (1926).—*C.A.* **21**, 500.

The retentive power of a starch film was greater the higher the temp., or the more prolonged the period of heating of its original prepn.

2313. Trotman, S. R. and Trotman, E. R. **Further experiments on the chlorination of wool.** *J. Soc. Chem. Ind.* **45**, 111-5T (1926).—*C.A.* **20**, 2586.

Only a small portion of the Cl_2 taken up by the wool entered into chem. combination with the wool under those conditions by which unshrinkable finish was generally produced. A more thorough understanding of the action was necessary to reach a satisfactory control of the "unshrinkable" process.

2314. Hock, L. and Bostroem, S. **Thermochemical comparison of various kinds of lamp and gas blacks.** *Kautschuk* 21-2 (1927).—*C.A.* **21**, 1335.

The particle size of the carbon blacks varied inversely with the heat of wetting by C_6H_6. By comparing the heat of wetting of various blacks, their relative mean particle size was detd. Based on a surface index of 11 for "Micronex" gas black, another American air-floated gas black had a relative surface of 137, several lamp blacks 18.5 to 44.6 and "Thermatomic" black 2.

2315. Lowry, H. H. and Kohman, G. T. **The mechanism of the absorption of water by rubber.** *J. Phys. Chem.* **31**, 23-57 (1927).—*C.A.* **21**, 1372.

A systematic study was made of the influence on the rate of absorption and on the final equil. of (1) the vapor pres. of the surrounding H_2O medium, (2) the H_2O-sol. components of the rubber, (3) the state (liquid or vapor) of the surrounding medium, (4) the combined S (an index of rigidity), (5) the temp., (6) the hydrostatic pres. of the surrounding medium, and (7) the aging of the rubber before and during absorption.

2316. Schumacher, E. E. and Ferguson, L. **A convenient apparatus for measuring the diffusion of gases and vapors through membranes.** *J. Am. Chem. Soc.* **49**, 427-8 (1927).—*C.A.* **21**, 837.

An efficient diffusion-measuring app., embodying a mech. clamp and Hg seal, was described in detail. This app. was useful for measuring the rate of diffusion of gases and vapors through wax, leather, rubber and similar membranes.

2317. Urquhart, A. R. **Moisture relations of cotton. Absorption of water by cotton mercerized with and without tension.** *J. Textile Inst.* **18**, 55-72T (1927).—*C.A.* **21**, 2069.

Changes in the absorptive capacity of cotton brought about by mercerization were very similar for all varieties of cotton examd. The application of tension acted in opposition to the swelling forces, so that the absorptive capacity of cotton mercerized with tension was less than that of cotton mercerized loose.

2318. Alekseevskii, E. V. **Adsorption of vapors by animal and vegetable fibers.** *Zhur. Prikladnoi Khim.* **1**, 184-9 (1928).—*C.A.* **23**, 4346.

CCl_3NO_2 was best adsorbed by dyed new wool and dyed used silk while linen was the poorest adsorbent. $AsCl_3$ was best adsorbed by wool, hairs and rubber. Paper was the poorest adsorbent, but disintegrated quickly, while the strength of wool fibers was not affected. Most of the adsorbents darkened on exposures because of deposition of As.

2319. Barker, S. G. **The hygroscopic nature of textile fabrics.** *Trans. Inst. Chem. Eng.* **6**, 162-7 (1928).—*C.A.* **24**, 1221.

Tables show the regain for various fibers under different conditions of temp. and relative humidity.

2320. Dubosc, A. **Adsorption and diffusion of gases through rubber and balloon fabrics.** *Rev. gen. caoutchouc Feb.*, **1928**, No. 39, 7-8.—*C.A.* **22**, 2078.

A review and discussion of the general phenomena.

2321. Fleming, Horace. **Conditioning small samples of fiber.** *Textile Colorist* **50**, 253 (1928).--*C.A.* **22**, 4824.

A simple method, ascribed to Rawson, for detg. the dry wt of small samples was described.

2322. Hill, S. E. **Method for demonstrating the diffusion of oxygen through rubber and various other substances.** *Science* **67**, 374-6 (1928).—*C.A.* **22**, 2091.

A simple visual demonstration of the diffusion of O_2 may be made by using luminous bacteria as an indicator.

2323. Kanata, Kazuo. **Permeabilities of colloidal substances to gases.** *Bull. Chem. Soc. Japan* **3**, 183-8 (1928).—*C.A.* **23**, 18.

The relative permeabilities were detd. for rubber, gelatin and celluloid for O_2, H_2, CO_2, SO_2 and NH_3. The permeability and hence the absorption was caused by the solution of gas in the colloidal substance.

2324. Newsome, P. T. **Note on the McBain-Bakr balance for the sorption of vapors by fibrous and film materials.** *Ind. Eng. Chem.* **20**, 827 (1928); *Chemistry & Industry* **47**, 594 (1928).—*C.A.* **22**, 3070.

The sorption of vapors by fibrous and film materials may be measured by suspending the sample from the spring, evacuating and introducing by stopcock controls a small quant. of liquid. The pressure and elongation of the spring are measured with a cathetometer.

2325. Schaposchnikoff, W. G. **Moisture content of textile fibers.** *Melliand Textiber.* **9**, 844-50 (1928).—*C.A.* **23**, 1273.

While 8.5% had been considered as the normal regain for cotton, the tests showed a min. of 6.87%, a max. of 15.28% and an av. of 11.66%. The av. regain of silk was 13.75%, of H_2O-retted flax 14.15%, of hemp 14.72%, of jute 16.35%, of rayon 18.79%, of woolen 19.56% and of worsted 19.54%. The av. relative humidity was 76.8%.

2326. Tammann, G. and Bochow, K. **The absorption of hydrogen by rubber at elevated pressures and the behavior of the rubber after the pressure is lowered.** *Z. anorg. allgem. Chem.* **168**, 322-4 (1928).--*C.A.* **22**, 2491.

When rubber, Zn and dil. H_2SO_4 were subjected to high pressures, e.g., 550 or 1150 kg per cm², the rubber became satd. with H_2. When the pressure was released the rubber was porous, and some time afterwards was still several times its original vol.

2327. Yamamoto, T. **The solubility of carbon dioxide in vulcanized rubber.** *Bull. Inst. Phys. Chem. Res. Tokyo* 7, 999-1001.—*C.A.* **23**, 2632.

Specimens of tubing, cut into bits, dried, and tested for increase of wt in 1 atm. of CO_2 at 25°C, showed that black tubing, d_4^{25} 0.9300, dissolved 0.146 g CO_2 per 100 g and bright brown tubing, d_4^{25} 0.9380, 0.166 g CO_2 per 100 g.

2328. Davey, W. Cecil and Ohya, T. **The permeability of rubber mixings.** *Trans. Inst. Rubber Industry* **5**, 27-30 (1929).—*C.A.* **23**, 5350.

The permeability of H_2 was lower in accelerated than in unaccelerated mixts.; it was lowered still further by softeners and by antioxidants and increased by mineral fillers. With the finest pigments, however, the increases were relatively small.

2329. King, A. T. **The regain of stretched fibers and the porous structure of wool.** *Trans. Faraday Soc.* **25**, 451-58 (1929).

Initial H_2O absorption by wool consisted of an adsorption layer on the internal surfaces of the pores; the second stage consisted of a filling up of the pores, and the third of an osmotic absorption.

2330. Kohman, G. T. **The absorption of oxygen by rubber.** *J. Phys. Chem.* **33**, 226-43 (1929).—*C.A.* **23**, 2600.

The influence of surface area on the rate of O_2 absorption by raw and vulcanized rubber and the changes in tensile strength which result from the O_2 absorption were studied.

2331. Morris, V. N. and Street, J. N. **Permeability of rubber to air. I. Effect of temperature, pressure and humidity.** *Ind. Eng. Chem.* **21**, 1215-1219 (1929).—*C.A.* **24**, 988.

The permeability was almost linearly proportional to the total pressure. The temp. coeff. of the permeability was very high, e.g. a drop of 20°F cutting the permeability to about 0.5 its value, and the permeability being extremely low at 0°C.

2332. Peirce, F. T. **A two-phase theory of the absorption of water vapor by cotton cellulose.** *J. Textile Inst.* **20**, 133-50T (1929).—*C.A.* **23**, 5381.

There are 2 distinct phases in which H_2O mol. were held in cotton cellulose: (1) H_2O mol. were definitely assocd. with 1 hexose unit as in a chem. compd. and (2) the H_2O mol. filled the spaces available under attractive forces like those in a liquid.

2333. Rosenzweig, Adolf. **The moisture content of textiles and its relation to the relative humidity of the air.** *The Melliand* **1**, 870-3 (1929).

Textiles strove to absorb humidity corresponding to the relative humidity of the air. Under com. condition they were able to absorb the relative moisture of the air slowly, and obtain equilibrium values in those rare cases, when the constant changes of humidity exceeded the daily variations continuing in this direction for months.

2334. Sheppard, S. E. and Newsome, P. T. **The sorption of water vapor by cellulose and its derivatives.** *J. Phys. Chem.* **33**, 1817-35 (1929).—*C.A.* **24**, 956.

All samples exhibited hysteresis. The increased sorption by the hydrated cellulose was accounted for on the basis of differences of "fine structure" between the native and mercerized cellulose. Sorption decreased as the amt. of esterification increased.

2335. Speakman, J. B. **The rigidity of wool and its change with adsorption of water vapor.** *Trans. Faraday Soc.* **25**, 92-103 (1929).—*C.A.* **23**, 5323.

The rigidity of dry wool fibers was slightly greater for fibers of intermediate diam. From the shape of the rigidity-water adsorbed curve, the reduction in rigidity was caused by adsorption of water by certain groups in the wool.

2336. Speakman, J. B. **Adsorption of water by wool.** *Nature* **124**, 411 (1929).—*C.A.* **24**, 1222.

The adsorption of H_2O by wool fibers (stretched 30% of their length under H_2O) was compared with the adsorption of H_2O by untreated wool fibers. Each sample was taken from dryness up to satn. in stages, and then in the reverse order to dryness. The stretched samples adsorbed more H_2O in every case than the untreated ones.

2337. Urquhart, A. R. **The mechanism of the adsorption of water by cotton.** *J. Textile Inst.* **20**, 125-32T (1929).—*C.A.* **23**, 5381.

Adsorption of H_2O took place at the OH groups of the long, spiral, somewhat flexible mols. of cellulose and on drying there was a tendency for twisting and rearrangement of the mols. or micelles so that the residual valences of the OH groups mutually satified each other, thereby reducing the hygroscopicity. During reabsorption there was a tendency to return to the original orientation, the reproducibility of the hyteresis loop being thereby explained.

2338. Wineland, Albert J. and Waters, Ralph M. **The diffusibility of anesthetic gases through rubber.** *Anesthesia and Analgesia* **8**, 322-3 (1929).—*C.A.* **24**, 468.

Ten-liter bags lost the following amts. of wt in 48 hrs: O_2, 0.32 g; C_2H_4, 1.00 g; CO_2, 4.68 g; and N_2O, 7.00 g.

2339. Abrams, Allen and Chilson, Warren A. **Vapor transmission through papers.** *Paper Mill* **53**, No. 38, 24-8 (1930).—*C.A.* **24**, 6010.

The resistance of paper to the penetration of water vapor was detd. It consisted essentially in exposing the paper to water vapor for a definite time, having satd. air on one side of the sheet and a definite lower humidity on the other side.

2340. Bancroft, W. D. and Barnett, C. E. **Phase-rule studies on the proteins. I. Determination of solid compounds with hydrogen chloride or ammonia.** *J. Phys. Chem.* **34**, 449-98 (1930).—*C.A.* **24**, 2151.

By means of pres.-concn. curves the type of combination which occurred between proteins and NH_3 or HCl was established. Casein, zein, arachin, fibrin and gliadin absorbed NH_3, without the formation of a chem. compd.. On the other hand, casein, arachin, fibrin, gliadin and edestin formed definite compds. with HCl, while zein did not.

2341. Collins, Geo. E. **The swelling of cotton hairs in water and in air at various relative humidities.** *J. Textile Inst.* **21**, 311-5T (1930).—*C.A.* **25**, 418.

The desorption and absorption of cotton hairs showed a close parallelism between the extent of the dimensional changes and the amt. of the absorption, at least over the temp. range of 20°-100°C studied.

2342. Davidson, G. F. and Shorter, S. A. **The dry weight of cotton.** *J. Textile Inst.* **21**, 165-78T (1930).—*C.A.* **24**, 6026.

The "true dry weight" was defined as the const. wt obtained by prolonged exposure at room temp. to an atm. dried by P_2O_5. The time required to reach apparent constancy of wt depended upon the accuracy required; under conditions of commercial testing the rate of loss was slow after a few hrs.

2343. Herzog, R. O. **Trends of research. The behavior of regenerated cellulose to water.** *Rayon Record* **4**, No. 6, 313-7 (1930).—*C.A.* **24**, 2878.

A review on the state of knowledge of behavior of regenerated cellulose to water, and investigations which threw light on the mechanism of water absorption.

2344. Jenkins, W. J. and Bennett, H. B. **Sorption experiments with cellulose nitrate. I. Sorption of vapors by cellulose nitrate.** *J. Phys. Chem.* **34**, 2318-29 (1930).—*C.A.* **24**, 5567.

The amt. of acetone sorbed by cellulose nitrate depended only slightly on the side from which equil. was approached. Sorption of acetone by stable cellulose nitrate increased up to a max. and then decreased.

2345. Larian, Maurice; Lavine, Irvin; Mann, C. A., and Gauger, A. W. **Studies on the development of Dakota lignite. II. Sorption of water vapor by lignite, peat and wood.** *Ind. Eng. Chem.* **22**, 1231-34 (1930).—*C.A.* **25**, 397.

The shapes of the vapor pres. vs. moisture curves were similar. Peat and wood dried to a lower moisture content than lignite at any given vapor pres. Hysteresis was greatest for lignite and least for birch.

2346. Lavine, Irvin and Gauger, A. W. **Studies on the development of Dakota lignite. I. Aqueous tension of the moisture in lignite.** *Ind. Eng. Chem.* **22**, 1226-1231 (1930).—*C.A.* **25**, 397.

A study of the desorption and adsorption of H_2O vapor by 3 lignites showed: (1) loss of moisture was accompanied by decrease in vapor pres.; (2) vapor-pres. lowering varied but little and was similar to that for wood; (3) in drying for storage there was little need to reduce H_2O below 16%; (4) marked hysteresis occurred; (5) increase of temp. shifted the dehydration curve toward the region of lower H_2O content.

2347. Mauersberger, Herbert R. **Relative moisture absorption of woven textile materials.** *The Melliand* **2**, 223-9 (1930).
The regain of any woven textile fabric in hygroscopic equil. with the surrounding atm. depended on the percent of the relative humidity and the temp. At a given relative humidity the higher the temp. the less the percent regain. The rate of absorption increased with each material fairly uniformly, but there was a point where the rate increased rapidly. The regain of a fabric was considerably below, at ordinary temps. and humidities, that of the raw materials from which it was made.

2348. Oguri, Sutezo and Nara, Masaaki. **Hygroscopic moisture of cellulose.** *J. Soc. Chem. Ind., Japan* **33**, Supp. binding 267-70 (1930).—*C.A.* **24**, 5479.
Standard cotton cellulose, bamboo cellulose, wood cellulose, and nitrocellulose were placed in a closed vessel satd. with H_2O vapor at const. temp., and the equil. moisture detd. The OH group in cellulose had a special attraction for H_2O as was shown by the fact that the equil. H_2O of the original cotton cellulose was higher than that of nitrocellulose. Cellulose required long exposure to satd. vapor to attain equil. The curves of velocity of satn. of moisture closely resembled those of adsorption.

2349. Pidgeon, L. M. and Maass, O. **Adsorption of water by wood.** *J. Am. Chem. Soc.* **52**, 1053-68 (1930).—*C.A.* **24**, 1974.
The adsorption of H_2O by certain coniferous woods and by cotton cellulose was measured by a new method. The complete range of vapor pressures was covered and adsorption isothermals produced between 12° and 42°C. In wood which had been dried for a long period of time the adsorption isothermals were the same at low vapor pressures, but differed at the higher vapor pressures. Adsorption isosteres were represented by log $a/c = B + AT$ for adsorption representing more than 2%.

2350. Pidgeon, L. M. and Maass, O. **The penetration of water vapor into wood.** *Can. J. Research* **2**, 318-26 (1930).—*C.A.* **24**, 4155.
The rate of diffusion of water vapor through wood was studied through a comparison of the time taken for samples of various thicknesses to become satd. Continuous measurements of the amt. of adsorption were carried out by the use of a quartz spring balance completely enclosed in the app. at a const. vapor pressure. The movement of water through wood, at concns. below the satn. point took place as vapor diffusion through the spaces of the wood structure.

2351. Rubenstein, L. **Sorption experiments with cellulose nitrate. II. Sorption of vapors by cellulose nitrate.** *J. Phys. Chem.* **34**, 2330-42 (1930).—*C.A.* **24**, 5567.
The sorption was measured for MeOAc, EtOAc, Me_2CO, and MeEtCO at 20°C and the absorbent at 30°C; the sorption increased to a max. and then decreased. With MeOH at 20°C and cellulose nitrate at 30°C, the sorption decreased with N content. The reversibility of sorption phenomena was also considered.

2352. Sheppard, S. E. and Newsome, P. T. **Sorption of water vapors by cellulose and derivatives. II. Kinetics of sorption.** *J. Phys. Chem.* **34**, 1158-65 (1930).—*C.A.* **24**, 3641.
The rate of sorption depended primarily on diffusion, but a structure factor of porosity intervened. One state of the sorption process was the attachment of water mols. to free hydroxyls of the cellulose mol. Some of the cellulose hydroxyls were free, since cellulose took up only 23% as "hydrate cellulose" and 16 to 18% as "native" cellulose.

2353. Speakman, J. B. **Adsorption of water by wool.** *J. Soc. Chem. Ind.* **49**, 209-13T (1930).—*C.A.* **24**, 3376.
The adsorptive and desorptive properties of purified wool fibers were studied over a wide range of atm. humidities. Marked hysteresis existed between the 2 processes. Water adsorption was dependent upon the polypeptide groups in these mols.

2354. Speakman, J. B. **Micelle structure of the wool fiber.** *Nature* **126**, 565 (1930).—*C.A.* **25**, 1387.
Existence of micelles within the wool fiber was proved by swelling and adsorption studied and by the action of Na_2S on wool. It was deduced that the micelles were lamellar in shape.

2355. Strachan, James. **Adsorption on the crystal lattice cellulose.** *Nature* **125**, 671 (1930).—*C.A.* **24**, 3149.
Light passing through natural cellulose fibers deeply stained with I_2 was completely polarized by absorption. Microscopic analysis of this phenomenon proved that the polarization was due to ultramicroscopic cryst. particles of I_2 oriented on the lattice. Oriented crystal overgrowths of $CaCO_3$ and $BaSO_4$ were also produced on cellulose.

2356. Urquhart, A. R. and Eckersall, Norman. **The moisture relations of cotton. VII. A study of hysteresis.** *J. Textile Inst.* **21**, 499-510T (1930).—*C.A.* **25**, 1089.
The absorption and desorption curves for cotton formed the boundaries of an equil. area, any point on which was capable of representing the amt. of H_2O present in cotton under appropriate conditions of humidity and pre-history. Data were given for Sakel cotton, raw and soda-boiled at 25°C, and for raw Webber and Acala cottons, soda-boiled and mercerized Sakel cotton at 20°C.

2357. Williams, Ira and Neal, Arthur M. **Solubility of oxygen in rubber and its effect on rate of oxidation.** *Ind. Eng. Chem.* **22**, 874-8 (1930).—*C.A.* **24**, 4660.
The soly. of O_2 in rubber followed Henry's law. Oxidation of rubber proceeded at a uniform rate as long as the concn. of O_2 remained above a certain min. In air at 70°C the concn. of O_2 in rubber was below that necessary for maintaining uniform

oxidation at a max. rate. Elevated temps. produced a type of oxidation, the course of which was sensitive to high concns. of O_2 and about which little was known.

2358. Filby, E. and Maass, Otto. **Volume relations of the system cellulose and water.** *Can. J. Research* 7, 163-77 (1932).—*C.A.* **26**, 5414^9.
The vol. of the system water vapor and cellulose was found to be much smaller than that given by the components as long as the amt. of adsorbed H_2O was below 4%. With more than 8% of adsorbed H_2O the d. of subsequently sorbed H_2O was found to be the same as that of the normal liquid.

2359. Bancroft, W. D. and Calkin, J. B. **The taking up of water by cellulose.** *Textile Research* **4**, 371-98 (1934).—*C.A.* **28**, 7025^3.
H_2O adsorbed by cotton could be removed partially by centrifuging. The amt. of moisture adsorbed by cotton from satd. H_2O vapor (at 25°C) was detd. by approaching the equil. from both sides. The amt. taken up from satd. H_2O vapor by a sample of cotton was 27%. Various forms and derivs. of cellulose took up different amts. of H_2O. The adsorption of moisture by cellulose being an exothermic reaction, increasing the temp. decreased the amt. taken up. Under present exptl. conditions there was a hysteresis effect.

2360. Steinberger, R. L. **The thermodynamics of swelling.** *Textile Research* 4, 451-62, 513-24 (1934).—*C.A.* **28**, 7111^8.
Entropy changes with swelling were related to the distribution of the H_2O mols. within the gel. Vol. contraction was ascribed to the dissocn. of ordinary H_2O which had a complex mol., to the simple unimol. form in the gel. Since swelling and capillarity were intimately related phenomena the important points of contact of the two were discussed.

2361. Argue, G. H. and Maass, Otto. **Measurement of the heats of wetting of cellulose and wood pulp.** *Can. J. Research* **12**, 564-74 (1935).—*C.A.* **29**, 5652^8.
When the H_2O was left as a result of partial desorption a higher value was obtained. The heats of wetting of wood meal and different wood pulps were detd. The heats of adsorption were calcd., and all the data were discussed from the point of view of the phys. structure of cellulose. A few preliminary measurements of the heat of adsorption of NaOH were made.

2362. Astbury, W. T. and Lomax, R. **An x-ray study of the hydration and denaturation of proteins.** *J. Chem. Soc.* **1935**, 846-51.—*C.A.* **29**, 6487^7.
The hypothesis was advanced that a fully extended polypeptide chain was characterized by 2 principal side-spacings, one (about 4.5 A.) arising from the effective thickness of the backbone of the chain, and the other (about 10 A.) from the lateral extension of the side chains standing out from the amino acid residues.

2363. Filby, E. and Maass, Otto. **Sorption of water on cellulosic materials.** *Can. J. Research* **13B**, 1-10 (1935).—*C.A.* **30**, 609^2.
Care was taken that no vapors other than water were present no matter how long a time was required for the establishment of equil. The adsorption and desorption isotherms of standard cellulose, spruce wood, surgical cotton, Kodak rag cellulose and bleached sulfite were detd.

2364. Lykov, A. V. **The kinetics of the sorption of vapors by cellulose.** *J. Phys. Chem. (U.S.S.R.)* **6**, 731-46 (1935).—*C.A.* **30**, 6620^1.
The kinetics of the adsorption and absorption of water vapor from moist air by a sphere of 6.6 cm diam. of pure dry celluloses at 20°-75°C and 62-100% relative humidity was studied. The internal temps. of the sphere were followed by 3 thermocouples. By use of the Fick surface layer and internal-diffusion laws, the sorption law and its coeffs. were detd.

2365. Stamm, Alfred J. and Loughborough, W. Karl. **Thermodynamics of the swelling of wood.** *J. Phys. Chem.* **39**, 121-32 (1935).—*C.A.* **29**, 2686^1.
Detns. were made (for the system Sitka spruce wood-water) of the relative vapor pres.-moisture content desorption isotherms. Temps. varied from room temp. to 100°C, and conditions were carefully controlled to minimize the hysteresis effect. Fiber-satn. points decreased linearly with increased temp., and were reduced by 0.1% per 1°C rise.

2366. Speakman, J. B. and Cooper, C. A. **The adsorption of water by wool. I. Adsorption hysteresis.** *J. Textile Inst.* **27**, 183-5T (1936).—*C.A.* **30**, 7857^6.
Adsorption and desorption data on wool at 25°C from relative humidities of 10.6% to 89.6% were given. The range of humidity over which wool must be dried to pass from adsorption to limiting desorption conditions appeared to be independent of regain and was about 18%.

2367. Speakman, J. B. and Stott, E. **The adsorption of water by wool. II. The influence of drying conditions on the affinity of wool for water.** *J. Textile Inst.* **27**, 186-90T (1936).—*C.A.* **30**, 7857^7.
The adsorption power of wool, dried from regains below satn., decreased with increasing temp. of drying. The decrease in H_2O absorption was produced by partial as well as complete drying but not by drying from satn. nor by heating wool which was dried at low temp. The normal affinity for H_2O of wool which had been dried at a high temp. was restored by allowing it to reach satn. with H_2O vapor. The reduced adsorptive power of wool heated over H_2O at a high temp. was irreversible.

2368. Speakman, J. B. and Cooper, C. A. **The adsorption of water by wool. III. The influence of temperature on the affinity of wool for water.** *J. Textile Inst.* **27**, 191-6T (1936).—*C.A.* **30**, 7857^8.
Adsorption isotherms of wool at intervals of 5°C from 25° to 55°C were given. Complete isotherms above 55°C could not be obtained owing to the susceptibility of the disulfide bond of wool to H_2O at high temp., as evidenced by formation of HgS on the fibers. At low partial pressures of H_2O vapor, the amt. of H_2O adsorbed decreased as a linear function of temp. At partial pressure 0.975 the isobar showed a min. at about 43°C, indicating that swelling of wool in H_2O was a min. near that temp.

2369. Boer, J. H. de and Fast, J. D. **Diffusion of hydrogen through regenerated cellulose and some cellulose derivatives.** *Rec. trav. chim.* **57**, 317-32 (1938).—*C.A.* **32**, 4778^{7}.

H_2 diffused through metals in the at. form, and through cellulose acetate in the mol. form. Diffusion through cellulose derivs. (celluloid, cellulose triacetate, cellophane) was greater than through cellulose. While H_2 diffused readily through nitrocellulose and cellulose acetate, these derivs. were practically impermeable to air; regenerated cellulose (cellophane) was practically impermeable to both of these gases. The temp. relationship of the diffusion of H_2 was detd.

2370. Galzova, E. S. **The drying of raw cotton with flue gases.** *Khlopchatobumazhnaya Prom.* **8**, No. 9, 24-6 (1938).—*C.A.* **34**, 8291^{5}.

The SO_2 adsorbed by the cotton during drying with flue gases was greater at the higher concn. of SO_2 in the gases, the higher moisture content of the cotton, and the longer time the cotton was in contact with the gases. Almost all the SO_2 adsorbed by the cotton was given off again when the material was allowed to lie in the open air.

2371. Daynes, H. A. **Note on the theory of water absorption by rubber.** *Rubber Chem. Tech.* **12**, 532-4 (1939); *Trans. Inst. Rubber Ind.* **14**, 191-3 (1938).—*C.A.* **33**, 3204^{6}.

The changes in water content of rubber with time of exposure to various conditions of humidity could not be calcd., either for practical use or for verifying theories of the mechanism of absorption.

2372. Houtz, C. C. and McLean, D. A. **Adsorption of water by papers at elevated temperatures.** *J. Phys. Chem.* **43**, 309-21 (1939).—*C.A.* **33**, 3654^{7}.

Adsorption isotherms for water on tissue papers at 100°-150°C and equil. water-vapor pressures from 0 to 25 mm Hg showed considerably higher adsorption on paper from kraft wood pulp than from linen rag. Values of the consts. in the Freundlich adsorption equation, which applied to the data, were given. Hysteresis was found.

2373. Neiman, R. S. and Kargin, V. A. **Sorption of water vapor by cellulosic fibers.** *Org. Chem. Ind. (U.S.S.R.)* **6**, 628-33 (1939).—*C.A.* **34**, 5278^{7}.

Sorption and desorption of water vapors by various cellulosic and casein fibers showed that equil. was attained in 1 to 15 hrs by the vacuum method of McBain. Different specimens of viscose fiber with closely resembling serimetric properties gave identical sorption isotherms.

2374. Wiegerink, James G. **The moisture relations of textile fibres at elevated temperatures.** *Textile Research* **10**, 357-371 (1939-40).

Data were obtained for both "desorption" and "adsorption," the yarns being brought to equilibrium from a wet condition and a dry condition, resp. The fibres studied were raw cotton, "purified" cotton, mercerized cotton, clothing wool, carpet wool, viscose rayon, cuprammonium rayon, raw silk, degummed silk and cellulose acetate. The temperatures ranged from 96°F to 302°F and the relative humidities ranged from 5% to 90% for temperatures below 212°F and up to the maximum obtainable at atmospheric pressure above 212°F.

2375. Goodings, A. C. and Turl, L. H. **The density and swelling of silk filaments in relation to moisture content.** *J. Textile Inst.* **31**, T69-80 (1940).—*C.A.* **35**, 3822^{2}.

The regain of degummed white Japanese silk was measd. at 25°C under both adsorption and desorption conditions for relative humidities ranging from dryness to satn. Measurements were made on small bundles of yarn hung on a quartz spiral in a closed chamber having controlled relative humidity. The density measurements were made on the same silk (benzene was used) at moisture contents ranging from dryness to satn. The longitudinal swelling of the filaments accompanying moisture absorption was also measd.

2376. King, G. and Cassie, A. B. D. **Propagation of temperature changes through textiles in humid atmospheres. I. Rate of absorption of water vapor by wool fibers.** *Trans. Faraday Soc.* **36**, 445-53 (1940).—*C.A.* **34**, 4276^{7}.

The time necessary to equilibrate with water vapor was entirely dependent on the rate of loss of the heat of adsorption. A temp. of 65°C was observed in the wool 30 sec after the introduction of the water vapor; a rise of 80°C was not inconsistent with the cooling curve observed. By correcting for the effect of the heat of adsorption it was found that the wool attained equil. in a time less than 15 sec.

2377. Sakai, Wataru. **Urea. III. The hygroscopicity of urea and inorganic salts.** *J. Soc. Chem. Ind., Japan* **43**, Suppl. binding 190 (1940).—*C.A.* 34, 7684^{6}.

The hygroscopicity of urea was compared with inorg. salts such as K and NH_4 salts by means of the stationary air method at 15°C under various degrees of humidity. Under suitable conditions, especially of surface and of soly. of the solid, urea could be nonhygroscopic.

2378. Sheppard, S. E., Houck, R. C., and Dittmar, C. **Structure of gelatin sols and gels. VI. Adsorption of water vapor and the electrical conductivity.** *J. Phys. Chem.* **44**, 185-207 (1940).—*C.A.* **34**, 2680^{4}.

Two types of gelatin were used: ash-free "lime-processed" calfskin gelatin (isoelec. point at pH 4.8) and ash-free "acid-processed" pigskin gelatin (isoelec. point at pH 8.2). The samples were used in the form of skins or films obtained by coating cellulose-nitrate surfaces with the gelatin soln. and then stripping off the gelatin skins. The sorption isotherms were curves of double flexure, resembling those obtained with cotton, cellulose wool, silk and other fibrous materials.

2379. Spoelstra, H. J. and Berenschot, G. H. **Moisture absorption and moisture loss in roselle and jute bags.** *Arch. Suikerind. Nederland en Ned.-Indie* **1**, 423-7 (1940).—*C.A.* **35**, 1232^{5}.

There was no difference in lab. expts. between the 2 kinds of material, either in the form of fiber or finished textile.

2380. TIBILOV, S. P. **Adsorption of organic vapors on organic adsorbents and the quenching of fluorescence.** *J. Phys. Chem. (U.S.S.R.)* **14**, 942-63 (1940).—*C.A.* **35**, 3873^4.

Vapors of quinone, nitrobenezene, $(CH_3)_2$-aniline, aniline and biacetyl were studied in the quenching of palmitic acid fluorescence. The intensity of fluorescence of all these adsorbents was greatest around 400 mμ and decreased to nearly zero around 600 mμ.

2381. STAMM, ALFRED J. AND MILLETT, MERRILL A. **Internal surface of cellulosic materials.** *J. Phys. Chem.* **45**, 43-54 (1941).—*C.A.* **35**, 1985^8.

Microscopical measurements, sorption of gases (CO_2, SO_2, NH_3, HCl), heats of swelling, adhesion tension of H_2O, and the selective adsorption of a solute (stearic acid, phenol) from soln. were detd. Wood (pine and spruce), various types of paper, cellulose acetate yarn and sulfite pulp were studied. Systems in which the cell walls were not swollen gave surfaces of about 2×10^3cm²/g and those in which the cell walls were swollen gave surfaces of about 3×10^6cm²/g.

2382. BABBITT, J. D. **Adsorption of water vapor by cellulose.** *Can. J. Research* **20A**, 143-72 (1942).—*C.A.* **37**, 16^9.

Adsorption on cotton was similar to that on wood, except that internal surface area available was less by a factor of 1.86. When the available heats of adsorption were plotted against the relative humidity there was no appreciable difference between cotton and wood. There was an excess of internal energy in the adsorbed state over that of the liquid state.

2383. BARKAS, W. W. **Wood-water relationships. VII. Swelling pressure and sorption hysteresis in gels.** *Trans. Faraday Soc.* **38**, 194-209 (1942).—*C.A.* **36**, 6872^7.

The hysteresis found in the isotherms of vapor pres. against moisture content of gels was based on the plasticity resulting from residual hydrostatic stresses. If during natural swelling a gel was subjected to restraints of such a type that shear stresses were called into play, then the plasticity induced hysteresis. If the applied restraints were purely compressive, no sorption hysteresis resulted, but the equil. values of H_2O content at any vapor pres. were lower than those of the free gel.

2384. CALVET, EDOUARD. **The constitution of gels of nitrocellulose and acetone.** *Ann. faculté sci. Marselle* **16**, 17-35 (1942).—*C.A.* **41**, 2303^b.

Acetone absorbed by nitrocellulose was not fixed on the NO_2 groups. Ordinary cellulose in the form of absorbent cotton (or cotton for nitration) would absorb acetone. The heat evolved per g of acetone was about 80 cal/g as with nitrocellulose.

2385. FREY-WYSSLING, A. AND SPEICH, H. **The permeability of cellulose fibers.** *Helv. Chim. Acta* **25**, 1474-84 (1942).—*C.A.* **37**, 6451^2.

Bleached, dried-ramie fibers were immersed in pure liquids for 24 hrs at 20°C and the birefringence of the fibers was detd. For lipophilic liquids (such as C_6H_6 or toluene), it was concluded that these liquids did not permeate the fibers. CO_2H groups in cellulose favored the adsorption of N-bases; such groups were absent in starch and the N-bases did not permeate starch grains.

2386. HINTZE, O. E. **Water absorption by paint surfaces in relation to pigment content.** *Fett u. Seifen* **49**, 332-9 (1942).—*C.A.* **37**, 6910^9.

The amt. of pigment had little effect on the H_2O absorption of films which contained (1) urea resins or glycerides of fatty acids having conjugated double bonds and which were very flexible, (2) compds. of a decided hydrocarbon character such as polyisobutylene, polystyrene, chlorinated rubber, asphaltic materials, (3) esters of mineral acids such as nitrocellulose or polyvinyl chloride, (4) polymers with carbonyl groups in which the latter were adjacent to a tertiary C atom, such as polymethacrylic acid ester.

2387. IGUCHI, MASAAKIRA. **Catalytic oxido-reduction by some metallic complex salts. XIX. The oxygen absorption of the cobalt cyanide-amine complexes.** *J. Chem. Soc. Japan* **63**, 1743-51 (1942).—*C.A.* **41**, 3353*b*.

The absorption of O_2 by the Co complex of CN, ethylenediamine, and triethanolamine was studied at 25°C with the Warburg manometer. The rate of absorption was expressed by a curve in each case.

2388. IGUCHI, MASAAKIRA. **Catalytic oxido-reduction by some metallic complex salts. XX. Catalytic reduction of sodium cinnamate and isatin by cobalt cynamide complex salt.** *J. Chem. Soc. Japan* **63**, 1752-4 (1942).—*C.A.* **41**, 3353*c*.

The absorption of H_2 by the system $CoCl_2KCN$ increased when the system contained Na cinnamate or isatin.

2389. KRISCHER, OTTO. **Heat and mass transfer in drying. The analytical and graphical treatment of the drying of porous hygroscopic materials.** *Forsch. Gebiete Ingenieurw.* **13**, *Ausgabe B, Forschungsheft* No. **415**, No. 4, 22 pp. (1942).—*C.A.* **37**, 6164^2.

The general case of drying was discussed where moisture could diffuse as liquid as well as a vapor while heat transfer could take place by conduction as well as direct internal heating. Numerical examples were presented for rayon and wool.

2390. LOWRY, H. H. **Relation of the physical constitution of coal to its chemical characteristics.** *J. Geol.* **50**, 357-84 (1942).—*C.A.* **37**, 743^5.

Extensive studies, employing solvent analysis, thermal decompn., oxidation, reduction and other methods, have failed to establish fundamental chem. differences corresponding to the recognized petrographic entities in coal.

2391. NICKERSON, R. F. **Structure, properties and utilization of cotton.** *Ind. Eng. Chem.* **34**, 1149-54 (1942).—*C.A.* **36**, 7326^2.

The concept of H-bonding between cellulose chains and between internal-fiber surfaces was used as a working hypothesis to interpret the properties and phenomena exhibited by cotton and its derivs. The effects of moisture, heat, stresses and time were emphasized.

2392. ONUSAǏTIS, B. A. **Sorption ability and the colloidal structure of coal.** *Bull. acad. sci. U.R.S.S., Classe sci. tech.* **1942**, No. 5-6, 17-28.—*C.A.* **38**, 4404².

Typical Donbass coals were studied in respect to sorption of water vapor, with the investigation of changes of porosity and sorption capacity after heating to 280°C at atm. pressure and in vacuo. The results confirmed the colloidal nature of the coal and the caking process.

2393. SIMRIL, V. L. AND SMITH, SHERMAN. **Sorption of water by cellophane.** *Ind. Eng. Chem.* **34**, 226-30 (1942).—*C.A.* **36**, 1830⁴.

Four sorption isotherms at temps. from 16.5° to 49.5°C were given for generated cellulose in the form of cellophane. ΔH, ΔF and ΔS values calcd. for the intermediate temp. range showed a low entropy (high ΔS) for the H_2O at low moisture contents. The entropy of the sorbed water on desorption was lower than that on adsorption at all moisture contents. The hysteresis loop was interpreted on the basis of the entropy of the sorbed water.

2394. WELTZIEN, W.; WINDECK-SCHULZE, K., AND PIEPER, J. **The measurement of the absorption of moisture by textiles.** *Zellwolle, Kunstseide, Seide* **47**, 57-67 (1942).—*C.A.* **37**, 4254⁹.

The samples (1 g) were first degreased with CH_3OH, dried at 85°C and washed twice with water. The flask contg. the sample was placed in a vessel used as a thermostat and the basket was suspended on a torsion balance by means of a long wire. After the weighing the sample was dried *in vacuo* over P_2O_5 and the moisture was calcd. to 100 g of absolutely dry fibers. A no. of rayons, loose staple rayons and staple-rayon fabrics thus tested yielded values of 13-15% for the absorption of moisture and approx. 1.5% higher values for the emission of moisture at 65% relative atm. humidity and 25°C.

2395. FLORY, PAUL J. AND REHNER, JOHN JR. **Statistical mechanics of cross-linked polymer networks. I. Rubberlike elasticity. II. Swelling.** *J. Chem. Phys.* **11**, 512-20; 521-6 (1943).—*C.A.* **38**, 291⁹.

A model was proposed for the structure of a cross-linked network which was amenable to statistical treatment. Expressions were derived for the structural entropy of the network, and for the entropy change on deformation. The max. degree of swelling of the network in contact with the pure solvent was related to the degree of cross-linking. The swelling capacity should have been diminished by the application of an external stress.

2396. KRISCHER, OTTO. **Thermodynamics of the drying of solid bodies.** *Chem. Tech.* **16**, 117-21, 129-32 (1943).—*C.A.* **38**, 5705³.

In drying wood which was to be free from cracks and strains the lowest possible moisture gradient was desirable. This could be attained by high-frequency drying, in which the interior of the piece was heated while the outside was cooled. It could also be attained by intermittent vacuum drying, in which the heat stored in the material was used for the evapn.

2397. MÜLLER, F. HORST. **A simple, rapid method for the determination of the maximum water absorption by substances, with special application to small absorption values and small test samples.** *Kolloid-Z.* **105**, 16-20 (1943).—*C.A.* **38**, 4491².

The sample, evacuated to low pressures, was first connected to a flask contg. pure H_2O. After equil., the moist sample was connected to a vessel immersed in a liquid-air bath. Afterward the H_2O from the sample condensed in the cold bath was removed and the vessel allowed to warm to room temp. The pressure was read on a Hg manometer, and from the known vol. of the vessel the wt of H_2O was detd. by the gas law. Typical results for the H_2O uptake were polystyrene 0.15-0.20%, Vinifol 0.3-0.4%, cellulose triacetate 6-10%.

2398. MURPHY, E. J. **Gases evolved by the thermal decomposition of paper.** *Trans. Electrochem. Soc.* **83**, 12 pp. (1943).—*C.A.* **37**, 4570³.

Curves were given to show the rate of evolution of gas by the thermal decompn. of paper as a function of time and also the dependence of rate on temp. The temp. dependence was in approx. agreement with the Arrhenius formula for reaction velocities. The gases evolved consisted of H_2O, CO_2 and CO; H_2O vapor was the most prominent constituent.

2399. TANIGUCHI, MASAKATSU AND HOSONO, MASAO. **Moisture adsorption by cellulose acetate.** *J. Soc. Chem. Ind. Japan* **46**, 1103-5 (1943).—*C.A.* **42**, 6531*a*.

Air-dry pulverized cellulose acetate did not reach equil. in 24 hrs at 25°C in an atm. of 95% relative humidity; a film prepd. from Me_2CO soln. reached equil. in 3 hrs. The degree of solvation of the film affected its adsorption of moisture; e.g., a film contg. 8.1, 3.2, and 0.1% Me_2CO adsorbed 2, 8.2, and 12.2%, resp., of moisture when equil. was reached.

2400. THIES, F. H. **Improvements in defining tension measurements. VI. Employment of surface-area refinements.** *Allgem. Textil-Z.* **1**, 11-13 (1943).—*C.A.* **39**, 420².

Textile techniques were discussed. The changes in fiber lengths and thickness during refining and the mode of action, which was demonstrated in the refining process, were explained.

2401. AMERONGEN, G. J. VAN. **A modified method for the direct estimation of the sorption of oxygen by rubber.** *Mededeel. Kunststoffeninst. Rubber-Stichting, Delft* No. **39**, 8 pp. (1944) *Rubber Chem. Tech.* **19**, 170-5 (1946) (in English).—*C.A.* **40**, 2674⁹.

The adsorption of O_2 by rubber could be read directly and made roughly 4 times as quickly as by a manometric method. Measurements of raw rubber, Buna-S, and gutta-percha (with and without antioxidants) at 80°C and of vulcanized rubber and Perbunan at 80°C, 90°C, and 100°C were tabulated. The rate was 2-3.5 times as great in O_2 as in air, i.e. roughly proportional to the sq root of the O_2 pressure.

2402. AMERONGEN, G. J. VAN . **The permeability of rubberlike substances to gases.** *Communication* No. **46**, *Rubber Stichting: Rev. gén. caoutchouc* **21**, 50-6 (1944).—*C.A.* **40**, 3924⁴.

The permeability of various elastomers were detd: H_2 to natural rubber, Buna-S, methylrubber, Perbunan, Neoprene G, Neoprene E, Koroseal, Oppanol B-200, Mipolam-MP, Thickol-B, Pliofilm, Triacel, cellophane, and gutta-percha; CO_2 to natural rubber, Buna-S, methylrubber, Perbunan, Neoprene G, Koroseal, Oppanol B-200, Mipolam-MP and Thiokol-B. With increase in the percentage of combined S in natural rubber, the permeability decreased progressively.

2403. Bull, Henry B. **Adsorption of water vapor by proteins.** *J. Am. Chem. Soc.* 66, 1499-1507 (1944).—*C.A.* 38, 6156^1.

Data were given for the rate of loss and gain of wt of gelatin, albumin and wool over H_2SO_4 and the effect of temp. on the moisture content of gelatin, albumin and wool in a vacuum oven. The H_2O adsorbed as a function of the relative pressure at 25° and 40°C was detd. for nylon, unstretched and stretched; silk; wool; *b*-zein; *c*-zein; salmin; elastin; collagen; gelatin; egg albumin lyophilized; unlyophilized and heat-coagulated; β-lactoglobulin lyophilized and wet crystals; serum albumin; α- and β-pseudoglobulin and γ-pseudoglobulin. The B.E.T. theory described water adsorption by proteins in a very satisfactory manner.

2404. Carson, Frederick T. **Effect of humidity on physical properties of paper.** *Natl. Bur. Standards (U.S.)*, Circ. No. C445, 12 pp. (1944).—*C.A.* 38, 3125^9.

A review was given of the changes in the phys. properties of paper with change in the hygrometric environment.

2405. Cleland, J. E. and Fetzer, W. R. **Moisture-absorptive power of starch hydrolyzates.** *Ind. Eng. Chem.* 36, 552-5 (1944).—*C.A.* 38, 4147^2.

The hydrolyzates dispersed on diatomaceous silica with 83.4 and 90.7% reducing sugars (as dextrose) had approx. the same equil. values after 150 hrs as invert sirup (42% H_2O at 78% relative humidity); glycerol absorbed approx. 70% more H_2O (70% H_2O at 78% relative humidity). The max. H_2O absorption of diatomaceous silica was 0.13% H_2O at 78% relative humidity, 0.63% H_2O at 100%.

2406. Doty, Paul M.; Aiken, W. H., and Mark, H. **Water-vapor permeability of organic films.** *Ind. Eng. Chem., Anal. Ed.* 16, 686-90 (1944).—*C.A.* 39, 854^8.

An app. for detn. of water-vapor permeability was described. It was also possible to measure the value of 2 consts., soly. coeff. and diffusion velocity, which together det. the vapor permeability of film. The dependence of permeability on film thickness, vapor pressure and temp. was discussed.

2407. Glückauf, E. **Permeability of adsorbing substances.** *Nature* 154, 831-2 (1944).—*C.A.* 39, 1097^4.

The adsorption of water vapor by keratin and by cellulose was explained by assuming 2 or more states of adsorption, in which the adsorbed mols. had markedly different mobilities. Fick's law applied only to the concn. of the mobile part, which attained appreciable values only at higher concns. of total water.

2408. Hermans, P. H. and Vermaas, D. **Velocity of penetration of water and glycerol in cellulose threads.** *Kolloid-Z.* 109, 5-9 (1944).—*C.A.* 41, 3291g.

The absorption of H_2O by dry cellulose fibers was observed by optical means. After a time a sharply defined line was detected along the periphery of the fiber which indicated the distance penetrated by the H_2O. In absolutely dry cellulose, H_2O penetrated very slowly. In cellulose which contained some moisture, the diffusion velocity increased with the 4th or 5th power of the equil. moisture in the fiber. Glycerol penetrated the cellulose fiber only when the latter was in equil. with a relative humidity of at least 40%.

2409. Hermans, P. H.; Hermans, J. J., and Vermaas, D. **Density and refractivity of cellulose fibers.** *Kolloid-Z.* 109, 9-16 (1944).—*C.A.* 41, 3291*b*.

The best interpretable d. values were obtained with liquids which did not penetrate the fiber substance. It was doubted if the d. values obtained in the He voluminometer were the true values. The d. measurements of natural (bleached cotton, standard cotton, α-pulp, Bemberg rayon) and synthetic (viscose) fibers in CCl_4 were correlated with the refractive properties of these fibers. There was close relationship between the d. percentage cryst. material, and sorption capacity of the fiber for H_2O.

2410. Hermans, P. H.; Vermaas, D., and Hermans, J. J. **Cellulose-water system. I. Space arrangement in the cellulose-water system and the degree of packing of cellulose fibers.** *J. makromol. Chem.* 1, 247-90 (1944).—*C.A.* 40, 201^7.

The distribution of H_2O within the hollow spaces of the fiber was used to interpret the d. data derived from x-ray analysis. The modified concept was used also for the evaluation of water-vapor sorption and desorption data of the model filaments.

2411. Hermans, P. H.; Hermans, J. J., and Vermaas, D. **System cellulose-water. III. Dependence of the optical properties of cellulose fibers on their water content.** *Kolloid-Z.* 109, 86-90 (1944).—*C.A.* 41, 3291*e*.

The influence of the moisture content on the double refraction of cellulose fibers could be evaluated quantitatively by the same simple equation developed for the effect of moisture on the refractive capacity of isotropic cellulose fibers. Good agreement was obtained between the phys. behavior of the cellulose-water systems and those of much simpler binary systems, such as H_2SO_4-H_2O.

2412. Lauer, K. **Cellulose fibers. V. Sorption of organic vapors by cellulose fibers.** *Kolloid-Z.* 107, 86-8 (1944).—*C.A.* 39, 183^4.

The adsorption isotherms of purified cotton for the org. liquids deviated from the S-shaped isotherm for H_2O. Nevertheless, the adsorption isotherms for MeOH and EtOH reflected the overlapping of adsorption and swelling phenomena, though in a different order. In contrast, propanol, isopropanol and butanol, as well as benzene, toluene, paraffin hydrocarbons, CCl_4 and $CHCl_3$, produced pure adsorption isotherms without involving swelling phenomena. Similar results were obtained with viscose rayons.

2413. MATTHES, A. **Theory of the swelling process in gels. Gel structure of artificial fibers from regenerated cellulose. II.** *Kolloid-Z.* **108**, 79-94 (1944).—*C.A.* **40**, 7609⁹.

The swelling of cellulose hydrate was considered a special case of adsorption, and was discussed at length, following a consideration of the sorption isotherms of active charcoal and cellulose hydrate. Sorption in the case of cellulose hydrate was ascribed to H_2O (a) held in solid soln., (b) held by adsorption, and (c) condensed in the capillaries of cellulose hydrate. The difference in adsorption and desorption isotherms was a measure of the no. of free points at which H_2O can be held.

2414. RIEHL, N. **The diffusion of gases through rubber membranes.** *Kolloid-Z.* **106**, 201-6 (1944).—*C.A.* **38**, 5710⁶.

Thin rubber membranes with a thickness of several hundredths mm when dried over P_2O_5 were highly permeable to all gases. This permeability was immediately reduced by several powers of 10 if the rubber was allowed to absorb even traces of moisture. On cooling to −57°C the permeability became many times greater than at ordinary temp.

2415. SHEPPARD, S. E. AND NEWSOME, P. T. **Electrical anisotropy of xerogels of hydrophile colloids. I.** *J. Chem. Phys.* **12**, 244-8 (1944).—*C.A.* **38**, 3894³.

Polyvinyl alc., gelatin, cellulose acetate (24.5% acetyl), polyvinyl acetal, hydrolyzed polyvinyl acetate, vinylite X, cellulose acetate (40% acetyl), cellulose nitrate, polyvinyl acetate, and polystyrene were coated in sheet form and "fibered" internally by stretching to 100% or more elongation. Circular disks were cut from the fibered sheets, and their degree of orientation was measured in an alternating elec. field.

2416. SPEAKMAN, J. B. **Analysis of the water adsorption isotherm of wool.** *Trans. Faraday Soc.* **40**, 6-10 (1944).—*C.A.* **38**, 3529¹.

The water adsorbed by wool appeared to be of 3 types: (1) that which combined with hydrophilic side chains with great evolution of heat (5.8 kg-cal per mol. of α-water adsorbed); (2) loosely bound β-water, which was responsible for the fall in rigidity of wool during water adsorption; (3) water condensed at relative humidities greater than 80%. Apart from capillary-condensed water, the total amt. of H_2O adsorbed by wool at different humidities was given by the equation $A = 0.1012\ H^{0.395} + 0.0002754\ H^{1.78}$.

2417. YEE, J. Y. AND DAVIS, R. O. E. **Accelerated method for determining moisture absorption.** *Ind. Eng. Chem. Anal. Ed.* **16**, 487-90 (1944).—*C.A.* **38**, 5351².

In a special humidity chamber with forced air circulation, the sample dishes were suspended from the top of the chamber. There was good agreement and reproducibility of results on duplicate samples in different chambers. Under identical conditions as much moisture was found to be absorbed during 4 hrs in the accelerated method as was absorbed in 24 hrs with a static method.

2418. AIKEN, W. H.; DOTY, PAUL M., AND MARK, H. **Water-vapor permeability—what it is and how it works.** *Modern Packaging* **45**, No. 12, 137-40, 166, 168 (1945).—*C.A.* **39**, 5125³.

The structure of film-forming materials, the measurement of permeability to water vapor, the permeability const., and the effect of plasticizers on the permeability consts. were discussed. Data were given for cellophane, Pliofilm, polyethylene, Saran, polyvinyl chloride-acetate copolymer VYNW, 3-ply glassine, ethylcellulose, polyvinyl chloride, rubber, and polystyrene.

2419. CALVET, J.; DALBERT, R., AND CHÉDIN, J. **Gelatinization phenomena: calorimetric study of the absorption of acetone by the Bakelites.** *Mém. services chim. état (Paris)* **32**, 220-39 (1945).—*C.A.* **42**, 4390*e*.

In unpolymerized phenolics the phenolic function alone explains the heat liberated by the absorption of Me_2CO. In polymerized phenolics the heat liberated at the start of absorption of Me_2CO (100 cal per g) is more than that accounted for by the –OH groups (71 cal). It is equal, however, to that accounted for by the two groups –OH (71 cal) and $-CH_2-$ (26.2 cal). The two groups have an independent and additive attraction for Me_2CO.

2420. KING, G. **Sorption of vapors by keratin and wool.** *Trans. Faraday Soc.* **41**, 325-32 (1945).—*C.A.* **39**, 5150⁵.

The rates of absorption and desorption of H_2O, MeOH, and EtOH were detd. on wool and horn keratin. The diffusion in these cases was the rate-controlling process. The rate was approx. linear. The diffusion coeff. (cm^2/sec) was estd.: water on horn, from 7.5×10^{-9} to 9.0×10^{-9}; MeOH on wool, 1.7×10^{-10}; MeOH on horn, 2.2×10^{-10}; EtOH on wool, from 3.6×10^{-12} to 11.6×10^{-12}. It was impossible to remove the last 6% of MeOH or EtOH from wool fibers.

2421. KING, G. **Permeability of keratin membranes to water vapor.** *Trans. Faraday Soc.* **41**, 479-87 (1945).—*C.A.* **40**, 786⁷.

The rate of diffusion of H_2O vapor through a horn keratin membrane was detd. at 20°, 25°, and 30°C and vapor pressure gradients from 10 to 95% relative humidity. The diffusion coeff. was a function of H_2O concn. and temp., and was to a large extent, independent of the elasticity of the keratin lattice.

2422. PAL'VELEV, V. T. **Sorption of methane by Don Basin coals under high pressures.** *Bull. acad. sci. U.R.S.S., Classe sci. tech.* **1945**, 578-91 (in Russian).—*C.A.* **41**, 2553*d*.

The equil. amt., reached after over 100 hrs of sorption, was roughly 2 cc. CH_4/g coal, at 25°C. From 100 to 150 kg/cm² upwards, sorption of CH_4 remained at a const. max. level independent of further rise of pressure; e.g., at 25, 75, 150, 500, 900 kg/cm² the amts. of sorbed CH_4 were 9, 12, 15, 15, 16 cc./g. That CH_4 was adsorbed, not absorbed, followed from the rapidity of establishment of equil., which was reached in a few min. Below 100 kg/cm², most of the CH_4 in coal was adsorbed; above 100-200 kg/cm², the amt. of compressed free gas exceeded adsorbed gas.

2423. REES, W. H. **Some experiments on the evaporation of water from a plane surface.** *J. Textile Inst.* 36, T165-8 (1945).—*C.A.* 39, 5494^2.

A method was described for measuring the effect of fabrics on the rate of evapn. of water from a moist surface with which they were in contact. In general, single layers of scoured and bleached samples had little effect of rate of evapn. from the bare porous plate. Waterproofed fabrics, however, greatly decreased the rate of evapn. With 2 layers of a scoured fabric, the rate was greater than for one layer.

2424. SOLOMON, M. E. **Use of cobalt salts as indicators of humidity and moisture.** *Ann. Applied Biol.* 32, 75-85 (1945).—*C.A.* 39, 5140^8.

Paper impregnated with cabaltous salts offered a simple procedure for measuring humidity in small spaces. $CoCl_2$ was blue at low humidities, pale red at high humidities, with a graded series of lilac colors between. Correspondence between color and relative humidity was close, though the color was influenced slightly by temp.

2425. THOMAS, A. MORRIS AND GENT, W. L. **Permeation and sorption of water vapor in varnish films.** *Proc. Phys. Soc. (London)* 57, 324-49 (1945).—*C.A.* 40, 1678^3.

Both the permeability and sorption of the films were detd. at const. moisture concns., that is, by using streams of moist air, the amts. permeating and the amts. sorbed being directly weighed. In addn. to moisture permeability, some measurements of that of H_2 and CO_2 were reported. The exptl. results could be interpreted by assuming that the diffusion process was analogous to that of substances in soln. The results for CO_2 and H_2 indicated that the diffusion process was dependent on the microphys. properties of the film.

2426. ZHURKOV, S. N. AND LERMAN, R. I. **Effect of the volume sorption of vapors on the solidification temperature of polymers.** *Compt. rend. acad. sci. U.R.S.S.* 47, 106-9; *Doklady Akad. Nauk. S.S.S.R.* 47, 109-12 (1945).—*C.A.* 40, 4277^8.

Characteristic S-shaped curves were obtained by plotting the log of the high elastic modulus E vs. temp. When the polymers were swollen in the vapors of org. solvents they gave identically shaped log E vs. temp. curves, but at a lower temp. It was found for 4 polymers, butadiene-acrylonitrile, polymethylacrylate, butadiene rubber, and polyisobutylene, that the lowering in temp. of solidification ΔT after swelling with any of 30 different solvents was a linear function of the no. of sorbed mols.

2427. ZHURKOV, S. N. **The effect of volume sorption of the mechanical properties of polymers.** *Compt. rend. acad. sci. U.R.S.S.* 49, 198-201 (1945) (English summary).—*C.A.* 40, 4278^2.

The effect of absorption of MeOH, EtOH, BuOH, acetone, and water on the elastic properties of cellulose acetate (28% free hydroxyl in fibers 20 μ in diam. and 1 m long) was detd. The quantity of vapor absorbed was measured by means of a spring balance having a quartz spiral. The observations obeyed the following equation: $E = E_0 - K(C/M)$, where E and E_0 were the elasticity moduli of the fiber in the dry and swollen states, resp., K was a const. equal to 1.37 to 1.4 for the above solvents, taking $M = 2 \times 18$ for H_2O, and (C/M) was the molar concn. of absorbate in the fiber.

2428. AMERONGEN, G. J. VAN. **Permeability of different rubbers to gases and its relation to diffusivity and solubility.** *J. Applied Phys.* 17, 972-85 (1946).—*C.A.* 41, 878^h.

The soly. of the gas was calcd. from the permeability and the diffusivity, and was also detd. by direct measurement. H_2, O_2, N_2, CO_2, CH_4, NH_3, SO_2 and He were tested at 5 temps. between 17° and 50°C with natural rubber, Buna-S, Perbunan, Neoprene-G, Oppanol B-200, Butadiene rubber, Methyl rubber, Mipolam-Mp, and Thiokol-B. Differences in permeability were caused by differences in soly. and rates of diffusion.

2429. CARSON, F. T. AND WORTHINGTON, VERNON. **Water-vapor-permeability tester.** *Paper Ind. Paper World* 27, 1799-1805, 1816 (1946).—*C.A.* 40, 3942^7.

The hygrometric conditions were maintained by equil. with a satd. soln, of an appropriate salt. The temp. of this soln. and of the testing chamber was held const. by means of an envelope of moving air that completely surrounded the testing chamber, an open-coil heater, and a thermoregulator used to control the temp. of this air bath. Devices for supporting and weighing the permeability cells in the cabinet, without disturbing the hygrometric conditions, were explained in detail.

2430. CASSIE, A.B.D. **Water absorption of keratin.** *Soc. Dyers Colourists, Symposium on Fibrous Proteins* **1946**, 86-95.—*C.A.* 41, 1529*c*.

The sorption isotherm and measured heat effects required the absorption at high regains to be due to an increase of entropy. This eliminated capillary condensation and potential theories which ascribed absorption to a decrease in the heat content of the system without increase of entropy. The isotherm was analyzed by means of an appropriate multimol. absorption theory, and the water-attracting groups in keratin (—CO—) gave the energy of bonding of the water to the groups of 6.6 kg-cal per mol. The increase in entropy due to absorption of water required the sorbed water to be present as discrete clusters, which seemed inconsistent with the water-repellency of cut horn keratin surfaces.

2431. CREUTZ, E. C. AND WILSON, ROBERT R. **Absorption of water by films of cellophane and polyvinyl alcohol.** *J. Chem. Phys.* 14, 725-8 (1946).—*C.A.* 41, 2302^h.

The absorption of water and dehydration of the these films was found to obey a diffusion equation by means of which a diffusivity may be defined. A rapid change in water content immediately after changing the ambient conditions suggested the presence of adsorbed surface layers. The total absorption was found to increase faster than the relative humidity.

2432. DOTY, PAUL M. **The diffusion of vapors through polymers.** *J. Chem. Phys.* 14, 244-51 (1946).—*C.A.* 40, 3961^3.

Available data on the permeability of gases through polymers showed that for a given gas there was a linear relation between log *Po* and *E* (the energy of activation for permeation). The effect of plasticization on permeation of water vapor was studied exptly. Lowering of the heat of soln. was the predominant effect. From the data, the entropy of soln. can be calcd. and interpreted as showing that water mols. dissolved in the unplasticized polymer exhibited much less freedom than when they were dissolved in plasticized polymer.

2433. DOTY, PAUL M.; AIKEN, W. H., AND MARK, H. **Temperature dependence of water-vapor permeability.** *Ind. Eng. Chem.* **38**, 788-91 (1946).—*C.A.* **40**, 5618^{3}.

The temp. was varied from -10° to 80°C, and measurements with 10 polymer films were made of the rate of moisture transfer, vapor-pressure driving force, film area, and film thickness. In all cases, an exponential dependence of permeability on temp. was shown to exist. Vapor transfer involved the processes of soln. of water mols. at the wet side of the film, movement by diffusion and possibly capillarity through the film, and evapn, at the dry side of the film.

2434. HAILWOOD, A. J. AND HORROBIN, S. **Absorption of water by polymers. Analysis in terms of a simple model.** *Trans. Faraday Soc.* **42B**, 84-92, discussion 94-102 (1946).—*C.A.* **42**, 7134*e*.

The model chosen was that of a two-phase system consisting of H_2O vapor and a solid soln. of H_2O in the polymer. The solid soln. contained hydrates formed between the H_2O and definite units of polymer, which hydrates were prevented by their immobility from forming any new phase. An equation giving sigmoid isotherms was derived from this model. Good agreement was obtained between this equation and published data for wool, hair, silk, nylon, and cotton.

2435. HERMANS, P. H. AND WEIDINGER, A. **The hydrates of cellulose.** *J. Colloid Sci.* **1**, 185-93 (1946).—*C.A.* **40**, 6810^{6}.

Cellulose hydrate was formed from "mercerized" cellulose by a process of intramicellar swelling. Native cellulose did not show intramicellar swelling. In the sorption of H_2O by cellulose, "mercerized" cellulose formed cellulose hydrate and "water cellulose," whereas native cellulose did not take part in the sorption process.

2436. KING, G. **Molecular rotation in keratin.** *Nature* **158**, 134 (1946).—*C.A.* **40**, 6319^{5}.

The effects of the sorption of H_2O, MeOH, and HCHO on the dielec. const. and on the reduction of relative rigidity of keratin were shown graphically. Equimolar amts. of H_2O and MeOH had about the same effect (up to 0.7 moles per 100 g keratin); HCHO was much more effective in the same concn. range.

2437. KOCH, H. **Relationships between the moisture content of textiles and the relative atmospheric humidity during absorption and desorption. Hysterises of swelling.** *Schweiz. Arch. angew. Wiss. Tech.* **12**, 176-84 (1946).—*C.A.* **40**, 6822^{7}.

Data were given for the absorption and desorption of hydrate cellulose.

2438. MACMILLAN, W. G.; MUKHERJEE, R. R., AND SEN, M. K. **The moisture relationships of jute. I. Adsorption isotherm and heat of wetting.** *J. Textile Inst.* **37**, T13-24 (1946).—*C.A.* **40**, 6281^{4}.

Adsorption and desorption isotherms for tossa (Corchorus olitorius) and white (C. capsularis) jute, detd. at 70°F (21°C), showed that the tossa was more hygroscopic than the white. Heating for 4 hrs at 110°C diminished the hygroscopicity. The heats of wetting of jute, wool, and cotton were measured and the data discussed. The regain values of jute for different humidities at 21°, 30°, 40°, and 50°C were tabulated. Between 40 and 85% relative humidity, a decrease of 0.5% regain for each 10° rise was noted.

2439. MCBAIN, JAMES W.; MYSELS, KAROL J., AND SMITH, GEROULD H. **Studies of aluminum soaps. VII. Aluminum soaps in hydrocarbons. The gels and jellies and transformations between them.** *Trans. Faraday Soc.* **42B**, 173-80 (1946).—*C.A.* **42**, 9208*e*.

The soaps were the dilaurate, distearate, dioleate, dinaphthenate (av. mol. wt of acid, 210), and monolaurate of Al, and the solvents were isooctane, heptane, cyclohexane, and benzene. Visual observation of the phases in evacuated glass tubes was supplemented by data obtained by x-ray diffraction, osmometry, viscosimetry, measurements on the McBain-Bakr sorption balance, and detns. of the mech. properties. Gels (i.e. discontinuous systems of cryst. soap, more or less swollen, and frequently intermeshed with sol or jelly) and Jellies (i.e. one-phase, homogeneous, transparent, isotropic, elastic systems) bridge the gap between dry cryst. Al soaps and their sols in hydrocarbons.

2440. MITTON, R. G. **Absorption of water vapor by chrome-tanned leather.** *J. Intern. Soc. Leather Trades Chem.* **30**, 330-4 (1946).—*C.A.* **41**, 876^{h}.

Samples of calf leather, Cr-tanned and mold-proofed with phenylmercuric nitrate but not fat liquored, colored or finished, were exposed to relative humidities from 0 to 98.8% at 21°C for 3 months. For the absorption curve the samples were preconditioned at 0% relative humidity for 3 months. These samples contained about 2.5% H_2O, as calcd. by math. extrapolation to infinite time of an exptl. drying curve continued to 16 months. For the desorption curve, the samples were preconditioned 3 months at 98.8% relative humidity.

2441. MUSSO, POMPILIO. **Water absorption by foils of plasticized Vipla.** *Materie plastiche* **12**, 26-31 (1946).—*C.A.* **40**, 6877^{5}.

Foils (polyvinyl chloride 60% and plasticizer 40%) were prepd. 10 × 2 × 0.05 cm (surface 41.2 cm^2) and were weighed after 3 days storage. Each was immersed in 100 cc. of H_2O of 20°, 50°, and 70°C and the wt increase observed after 1, 3, 5, 7, 10, and 30 days. The rate of absorption was influenced by the temp., the type of polyvinyl chloride and by the plasticizer; at 70°C, 7 to 10 days sufficed to show the trend. Washing (to remove emulsifiers or dispersing agents) reduced H_2O absorption markedly, and the foils retained full transparency even after immersion. H_2O absorption of plasticized polyvinylchloride was reversible and was typical of the particular combination used.

2442. SAKURADA, ICHIRO AND TANIGUCHI, MASAKATSU. **Wettability of high-molecular substances by water.** *J. Soc. Chem. Ind. Japan* 49, 35 (1946).—*C.A.* 42, 6206*c*.

The degree of adsorption of moisture and wettability were not the same thing, e.g. polyvinyl alc. had a very large value of the former in comparison with its wettability by water, whereas polyvinyl acetate had the opposite properties. Neither polystyrene nor pariffin absorbed moisture, but their wettabilities by water were different.

2443. SKAU, EVALD L. **The possible contribution of shape to the swelling and moisture-sorption behavior of cotton fiber at the saturation point.** *Textile Research J.* 16, 556-63 (1946).—*C.A.* 41, 869*h*.

Conclusions were drawn as to the effect contributed by the shape of a cotton fiber to its moisture-sorption behavior.

2444. SPEAKMAN, J. B. AND SAVILLE, A. K. **Some physical properties of nylon.** *J. Textile Inst.* 37, P271-93 (1946).—*C.A.* 40, 7640[9].

Water adsorption isotherms at 20°C to 35°C were detd. and the heats of reaction were calcd. Longitudinal and lateral swelling with adsorption of water was studied, preliminary to detns. of the rigidity of nylon at different relative humidities, temps., and pH values on the behavior of nylon under longitudinal stress were examined.

2445. ZETTLEMOYER, A. C.; SCHWEITZER, E. D., AND WALKER, W. C. **The internal surface area of hide.** *J. Am. Leather Chem. Assoc.* 41, 253-64 (1946).—*C.A.* 40, 5941[4].

The B.E.T. surface was detd. for limed hide, washed free of sol. salts, degreased in acetone, and dried *in vacuo* over P_2O_5. Hide samples were heated 1 hr in a high vacuum at 110°C, and N_2 was repeatedly adsorbed and desorbed before the final measurements. The results gave a surface area for untanned hide of 4.8 m^2/g. Pressing the untanned hide at 10,000 lb/ft^2 decreased the area to 1.0 m^2/g. Formaldehyde tanning decreased it to 0.8 m^2/g.

2446. CHERNYSHEV, A. B.; POMERANTSEV, A. A., AND FARBEROV, I. L. **The filtration of a gas through a reactive, porous medium.** *Doklady Akad, Nauk S.S.S.R.* 56, 727-9 (1947).—*C.A.* 44, 8197*i*.

When a gas penetrated a porous medium with which it reacted chemically, a reaction front was formed behind which the gas retained its total (inital) concn. and in front of which no gas existed. The velocity of displacement of this front was a linear function of the amt. of gas consumed. This was verified by measurements on the rate of filtration of air or N_2 satd. with I_2 vapor through dried starch paste.

2147. DEAN, R. B. AND MCBAIN, JAMES W. **The sorption of organic vapors by monolayers of soap.** *J. Colloid Sci.* 2, 383-5 (1947).—*C.A.* 42, 435*c*.

Na stearate monolayers spread on surfaces of 0.002 *M* Na_2HPO_4 and held at a const. pressure of 9.5 dynes/cm were found to expand in area to a detectable extent (about 1%) when exposed to the vapors of some volatile liquids, but other vapors had no measurable effect. Expansion indicated that the vapors were adsorbed by the Na stearate. In general, expansion was produced by those compds. whose spreading pressure on water was greater than 9.5 dynes/cm.

2448. DOLE, MALCOLM AND MCLAREN, A. D. **The free energy, heat, and entropy of sorption of water vapor by proteins and high polymers.** *J. Am. Chem. Soc.* 69, 651-7 (1947) *C.A.* 41, 3677*b*.

Published data were used to calculate differential free energies and differential and integral heats. The fraction of the polar groups assocd. with one H_2O mol. at satn. was shown to be equal to the fraction of amorphous polymer in stretched and unstretched nylon. Differential and integral free energies and heats of hydration were given for cellophane, cellulose acetate, polyvinyl alc., polyvinyl butyral, and vinylidene chloride-acrylonitrile copolymer.

2449. GLOCKLER, GEORGE AND HOLLINGSWORTH, C. A. **The rate of oxygen absorption by α-ray cuprene.** *Trans. Electrochem. Soc.* 92, 9 pp. (1947).—*C.A.* 41, 5771*e*.

An expression for the rate of O_2 absorption by α-ray cuprene was detd. At const. pressure it was the same law that expressed the rate of O_2 absorption after the initial stages, by the C_2H_2 polymer obtained in the silent elec. discharge. The equation had to be modified for variation of the O_2 pressure.

2450. HOOVER, SAM R. AND MELLON, EDWARD F. **Effect of acetylation on sorption of water by cellulose.** *Textile Research J.* 17, 714-16 (1947).—*C.A.* 44, 7057*i*.

Recalcn. of data for the adsorption of H_2O by cellulose esters on the basis of the cellulose content of the samples revealed that the apparent decrease of the H_2O adsorption of cellulose acetate was due to a diln. effect; the H_2O uptake of cellulose was not diminished by acetylation. Esters of cellulose with higher fatty acids (C_3, C_4, etc.) had reduced affinities for H_2O, the max. reduction (85%) being observed with esters of hexoic and heptoic acids.

2451. JACQUÉ, L. AND CARON, MLLE. **Hydration and dehydration of various phenolic plastics as a function of the surrounding media (water, humid and dry air) and of time. Influence of the immersion in water on the density as a function of time.** *Inds. plastiques* 3, 41-6 (1947).—*C.A.* 41, 4329*i*.

The change of wt and dimensions of phenolics which were molded to rods and slabs, and immersed in distd. H_2O or exposed to humid or dry aid, was studied during a period of 400 days. The change was greatest were phenolic was loaded with cotton flock; it was smaller with wood flour,and smallest with mica fillers.

2452. KUNO, HISASHI; YAMAGUCHI, GORO, AND NAGAI, SCHOICHIRO. **Moisture adsorption by urea nitrate.** *J. Electrochem. Soc. Japan* 15, 69-72 (1947).—*C.A.* 44, 9770*g*.

Urea nitrate from pure urea and HNO_3 and dried 5 hrs at 50°C adsorbed H_2O vapor much more slowly than $(NH_4)_2SO_4$ or urea. Addn. of $CaCO_3$ and variation in the amt. of urea in the salt increased the moisture adsorption.

2453. Magne, Frank C.; Portas, H. J., and Wakeham, Helmut. **A calorimetric investigation of moisture in textile fibers.** *J. Am. Chem. Soc.* 69, 1896-902 (1947).—*C.A.* 42, 371*e*.

The quantities of bound and free water in textile fibers were detd. calorimetrically by a mixt. method. The fibers used were a cord of Acala-1517 cotton, a yarn of Rowden cotton, a commercially mercerized cord of Wilds-13 cotton, a "Cordura" rayon yarn, a nylon cord, and glass fibers. Interpretation of the results for cellulose fibers permitted differentiation between water of primary adsorption and water adsorbed in multilayer formation or by capillary condensation.

2454. Noll, August. **Determination of tensile strength and water sorption of moistened paper.** *Wochbl. Papierfabrik.* 75, 50-2 (1947).—*C.A.* 42, 5222*a*.

The paper sample (after air conditioning) was dipped into distd. H_2O for 5 sec. After withdrawing, the excess H_2O was removed from either side by passing the strip rapidly over the prow of the base, placing it between the filters on an inlaid bronze plate, and weighting it with the overlay a carefully ground bronze plate for exactly 0.5 min. The tensile strength was immediately detd. and compared with that of a similar (conditioned) air-dried strip. In water sorption, the app. was similar to that used in wet strength.

2455. Pierce, S. W. and Holms, J. F. **Method for the determination of water-vapor permeability at low temperatures.** *Paper Trade J.* 124, No. 16, 64-6 (1947).—*C.A.* 41, 3623*h*.

The testing procedure was outlined which gave the following results: (g/100 in^2/24 hrs) for water-vapor transmission at 0°C, 0.017 in.-board 0.907, 0.0018 waved paper 0.042, creased 0.317, rubber HCl film 0.016, 0.0035 Al foil 0.012, 0.017 board (wax-coated) 0.004, 0.0009 moisture-proof regenerated cellulose 0.003, 0.0007 Al foil 0.00.

2456. Rouse, Prince E., Jr. **Diffusion of vapors in films.** *J. Am. Chem. Soc.* 69, 1068-73 (1947),—*C.A.* 41, 5363*i*.

The sorption isotherm coupled with permeation rates under several vapor-pressure differences could be used to calc. the diffusion coeff. of a vapor within a film as a function of concn. The rate of diffusion of water in a polythene film indicated that the gradient of vapor pressure within the film was approx. equal at a pressure about 1.0 cm. The transmission of water vapor through a nylon film increased very rapidly with increasing vapor pressure on the wet surface.

2457. Rowen, John W. and Blaine, R. L. **Sorption of nitrogen and water vapor on textile fibers.** *Ind. Eng. Chem.* 39, 1659-63 (1947).—*C.A.* 42, 1058*i*.

Water and N_2 sorption isotherms for cotton, wool, silk, nylon, and viscose and acetate rayons were detd., and fiber surface areas available to the nitrogen were found to vary from 0.31 m^2/g for nylon to 0.98 m^2/g for viscose rayon. Wool and viscose rayon had slightly greater adsorption capacities for both N_2 and water than did silk and cotton; adsorption capacities of acetate and nylon were lowest.

2458. Shreve, George W.; Pomeroy, Harold H., and Mysels, Karol J. **Studies of aluminum soaps. VIII. Water sorption and moisture content.** *J. Phys. & Colloid Chem.* 51, 963-6 (1947).—*C.A.* 41, 6739*f*.

The sorption isotherm of water vapor on $Al(OH)(OOCC_{11}H_{23})_2$ at 50°C showed less than 3% water sorbed at satn. The moisture content may be accurately detd. from the loss in wt on drying.

2459. Smith, Sherman E. **The sorption of water vapor by high polymers.** *J. Am. Chem. Soc.* 69, 646-51 (1947).—*C.A.* 41, 4358*d*.

The sigmoid type of sorption curve was characterized by two classes of sorbed water. The regain (wt ratio of sorbate to dry sorbent) was thus divided into two portions corresponding to bound water and condensed water. Plot of the data for the sorption of water on Cellophane, soda-boiled cotton, wool, and nylon confirmed the linear relation with hysteresis shown by parallel lines with the desorption curve having the higher intercept for bound water. The nylon isotherm showed no appreciable hysteresis.

2460. Tatsuno, Tsuneo. **Bagasse as water-absorbing material.** *Rept. Taiwan Sugar Expt. Sta. (Formosa)* No. 1, 111-16 (1947).—*C.A.* 42, 1031*i*.

Dried and powd. bagasse can absorb 20% of its weight of moisture from an atm. satd. at 25-30°C and can retain 3-5 times its wt of liquid water. A mixt. of 50 g of the air-dry powder and 200 ml of a 20% brine of $MgCl_2$, when dried, absorbed 155% of its wt of water from air of 100 relative humidity in 18 days. Pure $CaCl_2$ or $MgCl_2$ will not absorb as much under the same conditions.

2461. Vandoni, Robert and Marcel, Boivin. **Diffusion of water vapor across membranes of plastic materials.** *Mém. services chim. état. (Paris)* 33, 239-46 (1947).—*C.A.* 44, 3333*g*.

H_2O vapor from liquid H_2O (maintained at const. temp. slightly below room temp.) diffused through a membrane to an evacuated system where it was frozen by solid CO_2. Data were given for various types of wire-cable insulation contg. Thiokol, Gobanyl, and Oppanol.

2462. White, Howard J. Jr. and Eyring, Henry. **The adsorption of water by swelling high polymeric materials.** *Textile Research J.* 17, 523-53 (1947).—*C.A.* 42, 373*i*.

The process is not strictly a surface phenomenon; the adsorbent swells as water is adsorbed. The water uptake is a continuous function of relative humidity. It differs from adsorption by liquids by the fact that the adsorbent possesses and retains during the adsorption a certain amt. of dimensional stability. Data are outlined on the various phenomena assocd. with the adsorption process to give information on the fundamental adsorption process. The adsorption is expressed in terms of the relative humidity, regain, and mol. parameters in the simplest case.

2463. Barkas, W. W. **Hysteresis in the swelling of gels.** *Nature* 162, 32-3 (1948).—*C.A.* 42, 7523*c*.

Hygroscopic natural fibers generally show sorption hysteresis. If different hydrostatis stresses were present depending upon whether the gel was undergoing adsorption or desorption, the difference in hydrostatic pressure must produce a change in vol. of the gel. This was detd. experimentally for spruce and beech.

2464. Barkas, W. W. **Sorption, swelling and elastic constants of the cell-wall material in wood.** *Trans. Faraday Soc.* 42B, 137-50 (1948).—*C.A.* 43, 4009*a*.

Quant. information on the elastic properties of hygroscopic materials may be derived from data on their sorption and swelling. The elastic consts. of the natural wood and of the material composing the cell walls were calculated. Certain consequences of the theory of swelling stresses were discussed, e.g., sorption hysteresis, the instability of capillary spaces on drying, and the limiting value of the adsorption moisture content at the satd. vapor pressure.

2465. Barkas, W. W. **Sorption and swelling of cellulose under natural and imposed restraints.** *Proc. Tech. Sect. Paper Makers' Assoc. Gt. Brit. & Ireland* 28, 189-210 (Discussion, 211-16) (1948).—*C.A.* 43, 4009*b*.

The sorption and swelling of the natural material in cotton, wood, and paper were described. Both the sorption and swelling resulted from a given vapor-pressure rise and must be sensitive to applied stresses. The sensitivity of sorption to stress in a plastic material provided a plausible explanation of the sorption hysteresis found in cellulose and other fibers.

2466. Baughan, E. C. **Absorption of organic vapors by thin films of polystyrene.** *Trans. Faraday Soc.* 44, 495-506 (1948).—*C.A.* 43, 437*c*.

Absorption was detd. by weighing thin films of the polymer, on suitable supports, at 20°C at measured vapor pressures of the low-mol. component; these were obtained by soln. in the nonvolatile Bu sebacate. The solvents were benzene, toluene, m-xylene, CCl_4, Bu acetate, dioxane, and di-Et ketone (in which polystyrene dissolved at 20°C), cyclohexane, propyl ether, and nitromethane (in which it only swelled).

2467. Bond, R. L.; Griffith, M., and Maggs, F.A.P. **Some properties of water adsorbed in the capillary structure of coal.** *Discussions Faraday Soc.* **1948**, No. 3, 29-40.—*C.A.* 43, 1167*i*.

At satd. H_2O vapor five coals adsorbed more than required to fill the pores, but swelling measurements on meta-lignitous indicated quantitatively that the vol. adsorbed equaled the sum of the vol. swelling and the porosity or that the pore vol. of the swollen coal was filled. Dilatometer results, using dry coal and coal satd. with water vapor plus dibutyl phthalate satd. with water vapor, indicated no discontinuity in the adsorbed phase over the range -70° to +20°C. The effect of adsorbed water on the apparent dielec. const. was very marked.

2468. Brecht, W. **Estimation of the water content and the absorption of water by paper.** *Das Papier* 2, 18-22 (1948); *Melliant Textilber.* **29**, 1-3 (1948).—*C.A.* 45, 8246*c*.

Formulas, tables, and curves were given for converting moisture content as ordinarily detd. to moisture content referred to the dry wt.

2469. Cutler, Janice A. and McLaren, A. D. **Sorption of water vapor by proteins and polymers. III.** *J. Polymer Sci.* 3, 7292-4 (1948).—*C.A.* 43, 7294*b*.

Published data for the sol. and insol. proteins as well as for sol. polyvinyl alc. (PVA) and insol. nylon were analyzed on the basis of the equation: $\ln p/po = \ln v_1 + v_2\ (1-1/n) + \mu\ (v_2)^2$, where p/po was relative vapor pressure, v_1 and v_2 were vol. fractions of water and polymer, resp., n was no. of segments in polymer chain, and μ was energy interaction factor. The const. values for μ were given and the pressure range over which each was const., for nylon, PVA, salmine, egg albumin (unlyophilized and coagulated, resp.), gelatin, and collagen, resp., at 25°C.

2470. Davis, S. and McLaren, A. D. **Free energy, heat, and entropy changes accompanying the sorption of water vapor by proteins.** *J. Polymer Sci.* 3, 16-21 (1948).—*C.A.* 42, 3239*f*.

Integral and differential free energies and integral and differential heats and entropies of sorption were calcd. as functions of the amts. of water sorbed on silk, wool, egg albumin (unlyophilized and heat-coagulated), salmine, collagen, gelatin, and lactoglobulin (cryst. and lyophilized). All calcns were referred to satd. water vapor at the standard state. Some of the proteins showed pos. net differential entropies of sorption at low vapor pressures.

2471. Dole, Malcolm. **Statistical analysis of the sorption of vapors by high polymers.** *J. Colloid Sci.* 3, 411-12 (1948).—*C.A.* 43, 16*i*.

Sorption equations previously derived were applied to published data for the sorption of C_6H_6 and PhMe by rubber. The agreement between theory and expt. was excellent up to relative pressures of 0.8-0.95.

2472. D'yachenko, P. F. **Adsorption and bonding of water by casein.** *Kolloid. Zhur.* **10**, 199-202 (1948).—*C.A.* 43, 7787*c*.

Adsorption of H_2O from satd. vapor by casein (0.299 g/g) and the integral heat Q of adsorption (17.1 cal/g) were not affected by treating casein with HCOH vapor, during which 25 mg HCHO per g were taken up. HCOH little affected Q of wetting by 0.1 *N* NaOH (22.1-22.8 cal/g) but lowered Q of wetting by 0.1 *N* HCl (12.8 instead of 17.0 cal/g).

2473. Frey, Harold, J. and Moore, Walter J. **Adsorption of vapors on organic crystals. I. adsorption of water vapor on glycine, leucine, diketopiperazine, and diglycylclycine.** *J. Am. Chem. Soc.* 70, 3644-9 (1948).—*C.A.* 43, 2066*h*.

The water adsorption at 15°, 25°, and 40°C appeared to occur primarily on the ionic COO and NH_3^+ groups of the amino acids and on the peptide linkages in diketopiperazine. Thermodynamic treatment of the adsorption isotherms indicated that the free energy of adsorption at the mono layer point was about 1000 cals less than the free energy of condensation of water vapor to liquid water.

2474. GREEN, R. W. **Adsorption of water vapor on collagen and elastin.** *Trans. Proc. Roy. Soc. New Zealand* 77, 24-46 (1948).—*C.A.* 42, 8046*f*.

The isotherms for water-vapor adsorption on collagen, elastin, and CH_2O-, quinone-, and Cr-tanned collagen were measured by the isopiestic method. Equil. was attained much more rapidly by adsorption than by desorption. The isotherm exhibited hysteresis, especially in the tanned samples. Thus it was important to specify whether a given H_2O content was approached by adsorption or desorption.

2475. HAUSER, PAUL M. AND MCLAREN, A. DOUGLAS. **Permeation through and sorption of water vapor by high polymers.** *Ind. Eng. Chem.* 40, 112-17 (1948).—*C.A.* 42, 3640*a*.

Studies by Doty, et al. of H_2O vapor transmission by high polymers indicated that the permeability const. P could be broken down into two factors. These factors were D, the diffusion const and S, the soly. coeff.; that is P equaled DS. The values of S were obtained from H_2O-vapor sorption isotherms in air at 25° and 40°C. The P detns. were made by the cup method at several temps. These findings made the expression $P=DS$ useful only for describing the behavior of the vinyl polymers and only at low relative humidity.

2476. HEERING, H.; PUELL, H., AND DREWITZ, I. **Determination of the water-vapor permeability of cable sheath materials.** *Kunststoffe* 38, 49-51 (1948).—*C.A.* 43, 8738*a*.

The water vapor permeability D of several synthetic materials in 10^{-8} g hr^{-1} cm^{-1} tor^{-1}, measured in this manner, was found at 25°C: Oppanol-soot mixts. 0.006-0.08, paraffin 0.02, polyisobutylene 0.14, Thiokol mixts. 0.08-0.5, polyethylene 0.22, polybutylene-polystyrene mixts. 0.25, colophony 0.34, bitumen mass 0.80, rubber mixts. 2-10, polystyrene 3.3, benzylcellulose 16, polyacrylate 31, cellulose hydrate foil 77-200, cellulose triacetate foil 100.

2477. INGERSOLL, H. G. AND JOHNSON, A. A. **Ion exchange and fiber contraction.** *Nature* 162, 225 (1948).—*C.A.* 43, 468*g*.

Contraction in cellulose fibers was caused by H_2O migrating out of the filament to establish osmotic equil. Eventually, as the solute diffused into the filament, the osmotic forces were reversed and H_2O flowed into the filament, causing an increase in length.

2478. JOGARAO, A. **Water absorption and anistropic swelling of horn-keratin.** *J. Sci. Ind. Research* 7B, No. 8, 124-8 (1948).—*C.A.* 43, 2073*c*.

H_2O absorption was higher in buffalo-horn than in cow-horn keratin. Definite increase in H_2O absorbed from root to tip was shown by buffalo horn, but only random distribution was shown by cow-horn keratin.

2479. KETTERING, JAMES H. **Determination of the rate of water absorption of light-weight cotton fabrics.** *Am. Dye-stuff Reptr.* 37, 73-5 (1948).—*C.A.* 42, 3182*i*.

The rate of evapn. of H_2O from a plane surface was detd. The method distinguished between high and low-absorbency fabrics selected by 2 comparable methods.

2480. KOVACS, A. **Diffusion and absorption of water in plastic materials.** *J. chim. phys.* 45, 258-69 (1948).—*C.A.* 44, 10457*d*.

The rate of absorption of water from the vapor and liquid states by parallelopiped prisms of cellulose acetate, celluloid, and plexiglass followed Fick's diffusion law. Generally, 1-3% more water was absorbed from the liquid state than from vapor by the thermoplasts, and 5-10% more by the phenoplasts.

2481. LEROY, R. **Water of constitution and moisture.** *Inds. agr. et aliment* 65, 213-28 (1948).-*C.A.* 43, 1625*e*.

There was sufficient complexity in the interaction between water mols. to account for the variety of observed phenomena. The calcn. of the rate of water loss was an important practical application of this information. The water loss in cereals was more important at low temp. than at high temps., and the methods of moisture detn. led to conflicting results.

2482. MELLON, EDWARD F.; KORN, ALFRED H., AND HOOVER, SAM R. **Water absorption of proteins. II. Lack of dependence of hysteresis in casein on free amino groups.** *J. Am. Chem. Soc.* 70, 1144-6 (1948).—*C.A.* 42, 4818*g*.

The amino groups were responsible for the absorption of about 0.25 of the total amt. of water absorbed by casein, throughout the entire range of relative humidities (R.H.). The desorption expts. were all made at 30° ± 0.1°C and 51, 75, 84, and 93% R.H. by lowering the R.H. from the highest to the next lower level. Equil. was reached in 18 days, 3 times as long as required for absorption. The lowest R.H. reached was 6%.

2483. MELLON, EDWARD F.; KORN, ALFRED H., AND HOOVER, SAM R. **Water absorption of proteins. III. Contribution of peptide group.** *J. Am. Chem. Soc.* 70, 3040-4 (1948).—*C.A.* 43, 467*c*.

The vapor-phase H_2O absorption of glycine peptides from 2 to 6 units in length was detd.; the values showed clearly that nonhygroscopic amino acids may give hygroscopic peptides. Polyglycine peptides of longer chain length showed that the peptide linkage must be responsible for most of the H_2O absorption by these materials. The absorption of the peptide chain backbone was probably of the same magnitude, if not identical, for all long-chain poly-peptides and proteins.

2484. OOIWA, MASAYOSHI. **The capillary absorption of wood. I. The absorption of alcohols.** *J. Chem. Soc. Japan, Ind. Chem. Sect.*, 51, 35-6 (1948).—*C.A.* 44, 9214*h*.

After pieces of beech wood (2 × 3 × 0.16 cm) were dipped into H_2O, MeOH, EtOH, PrOH, or BuOH, their increase in wt Q was measured against time, t, at 5-25°C. The relation, $Q=Ad\ (\gamma t/2\eta)^{1/2}$, in which d

was d., γ surface tension, and η viscosity of the solvent, held well after about 10 min.

2485. OOIWA, MASAYOSHI. **The capillary absorption of wood. II. The absorption of water.** *J. Chem. Soc. Japan, Ind. Chem. Sect.* 51, 36-7 (1948).—*C.A.* 44, 9214*i*.

Water absorption by pieces of beech wood (initial H_2O content, Q_o, of 6, 14, and 25%) differed markedly in velocity after about 10 min. and was well expressed by $\ln (Q_S - Q_o)/(Q_S - Q) = -DAt/L$, where D = diffusion coeff., Q_S and Q were the amts. of H_2O at t and at equil., resp., and A and L were the cross section and length of the pieces, resp.

2486. SCHULMAN, J. H. **Water-protecting properties of cuticles.** *Discussions Faraday Soc.* 1948, No. 3, 169-72.—*C.A.* 43, 6043*b*.

The wax layer theory of water retention and the theory of lipoprotein lamellar organization of the epicuticle in the form of a porous valve system were examd. The latter better explained the asymmetrical behavior of the cuticle.

2487. SHREVE, GEO. W. **Sorption of cyclohexane vapor by aluminum dilaurate.** *J. Colloid Sci.* 3, 259-61 (1948).—*C.A.* 42, 6199*e*.

A silica-spring sorption balance was used to det. the sorption of cyclohexane by $Al(OH)(OOCC_{11}H_{23})_2$ at 50°C. Two runs were made the first on gel soap and the second on gel that transformed into elastic jelly during the run. The jelly sorbed much more than the gel and showed marked hysteresis on desorption.

2488. SIMHA, ROBERT AND ROWEN, JOHN W. **Distribution of water in cellulose and other materials.** *J. Am. Chem. Soc.* 70, 1663-5 (1948).—*C.A.* 42, 4743*i*.

The combination of H_2O with cellulose, silk, and wool in the limit of low vapor pressures can be described in terms of adsorption theory. However, as one approaches the limit of high vapor pressures, the system can be analyzed in terms of a theory of polymer-liquid mixts.

2489. STAMM, ALFRED J. **The passage of water through the capillary structure of wood.** *Discussions Faraday Soc.* 1948, 264-73.—*C.A.* 43, 3607*d*.

H_2O moved through wood by vapor diffusion, bound H_2O diffusion through the cell walls below the fiber-satn. point, and free-H_2O movement above the fiber-satn. point through the capillaries, under external pressure or capillary forces. The diffusion of solute through satd. wood, calcd. by analogy with elec. conduction, was in good agreement with expt.

2490. THOMA, PAUL J. **Moisture content of paper and its effect on printing.** *Am. Ink Maker* 26, No. 10, 28-9, 59 (1948).—*C.A.* 43, 1186*h*.

Moisture content below 4% resulted in poor mech. performance and a 4.5 to 5.5% moisture content gives best paper strength. The moisture content of paper had some effect on the finish of the ink; this may have been due in part to the fact that a higher moisture gives the supercalendar a better chance of working on the coating and sealing the surface.

2491. WEAVER, E. R. AND RILEY, RALPH. **Measurement of water in gases by electrical conduction in a film of hygroscopic material.** *Anal. Chem.* 20, 216-29 (1948).—*C.A.* 42, 4096*b*.

A film of H_3PO_4 was exposed to a known concn. of water vapor and its elec. resistance measured. The film was then exposed to the gas being tested, and the pressure of the latter varied until the elec. resistance of the film reached the above-mentioned value. If the total pressure of the sample was known, its H_2O content could be calcd.

2492. WEAVER, E. R. AND RILEY, RALPH. **Moisture determination by electrolytic film.** *Refrig. Eng.* 55, 266-7 (1948).—*C.A.* 44, 3843*a*.

This method had been applied to detg. the moisture content of a gas. A thin film of liquid such as H_3PO_4 in a gelatin or plastic material was spread over the surface of a solid insulator between metallic electrodes. The electrolyte tended to reach equil. with the water vapor in the gas; the cond. of the resultant equil. mixt. was a measure of the water content.

2493. WESTWATER, J. W. **Oxygen absorption by cast plastic films.** *Ind. Eng. Chem.* 42, 1494-500 (1948).—*C.A.* 42, 7567*f*.

Films (0.065 to 1.9 mils) of com. plastics on glass were exposed to dry O_2. Wt detns. were made at intervals up to about 1000 hrs max. Cast films had both oriented and unoriented mols., the ratio depending on the polymer, solvent, and film thickness. Absorbed O_2 was held by both chem. bonds and secondary forces.

2494. WITT, R. K.; WOLFE, P. D., AND RUST, D. M. **Cotton fabric laminates.** *Modern Plastics* 25, No. 9, 123-5, 184-91 (1948).—*C.A.* 42, 6578*a*.

Comprehensive data on the engineering properties of grade L and C cotton fabric specimens were presented.

2495. ZHURAVELVA, E. I. **Uptake of the moisture of air by corn starch.** *Kolloid. Zhur.* 10, 203-8 (1948).—*C.A.* 43, 9504*h*.

At relative humidity (x) of 0.5%, the amt. (w) of H_2O taken up by starch was $w_o[1 - \exp(-kt)]$, where t was time. At higher x, $w = w_o \exp(-n/t)$; the const. n depended on x and was, e.g., 1.4 day^{-1} in satd. vapor. Addn. of 0.5% sunflower oil did not affect the adsorption isotherm, and addn. of 5% crude sugar increased w_o only above x of 75%.

2496. ABBOTT, N. J. AND GOODINGS, A. C. **Moisture absorption, density, and swelling properties of nylon filaments.** *J. Textile Inst.* 40, T232-46 (1949).—*C.A.* 43, 5191*d*.

Absorption by both drawn and undrawn nylon was increased by immersion in alc., but decreased again by treatment in satd. benzoic acid soln. The regains of drawn and undrawn filaments were detd. for R.H. 0-100%, and when pretreated with alc., up to 90%. Appreciable differences in regain occurred only in the upper half of the R.H. range. Longitudinal swelling measurements were carried out over 0-100% R.H. The longitudinal and lateral swellings were equal in drawn nylon, but in undrawn, the former was 3 times the latter.

2497. Burleigh, Edward G. Jr.; Wakeham, Helmut; Honold, Edith, and Skau, Evald L. **Pore-size distribution in textiles.** *Textile Research J.* **19**, 547-55 (1949).—*C.A.* **43**, 8685*i*.

The pore-size distribution curves obtained for 10 selected fabrics indicated that the Hg-intrusion method could be used to show significant differences in fabric porosity in the range from 0.2 to 20μ. The curve peaks for all the fabrics fell between 2 and 4.5μ. These peaks were due predominantly to the interfiber pore-size distribution.

2498. Campbell, H. and Johnson, P. **Investigations on cellulose nitrate. II. Liquid- and vapor-phase adsorption of acetone.** *J. Polymer Sci.* 4, 247-63 (1949).—*C.A.* **43**, 8244*d*.

Vapor-phase adsorption isotherms were independent of the cryst.-amorphous ratio, but depended on its N-content. There was no limiting adsorption, because of complete soln. in acetone. In terms of the liquid-mixt. concns., there appeared to be limited adsorption, but this was due to the nonideal nature of the solns. When allowance was made for this, the liquid and vapor isotherms were the same within exptl. error.

2499. Crank, J. and Park, G. S. **Evaluation of diffusion coefficient for chloroform in polystyrene from simple adsorption experiments.** *Trans. Faraday Soc.* 45, 240-9 (1949).—*C.A.* **43**, 5654*g*.

Diffusion was considered to be the rate-controlling process in the rates of sorption and desorption of $CHCl_3$ by polystyrene sheet. Rectangular pieces of polystyrene sheet were suspended in vessels each contg. a fixed partial pressure of $CHCl_3$ by means of di-Bu phthalate-$CHCl_3$ mixtures at 25°C. When the rate of sorption was highest, the gradient of $CHCl_3$ concn. in the air was negligibly small.

2500. D'Agostino, Oscar. **Properties of some aerosols.** *Rend. ist. super. sanita* **12**, 398-416 (1949).—*C.A.* **44**, 6702*c*.

The elec. charge of some org. aerosols and also of NH_4Cl smoke, after filtration through media such as fine Fe and Al wire, glass wool, charcoal of various meshes, pumice, wool, and rayon, was studied. An attempt was made to correlate the nature and magnitude of the charge with the structure of the aerosol.

2501. Elod, Egon and Frohlich, Hans Gunther. **The effect of the fine structure of cellulose hydrate fibers on their properties.** *Textil-Rundschau* **4**, 117-26 (1949).—*C.A.* **43**, 5587*h*.

The swelling of cellulose hydrate fibers in H_2O increased with decreasing fiber d. Surface acetylation of the fiber did not change appreciably the d. or extent of swelling. If the acetylated portion of the fiber was dissolved away, the "stripped" fiber would show one of two distinct types of behavior.

2502. Gilby, A. R. and Heymann, E. **The rate of evaporation of water through duplex films.** *Australian J. Sci. Research, Ser. A,* **1**, 197-212 (1949).—*C.A.* **43**, 6884*f*.

The efficiency of duplex films in reducing evapn. was greater in wind than in still air and increased with the wind velocity. When duplex films thicker than 10 μ were placed on water surfaces, even a wind of 8 m.p.h. did not increase the evapn. rate. With all duplex films thicker than 10 μ the total evapn. resistance was proportional to the film thickness and depended on the nature of the spreader.

2503. Green, R. W. **Adsorption of water vapor on casein.** *Proc. Roy. Soc. New Zealand* 77, 313-17 (1949).—*C.A.* **43**, 4537*c*.

Adsorption isotherms were detd. for samples of casein dried at room temp. over 70% H_2SO_4 and over concd. H_2SO_4, at 100°C in vacuum and at 103°C in air oven. At water activities (*aw*) below 0.4 course of the isotherm was strongly influenced by the method of drying, but from 0.4 to 0.96 the isotherms coincided. The no. of layers of water was 6 to 7, which agreed with the no. for collagen and elastin. *Vm*, the wt of adsorbate required to fill the first mol. layer of 100 g of adsorbent, was calcd. on various assumptions of amino acid compn.

2504. Hall, A. J. **Properties of rayon and synthetic fibers in relation to their moisture-absorption qualities.** *Brit. Rayon Silk J.* **26**, No. 303, 55-6 (1949).—*C.A.* **43**, 9457*i*.

The water retained after hydroextraction and its counterpart, swelling, was given for ten fibers. These factors affected ease of dyeing.

2505. Howsmon, John A. **Water sorption and the polyphase structure of cellulose fibers.** *Textile Research J.* **19**, 152-62 (1949).—*C.A.* **43**, 4849*d*.

A large-scale equil. moisture-regain method was illustrated by a variety of cellulose materials covering a wide range of moisture sorption capacity. An attempt to evaluate both accessibility and crystallinity of cellulose from moisture-regain data was made, and a proposed revision of the scale of reported crystallinities of various types of cellulose was the result.

2506. Hutton, E. A. and Gartside, J. **Moisture regain of silk. I. Adsorption and desorption of water by silk at 25°C.** *J. Textile Inst.* 40, T161-9 (1949).—*C.A.* **43**, 4018*a*.

The isotherms were detd. by a vacuum adsorption app. for Japanese, Chinese, and Italian silks both before and after degumming. The degummed silks had lower regain at all humidities than the corresponding silks in the gum, and showed less hysteresis. All the degummed silks adsorbed H_2O to approx. the same extent.

2507. Hutton, E. A. and Gartside, J. **Adsorption and desorption of water by nylon at 25°C.** *J. Textile Inst.* **40**, T170-4 (1949).—*C.A.* **43**, 4018*c*.

The isotherms were detd. by vacuum adsorption and desiccator methods for parachute nylon fabric of delustered yarn. A small, but definite, hysteresis was found. Regain at satn. was approx. 8.70%. The adsorptive capacity decreased with increasing temp. of drying, but subsequent satn. with H_2O vapor restored the normal affinity for H_2O.

2508. Jackson, E. C. and Roper, E. R. **Water-absorbency apparatus.** *Am. Dyestuff Reptr.* **38**, 397-401 (1949).—*C.A.* **43**, 6423*h*.

The absorption rate of toweling was measured in an app. in which the specimen was in contact under definite pressure with a porous plate fed with H_2O from a calibrated horizontal tube at a neg. head. It was const. for any specimen in the range from 20 to 50%. Decreasing the flow resistance caused the influence of the head to be greatly increased and limited the range of samples that could be tested under a specific head.

2509. Karle, J. **Evaporation of polar hydrocarbon monolayers.** *J. Chem. Phys.* 17, 500 (1949).—*C.A.* 43, 7767*d*.

Monolayers of cerotic acid and n-octadecylamine were produced on soda glass from the melt. The rate of evapn. of these films in vacuo was studied from the rate of decrease of scattered electron intensity relative to that of the substrate. Throughout the course of the evapn. the structure of the films remained changed. If evapn. occurred from within the patches an increase in the angle of tilt should be expected as the evapn. proceeds.

2510. Launer, Herbert F. and Wilson, William K. **Photochemistry of cellulose. Effect of water vapor and oxygen in the far and near ultraviolet regions.** *J. Am. Chem. Soc.* 71, 958-62 (1949).—*C.A.* 43, 5941*b*.

Irradiation at 30-40°C of sheets of paper of varying cellulose content and cuprammonium degree of polymerization (D.P.) showed that at 254 mμ H_2O vapor retarded the decrease in α-cellulose and D.P., whereas O_2 had no effect. In the near ultraviolet (388 and 359 mμ), the reverse was found.

2511. Negishi, Michiharu; Shoji, Fumiko; Mori, Hideko, and Ito, Heihachiro. **Elasticity, tensile properties, and the mechanism of deformation of fibers. I. Influence of humidity of air on the elastic recovery of cellulose fibers.** *J. Soc. Textile Cellulose Ind.* (Japan) 5, 178-80 (1949).—*C.A.* 46, 3756*f*.

Natural and hydrated cotton fibers showed a slighter tendency of elastic recovery with higher relative humidity. Regenerated cellulose fibers showed more elastic recovery in humid air.

2512. Negishi, Michiharu; Shoji, Fumiko; Mori, Hideko, and Ito, Heihachiro. **Elasticity, tensile properties, and the mechanism of deformation of fibers. II. Influence of humidity of air on the strain-stress curve of cotton fibers.** *J. Soc. Textile Cellulose Ind.* (Japan) 5, 219-21 (1949).—*C.A.* 46, 3756*g*.

The S-shaped strain-stress curve and the tensile strength of natural and hydrated cotton fibers in the wet state were similar to those shown by rubber in a low-temp. range. The const. elastic elongation under a range of stresses seemed to result from the crystn. effect during the deformation.

2513. Oguri, Sutzeô; Tomabechi, Kazuo, and Ono, Takashi. **Nonpermeability of packing materials to water vapor. III. An experiment on permeability to water in carbon dioxide gas.** *J. Soc. Textile Cellulose Ind.* (Japan) 5, 343-5 (1949) (English summary).—*C.A.* 46, 4146*g*.

Com. wrappers (Cellophane, paraffin, asphalt, and other coated papers) were found less permeable to H_2O in CO_2 than in air.

2514. Pollack, Louis R.; McElwain, Robert E., and Wagner, Paul T. **Oxygen absorption of vulcanizates. A means of evaluating aging resistance.** *Ind. Eng. Chem.* 41, 2280-86 (1949).—*C.A.* 44, 868*h*.

The rates of absorption of Θ_2 by natural rubber, Neoprene (GR-M), GR-S, butadiene-acrylonitrile copolymer, Butyl, and Thiokol-FA vulcanizated at 120°C were measured. Comparative aging tests were carried out in O_2 under 300 p.s.i. at 70° and in air at 70°C. There was good correlation between absorption of O_2 and decrease in tensile strength, particularly during aging in O_2 under pressure.

2515. Preston, J. M. and Nimkar, M. V. **Measuring the swelling of fibers in water.** *J. Textile Inst.* 40, P674-86 (1949).—*C.A.* 43, 7690*e*.

Published data for transverse, axial, and vol. swelling H_2O of cotton, linen, jute, mercerized cotton, linen, rayons, wool, silk, and nylon was tabulated, showing many inconsistencies. An investigation was made of the centrifugal method for direct measurement of vol. swelling. A series of runs on viscose fibers for different lengths of time at 1000 G showed a rapid initial fall of retained H_2O for the first 4 min. followed by slower fall.

2516. Rowen, John W. and Simha, Robert. **Interaction of polymers and vapors.** *J. Phys. & Colloid Che.* 53, 921-30 (1949).—*C.A.* 43, 6491*d*.

The system adsorbent-adsorbate at high vapor pressures was a soln. in which equil. was detd. by the free energy of diln. and an elastic term. In regard to the former, use was made of current theories of polymer solns. An apparent elastic modulus of the order of 10^8-10^9 dyne cm^{-2} was derived from the high-vapor pressure portion of the adsorption isotherm of cellulose. The elastic term represented only a few % of the total effect.

2517. Schultz, T. H.; Miers, J. C.; Owens, H. S., and Maclay, W. D. **Permeability of pectinate films to water vapor.** *J. Phys. & Colloid Chem.* 53, 1320-30 (1949).—*C.A.* 44, 3333*f*.

Films were prepd. from alkali-deesterified pectin having a methoxyl content of 3.8% and an intrinsic viscosity of 3.2 in the form of Ca, Ca Na, NaH, and H pectinates. Transmission rates for permeation of water vapor through films 40 microns thick varied from 1400 to 4300 g per m^2 per day at 25°C with a relative humidity differential of 81-31% .

2518. Scott, Walter M. **Some recent developments in cotton research at the Southern Regional Research Laboratory.** *Textile Research J.* 19, 436-43 (1949).—*C.A.* 43, 6829*g*.

Rotproofing and weatherproofing methods for cotton were discussed, also the production of water-resistant cotton by self-sealing through swelling.

2519. Skark, Leopold. **Moistening and elongation of flat fibrous structures, especially fiber boards.** *Das Papier* 3, 82-5 (1949).—*C.A.* 43, 5591*e*.

When the H_2O was increased from an initial 0.6% to a final 4.0%, the stretched board was stronger than the unstretched sample. The increased H_2O had actually contributed to an increase in tensile strength and resistance to fracture of the stretched material. When the H_2O was raised from 0.7% to 9%, the stretched sample at the higher H_2O still showed somewhat better strength than did the unstretched sample, but the over-all strength was inferior.

2520. TONER, RICHARD K.; BOWEN, CAROL F., AND WHITWELL, JOHN C. **Moisture determination in textiles by electric meters. II.** *Textile Research J.* **19**, 1-8 (1949).—*C.A.* **43**, 2779*h*.

While the moisture meters tested, when properly calibrated and used, can give results comparable to those of oven analyses, expts. demonstrated clearly the necessity for calibrating for the material and condition of use. Isothermal calibration lines diverged as the moisture increased; for equal increments of temp. the difference increased as the temp. rose. For accuracy the meters should be used at the temps. of calibration or the readings corrected by an amt. experimentally detd.

2521. WAKEHAM, HELMUT AND SPICER, NANCY. **Pore-size distribution in textiles. A study of windproof and water-resistant cotton fabrics.** *Textile Research J.* **19**, 703-10 (1949).—*C.A.* **44**, 845*b*.

An improved method was described for studying the nature of interfiber and interyarn pore spaces in textile fabrics by means of a Hg-pressure porosimeter. The fibers in water-resistant fabrics swell when exposed to moisture, closing the pores of the fabrics and reducing the passage of water and other wetting liquids. A definite relationship apparently existed between pore size and vol. on the one hand and water permeability on the other.

2522. WINK, W. A. AND DEARTH, LEONARD R. **Measurement of water-vapor permeability at low temperature—the hygrometric sweep gas method.** *Tappi* **32**, 232-8 (1949).—*C.A.* **43**, 5948*c*.

The sensitivity of the new method resulted from a combination of the inherent sensitivity of the hygrometric principle and the ability of the small elec. hygrometer accurately to measure small changes in the relative humidity of the air passing over a specimen. Data were given for Cellophane, a Cellophane-kraft laminate, a glassine laminate, Pliofilm, and a sulfite laminate.

2523. YAICHNIKOV, I. S. **Absorption and elimination of water by casein.** *Zhur. Obshcheĭ Khim. (J. Gen. Chem.)* **19**, 527-30 (1949); *J. Gen. Chem. U.S.S.R.* **19**, 477-80 (1949).—*C.A.* **43**, 6882*b*; **44**, 5679*d*.

The rate of loss of H_2O by casein was detd. over H_2SO_4 at room temp. In 85 days, 10 g lost 1.2755 g, on subsequent drying *in vacuo* the loss rose to 1.2941 g after a total of 147 days, and, on drying at higher temps. (up to 100° to 110°C), the final loss, after 181 days, was 1.4617 g. The final amts. of H_2O given up or absorbed correspond to 350-475 moles, which gave the amt. of polar groups in casein.

2524. YOUNG, FRANK E. AND JONES, FRANCIS T. **Sucrose hydrates. The sucrose-water phase diagram.** *J. Phys. & colloid chem.* **53**, 1334-50 (1949).—*C.A.* **44**, 5200*h*.

The sucrose-H_2O system was studied over the range -30° to +40°C by warming curves, soly. detns., and microscopy. The warming curves gave evidence of the existence of 8 new solid phases, in addn. to ice and anhyd. sucrose. Transformations from one solid phase to another were extremely sluggish, so the solid-liquid equil. curves could be followed far into the region of metastability.

2525. BARTHOLOMEW, W. V. AND NORMAN, A. G. **Moisture sorption by some common plant materials.** *Agron. J.* **42**, 427-31 (1950).—*C.A.* **45**, 294*h*.

Moisture sorption by cotton, hemp, jute, oat straw, corn stalks, straw, oak leaves, alfalfa, pine needles, Sudan grass and grass roots, and clover was studied at relative humidities up to 100%. The moisture sorption increased geometrically with increase in relative humidity up to about 95% and above this the moisture sorption was small. Between 20 and 90%, $y = ax/(1-x)+c$, where y = percentage moisture, x = relative vapor pressure, and a and c were +consts.

2526. BELL, E. R., SEIDL, M. G., AND KRUEGER, N. T. **Water-vapor permeability of building papers and other sheet materials.** *Heating, Piping, Air conditioning* 22, No. 12, 109-15 (1950).—*C.A.* **45**, 3141*f*.

Dry and wet method of ASTM Tentative Standard Procedure C214-47T were used to test 100 products. Mean vapor-permeability values ranged from approx. 0 to 100 grains/(ft^2)/(hr)/(in. Hg). Wet-method values were nearly always greater than dry-method, but the ratio of the 2 values was not const.

2527. BENSON, SIDNEY W. AND ELLIS, DAVID A. **Surface areas of proteins. II. Adsorption of nonpolar gases.** *J. Am. Chem. Soc.* 72, 2095-2102 (1950).—*C.A.* **44**, 7119*b*.

The adsorption isotherms of N_2, O_2, CH_4, A, butane, SF_6, and neopentane were detd. on several samples of dry, lyophilized proteins. The isotherms were treated by the simple B.E.T. theory, and reasonable and fairly consistent values obtained for the surface area. The total lack of hysteresis and speed of attainment of equil. over a range of mol. symmetries and sizes, together with the small net heats of adsorption past the monolayer region, indicated that the proteins had no fine pore structure.

2528. BENSON, SIDNEY W.; ELLIS, DAVID A., AND ZWANZIG, ROBERT W. **Surface areas of proteins. III. Adsorption of water.** *J. Am. Chem. Soc.* 72, 2102-5 (1950).—*C.A.* 44, 7119*d*.

Measurements were made of the effect of surface area of 2 different dry, lyophilized proteins on their adsorption of H_2O. Within narrow limits, the H_2O adsorption was independent of surface area in the range below ¼ satn. pressure. It was inferred from this that H_2O adsorption was qualitatively different from N_2 adsorption and probably took place at specific sites on the protein mol.

2529. BONE, W. A. AND TURNER, H. A. **Some effects of the evaporation of water from cotton cellulose.** *J. Soc. Dyers Colourists* **66**, 315-27 (1950).—*C.A.* **44**, 8116*g*.

Cotton cellulose was modified when a strip of bleached cotton fabric was dipped in water to give two distinct types of products: (a) one, sol. and transportable in water, brown in color, markedly fluorescent in ultraviolet radiation, with enhanced reducing properties; (b) the other, solid, non-transportable in water, restricted to the boundary region, with higher cuprammonium fluidity and methylene-blue absorption than the original cellulose. Wide variations in the partial pressure of O_2 caused little change in the apparent intensity of the brown line.

2530. Brown, Hugh M. and Graham, John S. **Measurement of fineness of cotton by air-flow methods.** *Textile Research J.* **20**, 418-25 (1950).—*C.A.* **44**, 8117*b*.

When porosity meters were calibrated in units of wt per unit length of fiber (fineness), the curves for different varieties of cotton were quite different. Resistance to air-flow through a fiber plug correlated more closely with the surface area of the fibers composing the plug than with their fineness. This surface area varies with variety and maturity, independently of the fineness of the cotton.

2531. Childs, E. C. and Collis-George N. **The permeability of porous materials.** *Proc. Roy. Soc. (London)* **A201**, 392-405 (1950).—*C.A.* **44**, 8198*b*.

The pore-size distribution was obtained by an interpretation of the moisture characteristic of the material, i.e. of the curve of moisture content plotted against pressure deficiency. A simple statistical theory, based on the calcn. of the probability of occurrence of sequences of pairs of pores of all the possible sizes led to an expression of the permeability as the sum of a series of terms. A combined use of the moisture characteristic and the permeability detd. the coeff. of diffusion of H_2O in the material as a function of moisture content.

2532. Dean, Robert B. and Li, Fa-Si. **The sorption of vapors by monolayers. II. Organic vapors on stearic acid monolayers.** *J. Am. Chem. Soc.* **72**, 3979-82 (1950).—*C.A.* **45**, 1405*c*.

The increase in surface pressure of stearic acid monolayers upon exposure to satd. org. vapors, viz. n-C_6H_{14}, 2,3-dimethylbutane, CCl_4, MeC_6H_5, n-C_8H_{18}, n-$C_{10}H_{22}$, and C_6H_6, was measured. There is a small increase in pressure even at the highest available surface pressure; this indicates adsorption on the monolayer. The adsorption of C_6H_{14} on stearic acid was calcd. from measurements at various relative pressures using the simplified Gibbs adsorption equation. Adsorption appears to be nearly const. at about one mol. of n-C_6H_{14} per 28 A.^{2}, over a wide range in mol. area of stearic acid.

2533. Dole, Malcolm and Faller, I. Lucille. **Water sorption by synthetic high polymers.** *J. Am. Chem. Soc.* **72**, 414-19 (1950).—*C.A.* **44**, 4753*g*.

H_2O sorption data at 25°C were detd. for eleven synthetic linear polymers and interpreted in the light of the B.E.T. and other sorption theories. Sorption by the polyesters was so small that it probably occurred only on end-groups. Sorption by polyvinylpyrrolidone was so great that probably every peptide bond served as a sorption site. Sorption by the polyamides was small and greatly affected by the extent of disorder in the solid.

2534. Dwyer, Orrington E. and Baumann, J. A. **Desorption of unreacted isoprene from synthetic rubber latex. Effect of pressure, agitation, and latex depth.** *Ind. Eng. Chem.* **42**, 1230-9 (1950).—*C.A.* **44**, 7081*d*.

In its escape from the tiny polymer particles, isoprene must diffuse through the aq. film which seps. the particles from the vapor in the vapor bubbles and above the latex. The operating variables of temp., pressure, latex depth, and degree of satn. were studied for different operating conditions. Venting at 40° and 60°C showed that the rate of desorption depended greatly on the temp. The venting rate varied in an approx. way, inversely with the (abs. pressure)^2. An increase in the depth of the latex decreased the rate of venting; however, this effect was less pronounced at relatively great depths and with relatively great driving forces.

2535. Dwyer, Orrington E. and Burke, Lowell T. **Desorption of unreacted isoprene from synthetic rubber latex. Effect of temperature and agitation.** *Ind. Eng. Chem.* **42**, 1240-5 (1950).—*C.A.* **44**, 7081*h*.

The rate of monomer released from the latex was detd. by direct measurement of the accumulated vapor. Temp., pressure, and agitation were practicularly important, and moderate changes in any of these may change the rate of venting several fold. Temp. and agitation had beneficial effects, whereas an increase in pressure reduced the venting rate. An increase in depth decreased the venting rate per unit vol. of latex, e.g., a 4-fold increase in depth reduced the rate 40%.

2536. Evans, A. and Keiller, C. Q. **Apparatus for measuring the permeability to water vapor of bituminous emulsion films.** *J. Soc. Chem. Ind.* (London) **69**, Suppl. No. 1, S1-3 (1950).—*C.A.* **45**, 5462*i*.

Water vapor from a const.-humidity chamber diffuses through the test film and is collected in a dehydrating agent suspended from a calibrated spring. Films of bituminous emulsions of the clay-stabilized type gave permeabilities of approx. 120×10^{-8}g cm/cm^2/hr/mm Hg.

2537. Finkelshteĭn, T.; Kargin, V., and Rogovin, Z. **Changes in physical-mechanical properties of cellulose fibers under the action of elevated temperatures.** *Tekstil. Prom.* **10**, No. 8, 9-11 (1950).—*C.A.* **45**, 858*i*.

Heating hydrated cellulose fibers in a high vacuum for 2 hrs at 200°C did not affect the degree of polymerization and strength of fiber. At higher temps., dehydration and breakdown of the macromol. occurred as indicated by lowered mol. wt and poorer mech. properties.

2538. Freytag, Hans. **The loading (adsorption) of surfaces with hydrogen peroxide.** *Z. Naturforsch.* **5b**, 123 (1950).—*C.A.* **44**, 6701*i*.

Paper, printed with a picture or writing, was exposed to the vapors of 30-40% H_2O_2 for 5 min. and then pressed against a reagent paper (PbS pptd. on filter paper) for several min. The impression on the paper transferred to the reagent paper was a measure of the capacity of the surface of the paper to absorb H_2O_2 and thus was a property of the kind and nature of the surface. The part of the paper without an impression adsorbed H_2O_2 depending upon the nature of its surface; on coming into contact with the reagent paper, the adsorbed H_2O_2 oxidized the PbS to $PbSO_4$ and the imprinted part was transferred white, and the printed part black, to the reagent paper.

2539. GREEN, R. W. **The reaction of hydrogen chloride with dry proteins. I. Collagen.** *Trans. Proc. Roy. Soc. New Zealand* **78**, 291-300 (1950).—*C.A.* **45**, 1799*i*.

Standard hide powder, deaminized collagen, hypochlorite-treated collagen and that subsequently deaminized, and degummed silk (0.08% ash), were dried to const. wt in vacuum over P_2O_5, and treated with dry HCl gas in desiccators over concd. H_2SO_4 for periods up to 70 days. Max. wt gains were about 30 g/100 g protein for standard hide powder and deaminized collagen and about 17 g/100 g protein for degummed silk. Wt loss by desorption, when the HCl-treated proteins were placed in evacuated desiccators over CaO, was slow at room temp., and equil. was not established in 75 days. At 100°C the materials reached const. wt in 6 days.

2540. HELLMAN, N. N. AND MELVIN, E. H. **Surface area of starch and its role in water sorption.** *J. Am. Chem. Soc.* **72**, 5186-8 (1950).—*C.A.* **45**, 2746*c*.

The surface areas of dasheen, corn, tapioca, and potato starches available to N_2 at -195°C are 2.62, 0.70, 0.28, and 0.11 m^2/g, resp. Interpretation of the H_2O sorption isotherms of these 4 starches by the B.E.T. equation requires surface areas of 330, 334, 348, and 422 m^2/g, resp. The N_2-available surface area of starch does not give a quant. explanation of the water-sorptive capacity of starches.

2541. HOOVER, SAM R. AND MELLON, EDWARD F. **Application of polarization theory to sorption of water vapor by high polymers.** *J. Am. Chem. Soc.* **72**, 2562-6 (1950).—*C.A.* **44**, 8734*f*.

The equation $ln\ Po/P = K_2K_1^a$ (in which k_1 and k_2 were both dependent on temp.), fitted the exptl. data for the sorption of H_2O on a variety of high polymers. Results on casein, benzoylcasein, silk, polyglycine, wool, ovalbumin, cotton, mercerized cotton, nylon, and viscose rayon were presented as straightline functions (log log Po/P vs. a log K_1).

2542. HUNT, CHARLES M.; BLAINE, RAYMOND L., AND ROWEN, JOHN W. **Submicroscopical structure of cellulose from nitrogen sorption measurements.** *Textile Research J.* **20**, 43-50 (1950).—*C.A.* **46**, 9313*h*.

Cotton linters were soaked in cold 10% NaOH solution, washed, neutralized, treated with MeOH, then with C_6H_6, and dried under reduced pressure. N_2 adsorption-desorption measurements were then made at 78°K. Swollen cotton had a B.E.T. area (up to 71.3 m^2 per g). Conditioning in H_2O vapor to a moisture content of 11% almost destroyed all the available internal surface area.

2543. KAMIYOSHI, KAN-ICHI AND HASHIMOTO, HISAO. **Permeation through and sorption of water vapor by the thin film of Japanese lacquer.** *Science Repts. Research Insts. Tôhoku Univ.* **2**, 193-204 (1950).—*C.A.* **45**, 10610*g*

The Japanese decorative waterproof lacquer "Urushi" was used. The sorption of water vapor at 0°C followed the Freundlich isotherm, $x = kp^{1/n}$, and Hüttig's isotherm, $p/V(1+p/p_o) = p_o/cV_m + p/V_m$, but at higher temps. the Langmuir isotherm, $x = ap/(1+bp)$, fits the data more closely. Heat treatment of the lacquer in vacuum at 135-150°C caused a great decrease in the amt. of water adsorbed. The permeability of the Japanese lacquer was of the order of $2\text{-}3 \times 10^{-7}$ cc./sec for a film 1 mm in thickness and 1 cm^2 in area, when the pressure difference on opposite sides of the lacquer was 1 cm.

2544. KATCHMAN, BERNARD; CUTLER, JANICE, AND MCLAREN, A. D. **Sorption of water vapor by tobacco mosaic virus.** *Nature* **166**, 266-7 (1950).—*C.A.* **44**, 10444*e*.

The uptake of H_2O vapor by tobacco mosaic virus was detd. at 25°C and the adsorption isotherm was represented by a sigmoid curve, found typically for proteins and other polypeptides. The first sorbed H_2O mols. were not primarily adsorbed into the interior as in the case with other proteins.

2545. KNIGHT, GEO. D. **Wettability of paper surfaces by water and the surface adsorption of water by paper.** *Tappi* 33, 59-66 (1950).—*C.A.* **44**, 4250*i*.

The wettability was very sensitive to almost any type of treatment. The penetration of the ink into paper could be markedly increased by vacuum on the same side and adjacent to the ink, if the paper was backed by a nonporous solid. Modifications of the Kubelka-Munk equations made possible the calcn. of the quantity of dye adsorbed and the depth of penetration. The reflectance of the colored side of the tested sheet, backed by a pad of the original paper, was a measure of the amt. of dye absorbed.

2546. KOIZUMI, NAOKAZU AND ONO, SOZABURO. **Dielectric properties of starch. I. The behavior of water absorbed by starch in the field of ultrahigh frequency.** *Bull. Inst. Chem. Research, Kyoto Univ.* **20**, 47-8 (1950) (in English).—*C.A.* **47**, 2569*e*.

The measurements were made at 214 Mc., and the dielec. const. and loss were observed at various temps. 10°-55°C. The ϵ' (real part of the dielec. const.) of the system rose as temp. was raised, and the greater the water content, the higher was ϵ' at a given time. At low water content, ϵ'' (the imaginary part of the dielec. const.) rose with increasing temp., but at higher water content, ϵ'' had a max. and decreased at still higher temp. This loss may be due to rotation of dipoles of water mols. in starch.

2547. KUROSAKI, SHIGEHIKO. **Dielectric properties of sorbed water. I. Polarization of sorbed water in vinyl polymers.** *J. Chem. Soc. Japan*, Pure Chem. Sect., 71, 522-4 (1950).—*C.A.* **45**, 6444*i*.

The change of dielec. const. of powd. vinyl polymers due to the adsorption of moisture was detd. by the beat method. On the assumption that water was dissolved in vinyl polymers, the sp polarizations of sorbed water in polyvinyl chloride was about 30, in polyvinyl alc. 6.6-7.8, in polyvinylformal 4.7-6.4. The sorbed water was in the state of ionization sorption.

2548. Mason, S. G. **The specific surface of fibers-its measurement and application.** *Tappi* 33, 403-9 (1950); Pulp Paper Mag. Can. 51, No. 9, 109-15 (1950).—*C.A.* 44, 10458*e*.

2549. McLaren, A. D. and Ottesen, M. **Sorption of water vapor by plakalbumin.** *Compt. rend. trav. lab. Carlsberg, Sér. chim.* 27, 325-32 (1950) (in English).—*C.A.* 45, 4996*f*.

The sorption of H_2O vapor by plakalbumin at 20 °C agreed with that by ovalbumin. The B.E.T. equation applied up to a relative vapor pressure of 0.5.

2550. Mitchell, Thomas J. **The rate of evaporation in the determination of water.** *Chemistry & Industry* **1950**, 751-3.—*C.A.* 45, 3761*c*.

The rate of evapn. (W) of H_2O in the 1st stage of drying appeared to vary as the 0.8 power of the mass velocity of the air. In an oven with natural convection at 100 °C and ambient air at 20 °C calcd. $W = 255$ g/100 cm^2/hr. Actual rate of H_2O evapn., $W = 70$ g/100 cm^2/hr in an Al dish 69 mm in diam. and 20 mm deep in a steam oven. The rate through sand or celite in the dish was not appreciably lower than for water alone. Vacuum-oven rate was higher.

2551. Mitchell, Thomas J. **Determination of water in sugar solutions by desiccation at room temperature.** *Chemistry & Industry* **1950**, 815-17.—*C.A.* 45, 3761*e*.

The best method for detg. water is by drying in a vacuum oven. If desiccation at room temp. is desired, the use of vacuum, stirring, and an absorbent are necessary.

2552. Park, G. S. **Diffusion of some halomethanes in polystyrene.** *Trans. Faraday Soc.* **46**, 684-97 (1950).—*C.A.* 45, 929*g*.

The over-all rate of absorption of CH_2Cl_2, $CHCl_3$, CCl_4, CH_2Br_2, $CHBr_3$, and MeI by polystyrene sheet was detd. at several surface concns. The diffusion coeffs. penetrant D_0 were given for each penetrant at 25°C and for CH_2Cl_2, $CHCl_3$, and MeI at 15° or 35°C.

2553. Rånby, Bengt G. and Grinberg, Boris. **Sorption of water vapor by hydrolyzed cellulose and by micelles isolated from cellulose.** *Compt. rend.* **230**, 1402-4 (1950).—*C.A.* 44, 7532*d*.

The sorption isotherms of water vapor on hydrocellulose and cellulose micelles of different origins were detd. at 20°C by means of a McBain quartz spiral balance at relative humidities of 0-90%. The isotherms of hydrocellulose had the classical S form of normal celluloses; the isotherms of 5, 15, 40, 60, and 90-min. hydrolyzed products were close together and slightly below that of the original cellulose; the av. relative sorption between 5 and 60% relative humidity was 87% for hydrolyzed (5 min.) Egyptian cotton and 78% for hydrolyzed (5 min.) viscose rayon; other hydrocelluloses had intermediate values. The isotherms of the cellulose micelles were normal sigmoidal curves and the av. relative sorption varied from 73 to 85%.

2554. Rao, K. Subba; Rao, M. Bhimasena; Vasudevamurthy, A. R., and Rao, B. Sanjiva. **Hysteresis in sorption XVII. Hardening of sericin and its influence on sorption-desorption hysteresis.** *Proc. Natl. Inst. Sci. India* 16, 1-4 (1950).—*C.A.* 44, 8195*e*.

Sericin was hardened by HCHO and basic chromium sulfate. Sorption and desorption curves of H_2O vapor were conducted at 30 °C on the hardened and unhardened samples. The former exhibited a hysteresis effect which persisted in subsequent cycles. The latter showed a hysteresis loop which decreased in size with subsequent cycles of sorption and desorption and finally disappeared.

2555. Seidel, M. P. **The preparation and properties of resin saturating papers. The moisture sorption and dimensional stability of paper-base laminates.** *Tappi* **33**, 551-3 (1950).—*C.A.* **45**, 2667*g*.

All of the papers were impregnated with a phenol-HCHO varnish. The impregnated sheets were stacked with the machine directions all parallel and hot pressed at 1000 lb/in², and 170-175°C. Before removing from the press, the laminates were cooled to 50 °C. Test pieces for H_2O sorption and swelling were cut 1 × 3 × 0.065 in. and submerged edgewise in distd. H_2O at room temp. and measurements made at 1, 2, 7, 30, 60, and 90 days. Av. H_2O sorption, edge swelling, and cross-grain elongation were detd. after 30 days' submergence: The 2 kraft sheets showed definite superiority in these properties.

2556. Simril, V. L. and Hershberger, A. **Permeability of polymeric films to organic vapors.** *Modern Plastics* 27, No. 10, 97, 98, 100, 102, 150-2, 154, 156, 158 (1950).—*C.A.* 44, 6232*f*.

Permeability results for 16 polymeric films to 15 org. vapors were expressed in terms of a permeability const. P (no. of moles of vapor per sec per cm Hg across the film passing through 1 cm^2 of film having a thickness of 1 cm). The mechanism of transport was: (1) passage of small mols. through preformed holes or capillaries, (2) diffusion of small mols. through the mass by holes formed as a result of thermal motion in the polymer chains, and (3) diffusion resulting from the interaction of diffusing mols. with active spots in the film.

2557. Simril, V. L. and Hershberger, A. **Permeability of polymeric films to gases.** *Modern Plastics* 27, No. 11, 95, 96, 98, 100, 102 (1950).—*C.A.* 44, 7620*d*.

The gas permeability of 21 polymeric films with H_2, NH_3, N_2, O_2, H_2S, CO_2, and SO_2 was a function of existing holes or easily opened holes in the film structure. The introduction of side chains in the main polymeric chains and presence of plasticizers and water all tended to increase permeability.

2558. TAKEDA, BUNSHICHI. **Absorption, passage, and evaporation of moisture. I. Moisture-permeability and air-permeability of papers.** *Rept. Inst. Sci. Technol. (Univ. Tokyo)* 4, 120-5 (1950); *J. Chem. Soc. Japan, Pure Chem. Sect.* **72**, 598-603 (1951).—*C.A.* 45, 7790*c*.

Papers having large air-permeability generally showed large moisture-permeability, but small air-permeability did not always correspond to small moisture-permeability. Paraffin paper, asphalt paper, ryphan (hydrochlorinated rubber), metal foil, film of polystyrene resin, etc., belonged to good moisture-proof film. Cellophane, parchment paper, etc., had large permeability for moisture in spite of their small permeability for air.

2559. TAKEDA, BUNSHICHI. **Absorption, passage, and evaporation of moisture. II. Moisture permeability of cellulose derivatives and synthetic resins (1).** *Rept. Inst. Sci. Technol.* 4, 171-6 (1950).—*C.A.* 45, 7790*d*.

Moisture-permeability of cellulose acetate, cellulose nitrate, benzylcellulose, polyvinyl alc., polyvinyl acetate, polyvinylbutyral, polyvinyl chloride, copolymer of polyvinyl chloride and polyvinyl acetate, polystyrene, etc., was measured. The moisture-permeability of these substances had no relation to their permeability for H_2, but was greatly influenced by the existence of hydrophile groups.

2560. WELLER, SOL AND STEINER, WALDO A. **Separation of gases by fractional permeation through membranes.** *J. Applied Phys.* **21**, 279-83 (1950).—*C.A.* 44, 6216*c*.

The permeabilities of thin org. films of rubber, ethylcellulose, polyethylene, and polystyrene toward O_2 and N_2 were measured. For an ethycellulose film the studies were extended to include CO_2, A, He, and H_2. The enrichment of a binary gas mixt. in a single stage of permeation was calcd. for the extreme cases of perfect mixing and no mixing.

2561. WELLER, SOL AND STEINER, WALDO A. **Engineering aspects of separation of gases. Fractional permeation through membranes.** *Chem. Eng. Progress* 46, 585-90 (1950).—*C.A.* 45, 394*f*.

Permeability coeffs. toward a no. of gases were detd. for a variety of com. packaging films. Ethylcellulose seemed to be most suitable for the fractionation of air, and polystyrene most suitable for the sepn. of He and H_2 from gas mixts. Since the films were not perfectly selective, in general it is necessary to employ a multistage, recycle system to obtain gases of high purity, but the no. of stages can be small in favorable cases.

2562. YOSHIOKA, KOSHIRO. **Hydration of starch grains.** *J. Chem. Soc. Japan*, Pure Chem. Sect., **71**, 456-8 (1950).—*C.A.* 45, 6013*i*.

Various methods for the detn. of bound water of starch grains were compared. Almost the same results were obtained by means of $CuSO_4$, EtOH, and sucrose. The quantities of bound water of various starch grains detd. by $CuSO_4$ as an indicator were given.

2563. ZAIDES, A. L. **Effect of heating on the structure and properties of proteins. I. Collagen.** *Kolloid. Zhur.* **12**, 347-51 (1950).—*C.A.* 45, 889*a*.

Untreated collagen took up 10 and 40% H_2O at relative humidities of 10 and 90%, resp., while collagen treated at 170°C absorbed about 5 and 30%. Absorption of H_2O vapor by chrome-tanned leather was little affected by heating. The wt increase of untreated collagen in H_2O, 0.1 *N* HCl, and 0.1 *N* NaOH was 64, 231, and 188%, and of heated collagen 37, 54, and 90%, resp.

2564. ZETTLEMOYER, A. C.; CHAND, AMIR, AND GAMBLE, ERNEST. **Sorption by organic substances. I. Krypton and nitrogen on polyethylene, nylon, and collagen.** *J. Am. Chem. Soc.* 72, 2752-7 (1950).—*C.A.* 44, 8735*a*.

The adsorption of N_2 and Kr on polyethylene was measured at both liquid N_2 and liquid O_2 temps. For nylon and collagen, Kr adsorption was measured at two temps. The adsorption isotherms were typical Type II except for a rather gradual break where the monolayer was completed. The B.E.T. surface areas were of reasonable magnitude and agreed very well for the two gases at different temps. on the same sample. The heat of adsorption of Kr increased as more gas was added to the surface, and then decreased again after one monolayer was completed. The entropy curves for Kr on polyethylene and nylon fell toward limiting values as one layer was completed.

2565. ZHURAVELEVA, E. I. **Loss of moisture by corn starch to air.** *Kolloid Zhur.* 12, 32-5 (1950).—*C.A.* 44, 4273*e*.

Starch, which had been kept for some days in satd. H_2O vapor and acquired w_0 g H_2O per g, was transferred at 16°C into a desiccator in which the relative humidity was ϕ%. The amt. of H_2O decreased according to equation $w = w_0 - a \exp(-k/t)$, t was time (days). At $\phi = 0.5$, the const. $k = 0.31$, but at higher humidity k during the first 10 days was about 3 times as great as later. The final w was used to det. the desorption isotherm. This touched the adsorption isotherm at $\phi = 0.5$, but showed hysteresis of about 0.02 g H_2O/g at higher relative humidities.

2566. ZÍMA, RUDOLF. **Determination of moisture in commercial starches by drying.** *Chem. Listy* 44, 55-9 (1950).—*C.A.* 45, 5958*c*.

Predrying of starch at low temps. could be omitted. Drying 3 hrs at 120°C of 10-g starch samples gave const. values. The same results were obtained with 5-g samples in 1.5 hrs. The max. error was 0.1%.

2567. ARLOV, A. P. **Effect of surface roughness on rate of water absorption in paper.** *Norks Skogindustri* 5, 403-8 (1951)(in English).—*C.A.* 46, 6384*b*.

Sized papers (with contact angle over 90°C) absorbed H_2O slower the rougher the surface and the bulkier the sheet. With unsized sheets the opposite effect was found. Seven beater-sized samples from a paper sized with pronounced 2-sidedness, as regards water absorption and surface roughness, were tested and showed greater water absorption on the smoother surface in agreement with the lab. expts.

2568. Benson, Sidney W. and Seehof, Jerrold M. **The surface areas of proteins. IV. Sorption of polar gases.** *J. Am. Chem. Soc.* **73**, 5053-8 (1951).—*C.A.* **46**, 1845*g*.

The sorptions of NH_3, HCl, BF_3, and CH_3NH_2 gases by egg albumin were detd. at several temps. The sorption was independent of the state of dispersion of the solid protein but related to the specific nature of the protein. NH_3 and HCl sorption data and CH_3NH_2 desorption data, followed Freundlich-type isotherms. The partial molal differential heats of sorption were 7.5 ± 0.5 and 12 kcal./mole for NH_3 and HCl, resp. The attainment of equil. was very slow, and hysteresis was evident.

2569. Bergstrom Lourenco, Oscar. **Determination of the permeability of films used in packaging.** *Anais assoc. quim. Braxil* **10**, 313-18 (1951).—*C.A.* **47**, 5579*h*.

The moisture pickup of small (3 × 3 cm) cylindrical vials, contg. suitable chemicals and sealed with the foils to be tested was followed. The permeability of the films was calcd. from $Q = k\,\Delta P\,(a/e)t$, in which k was the permeability coeff., ΔP was the vapor pres. differential, a the film area, e the film thickness, t the elapsed time, and Q the moisture pickup. Brazilian impermeable Cellophane had a permeability ($k = 0.0012$-0.0072) comparable to that of Pliofilm (0.0010-0.0026) and about 1/50 that of ordinary Brazilian Cellophane (0.080-0.33).

2570. Cabrera, N. **Evaporation and mobility of naphthalene molecules.** *Nature* **167**, 766-7 (1951).—*C.A.* **45**, 7845*c*.

The values of the mean displacement of adsorbed mols. were of the order of 10^{-4}-10^{-6} cm.

2571. Cutler, Janice A.; Kaplan, E.; McLaren, A. D., and Mark, H. **The permeation of vapors through polyethylene.** *Tappi* **34**, 404-7 (1951).—*C.A.* **46**, 290*e*.

Data for a 0.0024-cm film in g/m^2-hr were given. The vapor pres. (mm Hg) and the permeability were, resp.: H_2O, 4.7, 0.021; 22.4, 0.108; propanol, 7.0, 0.07; 19.0, 0.26; acetone, 6.2, 0.25; 25.3, 0.18; propionitrile, 4.5, 0.03; 23.5, 0.35; benzene, 4.8, 0.09: 21.0, 1.16; hexane, 6.0, 0.025; cyclohexane, 6.1, 0.019; 24.0, 0.57; 1,2-dichloroethane, 7.7, 0.32; 21.2, 1.72; *trans*-dichloroethylene, 5.6, 0.23; 25.8, 2.10; *cis*-dichloroethylene, 6.4, 0.26; 22.8, 1.51; nitroethane, 4.5, 0.11; 19.5, 0.70.

2572. Dean, Robert B. and Hayes, Kenneth E. **The sorption of vapors by monolayers. III. A surface balance for the measurement of the effect of vapors on monolayers.** *J. Am. Chem. Soc.* **73**, 5583-4 (1951).—*C.A.* **46**, 2373*f*.

The monolayer chamber had a vapor vol. of 1.5 liter and was regulated to 0.1°C. Surface-pressure measurements were reproducible to ±0.05 dyne/cm and surface concns. to 0.1×10^{-10} moles/cm^2. Equil. was reached usually in one-half hr at 30°C using stearic acid and hexane vapor.

2573. Garin, A. **Determination of water in textiles.** *Bull. inst. textile France* **No. 23**, 9-24 (1951).—*C.A.* **46**, 1260*i*.

A survey of methods was given.

2574. Grinberg, B. **The sorption of water vapor by cellulose.** *Ann. chim.* **6**, 489-535 (1951).—*C.A.* **46**, 1251*h*.

The sorption isotherm of H_2O vapor on cellulose was S-shaped and showed hysteresis. The app. consisted of 5 McBain balances (quartz fiber). At the beginning of each expt., the cellulose samples were dehydrated at 50°C, and then put in contact with H_2O vapor at known temp. and pres. The samples used included Egyptian cotton, native and mercerized firwood cellulose, and rayon viscose. Hydrolysis, which decreased the degree of polymerization most during the first 5 min., caused a decrease in sorption. Sorption was measured for regenerated cellulose by using different times of aging of the alkali cellulose and of the viscose, and fibers made with no extension and with 100% extension. Aging had little effect on sorption, but decreased greatly the rate of penetration.

2575. Hayes, Kenneth E. and Dean, Robert B. **The sorption of vapors by monolayers. IV. Calculation of the amount of hexane adsorbed on a stearic acid monolayer.** *J. Am. Chem. Soc.* **73**, 5583-4 (1951).—*C.A.* **46**, 2373*g*.

The amt. of org. vapor adsorbed on a long-chain monolayer was detd. and applied to the system of stearic acid-hexane. The thermodynamic standard state used in the calcn. was chosen as the surface concn. of stearic acid given by the spreading pressure of stearic acid under hexane vapor. The adsorption of hexane followed a type-III isotherm at low stearic acid concns. and a type-V isotherm at high acid concns. with a limiting ratio of one mol. of hexane to one of stearic acid.

2576. Hellman, N. N. **Determination of moisture in starch by drying.** *Cereal Chem.* **28**, 79 (1951).—*C.A.* **45**, 3628*g*.

It was found that corn, potato, and tapioca starches dried at 25°C and 10^{-6} mm Hg pressure lost no more wt upon heating to 110°C at this same pressure.

2577. Hirota, Kozo and Kawamura, Fumio. **Determination of bound water in proteins.** *Monograph Ser. Research Inst. Applied Elec.* (Japan), *Research Biophys.* No. 2, 11-19 (1951)(in English).—*C.A.* **46**, 8702*c*.

Detns. were made on gelatin and its x-ray-radiated product. When g (g H_2O per g dry gelatin) was plotted as a function of a (activity of H_2O from vapor-pressure detn.), the 2 curves cross at $a = 0.8$ and below this the radiated gelatin held less H_2O. The constants v_m and c of the B.E.T. equation were detd. and the excess energy, per mol. of H_2O adsorbed on the first layer over that of pure H_2O, calcd. Since radiation reduced v_m by one half with little change in the excess energy adsorbed it was postulated that only those gelatin mols. which had absorbed an x-ray quantum were changed in structure and hence in adsorption properties.

2578. Katchman, Bernard and McLaren, A. D. **Sorption of water vapor by proteins and polymers. IV.** *J. Am. Chem. Soc.* 73, 2124-7 (1951).—*C.A.* 45, 7407*c*.

The H_2O vapor sorption isotherms of polymethacrylic acid, polyvinyl benzoate, polyisobutyl methacrylate, polyethylene, polyvinyl isobutyl ether, methoxypolyglycol, polyacrylonitrile, polyvinyl acetate, ethylene-vinyl alc., polyglycine-DL-alanine and polymethyl vinyl ketone, were detd. Cryst. insulin and soybean trypsin inhibitor sorb more H_2O than do the corresponding amorphous samples. A 1 to 1 correlation of polar groups and sorbed H_2O mols. in proteins and polymers was generally not observed because structural relations tend to limit sorption.

2579. Kawamura, Fumio and Hirota, Ginzo. **Change of bound-water content of gelatin by x-rays.** *Kagaku (Science)* 21, 469-70 (1951).—*C.A.* 46, 3369*e*.

Isotherms of bound water in gelatin were detd. for both x-ray-irradiated and -unirradiated samples at 10°C. The amt. of NH_3 vapor produced by x-rays was as small as 0.1 mg per 1 g of the sample. The B.E.T. consts. V_m and c (energy const.) were calcd., which showed that energy of adsorption decreased only slightly, but monolayer capacity V_m decreased appreciably, when the sample was irradiated by x-rays.

2580. Kovacs, A. **Study of water absorption of plastic materials.** *Ind. plastiques modernes* (Paris) 2, No. 6, 31-4 (1950); 3, No. 1, 30-2 (1951).—*C.A.* 45, 4479*g*.

The absorption in air followed Henry's law for relative humidities up to 0.75 after which there is marked deviation. In liquid the absorption was proportional to the vapor pressure, altered by any liquid-solid interaction. The absorption rose rapidly with temp. to a max. and then decreased slowly. The rate of satn. was characteristic of the plastic and increased with the temp. The permeability was the product of the amt. absorbed and the diffusion const. (D). D increased with the amt. of absorption and decreased with the amt. of desorption owing to swelling and deswelling of the plastic.

2581. Kroll, Karl. **Movement of moisture through softwoods during drying at 100°C. I. General considerations.** *Holz Roh-u. Werkstoff* 9, 176-81 (1951).—*C.A.* 45, 7847*d*.

In tubes closed at one end, the vapor movement was both a diffusion and streaming process. In large-diam. tubes, this outward streaming was a Poiseuille flow. When pore diam. was less than mean free path of vapor mols., the derived flow equation lost its significance, since the streaming was now a Knudsen mol. flow. A wide transition region existed between these two types of flow. The movement of bound water was not a diffusion phenomenon, but resulted from differences in capillary tensil forces.

2582. Kurosaki, Shigehiko. **Dielectric properties of sorbed water. II. Capillary condensation theory on the sorbed water in several high-polymer films.** *J. Chem. Soc. Japan*, Pure Chem. Sect., 72, 688-91 (1951).—*C.A.* 46, 1316*c*.

The dielec. consts. of paper, cellulose acetate, polyvinylformal, and polymethyl methacrylate films were detd. by resonance method for various amts. of sorbed water. The power factors of dried and wet films were also measured over the frequency range $10^3 \sim 10^7$ cycles/sec. No evidence was found of the existence of capillary-condensed water in these adsorbates for relative humidty less than 80%.

2583. Kurosaki, Shigehiko. **Dielectric properties of sorbed water. III. Sorbed water on polyvinyl chloride film.** *J. Chem. Soc. Japan*, Pure Chem. Sect. 72, 990-2 (1951).—*C.A.* 46, 7836*h*.

The moisture sorption isotherms of polyvinyl chloride were detd. at 12°, 20°, and 30°C. The increase of dielec. const. with moisture content was detd. at the frequency 500 kc. The heat of sorption at the initial stage was calcd. to be 7 kcal./mole.

2584. Mandelkern, Leo and Long, F. A. **Rate of sorption of organic vapors by films of cellulose acetate.** *J. Polymer Sci.* 6, 457-69 (1951).—*C.A.* 45, 4523*f*.

Cellulose acetate films, were suspended from a sensitive spring balance within an evacuated chamber, and Me_2CO or CH_2Cl_2 vapors admitted under known vapor pressure to det. the rate of their sorption by the films. Films that had been cast on glass took up vapors more easily when incompletely dried than when fully dried (50 days in a vacuum oven at 120°C) or when water-leached and dried 5 days. Films cast on Hg had an even lower rate of sorption. The rate of sorption of CH_2Cl_2 was found to be fundamentally like that of Me_2CO in spite of their different solvency as liquids.

2585. Mellon, Edward F. and Hoover, Sam R. **Hygroscopicity of amino acids and its relationship to the vapor phase water absorption of proteins.** *J. Am. Chem. Soc.* 73, 3879-82 (1951).—*C.A.* 45, 9333*g*.

Under conditions where the polar groups can be expected to be very highly coordinated into the crystal structure, amino acids absorbed little if any H_2O even at high humidities. However, all types of H_2O adsorption including hysteresis, were possible within these relatively simple substances. The polar groups of the proteins must be comparatively uncoordinated and completely available to H_2O mols. This situation was similar to that required by the polarization theory of adsorption and, therefore, this isotherm described the water adsorption curve of proteins from 6 to 93% relative humidity.

2586. Milligan, W. O.; Bushey, Gordon L., and Draper, Arthur L. **Isobaric and isothermal studies in the system soap-water.** *J. Phys. & Colloid Chem.* 55, 44-53 (1951).—*C.A.* 46, 3831*h*.

From dehydration isobars the definite existence of Ca palmitate monohydrate was shown. (Heat of hydration estd. to be -33 ± 5 kcal. per mole.) α-Na palmitate and stearate existed as hemihydrates, but the β, δ, and ω crystn. forms of these soaps were not definite hydrates.

2587. Nevell, T. P. **Oxidation of cotton cellulose by nitrogen dioxide.** J. *Textile Inst.* 42, T91-129 (1951).—*C.A.* 45, 5413*f*.

The oxidation of cotton cellulose with NO_2 was studied. The main reaction was shown to be the formation of uronic acid groups but in some cases nearly 3 atoms of O per C_6 unit, instead of 2, were consumed giving up to 700 millimoles of carboxy per 100 g. These oxycelluloses were found to be partially sol. in H_2O, and much more hygroscopic than unmodified cotton.

2588. Nice, G. R. **Apparatus for the measurement of the water vapor permeability of leather.** *J. Soc. Leather Trades' Chemists* 35, 17-20 (1951).—*C.A.* 45, 5958*i*.

Leather specimens clamped across the necks of wide-mouth bottles contg. a solid desiccant are exposed to an atm. of known high relative humidity. From the increased wt of the desiccant for a given time, the amt. of water vapor which has passed through the leather is detd. and the permeability calcd.

2589. Nissan, A. H.; Causer, L. W., and Underwood, N. C. **Rapid testing of large packages for water-vapor permeability. I. Apparatus.** *Brit. Paper and Board Makers' Assoc., Proc. Tech. Sect.* 32, 415-24 (1951).—*C.A.* 46, 2296*h*.

A conditioning cabinet was described designed for use in the detn. of water-vapor permeability of large packages in a tropical atm. of 38 ± 0.5° and 90 ± 2% relative humidity.

2590. Park, G. S. **Diffusion of some organic substances in polystyrene.** *Trans. Faraday Soc.* 47, 1007-13 (1951).—*C.A.* 46, 2873*e*.

Sorption rates were detd. at several pressures for CH_2ClCH_2Cl, $MeCHCl_2$, PrCl, BuCl, CH_2I_2, C_6H_6, and $CCl_2{:}CHCl$ by polystyrene sheet. Diffusion coeffs. (D_p) calcd. from the sorption half-times satisfy approx. the relation $D_p = D_0 \exp(\alpha v_p)$, where D_0 and α were parameters and v_p was the vol. fraction of the penetrant.

2591. Pomeroy, C. D. and Mitton, R. G. **The real densities of chrome- and vegetable-tanned leathers.** *J. Soc. Leather Trades' Chemists* 35, 360-82 (1951).—*C.A.* 46, 3784*f*.

The density of both leathers, detd. by displacement of N_2, ranged from 1.51 to 1.39 depending on the H_2O content as well as on the nature and extent of tannage. The density of both leathers increased to a max. (H_2O about 12%) and then diminished. The density varied with the nature of the gas used in measuring the vol., increasing in the order He, N_2, H_2, and O_2, probably as the result of a slight adsorption of the gases on the fibers. The d. by displacement with liquids having mols. of various sizes were the same for all, but slightly lower than that for He.

2592. Prager, Stephen and Long, F. A. **Diffusion of hydrocarbons in polyisobutylene.** *J. Am. Chem. Soc.* 73, 4072-5 (1951).—*C.A.* 45, 9333*f*.

The diffusion coeffs. of C_3H_8, C_4H_{10}, iso-C_4H_{10}, C_5H_{12}, and neopentane in polyisobutylene were calcd. from sorption data at 35°C. All increased exponentially with increasing concn. of the hydrocarbon in the polymer. An increase in both the degree of branching and the size of the diffusing mols. lowered the diffusion coeff., although the former effect was much more pronounced than the latter.

2593. Preston, J. M. and Chen, J. C. **Some aspects of the drying and heating of textiles. IV. The effect of drying conditions on the latent strain in the yarn of viscose cakes.** *J. Soc. Dyers Colourists* 67, 97-100 (1951).—*C.A.* 45, 4934*e*.

The effects of drying viscose in cake form by convection, infrared, and high-frequency methods were compared. The data for the cakes dried by the high-frequency method showed that it was possible to dry cakes substantially free from strain. As judged by the standard of freedom from latent strain, the next best method of drying appeared to be drying from the inside and very slow drying.

2594. Preston, J. M. and Bennett, A. **Some aspects of the drying and heating of textiles. V. Migration in relation to moisture content.** *J. Soc. Dyers Colourists* 67, 101-3 (1951).—*C.A.* 45, 4934*f*.

The higher the moisture content the more marked was the migration, and there was a characteristic lower limit at which it ceased. The cessation of migration and the second temp. step during drying corresponded to approx. the same stage in the dehydration of fibers. After this stage the residual moisture was all or nearly all in the fibers.

2595. Quackenbos, H. M. Jr. **Effect of adsorbed water on physical properties of molded phenolics.** *Modern Plastics* 28, No. 11, 107-8, 110, 170-1, 173 (1951).—*C.A.* 45, 7373*i*.

H_2O adsorption by molded phenolics under varying conditions of exposure was discussed. Information was presented to permit estimates of dimensional stability, warping, and stresses.

2596. Sato, Hideshi. **Water sorption by potato starch and its components.** *J. Chem. Soc, Japan*, Pure Chem. Sect., 72, 790-3 (1951).—*C.A.* 46, 5933*c*.

The sorption isotherms of water vapor were detd. for potato starch, fractionated amylose, and amylopectin at 10°, 20°, and 40°C. From the results, the isosteric differential sorption heat and entropy were calcd.

2597. Shelton, J. Reid and Cox, William J. **Volumetric oxygen absorption test for rubber aging.** *Ind. Eng. Chem.* 43, 456-63 (1951).—*C.A.* 45, 4081*i*.

Uncured Hevea rubber mixts. were much more resistant to oxidation than corresponding cured mixts., but after normal vulcanization, the degree of vulcanization had relatively little effect. The data on O_2 absorption indicated that the addnl. protection imparted by Hevea rubber was 2-fold; (1) a normal antioxidant activity, which reduced the O_2 absorbed, and (2) an effect on the nature of vulcanization, whereby absorption of a given percentage of O_2 in the early period of oxidation involved smaller changes in phys. properties.

2598. Thomas, A. Morris. **Moisture permeability, diffusion and sorption in organic film-forming materials.** *J. Applied Chem. (London)* **1**, 141-58 (1951).--*C.A.* 45, 7847*a*.

Sorption of H_2O vapor at 25-40°C by films of unplasticized polyvinylchloride (PVC), polymethyl methacrylate (Perspex), cellulose acetate, baked linseed oil, and electrical-insulating varnishes was a function of relative humidity and was independent of temp., facts which lead toward an equality of the heats of sorption and liquefaction. The results were expressed by the B.E.T. adsorption equations. The no. of polymer units per adsorption site were 160 for PVC, 29 for Perspex, and 12 for cellulose acetate. Diffusion consts. were calcd. from sorption and desorption rate measurements.

2599. Ashpole, D. K. **The moisture relations of textile fibers at high humidities.** *Proc. Roy. Soc.* (London) **A212**, 112-22 (1952).--*C.A.* 46, 11692*d*.

There is no true equil. at satn. The immediate satn. regain is identical with the moisture held by the fibers after centrifuging wet samples under standard conditions. The hysteresis loop closes at satn. Detns. of desorption regains can be expected to yield a unique curve for any one fiber only when desorbing from the satn. regain or above it. Desorption from lower initial regains will yield points within the hysteresis loop.

2600. Bogaty, Herman; Campbell, Kenneth S., and Appel, Wm. D. **The evaporation of water from cellulose.** *Textile Research J.* **22**, 75-81 (1952).—*C.A.* 46, 3755*h*.

The influence of H_2O on cellulose deterioration was discussed. A brown, fluorescent, water-sol. material resulted from evapn. of H_2O at the cellulose-water-air interface. Oxycellulose, of mildly reducing acid type, was formed, oxidation occurring in part at the primary OH group with the formation of polyglucuronic acid; this was followed by chain scission and formation of sol. fractions of low mol. wt.

2601. Bogaty, Herman; Campbell, Kenneth S., and Appel, Wm. D. **The oxidation of cellulose by ozone in small concentrations.** *Textile Research J.* **22**, 81-3 (1952).—*C.A.* 46, 3755*g*.

O_3 in amts. likely to occur in air at the earth's surface (up to 0.06 p.p.m.) deteriorated cotton textiles when wet. The deterioration was slight when compared with "weathering" elements such as light, heat, wetting, and drying, and microörganisms. Increased O_3 content causes increased cellulose deterioration.

2602. Bowler, Wm. W. **Water-vapor permeability and sorption of Hevea latex films.** *Ind. Eng. Chem.* **44**, 787-91 (1952).—*C.A.* 46, 10663*d*.

There was considerable difference between the structures of *Hevea* films vulcanized after drying and vulcanized as latex. This was evidenced by the different water-vapor permeability and sorption. The wt of water passing through an uncompounded film was inversely proportional to x in a wide range and directly proportional to Δp except when Δp is very high. This was not true of films vulcanized as latex. Films cast from vulcanized latex were found to be much more permeable, to sorb less, and to have a greater neg. temp. dependence of permeability than uncompounded films or films vulcanized dry.

2603. Broughton, G. and Hobbs, A. K. **Moisture determination in paper by oven drying.** *Tappi* **35**, 217-19 (1952).—*C.A.* 46, 7327*b*.

In analyzing the factors involved only in the actual drying operation, it was concluded that the temp. of drying was the most crit. variable in moisture detn. on paper. Supplying the oven with dry air increased the measured moisture content slightly; however, it did not increase the precision of the results.

2604. Brubaker, David W. and Kammermeyer, Karl. **Separation of gases by means of permeable membranes; permeability of plastic membranes to gases.** *Ind. Eng. Chem.* 44, 1465-74 (1952).—*C.A.* 46, 9932*h*.

A series of 22 com. and exptl. plastic films were subjected to permeation by CO_2, H_2, O_2, and N_2 at 20°, 30°, and 40°C to det. resp. permeability consts., *P*. Films examd. were vinyl chloride, ethylcellulose, and polyethylene types. No over-all predictable regularity in the temp. effect on *P* was noted.

2605. Dean, Robert B. and Hayes, Kenneth E. **The sorption of vapors by monolayers. V. The differential heats of adsorption of hexane on stearic acid monolayers.** *J. Am. Chem. Soc.* 74, 5982-4 (1952).—*C.A.* 47, 3652*d*.

Adsorption of hexane on stearic acid monolayers at 20°C was calcd. from surface-pressure measurements. Differential heats of sorption at 25°C were calcd. from these and data for 30°C reported previously. On close-packed monolayers the heat of sorption rose with increasing amts. of hexane sorbed, reaching the heat of vaporization of hexane when the mole ratio of hexane to stearic acid was 0.5. On a clean water surface the heat of sorption was not significantly different from the heat of vaporization of hexane.

2606. Denbigh, K. G. and Raumann, Gertrud. **The thermoösmosis of gases through a membrane. I. Theoretical. II. Experimental.** *Proc. Roy. Soc. (London)* **A210**, 377-87, 518-33 (1952).—*C.A.* 46, 10835*i*.

A theory was developed on the basis of Onsager's treatment of irreversible processes. The effect depended on the heat of soln. and the heat of transport within the membrane. Exptl. details were given for measurement of the thermoosmotic effect of CO_2, N_2, H_2 and water vapor through a natural rubber membrane. Observations agreed with the theory.

2607. Fujita, Hiroshi. **A numerical solution of the differential equation for adsorption-controlled diffusion in a solid.** *Textile Research J.* **22**, 281-6 (1952).—*C.A.* 46, 4877*g*.

An attempt is made to evaluate a numerical solution of a set of equations.

2608. Garin, A. **Factors influencing the determination of water in textiles.** *Bull. inst. textile France* No. **30**, 13-35 (1952).—*C.A.* 47, 2494*e*.

A general discussion of the importance of moisture detn. in textiles was followed by a survey of general principles of the various methods of detn.

2609. Grabe, Franz. **The full synthetic fibers and their chemical-technical utilization.** *Chem.-Ztg.* 76, 436-8 (1952).—*C.A.* 46, 11691*i*.

The water absorption and retention, the mech. strength, and the resistance to alkali, acid, and oxydans of Perlon (ϵ-amino caprolactam fiber), Pan (polyacrylic fiber similar to Orlon), and Rhovyl (polyvinyl chloride fiber) were studied and compared to natural fibers and rayon. The synthetic fibers showed higher resistance to rotting, low water absorption, and no penetration of dirt.

2610. Grahen, N. and Werner, G. **Passage of water vapor through textiles.** *Bull. inst. textile France* No. 30, 379-86 (1952).—*C.A.* 47, 2494*g*.

H_2O vapor was principally transferred through the pores of fabrics, but may also take place through extremely dense fabrics of low porosity. With hydrophobic fibers, H_2O vapor could also be transferred through the thin adhering water layer.

2611. Green, R. W. **Reaction of hydrogen chloride with dry proteins. II. Collagen, silk fibroin, elastin.** *Trans. Proc. Roy. Soc. New Zealand* 79, 485-93 (1952).—*C.A.* 46, 8683*e*.

Silk fibroin in gaseous HCl adsorbed from 1.24 g of HCl/100 g (0.24 hr) to 17.30 g HCl (2164 hrs). These samples retained from 0.47 to 2.90 g of HCl at 100°C *in vacuo* over CaO. In 0.2 *M* HCl in Et_2O silk fibroin adsorbed from 0.19 g of HCl (1 hr) to 2.47 g HCl (610 hrs). Elastin in gaseous HCl adsorbed from 17.8 g of HCl (2 hrs) to 30.3 g of HCl (1726 hrs) and retained from 1.32 to 2.80 g of HCl at 100°C *in vacuo* over CaO.

2612. Green, R. W. **Reaction of hydrogen chloride with dry proteins. III. Adsorption of water vapor on hydrochlorides of collagen and of silk fibroin.** *Trans. Proc. Roy. Soc. New Zealand* 79, 494-504 (1952).—*C.A.* 46, 8683*h*.

Water-vapor adsorption isotherms at 25°C were detd. for several modifications of silk fibroin and for hydrochlorides of silk fibroin and collagen at relative humidities from 6 to 95%. Analysis of the data supported the hypothesis of adsorption on polar groups. The power of basic groups and of aliphatic OH to coordinate H_2O was unaffected by reaction with HCl.

2613. Gregor, Harry P.; Sundheim, Benson R.; Held, Kalman M., and Waxman, Monroe H. **Ion-exchange resins. V. Water-vapor sorption.** *J. Colloid Sci.* 7, 511-34 (1952).—*C.A.* 47, 941*d*.

Sorption of H_2O vapor by com. ion-exchange resins was measured in a humidistat and a McBain sorption balance. The heat of sorption was measured in an isothermal calorimeter. At higher humidities, cross-linking decreased the sorption by the resins. Factors that increased sorption were: (1) decreasing divinylbenzene content and (2) existence of the resin in the hydrogen form. For a given resin, the sorption was least for the alkali or alk. earth metals with the largest hydrated ionic vols. Quaternary ammonium resins sorbed more H_2O when in the iodate state than in the chloride state.

2614. Grotjahn, H. and Hess, K. **Influence of the internal surface of cellulose samples.** *Kolloid-Z.* 129, 128-32 (1952).—*C.A.* 47, 5113*d*.

The internal surfaces of various cellulose samples were detd. by A adsorption at 90°K. The surface of various com. samples with a normal H_2O content was in the range 1.3-1.7 m^2/g, and did not change very much in vacuum drying at 100°C. Dried rayon fibers had internal surfaces of only 0.3 m^2/g. Cellulose samples dried by azeotropic distn. or extn. with C_5H_5N, EtOH, EtOH-Et_2O mixts., had 3.6-9.5 m^2/g, those with BuOH 22-38 m^2/g. If the samples were worked in a Strecker mill prior to drying with org. solvents, the final area was 40-200 m^2/g. The values for cellulose powder pptd. from viscose and dried with BuOH were of the order of 280 m^2/g.

2615. Haas, Howard C.; Farney, Leonard, and Valle, Claude Jr. **Properties of ethylcellulose films.** *J. Colloid Sci.* 7, 584-99 (1952).—*C.A.* 47, 4601*f*.

Films of ethylcellulose were cast on glass and Hg from solns. in C_6H_6, PhCl, Me_2CHNO_2, and a C_6H_6-CCl_4 mixt. The poorer solvents (C_6H_6 and PhCl) gave films of higher birefringence, higher d., lower brittle-point temp., and greater toughness. The higher cross-section birefringence observed with poorer solvents was attributed to the greater formation of a gel structure during drying of the film.

2616. Haller, R. **The effect of the vapor of various substances on textiles.** *Textil-Rundschau* 7, 359-65 (1952).—*C.A.* 47, 326*e*.

Fibers or fabrics were exposed to steam contg. various additives. AcOH had no effect on native or bleached cotton. ClO_2 had little effect on bleached cotton but gave pos. evidence of oxycellulose formation in native cotton. ClO_2 caused serious degradation of wool (special precautions were taken to avoid explosive concns. of ClO_2). NH_2Cl formed some oxycellulose in native cotton, but produced a much greater conversion to oxycellulose in bleached cotton. NH_2Cl degraded wool, especially affecting phys. properties and fiber structure, and had a similar, but less severe, effect on silk.

2617. Hammond, A. **The sorption of water by high-polymeric materials.** *Selected Govt. Research Repts.* (Gt. Brit.) Vol. 1, *Plastics, Rept.*, No. 4, 169-98 (1952).—*C.A.* 47, 2568*i*.

The theories of water sorption are reviewed: the mechanism of the sorption process, the mechanism of swelling, equil. water sorption and swelling of cellulosic materials and noncellulosic materials, water sorption and swelling under mech. pressure, hysteresis in sorption, effect of temp. on the equil. water sorption, rate of water sorption, sorption and swelling in liquids other than water.

2618. Harris, B. L. and Bialecki, A. **Permeability to water of thin unsupported films of pure drying oils.** *Am. Paint J.* 37, No. 12, 68-76; *Offic. Dig. Federation Paint & Varnish Production Clubs* No. 335, 884-7 (1952).—*C.A.* 47, 4628*g*.

Studies on the H_2O permeability of linseed-oil films revealed that probably no discreet pores existed, that soly. effects were not controlling factors, that surface effects were paramount, and that permeability followed Fick's Law for a const. humidity. H_2O permeability of the oils decreased in the order oleate < linoleate < linolenate < α-eleostearate. The glycerol esters are more permeable than the pentaerythritol esters.

2619. Hellman, N. N.; Boesch, T. F., and Melvin, E. H. **Starch-granule swelling in water-vapor sorption.** *J. Am. Chem. Soc.* 74, 348-50 (1952).—*C.A.* 47, 2522*g*.

Microscopic measurements of the swelling of individual starch granules occurring with the sorption of water vapor at various relative pressures showed that the linear granule swelling in a water-satd. atm. over the vacuum-dry dimension was corn, 9.1; potato, 12.7; tapioca, 28.4; waxy corn 22.7%.

2620. Higgins, James J. **The air drying of paper.** *Tappi* 35, 93-9 (1952).—*C.A.* 46, 6830*f*.

Air drying of paper was studied on handsheets, by using an exptl. tunnel drier in which temp., humidity, and air velocity were closely controlled. The paper showed an initial const. drying rate, followed by a period of falling rate. The rate of drying was shown to vary considerably from the leading to the trailing edge of the sheet. The curves obtained in this manner showed that the moisture did not vary with depth in the interior of the sheet during drying.

2621. Humphreys, F. E. **The drying of collagen and its reabsorption of water from humid atmospheres.** *J. Soc. Leather Trades' Chemists* 36, 90-6 (1952).—*C.A.* 46, 10657*a*.

Heating to const. wt in an oven at 110°C gave the same H_2O content for hide powder as prolonged desiccation at 20°C over P_2O_5 or drying at 60°C at 60 mm pressure. Drying in a steam oven (97°C) gave low results unless used under reduced pressure. Soaking in water or conditioning at 75% relative humidity previous to drying did not affect the results.

2622. Kast, W. and Schwarz, B. **Water absorption in the lattice region of cellulose II (cellulose hydrate).** *Z. Elektrochem.* 56, 228-33 (1952).—*C.A.* 47, 939*e*.

The 101 spacings in crystals of cellulose II (regenerated cellulose fibers) were measured. The results were: for bone-dry fibers (1) 7.020, fibers dried in a hot N_2 stream 7.227, dried fibers that were then moistened completely 7.365, hydrated fibers that had not been dried 7.560 A.

2623. Koshiyama, Kiichi and Takei, Kunio. **Diffusion of hydrogen sulfide through a built-up film of stearic acid on a copper plate.** *J. Chem. Soc. Japan*, Pure Chem. Sect. 73, 29-30 (1952).—*C.A.* 46, 9932*g*.

Built-up films of stearic acid and its salts were prepd. on a clear Cu plate, and the diffusion velocity of H_2S through the films was detd. The area of one mol. in a unimol. film on water was for Al stearate 29.0 A.^{2}, for stearic acid 18.8, and for Ba stearate 17.6.

2624. Landrock; A. H. and Proctor, B. E. **The simultaneous measurement of oxygen and carbon dioxide permeabilities of packaging materials.** *Tappi* 35, 241-6 (1952).—*C.A.* 47, 314*e*.

The test sheet, having an area of about 0.03 m^2, is clamped between 2 chambers and supported on both sides by a coarse screen. The lower chamber contains N_2; a mixt. of 80% O_2 and 20% CO_2 is swept through the upper chamber. The test is continued until the concn. of either test gas in the lower chamber is increased about 1% or until the pressure in the lower chamber is increased by no more than ½ in. Hg. At the conclusion of the test, some gas is drawn off from the lower chamber and analyzed in a conventional Orsat app. When the relative humidity is above 0%, it is necessary to correct for the vol. occupied by the water vapor.

2625. Magne, Frank C. and Skau, Evald L. **Nonfreezing water and nonfreezing benzene capacities of cottons and modified cottons.** *Textile Research J.* 22, 748-56 (1952).—*C.A.* 47, 871*d*.

The calorimetric, heat-of-fusion method was used to det. the amt. of nonfreezing water present in cotton and modified cotton fibers at various moisture contents. Results indicate that the nonfreezing water capacity was related to the total available surface, the proportion of amorphous cellulose, and the degree of distention of the wetted fibers.

2626. Marshall, Patricia A. and Moore, Walter J. **Sorption of ammonia by silk fibroin.** *J. Am. Chem. Soc.* 74, 4779-83 (1952).—*C.A.* 47, 1459*a*.

The sorption of NH_3 by silk fibroin was measured at -77° and -63°C with an app. of the volumetric type. There was a marked hysteresis in the sorption isotherms; the loop closes at zero pressure. The B.E.T. monolayer point for adsorption occurred when 1 NH_3 mol. was held for each 2 peptide links in the adsorbent, whereas the monolayer point on desorption occurred at 1 NH_3 for each peptide link.

2627. Meissner, H. P. and Byrne, J. **Bonding of thin films.** *J. Applied Phys.* 23, 1170-3 (1952).—*C.A.* 47, 378*i*.

Unsupported films of nitrocellulose of 0.25 micron and less in thickness bonded immediately and spontaneously in air to solid surfaces that they were made to touch. Bond strength increased with diminishing film thickness. Similar behavior was shown by films of Au, regenerated cellulose, polymethyl methacrylate, and gelatin.

2628. Milligan, W. O. and Draper, Arthur L. **Isobaric and isothermal studies in the system soap-water. II.** *J. Phys. Chem.* 56, 123-8 (1952).—*C.A.* 46, 9379*a*.

Sorption-desorption isotherms at 12 and 2°C were obtained for certain cryst. forms of Na stearate and Na palmitate, using water vapor as the adsorbate. The adsorption isotherms for the β-form (small crystals) produced by the dehydration of the α-form and for the δ-form had two inflection points below 0.3 p/p_o, whereas those for the β- (large crystals) and ω-forms were regular in this region. The B.E.T. function gives a linear plot. Heats of adsorption calcd. using the Clausius-Clapeyron equation declined rapidly from extremely high values at low pressures, rose slightly at intermediate pressures, and declined to approach the heat of liquefaction of water at the satn. pressure. The desorption isotherms exhibited low-pressure hysteresis.

2629. Miyake, Akira. **Dielectric constant and sorption property of high polymers.** *Busseiron Kenkyû* (Researches on Chem. Phys.) No. 48, 1-10 (1952).—*C.A.* 46, 5384*e*.

Statistical mech. theory is given of the relation between the change of dielec. const. and amt.

of gas sorbed on high polymers for cases in which the sorbed mols. are bound weakly and tightly.

2630. NAGHSKI, J.; MELLON, E. F.; KORN, A. H., AND OGG, C. L. **Water sorption studies on rutin and the determination of moisture.** *J. Am. Pharm. Assoc.* 41, 599-602 (1952).—*C.A.* 47, 1338*b*.

Absorption and desorption curves for H_2O at various relative humidities demonstrate the extremely hygroscopic nature of rutin High temp., vacuum, and an extremely dry atm. in the oven are essential to insure complete drying.

2631. OKAMURA, ISAO. **Drying of regenerated cellulose fibers.** *Teijin Times* 22, No. 4, 4-5 (1952).—*C.A.* 46, 6826*g*.

The swelling degree of regenerated cellulose fibers decreased upon reimmersion in H_2O after drying. The conditions of drying affected also the phys. properties of rayon fibers.

2632. QUACKENBOS, H. M. JR. AND HILL, J. M. **Effect of absorbed water on physical properties of phenolic plastics.** *Trans. Am. Soc. Mech. Engrs.* 74, 41-50 (1952).—*C.A.* 46, 3793*g*.

The absorption of water by phenolic plastics obeys Fick's law and can be described completely by a satn. const., a diffusion const., and a simple relation between diffusion const. and temp. Two important consequences of water absorption are that mech. properties change and all dimensions expand, the magnitude of each seeming to remain roughly const. for each percentage of water absorbed.

2633. RICHTER, G. A.; HERDLES, L. E., AND WAHTERA, W. E. **Vapor sorption of cellulose at high relative humidities.** *Ind. Eng. Chem.* 44, 2883-93 (1952).—*C.A.* 47, 2978*a*.

Sorption of H_2O was affected more by changes in fiber at 95-100% relative humidity than at lower relative humidities. Sorption of org. vapors at high relative humidities depended on the vapor in question and on the extent to which the fiber had been swollen at the time of exposure to the vapor.

2634. RICK, ANTON W. **Water vapor permeability and its measurement.** *Deut. Farben Z.* 6, 351-3 (1952).—*C.A.* 46, 10710*h*.

The *static method* consists in placing water, salt soln., or a hygroscopic agent inside a dish closed by a film of the material to be tested, and detg. the wt changes of the dish in a desiccator or a humidity chamber. In the *dynamic method*, a window covered by the test film is passed by a stream of moist air on one side, and by a stream of dry air on the other, and the moisture carried off by the dry air is held by drying tubes and weighed. In the *manometric method*, the film is placed between 2 evacuated systems, one contg. water to produce vapor of the partial pressure prevailing at the given temp., the other held dry by a freezing trap, measuring the vapor pressure of the water thus held by vaporizing it periodically against a manometer.

2635. SPIERS, C. H. **The hydration of collagen and leather.** *J. Soc. Leather Trades' Chemists* 36, 20-5 (1952).—*C.A.* 46, 8402*i*.

The real d. of dry and hydrated samples of collagen, vegetable leather, and Cr leather were detd. by means of an air-displacement method. The d. increased to a const. value with increasing hydration. The values for the dry and hydrated states were: collagen, 1.22 and 1.40; Cr leather, 1.33 and 1.48; vegetable leather 1.38 and 1.43. When H_2O is absorbed by collagen or leather the increase in real vol. is much less than the vol. of H_2O absorbed. For Cr and vegetable leathers the initial compressions are 6- and 4-fold, resp., and diminish to the same value as that for collagen.

2636. TAKEDA, BUNSHICHI. **Absorption, passage, and evaporation of moisture. III. Relation between the permeability and absorption of moisture. IV. A relation between the moisture permeability and the thickness of the film.** *Rept. Inst. Sci. and Technol., Univ. Tokyo* 6, 235-42; 243-6 (1952).—*C.A.* 47, 1468*a*.

Both the moisture permeability and absorption of org. films (bladder membrane, cellophane, cellulose acetate, polyvinyl alc., and polyvinyl acetate) were measured. Moisture permeability increased with increasing pressure of water vapor, especially in polyvinyl alc. At the same time the moisture absorption increased with vapor pressure. A relation between the moisture permeability and the thickness of the film was derived.

2637. TAYLOR, J. B. **Sorption of water by viscose rayon at low humidities.** *J. Textile Inst.* 43, T489-515 (1952).—*C.A.* 46, 11693*d*.

Sorption data were given for moisture regains below 2 ½% at 25-65°C for a com. viscose rayon. The isotherm was reproducible so long as H_2O was not removed at too high a temp.

2638. TRELOAR, L. R. G. **Absorption of water by hair, and its dependence on applied stress.** *Trans. Faraday Soc.* 48, 567-76 (1952).—*C.A.* 46, 10739*d*.

Expts. with horsehair, in which the water content in the stressed and unstressed states at 75.5% relative humidity was detd. by weighing, showed a small increase of 0.28% on the dry wt for a stress of 482 $kg/cm.^2$ Data were presented for the length changes which accompanied water absorption, and for the water absorption as a function of relative humidity. In yarn or cord, the effect of tension together with twist was to produce a lateral compression on the fibers.

2639. TSUBOI, MASAMICHI. **The molecular state of water bound to the peptide linkage.** *Bull. Chem. Soc. Japan* 25, 160-4 (1952).—*C.A.* 47, 5218*h*.

Infrared study in the 3-μ region of a film of "Amilan" (Toyo Rayon Co.), polycaprolactam, in both wet and dry state revealed a band at 2.86 μ, attributable to H_2O bound to the peptide linkages. No absorption was observed at 2.90-3.03 μ. Considerations of the effect on absorption caused by H-bonds led to the conclusion that the bound H_2O of the polymer was held to two O atoms and no free OH was present.

2640. VILLABONA, JOSÉ. **Permeability of polyethylene to gases, vapors, and liquids.** *Rev. plásticos* (Madrid) 3, 304-6 (1952).—*C.A.* 47, 4646*f*.

The loss in wt in g/24 hrs from 200-ml polyethylene bottles of 188 cm^2 surface area at 35°C was

15 for 42 g C_2HCl_3, 19 for 120 g C_2HCl_3, 36 for 240 g C_2HCl_3, 13 for 142 g CCl_4, 6 for 77 g C_6H_6, 5 for 72 g C_6H_6, 7 for 106 g C_6H_6, 16 for 115 g 50/50 mixt. C_6H_6-C_2HCl_3 mixt., 3 for 70 g ligroine, 1 for 64 g petroleum or 93 g 50/50 petroleum-acetone mixt., and 0 for AcOH, AcOH-water mixt., acetone, acetone-water, acetone-paraffin oil, paraffin oil, H_2O, EtOH, or EtOH-paraffin oil-amyl alc. mixt.

2641. WINGARD, R. E. AND ROZIER, W. H. **Comparative drying rates—infrared versus heated air.** *Alabama Polytech. Inst. Bull.* 47, No. 4, *Eng. Expt. Sta., Eng. Bull.* No. 15, 3-14 (1952).--*C.A.* 46, 6870*h*.

For seven different materials (sand, sawdust, sugar, Celotex, Filter-cel, cotton cloth, and $CaCO_3$), a combination of steam and infrared heating gave the highest rates of drying and the lowest drying times. Steam heating alone gave the lowest rates and the longest times. Infrared heating alone gave more rapid drying than steam but the rates were not quite as high as for combined steam and infrared heating.

2642. YAVOROVSKAYA, S. F. **Evaluation of some construction materials and technical substances in respect to their permeability and adsorbability of mercury vapor.** *Gigiena i Sanit.* **1952**, No. 12, 35-9.—*C.A.* 47, 4058*i*.

Plywood, asbestos cardboard, microporous rubber, tiles, and other materials of construction showed a considerable (1.8 to 7-fold) decrease of permeability to Hg vapor after they had been satd. with H_2O vapor. Generally, an increase in temp. increased permeability of these substances to Hg, which was especially well shown in microporous substances. Introduction of S into the formulations of wall construction materials (plaster) can serve as an addnl. method for removal of Hg from the air-spaces of buildings.

2643. BRUBAKER, DAVID WILLIAM AND KAMMERMEYER, KARL. **Flow of gases through plastic membranes.** *Ind. Eng. Chem.* 45, 1148-52 (1953);—*C.A.* 47, 6708*h*.

The effects of ambient conditions, mol. wt, thickness, and type of membrane on the permeability const. *P* (cc.-cm/sec-cm²-cm Hg) were detd. in the transmission of He, H_2, CO_2, O_2, and N_2. Of 56 samples tested, in nearly all cases, log *P* vs. $1/T$ from -75° to 50 °C was a straight line. Membrane thickness (0.0003-0.037) and pressure (up to 6 atm.) did not affect *P*.

2644. DAY, A. G. **Vacuum microbalance for measuring sorption in dielectrics.** *J. Sci. Instr.* 30, 260-3 (1953).—*C.A.* 48, 405*d*.

A balance for measuring the rate of sorption of water vapor by nonpolar dielectrics consisted of a glass-beam assembly contained in a vacuum-tight brass case and equipped with a fused-quartz torsion fiber to measure wt changes. The period of swing was 10 sec., capacity 300 γ, sensitivity of fiber $8°/\gamma$, and sensitivity of the balance 2×10^3 radians/g. With a load of 0.1 g, a change of 0.02 γ was indicated.

2645. DRECHSEL, PAUL; HOARD, J. L., AND LONG, F. A. **Diffusion of acetone into cellulose nitrate films and study of the accompanying orientation.** *J. Polymer Sci.* **10**, 241-52 (1953).—*C.A.* 47, 5114*c*.

Sorption and desorption of acetone by films of cellulose nitrate (11 and 12% N) were studied at 30 °C by following the wt of vapor takeup or loss as a function of time. The takeup-time, *t*, curves showed marked inflections. The rate of vapor takeup was much more rapid for films cast on glass than for films cast on Hg. Studies of the optical anisotropy of the films showed that the orientation of the polymer mols. normal to the plane of the film was increased by the diffusion process.

2646. JERGER, EDWARD W. **Mechanism of moisture movement in the drying of organic granular solids.** *Iowa State Coll. J. Sci.* 27, 198-9 (1953).—*C.A.* 47, 5729*i*.

Equations for the drying of soybeams and of corn were derived on the assumption that diffusion is the method of movement of moisture. Expts. showed that velocities of 23-52ft/min. had no effect on the rate of drying.

2647. MAGGS, F. A. P. **Reversal of temperature dependence for physical adsorption of nitrogen.** *Research Correspondence* 6, 13-14S (1953).—*C.A.* 47, 7285*g*.

The adsorption of N_2 on coal shows the normal temp. effect over the range 77°-273°K and also a reversed effect over a limited temp. range. Argon and H_2 show similar reversed effects; only the adsorption-temp. curves peak at a different temp.

2648. SAXENA, A. P. **The theory and testing of fabric wettability.** *Indian Textile J.* 63, 234-7 (1953).—*C.A.* 47, 6662*f*.

The kinetic effect is more important in wetting fabrics than the static contact angle. A simple method is described for measuring the speed of wetting. The wt increase of a 2-in.square fabric just touching a water surface is measured by an analytical balance after every 30 sec. Three distinct parts appear on the curves representing the water uptake of woolen gabardine, cotton duck, and cotton gabardine: (1) in the induction period no water is absorbed; (2) in the S-shaped part wetting occurs at a rapid and variable rate; and (3) in the end part water uptake is steadily rising.

Chapter II. ADSORPTION FROM SOLUTIONS ON SOLID ADSORBENTS

This chapter on the solid-solution interface is concerned with publications of a fundamental nature; those concerned with direct applications have been entered in Chapter V. As indicated in the Table of Contents, the publications given in Chapter II have been arranged to some extent according to the chemical composition of the adsorbent. Both the carbon adsorbents in Sections 1 and 2 and the noncarbon adsorbents in Sections 3 and 4 (clays, silica and alumina gels, soils, etc.) are materials with adsorbing surfaces which are rather poorly defined from a chemical and structural point of view. The overall chemical composition of these materials may not in general be a good indication of the actual composition at or near the surface. The boundary surfaces of inorganic solids (Sections 5 and 6) and metals (Section 7) may be defined with a little more certainty.

Studies on carbon adsorbents in various solutions constituted about 40 percent of this part of the literature for the period 1900–42. Between 1943–53 the number of publications on the same subject decreased to 5 percent. The main factor contributing to this change was not so much the decrease of interest in carbon adsorbents as the increase in the number of publications concerned with natural materials, such as the clays, bleaching earths, soils, etc., and with synthetic inorganic materials such as the porous oxides, catalyst supports, single crystals, etc. Some of these new materials became successful commercial adsorbents in the period after the outbreak of World War II.

The abstracts concerned with the literature on ion exchange (Section 8) and chromatography (Sections 9 and 10) show the extensive development of these techniques. The ion exchangers can now be applied to the removal of many inorganic constituents and a high degree of selectivity can often be realized. This has had immediate and important applications. Investigations in ion exchange have been principally in columns, although considerable work has also been reported in what is generally termed batch testing. The adsorption column has many inherent advantages and a high degree of separation is potentially possible.

The investigations concerned with chromatography have been quite numerous. Approximately half of the publications on this subject in Chapter II are concerned with the column technique and an equal number employed paper chromatography in many ingenious procedures. The ramifications of chromatography have furnished the chemist with a large number of varied techniques which provide a potential selectivity not previously possible. The literature reveals that this tool is very productive in many fields of investigation and it is being actively used by both the analyst and the chemical engineer.

The techniques of ion exchange and chromatography are having a major influence on the newer developments in analytical chemistry. A lack of exact reproducibility in various batches of the same adsorbent appears to be the principal handicap to the general adoption of a proposed scheme of analysis. There are now available a large selection of adsorbents, many of which are tabulated with their sources of supply in a concluding section of this volume (page 1365). The ability to specify the detailed requirements of the adsorbent for certain analytical separations might be a material aid to the manufacturer in production control.

Partition chromatography has been entered under the general classification of Chromatography in Columns. It is considered as a case where the solid adsorbents and some one of many varieties of adsorbates act together as a special adsorbent system.

Lattice imperfections at the boundary planes of solids has long been considered as a contributory source to the adsorption potential. Current activities in the growth of special crystals and in solid state physics in general have stimulated a great deal of new interest, and the results of these researches should be closely followed for pertinent facts relevant to the adsorption problem. Conversely, in the formation of any solid from the gas, liquid, or solution phase, there are attendant adsorption phenomena, the recognition of which will contribute to the understanding of reactions in solid state physics.

II-1. Carbon Adsorbents With Organic Solutions

2649. GINZBURG, D. Z. **The relation of the structure of organic acids to their adsorption from mixed solvents.** *Trudy Akad. Nauk Belorusskoi S.S.R.* **1939**, No. 5, 27-43; *Khim. Referat. Zhur.* 4, No. 2, 20 (1941).—*C.A.* **37**, 2243^{6}.

Adsorption of homologous series of fatty acids and of m- and p-$NO_2C_6H_4$-COOH on activated charcoal from the following mixts. of solvents was investigated: H_2O-EtOH; CCl_4-C_6H_6; CCl_4 (or C_6H_6)-EtOH. Adsorption of fatty acids from pure polar solvents (H_2O and EtOH) and from their mixts. obeyed Traube rule. During the adsorption from the system CCl_4-C_6H_6 the Traube rule was obeyed by the first members of the homologous series (up to valeric acid); then the adsorption increased somewhat with the increase in the no. of C atoms. The curves adsorption-compn. of the solvent mixts. had a min., corresponding to the max. of the curve of mol. polarization of the mixt.

2650. RĂDULESCU, DAN; RĂDULESCU, FLUOR, AND OPREANU, ROMULUS. **Capillary properties of pure liquids. Desorption isotherm of carbon tetrachloride.** *Bul. Chim. Soc. Chim. România* [2], 1, 56-64 (1939) (in French).—*C.A.* **37**, 3315^{8}.

The desorption of CCl_4 from charcoal at 0°C was studied. From breaks in the desorption curve it was deduced that the thickness of the capillary layer of adsorbed CCl_4 was not greater than 10 times the radius of the molecule. Possible sources of error were discussed.

2651. DYBINA, P. V. **Obtaining sodium thiosulfate from the waste products of sulfur dyes.** *J. Chem. Ind. (U.S.S.R.)* **17**, No. 1, 58-9 (1940).—*C.A.* **34**, 4577^{4}.

The filtrate from the sulfur dyes was purified with activated charcoal and evapd. to crystn. The final product contained 95.8% $Na_2S_2O_3$.

2652. DOBINE, MATHIEU. **Adsorption of concentrated solutions of acetic acid by blood charcoal.** *Compt. rend.* **212**, 155-7 (1941).—*C.A.* **39**, 4276^{7}.

Three curves were presented for the adsorption isotherms of moist charcoal, charcoal dried at 130°C, and a charcoal with a very small proportion of water (0.35 g water for 2 g charcoal). The curve for the last case climbed rapidly to a concn. 4 N to 5 N after which the curve was nearly sym. with charcoal dried at 130°C, then followed a further rapid climb to concn. 13 N to 14 N after which the curve fell off again. If the necessary correction was made by detg. the titer of the acid, the isotherms became identical.

2653. DOBINE, MATHIEU. **Adsorption of concentrated aqueous solutions of acetic acid by blood charcoal—true adsorption of the solvent and of the solute—reciprocal action of each of these substances on the adsorption of the other.** *Compt. rend.* **212**, 339-42 (1941).—*C.A.* **39**, 4276^{9}.

The adsorption of HAc initially increased slowly with concn., then increased rapidly, and in the range between 13 N and water-free rose almost vertically. The adsorption of HAc became very large at very high concns., where the amt. of water was small. The two isotherms crossed at a point corresponding to a concn. of 11 N. Between 0 and 11 N the curve obtained by dehydration lay over that by diln. min., above 11 N the positions were reversed. Dil. HAc activated the adsorption of water because the wetting of the charcoal was facilitated. At higher concns. HAc displaced water mols. from the surface of the charcoal by reason of its larger mol. size. Solvation, which diminished with concn., brought about a weaker displacement of water and resulted in a weaker adsorption of water.

2654. JAIN, KESHO DASS AND JHA, J. B. **Adsorption of mono- and polybasic acids by sugar charcoal.** *J. Indian Chem. Soc.* **17**, 685-90 (1941).—*C.A.* **35**, 5764^{4}.

Aliphatic and aromatic monobasic acids were adsorbed from aq. soln. by sugar charcoal (sugar was carbonized with H_2SO_4, washed, dried, ground, passed through a 120-mesh sieve and finally heated at 800-850°C for almost 1 hr) in a regular manner, but adsorption curves obtained from adsorption values for org. and inorg. di- and tribasic acids were periodic in nature. Amts. of acids adsorbed from 100 cc. of soln. by 1 g sugar charcoal during 18 hrs were given for oxalic, malonic, succinic, phthalic and citric acids, and hydrogen phthalate, Na-hydrogen succinate and Na-hydrogen oxalate.

2655. KRATZ, A. **Removal of oil from engine and heating condensates with the activated carbon Hydraffin.** *Papier-Fabr.* **39**, 85-6 (1941).—*C.A.* **37**, 6781^{5}.

The effectiveness in removing oil and the percentage load which the carbon was capable of adsorbing increased with increase in the condensate temp. A condensate temp. almost as high as the b. p. under the operating pressure should be used. Pure mineral oils were better adsorbed by the Hydraffin than fatty oils, since fats or sapond. fractions may close the pores of the charcoal.

2656. STEENBERG, BÖRJE. **The adsorption of strong electrolytes on active charcoal.** *Svensk. Kem. Tid.* **53**, 447-50 (1941).—*C.A.* **38**, 5446^{9}.

H ions were primarily adsorbed on activated ash-free charcoal from dil. solns. of strong inorg. electrolytes. From strong org. electrolytes the cations were preponderantly adsorbed. In the presence of large nos. of anions in the soln. the elec. work decreased and at equil. more H ions were adsorbed. This action of the ions was influenced by their valence, concn. and individual properties. The latter may be connected with the hydrophobic character of charcoal.

2657. TISELIUS, ARNE. **Adsorption analysis: experimental arrangement and some results with mixtures of glucose and lactose.** *Arkiv Kemi, Mineral. Geol.* **14B**, No. 32, 8 pp. (1941).—*C.A.* **35**, 5407^{1}.

The necessary app. was described and the results of tests made on glucose and lactose solns. tabulated. The method will be found applicable to solns. of other saccharides. The adsorption of saccharides from aq. solns. by charcoal were governed chiefly by the size of the mol.

2658. Bhatia, S. L. and Lal, Manohar. **Adsorptive power and activation of vegetable charcoal. II.** *J. Indian Chem. Soc., Ind. & News Ed.* **5**, 111-13 (1942).—*C.A.* **37**, 1637^1.

Wood charcoal adsorbed 20.32 g I_2 per 100 g; when heated for 2 hrs at approx. 350-360°C, it adsorbed 44.196 g I_2. In a series of tests, 5-g samples of sieved wood charcoal were soaked for 24 hrs in 10 cc. of the particular org. liquids, filtered, dried at 100°C and then heated 2 hrs at 350-360°C; one g of each treated charcoal was allowed to stand overnight with 50 cc. of 0.1 *N* I_2 soln. and then the mixture was shaken for 2 hrs, after which the amt. of I_2 adsorbed was detd. The highest increase in adsorptive power (188.18%) of vegetable charcoal for I_2 was obtained by treatment of the charcoal with PrOH.

2659. Cheldelin, Vernon H. and Williams, Roger J. **Adsorption of organic compounds. I. Adsorption of ampholytes on an activated charcoal.** *J. Am. Chem. Soc.* **64**, 1513-16 (1942).—*C.A.* **36**, 5403^7.

Adsorption data were given for the following compds. on charcoal: acetic acid, propionic acid, glycine, *dl*-alanine, *β*-alanine, *l*-tyrosine, *dl*-*a*-aminobutyric acid, *dl*-norleucine, *dl*-valine, *dl*-leucine, *dl*-isoleucine, *dl*-serine, *dl*-threonine, *dl*-methionine, *l*-lysine, *l*-aspartic acid, *l*-asparagine, benzoic acid, aniline, *o*-, *m*- and *dl*-tryptophan, urea, *d*-glucose, *i*-inositol, *l*-hydroxyproline, caffeine, creatine, creatinine, Ca pantothenate (dextro), Ca pantothenate (from liver ext.), biotin, pyriodoxine-HCl, thiamine-HCl. The exptl. data fit the Freundlich adsorption isotherm.

2660. Eyster, H. C. **Enzyme action.** *Science* **96**, 140-1 (1942).—*C.A.* **37**, 897^2.

Threshold values were determined for some narcotics that affected the adsorptivity of activated charcoal for methylene blue. Threshold value was the maximum amount of drug which would not produce any decrease in adsorption. Values in % were: EtOH 8, Et_2O 1, $CHCl_3$ 0.5, Na barbital 0.1, sulfanilamide 0.025, saponin 0.06.

2661. Rao, Nagamani Shama and Jatkar, S. K. K. **Binary systems. Introduction.** *Quart. J. Indian Inst. Sci.* **5**, 65-72 (1942).—*C.A.* **40**, 1078^3.

Complex formation in liquid binary mixts. influenced the selective adsorption of either component by charcoal or silica gel. Mixts. of C_6H_6 and CCl_4 with EtOH, iso-AmOH, and AcOH were used. The dielec. polarization was found to indicate complex formation where other phys. properties were not sensibly affected. The curves usually obtained on plotting adsorption isotherms for binary liquid mixts., equil. concn. C vs. the change due to adsorption $(C_o - C)$, were discussed covering U-, inverted U-, S-, and M-shaped curves.

2662. Rao, Nagamani Shama and Jatkar, S. K. K. **Binary systems. V. System benzene-ethyl alcohol.** *Quart. J. Indian Inst. Sci.* **5**, 73-9 (1942).—*C.A.* **40**, 1078^7.

Adsorption studies gave S-curves for sugar charcoal, blood charcoal and carbon or silica gel, and inverted U-curves for Norit and sugar charcoal activated by steam and CO_2. The shapes of the curves were explained on the basis of complex formation and the assocn. of polar mols. to form nonpolar ones. The S-curves had max. at 20 mole % EtOH, and zero adsorption at 90% for carbon or silica gel and 25% for sugar charcoal.

2663. Rao, Nagamani Shama and Jatkar, S. K. K. **Binary systems. VI. Systems isoamyl alcohol-benzene.** *Quart. J. Indian Inst. Sci.* **5**, 80-6 (1942).—*C.A.* **40**, 1078^8.

Adsorption on carbon or silica gel gave an S-curve (max. at 10 mole % iso-AmOH and zero selectivity at 35 mole % 10 mole %; iso-AmOH) and on Norit an inverted U-curve with min. in both cases at 65-75 mole % 10 mole %; iso-AmOH.

2664. Rao, Nagamani Shama and Jatkar, S. K. K. **Binary systems. VII. System isoamyl alcohol-carbon tetrachloride.** *Quart. J. Indian Inst. Sci.* **5**, 87-90 (1942).—*C.A.* **40**, 1078^9.

Adsorption on both carbon or silica gel and Norit gave S-curves with max. at 10 mole % iso-AmOH, zero selectivity at 25 mole % and min. at 50 mole %. The *n*-compn. curve showed an abrupt fall at 97 mole % 10 mole % iso-AmOH where the dielectric const. showed a max.

2665. Rao, Nagamani Shama and Jatkar, S. K. K. **Binary systems. VIII. System benzene-carbon tetrachloride.** *Quart. J. Indian Inst. Sci.* **5**, 91-7 (1942).—*C.A.* **40**, 1079^1.

The selective adsorption curve for carbon or silica gel, which showed C_6H_6 to be adsorbed in moderate concns. and CCl_4 in concd. solns., was S-shaped with max. at 45 mole % C_6H_6, zero selectivity at 50 and a min. at 20-25 mole %. Norit gave an inverted U-curve with min. at 75-80 mole % C_6H_6. The evidence, aided by cryoscopic study, indicated the probable complex formation of $CCl_4.4C_6H_6$.

2666. Rao, Nagamani Shama and Jatkar, S. K. K. **Binary systems. IX. System benzene-acetic acid.** *Quart. J. Indian Inst. Sci.* **5**, 98-102 (1942).—*C.A.* **40**, 1079^2.

Adsorption studies in C_6H_6-AcOH solns. showed S-curves for blood charcoal and sugar charcoal (max. at about 20 mole % HOAc, zero selectivity at 40 for blood charcoal and 25 for sugar charcoal, min. at about 80 mole %) and an inverted U-curve for carbon or silica gel (max. at 20 mole % AcOH). This behavior was attributed to the existence of polar single mols. of AcOH in dil. soln. and of the relatively nonpolar dimeric form in which AcOH mostly existed in more concd. soln.; the dimer was more polar than C_6H_6. On the surface of the adsorbents the complex $C_6H_6.2(AcOH)_2$ may be formed.

2667. Rao, Nagamani Shama and Jatkar, S. K. K. **Binary systems. X. System ethyl alcohol-water.** *Quart. J. Indian Inst. Sci.* **5**, 103-6 (1942).—*C.A.* **40**, 1079^4.

The dielectric const. for the H_2O-EtOH system were measured at 96 kc; the calcd. P_2 curve had an abrupt min. at 50 mole % EtOH and a max. at 25, corresponding to $EtOH.H_2O$ and $EtOH.3H_2O$. Various phys. properties of the system and selective adsorption by carbon confirmed these results.

2668. SASTRI, M. V. C. **Active carbon. IV. Adsorption of methylene blue by activated charcoal: effect of anions and cations.** *Quart. J. Indian Inst. Sci.* **5**, No. 3, 145-61 (1942).—*C.A.* **40**, 3959^4.

The pH values of solns. contg. 0.15% methylene blue and varying amts. of HCl, H_2SO_4, NaOH, and NaCl were detd. before and after adsorption with active charcoal. The adsorption changed abruptly in a crit. range of pH characteristic for each specimen because of its buffer action. The adsorption of methylene blue was enhanced by conditions that favor the adsorption of anions.

2669. SASTRI, M. V. C. **Active carbon. V. Adsorption of methylene blue by activated charcoal: examination of the theory of hydrolytic adsorption.** *Quart. J. Indian Inst. Sci.* **5**, No. 3, (1942) 162-76.—*C.A.* **40**, 3959^5.

Adsorption of methylene blue by active charcoal produced a decrease in pH with a liberation of acid. The theory of hydrolytic adsorption was not supported by the exptl. results.

2670. KUHN, A. AND GERHARD, H. **The adsorption of vitamin C.** *Kolloid-Z.* **103**, 130-5 (1943).—*C.A.* **38**, 289^4.

The effect of various treatments on the adsorption of ascorbic acid by active charcoals was investigated. Without special treatment the charcoals adsorbed the acid and partly oxidized it. This oxidation could be greatly diminished by treating the charcoals with reducing agents, especially Na_2S and $Na_2S_2O_4$. The Fe content of the charcoals did not affect the oxidation. Other adsorption agents were tried; of these floridin, frankonite and bentonite did not adsorb ascorbic acid in practical quantities.

2671. LOCKHART, CARLOS E. H. **Activated charcoal. Methods of determining the adsorbing power.** *Rev. facultad cienc. quím.* **18**, 23-34 (1943) (Pub. 1945).—*C.A.* **41**, 1070^c.

The methylene blue test gave consistent results. Variation of the time of contact from 5 to 30 min. did not cause a noticeable difference. The adsorbing power for methylene blue and for H_2O in an atm. satd. with H_2O vapor at 24° to 28°C were parallel. Charcoal of high adsorbing power must be used in quantities smaller than those prescribed in the method of the Argentine Pharmacopeia.

2672. RAO, NAGAMANI SHAMA AND JATKAR, S. K. K. **Binary systems. XI. Hydrogen bond in benzene.** *Quart. J. Indian Inst. Sci.* **6**, 1-42 (1943).—*C.A.* **40**, 1079^5.

The mol. polarization P_2 and the electronic polarization P_{E2} of the polar component, and selective adsorption by carbon or silica gel and activated coconut-shell charcoal were studied in the entire concn. range for the binary systems formed with C_6H_6 by CCl_4, $CHCl_3$, CH_2Cl_2, ethylene dichloride, ethylene dibromide, C_6H_5Cl, tert-BuCl, iso-AmBr, and iso-BuCl. Anomalous apparent polarization P_2 in concd. solns. was accompanied by still more marked anomalous selective adsorption at compns. corresponding to the possible mol. complexes. The apparent selective adsorption curves indicated all the possible compds. that can be formed by H-bonding of C_6H_6 to the halogenated compds.

2673. ROZEN, A. M. **Adsorption from solutions at high pressure.** *Compt. rend. acad. sci. U.R.S.S.* **41**, 296-7 (1943) (in English).—*C.A.* **38**, 6155^8.

Adsorption isotherms of AcOH by activated carbon were detd. at 25°C under pressures of 1, 1000 and 2000 kg/cm². The isotherms at all 3 pressures were of the same type; none of them conformed to Freundlich's equation. On plotting increment of adsorption against pressure, straight lines were obtained for representative concns., viz., 0.1, 0.15, 0.05, 0.02 and 0.01 *M*.

2674. SEILER, K. AND BOLLIER, P. **Moisture content and decolorization power of granulated adsorbent carbon, Swiss Pharmacopeia. V.** *Hundert Jahre Schweiz. Apoth.-Ver (Centenaire soc. suisse pharm.)* **1843—1943**, 526—30 (1943).—*C.A.* **38**, 1843^6.

The abnormally high moisture content of treated carbon could not be ascribed to subsequent adsorption of H_2O from the air, but rather to insufficient length of drying. The moisture content did not exert an unfavorable influence on the decolorization power. The max. adsorption by the carbon was detd. in a humid atm. and under normal conditions. The efficacy of adsorption of methylene blue was tested by the saponin foam method.

2675. TISELIUS, A. AND HAHN, L. **Adsorption analysis. II. Analytical separation of the products formed in the breaking down of starches.** *Kolloid-Z.* **105**, 177-82 (1943).—*C.A.* **38**, 3921^4.

Mono- to tetra-saccharides could be adsorbed on charcoal and removed selectively with the aid of ephedrine. Losses during the process were prevented by treating the charcoal 2-10 times with the dil. displacement soln. of ephedrine before attempting to adsorb the desired compds. In this way, the differences in adsorption tendencies of the various products became more pronounced and their sepn. from mixts. was facilitated.

2676. TOLMACHEV, YU. M. **The adsorption of uranyl salts on solid adsorbents.** *Bull. acad. sci. U.R.S.S., Classe sci. chim.* **1943**, 28-34 (English summary).—*C.A.* **38**, 1158^9.

UO_2 ion was reversibly adsorbed by activated charcoal at room temp. from UO_2-$(NO_3)_2$ solns. in accordance with the Freundlich equation. Its adsorption on schists from Central Asia and the Leningrad region was irreversible and was probably accompanied by chem. reaction. The schists with greater adsorptive power had a higher initial U content.

2677. ZAREZHINSKIĬ, YA. L. **Kinetics of sorption on granular substances.** *J. Phys. Chem. (U.S.S.R.)* **17**, 32-44 (1943).—*C.A.* **37**, 6515^6.

Exptl. data on the isotherms and the rates of adsorption and desorption of H_2O and Me, Et, iso-Pr and Pr alcs. as a function of concn. were detd. Measurements were made on single grains of activated charcoals prepd. from anthracite, birch wood and from bones. While the adsorptive capacities of the 3 charcoals differed by a factor of 8, the initial rates of adsorption differed by only 30-40%.

2678. Burgers, W. G. **Dependence of the adsorption isotherm on the amount of adsorbent.** *Rec. trav. chim.* **63**, 46-52 (1944) (in French).—*C.A.* **39**, 1584¹.

The adsorption of AcOH in dil. aq. soln. (0.01 to 0.4 *N*) was measured for 1, 2 and 3 g of carbon (Norit). The adsorption proceeded to equil. and in the range observed the diminution of the specific amt. adsorbed with increasing amt. of adsorbent was probably solely attributable to the exhaustion of the soln.

2679. Claesson, Ingrid and Claesson, Stig. **The adsorption of some high-molecular substances on active carbon.** *Arkiv. Kemi, Mineral. Geol.* **A19**, No. 5, 12 pp. (1944) (in English).—*C.A.* **41**, 1524*b*.

When a soln. of high-molecular substances such as nitrocellulose, synthetic rubber, or polyvinyl acetate was adsorbed on carbon, it was found that adsorption increased with decreasing mol. wt for the same class of substances. The adsorption equil. was not obtained immediately and the time was longer for lower mol. wts. With decreasing mol. wt the affinity factor *f* increased more than the space factor.

2680. Damerell, V. R. and Urbanic, A. **A study of the colloidal system carbon dispersed in xylene.** *J. Phys. Chem.* **48**, 125-33 (1944).—*C.A.* **38**, 3532⁵,

Certain surface-active chemicals greatly increased the degree of dispersion of carbon in xylene, as judged by sedimentation and ultramicroscopic analysis. Lecithin, Cu oleate, Co naphthenate and Aerosol OT (Na dioctyl sulfosuccinate) were most effective, in the order named. Results varied somewhat for the 3 different types of carbons investigated. The best dispersions were obtained with the type which had the least adsorbed O_2 and the smallest surface area. Oleic acid, which was one of the several surface-active agents which did not increase the degree of dispersion, was not adsorbed by the carbon particles, but Cu oleate and Co napthenate were adsorbed.

2681. Gyani, B. P. **Studies of adsorption in relation to constitution. III. Adsorption of carbohydrates from aqueous solutions by charcoal.** *J. Indian Chem. Soc.* **21**, 79-82 (1944).—*C.A.* **39**, 2240⁷.

Ten of the simpler saccharides, arabinose, dextrose, galactose, levulose, maltose, mannose, raffinose, rhamnose, sucrose, and xylose, were studied; animal charcoal was used as adsorbent. The adsorption increased with increasing mol. wt, and sugars of the same family form distinct groups of adsorption isotherms. The adsorption coeffs. of the various sugars of the same family were close together and increased in regular steps in passing from the pentoses to the bioses. The adsorption equation $x/m = ac^{1/n}$ was generally obeyed. Silica gel adsorbed the sugars poorly.

2682. Kiselev, A. V. and Shcherbakova, K. D. **Adsorption from solutions and the microporosity of activated charcoals.** *Doklady Akad. Nauk S.S.S.R.* **45**, 257-9 (1944); *Compt. rend. acad. sci. U.R.S.S.* **45**, 241-3 (1944).—*C.A.* **39**, 5150⁹.

The adsorption of aliphatic alcs. (butyl through heptyl), fatty acids (acetic through heptylic), and Na salts of oleic and erucic acids from aq. solns. by a specially purified activated charcoal was studied. At low concns. the adsorption, which increased with an increase in mol. wt, was apparently controlled by contending forces acting on the adsorbate. At higher concns., corresponding to max. adsorption, the vol. of the micropores of the adsorbent was the factor controlling the extent of adsorption.

2683. Papps, George and Othmer, Donald F. **Tall oil-separation of stearic and abietic acids by selective adsorption after hydrogenation.** *Ind. Eng. Chem.* **36**, No. 5, 430-4 (1944).—*C.A.* **38**, 3181¹.

Equil. studies were made to det. the adsorption isotherms of stearic acid by activated charcoal at 35.5°C, with the following solvents: hexane, heptane, petroleum ether, isoöctane, Solvesso 1, Solvesso 2, iso-PrOH, PrOH, MeOH, EtOH, nitromethane, nitroethane and 1- and 2-nitropropanes. Similar data were reported for pure abietic acid with Solvesso 1, Solvesso 2, MeOH, EtOH, iso-PrOH, PrOH, nitromethane, nitroethane and 1- and 2-nitropropanes. Selective-column studies for mixts. contg. 50% of each acid and for hydrogenated tall oil were reported. Stearic acid was preferentially adsorbed and the sharpness of sepn. depended mainly on the solvent, the best of which was 1-nitropropane.

2684. Régnier, Jean; Bazin, Suzanne and Féré Jacqueline. **Adsorption on charcoal, without agitation, of different salts of procaine base. Determination of cation and anions.** *Compt. rend. soc. biol.* **138**, 159-61 (1944).—*C.A.* **39**, 4539⁴.

The solns. were filtered through purified vegetable charcoal under identical conditions, and the adsorption of cation and anion was detd. Fixation increased in the order: isobutyrate, hydrochloride, phenylpropionate, monobasic citrate, dibasic citrate. In every case fixation of cation and anion was nearly equal, as though mols. of salt were adsorbed, although the compds. were known to be highly ionized.

2685. Régnier, Jean and Bazin, Suzanne. **Fixation on charcoal, without agitation, of different sodium salts. Determination of base and acids.** *Compt. rend. soc. biol.* **138**, 337-8 (1944).—*C.A.* **39**, 4539⁵.

Na salts in solns. of NaCl, Na isobutyrate, and Na citrate, 0.1-0.001 *M*, were adsorbed to a lesser degree than the corresponding procaine salts. fixation of Na was about the same for chloride and citrate and considerably less for isobutyrate. Approx. equal amts. of cation and anion were adsorbed.

2686. Régnier, Jean and Bazin, Suzanne. **Fixation on charcoal, without agitation, of salts of procaine base mixed with sodium salts. Determination of bases and acids.** *Compt. rend. soc. biol.* **138**, 375-6 (1944).—*C.A.* **39**, 4539^{6}.

Mixts. of procaine isobutyrate and NaCl, and procaine-HCl and Na isobutyrate, 0.1-0.002 *M*, were used. In either case approx. as much cation as anion was fixed, but a larger proportion of the procaine than of the Na, and a larger proportion of the HCl than of the isobutyric acid.

2687. Rozen, A. M. **Adsorption from solutions at high pressures.** *J. Phys. Chem. (U.S.S.R.)* **18**, 383-5 (1944).—*C.A.* **39**, 3190^{9}.

Exptl. data on the adsorption of HOAc on active charcoal at 25°C and at pressures of 1, 1000, and 2000 atm. were shown in 4 sets of graphs. The form of the adsorption curves was the same at all three pressures, and the relations of pressure to percentage increase in adsorption were strictly linear.

2688. Bodforss, Sven and Ehrlen, Inge. **Adsorption of amine bases on activated carbon.** *Kgl. Fysiograf. Sällskap. Lund, Förh.* **15**, 3-12 (1945) (in German).—*C.A.* **43**, 6037*d*.

The adsorption of amine bases on activated carbon (Kahlbaum, dried at 110° to const. wt) was detd. at 19°C ± 1°. Bases that were sufficiently strong, such as mono-, di-, and trimethylamine, mono-, di-, and triethylamine, nicotine, and piperidine were detd. by tritration with HCl. Special methods for weaker bases were described. Tables of the adsorption data were given. In water, adsorption of the aliphatic bases increased with mol. wt. Aliphatic bases were adsorbed much less than aromatic bases. However, piperidine was adsorbed less than diethylamine. Nicotine demonstrated the constitutional factor in adsorbability. In EtOH, increased mol. wt usually increased adsorption.

2689. Ferrandis, Vincente Aleixandre. **Adsorption from nonaqueous solutions.** *Anales fis. y quim (Madrid)* **41**, 709-45 (1945).—*C.A.* **41**, 4350*e*.

Adsorption by activated charcoal or activated Al_2O_3 was studied from non-aq. solns. of oxalic, malonic, succinic, glutaric, latic, malic, tartaric, citric, mono-, di-, and trichloroacetic, bromoacetic, cyanoacetic, phenylacetic, fumaric, maleic, mesaconic, and cetraconic acids. The solvents were MeOH, EtOH, iso-PrOH, isoBuOH, Et_2O, nitrobenzene, $CHCl_3$, CCl_4, and CS_2. In general, there was competition between soly. and adsorbability. The greater the adsorption of a substance, the less was the degree of ideality of its soln. The presence of OH or COOH groups and double bonds raised the adsorbability of the acids. Cis isomers were adsorbed better than trans in all solvents tested.

2690. Hassler, John W. and McMinn, W. E. **The nature of active carbon.** *Ind. Eng. Chem.* **37**, 645-9 (1945).—*C.A.* **39**, 3989^{4}.

Adsorption isotherms were detd. at 25°C of methylene blue, malachite green, alizarin red, ponceau red, blackstrap molasses, caramel, phenol, and I_2 in aq. solns., (the first 3 in EtOH soln.) on 9 com. carbons. The sp. adsorptive power changed with grinding of the various carbons. Variation of sp adsorptive power was brought about by changes in the carbons by oxidation. With carbons prepd. by activating cellulose waste in CO_2 for various lengths of time, the adsorption of I_2 increased with activation time of 15, 20, and 30 mins. The Freundlich isotherms were parallel. Impregnation with $ZnCl_2$ and with $CaCl_2$ changed the slope of the isotherm. Adsorption of CCl_4 vapor decreased the adsorption of methylene blue from aq. soln.

2691. Velasco, J. R. and Ruiz, J. Oliver. **Adsorption of dyes.** *Anales fís. y quím. (Madrid)* **41**. 1409-28 (1945).—*C.A.* **42**, 7129*d*.

The adsorptions of aq. solns. of Alizarin Red, Alizarin Brilliant Orange, Acid Navy Blue, Brilliant Scarlet, and Brilliant Green by activated carbon (Merck) were detd. The results could be interpreted rigorously up to the point of inflection by $a = (abc + abfc^2)/(1 + ac + abc^2)$. After the point of inflection there was a different phenomenon, since, when it appeared that the surface reached satn., the quantity adsorbed began to increase on increasing the concn. equil. The theoretical assumption of Langmuir for gases was generalized to apply to the present aq. solns.

2692. Agroskin, A. A. and Pentrenko, I. G. **Selective wetting of coal.** *J. Applied Chem (U.S.S.R.)* **19**, 737-46 (1946) (in Russian).—*C.A.* **41**, 4290*d*.

Contact angles θ were detd. at the boundaries coal-water-air and coal-water-org. liquid by projecting the contours of the drop with a 10,000-fold magnification. Drops of $C_6H_4(CH_3)_2$, $C_6H_5CH_3$, C_6H_6, gasoline, kerosene, deposited on polished coal immersed in water, showed a neg. wettability $B = \cos\theta$, the org. liquid failing to displace the water; the energy necessary to overcome the hysteresis was higher than the energy liberated in wetting. Owing to hysteresis, a water drop hanging vertically from a polished coal surface was not torn off by a spreading kerosene film, despite the equil. gain in surface energy (26.7-12.4 = 14.3 ergs/cm^2).

2693. Dzhigit, O. M.; Dubinin, M. M.; Kiselev, A. V., and Shcherbakova, K. D. **Active charcoals and adsorption from solutions.** *Compt. rend. acad. sci. U.R.S.S.* **54**, 141-4 (1946) (in English).—*C.A.* **41**, 2625*f*.

The adsorption of mainly butyl and heptyl alcs. from water solns. by means of 6 different charcoals ranging widely in pore size was investigated. The charcoal structure was shown to have a strong effect on the shape of the adsorption isotherms and on the values of limit adsorption. The rule of const. adsorbed limit vols. was approx. true for each of the carbons studied for the 4 alcs. butyl to heptyl. The micropores of the charcoals were equally accessible to the different alcs.

2694. Ghosh, B. and Khan, Ava. **Studies on the absorption of quinine by different adsorbents with a view to its extraction from very dilute solutions.** *J. Indian Chem. Soc.* **23**, 344-8 (1946).—*C.A.* **41**, 4894b.

As much as 96% of the quinine was adsorbed from a 0.15% soln. by the amt. of charcoal which was only twice the wt of the quinine sulfate.

Fuller's earth and kieselguhr adsorbed 86% and 62%, resp. Kaolin, MnO_2, tin oxide, silicic acid, and $Al(OH)_3$ adsorbed less in that order. Elution of the charcoal with Na_2CO_3 soln. recovered 84% of the quinine. Totaquine behaved similarly to quinine.

2695. GUPTA, PROMODERANJAN AND DE, PADMALOCHAN. **Polarity of molecules in relation to their adsorption by charcoal.** *J. Indian Chem. Soc.* **23**, 353-60 (1946).—*C.A.* **41**, 6106*b*.

Tests with a sugar charcoal in a medium showed that the trans form was better adsorbed in the case of fumaric and maleic acids. Introduction of a chloro group increased the adsorption, whereas a hydroxyl group, and particularly an amino group, decreased the adsorption. The hydroxyl group also decreased the adsorption in the case of BzOH and salicylic acid. Aniline was adsorbed better than phenol and BzOH adsorbed better than salicylic acid in aq. medium but the reverse held in C_6H_6 and $CHCl_3$ mediums.

2696. HARTMAN, ROBERT J.; KERN, RAYMOND A., AND BOBALEK, EDWARD G. **Adsorption isotherms of some substituted benzoic acids.** *J. Colloid Sci* **1**, 271-6 (1946).—*C.A.* **40**, 5317^2.

Adsorption isotherms for 7 acids on charcoal from C_6H_6 showed the following descending order: *o*-aminobenzoic, salicylic, *o*-chlorobenzoic, *p*-toluic, benzoic, *m*-toluic, and *o*-toluic. The adsorptions followed the Freundlich equation and the consts. of the equation were evaluated.

2697. KISELEV, A. V. AND SHCHERBAKOVA, K. D. **Adsorptive properties and structure of adsorbents. I. Limiting adsorption from solutions on activated charcoal.** *Acta Physicochim. U.R.S.S.* **21**, 539-54 (1946) (in English).—*C.A.* **41**, 19^h.

Investigation of the adsorption from aq. soln. by ash-free charcoal of the homologous series of acids from acetic to caprylic and alcs. from butyl to heptyl showed that the limiting adsorbed vols. were const. at about 0.28 cc. per g. Adsorption (the difference between the amt. of adsorbate in the adsorption space and in the same vol. of the surrounding soln.) passed through a max. for adsorbates of high soly. Dimethylethylcarbinol, cyclohexanol, phenol, benzoic acid, salicylic acid, methylene blue, and Congo red yielded adsorption vols. of 0.2, 0.24, 0.27, 0.22, 0.19, 0.20, and 0.04 cc. per g, resp.

2698. VOLMAN, D. H. AND KLOTZ, I. M. **Adsorption isotherms for hydrogen-bonded liquids on charcoal.** *J. Chem. Phys.* **14**, 642 (1946).—*C.A.* **41**, 1906d.

In van der Waals adsorption on charcoal, a plot of the wt adsorbed as a function of the relative pressure of the vapor gave curves roughly the same for most compds. The exceptions were characterized by strong H-bonds in the liquid state. When the b.p. was plotted against the van der Waals a, "normal" liquids lay in a narrow range between 2 curves. The compds. H_2O, EtOH, MeOH, NH_3, H_2S, and HCl, which lay outside the "normal" region, were characterized by strong H bonds in the liquid state. Evidently there was a strong parallelism between the adsorbability and condensation properties of a gas.

2699. WETTERHOLM, ALLAN. **Frontal adsorption analysis as a quantitative method.** *Harald Nordenson Anniv. Vol.* **1946**, 460-7.—*C.A.* **43**, 5325*e*.

The analysis was first carried out with known solns. of each of the pure components of the mixt. to det. the change in the concn. which would cause unit change in the n, $\Delta\mu$. The percentage content of each component became $fX\Delta\mu/g$, were $g=$ grams of sample/100 ml of soln. The method was employed in the analysis of mixts. of glycerol and ethylene glycol, with water as solvent and highly activated Höganäs MK carbon as adsorbent. Under these conditions no adsorption displacement took place, even when aniline was added to the mixt. as a further test. The analysis could be carried out with as little as 25 ml of the 0.5% soln. of the unknown used.

2700. AKAMATU, HIDEO AND NAGAMATSU, KAZUO. **A new suggestion for a model representing the structure of carbon black.** *J. Colloid Sci.* **2**, 593-8 (1947).—*C.A.* **42**, 2488*c*.

X-ray diffraction patterns were obtained for violanthrone, $C_{34}H_{16}O_2$; isoviolanthrone, $C_{34}H_{16}O_2$; and pyranthrone, $C_{30}H_{14}O_2$, which, because of their high content of 6-membered C rings, were considered to be models for elementary carbon. Patterns for 3 dyes representing violanthrone (Indanthrene Dark Blue B.O., Color Index No. 1099), Isoviolanthrone (Indanthrene Violet R extra, Color Index No. 1103), and pyranthrone (Indanthrene Gold Orange G, Color Index No. 1096), closely resembled those of carbon black. The pure compds. gave patterns quite different from either carbon black or graphite. When the three compds. were all mixed and repptd., the product gave a diffraction pattern almost indistinguishable from carbon black.

2701. DAVIDSON, G. F. **Determination of methylene blue.** *Shirley Inst. Mem.* **21**, 29-39 (1947).—*C.A.* **42**, 841*c*.

Wts of H_2O obtained by drying methylene blue at 105°C for 4-22 hrs agreed with those obtained by drying over P_2O_5 at room temp. for 13-27 days. A soln. contg. approx. 0.08 millimoles of I_2 and 0.2 moles of H_2SO_4 in 100 ml was reduced at 50°C with a slight excess of $CrSO_4$ soln. after removal of air with CO_2. The soln. was stirred for 0.5 hr with CO_2 and titrated potentiometrically with 0.01 *N* $K_2Cr_2O_7$. The vol. $K_2Cr_2O_7$ required to oxidize the reduced I_2 was detd. from the 2 breaks in the titration curve. The error was ±0.5%.

2702. GROVES, T. E.; BOWDEN, S. T., AND JONES, W. J. **Quantity of adsorbent and temperature as factors in adsorption from solution.** *Rec. trav. chim.* **66**, 645-54 (1947) (in English).—*C.A.* **42**, 2490*a*.

Adsorption of AcOH from aq. soln., up to 0.4 N, was detd. using 1, 2, and 3 g of activated charcoal powder per 50 cc. of soln. The isotherms were independent of the amt. of adsorbent. The isotherms obeyed the equation, $x/m = k\ c^n$, with the following values for the consts. k and n, resp.; at 0°C, 3.16, 0.58; 18°C, 3.08, 0.63; 50°C, 2.42, 0.77; 80°C, 2.17, 0.80.

2703. Hesse, Gerhard and Sauter, Oskar. **The pH dependence of adsorption of acids and bases.** *Naturwissenschaften* **34**, 251 (1947).—*C.A.* **43**, 6035*c*.

Acids were best adsorbed on amphoteric adsorbents in acid medium and vice versa. True adsorption was assumed with charcoal and the fact that acids adsorb best in acid medium was explained by preference of the charcoal for unionized acid.

2704. Innes, W. B. and Rowley, H. H. **Adsorption equilibriums of liquid mixtures of carbon tetrachloride and methanol with charcoal.** *J. Phys. & Colloid Chem.* **51**, 1172-81 (1947).—*C.A.* **42**, 1101*f*.

The selective adsorption of CH_3OH and CCl_4 on charcoal from a liquid mixt. of the two was measured directly and found to agree reasonably well with values calcd. from adsorption measurements of the mixed vapors. At 25°C, CCl_4 was preferentially adsorbed on charcoal below 0.6 mole fraction of CCl_4 in the liquid phase. At higher mole fractions of CCl_4, CH_3OH was selectively adsorbed.

2705. Kuznetsov, M. I. and Dybskiĭ, V. V. **Kinetics of the swelling of coal in pyridine.** *J. Applied Chem. (U.S.S.R.)* **20**, 976-96 (1947) (in Russian).—*C.A.* **42**, 5205*f*.

The rates of swelling were detd. by the vol. of C_5H_5N adsorbed by 7 types of coal ground to 900 mesh/cm^2 and pressed, under 30 atm., into 1-g cylindrical briquets of 2 cm diam. The briquets were supported by a glass filter, giving access to the liquid from the bottom. A pyridine reservoir, connected with the measuring pipet, permitted uninterrupted observation during 96 hrs. The "physical" capacity of the sample, as distinct from the absorption due to swelling, was detd. in each case with alc.; the corresponding amt. was subtracted from the vol. of C_5H_5N absorbed, giving the pure colloidal swelling effect. The figures were further corrected for moisture and ash content and reduced to 1 g dry and ash-free substance. Three coals swelled very rapidly in the initial stages and reached satn. in a few hrs; the remaining coals progressed gradually and there was no indication of satn. after 96 hrs.

2706. Lemieux, R. U. and Morrison, J. L. **Adsorption of aliphatic acids on activated charcoals.** *Can. J. Research* **25B**, 440-8 (1947).—*C.A.* **42**, 434*i*.

Max. adsorption on charcoals of different degrees of activation was detd. for acetic acid about 2.0 *N*, propionic acid about 0.5 *N*, butyric acid about 0.35 *N*, valeric acid about 0.25 *N*, and caproic acid about 0.04 *N*. The amt. adsorbed per g plotted against the concn. in the substrate exhibited a typical Langmuir curve. The activation process was discussed.

2707. Ruderman, L. Ya. **Physicochemical properties of the mixtures obtained in the recovery of organic solvents with activated carbon.** *J. Applied Chem. (U.S.S.R.)* **20**, 908-11 (1947) (in Russian).—*C.A.* **42**, 4829*b*.

Numerical calcn. of the amts. of upper and of lower liquid layer.(obtained with a ternary liquid mixt. of given compn. with the aid of the miscibility triangle) was illustrated by the example of the H_2O -EtOH-Et_2O.

2708. Swann, Sherlock, Jr. and Kerfman, H. D. **The electrolytic reduction of carbonyl compounds at carbon cathodes.** *Trans. Electrochem. Soc.* **92**, 11 pp. (1947).—*C.A.* **42**, 41*g*.

Several types of carbon were used as cathodes in the electrolytic reduction of EtMeketone, benzophenone, acetophenone, benzoic acid, *N, N-dimethylvaleramide*, and *p*-aminobenzanilide in acid soln. and of dipropyl ketone, benzophenone, and acetophenone in alk. soln. The cathodes were active only in the reductions of EtMeketone in acid soln., benzophenone in alk. solns., and acetophenone in both acid and alk. solns. Marked differences in the activities of the different forms of carbon were noted.

2709. Dzhigit, O. M.; Kiselev, A. V.; Terekhova, M. G., and Shcherbakova, K. D. **Adsorptive properties and the structure of adsorbents. II. Adsorption by active carbon from solutions in a wide range of concentrations.** *J. Phys. Chem. (U.S.S.R.)* **22**, 107-20 (1948) (in Russian).—*C.A.* **42**, 5298*c*.

Charcoal from a fruit stone, contg. 0.66% ash, was used. The adsorbed amt. of partially miscible fatty acids and alcs. increased with concn. to a limit which, when expressed as vol. adsorbed, was almost identical for valeric, hexanoic, heptanoic, and octanoic acids, and butyl, amyl, hexyl, and heptyl alcs. The max. varied from 0.50 to 0.57 cc./g and the liquid vol. of MeOH adsorbed from the vapor at the start of the hysteresis curve was 0.53 cc./g. The amt. adsorbed of highly sol. substances first increased with concn., reached a max., and decreased again. The concn. of the max. adsorption was 2.5, 2, and 13. mol. for AcOH, propionic, and butyric acids, and 3.3 and 1.8 M for EtOH and propanol, resp. The max. values of isobutylcarbinol, dimethylethyl-carbinol, phenol, and cyclohexanol were 0.46, 0.39, 0.47, and 0.38 cc./g, resp.

2710. Hansen, Robert S. **Multimolecular adsorption from binary liquid solutions.** *Univ. Microfilms Publ.* No. **1052**, 141 pp. (microfilm $1.76, paper enlargements $14.10); Microfilm Abstracts 8, No. 2, 33-4 (1948).—*C.A.* **43**, 4536*h*.

2711. Holman, Ralph T. and Hagdahl, Lennart. **Displacement analysis of lipides. Preliminary studies with normal saturated fatty acids.** *Arch. Biochem.* **17**, 301-10 (1948).—*C.A.* **42**, 6392*b*.

Satd. fatty acids can displace their lower homologs from charcoal. Cetyl pyridinium chloride and especially picric acid serve as displacement agents. The displacements are not quant. but may serve in qual. studies.

2712. Iwakami, Yoshimoto. **Adsorption of iodine in various organic solvents.** *J. Chem. Soc. Japan*, Pure Chem. Sect., 69, 9-10 (1948).—*C.A.* **46**, 8460*c*.

I_2 was adsorbed by active charcoal from the solns. (1) in MeOH, ethyl ether, (2) CS_2, toluene. From the results, the brown color in (1) was attributed to the combination of I_2 and solvent through polar force. The violet color in (2) was attributed to the condition in which I_2 existed in the free state.

2713. Kharin, A. N. and Protasov, P. N. **Uptake of substances by granulated carbon from a stream of solution. I. The dynamics of the sorption of acetic acid by carbon with coarse pores.** *Zhur. Fiz. Khim.* 22, 1219-39 (1948).—*C.A.* 43, 1238*e*.

AcOH solns., 0.005-0.05 *N*, were filtered through 20-125 cm long columns of birch charcoal, of which the ash content was 0.20% and the pore vol. 80%, at a speed of 0.5 cm/min. The amt. of AcOH between the adsorbent grains could not be neglected.

2714. Kipling, J. J. **The adsorption of acetic acid and butylamine from aqueous solutions by activated charcoals.** *J. Chem. Soc.* **1948**, 1483-7.—*C.A.* 43, 2485*d*.

Granular charcoal, steam-activated, showed a max. adsorption of AcOH in acid soln., a marked inflection point at pH 5-6, and negligible adsorption in alk. soln. Adsorption of $C_4H_9NH_2$ showed a max. in alk. soln. decreasing to zero at pH 6. Max. adsorption increased with continued activation of the charcoal, characterized by "activation yield" but the inflection point remained unchanged. The no. of mols. of AcOH and $C_4H_9NH_2$ (having approx. the same area per mol.) adsorbed was a function of the activation yield; this indicated adsorption of undissocd. mols.

2715. Kipling, J. J. **The behavior of charcoal columns in the adsorption and desorption of acid in aqueous solution.** *J. Chem. Soc.* **1948**, 1487-96.—*C.A.* 43, 3686*i*.

Breakdown and distribution phenomena in the adsorption of AcOH soln. on graded charcoal were studied as functions of time, length of column, flow rate, initial concn. and granule size. Results were expressed on the basis of the theory of the kinetics of adsorption of gases from air streams.

2716. Lesokhina, G. F.; Gol'bert, K. A., and Zhukhovitskii, A. A. **Adsorption from solutions by porous adsorbents.** *J. Phys. Chem. (U.S.S.R.)* 22, 363-77 (1948) (in Russian).—*C.A.* 42, 5741*f*.

C_6H_6 was positively adsorbed from its mixts. with CCl_4 at all concn. by sugar charcoal, bakelite charcoal, birch charcoal, anthracite charcoal, silica gel, hopcalite, and askanite (activated clay). The max. of the apparent adsorption was near 20 mol. % of C_6H_6. C_6H_6 was positively adsorbed also from cyclohexane by charcoal and silica gel, and the max. was near 25% C_6H_6. From CCl_4-C_6H_{12} mixts., CCl_4 was adsorbed by charcoal and silica gel, and the max. was near 20% CCl_4. In the systems C_6H_6-heptane and CCl_4-heptane, C_6H_6 and CCl_4 were adsorbed by birch charcoal, and the max. was near 50 and 55 mol. %, resp.

2717. Lesokhina, G. F.; Gol'bert, K. A., and Zhukhovitskii, A. A. **Adsorption from solutions of partially miscible liquids.** *Zhur. Fiz. Khim.* 22, 968-74 (1948).—*C.A.* 43, 461*d*.

If two-phase mixts. of cyclohexane + acetonitrile and cyclohexane + nitromethane were shaken with birchwood charcoal, the liquid might become homogeneous since the charcoal adsorbed preferentially that compd. which was present in the smaller amt. The compn. of the adsorbed part could be calcd. if the vol. of the adsorption space was assumed to be const. (0.53 cc./g). This compn. was 33 mol. % cyclohexane + 67 mol. % acetonitrile when the equil. soln. contained 6 mol. % cyclohexane.

2718. Mukherjee, J. N.; Chatterjee, B., and Ray, A. **Liberation of hydrogen, aluminum, and ferric ions from pure clay minerals on repeated salt treatment and desaturation.** *J. Colloid Sci.* 3, 437-45 (1948).—*C.A.* 43, 372*c*.

The treatment was a two-step process involving leaching the mineral with N $BaCl_2$ and then leaching with 0.02 N HCl. The treatment was carried through 4 cycles for montmorillonite, 8 cycles for kaolin and 5 cycles for pyrophyllite. The base-exchange capacity of montmorillonite, and pyrophyllite decreased markedly with repeated cyclic treatments, but the capacity of kaolin was unchanged after 8 cycles. The presence of dissolved SiO_2 in the exts. from the first 2 cycles with montmorillonite and pyrophyllite showed that decompn. of the absorption complex occurred with these minerals.

2719. Sulzbacher, M. and Pariser, R. **II. Isolation of ethylene chlorohydrin by adsorption.** *J. Soc. Chem. Ind.* 67, 205-6 (1948).—*C.A.* 43, 6*a*.

Ethylene chlorohydrin can be removed from dil. aq. soln. by adsorption on granulated active charcoal. However, such charcoal will not remove the chlorohydrin from an EtOH soln.

2720. Tendeloo, H. J. C.; Mans, A. E., and Hoogh G. de. **Titration of adsorbed acids.** *Rec. trav. chim.* 67, 397-403 (1948).—*C.A.* 43, 5343*a*.

Titration curves obtained by the potentiometric titration of picric acid, salicylic acid, maleic acid, and phosphoric acid in the presence of varying amts. of Norit had the form typical of weak acids. Curves showed the large buffering effect.

2721. Tendeloo, H. J. C.; Mans, A. E., and Hoogh, G. de. **The weak-acid behavior of adsorbed strong acids in solutions containing activated carbon.** *VII° Congr. intern. inds. agr., Paris* 2, 182-8 (1948).—*C.A.* 44, 8196*b*.

Activated carbon (Norit) was purified according to Miller. The acids investigated were picric, *o*-nitrobenzoic, maleic, and phosphoric. From titration curves a buffer capacity was found when activated carbon was added.

2722. Velasco, J. R. and Ruiz, J. Oliver. **Adsorption in solutions. V. Theoretical discussion of experimental results.** *Anales real. soc. españ. fís. y. quím., Ser, B,* 44, 69-94 (1948).—*C.A.* 42, 7129*h*.

For distd. water solns. of Brilliant Scarlet R, Direct Violet, ammonium eosinate, Alizarin Red, Alizarin Orange, Formyl Violet, Brilliant Green, Crystal Violet, and Diphenyl Orange, adsorption isotherms at 2 and 25°C with Merck active carbon showed that the quantity adsorbed per g of adsorbent varied regularly and continuously with the concn. in equil. under given conditions. The isotherms showed a regular portion, with a tendency toward a limiting adsorption, in which the adsorbed layer was unimol. The quantity adsorbed per g of adsorbent diminished with rise of temp. The adsorbability changed regularly and continuously, decreasing on increase of initial concn. It was shown that, for various solns., adsorbability at a given concn. was greater the less the soly. of the dissolved substance.

2723. Vogt, H. **Adsorptive power of carbon and other substances for 8-hydroxyquinoline in aqueous solution.** *Pharm. Zentralhalle* **87**, 38-44 (1948).—*C.A.* **44**, 6700*g*.

The adsorption of 8-hydroxyquinoline from aq. soln. was studied by shaking small amts. of adsorbent (0.1-1.0 g) with the soln. and detg. the amt. of the base unadsorbed by titration with 0.1 *N* $KBrO_3$ and 0.1 *N* $Na_2S_2O_3$. Charcoal was much more efficient than silica gel, Al_2O_3, or clay, and different brands of charcoal showed considerable variation. The amt. adsorbed increased with increasing pH over the range pH 1-5.2.

2724. Weizmann, C.; Bergmann, E.; Sulzbacher, M., and Pariser, E. R. **III. Adsorption of acetone, butyl alcohol, and 2.3-butylene glycol from dilute solutions.** *J. Soc. Chem. Ind.* **67**, 225-7 (1948).—*C.A.* **43**, 6*b*.

From dil. (2-4%) aq. solns., butylene glycol synthesized by *Clostridium polymyxa* and acetone, and butyl alc. produced simultaneously by *Cl. acetobutylicum* can be adsorbed on active charcoal. The affinity of the glycol for the adsorbent was so great that desorption was a more difficult operation. Acetone will perform the extn. In the case of acetonebutanol, it was possible not only to adsorb the mixt., but also to isolate the two components separately by selective adsorption.

2725. Akazawa, Yasaburo; Nakazawa, Taichi, and Okada, Mitsuo. **Adsorbability tests on activated charcoal by capillary analysis. II.** *J. Pharm. Soc. Japan* **69**, 328-30 (1949).—*C.A.* **44**, 1671*g*.

The correct value was found by filtering 50 ml soln. of 0.025-0.0025% methylene blue through a 9-cm paper, discarding the first 30 ml of filtrate, and colorimetric examn. of the next filtrate.

2726. Akazawa, Yasaburo; Nakazawa, Taichi; Okada, Mitsuo, and Ihara, Fujio. **Adsorbability tests on activated charcoal by capillary analysis. III.** *J. Pharm. Soc. Japan* **69**, 330-41 (1949).—*C.A.* **44**, 1671*g*.

The max. concn. of methylene blue which gave a stable curve for each estn. was 0.1%; a concn. of 0.05% was the best.

2727. Chmutov, K. V. and Alekseev, N. G. **Effect of irradiation by supersonic waves on the adsorption of fatty acids by finely porous carbon.** *Doklady Akad. Nauk S.S.S.R.* **67**, 321-3 (1949).—*C.A.* **43**, 7774*f*.

The supersonic field was applied to: (a) 0.1-g samples of carbon in contact with pure H_2O, before adsorption, (b) the carbon in contact and in adsorptive equil. with the 0.01 *N* solns. of the fatty acids. Equil. was reached in 1 hr. On coarse-pore carbon, the adsorptions of propionic, valeric, and heptylic acids, amounted to 1.190, 2.210, and 2.720 mmllimoles/g, resp.; preliminary supersonic irradiation had no effect and irradiation of the equil. system resulted only in very slight increases (1.238, 2.224, and 2.816). With a finely porous carbon, the adsorptions, without irradiation, were 0.749, 0.210, and 0.119, on irradiation (a), 0.475, 0.093, and 0.197, on irradiation (b), 0.895, 0.247, and 0.275. With an open-pore lampblack, the adsorption remained unchanged.

2728. Corrin, M. L.; Lind, E. L.; Roginsky, Adelle, and Harkins, W. D. **Adsorption of long-chain electrolytes from aqueous solution on graphite known area and on polystyrene.** *J. Colloid Sci.* **4**, 485-95 (1949).—*C.A.* **44**, 19*f*.

The adsorption of Na dodecyl sulfate and K myristate from aq. solns. on ash-free graphite of area 3.47 m^2/g (detd. by N_2 adsorption) was measured as a function of the concn. of long-chain compds. at 30°C for Na dodecyl sulfate and 35°C for K myristate. The area of the adsorbed soap mols. reached a min. of 51.0 $A.^2$/mol. for Na dodecyl sulfate and 36.6 $A.^2$/mol. for K myristate. A discontinuity was observed in the adsorption isotherms for Na dodecyl sulfate at a low concn. which corresponded to the crit. concn. for micelle formation. Measurements were also made of the adsorption of Na dodecyl from aq. solns. on polystyrene whose area (detd. by N_2 adsorption) was of the order of 100 m^2/g.

2729. Delga, Jean. **Adsorption of sulfonamides by activated charcoals. Properties of some adsorption complexes.** *Compt. rend.* **229**, 121-3 (1949).—*C.A.* **44**, 6578*i*.

Solns. of *p*-aminobenzenesulfonamide, *p*-aminobenzenesulfonamidopyridine, *p*-aminobenzenesulfonamidothiazole, *p*-aminobenzenesulfonylaminomethyldiazine, and *p*-aminobenzenesulfonylguanidine in H_2O, $(CH_3)_2CO$, EtOH, *N* HCl, and *N* NaOH when stirred with activated charcoal reached an equil. adsorption in 30 mins. obeying Freundlich's rule. The adsorbed sulfonamides were strongly held and were not removed by the above solvents, the most stable adsorption complex was formed from HCl soln.

2730. Dubinin, M. M.; Chmutov, K. V., and Alekseev, N. G. **Structure of active carbons and time of attainment of the adsorption equilibrium.** *Doklady Akad. Nauk S.S.S.R.* **66**, 875-8 (1949).—*C.A.* **43**, 7289*d*.

Adsorption of propionic, valeric, and enanthic acid (25 ml of a 0.01 *N* aq. soln.) was studied on 0.1-g samples of sucrose-carbon activated with CO_2 to different losses of wt: (a) 45.2%, (b) 13.8%, (c) 7.5%, and (d) 3%. Equil. was reached on (a) at room temp. within 1 hr, with 1.30, 2.14, and 2.43 millimoles/g adsorbed, resp. In the case of (b), (c), and (d), equil. was not yet reached after 1 month. For the initial stage of the adsorption, the usual series was reversed. After 48 hrs, the series was still reversed on (c) and on (d). After 16 yrs, the figures were, on (b), 1.24, 1.66, and 1.56 (mixed series), on (c) 1.07, 0.80, and 0.81, on (d) 0.85, 0.41, and 0.25 (reversed series). Since there remained some doubt as to whether the figures obtained after 16 yrs at room temp. corresponded to actual equil., accelerated expts. were made in which the samples were additionally kept at 100°C for from 10 to 29 hrs, then 1 more hr at room temp. The data after 16 yrs at room temp., did not quite repeat itself in the accelerated expt.

2731. Dubinin, M. M. and Zaverina, E. D. **Sorption and structure of active carbons. IV. Structure and sorptive properties of active carbons from phenolaldehyde resins.** *Zhur. Fiz. Khim.* **23**, 469-83 (1949).—*C.A.* **43**, 6037*c*.
Bakelite coke and the activated carbon obtained from it with a small wt loss adsorbed more AcOH than higher acids (C_3, C_5, C_7). When the wt loss was 16%, 20%, and 60%, resp. (activation temps. 1000°, 850°, and 750°C), the adsorption started to rise with the mol. wt of the acid. The adsorption of PhOH increased with the wt loss except in case of the highest loss.

2732. Fu, Ying; Hansen, Robert S., and Bartell, F. E. **Thermodynamics of adsorption from solution. II. Free-energy changes and surface-pressure-area relationships of adsorbed layers.** *J. Phys & Colloid Chem.* **53**, 1141-52 (1949).—*C.A.* **44**, 4305*e*.
The surface excesses (calcd. from the aq. soln. adsorption curves of BuOH, phenol, cyclohexanol, and amyl alc. by sugar char, 2 graphites, and a channel black) were used to derive force-area, force-surface excess, and force-area vs. force curves. The forms of the curves provided addnl. evidence for multilayer adsorption from aq. solns. by graphites and carbon blacks.

2733. Hansen, Robert S.; Fu, Ying, and Bartell, F. E. **Multimolecular adsorption from binary liquid solutions.** *J. Phys. and Colloid Chem.* **53**, 769-85 (1949).—*C.A.* 43, 7288*i*.
Caproic acid, valeric acid, amyl alc., butyl alc., aniline, phenol, and cyclohexanol exhibited multilayer adsorption from aq. solns. on 3 different samples of graphite and on 2 non-porous devolatilized carbon blacks. The amt. of adsorption plotted as a function of the reduced concn., c/c_o, obeyed the B.E.T. equation for multilayer physical adsorption of gases on solids. The adsorption on a porous sugar charcoal, on the other hand, obeyed the Langmuir equation and was limited for the most part to monolayer adsorption. The mol. areas deduced from adsorption values at the monolayer and from areas of the adsorbents as measured by N_2 adsorption were 40 to 150% greater than those obtained for the same solutes as close-packed films on liquid surfaces.

2734. Kharin, A. N. and Voitko, L. M. **The dynamics of sorption of coriander essential oil from aqueous solutions by coarse-porous charcoal.** *Zhur. Priklad. Khim.* **22**, 835-45 (1949).—*C.A.* **45**, 3221*g*.
Coriander oil used was to 75% sol. in H_2O (as *d*-linaloöl?). The aq. exts. were filtered through birch charcoal of 0.1-0.3 cm grains and 80% porosity until satn. Between 0.17 and 0.85 g/liter, the amt. (g) adsorbed by 1 g carbon was 0.26 C.(0.13 + C). The time of "break-through" θ was $KL - \tau$, when the length L of the C column varied between 19 and 109 cm. The const. K was 24-100 min./cm and the const. τ was 700-1900 min.; there was no definite effect of either concn. or the rate of flow (1-2 cm/sec).

2735. Reade, Marguerite A.; Weatherburn, A. S., and Bayley, C. H. **The adsorption of sodium myristate by carbon black.** *Can. J. Research* **27F**, 426-8 (1949).—*C.A.* **44**, 2819*d*.
Adsorption of Na myristate from 0.1% aq. soln. by a series of carbon blacks and an activated charcoal was measured at 70°C. In all cases a preferential adsorption of fatty acid was observed. The extent of adsorption of both the fatty acid and alkali components of the soap increased with decreasing particle size, i.e., with increasing surface area, of the carbons. The adsorption by activated charcoal was considerably higher than that obtained with the finest of the carbon blacks.

2736. Smith, Hilton A. and Hurley, R. B. **The adsorption of fatty acids on carbon blacks. Calculation of particle size.** *J. Phys. & Colloid Chem.* **53**, 1409-16 (1949).—*C.A.* 44, 4747*e*.
Acetic, behenic, capric, lauric, palmitic, and stearic acids from various solvents were adsorbed at 25°C on nine common carbon blacks. The blacks were activated with steam prior to the adsorption studies. Surface areas, calcd. on the assumption of 20.5 A.^{2} for the cross section of the acid mols., were in fair agreement with areas calcd. by other methods. When acetic acid was adsorbed using cyclohexane as the solvent, the isotherm indicated that a unimolecular layer was readily formed on the carbon surface.

2737. Tendeloo, H. J. C.; Mans, A. E., and Hoogh, G. de. **Titration of adsorbed acids. III.** *Rec. trav. chim.* **68**, 253-60 (1949) (in English).—*C.A.* **43**, 6883*b*.
Titration curves of HCl plus gelatin against NaOH, and of picric acid with and without activated charcoal (Norit) against NaOH were interpreted. The titration of adsorbed acids were considered as the prototype of the titration of polyacids, the carboxyl groups mutually interacting.

2738. Vold, Robert D. and Konecny, Christine C. **Suspensibility of carbon in detergent solutions.** *J. Phys. & Colloid Chem.* **53**, 1262-79 (1949).—*C.A.* **44**, 2329*d*.
Channel black and furnace black remaining in suspension 4 hrs after 0.5 g had been shaken in 100 ml of solns. of detergents were detd. with a photoelec. colorimeter. Detergents studied over a range of concns. were Oronite ($C_{12}H_{25}C_6H_4SO_3Na$), Aerosol OT (Na dioctylsulfosuccinate), P-$CH_3C_6H_4SO_3Na$, Na oleate, and Triton X-100 (alkaryl polyether alc.). All curves for carbon vs. concn. passed through a max. with differences in shapes of curves and concn. for max. The data and observations with an electron microscope showed deflocculation of coarse aggregates.

2739. Weatherburn, A. S.; Rose, G. R. F., and Bayley, C. H. **Adsorption of soap by carbon black.** *Can. J. Research* **27F**, 179-93 (1949).—*C.A.* **43**, 7289*b*.
The adsorption of Na soaps from aq. solns. by carbon black was studied. Adsorption of fatty acid and alkali components followed the Freundlich adsorption equation; the extent of adsorption increased with chain length. Adsorption of fatty acid exceeded that of alkali, the more so the

greater the chain length. Excess fatty acid resulted in increased adsorption of fatty acid, but did not affect adsorption of soap, whereas excess alkali increased adsorption of alkali but decreased that of fatty acid and of soap. Adsorption from 95% and abs. EtOH was much lower than from aq. soln.

2740. ZÂFIR, MÂLIK. **Considerations concerning the adsorption of colored solutions. Theoretical part.** *Folia Pharm. (Turkey)* 1, No. 3, 29-31 (1949).—*C.A.* **44**, 7119*g*.

Freundlich's empirical formula for colored solns. rearranged in $x = VdKC/n$, wherein for a given adsorption-tube diam. a vol. change can occur only when the layer height was altered. When a colored soln. of vol. V and concn. C passed through the tube, a gradual loss of pigment occurred by adsorption.

2741. HOLMAN, RALPH T. AND HAGDAHL, LENNART. **Displacement analysis of lipides. III. Separation of normal saturated fatty acids from formic to behenic.** *J. Biol. Chem.* **182**, 421-7 (1950).—*C.A.* **44**, 3883*h*.

The Tiselius-Claesson interferometric adsorption analysis app., packed with a mixt. of 1 part Darco G-60 and 2 parts Hyflo Super-Cel, was used. Solvent mixts. in which the displacer fatty acid was near its soly. limit gave the best sepns. The C_1-C_6 acids were displaced by a 0.4% aq. soln. of $C_9H_{19}CO_2H$; The C_6-C_{10} acids by 2% $C_{12}H_{25}CO_2H$ in 50% EtOH; the C_{10}-C_{13}acids by 1% $C_{14}H_{29}CO_2H$ in 65% EtOH; the C_{14}-C_{15} acids by 1% $C_{16}H_{33}CO_2H$ in 80% EtOH; the C_{16}-C_{20} acids by 1% $C_{22}H_{45}CO_2H$ in EtOH-$CHCl_3$ (78:22).

2742. INOUYE, KATSUYA. **The classification of coal by simple adsorption methods.** *J. Fuel Soc. Japan* **29**, 112-16 (1950).—*C.A.* **44**, 10294*h*.

I_2 and methylene blue adsorption from aq. solns. were suggested to classify coals according to their characteristic inner structures. The essential point was the specific surface areas of both series calcd. from the adsorption data with the assumption of monomol. adsorption. Lignites, sub-bituminous, bituminous coals, and anthracites were classified by this method.

2743. IOFA, Z. A. AND FLORIANOVICH, G. M. **Polarographic determination of adsorbability of charcoal with methylene blue.** *Zavodskaya Lab.* **16**, 142-4 (1950).—*C.A.* **44**, 6768*d*.

Agitate 0.2 g of dried sample for 10 min. with 0.5% methylene blue soln. Treat a 10-ml aliquot with 0.2 ml N H_2SO_4 and make a polarogram in an open vessel against a calibration curve. Charcoal high in ash should be washed with 6 N HCl, followed by H_2O.

2744. LINNER, EDWARD R. AND WILLIAMS, ARDIS P. **The effect of previous heat-treatment on some of the adsorption properties of sugar carbon.** *J. Phys. & Colloid Chem.* **54**, 605-18 (1950).—*C.A.* **44**, 7616*g*.

Purified sugar carbon, which had been subjected to heat-treatment within the range 500-110°C, was used as the adsorbent for acetic, propionic, butyric, and valeric acids. Surface areas were detd. by I_2 adsorption and pH values of aq. suspensions of the carbons. The consts. of the Langmuir equations were detd. for each acid with each carbon sample. The max. amt. of acid adsorbed was used to est. the relative surface area available to each of the acids. The max. surface available for adsorption occurred in all cases for the 800°C sample; pH values of the suspensions were unsatisfactory in explaining the possibility of the formation of oxides at the surface of the carbon during the heat-treatment.

2745. MUKHERJEE, SUDHAMOY AND BHATTACHARYA, SUKHAMOY. **Effect of chemical treatments on the properties of activated charcoal. Adsorption isotherms for methylene blue, iodine, and acetic acid.** *J. Indian Chem. Soc. Ind. & News Ed.* **13**, 240-6 (1950).—*C.A.* **46**, 318*a*.

The variations in the adsorptive power of various charcoal samples for methylene blue, I_2, and AcOH, in different concns., were studied. Each expt. was made with 0.05 g charcoal, prepd. from powd. coconut shell, and the vol. of the adsorbate was 50 cc. for methylene blue and 25 cc. for I_2 and AcOH. Isotherms were given for nonactivated and $ZnCl_2$- or $CaCl_2$-activated charcoals, untreated and after treatment with oxidizing agents. In general, the adsorptive power increased by treatment with oxidizing agents.

2746. NESTLER, F. H. MAX AND CASSIDY, HAROLD G. **Adsorption of low-molecular-weight fatty acids by an activated charcoal. Use of chromatography to obtain adsorption isotherms.** *J. Am. Chem. Soc.* **72**, 680-9 (1950).—*C.A.* **44**, 4747*f*.

Adsorption isotherms for acetic, propionic, and butyric acids on charcoal showed the acids to be preferentially adsorbed throughout the 0 to 100% concn. range. The Freundlich equation was obeyed only between 0.005 and 0.5 wt % concn. Frontal-analysis technique was applied to binary mixts. of these acids and yielded adsorption-isotherm data obeying the Freundlich equation between 0.3 and 1.5 wt % concn. Adsorbed water on the charcoal seemed to act merely as a diluent. Changes in adsorption as evidenced by frontal-analysis diagrams were not observed on changing the method of packing the column, doubling the pressure applied to the column, adding a solid diluent to the charcoal, or prewetting the column with solvent.

2747. PROTASOV, P. N.; KHARIN, A. N.; VOITKO, L. M.; BOGOLYUBOVA, T. G., AND SVINTSOVA, L. G. **The uptake of substances by granulated carbon from a stream of solution. Sorption dynamics of butyric acid from aqueous solution.** *Zhur. Fiz. Khim.* **24**, 182-91 (1950).—*C.A.* **44**, 6231*i*.

Butyric acid solns. (0.01-0.03 N) were filtered through columns (L cm long) of birch charcoal (particle diam. d was 0.15-0.325 cm). The time θ of break-through was $[\theta_0 - (kL/\alpha)]$; α(cm/sec) was the rate of filtration. The consts. θ and k were given. The kinetic coeff. $\beta = -0.027\ \alpha^{0.52}/d^{1.06}$; the factor in it (0.037) seemed to be inversely proportional to $M^{1/2}$; M = mol. wt.

2748. ROWLEY, H. H.; OLNEY, R. B., AND INNES, W.B. **Adsorption equilibria of liquid mixtures of benzene and methanol with charcoal.** *J. Am. Chem. Soc.* **72**, 5180-2 (1950).—*C.A.* **45**, 2741*g*.

The selective adsorptions evaluated by 2 independent methods as a function of liquid compn. were compared with directly measured values for the adsorption of C_6H_6 and MeOH on charcoal. Reasonable agreement was obtained. Surface compn. and spreading-pressure data were given.

2749. Spengler, Günter and Krenkler, Karl. **Selective adsorption of hydrocarbons. I.** *Erdol u. Kohle* **3**, 120-4 (1950).—*C.A.* **44**, 5676e.

A purified benzine fraction (b. 40-48°C) was used as solvent. Small-pored silica gel and active charcoal were found superior to Al_2O_3, fuller's earth, kieselguhr, MgO, SnO, $CaCO_3$, and cryolite. Adsorption isotherms showed the following sequence in order of diminishing adsorption: (Silica gel) 1-methylnaphthalene, (1,2,3,4-tetrahydronaphthalene, xylene, benzene, toluene), cyclohexene, and cetene; (active charcoal) 1-methylnaphthalene, 1,2,3,4-tetrahydronaphthalene, xylene, toluene, (cetane, cetene, octadecane) (benzene, dodecane, cyclohexene), and decahydronaphthalene. Silica gel, therefore, was suited for the sepn. of satd. from unsatd. hydrocarbons, whereas active charcoal would enable sepn. on the basis of side chains on other satd. groups and mol. size.

2750. Trillat, J. J. and Millet, J. **Photocolorimetric study of adsorption of carbon black.** *J. recherches centre natl. recherche sci. (Paris)* **(1950)**, No. 10, 32-5; *Rev. inst. franc. petrole* **5**, 9-12 (1950).—*C.A.* **44**, 3766*a*; **45**, 416*g*.

The amt. of tar oil adsorbed by various carbon blacks from benzene solns. was detd. by measuring the amt. of oil left in the benzene colorimetrically after removing the carbon black. The amt. adsorbed was characteristic of the variety of the black, and the heavier components of the oil were adsorbed the least strongly.

2751. Bartell, F. E.; Thomas, Tudor L., and Fu, Ying. **Thermodynamics of adsorption from solution. IV. Temperature dependence of sorption.** *J. Phys. & Colloid Chem.* **55**, 1456-62 (1951).—*C.A.* **46**, 2873*g*.

Adsorption normally decreased with increase in temp., since it was an exothermic process. The effect of soly. was superimposed on the normal temp. effect and was studied only to a limited extent. The adsorption of Bu alc. from aq. soln. was detd. at 0°, 25°, and 45°C on purified cryst. artificial graphite and highly porous blood char. At low concns. adsorption decreased with rising temp., whereas at higher concns. the adsorption increased with rising temp., reflecting the effect of the decrease in soly. of Bu alc. in H_2O with rising temp.

2752. Chatterji, A. C. and Srivastava, R. D. **Adsorption from nonaqueous solvents I.** *J. Indian Chem. Soc.* **28**, 315-18 (1951).—*C.A.* **46**, 5928*g*.

The adsorption of BzOH on phosphate- and chloride-free animal charcoal from solns. in CCl_4, C_6H_6, $C_6H_5CH_3$, *o*-xylene, *m*-xylene, C_6H_5Cl, $C_6H_5NO_2$, MeOH, EtOH, PrOH, BuOH, and acetone, and of *o*-nitrobenzoic acid and phthalic acid in the last 5 solvents was detd. at 30°C. Adsorption increased as the soly. of the solute decreased in the solvent.

2753. Glueckauf, E. **The "exponential" adsorption isotherms of fatty acids on activated charcoal.** *J. Am. Chem. Soc.* **73**, 849-50 (1951).—*C.A.* **45**, 5484*e*.

Since it was known that active charcoal in a mixt. of strong acids acted as an anion exchanger, the primarily adsorbed group being H_2O, it was suggested that: (1) H_2O was adsorbed according to a Langmuir adsorption; as long as only one species of acid was present, this mechanism was indistinguishable from mol. adsorption following an "exponential" isotherm; (2) when 2 or more acids (HAc, propionic, and butyric) were present, the adsorbed H_2O acted as an anion-exchanger with respect to the acids in soln.; (3) in mixts. of 2 acids, the coeff., $k_{1,2}$, of adsorption of H_2O was taken as the appropriate mean of the single solute coeffs., k_1 and k_2.

2754. Harrap, B. S. **Adsorption of mixed films on activated carbon.** *Trans. Faraday Soc.* 47, 645-9 (1951).—*C.A.* **45**, 9993f.

Adsorption data were given for mixts. of $PhNH_2$ and oleyl alc. on activated charcoal. The wt of oleyl alc. which 0.1000 g adsorbent could adsorb was within the limits 0.0535-0.0545 g and was independent of the pH of the system over the pH range 2-12. The capacity for the adsorption of oleyl alc. was detd. using a Langmuir-type surface balance to detect any excess alc. over that adsorbed at the charcoal-water interface. The adsorbent was prepd. by making Nuchar ash-free (could not adsorb NaOH from aq. soln.).

2755. Jenckel, E. and Rumbach, B. **Adsorption of high polymers from solution.** *Z. Elektrochem.* **55**, 612-18 (1951).—*C.A.* **46**, 4882h.

The adsorption of polymethylmethacrylate, polystyrene, and polyvinyl chloride on Al granules, quartz sand, glass wool, and activated charcoal from soln. in 1,2-dichloroethane, toluene, and 1,4-dioxane was measured at 25 and 50°C at several concns. up to 1 g per liter. Mol. wts of the polymers were 1,200,000, 512,000, and 37,000, resp. Surface areas of the 1st 3 adsorbents were detd. microscopically, but that of the charcoal was detd. with methylene blue. The calcd. no. of mol. layers adsorbed ranged from 1 to 80. The data indicated that very little adsorption occurred on the internal surface of the charcoal.

2756. Rose, G. R. F.; Weatherburn, A. S., and Bayley, C. H. **The sorption of synthetic surface-active compounds by carbon black.** *Textile Research J.* **21**, 427-32 (1951).—*C.A.* **45**, 6895*f*.

The sorption on carbon black of a no. of anionic, cationic, and nonionic surface-active compds. from aq. solns. was measured. The sorption did not conform to the Freundlich isotherm over the concn. range of 0.01%-0.2% by wt. In many cases an abrupt change in slope of the curve occurred at concns. that appeared to correspond approx. to the crit. micelle concns. of the various compds. At concns. above this crit. point the plot of log *X* vs. log *C* appeared to be linear. The sorption of Na alkyl sulfates, 12-18 carbon atoms, increased with increasing chain length of the alkyl group at const. temp., and decreased with increasing temp. at const. chain length. The typical nonionic compds. were sorbed more strongly than were any of the other compds. tested.

2757. Steigmann, Albert. **Photographically active impurities in gelatins.** *Science et inds. phot.* **22**, 441-53 (1951).—*C.A.* **46**, 843b.

Powd. acid pigskin gelatin, extd. with hot, satd. Na_2SO_4 soln., yields compds. of the 4-carboxythiazolidine type, whereas lime process gelatins yielded thiosulfates and trithionates. The exts. contain traces of proteins which could be eliminated by filtration over Mg silicate. Compds. of the 4-carbon types were largely retained by Mg silicate, which did not retain trithionates and thiosulfates. At pH 9.0, active carbon adsorbed only the trithionates and permitted isolation of the thiosulfates.

2758. Tendeloo, H. J. C.; Mans, A. E., and Hoogh, G. de. **Titration of adsorbed acids.** *Rec. trav. chim.* **70**, 191-201 (1951) (in English).—*C.A.* **45**, 6006*c*.

The titration curves of the 3 isomeric hydroxybenzoic acids, and the curves for maleic and fumaric acids, were detd. with NaOH and $Ca(OH)_2$ without any adsorbent and with the acids adsorbed on different amts. cf Norit. The 3 hydroxybenzoic acids did not show any difference in the adsorbed state; the adsorption of maleic acid was less than that for fumaric acid, although the great difference in acidity between the 2 isomers was greatly reduced by adsorption. The titration curves of adsorbed salicylic acid obtained with NaOH and $Ca(OH)_2$ did not coincide.

2759. Thomas, G. Garrod. **Adsorption on coal.** *Nature* **168**, 474 (1951).—*C.A.* **46**, 2872*a*.

From studies of the adsorption of org. mols. from aq. and alc. solns. on coal, the area per mol. of solute decreased as the rank of the coal (and C-content) decreased and the O-content increased. The slope of these curves depended on the particular solute. Adsorption presumably took place through the nonpolar portion of the solute mol.

2760. Waarden, M. van der. **Adsorption of aromatic hydrocarbons in nonaromatic media on carbon black.** *J. Colloid Sci.* **6**, 443-9 (1951).—*C.A.* **46**, 803*d*.

The adsorption of benzene, naphthalene, anthracene, phenanthrene, xylene, and alkylated naphthalenes on carbon black of area 325 m^2/g from n-C_7H_{16} or white mineral oil was measured at room temp. The max. adsorption corresponded to a unimol. layer of aromatic mols. in which the nuclear ring was oriented in a flat position on the carbon surface.

2761. Chatterji, A. C. and Srivastava, R. D. **The adsorption from nonaqueous solvents. II.** *J. Indian Chem. Soc.* **29**, 327-30 (1952).—*C.A.* **47**, 5760*h*.

The adsorptions of naphthalene and acenaphthene in MeOH, EtOH, PrOH, BuOH, acetone, AcOH, C_6H_6, toluene, C_6H_5Cl, n-hexane, $CHCl_3$, and CCl_4 solns. on animal charcoal were detd. at 35°C. Adsorption decreased as the ratio of the solvent surface tension at the air-liquid interface to the solubility decreased. A reciprocal relation was found between soly. and adsorption for acenaphthene when soly. was expressed as mols. per 100 mols. of soln.

2762. Edeskuty, F. J. and Amundson, N. R. **Effect of intraparticle diffusion. I. Agitated nonflow adsorption systems.** *Ind. Eng. Chem.* **44**, 1698-1703 (1952).—*C.A.* **46**, 9894*e*.

The theoretical foundation for the diffusion of solute inside the adsorbent particles was developed for the special case where the particles were cylinders with impervious ends. Exptl. confirmation was obtained with activated charcoal as the adsorbent and phenol in water soln. as adsorbate.

2763. Elton, G. A. H. **Adsorption from binary solutions of completely miscible liquids. II. Thermodynamic requirement for complete preferential adsorption.** *J. Chem. Soc.* **1952**, 1955-6.—*C.A.* **46**, 8460*e*.

Complete preferential adsorption is defined as the case when the surface mole-fraction of one component exceeds its bulk mole-fraction over the whole range between zero and unity. The necessary thermodynamic condition is that the adsorption potentials of the two adsorbates differ in sign. This follows from an activity analysis of the system in terms of the adsorption potentials, which refer to arbitrarily defined standard states in the soln. and surface, resp. These are estd. as 1.0 and 1.1 kcal. for MeOH and CCl_4 on charcoal.

2764. Falk, Hans L. and Steiner, Paul E. **The identification of aromatic polycyclic hydrocarbons in carbon blacks.** *Cancer Research* **12**, 30-9 (1952).—*C.A.* **46**, 8831*h*.

Benzene exts. of some carbon blacks contained the strong carcinogen 3,4-benzopyrene, the weak carcinogen 1,2-benzoperylene, and pyrene, fluoranthene, 1,12-benzoperylene, anthanthrene, and coronene. Furnace blacks, with an av. particle diam. of 80 mμ or more, possessed all 7 of these aromatic hydrocarbons. Soot itself appeared to be carcinogenic on skin but possibly not on respiratory tract epithelium, possibly because lipide solvent was present in the skin and absent in the respiratory tract. The differences in extractable aromatic hydrocarbon from carbon blacks might be related to adsorption phenomena.

2765. Falk, Hans L. and Steiner, Paul E. **The adsorption of 3,4-benzopyrene and pyrene by carbon blacks.** *Cancer Research* **12**, 40-3 (1952).—*C.A.* **46**, 8832*a*.

The adsorption of 3,4-benzopyrene and pyrene on 10 different carbon blacks with an av. particle diam. varying from 10-80 mμ was inversely proportional to particle size. The elution of these hydrocarbons depended on the nature of the black, the nature and vol. of the solvent, and the temp. With each extn., only a fraction of the total adsorbate could be eluted.

2766. Hellström, Nils. **Comparative adsorption experiments. I. Some hydrocarbons in ethyl alcohol and in heptane with some different kinds of carbons.** *Svensk Kem. Tid.* **64**, 263-70 (1952) (in English).—*C.A.* **47**, 2011*e*.

The adsorptions of retene, phenanthrene, and naphthalene dissolved in abs. EtOH were studied for 3 different carbons: Carboraffin carbon, FNX

Special, and an exptl. carbon "606". In case of Carboraffin carbon, heptane was also used as the solvent. The method of frontal analysis was used for the adsorption expts., and adsorption isotherms were calcd. according to Langmuir. Retene and phenanthrene were adsorbed almost equally well and better than naphthalene, in all cases. The satn. capacities in case of Carboraffin carbon were practically the same whether abs. EtOH or heptane was the solvent.

2767. Hocking, C. S. **Separation by modified carbons.** *Research (London)* **5**, 288-9 (1952).—*C.A.* **46**, 8458*f*.

The behavior of activated charcoal coated with diphenylamine or oleic acid was studied with respect to the adsorption and desorption, at different pH values, of methylene blue and picric acid. Adsorption was stronger on diphenylamine-coated charcoal than on oleic acid-coated charcoal.

2768. Izmaĭlov, N. A.; Shostenko, Yu. V., and Bezuglyi, V. D. **Adsorptional method for isolation of caffeine.** *Zhur. Priklad. Khim. (J. Applied Chem.)* **25**, 543-52 (1952).--*C.A.* **46**, 9249*i*.

Adsorption of caffeine from aq. solns. was superior to extn. with immiscible solvents. Adsorption of caffeine by activated charcoal (air-dry) was studied from water, $CHCl_3$, EtOH, $ClCH_2CH_2Cl$, and $CHCl_3$-$ClCH_2CH_2Cl$ solns. The most effective adsorption occurred from H_2O, the mixt. of $CHCl_3$ with $ClCH_2CH_2Cl$ (80-20) was next, while $CHCl_3$ was least satisfactory. For aq. solns. the isotherms equation was $a = 35.5°C$, where a was g and C was g/100 ml. The % adsorption remained essentially constant from pH 3.85 to 8.5, and expts. with adsorption from tea exts. indicated that a temp. rise from 20 to 45°C actually increased by 14-15% the amt. of removed caffeine. The use of a 4-stage countercurrent adsorption set-up resulted in 95.5-98.0% extn. of the caffeine present in tea exts. The charcoal with adsorbed caffeine was washed free of mother soln. by pure water with almost zero loss.

2769. Ixmaĭlov, N. A. and Shostenko, Yu. V. **Adsorption method of isolation of substances from dilute solutions. II. Some peculiarities of molecular adsorption from a stream of solution.** *Zhur. Priklad. Khim.* **25**, 602-9 (1952).—*C.A.* **47**, 6706*c*.

For a caffeine soln. there was a limiting rate of flow of the soln. past the adsorbent at which the max. satn. of the adsorbent still corresponded to its static activity; there also existed a critical flow rate above which the max. adsorption no longer depended on flow rate. The processes appeared to be connected with diffusion within the pores of the adsorbents. The independence of max. adsorption of flow rate appeared in the present case to arise above 2400 liters/hr/m². The relation between max. adsorption and flow rate was given satisfactorily by $A = 34.67\ v^{-0.083}$, where A was max. adsorption in percentage, and v was flow rate.

2770. Kipling, J. J. and Tester, D. A. **Adsorption from binary mixtures: determination of individual adsorption isotherms.** *J. Chem. Soc.* **1952**, 4123-33.—*C.A.* **47**, 3079*h*.

Adsorption from binary mixts. by a solid could not be represented by simple Freundlich or Langmuir equations for the adsorption isotherms of the individual components. A derivation based on the assumption that under all conditions of equil. the surface was completely covered with adsorbate gave results in accord with expt. for either liquid or vapor-phase adsorption. The equations derived are: For the vapor phase $\sigma_1 = x^v/[x^v + K(1 - x^v)]$, where $\sigma_1 =$ fraction of surface covered by component 1, $x^v =$ mole fraction of vapor 1 in vapor phase, and $K =$ a const. In the liquid phase 2 cases must be considered: Case I; ideal case where $p_1 = p_1°x_1$, where $x =$ mole fraction of component present. Case 2: when Raoult's law was not obeyed, i.e., $p_1 \neq p_1°x_1$. The equations were used in calcg. the adsorption of $CH_3OH + CCl_4$ and $C_6H_6 + C_2H_5OH$ mixts. on carbon. Exptl. and theoretical curves were in excellent agreement.

2771. Kiselev, A. V. and Kulichenko, V. V. **Adsorption from solutions in the vicinity of the lower critical temperature. Trimethylamine-water on active carbons and on lampblack.** *Doklady Akad. Nauk S.S.S.R.* **82**, 89-92 (1952).—*C.A.* **46**, 4886*h*.

Adsorption isotherms of Me_3N in soln. in H_2O (18°C), at 0, 32.7, and 70°C, were detd. on 3 types of adsorbents: a peat active carbon, a $ZnCl_2$-activated sucrose carbon, and lampblack with spherical particles. At 0°C, the isotherms passed through a max., as expected for a completely miscible system; above t_c, the curves were S-shaped. The adsorption isotherms of Me_3N on sucrose carbon from aq. soln. and from vapor gave the same final amt. adsorbed at c/c_s. The vapor and the soln. isotherms on lampblack coincided up to the point of beginning multi-mol. adsorption, whereafter the vapor isotherm rose rapidly above the soln. isotherm; formation of the unimol. adsorption layer was the same from vapor and from soln.

2772. Doss, K. S. G. and Singh, Ajit. **Adsorption of thymol blue on activated carbon.** *J. Sci. Ind. Research (India)* **12B** 79-83 (1953).—*C.A.* **47**, 7285*h*.

The adsorption of thymol blue on activated carbon was studied with solns. buffered at pH from 1.26 to 10.0. In general, the amt. of adsorption decreased with increasing pH. The satn. of the adsorbent occurred at lower adsorptions in alk. solns. than in solns. of lower pH. The presence of $CaCl_2$ increased the amt. of adsorption as well as the satn. concn.; as expected, the effect of KCl was small.

2773. Hansen, Robert S.; Hansen, Robert D., and Craig, Roy P. **The effect of steam activation on multilayer adsorption from solution by carbon.** *J. Phys. Chem.* **57**, 215-19 (1953).—*C.A.* **47**, 7287*i*.

The adsorption of n-valeric and n-caproic acids from water on Spheron 6 carbon black (activated by steam) showed that the primary effect of the steam activation was to increase the surface area and not the adsorption per unit area. The indicated monolayer adsorption corresponded to mol. areas of 55 to 70A.² for the acid adsorbates. Considerable water was also retained by the surface.

2774. Hobden, Joan F. and Jellinek, H. H. G. **Adsorption of high polymers from solution onto solids. I. Adsorption of polystyrene on charcoal.** *J. Polymer Sci.* **11**, 365-78 (1953).—*C.A.* **48**, 2441*g*.

The amts. and rates of adsorption of polystyrene from solns. on charcoals at 25°C increased when the MeOH solvent was dild. with MeCOEt, or when the polymer mol. wt was decreased. Langmuir's equation fitted the adsorption isotherms. Amts. adsorbed at equil. were far below that needed to give a monolayer. Fractionated polymer showed a stepwise increase in rate after the char was about half way to equil.

2775. Minne, J. L. van der and Hermanie, P. H. J. **Electrophoresis measurements in benzene; correlation with stability. II. Results of electrophoresis, stability, and adsorption.** *J. Colloid Sci.* **8**, 38-52 (1953).—*C.A.* **47**, 5214*h*.

The effect of Ca diisopropylsalicylic acid and tetraisoamylammonium picrate on the flocculation, electrophoretic velocity, and electroendosmotic velocity of the particles of a 0.1% suspension of carbon black in C_6H_6 was detd. Electrophoresis did not occur unless there was a crit. concn. of ions in soln. The ionic concns. of electrolyte necessary to cause flocculation in the C_6H_6 system were smaller by a factor of 10^{-7} than the concns. causing flocculation in aq. solns. The adsorption of diisopropylsalicylic acid by the suspended carbon black reached a max. at the concn. corresponding to the max. ζ-potential on the carbon.

2776. Smith, R. Nelson; Geiger, C. F., and Pierce, Conway. **The equilibrium exchange rates of adsorbed species with unadsorbed species in solution.** *J. Phys. Chem.* **57**, 382-4 (1953).—*C.A.* **47**, 6214*a*.

The rate of exchange, at equil., of adsorbed radioactive benzene with nonradioactive BzOH in soln. was studied with 5 different types of charcoal. Steam-activated charcoal permitted a more ready exchange of BzOH; this indicated that the capillary pores had been enlarged on activation. Exchange was almost immediate with a carbon black or with a very wide-pore decolorizing charcoal.

2777. Treiber, E.; Porod, G.; Gierlinger, W., and Schurz, J. **The adsorption of macromolecules on active surfaces.** *Makromol. Chem.* **9**, 241-3 (1953).—*C.A.* **47**, 7285*f*.

The adsorption of a high-mol. and a low-mol. polystyrene fraction from cyclohexane soln. on active carbon (followed spectrophotometrically) obeyed Freundlich's equation with exponent $n = 1$, but approached a limiting value at concns. above 0.2 millimole of monomer per liter. Similar adsorption of toluene, used as a polystyrene model, obeyed Freundlich's equation with $n = 0.55$.

II-2. Carbon Adsorbents With Inorganic Solutions

2778. Burshtein, R. and Frumkin, A. **Hydrogen peroxide formation in the adsorption of acids by activated charcoal.** *Compt. rend. acad. sci. U.R.S.S.* **32**, 327-9 (1941) (in English).—*C.A.* **37**, 2243^4.

H_2O_2 was formed when H_2SO_4 was adsorbed on charcoal in the presence of freshly adsorbed O_2, the yield increasing with the concentration of H_2SO_4. The quantity of H_2O_2 reached a max. in about 10 min. and then decreased because of the catalytic decomposition on charcoal. The yield was very low when inert gases instead of O_2 were bubbled through the solution. The formation of H_2O_2 stopped when the adsorption of the acid was complete. At a polarized cathode in the presence of freshly adsorbed O_2, the yield of H_2O_2 increased from 6.5×10^{-5} to 130×10^{-5} amperes per 0.1 g of charcoal. With further increase, the yield decreased.

2779. Vournazos, A. C. **Ionization effects in carbon.** *Prakt. Akad. Athenon* **16**, 80-94 (1941).—*C.A.* **47**, 54*c*.

Chem. analysis of complex hydroxy carbons from electrolysis showed a C-rich system, but with O- and still smaller H-contents, the av. compn. was C 97.24, O 2.59, and H 0.17%. From a dil. soln. of this product carbon had been sepd. electrolytically, the resulting ion migrating slowly to the cathode. A small rod of petroleum coke contg. about 25% low Fe ash served as anode and the cathode was Pt foil. The electrolyte was 28% NaOH and a 30 v. current at 2.5-3 amp. was used at 70°C. In about 3 hrs the anode was consumed by nascent O, while the electrolyte became deep brown. The suspended carbon was allowed to stand and then, with 200 cc. of the supernatant fluid, was decanted and electrolyzed. For this purpose glass cells with Pt-foil anodes and 2-3 mm Pt-wire cathodes were used; 5.5 amp. at 94-96 v. was applied. After 3 hrs the cathode was coated with smooth electrolytic carbon.

2780. Baichikov, A. G. and Selimov. **Adsorption of iodine from oil-well waters by means of activated charcoal.** *J. Applied Chem. (U.S.S.R.)* **15**, 228-36 (1942).—*C.A.* **37**, 2548^9.

Extraction of I_2 from oil-well waters in southern U.S.S.R. by means of activated charcoal was feasible even in waters containing naphthenic acids, which were adsorbed also. Under the best technological conditions thus far obtained, it was possible to recover up to 66% of the I_2. The charcoal could be used in acid waters. Treatment of the charcoal with alkali almost completely desorbed I_2.

2781. Kishi, Haruo. **Analysis by means of radioactive indicators. IX. Sorption of minute quantity of lead by active charcoal.** *J. Chem. Soc. Japan* 63,668-76 (1942).—*C.A.* **41**, 2986*a*.

A dil. soln. of Pb (10^{-4} *N* $Pb(NO_3)_2$) contg. Th B was adsorbed by active charcoal. According to the procedure given, the measurement of the radioactivity detd. the amount of Pb.

2782. Kishi, Haruo. **Analysis by means of radioactive indicators. X. Sorption of minute quantity of lead by active charcoal.** *J. Chem. Soc. Japan* 63, 677-87 (1942).—*C.A.* 41, 2986*b*.

When the concn. of HNO_3 contained in the Pb soln. was small, the amount of adsorbed Pb followed the Freundlich relation. The adsorbed amount decreased with rise of temp. and increased gradually with increase of the time of contact.

2783. Sastri, M. V. C. **Active carbon. II. Ionic adsorption by active carbon.** *Quart. J. Indian Inst. Sci.* 5, No. 3, 107-19 (1942).—*C.A.* 40, 3959^3.

The behavior of active charcoal as a polar adsorbent and the "chemisorption" or chem. interaction with O_2 was discussed.

2784. Sastri, M. V. C. **Active carbon. III. The pH values of aqueous suspensions of activated charcoal.** *Quart. J. Indian Inst. Sci.* 5, No. 3, 120-44 (1942).—*C.A.* 40, 3959^3.

Instantaneous (one min.) and final (10 min.) pH for suspensions of four activated charcoals in pure water were detd. with a glass-electrode assembly. The pH of suspensions of partially washed specimens varied with time, concn., and initial pH of the water. Steady values were reached in ten min. Each thoroughly washed active charcoal had a characteristic pH unaffected by concn. of charcoal or initial pH of the water.

2785. Hamdi, H. **The colloidal chemical properties of humus. Dispersoid chemical observations with graphite oxide.** *Kolloid-Beihefte* 54, 554-634 (1943).—*C.A.* 38, 4495^1.

Finely powd. graphite for electroplating was oxidized with H_2SO_4, HNO_3 and $KClO_3$, washed and electrodialyzed. After drying at 50°C and grinding, it consisted of 60.01% C, 2.09% H and 37.9% O and contained 6.6% water removable by drying over P_2O_5 *in vacuo*. Suspensions, exposed for 16 days to aq. solns. of various alkalies at different concns., were back-titrated with HCl to pH 8.2 and 5.2. The amt. of alkali retained in combination increased in the order $LiOH < NaOH < NH_4OH < KOH$; even stronger sorption was observed with alk. earth hydroxides in the series $Sr(OH)_2 < Ca(OH)_2 < Ba(OH)_2$. Extent of sorption of amino acids at pH 3, 6 and 9 increased with their mol. wt. Max. sorption of NH_4OH, glycylglycine and gelatin was observed, resp., at pH 4.0, 8.5 and 4.8.

2786. Stark, Walter. **Gold from sea water.** *Helv. Chim. Acta* 26, 424-41 (1943).—*C.A.* 37, 6505^3.

The Au in sea water from 3 sources was pptd. by adsorption on charcoal, and the residue was dried and ashed in a porcelain tube. After dissolving in HCl, granulated Zn-Pb was added, and the Pb alloy obtained was cupelled. Water from the Adriatic Sea contained 0.02 mg of Au/m^3, from the Mediterranean Sea 0.4 mg/m^3, and from the Iberian coast of the Atlantic Ocean 2 mg/m^3. The Au content of seaweed was relatively high, 0.17 mg/1000 g of dried material.

2787. Cantino, E. C. **Elimination of nitrate impurities from 30% hydrogen peroxide.** *Ind. Eng. Chem., Anal. Ed.* 16, 181-2 (1944).—*C.A.* 38, 2169^9.

Percolation through activated carbon in a H_2O-cooled column was used to produce a product having a nitrate content of less than 10 p. p. m. and a H_2O_2 concn. of approx. 27 to 29%. Details of the column construction and packing were given.

2788. Tiselius, Arne. **Quantitative adsorption analysis of some amino acid and peptide mixtures on active carbon.** *The Svdeberg (Mem. Vol.)* 1944, 370-8.—*C.A.* 39, 1117^7.

Adsorption analysis was applied to the sepn. of monoamino-monocarboxylic acids and some peptides of the same type with an active carbon as adsorbent. Quant. sepns. were possible with the amino acids and with those peptides which showed low adsorption affinity for carbon. Losses occurred with the higher peptides and some methods of eliminating this difficulty were discussed.

2789. Bachelet, M. **The extraction of actinium and its concentration in the rare earths.** *J. chim. phys.* 42, 98-107 (1945).—*C.A.* 40, 4307^7.

The sorption of *actiniferous* La by insol. sulfates or active carbon was detd. Enrichment by fractional pptn. of hydroxides showed that Ac pptd. between La and Mn. Coeffs. of fractional crystn. of double nitrates of rare earths and Mg were detd. Such fractionation eliminated, in the inactive state, most of the La.

2790. Palacios, J. and Vigón, M. T. **Adsorption of cations by active carbon. Experimental confirmation.** *Portugaliae Phys.* 1, 295-320 (1945).—*C.A.* 40, 2055^2.

The voltaic cells were identical as to electrodes (active carbon and Zn) and electrolyte ($ZnSO_4$ soln.); one could be evacuated, and the other exposed to air. To ensure freedom from O_2, the carbon electrode was baked for several hrs in a vacuum furnace. The current yield of the evacuated cell was closely parallel to that of the control cell, whence it is concluded that O_2 was not the fundamental factor in producing the potential difference in the cells. Cells in which the carbon electrode contained O_2 recovered after discharge more quickly than those without O_2.

2791. Harkins, W. D.; Jura, G., and Loeser, E. H. **Surface of solids. XVI. Adsorbed films of water and normal heptane on the surface of graphite.** *J. Am. Chem. Soc.* 68, 554-7 (1946).—*C.A.* 40, 3665^8.

The adsorption isotherms of water and heptane were detd. on 2 samples of graphite contg. 0.46% ash by weight and less than 0.004% ash by weight. The latter samples had also been treated so that the surface should be free of any O-C "complex." The films of water became thicker than a monolayer at relative pressures above 0.9, attaining an av. of thickness of 3 layers at the max. pressures measured, 0.98. A detailed study of the curve for low values of p/p_o showed that the adsorption curves were convex rather than concave to the pressure axis. The spreading coeff., free energy of emersion, and work of adhesion of water were -47, 25, and 97 ergs cm^{-2}, resp., whereas for heptane the corresponding values were 69, 89, and 109 ergs cm^{-2}.

2792. LEPIN, L. AND STRAKHOVA, G. **Surface reactions. III. Reaction between solutions of hydrolyzed salts and ash-free active carbons.** *J. Phys. Chem. (U.S.S.R.)* 20, 743-52 (1946) *Acta Physicochim. U.R.S.S.* 21,1089-1104 (1946) (in English).—*C.A.* 41, 330*a*.

Adsorption of Cl^- from solns. of $AlCl_3$, $CuCl_2$, $FeCl_2$, and $PbCl_2$ by ash-free carbon was greater than from solns. of KCl or $BaCl_2$. Addn. of HCl increased the adsorption of Cl^- from KCl, $BaCl_2$, or $AlCl_3$ solns. because H^+ neutralized the OH^- ions leaving the carbon. Addn. of HCl lowered the adsorption of Cl^- from $CuCl_2$, $FeCl_2$, and $PbCl_2$ solns. because of the formation of $[CuCl_4]^{--}$ and similar ions. The carbon formed ppts. in solns. of $CuCl_2$, $FeCl_2$, and $PbCl_2$.

2793. QUARTAROLI, ALFREDO. **Unusual adsorption phenomenon with various adsorbing agents.** *Ann. chem. applicata* 36, No. 9/10, 260-5 (1946).—*C.A.* 41, 4692*f*.

Salts which form hydrates facilitated adsorption when present in large quantity. With animal carbon as adsorbent, the presence of 20 g NaCl was found to increase the adsorption of org. acids as follows: formic 17.2-22.0%; acetic 18.0-23.4%; propionic 20.4-26.7%. Benzoic acid (55.8% adsorbed by 1 g of animal carbon) was found to be adsorbed 75% in the presence of 20 g of NaCl.

2794. QUARTAROLI, ALFREDO. **Evaporation and adsorption of ammoniacal solutions in the presence of salts and organic compounds.** *Ann. chim. applicata* 36, No. 9/10, 266-72 (1946).—*C.A.* 41, 4692*h*.

Adsorption of NH_4 compds. by animal carbon increased in the presence of salts. In a 0.05 *N* NH_4OH soln., 32.0% was adsorbed when no salt was present; this was increased with 10 g KCl to 42.3%, with 20 g KCl to 49.0%, with 10 g NaCl to 43.2%, with 20 g NaCl to 49.9%, with 5 g LiCl to 42.7%. The above was true at 30°C, but at 18°C the reverse was true owing to formation of complex salts.

2795. RÉGNIER, JEAN AND BAZIN, SUZANNE. **Fixation of different sodium salts by charcoal without agitation. Determination of the base and of the acid radicals.** *Ann. pharm. franc.* 4, 93-4 (1946).—*C.A.* 41, 2957*h*.

The Na salts were much less strongly fixed by charcoal than the corresponding salts of procaine base. The fixation of Na varied for each salt; it was of about the same order for the chloride and citrate, and definitely less for the isobutyrate. The percentage fixation of the base and of the acid were very close to each other. The anion for the procaine salts, accompanied the cation in the same proportions as present in the mol.

2796. VICKERY, R. C. **Adsorption on carbon of rare earth organic complexes.** *Nature* 158, 623-4 (1946).—*C.A.* 41, 1524^a.

The adsorption on decolorizing charcoal of the violet p-phenetidine complex of Ce was studied. Using 100 mg charcoal with 3-12 mg of CeO_2, recoveries were 95-98%, even in the presence of 10 g La_2O_3. There was zero adsorption of Ce^{++++} in the absence of the org. complex. The aq. filtrates were spectroscopically free of Ce.

2797. CALLER, CLORINDA DE SANDAAL. **Reducing action of charcoal on As_2O_3 and Sb_2O_3.** *Bol. soc. quim. Peru* 13, 94-7 (1947).—*C.A.* 42, 7006*e*.

Charcoal of different kinds of native woods had a different reducing effect on As_2O_3, but no, or only a very slight, action on Sb_2O_3.

2798. COURTY, CLEMENT. **Oxidizing properties of active carbon saturated with air.** *Bull. soc. chim. France* 1947, 642-52;—*C.A.* 42, 1102*h*.

Arsenious acid was oxidized by the O_2 adsorbed on active carbon, as well as being adsorbed directly by the carbon itself. The ratio of the two actions was extremely variable. It depended on the carbon, its condition, time, etc. Magnetic measurements over long periods of time (up to a year) indicated that an equil. content of at. O was slowly established. These same measurements, and other speculations, rule out the appreciable influence of CO_2, O_3, or ion formation.

2799. KRIVOLUTSHAYA, N. S.; TEMERIN, S. A., AND LUKOVTSEV, P. D. **Effect of adsorbed oxygen on the potential and the kinetics of discharge of the carbon-manganese oxide electrode.** *J. Phys. Chem. (U.S.S.R.)* 21, 313-23 (1947) (in Russian).—*C.A.* 41, 6159*f*.

The e.m.f. of the cell MnO_2/4 *N* NH_4Cl/satd. KCl/Hg_2Cl_2/Hg was lowered by 0.009-0.07 v., according to the purity of MnO_2, when MnO_2 and the NH_4Cl soln. were freed from adsorbed and absorbed O_2. If a MnO_2-graphite mixt. was used instead of MnO_2, the shift of the e.m.f. could exceed 0.1 v. When the cell was discharged at a const. current (5-10 milliamp.), the e.m.f. of evacuated cells decreased more rapidly than that of ordinary cells.

2800. SASAKI, TSUNETAKA. **Ionic adsorption by coal dusts. I. Conditions of treatment of coal affecting the adsorption.** *Repts. Research Sci. Dept. Kyushu Univ.* 1, 23-31 (1947).—*C.A.* 46, 7732*c*.

Powd. coke, bituminous coal, and lignite, ranked from greater to lesser carbonization, showed ionic adsorption in the reverse of the above order as detd. by Ca ion adsorbed from 0.005 M $CaCl_2$ in 24 hrs. The adsorption of bituminous coal and lignite increased after heating with $Ca(MnO_4)_2$, $K_2Cr_2O_7$, or other oxidizing agents, especially in the presence of a small amt. of $HgSO_4$.

2801. THIELE, HEINRICH. **Directional effect of ions on anisotropic colloids, ionotropy.** *Naturwissenschaften* 34, 123 (1947).—*C.A.* 43, 4539*e*.

Ions caused a directional effect on anisotropic particles of sols or gels (graphitic acid, Hg sulfosalicylate, V_2O_5, etc.). Addn. of a grain of solid salt in a layer of the colloid caused optical anisotropy.

2802. VILLARS, D. S. **Studies of Carbon Black. I. Electrometric titration.** *J. Am. Chem. Soc.* 69, 214-17 (1947).—*C.A.* 41, 2960*g*.

Carbon blacks (MPC, EPC, acetylene black, and ink black) along with some exptl. blacks were titrated electrometrically with 0.5 *N* KOH by using a glass electrode. The curves of pH vs. ml of base showed no inflection point. A linear relation, however, was found between pH and log ml of base. The slopes of these curves were negatively correlated with their intercepts, and, particle size remaining const., were positively correlated with the O-content of the black. The system behaved as if the presence of O_2 combined on the surface increased the free space required by the H^+ ions before they could successfully adhere to the surface.

2803. WINSLOW, N. M. **Electrode potentials of carbon in acid electrolytes.** *Trans. Electrochem. Soc.* **92**, 14 pp. (1947) (Preprint).—*C.A.* **41**, 6159*d*.

When carbon was exposed to O_2 in the presence of acid, oxidizing characteristics were developed measurable as potential or as capacity to oxidize reducing agents (Fe^{++}). Sorption of both acid and oxygen was essential to the development of oxidizing properties. Quant. correlations of active O and potential with acid sorption were given which indicated a possible chem. mechanism for the formation of active surface complexes on carbon. Typical of results were the following potential readings: hardwood charcoal calcined at 1000°C 0.599 v. vs. satd. calomel; acetylene black 0.540; channel black 0.541; calcined petroleum coke 0.440; natural graphite 0.440; artifical graphite 0.471.

2804. IKEDA, TOSHIO. **Adsorption of boric acid by charcoal.** *J. Electrochem. Soc. Japan* **16**, 109-12 (1948).—*C.A.* **44**, 9767*i*.

The amts. of H_3BO_3 adsorbed on bone charcoal were 11.5, 20.5, 24.8, and 30.8 mg/g at 10°C when the initial concns. of H_3BO_3 were 2.91, 5.71, 8.52 and 11.60 g/liter, resp. Soln. of ash during the adsorption or by ion exchange did not occur. From $Na_2B_4O_7$ solns. HBO_2 produced by dissocn. was adsorbed more strongly than $NaBO_2$, also simultaneously produced. The adsorption of H_3BO_3 in aq. soln. was larger than in alc. soln., and there was a min. in their 50% mixt. at 27°C.

2805. KISELEV, A. V. **Effect of volume layering on the shape of the adsorption isotherms of surface-active substances from the gas phase and from liquid solutions.** *Doklady Akad. Nauk S.S.S.R.* **61**, 657-60 (1948).—*C.A.* **43**, 462*c*.

In the absence of a sepn. of the vol. phase into 2 layers or phases, as in the adsorption of gases under high pressures and in adsorption from mixts. of completely miscible liquids, the excess of one substance in the adsorbed layer over its amt. in the vol. phase passed through a max. If the vol. phase sepd. into 2 layers, one of which was a well-wetting liquid, S-shaped adsorption isotherms were observed. (C_6H_6 vapor on fused quartz, MeOH vapor on carbon black, PhOH from aq. soln. on Hg, AmOH from aq. soln. on carbon black, MeOH vapor on coarse-grained silica gel, BuOH from aq. soln. on carbon.) The capillary condensation of vapors had its counterpart in a capillary layering in the case of incomplete miscibility.

2806. KUKHARENKO, T. A. **Study of lignins by the chemisorption method.** *Zhur. Priklad, Khim. (J. Applied Chem.)* **21**, 291-4 (1948).—*C.A.* **44**, 836*i*.

Detns. of equil. adsorption of $Ba(OH)_2$ and of $Ca(OAc)_2$ on lignin, resulting in definite satn. values characteristic of the given lignin, gave a measure of the ($OH + CO_2H$) and CO_2H group contents, resp. The method was tested on 3 lignin prepns., purified by extn. with $EtOH + C_6H_6$, then with boiling H_2O and dild. HCl, finally by hydrolysis with concd. HCl at 0°. Detns. of the total active group content and of the CO_2H group content by the chemisorption method and by methylation with MeOH and Me_2SO_4 coincided exactly.

2807. LESOKHINA, G. F.; PODUROVSKAYA, O. M., AND GOL'BERT, K. A. **Adsorption of vapor mixtures by porous adsorbents.** *Zhur. Fiz. Khim. (J. Phys. Chem.)* **22**, 961-7 (1948).—*C.A.* **43**, 461*a*.

Birchwood charcoal was placed in one-half of an inverted U tube, and the soln. in the other half. The two halves were kept at one temp. or the soln. was 25°C lower than the charcoal. The charcoal was weighed before and after the expt., and the soln. was weighed and its compn. detd. The "effective adsorption" $a = n_1 - (n_1 + n_2)\ N$ was detd., n_1 and n_2 being the amts. in moles of the 2 components adsorbed by 1 g. For adsorption from satd. vapor N was the mole fraction of the first component in the final soln. For adsorption from dil. vapor, N was the mole fraction in the soln. If a was plotted against N, the curves for the vapor mixts. C_6H_6-CCl_4, benzene-cyclohexane, and CCl_4-cyclohexane were almost identical with the adsorption isotherms from the liquid mixts. of these compds. Adsorption from solns. could be used to predict adsorption from vapor.

2808. TENDELOO, H. J. C.; MANS, A. E., AND HOOGH, G. DE. **Titration of adsorbed acids.** *Koninkl. Nederland. Akad. Wetenschap. Proc.* **51**, 37-40 (1948) (in English).—*C.A.* **42**, 4428*c*.

Titration curves of maleic acid and fumaric acid with NaOH in the presence of activated charcoal (Norit) were compared with similar curves obtained in the absence of the charcoal. The effect of the charcoal added was an apparent decrease in the acid strength. The buffer capacity of the charcoal-contg. solns. was also increased over a wide pH range.

2809. THIELE, HEINRICH. **Viscosity and formation of graphitic acid.** *Kolloid-Z.* **111**, 15-19 (1948).—*C.A.* **43**, 4539*g*.

Micellar solns. of graphitic acid in H_2O had high viscosities (η) that increased rapidly and nonlinearly with increasing concn. They were prepd. by oxidizing purified graphite with HNO_3, H_2SO_4, and $KClO_3$, washing the resulting graphitic acid with H_2O at 40°C to remove H_2O-sol impurities, and shaking with water to form a clear, yellowish soln. that was sepd. from the unpeptized material by filtration through raw silk or sintered glass. The addn. of LiOH or NH_4OH initially decreased η, but acids and flocculating agents had the opposite effect. These micellar solns. were optically clear, in contrast to the graphitic acid suspensions that gave active images under the ultramicroscope.

2810. MUKHERJEE, SUDHAMOY AND BHATTACHARYA, SUKHAMOY. **Influence of oxidizing agents on the adsorptive power of charcoal. I. Potassium permanganate.** *J. Indian Chem. Soc. Ind. & News Ed.* **12**, 137-41 (1949).—*C.A.* **44**, 10444*b*.

The variation in adsorptive power of activated and non-activated charcoals on boiling with 0.02

N, 0.1 *N*, 1.0 *N*, and 2.5 *N* solns. of $KMnO_4$ was studied. The adsorptive powers of both types for methylene blue, I_2, and caramel at first increased and then decreased with increasing $KMnO_4$ concn., optimum adsorption occurring at approx. 0.1 *N*. Optimum adsorption of HOAc by non-activated charcoal occurred with 0.02 *N* $KMnO_4$, and with activated charcoal was not reached within the concn. range studied. No further change was observed on increasing the concn. beyond 1.0 *N*. Non-activated charcoals were more susceptible to oxidation than activated ones. The effects of acid and alk. $KMnO_4$ were similar.

2811. PALMER, R. C. **Effects of salts on soluble ionized monolayers.** *Research (London), Suppl. Surface Chemistry* **1949**, 79-85.—*C.A.* **43**, 8796*h*.

In the adsorption of HCl on charcoal or in the adsorption of detergents on oil-water interfaces, the adsorption H^+ or detergent ions was primary adsorption, and the consequent adsorption of oppositely charged ions ("gegenions") was secondary adsorption. Equations are derived that relate the concn. of primary substance and salts of different valency types necessary to give a const. amt. of primary adsorption. The thickness of the adsorbed film could be related to the degree of thermal vibration of the mols. normal to the film.

2812. PETER, S. **The thixotropy of graphite suspensions in relation to particle size and to the suspending medium.** *Kolloid-Z.* **113**, 29-37 (1949).—*C.A.* **44**, 5184*i*.

The yield point of suspensions was measured by detg. the force required to withdraw a microscope cover-glass. Graphite powder was sepd. by elutriation into 3 fractions, having av. particle diams. of 2.8, 1.7, and 0.8 μ. The yield point increased with concn. and with decreasing particle size. Its increase with time after stirring was a first-order process after the first few min. The elec. cond. increased with time, parallel with the yield point and had nearly the same k. Graphite suspensions in $CHCl_3$, CCl_4, PrOH, and MeOH reached a much lower yield point than those in water and the change with time was very different.

2813. TSVETKOV, V. N. AND SOSINSKIĬ, M. **Rotating magnetic field as a method of studying colloidal systems.** *Kolloid. Zhur.* **11**, 197-208 (1949).—*C.A.* **43**, 7291*c*.

Sols prepd. by mixing alc. solns. of *p*-azoxyanisole or anisaldazine with much H_2O showed proportionality between sin 2α and the frequency of rotation ν as long as ν was less than 3 sec^{-1}. At greater ν the whole liquid in the container rotated. Graphite sols showed proportionality between sin α and H^{-1} as if graphite particles had a const. magnetic moment; and sols prepd. by elec. dispersion of Fe in H_2O behaved as a ferromagnetic subst.

2814. WENZEL, ROBERT N. **Surface roughness and contact angle.** *J. Phys. & Colloid Chem.* **53**, 1466-7 (1949).—*C.A.* **44**, 3334*g*.

Roughness that modifies wetting cannot be detd. from surface profiles. The roughness factor is the ratio of actual surface to that of a smooth surface having the same geometric shape and dimensions and might be detd. by measurements for total area (B.E.T.).

2815. YAMADA, MASAMORI AND KATO, HARUO. **The halogen adsorption of polyvinyl acetal. I. Adsorption by polyvinyl formals. II. Relation between kind of acetal and adsorbability.** *Chem. High Polymers* **6**, 356-66 (1949).—*C.A.* **46**, 1294*f*.

Preliminary expts. on the adsorption of I_2 by polyvinyl formal were given. The abilities of polyvinyl formal, acetal, and butyral to adsorb I_2 were compared with that of active charcoal, and the mechanism of adsorption was discussed.

2816. BOND, R. L.; GRIFFITH, M., AND MAGGS, F.A.P. **Water in coal.** *Fuel* **29**, No. 4, 83-93 (1950).—*C.A.* **44**, 5078*a*.

The submicroscopic pores of coal in contact with satd. water vapor became filled with adsorbed moisture, the properties of which differ greatly from normal liquid water. Some coals adsorbed more water than corresponded to their porosity; but the vol. adsorbed at satn. was equal to the sum of the vol. swelling and the porosity. Volume swelling (% by vol.) of a given coal was 15% in MeOH, 9% in C_6H_6, and 2% in H_2O; hence, water was best for detg. porosity in coals. Isotherms were presented for moisture adsorption at various relative humidities. The heats of wetting of the various coals were also detd. and found to fall in the same order with MeOH and H_2O.

2817. HERRMANN, E. AND STIPETIC, J. **The precipitation of aluminum hydroxide according to Bayer as a problem on the formation of a nucleus.** *Z. anorg. Chem.* **262**, 258-87 (1950).—*C.A.* **44**, 8208*f*.

The kinetics were examd. using seeding crystals of various sizes and histories. The reaction was said to be a genuine process of crystn. The results were evaluated in the light of more recent theories and apparently only $Al(OH)_3$ served as seed. The reaction was classified as autocatalytic.

2818. HUBACEK, JOSEF. **The determination of combined acids and their bonds in solid fuels.** *Paliva* **30**, 259-62 (1950).—*C.A.* **45**, 4443*h*.

One g of powd. coal was washed with H_2O and treated with NaOAc to convert free acids and their salts to Na humates. Portions of the filtrate were titrated with KOH to det. free humic acids, and Fe, Ca, and Mg were detd. in acidified portions and calcd. to the corresponding humates. Dissolved $CaSO_4.2H_2O$ in the filtrate may give high results for Ca humates and was corrected by a sulfate detn. Total humic acids were detd. by treating Na humates with $Ba(OAc)_2$ soln. and noting loss of Ba in the filtrate.

2819. KOIDE, TAKEKI; KUBOTA, TAKEO, AND KUROI, TETSUO. **The iodine adsorption of carbon black.** *J. Soc. Rubber Ind. Japan* **23**, 111-21 (1950).—*C.A.* **47**, 3544*c*.

Fundamental expts. were conducted in a study of the I_2 adsorption of carbon black. The amt. of adsorption (per g carbon) increased as the initial concn. of I_2 soln. became high. The amt. of adsorption was effected by the addn. ratio (carbon/total I_2), and for solns. of the same concn. adsorption decreased as the addn. ratio became larger. The amt. of adsorption was influenced by KI in the I_2 soln., and it decreased inversely proportional to KI/I_2. Between 10 and 40°C, the amt. of adsorption became slightly larger with temp. rise.

2820. Akamatsu, Hideo; Takahashi, Hiroshi, and Tamaru, Kenji. **The wet oxidation and the structure of carbon.** *Bull. Chem. Soc. Japan* **24**, 27-32 (1951).—*C.A.* 46, 7411*e*.

The rate of oxidation was followed by detg. the amt. of CO_2 evolved as a function of time from 0.03 to 0.05 g of carbon immersed in 7 cc. of a $K_2Cr_2O_7$ and phosphoric acid soln. The rate of oxidation increased in the order: charcoals, pitch cokes, graphites, carbon blacks. For graphite and carbon blacks, it appeared to be faster for carbons having smaller crystallite dimensions. Activated carbons had a rate of oxidation similar to that of carbon blacks until 20-30% was oxidized, after which the rate slowed down sharply and became similar to that for charcoals.

2821. Erkut, H. **Adsorption in dilute solutions of hydrochloric acid and sodium hydroxide by active carbon.** *Rev. faculté sci. univ. Istanbul* **16A**, 200-20 (1951) (in French).—*C.A.* 46, 4318*e*.

The adsorption on active carbon of HCl and NaOH from very dil. (1-16 millimoles/liter) solns. at temps. of 0 to 45°C was detd. by elec. cond. measurements. Results obtained indicated that about 1% of the surface (574 m^2) was covered. NaOH and HCl mols. are not adsorbed on the same spots on the surface and about twice as much NaOH as HCl was adsorbed. The adsorption results agreed best with Freundlich's equation. Heats of adsorption, calcd. by use of Gibbs' equation and Freundlich's isotherm, were 3400 cal/mol. for HCl and 4700 cal/mol. for NaOH adsorbed.

2822. Herrmann, E.; Stipetić, J., and Ledinski, V. **Formation of crystal nuclei and growth of crystals in the precipitation of aluminum hydroxide in the Bayer process.** *Acad. Sci. et Art. Sloven.* (Ljubljana). Class III, Ser. A, *Dissertationes*, No. 2, 93-120 (in English 120-4) (1951).—*C.A.* 46, 9935*e*.

In the study of the kinetics of pptn. of $Al(OH)_3$ from Na aluminate solns., the neg. effect of org. compds. was eliminated by the addn. of active carbon. The question of the slow rate in contrast to the behavior of undercooled solns. remained unsolved.

2823. Stempel, R. **Separation of iodine from alkali and alkaline-earth halides with active charcoal.** *Z. Anal. Chem.* **133**, 412-14 (1951).—*C.A.* 46, 61*d*.

To 10-20 ml of approx. 0.1 *N* soln. add 0.5-1.0 g of active charcoal, shake well, and filter. Wash 3 times with 10 ml portions of water. Titrate the filtrate with $AgNO_3$ soln.

2824. Suzutani, Toru. **Polarographic studies on adsorption from solutions; discontinuities in adsorption isotherms and the application of this phenomenon to the molecular-weight determination of proteins.** *Japan. J. Physiol.* **1**, 213-32 (1951).—*C.A.* 45, 6895*h*.

$Pb(NO_3)_2$ at several concns. was adsorbed by charcoal (0.35% suspension) and 0.1% suspensions of egg albumin, hemoglobin, and gelatin. Upon completion of adsorption (20 hrs or more), free Pb ions were detd. polarographically (pH 7.0, temp. 20.0 ± 0.1°C). The half-wave potential of Pb ion (-0.44 v. *vs.* normal calomel electrode) was the same in the presence of protein as when detd. from standard soln., and the time (3.5 sec) for a drop to form and fall at the cathode was too short for a significant amt. of desorption. Adsorption isotherms for all proteins studied were steplike.

2825. Adler, I. and Steigman, J. **Adsorption of UX_1 and RaE by an Aquadag-coated dipping Geiger-Müller tube.** *J. Phys. Chem.* **56**, 493-8 (1952).—*C.A.* 46, 8929*a*.

A dipping Geiger-Müller tube coated with an adsorbent such as colloidal graphite was used. The counting rate of the tube then depended on the rate of adsorption of the radiocolloid on the coating. Data were given on the method of coating the G.M. tube with Aquadag, the reproducibility of results, and the behavior of salts of UX_1 (thorium) and RaE (bismuth) in various aq. media.

2826. Hamdi, H. **Coagulation of graphitic oxide sols.** *Kolloid-Z.* **128**, 22-6 (1952).—*C.A.* 47, 25*c*.

Graphitic oxide sol was prepd. by dialyzing the product obtained from the oxidation of graphite by concd. H_2SO_4, concd. HNO_3, and $KClO_3$. A suspension contg. 0.4 g/liter at pH 3.75 was obtained.

2827. Mans, A.E. and Vervelde, G.J. **Titration of adsorbed acids.** *Rec. trav. chim.* **71**, 977-86 (1952) (in English).—*C.A.* 47, 4165*b*.

Titration curves of dil. salicylic acid were detd. with NaOH and $Ca(OH)_2$ with and without the addn. of varied amts. of activated charcoal to the acid soln. The addn. of adsorbent caused a marked change in the dissocn. const. of the acid, and the titration curve shifted from that of a strong acid (without adsorbent) to that of a very weak acid, as amts. of the charcoal were added. The greater the amt. of adsorbent added to the salicylic acid solns., the higher the initial pH of the soln. and the greater the difference between the curves for uni- and bivalent bases; the tritration curve with the NaOH always resembled that of a weaker acid than the curve using $Ca(OH)_2$.

2828. Tovbin, M.V. and Grinberg, A.D. **Dynamics of desorption from solutions.** *Zhur. Fiz. Khim.* **26**, 156-64 (1952).—*C.A.* 47, 4688*a*.

Birch charcoal activated by CO_2 at 1000°C until its porosity was 60.2-67.0%, was satd. with I_2 from a soln. in 0.1 *N* KI. The adsorbed amt. *a* (mg I_2/g) was 230 when the equil. concn. *c* of I_2 in the soln. was < 0.1 mg/liter and 1100 at 7g/liter. Then the charcoal was washed with 0.1 *N* KI soln. No I_2 could be displaced as long as *a* was less than 230. Increase of temp. from 10° to 40°C raised the rate of desorption 2.5-fold. Probably the measured rate of desorption was smaller than the real rate of desorption, because the I_2 desorbed from one patch on the adsorbent was readsorbed by another patch.

2829. JACOBSON, M. G. **Electrochemical method for oxygen determination in gases.** *Anal. Chem.* 25, 586-91 (1953).—*C.A.* 47, 6306*i*.

The depolarization of a carbon cathode in a cell with Zn anode by O_2 was used to det. the O_2 concn. of gas mixts. To obtain the high current d. required, the tubular carbon cathode, through which the gas sample circulated, was covered with insulating varnish except for several "windows," permeable to gas but not to electrolyte. A continuous O_2 indicator was described in which a thermostat controlled the temp. The total change in elec. power, *W*, was proportional to the O_2 concn., *C*. This could be used directly. The electrolyte was oxolite, a soln. of pH 3, which made the instrument insensitive to CO and up to 24% CO_2.

2830. KORDESCH, K. AND MARTINOLA, F. **The galvanic cell: oxygen (on carbon)/potassium hydroxide/zinc.** *Monatsh.* 84, 39-53 (1953).—*C.A.* 47, 6278*g*.

Catalyzed O_2 electrodes in alk. electrolytes were studied in open-circuit and current-supplying states. Potential measurements with varying O_2 partial pressure and pH suggest a reversible O_2/H_2O_2 electrode. Ionic activities in 0.5-10 *M* KOH solns. were detd. The temp. coeff. of the O_2-carbon electrode between 12 and 35°C with a drain of 5 ma./cm^2 was 0.5 mv./degree.

II-3. Non-Carbon Adsorbents With Organic Solutions

2831. EISENACK, ALFRED. **Catalytic action of clays and other silicate minerals and compounds on aromatic amines and phenols.** *Zentr. Mineral., Geol.* 1938A, No. 10, 305-8.—*C.A.* 34, 1976^8.

Clays, mixed with solid amines or suspended in liquid amines, catalyze slow reactions producing dyes and colorless by-products. The reactions, obtained with a large no. of amines and with phenol, were also catalyzed by kaolin, weathered feldspar and basalt, serpentine, pptd. Mg and Al silicates, silica gel, permutite, and $Fe(OH)_3$, but not by active C, pptd. $CaCO_3$ or cellulose. The materials which catalyze the reactions were excellent adsorbents for the dyes produced.

2832. HENDRICKS, S. B. AND ALEXANDER, L. T. **Qualitative color test for montmorillonite (bentonite) type of clay minerals.** *J. Am. Soc. Agron.* 32, 455-8 (1940) Rev. Current Lit. Paint, Colour, Varnish & Allied Ind. 15, 113 (1942).—*C.A.* 36, 6450^2.

Benzidine was slowly oxidized to a blue or greenish blue color in the presence of montmorillonite; Fe^{+++} probably participated in the reaction although $Fe(OH)_3$ and other Fe compds. in the soil did not give the reaction in the absence of montmorillonite. Mn^{++} interfered with the reaction and org. matter had to be removed by treatment with H_2O_2 prior to the test. Kaolin minerals did not give the test.

2833. BIELENBERG, W. AND GOLDHAHN, H. **The adsorption of hydroxybenzenes on bleaching earths.** *Kolloid Z.* 97, 151-3 (1941).—*C.A.* 37, 17^5.

The selective adsorption of various mono-, di-, and trihydroxybenzenes on Floridin XXF and on Tonsil AC was measured. The point was measured at which the color reaction of the solutions of the hydroxybenzenes with a 1% alk. solution of fluorenediazonium chloride disappeared when the solutions were shaken with the adsorbent. Complete adsorption of pyrocatechol took place much faster than that of the univalent phenols (phenol, o-, m-, p-cresol, carvacrol, 1-2-dimethyl-4-hydroxybenzene, 1,4-dimethyl-2-hydroxybenzene, and guaiacol).

2834. BROCKMANN, HANS AND SCHODDER, HELLA. **Aluminum oxide with buffered absorptive properties for purposes of chromatographic adsorption.** *Ber.* 74B, 73-8 (1941).—*C.A.* 35, 2390^8.

Al oxides of various adsorptive activities were prepd. by heating Merck's tech. $Al(OH)_3$ to strong red-heat and then partially deactivating by shaking for shorter or longer periods with moist air. Various dyestuffs showed increasing tendencies toward absorption (methoxyazobenzene, azobenzene, Sudan Yellow, Sudan Red, aminoazobenzene, hydroxyazobenzene).

2835. EICKE, H. **Application of adsorption technique to investigation of tar and bitumen.** *Teer u. Bitumen* 39, 113-15, 122-5, 133-5, 144-9, 154-7, 161-3 (1941).—*C.A.* 37, 1847^5.

The adsorption method, especially when combined with fractional extn., was a valuable aid to the analysis of bitumens. Conditions in the road bed were approached as nearly as possible by a new method of testing based on treatment of solns. of the tar or bitumen with bleaching earth. Fractional extn. was combined with adsorption analysis so that the original substance was sepd. by the adsorption tests into separate groups by means of selective solvents which subsequently serve as sepg. or adsorption media.

2836. ENDELL, JOACHIM; ZORN, RENATE, AND HOFMANN, U. **The benzidine test for montmorillonite.** *Angew. Chem.* 54, 376-7 (1941).--*C.A.* 35, 7878^8.

The widespread use of the blue color given with benzidine as a sp. test for montmorillonite in rocks and soils depended on an oxidizing action leading to formation of semiquinones. Other similar diamines likewise gave a blue color. The blue color cannot, however, be regarded as a test for montmorillonite. Adsorption probably was an important factor.

2837. ERDHEIM, EDUARD. **Dependence of the bleaching power of highly active bleaching earths on their water content and the bleaching temperature used.** *Osterr. Chem.-Ztg.* 44, 217-23 (1941).—*C.A.* 37, 2523^7.

Three mineral oils were bleached with an American active earth and a comparable Rumanian bleaching clay at 110°, 160°, 168°, and 230°C. The best results were obtained at 110°C. Another series was run with a bleaching earth containing 2.7-25.7% water, with 3 mineral oils, soybean, and rapeseed oil at 100°C. Oils having a higher water content bleach better. Earths with high and very low water content could be used to advantage for bleaching at elevated temp. preferably under a CO_2 blanket.

2838. ESME, A. **The use of bentonite as a gel-producing medium and carrier.** *Industrie chimique* **28**, 230-1 (1941).—*C.A.* **37**, 6371^1.

Bentonite swelled in water and could absorb 25-30 times its original vol. It was suitable as a basis for the prepn. of emulsions particularly as a substitute for fatty carriers. The tendency of these gels to dry easily could be greatly reduced by the addn. of glycerol or glycol, sugar soln., and Zn or Mn nitrate or $CaCl_2$.

2839. KRUGER, DEODATA AND OBERLIES, FRIDEL. **Catalytic oxidation of amines at the surface of negative adsorbents. II. Realization of a different course of the reaction in the oxidation of dimethylaniline and some of its homologs on bentonite and on other surfaces.** *Ber.* **74B**, 1711-19 (1941).—*C.A.* **37**, 365^4.

The reaction occurred on various silicates (talc, certain kaolins, asbestos). The prerequisite seemed to be a surface with negatively polar free affinities which made possible the adsorption of the aromatic amine and its further basic oxidation and condensation products, with formation of salt-like complexes. TiO_2 did not become colored in a $PhNMe_2$ atmosphere. Bentonite reacted differently from other silicates.

2840. PACSU, EUGENE AND MULLEN, JAMES W., 2ND. **Separation of starch into its two constituents.** *J. Am. Chem. Soc.* **63**, 1168-9 (1941).—*C.A.* **35**, 3843^7.

Selective adsorption of β-amylose from a mixt. with α-amylose occurred on activated charcoal, fuller's earth and Brockmann Al_2O_3 but best results were obtained with cotton. This adsorbate was formed instantaneously when a cold 1% cornstarch paste was brought into contact with cotton and could be washed free of α-amylose with cold H_2O.

2841. PAGE, J. B. **Unreliability of the benzidine color reaction as a test for montmorillonite.** *Soil Sci.* **51**, 133-40 (1941).—*C.A.* **35**, 6296^5.

The benzidine color test for the presence of montmorillonite in soils and minerals was used on a group of about 35 samples. In one case a strong pos. reaction was given by a colloid whose predominating mineral was of the kaolinitic type. Also, in a few cases bentonites gave weak or no color intensity. The presence of slightly sol. Fe was responsible for some color reaction.

2842. POSPISCHIL, F. **A note on the term "adsorption" in dyeing and dye analysis.** *Wollen- u. Leinen-Ind.* **61**, 67 (1941).—*C.A.* **37**, 6898^7.

"Adsorption" is the ability of a substance to fix other substances without the formation of a chem. compd. This occurred, e.g., in the deposition of inorg. pigments ($BaSO_4$, TiO_2 etc.) on fibers. Filtration of the dissolved dye through $CaSO_4$, silica gel, and kaolin was also discussed.

2843. SUZUKI, SHIN-ICHI. **Titanium compounds. XVIII. Adsorption by titania gel.** *J. Japan Ceram. Assoc.* **49**, 530-41 (1941); *J. Am. Ceram. Soc.* **32**, No. 8, Ceram, Abstracts Sect., 195 (1949).—*C.A.* **44**, 10282*e*.

The adsorption of Benzo Copper Blue 2B by titania gel was studied. Gels were obtained by heating the sol made by the hydrolysis of $TiCl_4$ at 60° and 85°C. The addn. of salt to the sol increased the adsorption of gel in the following decreasing order: $AlCl_3$, $CaCl_2$, $MgCl_2$, $MnCl_2$.

2844. GYANI, B. P. AND GANGULY, P. B. **Adsorption in relation to constitution. I. Adsorption of alkaloids by silica gel.** *J. Indian Chem. Soc.* **19**, 453-60 (1942).—*C.A.* **37**, 3990^4.

Alc. solns. (25 cc.) of the alkaloids were shaken with 2-5 g silica gel, left until equil. was attained and analyzed to find the amt. of adsorption (direct titration with suitable indicators). Silica gel was activated by water washing for several days, drying at 100°C and heating to about 300°C for 3 hrs in a current of CO_2-free air. About 90% of the adsorption took place within 24 hrs, but complete equil. was established only after 20 days (nicotine 3 days and brucine 60 days). The following adsorption values were found: morphine 63.7%, nicotine 78.5%, quinine 49.0%, quinidine 61.8%, cinchonidine 63.2%, brucine 83.1%, strychnine 80.6%, caffeine 20.8%, piperine neg. absorbed. The adsorption isotherms followed Freundlich's equation.

2845. JAMISON, M. M. AND TURNER, E. E. **Separation of diastereoisomerides by selective adsorption on optically inactive material.** *J. Chem. Soc.* **1942**, 611-12.—*C.A.* **37**, 5299^2.

l-Menthyl, d-and *l*-mandelates was adsorbed selectively on Al_2O_3.

2846. KAUTSKY, H. AND MULLER, G. O. **Chemiluminescence of adsorbed dyes.** *Naturwissenschaften* **30**, 315-(1942).—*C.A.* **37**, 4305^1.

Chemiluminescence (produced by O_3) and fluorescence (ultraviolet light) of a series of dye adsorbates on silica gel or alumina gel emitted light of essentially the same color for each dye. Colors ranged from orange red to green. The intensity of chemiluminescence was strongest in the red region.

2847. MEHLICH, ADOLPH. **Adsorption of barium and hydroxyl ions by soils and minerals in relation to pH.** *Soil Sci.* **53**, 115-24 (1942).—*C.A.* **37**, 2861^9.

Natural soils and various H-saturated soil materials were treated with increasing amounts of triethanolamine and NaOH in the presence of a constant amount of $BaCl_2$. After shaking, leaching, and washing, the amounts of Ba and OH ions adsorbed were measured volumetrically. Adsorption of Ba by soils reached a maximum coincident with neutralization of exchangeable H. With humic acid, this occurred at about pH 6.0, peat at 6.8, Eutaw soil at 8.2, and kaolin at 9.6. Equivalent adsorption of Ba and OH ions by these materials occurred above pH 5.2 for lignite, pH 7.6 for halloysite, and pH 8.7 for Permutit.

2848. Meunier, Paul. **The action of montmorillonite clay on vitamin A and the phenomenon of mesomerism in the carotenoid group.** *Compt. rend.* **215**, 470-3 (1942).—*C.A.* **39**, 11³.

Montmorillonite clay in adsorbing vitamin A in nonpolar soln. gave a blue color. Other clays after treatment with HCl or H_2SO_4 behaved in the same way. The color was persistent, but was dispelled by a trace of polar solvent. On repassage through a nonpolar solvent color reappeared. The fact that the blue product could not be isolated from its support showed that the coloration resulted from adsorption.

2849. Munro, L. A. and Monteith, G. E. **The syneresis of silica gels containing addition agents.** *Can. J. Research* **20B**, 212-20 (1942).—*C.A.* **37**, 20⁹.

The method of measurement of syneresis gave duplicate results agreeing within 1.2%. The effect of a series of alcohols—methyl, ethyl, glycol, glycerol, and erythritol—on syneresis was studied. The results indicated that the total volume of syneretic liquid at equilibrium was the same as that of the control (within the experimental error) and that no adsorption had taken place in the gel itself.

2850. Capell, R. G.; Amero, R. C., and Moore, J. W. **New data on activated bauxite desiccants.** *Chem. & Met. Eng.* **50**, No. 7, 107-10 (1943).—*C.A.* **37**, 5802⁵.

Dehydration of org. gases and liquids with an activated bauxite desiccant, Florite, was described. Equil. dryness obtainable, H_2O-adsorption capacity, regeneration and effects of pressure drop and fluid velocity were discussed.

2851. Damle, N. R.; Forster, R. B., and Kudva, K. G. **Green earth of Indian origin as a base-exchanging body.** *J. Indian Chem. Soc., Ind. & News Ed.* **6**, 30-9 (1943).—*C.A.* **38**, 5708⁵.

Green earth adsorbed only basic dyes (methylene blue, malachite green, brilliant green GX) and bases ($PhNH_2$, benzidine). Previous treatment of green earth with aq. solns. of $CaCl_2$, $ZnCl_2$, NaCl or NaOH increased the adsorption; variation of pH had no effect; preheating green earth to 400°C reduced adsorption, preheating to 800°C prevented it. The adsorbed substances could not be replaced by NaCl or removed by water or org. solvents. The "sorption" curves were similar and did not obey Freundlich's law.

2852. Franck, James and Pringsheim, Peter. **Phosphorescence of adsorbed trypaflavine and its quenching by oxygen.** *J. Chem. Phys.* **11**, 21-7 (1943).—*C.A.* **37**, 833⁶.

Dyes adsorbed on, or imbedded in, solids had a greater yield of fluorescence and phosphorescence than they did in liquid solutions. The green phosphorescence of trypaflavine adsorbed on silica gel was half quenched by O_2 at 5×10^{-5} mm pressure; the quenching at higher O_2 pressures was much smaller than would be expected. This indicated that two long-lived excitation states (tautomers of tyrpaflavine) shared in causing the green phosphorescence.

2853. Gyani, B. P. and Ganguly, P. B. **Adsorption in relation to constitution. II. Adsorption of organic acids on activated silica gel.** *J. Indian Chem. Soc.* **20**, No. 10, 331-7,(1943).—*C.A.* **38**, 3180⁷.

The adsorbabilities of a large number of org. acids on active silica gel were investigated. With the exception of HCOOH (adsorbability abnormally large - 92%), the first 13 members of the fatty acid series had adsorbabilities lying between 52.8 and 60%. The adsorbabilities of dibasic acids from alc. solns. showed a regular decrease with an increasing number of C atoms in the chain. With the exception of oxalic acid, the product of adsorption coeff. and the number of C atoms in the mol. was a const. The substitution of OH groups, halogens, and other active groups in the fatty acid mol. increased the adsorbability on silica gel in nearly all cases.

2854. Hartmann, M. and Druey, J. **Adsorption of sulfanilamide, sulfathiazole and *p*-aminobenzoic acid.** *Schweiz. med. Wochschr.* **73**, 558-60 (1943).—*C.A.* **38**, 4098⁸.

Inorg. adsorbents took up more sulfathiazole than *p*-aminobenzoic acid at alk. reaction but less at acid pH. Both sulfanilamide and sulfathiazole were able to replace *p*-aminobenzoic acid in adsorbates.

2855. Meunier, Paul. **Action of acid clays on aromatic amines. Coloration and electromeric effect.** *Compt. rend.* **217**, 449-51 (1943).—*C.A.* **39**, 1794⁸.

Coloration accompanying adsorption of aromatic amines, e.g., aniline, by acid clays (bentonite, montmorillonites) was attributed to dipolar mols. Each dipolar mol. of aniline in contact with clays (whose ions were immobilized since the H^+ ions were retained between layers of silicate anions) could so orient itself that it fixed a proton and formed an ionic bond. Electron-donor solvents (H_2O, EtOH) did not elute the adsorbed aniline, since it had no atom with an incomplete electron shell.

2856. Yadava, B. P. **Charge and stability of colloids. II. Effect of nonelectrolytes.** *J. Indian Chem. Soc.* **20**, 110-14 (1943).—*C.A.* **37**, 6519³.

Addns. of MeOH reduced the adsorption both of Ba^{++} on As_2S_3 and of SO_4^{--} on $Fe(OH)_3$ by about 1/3 or 1/4. For EtOH small increases were noted, for agar-agar changes were slight, and for gelatin small decreases were noted.

2857. Aldrich, D. G.; Hellman, N. N., and Jackson, M. L. **Hydration control of montmorillonite as required for its identification and estimation by x-ray diffraction methods.** *Soil Sci.* **57**, 215-31 (1944).—*C.A.* **38**, 4535¹.

To control the degree of hydration of montmorillonite, clay particles less than 0.2 μ in diam., conditioned and satd. with Ca, were suspended in a ternary soln. of benzene, ethanol and water, the compn. of which was such as to provide true soln. but near-satn. with respect to water.

Benzene was added to the suspension which set free a water-rich 2nd phase in finely divided form throughout the suspension so that it was sorbed uniformly by all of the clay. Most of the supernatant liquid was decanted and the clay dried under controlled conditions.

2858. BATCHELOR, R. W. AND FOSTER, A. G. **Freezing point of adsorbed liquids.** *Trans. Faraday Soc.* 40, 300-5 (1944).—*C.A.* 38, 6156^{4}.
Dioxane adsorbed on Fe_2O_3 gel melted sharply about 6 °C below the normal m. p. (11.7 °C) and had a lower vapor pressure. The gel of coarse capillary structure had an av. capillary radius of the order of 100 A. and the isothermals resembled those of water on Fe_2O_3 gel. Water adsorbed on silica gel of pore radius approx. 11 A. remained liquid even on cooling to -65 °C.

2859. BOSAZZA, V. L. **The adsorption of some organic dyes by clays and clay minerals.** *Am. Mineral,* 29, 235-41 (1944).—*C.A.* 38, 4219^{8}.
Quant. data were detd. for the adsorption of malachite green, Congo red and methyl violet by 3 kaolinites and 2 bentonites. Qual. tests showed that naturally-colored dyes were adsorbed in varying amts. by all the clays tested. Colorless or nearly colorless amines such as benzidine, o-toluidine, diphenylamine reacted to give blue or green colors only with moist illite or montmorillonite clays, not with kaolinite, moist or dry, nor with dry illite or montmorillonite.

2860. ERLENMEYER, H.; BOSSARDT, ALFRED A., AND THEILHEIMER, W. **Comparative flotation experiments with fatty acids as a-hydroxy fatty acids as collectors.** *Helv. Chim. Acta* 27, 1429-32 (1944).—*C.A.* 39, 2471^{4}.
α-Hydroxy acids were particularly suited as collectors. In tests upon the flotation of Fe_2O_3 with valeric, hydroxyvaleric caproic, hydroxycaproic, lauric and hydroxylauric acids, the last two of the acids were outstanding in their action; in the ratio of less than 0.1 mg of the acid to 2 g of Fe_2O_3, they were effective collectors. An artificial mixt. of hydrated Al_2O_3 and quartz was well sepd. with hydroxylauric acid.

2861. GOLDHAHN, H. **Formation of color lakes on fuller's earths.** *Angew. Chem.* 54, 377 (1944); *Chem. Zentr.* **1941, II,** 2871.—*C.A.* 38, 1882^{9}.
The appearance of the adsorption colors of different hydroxyazobenzene dyes on Tonsil (clay), floridin and Al_2O_3 were discussed. The hydroxy benzenes corresponding to hydroxyazobenzene dyes frequently gave, an adsorption on fuller's earths from non-aq. soln., characteristic colors which often corresponded to the colors produced by hydroxyazobenzene dyes.

2862. GRAFF, MORRIS M.; O'CONNOR, ROBERT T., AND SKAU, EVALD L. **Purification of solvents for adsorption spectroscopy. An adsorption method.** *Ind. Eng. Chem., Anal. Ed.* 16, 556-7 (1944).—*C.A.* 38, 6198^{3}.
Hydrocarbon solvents were purified by selective adsorption on silica gel columns. The method was superior to the usual tedious chem. and phys. methods for removing impurities which absorb light in the ultraviolet. Com. samples of cyclohexane, n-heptane, isooctane, Skellysolve-B, and Skellysolve-F, purified in this manner, were found to be transparent in the ultraviolet.

2863. KUL'SKIĬ, L. A. AND KOGANOVSKIĬ, A. M. **Colloid adsorption from water by aluminum and iron hydroxide gels. I. Influence of ferrogel dehydration on Congo red adsorption.** *J. Applied Chem. (U.S.S.R.)* 17, 599-605 (1944) (English summary).—*C.A.* 40, 2054^{9}.
Adsorption of Congo red from colloidal solns. onto active charcoal and Fe hydroxide gels was studied. All isotherms fit the Langmuir equation. Strongly hydrated Fe hydroxide gels had a large sorption capacity which fell sharply with dehydration. Contraction and adsorption loss on dehydration were attributed to decrease in diam. of microcapillaries during dehydration.

2864. LEONT'EVA, A. A. **An attempt to apply thermal analysis to the study of adsorption processes.** *J. Phys. Chem. (U.S.S.R.)* 18, 469-72 (1944).—*C.A.* 39, 2918^{9}.
Brilliant green and, in some expts., methyl violet were adsorbed on kaolin (no Fe), ocher (Fe as hydroxide outside the lattice), glauconite, and nontronite (both have Fe in the lattice). The amts. of dye adsorbed at room temp. were nearly equal for the 4 adsorbents, but boiling EtOH exts. more dye from kaolin and ocher than from glauconite and nontronite. Heating curves of kaolin + dye showed an endothermic effect ascribed to a sublimation of dye above 120 °C.

2865. BRADLEY, W. F. **Molecular associations between montmorillonite and some polyfunctional organic liquids.** *J. Am. Chem. Soc.* 67, 975-81 (1945).—*C.A.* 39, 3190^{9}.
The org. liquids were chiefly: (1) aliphatic di- and polyamines and (2) glycols, polyglycols and polyglycol ethers. Small amts. of clay were simply soaked in the solvent, the solvent was poured off, and the clay washed superficially by decantation, and permitted to air-dry. X-ray diffraction diagrams of the powder were then made with either filtered Fe or Cu radiation. Org. solvents of both the above groups yielded characteristic complexes whether they were used as the pure liquids or as water solns. as weak as molal or one-half molal for the glycols, weaker for the amines.

2866. BROAD, D. N. AND FOSTER, A. G. **The sorption of condensable vapors by porous solids. II. The validity of Gurvitsch's rule.** *J. Chem. Soc.* **1945,** 366-71.—*C.A.* 39, 4785^{9}.
Isothermals of the following liquids were detd. on silica gel at 25 °C: AcOH, acetone, diisopropyl ether, dioxane, n-hexane, morpholine, n-octane, toluene, and tri-ethylamine. The amts. adsorbed at satn. decreased as the diam. of the adsorbed mol. increased. The observed relations could be explained by assuming that the adsorbent contained tapering capillaries. The no. of mols. held in the unimol. layer also decreased as the mol. diam. increased.

2867. DUUREN, A. J. VAN. **Dependence of the adsorption isotherm on the quantity of adsorbent.** *Rec. trav. chim.* 64, 303-4 (1945) (in French).—*C.A.* 40, 3958^{7}.

Aniline and AcOH were adsorbed from C_6H_6 soln. by Terrana, an activated com. decolorizing agent (montmorillonite). The amt. adsorbed at const. concn. per gram of earth was greater for smaller amts. of earth, which ranged from 0.25 to 1.00 g/100 cc. of soln.

2868. GYANI, B. P. AND GANGULY, P. B. **Adsorption in relation to constitution. V. Adsorption of alcohols, esters, and ketones on silica gel.** *J. Phys. Chem.* 49, 226-38 (1945).—*C.A.* 39, 3715^4.

The adsorption of the lower members of the series of alcs., esters, and ketones on active silica gel was measured by a static method. Silica gel was a powerful adsorbent for all the vapors studied. At high relative pressures the amounts of adsorption were always in the inverse order of the mol. wts in the same series of compds. These orders were not maintained at lower relative pressures, and might further change according to the mode of plotting adopted.

2869. KISELEV, A. V.; VORMS, I. A.; KISELEVA, V. V., AND SHTOKVISH, N. A. **Adsorption of fatty acids on silica gel and its ultraporosity.** *J. Phys. Chem. (U.S.S.R.)* **19**, 83-91 (1945).—*C.A.* 39, 3715^6.

The adsorption of AcOH, propionic acid, and stearic acid from CCl_4 at room temp. on silica gel was less the higher the temp. (T) of dehydration of the gel. The vols. of AcOH and stearic acid adsorbed at satn. (extrapolated for AcOH) were nearly identical at 485° and 800°C. For a silica gel of T 200°C (adsorbed a larger vol. of stearic acid than of AcOH) the surface was about 3×10^6 cm^2/g.

2870. SIEGL, W. **Detection of montmorillonite with benzidine.** *Neues Jahrb. Mineral., Geol., Monatsh A*, **1945-48**, 40-3.—*C.A.* **43**, 1287h.

Montmorillonites, which did not react with benzidine alone, gave the blue color if a few drops of dil. FeCl soln. was added. Kaolinites also gave a bluish color after FeCl soln. was added, but gave grayish or violet hues distinguishable from the ultramarine blue given by montmorillonite.

2871. VEDENEEVA, N. E. **Chromatographic adsorption in clay analysis.** *Doklady Akad. Nauk S.S.S.R.* **50**, 429-32 (1945).—*C.A.* **44**, 5274d.

A suspension of the powd. mineral with a dil. soln. of one or two org. dyes were shaken. After sedimentation, characteristic rings appeared, usually rather indistinct, but sometimes in sharp thin zones, or spots on a uniformly colored background. Usually, the chromatograms became increasingly distinct during standing. Expts. with kaolinite, montmorillonite (bentonite), nontronite, and halloysite were described, with methylene blue as a dye. In the special case of halloysite, diiodofluorescein (in acetone soln.) was superior.

2872. BUCHADER, G. AND LEBESGUE, JACQUES. **Evolution during the formation of a silica gel of the fluorescence of a substance dissolved in it.** *Compt. rend.* **223**, 324-6 (1946).—*C.A.* **41**, 29^i.

The intensity and polarization of the fluorescence emitted by rhodamine S when added to a fresh mixt. of Na silicate and H_2SO_4 were measured at different times during formation of the gel. The most rapid increase in intensity was found to occur during the first hrs; after 48 hrs the intensity was 3 times the initial value. During the formation of the gel there was a decrease in the de-cativation of the mols. without emission.

2873. ESME, A. **Chemical control of bentonites by color test for montmorillonite.** *Ann. chim. anal.* **28**, 31 (1946).—*C.A.* **40**, 2762^3.

Montmorillonite gave a blue color in the presence of benzidine: Treat the sample with 3% H_2O_2, evap. to dryness below 100°C and treat 1 g of the residue with a cold, satd. soln. of benzidine. Shake vigorously and allow to stand for a few hrs. The blue superficial color was the result of an oxidizing effect which was really caused by ferric ions present.

2874. FOSTER, A. G. **Validity of Gurwitsch's rule.** *Nature* **157**, 340-1 (1946).—*C.A.* **40**, 3323^1

The sorption isothermals of a no. of org. liquids on silica gels were examined.

2875. GANGULY, P. B. AND GYANI, B. P. **Orientation of molecules in adsorbed layers.** *Bull. Patna Sci. Coll. Phil. Soc.* No. **16**, 92-6 (1946).—*C.A.* **40**, 5316^9.

Adsorption of 14 monobasic acids [not specified] on silica gel from anhyd. alc. indicated the mols. to be adsorbed in a vertical position. Dibasic fatty acids appeared to lie flat except at high concn. Results given for satd. pentane, hexane, heptane, and octane vapors showed the product of adsorption coeff. and mol. area to be const., indicating flat orientation.

2876. MACEWAN, D. M. C. **Halloysite-organic complexes.** *Nature* **157**, 159-60 (1946).—*C.A.* **40**, 2419^9.

Complexes of halloysite with CH_2OHCH_2OH, glycerol, $HO(CH_2)_3OH$, CH_2ClCH_2OH, CH_2BrCH_2OH, and MeOH were described. There was room for one flat layer of alc. mols. between the halloysite sheets; there were two such layers in montmorillonite complexes.

2877. NEDERBRAGT, G. W. AND JONG, J. J. DE. **The separation of long-chain and compact molecules by adsorption.** *Rec. trav. chim.* **65**, 831-4 (1946) (in English).—*C.A.* **41**, 2299^a.

Binary mixts. of satd. hydrocarbons, paraffins, and naphthenes, dissolved in pentane were passed through columns of large quantities of Floridin earth, previously ground and dried at 300°C. Pentane was used as eluant. Extremely good sepns. were accomplished with mixts. of equal amts. of tetracosane ($n_D^{70} = 1.4281$) and di-sec-butyldecahydronaphthalene ($n_D^{70} = 1.4625$), and of octadecyclohexane ($n_D^{70} = 1.4420$) and di-sec-butyldecahydronaphthalene, the paraffins were better adsorbed.

2878. RYKHLIKOV, G. P. AND GAPON, E. N. **Adsorption of organic acids by silica gel. II.** *J. Phys. Chem. (U.S.S.R.)* **20**, 1029-41 (1946) (in Russian).—*C.A.* **41**, 2298^h.

Formic, acetic, propionic, and butyric acid solns. in CCl_4 were shaken with 4 different silica gels. The amt. x (in g-mol.) adsorbed by 1 g of gel, without regard to the adsorption of CCl, satisfied the equation $x = Sc^{1/3}/(c^{1/3} + K)$, S and K being consts. and c the equil. concn. of the acid (g-mol./liter). Distribution of the fatty acids between H_2O and CCl_4 showed that the acids were assocd. in CCl_4 to triple mols. At a given c, x increased from acetic, propionic, and butyric to formic on all gels.

2879. Balma-Perrier, Francoise and Darmois, Eugene. **The measurement of the specific surface of silica powders.** *Compt. rend.* **224,** 1562-4 (1947).—*C.A.* **41,** 6107*e*.

The method was based on the speed of mutarotation of an aq. soln. of tartaric acid and SbF_3 in contact with SiO_2. Powd. silica gave a value of 1000 cm^2/g, compared with 1300 by microscopic examn., and 800 by adsorption of Diamond Magenta dye. The change in surface area of pptd. silica with temp. of calcination was shown, falling from 6.1 to 0.3×10^5 cm^2/g for one prepn. as the temp. was raised from 280° to 1270°C.

2880. Graham, Ronald P. and Crawford, Donald J. **The sorption of oxalate by hydrous alumina.** *J. Colloid Sci.* **2,** 509-19 (1947).—*C.A.* **42,** 1103*e*.

The sorption of $(COOH)_2$ by hydrous Al_2O_3 from 0.05 M solns. at 25°C reached a max. after 1-4 hrs and then decreased steadily. The neutralization of H_3O^+ ion by the alumina during this time increased steadily. The oxalate sorption was ten times that observed for Cl^- under comparable conditions. Expts. with hydrous Al_2O_3 samples prepd. at 30°, 60°, and 95°C demonstrated that the sorption capacity was greatest for the samples prepd. at 60° or 95°C.

2881. Grim, R. E.; Allaway, W. H., and Cuthbert, F. L. **Reaction of different clay minerals with some organic cations.** *J. Am. Ceram. Soc.* **30,** 137-42 (1947).—*C.A.* **41,** 4901*i*.

Kaolinite, illite, and montmorillonite were washed with 0.05 *N* HCl until free from replaceable bases, washed with H_2O or CH_3OH, and then made to react with sufficient KOH to sat. the exchange complex with K^+ at pH 7. These K clays were given variable dosages of n-butylamine acetate, dodecylamine acetate, and ethyldimethyloctadecenylammonium bromide. Addns. of amines or other org. cations in amts. less than equiv. to the base-exchange capacity of the clay were rather completely absorbed in base-exchange reactions. The ability of clays to absorb H_2O was greatly reduced by treating the clays with certain compds. that furnished large org. cation.

2882. Hesse, Gerhard and Sauter, Oskar. **Mutual independence of exchange absorption and van der Waals adsorption on alumina.** *Naturwissenschaften* **34,** 250 (1947).—*C.A.* **43,** 6035*b*.

Al_2O_3 contained enough Na aluminate on the surface to make it an exchange adsorbent. By treatment with HCl it could be changed to an adsorbent of acid character. Adsorption of azobenzene, a neutral substance, was equally strong on acid or on basic adsorbent (pH 5 to 9). Adsorption of a basic dye, p-aminoazobenzene, increased with pH; that of an acid dye, Sudan III, decreased with pH.

2883. Hesse, Gerhard and Sauter, Oskar. **The pH dependence of the adsorption of amphoteric substances.** *Naturwissenschaften* **34,** 277-8 (1947).—*C.A.* **43,** 6035d.

With Al_2O_3 contg. small amts. of alkali, which represented a typical amphoteric absorbent, alanine and asparaginic acid (aq. soln.) were selectively adsorbed with max. at the isoelec. points of these amino acids (6.15 and 2.98, resp.). Curves of adsorption vs. pH were given. The max. were quite sharp.

2884. Hori, Kazuhiko and Kajisaki, Chiyotoshi. **Properties of active earths.** *Bull. Govt. Research Inst. Ceramics* (Kyoto) **1,** No. 1, 9-11 (1947).--*C.A.* **46,** 6346*f*.

Properties were studied of active earths such as acid earths or clay, and activities were measured by adsorption of tar pitch and methylene blue soln. Adsorption activity depended on the H_2O content. Earths consisting of fine particles had higher activities.

2885. Kayser, F. and Bloch, J. M. **The effect of several agents on thixotropic bentonite suspensions.** *Bull. soc. chim. France* **1947,** 741-6.—*C.A.* **42,** 1106*d*.

The thixotropic behavior of 2 com. bentonites from Wyoming and Morocco was observed by the submergence of a metal cylinder under exactly defined conditions. The thixotropic cycle was faster and more pronounced at higher temps. Aging had an effect—usually emphasizing the thixotropic behavior. Prolonged heating destroyed the thixotropic capacity of a gel or promoted syneresis. Freezing did likewise, and if prolonged enough caused flocculation. The addn. of Na citrate, to suppress the thixotropic nature, was recommended for detg. the viscosity of bentonite suspensions.

2886. Low, P. F. and Black, C. A. **Phosphate-induced decomposition of kaolinite.** *Soil Sci. Soc. Am., Proc.* **12,** 180-4 (1947) (Pub. 1948).--*C.A.* **43,** 1511*i*.

The addn. of both phosphate and 8-hydroxyquinoline to kaolinite produced a considerable increase in the concn. of SiO_2 in the soln., whereas NH_4Cl caused only a small decrease in dissolved SiO_2. Data indicated that phosphate in the phosphated kaolinite were present as an Al phosphate.

2887. Mair, Beveridge J.; Gaboriault, Andrew L., and Rossini, Frederick D. **Assembly and testing of 52-foot laboratory adsorption column. Sepn. of hydrocarbons by adsorption.** *Ind. Eng. Chem.* 39, 1072-81 (1947).--*C.A.* **41,** 7167*h*.

Data were given in testing the column of silica gel with 2 different mixts. The fractionation obtained in a smaller adsorption column was given on binary mixts. of hydrocarbons selected to disclose differences in adsorbability arising from differences in mol. size and structure.

2888. Maxted, E. B. **Detoxication of catalyst poisons. V. Thiophene.** *J. Chem. Soc.* **1947,** 624-7.—*C.A.* **41,** 6801*f*.

Thiophene was hydrogenated first to thiophane by virtue of its preferential adsorption on the catalyst. This in turn was oxidized to thiophane sulfone. The hydrogenation stage was effectively limited to the amt. originally adsorbed. Larger quantities led to very slow reactions, owing to the low rate of exchange of C_4H_4S and C_4H_8S between the free and adsorbed phases.

2889. MUKHERJEE, SUDHAMOY; DAS GUPTA, K. K., AND POCHHALI, LOCHHU. **The characterization of Indian bentonites and kaolins.** *J. Proc. Inst. Chemists (India)* **19**, 67-73 (1947).—*C.A.* **42**, 2209 h.

Chem. analysis, quinine and methylene blue adsorption, sedimentation vol., moisture capacity, and the pH and sp cond. in aq. suspension were tabulated for a series of three Indian bentonites (all values less than for Wyoming Na bentonite) and for several natural and activated kaolins.

2890. VEDENEEVA, N. E. **Changes in the spectra of dyes when adsorbed on clay minerals.** *J. Phys. Chem. (U.S.S.R.)* **21**, 881-91 (1947) (in Russian).—*C.A.* **42**, 2517*i*.

Clay suspensions in H_2O were colored with org. dyes, drops of the suspension placed on a white surface, and the amt. of light reflected by the surface through the drop was detd. for 10 regions of the visible spectrum. The expts. were repeated after evapn. of water when a film of clay remained on the support. When the intensity of coloration of kaolinite by methylene blue increased, the max. of adsorption was shifted from 590 to 550 mμ, but drying caused an opposite shift by 40 mμ. When quartz powder dyed with new methylene blue and showing a max. at 560 mμ was placed in contact with silica gel in water, the dye migrated to the gel and then showed a max. at 610 mμ. Brilliant green dyed all bentonite samples in the same color.

2891. BOUTARIC AUGUSTIN AND FABRY, SIMONE. **Phenomenon of adsorption in colloidal solutions.** *Ann. soc. sci. Bruxelles* **62**, Ser. **1**, 47-54 (1948).—*C.A.* 42, 7599*g*.

The degree of adsorption of colored substances such as Fehling soln., eosin, and methylene blue in colloidal soln. was detd. by measuring optical density of the mixed and unmixed solns. It was demonstrated that particles dispersed in a hydrosol have only a feeble adsorbing power for substances that were dissolved and introduced into the hydrosol. They showed a strong adsorbing power only in the flocculated state.

2892. BRADLEY, W. F. AND GRIM, R. E. **Colloid properties of layer silicates.** *J. Phys. & Colloid Chem.* **52**, 1404-13 (1948).—*C.A.* **43**, 2841*c*.

Prepd. montmorillonite-aliphatic amine complexes were subject to dehydrogenation by heat alone at about 300°C, yielding montmorillonite-carbon complexes of interlayered type. The process was considered an extension of the mechanism of catalytic cracking.

2893. KRASIL'NIKOV, K. G. AND KISELEV, A. V. **Adsorption isotherms from solutions on layering or crystallization. Adsorption of phenol on silica gel from solutions in heptane.** *Doklady Akad. Nauk S.S.S.R.* **63**, 693-6 (1948).—*C.A.* **43**, 4536e.

On a fine-pore (15-20A.) and a coarse-pore (50 A.) silica gel, (liquid H_2O adsorption at satn. of 0.53 and 0.92 cc/g, resp.) adsorption curves of PhOH in C_7H_{16} soln. at 20°C were similar and showed no S-shape. The adsorption curve on a coarse-pore became S-shaped at 40°C, whereas the curve on a fine-pore remained normal. At high relative concns., PhOH and C_7H_{16} were adsorbed in a ratio corresponding to the compn. of the PhOH-rich layer. The limiting amts. of PhOH adsorbed at 40°C were on a fine-pore and a coarse-pore, resp., 4.2 and 7.4 millimoles/g corresponding to 0.50 and 0.90 cc./g, resp.

2894. MACEWAN, D. M. C. **Complexes of clays with organic compounds. I. Complex formation between montmorillonite and halloysite and certain organic liquids.** *Trans. Faraday Soc.* **44**, 349-67 (1948).—*C.A.* **43**, 463*e*.

Mols. penetrated between the structural sheets, expanding the whole crystallite structure, and a change could be followed on an x-ray powder diagram. In these complexes the org. mols. entered between the structural sheets of the clay mineral, formed a two-dimensional liquid and lay as flat as possible. Montmorillonite complexes with 1, 2, and 3 such layers were described, but halloysite complexes had not been obtained with more than one. The relation of this type of adsorption phenomena to surface adsorption was briefly discussed.

2895. MACKENZIE, R. C. **II. Investigation of the ethylene glycol-water-montmorillonite system using the Karl Fischer reagent.** *Trans. Faraday Soc.* **44**, 368-75 (1948).—*C.A.* **43**, 463f,

The amts. of water in samples of montmorillonite corresponded to the total water reversibily removable by heating at 195°C. Detn. of the water and glycol in montmorillonite-glycol-water complexes, in conjunction with x-ray examn. led to the conclusions: (a) the (001) spacing of the complex remained const. at 17.1 A.; (b) the min. amts. of glycol and water necessary to give this spacing were interdependent; (c) in the absence of water, 3.3 mols. of glycol per unit cell, in the form of a bimol. layer, was required for production of the 17.1 A. spacing.

2896. MERRILL, R. C.; SPENCER, R. W. AND GETTY, R. **The effect of sodium silicates on the absorption spectra of some dyes.** *J. Am. Chem. Soc.* **70**, 2460-4 (1948).—*C.A.* **42**, 8650*a*.

The addn. of various sodium silicates to a pinacyanol chloride changed the adsorption spectra. The visual color change was from blue to purple. Silicates shifted the band maxima of Rhodamine 6G about 6 mμ toward the violet but did not alter the intensity by more than 2%. This dye was orange and fluorescent in water and red and nonfluorescent in silicate solns. Their effects were attributed to sorption and electrostatic interaction of the dye ion with the silicate ions and micelles.

2897. PRONINA, M. V. **Adsorption analysis applied to the separation of aldehydes and ketones.** *Zavodskaya Lab.* 14, 1493 (1948).—*C.A.* 43, 5341*c*.

The sepn. of aldehydes and ketones from tars was made by the adsorption technique: Dissolve the sample in petr. ether and treat with semicarbazide soln. (1 part semicarbazide, 1 part NaOAc, and 3 parts water) in a separatory funnel with shaking; after standing overnight, remove the aq. layer, wash the petr. ether with water and dry with Na_2SO_4. Pass through silica gel (65-115 mesh) and wash the column with petr. ether until a colorless effluent is obtained; the semicarbazones remain adsorbed and can be readily eluted by Et_2O.

2898. TISELIUS, ARNE. **Adsorption separation by salting out.** *Arkiv. Kemi, Mineral. Geol.* **26B**, No. 1, 5 pp. (1948).—*C.A.* 43, 1624*e*.

Proteins, enzymes, and similar substances of high mol. wt were adsorbed quite strongly in the presence of salt solns. in low concn., especially on some adsorbents (silica gel) that in salt-free solns. showed no or only slight affinity for these substances. Egg albumin was completely adsorbed at the highest salt concn., which was far from the pptn. point of 2.5 *M* $(NH_4)_2SO_4$. Phycoerythrin and hemoglobin (at concn. of 0.3%) were also investigated on filter paper at salt concn. of 0 to 0.73 *M* (the phosphate soln. was 1:1 KH_2PO_4:K_2HPO_4). A no. of dyes were also investigated, and in all cases a marked salting out adsorption was observed.

2899. VENTURELLO, G. AND BURDESE, A. **Discontinuity in adsorption processes with systems of solids and solutions. I.** *Gazz. chim. ital.* **78**, 254-71 (1948).—*C.A.* 42, 8576*c*.

Adsorption was detd. for the systems: calcined Al_2O_3-aq. $CuSO_4$, $Al(OH)_3$-aq. $CuSO_4$, silica gel-aq. $CuSO_4$, calcined Al_2O_3-iodine in C_6H_6, pptd. $CaCO_3$-aq. purpurin, wood charcoal-purpurin, Al_2O_3-aq. eosin, and Al_2O_3-aq. azofuchsin. The isotherms showed discontinuity phenomena in some cases. With I_2 on Al_2O_3, $Al(OH)_3$, silica gel, and calcined Al_2O_3, the action was between ions and dipoles, and an adsorption bond formed between mols. of polarized I_2 and neg. surface ions. In general, discontinuity phenomena did not depend on the type of force between adsorbent and adsorbed substance; hence, they could appear in every adsorption isotherm.

2900. WEIL-MALHERBE, H. AND WEISS, J. **Color reactions and adsorption of some aluminosilicates.** *J. Chem. Soc.* **1948**, 2164-9.—*C.A.* 43, 6035*e*.

Color reactions accompanying adsorption were detd. on clarite, fuller's earth, bentonite, montmorillonite, and kaolin. Color formed on adsorption of dicinnamylideneacetone, dianisylideneacetone, vitamin A, dimethylaminoazobenzene, and other azo dyes was due to an acid-base type of reation. The second type involved an oxidation-reduction mechanizm and was typified by the adsorption on centers of high adsorption energy probably involving chem. interaction.

2901. WHITE, JONATHAN W. JR. **Chromatographic separation of aliphatic 2, 4-dinitrophenylhydrazones.** *Anal. Chem.* 20, 726-8 (1948).—*C.A.* 43, 1289*i*.

Volclay bentonite (325 mesh) was found to adsorb strongly and to give excellent sepn. of many dinitrophenylhydrazones. The adsorbent used consisted of 3 parts by wt of bentonite to 1 part of a diatomaceous filter aid. Results were given for 22 pairs of derivs. involving 12 aldehydes and ketones including Et_2O, Me_2CO in Et_2O, and C_6H_{14} in Et_2O.

2902. ALFREY, TURNER JR. AND RODEWALD, CHARLES W. **Thixotropy in bentonite suspensions.** *J. Colloid Sci.* 4, 283-98 (1949).—*C.A.* 43, 6885*b*.

The app. used was a torsional pendulum thixotrometer consisting of a cylindrical shell suspended, by a torsion wire, within the annular space between 2 concentric cylindrical shells. Thoroughly agitated bentonite suspensions approached linear behavior, but deviated within a few sec after agitation had ceased. The gelation of bentonite suspensions was reversible, but there was also a slower, mechanically irreversible process of consolidation, whose rate was temp.-dependent. Measurements were made with approx. 6% aq. suspensions of com. bentonite at 2-23°C, with or without addn. of 1% EtOH or dioxane. EtOH had very little effect, but dioxane markedly reduced the gelation.

2903. BHATNAGER, S. S.; KAPUR, A. N., AND BHATNAGAR, M. S. **Adsorptive properties of synthetic resins. IV.** *J. Indian Chem. Soc.* 17, 361-9 (1949).—*C.A.* 35, 1288^5.

Protein-CH_2O resin was prepd. from powd. soybean meal. In all adsorption expts. 1 g powd. resin was shaken for 5 min. with 100 cc. of the 0.01 *M* acid soln. and the mixt. set aside for 36 hrs, after which the supernatant soln. was titrated with standard NaOH soln. and the amt. of acid adsorbed was calcd. Adsorption of HCO_2H, AcOH and butyric acid from aq. solns. by acid-condensed phenolic resins followed Traube's rule, whereas with base-condensed phenolic resins, amino resins and protein resins the order was reversed.

2904. BJÖRLING, CARL O. **The adsorption of some phenolic compounds on aluminum oxide.** *Farm. Revy* 48, 588-99 (1949).—*C.A.* 44, 1227*h*.

The o-diphenolic compds. were adsorbed more strongly than were the monophenolic substances. The nonphenolic compds. were adsorbed least. Adrenaline, apomorphine, and catechol were retained by Al_2O_3 both in alc. and aq. soln., and were eluted fully only by acid. Oxedrine, morphine, phenol, and guaiacol were eluted slowly and incompletely by EtOH, fully by H_2O. The o-diphenolic substances were strongly adsorbed compared with the other diphenols. Oxedrine (p-$HOC_6H_4CH(OH)$-CH_2NHMe), ephedrine, apomorphine, morphine, codeine, dionine, pyrocatechol, resorcinol hydroquinone, guaiacol, phenol, veratrole, and anisole were tested.

2905. Blackburn, S. **Separation of 2,4-dinitrophenyl amino acids on buffered silica gel.** *Nature* **163**, 955-6 (1949).—*C.A.* **43**, 7379*a*.

Successful sepns. of 2,4-dinitrophenyl amino acids on silica gel resulted by using concd. phosphate buffers instead of water as the stationary phase. Varying the pH of the buffer, the rate of movement of the band of a particular acid varied within wide limits, the higher the pH the slower the rate. Buffered $CHCl_3$ columns were used for initial sepns. Buffered 5% PrOH-cyclohexane columns were used for sepg. the dinitrophenyl amino acids from each other, e.g., dinitrophenyl leucine from dinitrophenyl valine and I from dinitrophenyl alanine.

2906. Carlén, Sölve. **Surface activity of burnt pholerite preparations.** *Arkiv. Kemi, Mineral. Geol.* **26A**, No. 31, 10 pp. (1949) (in English).—*C.A.* **43**, 6035*h*.

Pholerite consisting essentially of diokite (analyzing the same as pure kaolinite) was treated by heating in H_2O- and CO_2-free air for 2 hrs from 115° to 1200°C and tested at 20°C for adsorption of Fast Red and methylene blue dyes at pH 3-11 in buffered solns. The acid red dye adsorbed more strongly at low pH with a max. between 4 and 6. The alk. methylene blue adsorbed the reverse, with a min. between pH 5 and 7, agreeing with other work that adsorption mainly depends upon adsorbate and pH.

2907. Carroll, Benjamin and Thomas, Arthur W. **Spectral changes of dyes in colloidal solutions of hydrous oxides.** *J. Chem. Phys.* **17**, 1336 (1949).—*C.A.* **44**, 4750*i*.

In the case of Orange I the molor extinction coeff. at 475 mμ showed a decrease of about 40% in the presence of colloidal hydrous Al_2O_3 and the adsorption max. was shifted some 30 mμ toward the violet. In the case of sulfate ion, complete displacement of the dye was observed when the total concn. of sulfate was comparable to that of the dye. When the dye and sol were mixed, the greater part of the spectral change took place within a few min. About 10 to 20 hrs were required to reach the equil.

2908. Dickey, Frank H. **Preparation of specific adsorbents.** *Proc. Natl. Acad. Sci. U. S.* **35**, 227-9 (1949).—*C.A.* **43**, 6489*c*.

Silica gel formed in the presence of methyl, ethyl, propyl, and butyl orange was 4 to 20 times as effective in adsorbing the particular dye as a control gel. Max. adsorption was shown for the dye used in prepn. of the adsorbent, with decreasing effectivity for dyes with decreasing similarity of mol. structure.

2909. Emodi, B. S. **Adsorption of dyestuffs by montmorillonite.** *Clay Minerals Bull.* **3**, 76-9 (1949).—*C.A.* **47**, 6215*c*.

Strong aq. solns. of various basic dyes (in excess) were shaken with small weighed quantities of fairly pure Ca montmorillonite. After shaking, the mixts. were filtered, and the amts. of Ca and dye detd. in the filtrate. The so-called "ionic adsorption" of dyes was not a single base-exchange reaction, but resulted in excess of Ca ions being left in the clay structure.

2910. Jordan, John W. **Alteration of the properties of bentonite by reaction with amines.** *Mineralog. Mag.* **28**, 598-605 (1949).—*C.A.* **43**, 6121f.

Dodecyl- and octadecylammonium bentonite complexes were prepd. and studies were made of alteration of the affinities of bentonite from Clay Spur, Wyoming, with various org. liquids. The mechanism of the adsorption was discussed.

2911. Jordan, John W. **Organophilic bentonites. I. Swelling in organic liquids.** *J. Phys. & Colloid Chem.* **53**, 294-306 (1949).—*C.A.* **44**, 10456*g*.

Hydrophilic bentonite was altered by treating each 100 g of washed and dispersed material with 100 milliequiv. of various aliphatic ammonium salts. Swelling of these complexes in a wide variety of org. liquids generally increased with the dielec. const. of the liquid.

2912. Kamieński, B. **Potentiometric indication of substances in selective adsorption (chromatography). I.** *Bull. intern. acad. polon. sci., Classe sci. math. nat.* **10A**, 127-33 (1949).—*C.A.* **43**, 8911*c*.

Pt-wire electrodes were sealed at intervals through the glass tube of a chromatographic adsorption column so that measurements could be made. A thin conducting film of dialyzed silicic acid was evapd. onto the inside of the glass tube; buffers or quinhydrone may be added to the colloid. Micro calomel electrodes were also connected through the tube wall by sintered-glass filters. Differences of 100 or more mv. may be observed between different electrodes when dil. quinhydrone in C_6H_6 was poured into the glass tube.

2913. Kamieński, B. **Potentiometric chromatography. II. A microelement for the detection of weak acids and bases in gasoline solutions.** *Bull. intern. acad. polon. sci., Classe sci. math. nat.* **1949A**, 75-80.—*C.A.* **44**, 8098*e*.

A micro cell consisted of 2 concentric tubes; the center one contained a Pt wire sealed in a glass tube and tipped with a thin adsorption layer of silica gel contg. quinhydrone, and the outer tube was a micro calomel electrode tipped with a sintered glass filter satd. with KCl soln. When the cell was immersed successively in gasoline-cinchonidine and gasoline-caproic acid (hexanoic acid) solns., a difference of 85 mv. at concn. of about 0.05%, 40 mv. at 0.005%, and 22 mv. at 0.0005% was obtained.

2914. Kamieński, B. **Electrometric analysis of adsorptives. (Potentiometric chromatography).** *Polska Akad. Umiejetności, Rozprawy Wydzialu Mat.-Przyrod.* **74A**, No. 3, 47 pp. (1949) (Pub. 1951).—*C.A.* **46**, 11013*b*.

The chromatographic adsorption of colorless substances was accomplished through the use of specially constructed Pt or Sb electrodes sealed in glass (Pyrex or "Geräteglas") in a system Pt or Sb|absorptive layer of pure silicic acid (10^{-4} or 10^{-5} cm thick)|0.1 *N* KCl|calomel|Hg. As the ions reached the electrode, either sealed or soldered into the absorptive column, or in contact with the chromatogram on paper, etc., a change in potential was observed which was correlated with the concn. of the ion.

2915. KAPLAN, S. AND MELLER, F. **Aluminum oxide as a chromatographic adsorbent and characterization of its activity.** *Zhur. Obshchei Khim.* **19**, 2038-44 (1949); *J. Gen. Chem. U.S.S.R.* **19**, No. 11, a507-12 (1949).—*C.A.* **44**, 4306*e*, 6702*h*.

Al_2O_3 used in the catalytic decompn. of alc. to ethylene was pulverized to yield fractions ranging in size from 0.044 to 0.196 mm. These were heat-activated at 300 °C in a muffle furnace for 3 hrs. Fractions varying in activity were obtained by rotating a sample of the heat-activated powder at 20 °C in a specially constructed humidor. Samples ranging in moisture content from 0 to 11.5% were prepd. The activity was detd. with 5 pairs of dyes in solns. contg. 0.04 g dye per 100 ml soln. (benzene in gasoline in the proportion of 1:4). The activity group to which the various samples of Al_2O_3 belonged was related linearly to its moisture content.

2916. KOGANOVSKII, A. M. **The sorption of colloids. I. Sorption isotherms of substantive dyes and humic acids by the gels of iron hydroxide and aluminum hydroxide.** *Kolloid. Zhur.* **11**, 237-43 (1949).—*C.A.* **44**, 403*a*.

Dry Fe_2O_3 and Al_2O_3 took up little Congo red from solns. in 0.01 *N* NaCl, and the sorption isotherm was of the Langmuir type. The isotherms of sorption of dyes and Na humate by wet Fe_2O_3 and Al_2O_3 from solns. in 0.01 *N* NaCl showed sharp min. and max.; often these were more pronounced and the sorbed amt. x/m was greater the more H_2O was present in the sorbent (up to 95%). The electrophoretic velocity of Fe_2O_3 decreased when x/m increased without any singular point. The max. x/m observed along the first branch of the isotherm (at low concns. of dye) for Fe_2O_3 contg. 87.5% H_2O was 64, 44, 4.9, 0.6, 5.7, and 0.2 mg/g for water blue, Congo red, indigo carmine, methyl orange, neutral red, and methylene blue, resp.

2917. KRASIL'NIKOV, K. G. AND KISELEV, A. V. **Adsorption by porous bodies from solutions in the neighborhood of the critical temperature of mixing. The system silica gel-acetic acid-heptane.** *Doklady Akad. Nauk S.S.S.R.* **69**, 817-19 (1949).—*C.A.* **45**, 6455*g*.

Adsorption isotherms of AcOH in soln. in C_7H_{16}, on a uniformly coarse-pore silica gel, were detd. in sealed tubes, by interferometric analysis, at 45, 30, 20, 8, 4.5, and 0 °C. At 45° and 30°, i.e. in the range of unlimited miscibility, the adsorption isotherm was a curve with a max. At 0 °C, where there were two liquid layers, the isotherm had an upward S-shaped bend.

2918. MACEWAN, D. M. C. **Interlamellar adsorption. I. Natural adsorbents.** *Bull. soc. chim. France* **1949**, D37-40.—*C.A.* **43**, 5254*i*.

Clays (montmorillonite and halloysite) adsorbed various org. substances between the layers in the lattice. These substances must be polar. Adsorption of 1, 2, or 3 layers occurred with montmorillonite, the no. of layers increasing with the ratio of the dipole moment to the parachor. With halloysite, only one layer was formed and the adsorption was less general.

2919. MALQUORI, ALBERTO. **The surface activity of argillaceous materials. IV. Adsorption of alizarin.** *Ann. chim. applicata* **39**, 447-52 (1949).—*C.A.* **45**, 9785*d*.

The adsorption of alizarin (5% alc. soln., with boric acid buffer, pH 3.2) was only significant on clays which were readily dissolved by HCl. No adsorption took place if the clay was preheated to 750 °C.

2920. MORTLAND, M. M. AND GIESEKING, J. E. **Anion sorption and exchange by amine-clay complexes.** *Soil Sci.* **68**, 391-7 (1949).—*C.A.* **44**, 3187*f*.

Radio-P was used to det. the importance of org. matter in anion exchange. The sorption and exchange of anions by free amino groups were not important phenomena in the soil org. matter used.

2921. ORTH, E. **The methylation of bleaching earths.** *Mitt. chem. Forsch.-Inst. Ind. osterr.* **3**, 31-2 (1949).—*C.A.* **43**, 7607*e*.

It was assumed that after reaction of HCl on bentonite, the Al hydroxide was converted from its water-poorer, acid-reacting form into the water-rich basic form. The exchange reactions detg. the (H + Al) value could take place on the acid but not on the basic portions. OH groups in the clay could be etherified by diazomethane.

2922. PHILLIPS, W. M. AND WAKE, W. C. **Micro method for the determination of unsaturation.** *Analyst* **74**, 306-10 (1949).—*C.A.* **43**, 7368*c*.

Cyclohexane was passed through an Al_2O_3 column under pure N_2 to remove peroxide and used as a standard. Capillaries contg. about 6 mg of material were crushed under CCl_4 in a special I_2 flask and treated with a calcd. vol. of ICl soln. from an automatic buret. KI soln. was added and the stoppered vessel placed in a dark place. The excess ICl was finally titrated with Na_2-S_2O_3 soln.

2923. TSUCHIYA, RYOKICHI. **Decolorizing action of various clays.** *J. Chem. Soc. Japan*, Pure Chem. Sect., **70**, 88-90 (1949).—*C.A.* **45**, 4419*b*.

The adsorption of methylene blue by various clays from Niigata Prefecture and by diatomaceous earth from Ishikawa Prefecture was studied with solns. contg. 0.5, 1.0, and 1.5 g/liter. Acid clays generally showed greater adsorbing power than diatomaceous earth.

2924. VAZHENIN, I. G. **Colorimetric determination of adsorbed ammonia by the phenol method.** *Pochvovedenie (Pedology)* **1949**, 359-61.—*C.A.* **44**, 975*g*.

The method was good when equiv. quantities of phenol and hypochlorite were present and the vols. of sample and reagents were kept small and const. The phenol was added first to the soln., mixed thoroughly, and the mixt. treated with hypochlorite; the diln. of the soln. for colorimetric observations was made after heating and cooling about 15 ml of soln.

2925. BERGMAN, W. E. AND FISHER, H. B. **Bentonite suspensions. Effect of sodium chloride, sodium hydroxide, quebracho, and sodium carboxymethylcellulose upon physical properties.** *Ind. Eng. Chem.* **42**, 1895-1900 (1950).—*C.A.* **45**, 849*d*.

In the absence of contamination with NaCl, treatment of aq. bentonite suspensions (oil-field *drilling muds*) with NaOH and quebracho effectively controls the viscosity and gel strength. Use of Na carboxymethylcellulose in addn. permits attainment of low water-loss values. With NaCl present, (above 10,000 p.p.m.) Na carboxymethylcellulose facilitates control.

2926. DEUEL, H.; HUBER, G., AND IBERG, R. **Organic derivatives of clay minerals.** *Helv. Chim. Acta* 33, 1229-32 (1950).—*C.A.* 45, 548*g*.

$S(C_2H_4Cl)_2$ in alc. reacted with the Na salt of bentonite clay to form 88% of the ether, which swelled in EtOH. The acid-form of the clay with propylene oxide formed 89% of the hydroxypropyl ester, which was decompd. by H_2O. The dried acid form with $SOCl_2$ formed the chloride, which reacted with many OH compds. and $(CH_2NH_2)_2$.

2927. GRACIAN Y TOUS, J. AND VIOQUE PIZARRO, A. **Separation of fatty acids by selective adsorption. II. The use of silica as adsorbent.** *Anales real soc. espan. fis. y quim.* **46B**, 375-84 (1950).—*C.A.* 46, 3300*g*.

The following binary acid pairs could be sepd. completely: caprylic-oleic, caprylic-stearic, and oleic-stearic (3.1 ratio); almost completely: caproic-caprylic, palmitic-stearic (in both cases fractions with pure components were obtained), and stearic-oleic (1:4, 1:10, 10:1); and not sepd.: valeric-caproic and palmitic-oleic.

2928. GYANI, B. P. **Adsorption of organic dyes on silica gel. I.** *J. Indian Chem. Soc., Ind. and News Ed.*, **13**, No. 1, 1-7 (1950).—*C.A.* **45**, 1837*i*.

The adsorption by silica gel of night blue, methylene blue, and crystal violet from aq. soln. was studied over a range of dye concns. About 80% of the initial dye concn. was adsorbed on the SiO_2 gel. The adsorption isotherms were similar but failed to follow either Langmuir's or the classical adsorption equation. They were more nearly similar to isotherms for vapor adsorption on solids. The extent of adsorption of dyes on silica gel probably was more closely related to their chem. nature than to their mol. size or mol. wt.

2929. HENDRICKS, S. B. AND DYAL, R. S. **Surface measurement for ethylene glycol retention of clays and its application to potassium fixation.** *Trans. 4th Intern. Congr. Soil Sci., Amsterdam* 2, 71-2; 4, 60-1 (1950).—*C.A.* **46**, 4718*c*.

Ethylene glycol retention, which gave an index of clay surfaces, was measured by weighing the solvate formed from an excess of liquid and a known amt. of clay. This surface minus the external surface as detd. by gas adsorption gave the surface available upon swelling. K clays had 40-70% as great retention of ethylene glycol as the H_2, Ca, or Na clays.

2930. HOYOS, ANGEL DE CASTRO AND LOPEZ-GONZALEZ, JUAN DE DIOS. **Adsorption of Sudan Red by activated bentonites.** *Anales edafol. y fisiol. vegetal* (Madrid) 9, 623-37 (1950).—*C.A.* **45**, 9815*f*.

Samples of a montmorillonite-beidelite and a subbentonite with and without prior activation with acid (preferably 2 *N* HCl) were dried at 110°C, immersed in benzene and slowly titrated with a 5% soln. of the dye. The activated material acquired a blue color.

2931. JORDON, J. W.; HOOK, B. J., AND FINLAYSON, C. M. **Organophilic bentonites. II. Organic liquid gels.** *J. Phys. & Colloid Chem.* 54, 1196-1208 (1950).—*C.A.* 45, 930*c*.

Various aliphatic ammonium bentonite complexes were made by cation-exchange reaction with org. ammonium salts. Gels of these materials were prepd. in several org. liquids, such as benzene, toluene, mineral spirits, alcs., ketones, and their mixts. The org. gels swelled much more than do their untreated counterparts in water. Approx. 50% coverage of the clay flakes by org. matter attached through ion-exchange reaction appeared essential for good gelation. Gels studied were dodecyl-, hexadecyl-, and octadecylammonium bentonites, and dimethyldihexadecyl-, dimethyldodecylhexadecyl-, and dimethyldioctadecylammonium bentonites.

2932. KRAVETS, T. P.; PES'KINA, A. L., AND ZHIDKOVA, Z. V. **New data on light absorption in solutions and in adsorbed layers.** *Izvest. Akad. Nauk S.S.S.R., Ser. Fiz.* 14, 493-501 (1950).—*C.A.* 45, 4139*d*.

In some dyes of the triphenylmethane series the optical d. of the soln. varied linearly with the thickness, but the straight line started with an ordinate of a magnitude detd. by the wave length. This was attributed to the formation of a film of dye on the walls of the vessel. Spectral adsorption tests were made on chromatographic adsorptions of crystal violet dye on γ-Al_2O_3, α-Al_2O_3, and TiO_2. Results showed that the curves depended (1) on the nature of the adsorbent, (2) on the nature of the remaining solvent, if not completely dried, (3) on the temp. rise, which caused loss of adsorption.

2933. RUSSELL, ALLEN S. AND COCHRAN, C. NORMAN. **Alumina surface area measurement by nitrogen, butane, propane, and stearic acid sorption.** *Ind. Eng. Chem.* 42, 1332-5 (1950).—*C.A.* 44, 8735*g*.

B.E.T. theory applied to n-butane adsorption gave reliable surface areas over the range 2.3-383 m^2/g for Al_2O_3 gels, molybdena-impregnated Al_2O_3 dehydrocyclization catalysts, and fresh and coked SiO_2-Al_2O_3 cracking catalysts. Wide differences in pore size and crystal structure occurred in these samples. Mol. areas for n-butane and propane (calcd. from adsorption) were essentially identical at 39 $A.^2$ (assuming N_2 area of 16.2 $A.^2$). Adsorption of stearic acid on nonporous aluminas yielded areas consistent with N_2 areas if the stearic acid mol. area was 17 $A.^2$.

2934. SIDOROVA, A. I. AND TERENIN, A. N. **Nature of the absorption-spectrum shift in the adsorption of aromatic amines on active clays.** *Izvdst. Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* **1950**, 152-61.—*C.A.* 44, 6721*h*.

A blue color was produced on the surface of bentonite powder, fired at 800°C and outgassed, when Ph_2NH vapor was passed over it in vacuo at about 150°C. This color did not disappear on heating, but was destroyed immediately by passing dry NH_3 under 10 mm Hg. Preliminary 2-4 hrs extn. of the clay with 30% H_2SO_4, which resulted in removal of Al, Mg, and Fe cation, without changing the specific surface area (87 m^2/g), followed by washing, drying, and outgassing, prevented the appearance of the coloring with Ph_2NH. The absorption spectrum of the blue-colored powder showed 2 max. at 675 and at 500 mμ, the 1st of which was very close to the 680-mμ absorption max. of the mol. ion (semiquinone) $(Ph_2NH)^+$ formed by the loss of one of the 2 nonbonded electrons of the N atoms in the neutral Ph_2NH.

2935. Talib-Uddeen, O. **Interlamellar adsorption of protein monolayers on pure montmorillonoid clays.** *Nature* **166**, 236-(1950).—*C.A.* **45**, 924*i*.
Flakes of montmorillonite smaller than 0.5 were dipped in a 1% suspension of gelatin (pH 2.5). The x-ray pattern showed 2 monolayers of polypeptide chains in the interlamellar space. Each monolayer was strongly adsorbed to the mineral sheet and exhibited a high degree of order. Under other concns. and pH conditions a single monolayer or four layers were formed.

2936. Vedeneeva, N. E. **The mechanism of the color reaction of benzidine with montmorillonite.** *Kolloid. Zhur.* **12**, 17-24 (1950).—*C.A.* **44**, 3799*e*.
Montmorillonite adsorbed benzidine; the product was blue and had absorption max. at 600 mμ if the clay was moist; on drying, it became pale yellow. Chrysoidine colored the clay whether moist or dry, brick-red. The dyes were attached to the O ions of the mineral surface. The face of this attachment was sufficient for adsorption because the distance between the 2 NH_2 groups was almost equal to that between 2 O ions.

2937. Vedeneeva, N. E. and Rateev, M. A. **Identification of disperse clay minerals by dye.** *Doklady Akad. Nauk S.S.S.R.* **71**, 141-4 (1950).—*C.A.* **44**, 9308c.
Systematic staining expts. with 25 different clays from young sediments were classified in three groups: I. montmorillonite type, with a max. at 605 mμ, and a second max. (for methylene blue, in the presence of KCl) at 625-630 mμ; II. hydromica type, with the max. shifted to 560-575 mμ (benzidine), and 600 mμ (KCl-methylene blue); III. kaolinite type, not stained by benzidine, with methylene blue at 560 mμ (without an effect of added KCl).

2938. Walker, G. F. **Vermiculite-organic complexes.** *Nature* **166**, 695-6 (1950).—*C.A.* **45**, 1839*e*.
Complexes of vermiculite with codeine p-phenylenediamine, benzidine- HCl, and brucine sulfate were found. The existence of van der Waals-type adsorption in vermiculite was discovered by the observation of a stage during the weathering of biotite to vermiculite where a single layer of glycerol mols. penetrated with displacement of the basal reflection from 10 to 14 A. If a small flake of vermiculite was boiled a few min. in glycerol, it acquired a black metallic coating, and the basal spacing moved to 14.06 A.

2939. Walling, Cheves. **The acid strength of surfaces.** *J. Am. Chem. Soc.* **72**, 1164-8 (1950).—*C.A.* **44**, 5181*e*.
By observation of the colors of suitable adsorbed indicators the acid strengths of the surfaces of a no. of materials were semiquantitatively detd. Colors of the adsorbed indicators are, in every case, those of the indicator, or its conjugate acid, as observed in homogeneous soln. Acid strengths appear independent of the indicator used. Although Al_2O_3 and pure SiO_2 appear to have neutral surfaces, SiO_2-Al_2O_3 and SiO_2-MgO are strongly acid.

2940. Bloch, J. M. and Gommery, G. **Relation between the thixotropy of sodium bentonite suspensions under the effect of heat and alcohol, and the molecular adsorption of sodium hydroxide by this clay.** *Bull. soc. chim. France* **1951**, 563-5.—*C.A.* **46**, 2878*e*.
Thixotropic gelation increased with temp., especially above 70°C, but the quantity of NaOH adsorbed remained practically const. When EtOH was added, the gelation passed through a max. at 30% concn., but the amt. of adsorbed NaOH was not affected by the gelation.

2941. Deuel, H. and Huber, G. **Organic derivs. of clay minerals. II. Alkoxy, alkyl, and aryl derivs. of montmorillonite.** *Helv. Chim. Acta* **34**, 1697-1701 (1951).—*C.A.* **46**, 6585*i*.
The chloride of Wyoming bentonite was prepd. by refluxing 20 g of the Na salt with 15 ml $SOCl_2$ in 70 ml $CHCl_3$, washing with $CHCl_3$, and vacuum-drying at 70°C. The chloride yielded alkoxy derivs, of montmorillonite on refluxing in MeOH or EtOH, the Et deriv. on refluxing in Et_2O with EtMgI, and the Ph deriv. on refluxing in C_6H_6 with slow addn. of $AlCl_3$. All the derivs. were vacuum-dried at 70°C. The exchange capacity of the derivs. was 28-57% of the Na salt.

2942. Freĭdlin, L. Kh. and Levit, A. M. **Determination of the relative adsorption coefficients of water and of formic acid on silica gel.** *Izvest. Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* **1951**, 799-805.—*C.A.* **46**, 3826g.
HCO_2H in aq. soln., at mol. concns. *M* from 10 to 100%, was passed over dry silica gel (4.5 g, 10 ml, length 3 cm), at feed rates varying with *M*. At 285°C, the gas consisted entirely of CO. The ratio of the relative adsorption coeffs. of H_2O and of HCO_2H on the catalyst were calcd. Promotion of the silica gel with K_2O increased the adsorability of the acid. Igniting lowered the adsorbability of HCO_2H even more strongly than of H_2O. The catalyst was more active, the smaller the adsorability of H_2O as compared with HCO_2H.

2943. Funakubo, Eiichi and Matsumoto, Yutaro. **The theory of chromatography and its application. III. The method of determination of adsorption power of alumina and its activation conditions.** *J. Chem. Soc. Japan*, Pure Chem. Sect., 72, 484-7 (1951).—*C.A.* 46, 5407b.
The adsorption of anthracene, anthraquinone, and carbazole by alumina (ignited at various temps.) was studied. For the reactivation of alumina, the ignition method was found to be superior to the washing method. The adsorption power of alumina varied considerably with the time between the process of activation and the actual use.

2944. KARYAKIN, A. V. **Quenching of the fluorescence of acridine compounds in an adsorbed state by oxygen.** *Izvest. Akad. Nauk S.S.S.R., Ser. Fiz.* **15**, 556-64 (1951).—*C.A.* **46**, 8971*h*.

Quenching of the fluorescence of acridine compds. adsorbed on SiO_2 was not observed on acridines, acridone, 1(and 2)-aminoacridine; 10, 10′-dimethyl 9,9′-biacridan, 10,10′-dimethyl-$\Delta^{9,9'}$-biacridan, and lucigenin bromide (10,10′-dimethyl-9,9′-biacridinium dibromide). The quenching was strong in acridan, 9-iminoacridan, 3,6-diaminoacridine, and 3-aminoacridine. These latter compds. also showed considerable afterglow, and in these mols. the singlet and triplet levels were close together, so that paramagnetic O_2 could transfer the energy from the excited singlet to the metastable triplet state.

2945. KOIZUMI, MASAO AND IMAMURA, MASASHI. **Effect of light on the adsorption equilibrium of dyes.** *J. Chem. Soc. Japan*, Pure Chem. Sect. **72**, 323-6 (1951).—*C.A.* **46**, 739*e*.

Studies were made on silica gel in aq. solns. Rhodamine 6G irradiation caused a slight decrease of adsorption. The excited dye mols. produced by irradiation participated in the adsorption and caused a shift of the equilibrium.

2946. KRASIL'NIKOV, K. G. AND KISELEV, A. V. **Absolute adsorption isotherms from solution.** *Doklady Akad. Nauk S.S.S.R.* **77**, 1047-50 (1951).—*C.A.* **45**, 8847c.

Adsorption isotherms were detd. for solns. of PhOH in C_7H_{16} at 20° and 40°C on the highly coarse silica gel "E", coarse silica gel, a relatively fine-pore silica gel and nonporous $BaSO_4$. Total pore vol. in cc./g, most frequent pore diam. in A., and surface area in m^2/g were, resp.: 1.72, 200, 320; 0.92, 90, 350; 0.53, 30, 600; —, —, 9.7. The porosity of the silica gel showed no effect on the adsorption up to a pore size of 30 A. Adsorption of PhOH from soln. in C_7H_{16} could be used to det. the unknown surface area of a silica gel.

2947. MERRILL, REYNOLD C. AND SPENCER, ROBERT W. **Some quaternary ammonium silicates.** *J. Phys. & Colloid Chem.* **55**, 187-95 (1951).—*C.A.* **45**, 6115a.

The solubilities of micronized silica gel in strong org. bases, particularly quarternary ammonium hydroxides, were reported. The soly. of silica gel in quaternary ammonium hydroxides was about the same as in K or Na hydroxides at equiv. concns.

2948. MILLER, JOHN G.; HEINEMANN, HEINZ, AND MCCARTER, W. S. W. **The effect of solvent on the adsorption of liquids by bauxite and attapulgus clay.** *J. Phys. & Colloid Chem.* **55**, 515-23 (1951).—*C.A.* **45**, 6005*c*.

The adsorption of a large no. of liquids on activated bauxite and attapulgus clay was measured for binary solns. The results were listed in terms of the Freundlich isotherms and were classified into 3 groups: (1) the solvent adsorption was negligible; (2) the solvent adsorption was considerable but unaffected by the adsorption of the solute; (3) the adsorption of the solvent was high and affected the solute adsorption. A large part of the CCl_4 is held by attraction to the adsorbed solute mol.

2949. SCHONBERG, ALEXANDER AND ASKER, WAFIA. **Some adsorption colors and their significance for tautomeric and thermochromic effects.** *Science* **113**, 56-7 (1951).—*C.A.* **45**, 4995i.

When a piece of activated Al_2O_3 was added to a cold colorless soln. of β-dinaphthaspiropyran in xylene, the surface of the Al_2O_3 became bluish-green immediately. The adsorbed compd. could be eluted with MeOH. In C_6H_6, 1,3-diketohydrindene was colorless, but when adsorbed became violet.

2950. SCHROEDER, W. A. **Hydrogen bonding and relative adsorption affinities on silicic acid of certain derivatives of diphenylamine and *N*-ethylaniline.** *J. Am. Chem. Soc.* **73**, 1122-7 (1951).—*C.A.* **45**, 6004*h*.

The unexpected relative adsorption affinities that were shown by nitro and nitroso derivs. of Ph_2NH and PhNHEt on silicic acid columns were correlated with the strength of the H-bonds between the adsorbed compd. and the adsorbent. The order of decreasing adsorption affinity of derivs. of diphenylamine on silicic acid-celite were given.

2951. SLABAUGH, W. H. AND CULBERTSON, J. L. **The effect of certain reagents on the properties of bentonite colloids. II. Organic amines.** *J. Phys. & Colloid Chem.* **55**, 1131-9 (1951).—*C.A.* **46**, 318*e*.

Viscometric and electrophoretic analysis of reaction systems between hydrogen bentonite and org. amines indicated that the reactivity of the bentonite was stoichiometric. Monobasic amines produced dehydration of the clay micelle in proportion to their hydrophobic nature. Dibasic amines produced a type of cross linkage between clay micelles.

2952. TEWARI, SWARUP N. AND GHOSH, SATYESHEWAR. **Adsorption on hydrated chromium oxide and its amphoteric nature.** *Kolloid-Z.* **124**, 31-6 (1951).—*C.A.* **46**, 2873c.

Adsorption of methylene blue, malachite green, and Orange II from solns. of different concns. was detd. on hydrated Cr oxides, pptd. with (a) 10% excess, (b) an equiv., and (c) 10% deficiency of alkali. Adsorption followed the Freundlich equation, and fell off with age, also with increasing temp. With basic dyes adsorption was greatest on a and $a > c > b$, whereas with the acid dye the order was $b > c > a$.

2953. BARSHAD, ISAAC. **Factors affecting the interlayer expansion of vermiculite and montmorillonite with organic substances.** *Soil Sci. Soc. Am., Proc.* **16**, 176-82 (1952).—*C.A.* **46**, 8303*f*.

The extent of interlayer expansion was detd. by the size, charge, and total amt. of the interlayer cations and by the magnitude of the dipole moment and the dielec. const. of the immersion liquid.

2954. Deuel, H.; Huber, G., and Günthard, Hs. H. **Organic derivatives of clay minerals. III. Phenyl-montmorillonite.** *Helv. Chim. Acta* 35, 1799-1802 (1952) (in German).—*C.A.* 47, 452b.
$AlCl_3$ (0.6-3 g) was added to 10 g of the chloride of Wyoming bentonite in 50 ml C_6H_6 at 70°C. The product after washing with H_2O was purified by treatment with a mixt. of Amberlite IR-120 in the H-form and Amberlite IRA-400 in the OH-form. After vacuum drying at 70°C, the product was the phenyl deriv. of the bentonite.

2955. Dyal, R. S. and Hendricks, S. B. **Formation of mixed layer minerals by potassium fixation in montmorillonite.** *Soil Sci. Soc. Am., Proc.* 16, 45-8 (1952).—*C.A.* 46, 5239*i*.
The amt. of ethylene glycol retained by a clay was used as an index of interlayer swelling. K montmorillonites after drying at 100°C showed markedly lower glycol retention than did Ca and H montmorillonites.

2956. Hellström, Nils. **Comparative adsorption experiments. II. Some hydrocarbons in heptane with silica gel.** *Kungl. Lantbrukshögskol. Ann.* 19, 109-12 (1952) (in English).—*C.A.* 47, 7287*d*.
After prepn. and heating 1 hr at 200°C various different steps were taken before the silica gel was immersed in heptane. The adsorption capacity was tested for naphthalene, biphenyl, phenanthrene, and retene. The ratio sequence for naphthalene, phenanthrene, and retene (1/0.30/0.18) was in general agreement with the same ratio as found for activated charcoals. The eventual satn. capacity of the various prepns. was the same in spite of differences in the water content.

2957. Iler, R. K. **Association between polysilicic acid and polar organic compounds.** *J. Phys. Chem.* 56, 673-7 (1952).—*C.A.* 46, 8933*c*.
With $MeO(C_2H_4O)_4Me$ as a standard, detns. were made by titrating a standard silica sol. contg. the org. compd. with a standard gelatin soln. until a definite turbidity was noted. The effect was measured for alcs., glycols, ketones, amides, and amines and was related to H-bonding activity.

2958. Imamura, Masashi; Kato, Shunji, and Koizumi, Masao. **Influence of light on the adsorption equilibrium of dyes. III. Relative measurement.** *J. Chem. Soc. Japan*, Pure Chem. Sect. 73, 770-3 (1952).—*C.A.* 47, 5121h.
The amt. of adsorption slightly decreased by light irradiation in the adsorption of an aq. soln. of Rhodamine 6G by silica gel.

2959. Karyakin, A. V. **Absorption spectra of acridine derivatives in solution and in the adsorbed state.** *Zhur. Fiz. Khim.* 26, 96-102 (1952).—*C.A.* 46, 9983*e*.
Absorption spectra (between 230 and 850 mμ) in EtOH solns. (10^{-4} mole/liter) and reflection spectra of acridine derivs. adsorbed from the vapor on silica gel (between 330 and 1000 mμ) were recorded and tabulated. The compds. studied were acridine, acridone, acridan, 1-, 2-, 3-, and 9-aminoacridine, 3,6-diaminoacridine, dimethylbiacridan, dimethylbiacridene, dimethylbiacridene oxide, and luicigenin bromide. The absorption max. above 330 mμ generally had the same position in the adsorbed state as in soln. The adsorbates however showed new absorption max. in the visible.

2960. Koizumi, Masao; Imamura, Masashi, and Watanabe, Ai. **Effect of light on the adsorption equilibrium of dyes. I. Qualitative experiments on some dyes. II. Adsorption isotherms for Rhodamine 6G.** *J. Chem. Soc. Japan, Pure Chem. Sect.* 73, 802-5; 865-8 (1952).—*C.A.* 47, 6143e.
Adsorption of basic dyes by silica gel and of acidic dyes by alumina was studied. The amt. of Rhodamine 6G adsorbed by silica gel decreased slightly by irradiation. The reaction isotherms of Rhodamine 6G and Rhodamine B by silica gel were studied in darkness and under the irradiation of light. The adsorption decreased with irradiation only in the first case.

2961. Martin, Vivaldi Juan L. and Hendricks, Sterling B. **Reactivity of the hydrogen ions of clays in nonpolar solutions. I. Action of diazomethane.** *Anales edafol. y fisiol. vegetal* (Madrid) 11, 601-29 (1952).—*C.A.* 47, 5211*i*.
Acid clay minerals of the kaolinite, montmorillonite, and illite groups reacted with diazomethane in anhyd. ether to form methoxyl compds. About 50% of the exchangeable H ions in illite and kaolinite esterify rapidly, but the remaining H ions reacted very slowly. In hydrogen montmorillonite, dried at 300°C, only 10% of the exchangeable H ions reacted rapidly without alteration of the basal spacing. The methylation of the Ca and Na salts of montmorillonite indicated that these salts, formed at a pH of 7, contain about 30 meq./100 g H ions capable of reacting and without causing polymer formation.

2962. Slabaugh, W. H. **Stoichiometry of complex silicates.** *Trans. Kansas Acad. Sci.* 55, 484-8 (1952).—*C.A.* 47, 5211*f*.
The ionic exchange of bentonite (montmorillonite) was studied with org. agents; the elementary reactions of Na- and H-bentonite with RNH_3Cl and RNH_2 result in RNH_3-clays. The direct reaction of Na-bentonite with alkyl halides was not successful, but much better was that with acyl halide, to form RCO-clays. The extent of the formation of "mixed anhydrides" with clay was greatly affected by the nature of the cations in the base-exchange position of the clay crystal.

2963. Spencer, W. F. and Gieseking, J. E. **Organic derivatives of montmorillonite.** *J. Phys. Chem.* 56, 751-3 (1952).—*C.A.* 46, 8928h.
Sodium Wyoming bentonite was treated with dil. HCl and product (14 g) treated with 150 ml of thionyl chloride. The resulting chloride was suspended in abs. ether, and PhMgBr added. The phenyl deriv. so obtained had a higher C content and lower cation exchange capacity than did H-montmorillonite. X-ray data indicated that the phenyl groups were in the crystal lattice in a regular manner between the planes.

2964. Stevenson, F. J.; Marks, Joy D.; Varner, J. E., and Martin, W. P. **Electrophoretic and chromatographic investigations of clay-adsorbed organic colloids. I. Preliminary investigation.** *Soil Sci. Soc. Am., Proc.* **16**, 69-73 (1952).—*C.A.* **46**, 5237f.

Aspartic and glutamic acids, glycine, serine, threonine, alanine, valine, leucine, galacturonic acid, and xylose were identified in the hydrolyzate of the colloids by paper chromatography. Traces of ribose and glucurone were detected. An unidentified spot was found which was probably a mixt. of mannose, arabinose, glucose, and galactose.

2965. Tewari, Swarup Narain. **Adsorption of dyes on hydrated aluminum oxide. Investigation of the amphoteric nature.** *Kolloid-Z.* **128**, 19-22 (1952).—*C.A.* **47**, 21*a*.

Several specimens of hydrated Al_2O_3 adsorbed more acid color (Orange II) than basic (methylene blue). The total and relative capacities decreased upon warming and aging and depended upon the method of prepg. the oxide.

II-4. Non-Carbon Adsorbents With Inorganic Solutions

2966. Cernescu, N. **The exchange capacity and the exchangeable cations of soils. Methods.** *Inst. geol. României, Compt. rend., Studii tech. econ., Ser. C,* **1939**, No. 5, 3-61.—*C.A.* **38**, 2151^4.

Satn. of the soil with NH_4 (by washing with NH_4OAc of pH 7) after destruction of the carbonate with acetic acid gave values of the exchange capacity which corresponded to the degree of satn. of soils in equil. with the $CaCO_3$. By percolation with a normal soln. of K acetate of pH 8.3, H in the complex was replaced by K.

2967. Cernescu, N. **The exchange capacity of soils in relation to the clay and humus content.** *Inst. geol. României, Compt. rend., Studii tech. econ., Ser. C,* **1939**, No. 6, 3-46.—*C.A.* **38**, 2151^6.

The extent to which clay and humus took part in the exchange capacity was established by detn. of the exchange capacity before and after destruction of org. matter by H_2O_2. Different soil types were investigated and agreement was found between calcd. and exptl. values. In chernozem over 40% of the exchange capacity was due to the humus, in degraded chernozem 25-30%, in rust-colored forest soils only 18-22%.

2968. Marshall, C. E. **Use of zeolitic membrane electrodes.** *J. Phys. Chem.* **43**, 1155-64 (1939).—*C.A.* **34**, 1539^8.

Exptl. data on the use of zeolitic membrane electrodes to measure cationic activity were detd. Details of the prepn. of electrodes, app., and technique were described. Chabazite and apophyllite crystals were used and measurements made using both uni- and bivalent cations.

2969. Bower, C. A. and Truog, Emil. **Determination of base-exchange capacity of soils and other materials.** *Ind. Eng. Chem., Anal. Ed.* **12**, 411-13 (1940).—*C.A.* **34**, 5984^6.

Base-exchange capacity was detd. in soils and other materials by treating a 1-g of sample with 5 sep. 50-cc. portions of *N* $MnCl_2$ soln. A centrifuge was used to aid the sepn. The excess of $MnCl_2$ was removed by 5 washings with 95% alc. The Mn-satd. soil thus formed was treated with 5 portions of *N* NH_4 acetate to remove the exchangeable Mn. An aliquot of this soln. was used to detn. Mn by oxidation with Na paraperiodate and comparison with standard $KMnO_4$ soln.

2970. Colon, Angel Alberto. **The effect of temperature upon the base-exchange capacity of clays.** *Bol. official asoc. quim. Puerto Rico* **1**, No. 4, 26-30 (1940) (in English).—*C.A.* **37**, 6065^6.

The replaceable K of K-clay decreased in 46 days from 40.8 milliequiv. to 31.93 and 26.9 milliequiv. at 25° and 100°C, resp. The total replaceable bases of the K clay increased from 78.37 to 96.53 and 88.23 milliequiv. at 25° and 100°C, resp. Also in Ca clay the amt. of replaceable Ca decreased with increasing temp. and prolonged heating of the sample; the total exchangeable bases showed a slight decrease upon prolonged heating.

2971. Eitel, W. and Radcqewski, O. E. **Characterization of the mineral clay montmorillonite by ultramicroscope.** *Naturwissenschaften* **28**, 397-9 (1940).—*C.A.* **35**, 3195^7.

Wyoming montmorillonite (natural bentonite) sepd. by sedimentation to give a fraction of smaller than 0.5 μ diameter particle size was studied with 20 to 30,000 magnification. Peculiar ragged skin-like aggregations were found in the microscopic picture after dispersion, with 0.01 *N* NH_4OH soln. These skins were true constituents of a two-dimensional gel.

2972. Filosofov, B. I. **The effect of drying soil on the determination of exchange aluminum.** *Izvestiya Azerbaidzhan. Filial. Akad. Nauk* **1940**, No. 5, 75-7.—*C.A.* **37**, 6390^2.

Air-dry samples could be used for the analysis.

2973. Filosofov, B. I. **Determination of exchange aluminum of the soil in salt extracts.** *Izvestiya Azerbaidzhan. Filial. Akad. Nauk* **1940**, No. 5, 77-8.—*C.A.* **37**, 6390^2.

In detns. of exchange Al in the $BaCl_2$ ext. of the soil, Ba must be removed preliminarily as $BaSO_4$. A part of the Al was co-pptd. with $BaSO_4$. This loss of Al was avoided by extn. of the soil with KCl instead of $BaCl_2$.

2974. Grim, R. E. **The significance of pH in the control of the properties of clay.** *Illinois State Geol. Survey, Bull. No.* **68**, 268-72 (1940) (Pub. 1944).—*C.A.* **39**, 2171^4.

Available data showed that Na^+ and H^+ changed the properties of clay in opposite directions and to a greater degree than other cations such as Mg and Ca. Na^+ or H^+ need not occupy all the exchange positions before they greatly affect phys. properties. The effect was greatest for clays that contained montmorillonite. Ca was the exchangeable ion in the natural clays.

2975. Mitra, R. P.; Mukherjee, S. K., and Bagchi, S. N. **The nature of the reactions responsible for soil acidity. VI. The variability of the total neutralizable acid of colloidal solutions of hydrogen clays.** *Indian J. Agr. Sci.* **10**, 303-16 (1940).—*C.A.* **35**, 555⁴.

The titration curves of colloidal solns. of H-clays showed definite inflection points and minima. The total neutralizable acid of a H-clay sol at these points and also at pH 7.0 was a variable quantity. The total acidities at the inflection point and at pH 7.0 which reacted with different bases were in the order $Ca(OH)_2 > Ba(OH)_2 > NaOH$. $Ca(OH)_2$ reacted with the sol more strongly than baryta.

2976. Mitra, R. P. **The nature of the reactions responsible for soil acidity. VII. The electrochemical properties of colloidal solutions of hydrogen clays.** *Indian J. Agr. Sci.* **10**, 317-43 (1940).—*C.A.* **35**, 555⁶.

The free and total acids of H-clay sols were considerably greater than those of their ultrafiltrates. The actual aq. cond. of the sol was often less than that due to its free H ions whose concn. had been calcd. from the observed pH of the sol. When a neutral salt was added to a H-clay sol, its H-ion activity showed a marked increase.

2977. Mitra, R. P. and Mitra, A. K. **The base-binding capacities of hydrogen clays as determined by different methods.** *Indian J. Agr. Sci.* **10**, 344-51 (1940).—*C.A.* **35**, 554⁵.

The total acidities of colloidal solns. of H-clays calcd. from their electrometric titration curves were compared with their base-binding capacities. There was a marked variability of the total neutralizable acid. Titration with baryta in the presence of N $BaCl_2$ or Ba acetate yielded the highest total acid.

2978. Saidel, Theodor. **New results from investigations on the solution laws as applied to the exchange of soil cations.** *Bodenkunde u. Pflanzenernähr.* **21/22**, 601-21 (1940).—*C.A.* **37**, 6793⁸.

Exchange reactions in soils were discussed theoretically and mathematically. Exchange reactions might be considered as a special case in the realm of heterogeneous reaction systems with incomplete equilibria.

2979. Staĭkov, Ts. **The influence of the degree of acidity on the sorption of calcium and magnesium in soils.** *Bodenkunde u. Pflanzenernähr.* **21/22**, 581-601 (1940).—*C.A.* **37**, 6794⁹.

In the soils studied, the exchangeability of soil Mg increased as the pH increased, relative to that of soil Ca. The exchangeability of Mg differed from that of Ca much more in the peat soils than in the mineral soils. Under the conditions of the tests pure exchange sorption of Mg was observed up to pH 9.3 in peat soils and up to pH 7.4 in mineral soils. In the latter soils pptn. sorption of Mg as the hydroxide was noticeable above pH 7.4 and very apparent above pH 8. The difference between the exchangeability of Mg and Ca increased somewhat in the presence of NaCl. When NH_4Cl was present, it increased strongly.

2980. Stelling, Otto. **The so-called activated bleaching earths.** *Tekn. Samfund. Handl.* **1940**, 109-30.—*C.A.* **38**, 2797².

A bleaching earth was obtained by activating a Swedish clay contg. montmorillonite. The activation process could not be considered to be just an exchange of bases by substitution of metal ions with H ions. The bleaching action attained a max. with the increase of the time for treatment with acid. The higher the concn. of the acid, the more readily was the max. attained. The bleaching action decreased with increased moisture content and grain size.

2981. Yarusov, S. S. **Molecular adsorption of electrolytes on soils.** *Chemisation Socialistic Agr. (U.S.R.R.)* **1940**, No. 6, 49-57.—*C.A.* **37**, 990⁹.

Molecular adsorption of LiCl, NaCl, KCl, NH_4Cl, $CaCl_2$, $SrCl_2$, $BaCl_2$, KBr, and KI from a aq.-alcohol solutions and from their aq. solutions on chernozem soils was studied. Up to 5.7 molecular equivalents of salt per 100 g was adsorbed from aqueous EtOH and up to 3.6 molecular equivalents from aqueous MeOH. A negative adsorption of anions was observed from aqueous solutions of salts in *N* concentration. Equivalent amounts of Ba^{++} and Cl^- were adsorbed from $BaCl_2$ in alcoholic solutions.

2982. Amiot, Raymond. **A study of the adsorption of various cations by a polarographic method.** *Compt. rend.* **212**, 892-3 (1941).—*C.A.* **38**, 5447⁵.

The adsorption of Ba, Cu, Ni and Al ions by a bentonite suspension was studied. The metals were added as the chlorides. The flocculated bentonite was sepd. by centrifugation and the concn. of the metal ion left in soln. was detd. polarographically. A methyl ether of cellulose (tylose) was used to suppress certain disturbing influences. Dissolved O_2 had to be removed only for the measurements of the dil. Cu solns.

2983. Damsgaard-Sorensen, P. **Cation exchange in the soil.** *Kem. Maanedsblad nord. Handelsbl. kem. Ind.* **22**, 65-8 (1941).—*C.A.* **37**, 6389⁹.

At equil. there was a distinct retardation of the ion exchange reaction, which evidently caused a variation of the equil. const. A cation was bound more strongly to the ion exchanger, the lower its ratio to the total amt. of cations. A practical method of calcn. and detn. was described.

2984. Damsgaard-Sorensen, P. **Exchange of cations in soil. III. Contribution to the general theory of cation exchange and its use in the determination of the exchangeable potassium in soil.** *Tids. Planteavl* **46**, 1-150 (1941).—*C.A.* **37**, 5814⁹.

The content of a soil in exchangeable K ions could be considered as a measure of its "available" K_2O content; the water-sol. K_2O was calcd. with the exchangeable K_2O. The simple mass-action equation held for ion exchange only if the atom groups producing the exchange were univalent, identical in structure and orientation with the environment, and did not react one upon the other.

2985. GAPON, E. N. AND VOSHCHINSKAYA, M. A. **The oxyaluminum of podsolized soils as an exchangeable cation.** *Chemisation Socialistic Agr. (U.S.S.R.)* **10**, No. 2, 37-42 (1941).—*C.A.* **37**, 489^{7}.

A 0.1 *N* KCl extract of a podzol (ratio of soil to KCl liquid being 1:2.25) showed that the exchange acidity in terms of milliequivalents (m.e.) per 100 g of soil was equal to the m.e. of Al. When the extract was treated with $(NH_4)_2SO_4$ the oxysulfate of Al, $(Al_2O_3H)_2SO_4$, formed. In another precipitation of $(Al_2O_3H)_2SO_4$ the precipitate was allowed to stand for 2 to 3 days, the salt washed and dried, and then treated with sufficient $BaCl_2$ solution to precipitate the sulfate. Ten percent of the Al existed either as Al^{+++} or as colloidal Al_2O_3. The rest of the Al in podzols was in the form of the oxyaluminum cation, $Al_2O_3H^+$, which may be exchanged for any ion.

2986. GINZBURG, I. I. AND MARGOLINA, N. S. **The sorption of Ni by silicates from dilute solutions in relation to the phenomena of hydrolytic decomposition.** *Bull. acad. sci. U.R.S.S., Sér. geol.* **1941**, No. 3, 159-62.—*C.A.* **38**, 1931^{8}.

The exchange adsorption of Ni by penninite, montmorillonite and nontronite took place differently in dil. than in concd. solns. The silicates were hydrolyzed, and the adsorption paralleled the hydrolysis. More base was displaced than corresponded to the amt. of adsorbed Ni. Mg was more strongly displaced than Ca.

2987. GRAHAME, DAVID C. **Properties of the electrical double layer at a mercury surface. I. Methods of measurement and interpretation of results.** *J. Am. Chem. Soc.* **63**, 1207-15 (1941).—*C.A.* **35**, 4267^{8}.

Accurate values of the differential capacity of the double layer were measured. Equations were given whereby the static capacity and the surface charge could be calcd. from several independent kinds of data. Results of such measurements were given for a no. of solns. It was shown that an incipient pptn. of certain anions gave rise to large values of the capacity of the double layer under appropriate conditions.

2988. HAUSER, E. A. AND LE BEAU, D. S. **Colloidal clays. II.** *J. Phys. Chem.* **45**, 54-65 (1941).—*C.A.* **35**, 1290^{6}.

The cataphoretic velocity of purified, colloidal, monodisperse fractions of bentonite increased with decreasing particle size. With const. particle size it decreased with increasing concn., the drop being most pronounced with the smallest particles. In extreme dilns. (up to 0.5%) the cataphoretic velocity remained const. for a given particle size. The apparent sp. gr. of bentonite at low concns. was smaller than that of dry bentonite; at high concns. it was greater.

2989. HELLER, WILFRIED. **Reversible aggregations of colloidal particles. I. Centrifugal experiments on thixotropic iron oxide sols.** *J. Phys. Chem.* **45**, 1203-37 (1941).—*C.A.* **36**, 311^{8}.

Two dialyzed Fe_2O_3 sols were treated with sufficient NaCl to make them thixotropic. The systems were allowed to age for a week before they were centrifuged. When a thixotropic sol was centrifuged, it sepd. into an upper dil. sol phase and a lower concd. phase which was a thixotropic gel. The kinetics of this sepn. and the effect of aging, electrolyte concn., addn. of various org. substances, and of weak mech. vibrations upon the system were studied.

2990. HURD, CHARLES B. AND THOMPSON, LOUIS W., JR. **Silicic acid gels. XIII. Some examples of re-gelation.** *J. Phys. Chem.* 45,,1263-7 (1941).—*C.A.* **36**, 312^{3}.

Silica gels (contg. 3.5% SiO_2) were broken into lumps and beaten into fine particles in an equal vol. of distd. H_2O. Tabulated data showed the no. of times of re-gelation *vs.* pH of original gel of each mixt. Acidic mixts. (pH = 5.1) reset 8 times whereas basic mixts. did not re-gel at all.

2991. MARSHALL, C. E. AND BERGMAN, W. E. **The electrochemical properties of mineral membranes. I. The estimation of potassium-ion activities.** *J. Am. Chem. Soc.* **63**, 1911-6 (1941).—*C.A.* **35**, 5772^{4}.

Data were given for the charge on the following membranes (expressed as an ionic activity) as related to the temp. of drying: Ca-, H- and K bentonite; for the membrane (bentonite) potentials with the following salt solns.: $CaCl_2$ and $MgSO_4$; and for the effect of pH and large anions (acid phthalate, p-toluenesulfonic acid and p-nitrophenol). The results indicated that K^+ activities could be detd. in the absence of other univalent cations with a precision within 5% at pH values above 4. A high degree of reproducibility was possible with com. Wyoming bentonite from which all particles larger than 200 mμ in equiv. spherical diam. were removed by supercentrifuging.

2992. MEHLICH, ADOLF. **Base unsaturation and pH in relation to soil type.** *Soil Sci. Soc. Am. Proc.* 6, 150-6 (1941).—*C.A.* **37**, 491^{5}.

The base unsatn.pH relationship of base-exchange colloids exhibited a const. and specific characteristic for each mineral, except montmorillonite and hydrous mica, which appeared to be very similar. This relationship of the soils examd. was similar to the principal characteristics of the known base-exchange materials. The base unsatn.-pH relationship was not influenced by base-exchange capacity or buffer activity.

2993. PEECH, MICHAEL. **Determination of exchangeable bases in soils.** *Ind. Eng. Chem., Anal. Ed.* **13**, No. 6, 436-41 (1941).—*C.A.* **35**, 4891^{6}.

The bases were extd. with 1 *N* $AcONH_4$ soln. Magnesium was pptd. with 8-hydroxyquiniline, potassium as cobaltinitrite which was subsequently detd. colorimetrically with a nitroso-R-salt. Sodium was not detd. The data given showed satisfactory recoveries of added quantities of the various bases. Exchangeable hydrogen was computed by subtracting the sum of the exchangeable bases from the base-exchange capacity. Base-exchange capacity was detd. by distn. of NH_3 absorbed by the soil.

2994. VINOKUROV, M. A. **Exchange capacity of the mineral and organic complexes in the soil.** *Pedology (U.S.S.R.)* 1941, No. 5, 33-43.—*C.A.* 37, 4841^7.

Soil satd. with Na was oxidized with boiling H_2O_2 and the exchange capacity of the mineral fraction residue detd. by $BaCl_2$ treatment. Na concn. in the oxidized soln. was a measure of the exchange capacity of the org. fraction. Exchange capacity of a soil varied with the mineral and org. colloid contents at any point in the profile.

2995. BLACK, C. A. **Phosphate fixation by kaolinite and other clays as affected by pH, phosphate concentration and time of contact.** *Soil Sci. Soc. Am., Proc.* 7, 123-33 (1942). (Pub. 1943).—*C.A.* 37, 5538^2.

Finely ground kaolinite retained a max. of phosphate at pH 3.5-4.0. The fixation was apparently mainly an OH-ion replacement. Two other kaolinitic clays showed no max. in fixation at pH 3-4 from a soln. contg. 1 p. p. m. P. In dil. solns. fixation due to Al showed a max. at pH 5-7. This fixation was covered up by the much greater fixation caused by OH replacement in the concd. solns. over the longer period of contact.

2996. BOUTARIC, AUGUSTIN AND BERTHIER, PAULETTE. **The additive law of magnetic properties in the mixtures where the phenomena of adsorption occur.** *Compt. rend.* 215, 62-4 (1942).—*C.A.* 38, 6144^3.

A sol of $Fe(OH)_3$ and a soln . of $FeCl_3$ were mixed in various proportions with a suspension of bentonite which served as an adsorbent. The magnetic susceptibilities of the mixts. were measured. Apparently, adsorption by the bentonite increased the coeff. of magnetization of the fixed substance.

2997. CHATTERJEE, B. AND PAUL, M. **Interaction between hydrogen clays and neutral salts. II. Role of aluminum ions in relation to free and total acids of hydrogen clays.** *Indian J. Agr. Sci.* 12, 113-20 (1942).—*C.A.* 39, 4420^5.

Both Al and H ions were present on the surface of the H-clay particle. Treatment with a neutral salt caused the displacement of some of these ions into the intermicellary liquid, while the remainder continued to be closely assocd. with the clay particle. The proportion of ions remaining assocd. with the clay depended on the displacing power of the cation used.

2998. CHATTERJEE, B. AND SEN, A. **Variation in the electrochemical properties of H-clay sols with temperature.** *J. Indian Chem. Soc.* 19, 189 (1942).—*C.A.* 38, 3182^9.

The H-clay sol was prepd. from the entire clay fractions of a nonlateritic calcareous soil. Free acidity increased from 1.1×10^5 N to 7.9×10^5 N with variations of 1-50 C, resp. Total acidity increased from 200×10^{5}N to 252×10^5N, degree of dissocn. increased from 1 to 50%, and pH at inflection decreased from 9.15 to 7.75 under the same change of temp.

2999. COLEMAN, R. **The adsorption of phosphate by kaolinitic and montmorillonitic clays.** *Soil Sci. Soc. Am., Proc.* 7, 134-8 (1942) (Pub. 1943).—*C.A.* 37, 5538^7.

The H- and NH_4-montmorillonitic clays adsorbed more PO_4 from phosphate solns. at pH 7 and 9.5 than did the corresponding kaolinitic clay. The H- and NH_4-kaolinitic clays adsorbed more PO_4 from the phosphate solns. at pH 3. In the case of montmorillonitic clay PO_4 adsorption was not greatly influenced by changes in reaction, while in the case of kaolinitic clay changes in reaction greatly influenced phosphate adsorption. The fixation by both these clays was due largely to the free Fe and Al oxides in the clays.

3000. DOBROWSKY, ALFRED. **Silica gel as a new adsorbent for the electrolyte in dry cells.** *Z. Elektrochem.* 48, 467-9 (1942).—*C.A.* 37, 5662^9.

Silica gel contg. 10% SiO_2 offered advantages over customary gels (from flour) or bentonite. It showed no syneresis and was not thixotropic; it was sufficiently viscous, indifferent to admixts. and stable in the absence of air. The elec. properties of dry cells prepd. with silica gel meet standard specifications.

3001. GADDIS, SHIRLEY. **New precipitant for Group II ions.** *J. Chem. Education* 19, 327-8 (1942).—*C.A.* 36, 5107^2.

A resin of the amine-formaldehyde condensation type, known commercially as amberlite IR-4, absorbed 12% of its wt of H_2S when left in contact with the gas for several days. The green product was fairly stable and could be used instead of H_2S gas. In elementary classes, 0.4 g of the product was recommended for 2-mg portions of one or more members of the Cu-Sn group. The procedure with respect to Cu imparted a deep-orange color to the ammoniacal soln., so that a supplementary test for Cu was necessary. The resin also absorbed H_3PO_4; this simplified the examn. of Group III.

3002. KELLEY, CARL W. AND THOMAS, R. P. **A method of estimating the organic exchange complex of a soil.** *Soil Sci. Soc. Am. Proc.* 7, 201-6 (1942).—*C.A.* 37, 6074^4.

The org. matter of 10 Maryland soils was detd. by 9 methods and the total exchange capacity was estd. for each soil before and after treatment with H_2O_2. The H_2O_2 treatment did not remove all of the org. matter from a soil. Org. material, fertilizer and CaO treatments influenced the org. matter content and exchange capacity of a soil. Maryland soils had 50-80% of their exchange capacity in org form.

3003. KISHI, HARUO. **Analysis by means of radioactive indicators. X. Sorption of minute quantity of lead by silica gel. 1.** *J. Chem. Soc. Japan* 63, 715-23 (1942).—*C.A.* 41, 2986c.

The dehydration of silica gel was studied from room temp. to 300 °C. The water content decreased suddenly at 25-50 °C and then gradually up to 300 °C. The gel dried at high temp. had a greater tendency to adsorb Th B as well as a dil. soln. of $Pb(NO_3)_2$ containing Th B. The adsorbed Pb increased gradually with increase of the gel, and finally reached a const. value.

3004. KISHI, HARUO. **Analysis by means of radioactive indicators. X. Sorption of minute quantity of lead by silica gel. 2.** *J. Chem. Soc. Japan* 63, 724-33 (1942).—*C.A.* 41, 2986*d*.

The adsorbed quantity of Pb decreased with rise of temp. and increased gradually with the time of contact between the soln. and the gel. In $10^{-4} \times 2.5$ N HCl, HNO_3, or tartaric acid, the adsorbed quantity decreased with increase of acid concn. In NH_4OH or NaOH, the adsorbed quantity was almost independent of concn.

3005. KISHI, HARUO. **Analysis by means of radioactive indicators. XI. Sorption of a minute quantity of lead by silica gel in the course of its formation from silicate solution. 1.** *J. Chem. Soc. Japan* 63, 734-9 (1942).—*C.A.* 41, 2986*e*.

Th B, or 10^{-4} N $Pb(NO_3)_2$ contg. Th B, was added to the aq. soln. of Na silicate. Most of the Th B or Pb was lost during the prepn. of the gel.

3006. KISHI, HARUO. **Analysis by means of radioactive indicators. XI. Sorption of a minute quantity of lead by silica gel in the course of its formation from silicate solution. 2.** *J. Chem. Soc. Japan* 63, 740-5 (1942).—*C.A.* 41, 2986*f*.

The influence of washing upon the amt. of Pb adsorbed by silica gel was studied. A minute quantity of the adsorbed Pb could not be removed by repeated washing.

3007. KISHI, HARUO. **Analysis by means of radioactive indicators. XII. Sorption of a minute quantity of lead by silica gel obtained from acid clay. 1.** *J. Chem. Soc. Japan* 63, 878-82 (1942).—*C.A.* 41, 2986*f*.

The Kambara clay was fused with the mixt. consisting of Na_2CO_3 and K_2CO_3. By adding water to the fusion product and by shaking, a turbid suspension of water glass contg. impurities from the clay was obtained, and was used for the expt. of sorption.

3008. KISHI, HARUO. **Analysis by means of radioactive indicators. XII. Sorption of a minute quantity of lead by silica gel obtained from acid clay. 2.** *J. Chem. Soc. Japan* 63, 883-7 (1942).—*C.A.* 41, 2986*g*.

After adding the $Pb(NO_3)_2$ contg. Th B to the suspension, the suspension was decompd. by the addn. of acid, and the amt. of Pb adsorbed in the resulting gel was detd. by radioactive analysis. Only a very small portion of Pb was adsorbed by the gel.

3009. LUCAS, ROBERT E. **Reliability of lime-requirement calculations based on the rapid Cu method for exchange capacity.** *Soil Sci. Soc. Am., Proc.* 7, 362-7 (1942) (Pub. 1943).—*C.A.* 38, 197^6.

Cu acetate gave higher readings for exchange capacity than NH_4 acetate for soils low in exchange capacity and lower readings than NH_4 acetate for soils of high exchange capacity. When the ammonia procedure was omitted, the colorimetric measurement of Cu as the acetate rather than as the cupra-ammonia form was quite time-saving and sufficiently accurate for the practical detn. of exchange capacity values. There was a pos. correlation ($r = 0.98$) between the exchange capacity by this rapid method and CaO requirement.

3010. MALQUORI, ALBERTO. **Properties of base exchange and swelling in the evaluation of the surface activity of clays.** *Ricera Sci.* 13, 777-82 (1942).—*C.A.* 38, 3893^4.

The property of cation exchange, T, and the swelling (measured for dry cylinders by means of a lever balance) were measured for a no. of different kinds of clay. By comparing the 2 values it appeared that swelling roughly paralleled T for clays of the groups of kaolinite and halloysite, whereas for sericite and montmorillonite there was no such simple relation. The probable reasons for the differences in behavior were discussed and the opinion was expressed that the differences between univalent and bivalent ions probably play a part.

3011. MARSHALL, CHARLES E. **The use of membrane electrodes in the study of soils.** *Soil Sci. Am. Proc.* 7, 182-6 (1942).—*C.A.* 37, 6072^2.

Electrodes sensitive to metallic elements and the direct electrometric detn. of Ca, Mg, K or Na were discussed. It was possible to prep. clay membranes which were, for practical purposes, sensitive only to univalent cations, others sensitive both to univalent and bivalent cations and still others sensitive to uni-, bi-and trivalent cations.

3012. MARSHALL, CHARLES E. AND BERGMAN, W. E. **The electrochemical properties of mineral membranes. II. Measurement of potassium-ion activities in colloidal clays.** *J. Phys. Chem.* 46, 52-61 (1942).—*C.A.* 36, 2462^3.

A membrane electrode composed of a film of electrodialyzed bentonite dried at 490 °C was used to measure K-ion activities from 0.1 N to $10^{-4}N$. Data were given for K-ion activities in 0.5% suspensions of electrodialyzed agar contg. various amts. of K; for pH and K-ion activity for suspensions of Putnam clay, bentonite and illite; and for the effect of salts on K-ion activity in 2.00% bentonite and 4.56% Putnam clay suspensions.

3013. MARSHALL, CHARLES E. AND BERGMAN, W. E. **The electrochemical properties of mineral membranes. IV. The measurement of ammonium-ion activities in colloidal clays.** *J. Phys. Chem.* 46, 327-34 (1942).—*C.A.* 36, 2462^6.

The clay-membrane electrode (hydrogen montmorillonite dried at 490°C) could be used to measure NH_4-ion activities below 0.1 N in solns. in which it was the only univalent cation and in which the concn. of bivalent ions was less than that of the NH_4 ion. Hydrogen ions interfered, but a correction could be applied provided the membrane was not attacked. The pH should be over 4. Titration curves with NH_4OH were given for the following clays: Putnam (beidellite), Wyoming bentonite (montmorillonite), illite and kaolinite.

3014. MARSHALL, CHARLES E. AND KRINBILL, C. A. **The electrochemical properties of mineral membranes. V. Beidellite membranes and the determination of sodium.** *J. Am. Chem. Soc.* 64, 1814-19 (1942).—*C.A.* 36, 6062^8.

Clay membranes were described that were sensitive only to univalent cations (H-montmorillonite 490 °C); to univalent and bivalent cations (H-montmorillonite 350 °C); and to uni-, bi-and trivalent cations (H-beidellite 600 °C). For Na estns., beidellite membranes gave excellent reproducibility. The potentials obtained with solns. less concd. than 0.03 *N* were within 1 millivolt of those calcd. by the Nernst equation.

3015. MARSHALL, CHARLES E. AND KRINBILL, C. A. **The clays as colloidal electrolytes.** *J. Phys. Chem.* **46**, 1077-90 (1942).—*C.A.* 37, 1638^8.

The pH, Na-ion activity and sp. conductance of dialyzed beidellite, montmorillonite, illite and kaolinite samples were detd. for various addns. of NaOH. The fraction of cations active or dissocd. was a function of: (a) the nature of the cations, (b) the nature of the clay, (c) the concn. of the clay, and (d) the degree of neutralization of the clay.

3016. MEHLICH, A. **The significance of percentage base saturation and pH in relation to soil differences.** *Soil Sci. Soc. Am. Proc.* 7, 167-74 (1942).—*C.A.* 37, 6073^7.

Total exchangeable H and the base-exchange capacity were detd. with $BaCl_2$-triethanolamine buffered at pH 8.2. After this 10-g portions of the soil were weighed into containers suitable for shaking in a mech. shaker and increasing amts. of 0.1 *N* $Ba(OH)_2$ added. The soil suspensions were shaken 3 days in the stoppered containers. After the 3rd day the pH was detd. by means of a glass electrode. Percentage base satn.-pH relationship was useful in indicating trends regarding the compn. of the base-exchange colloids present, but it did not permit their pos. identification.

3017. MITRA, R. P. AND RAY, S. P. **Free and titratable acids per particle of subfractions of hydrogen clay.** *J. Indian Chem. Soc.* 19, 401-2 (1942).—*C.A.* 37, 4288^2.

Free and titratable acids for suspensions of H clays of known equiv. diam. were calcd., resp., from the pH and from potentiometric titration with NaOH. Free H^+ was about 1% of the titratable. Free H^+ per particle ranged from the magnitude of 10^6 for 1μ particles to 10 for 0.018-μ particles.

3018. MUKHERJEE, J. N. AND CHATTERJEE, B. **Interaction between hydrogen clays and neutral salts. I. Nature of interaction responsible for liberation of aluminum.** *Indian J. Agr. Sci.* **12**, 105-12 (1942).—*C.A.* **39**, 4419^9.

Acidity developed on treatment of H-clay with a neutral salt was not entirely accounted for by the amt. of Al released. The titratable acid in an aq. $BaCl_2$ ext. of a H clay was approx. equiv. to the amt. of Ba adsorbed. At the same pH, $BaCl_2$ displaced much more Al from the clay than did HCl, the effect of $BaCl_2$ being the same whether the pH was allowed to decrease or kept const. by buffers.

3019. MUKHERJEE, J. N.; CHATTERJEE, B, AND GOSWAMI, P. C. **Limiting exchange of aluminum ions from hydrogen clays on the addition of neutral salts.** *J. Indian Chem. Soc.* 19, 405-7 (1942).—*C.A.* 37, 4288^3.

An estimate of the importance of exchangeable Al^{+++} on H clays was made by alternately leaching a H-clay sol from Latekujan with neutral salt (*N* $BaCl_2$) and with acid through 9 cycles. Al^{+++} recoveries fell off progressively. For the first cycle, of the 31-milliequiv. total capacity of the sol, 25 milliequivs. of Al^{+++} were recovered; for the ninth only 3.4 milliequivs. of Al^{+++}. Total exchange capacity was unaltered.

3020. MUKHERJEE, J. N.; MITRA, R. P., AND BANNERJEE, S. **Alterations in properties of hydrogen clays on removal of free inorganic oxides contained in them. I.** *Indian J. Agr. Sci.* 12, 303-12 (1942).—*C.A.* 39, 4420^6.

Removal of free SiO_2 and sesquioxides from H clays decreased the base-exchange capacity and caused changes in titration curves indicative of modifications in the exchange complex. Another method caused no appreciable change in exchange capacity or titration curves and only a slight modification in chem. compn.

3021. MUKHERJEE, J. N.; MITRA, R. P., AND CHAKRAVORTY, S. K. **Properties of sub-fractions of hydrogen clay prepared from Indian soils. I.** *Indian J. Agr. Sci.* **12**, 291-302 (1942).—*C.A.* **39**, 4419^8.

The sub-fractions of the entire clay of a red lateritic (Bengal) and a black (Central Provinces) soil was studied. With decrease in particle size the Al_2O_3 content increased and both the SiO_2 and and Fe_2O_3 contents diminished. The base-exchange capacity and the free H ions per g of clay showed a rapid increase with decrease in diam. of particles. The exchange capacity per unit external surface varied uniformly with particle size.

3022. MUKHERJEE, J. N.; MITRA, R. P.; CHATTERJEE, B, AND MUKHERJEE, S. K. **Nature of reactions responsible for soil acidity. VIII. Acid character of hydrogen clay in relation to some problems of soil science.** *Indian J. Agr. Sci.* 12, 86-104 (1942).—*C.A.* 39, 4421^8.

The base-exchange capacity of a H-clay varied with the cation of the base used in titration and with the pH. The value observed by titration was increased in presence of neutral salts. In absence of salts the capacity showed by titration with different bases was in the order: $Ca(OH)_2 > Ba(OH)_2 > NaOH$. In presence of fixed proportions of the corresponding chlorides the order was: $Ba(OH)_2 > Ca(OH)_2 > NaOH$. All sub-fractions of a black cotton soil clay showed a similar form of titration curve. Removal of free sesquioxides and SiO_2 from clay materially altered the exchange capacity and the form of the titration curve.

3023. MUKHERJEE, J. N. AND MITRA, R. P. **Nature of reactions responsible for soil acidity. IX. Acid character of H-clays.** *Indian J. Agr. Sci.* 12, 433-73 (1942).—*C.A.* 38, 4734^7.

H-clay was titrated under various conditions and the features of the curves were analyzed. Comparisons were made with the curves of simple polyphase acid systems: satd. solns. of cinnamic acid contg. the solid acid, palmitic and stearic acid hydrosols, and silicic acid hydrosol. The adsorption of the cations was detd. by their valencies, mobilities, and states of hydration if adsorption was due mainly to electrostatic forces, but when it was due to valency forces solubility and other factors were important.

3024. Mukherjee, J. N.; Mitra, R. P., and Ghosh, K. C. **Mixed cation effects in the estimation of base-exchange capacities of hydrogen clays.** *J. Indian Chem. Soc.* 19, 397-8 (1942).—*C.A.* 37, 4512^1.

Total neutralizable acid was detd. at pH 7.0 for the H-clay from a black cotton soil from Padegaon for the permutations of NaOH, $Ba(OH)_2$ and $Ca(OH)_2$ in the presence of 0.002 *N* and 0.1 *N* NaCl, $BaCl_2$ and $CaCl_2$. The neutralizable acid with a given base in the presence of a fixed concn. of salts followed the order: $BaCl_2$, $CaCl_2$, NaCl.

3025. Raychaudhuri, S. P. and Basuraychaudhuri, P. K. **Indian red soils. V. Factors responsible for buffer capacities and base-exchange properties.** *Indian J. Agr. Sci.* 12, 137-52 (1942).—*C.A.* 39, 4419^5.

In red and lateritic soils, the % base satn. tended generally to increase with depth and, in some cases, a max. was reached at an intermediate depth. Buffer curves in general showed a point of inflection at pH 9.8 with a secondary inflection at pH 2.9 or 4.6. Buffer curves of limonite, bauxite, halloysite, kaolin, and montmorillonite show inflections at pH 2.9 and that of humic acid at pH 4.6.

3026. Raychaudhuri, S. P. and Qudrat Ghani, A.K.M. **The physichochemical and electrokinetic properties of gels of silicic acid and aluminum hydroxide.** *J. Indian Chem. Soc.* 19, 311-30 (1942).—*C.A.* 37, 2242^9.

Silicic acid and aluminum hydroxide sols were mixed in varying proportions, and the ppts. purified. Up to a SiO_2-Al_2O_3 ratio of 2, the pptd. gels and mixing ratios were approx. the same, but above this ratio the pptd. gel contained more Al_2O_3. Al_2O_3 could combine with silica even after lump formation. Cation adsorption followed: $Li^+ < Na^+ < K^+ < Mg^{++} < Ca^{++} < Ba^{++} < Al^{+++}$; anion adsorption occurred in the decreasing order: $Fe(CN)_6^{IV}$, HPO_4^{--}, SO_4^{--}, Br^-, Cl^-, NO_3^-. Anion adsorption dropped with SiO_2 content of the ppts. Within moderate limits, the intensity of cation adsorption increased with SiO_2 content of the gel.

3027. Schachtschabel, P. **Investigations of sorption in soils.** *Forschungsdienst, Sonderh.* 16, 87-90 (1942).—*C.A.* 37, 4510^7.

The ions of the soil were not adsorbed in a proportionate manner. K and NH_4 ions were for the most part bound to the mica, Ca ions to the humus, and Mg ions to the montmorillonite. Since the Ca ions were generally in excess, both the montmorillonite and mica held a greater or lesser amt. of Ca ions by selective sorption. This disproportionate distribution also held for H ions as well as for Fe and Al ions.

3028. Thiessen, P. A. **The reciprocal adsorption of colloids.** *Z. Elektrochem.* 48, 675-81 (1942).—*C.A.* 37, 5898^5.

Colloidal Au particles were adsorbed only on the edges of platelike kaolin particles, but were adsorbed on the surface of mica particles and asbestos fibers. When the kaolin was treated with Ba ions, the Au particles are adsorbed on the surface. Anion-active substances (soaps) and nonionic wetting agents did not increase the surface adsorption on kaolin, whereas cation-active substances (invert soaps) did increase the surface adsorption.

3029. Weiser, Harry B.; Milligan, W. O., and Simpson, W. C. **Elimination of sorption-desorption hysteresis in hydrous oxide gels. II. Tantalum pentoxide, stannic oxide and TiO_2.** *J. Phys. Chem.* 46, 1051-9 (1942).—*C.A.* 37, 1911^8.

Sorption-desorption hysteresis with water was greatly modified or eliminated in gels formed by hydrolysis at the b.p. and aging of the resulting sol particles before coagulating the sols to gels. Aged gels of SiO_2 and Ta_2O_5 gave amorphous-type diffraction patterns with both x-ray and electrons, whereas aged gels of SnO_2 and TiO_2 gave weak x-ray patterns corresponding to cassiterite and anatase, resp.

3030. Allison, L. E. **The trend of phosphate adsorption by inorganic colloids from certain Indiana soils.** *Soil Sci.* 55, 333-42 (1943).—*C.A.* 37, 5180^1.

With Na^+ as the exchangeable cation, the curves of P_2O_5 adsorption presented a characteristic max. and min. effect. In general, the first adsorption peak occurred in the pH range of 3.0 to 3.5 and appeared to be due to adsorption by hydrous Fe and Al oxides. At approx. pH 4.5 the curves abruptly changed direction from a strong downward slope to an equally strong upward slope and reached a second high peak at about pH 6.0. This second max. was probably due to adsorption by aluminosilicate clay minerals. With Ca^{++} as the exchangeable cation, the trend of adsorption over much of the reaction range was unlike that in the situation in which Na^+ was the cation.

3031. Antipov-Karataev, I. N. and Zaitseva, N. I. **Methods of determining the absorptive capacity and composition of exchangeable ions in carbonate soils.** *Pedology (U.S.S.R.)* **1943**, No. 9-10, 42-8 (English summary).—*C.A.* 40, 153^9.

Soil (4 g) satd. with Ba (0.5 *N* $BaCl_2$ and 0.01 *N* Ba acetate were used) was treated with 80 cc. 0.05 *N* K_2CO_3, free from $KHCO_3$. The mixt. was allowed to stand for 2 to 4 hrs and shaken occasionally. The suspension was allowed to settle for 40-48 hrs, or a filtrate obtained by passing it through a colloidal filter. To 20 cc. of the filtrate 10 cc. of 0.1 *N* H_2SO_4 was added. The CO_2 formed was driven off by boiling the residual H_2SO_4 titrated with NaOH (0.05 *N*) with a mixt. of bromo cresol purple and bromothymol blue as the indicator.

3032. Brown, Irvin C. **A rapid method of determining exchangeable H and total exchangeable bases of soil.** *Soil Sci.* 56, 353-7 (1943).—*C.A.* 38, 2432^3.

To det. exchangeable H, 2.5 g of soil was placed in a 50-ml Erlenmeyer flask, 25 ml of neutralized *N* NH_4OAc added, the flask stoppered, and the 1 to 10 mixt. allowed to stand for 1 hr with occasional shaking. The pH was detd. on the mixt. From a graph the milliequivs. of exchangeable H per 100 g of soil were read directly. To det. total exchangeable bases, 2.5 g of soil and 25 ml of *N* HOAc were mixed and treated in the same manner as the mixt. prepd. for exchangeable H detn.

The pH of the mixt. was detd. From a graph the milliequivs. of exchangeable bases per 100 g of soil were read directly.

3033. CHARRIN, VICTOR. **Mineral exchange materials.** *Chimie & industrie* 49, 349-50 (1943).—*C.A.* **38**, 6428[3].
Kieselguhr, pumice and $CaCO_3$ were discussed.

3034. CHATTERJEE, B. AND SEN, A. **Properties of synthetic mixtures of colloidal solutions of silicic acid and aluminum hydroxide. I.** *Indian J. Agr. Sci.* **13**, 59-65 (1943) (Pub. 1944).—*C.A.* **42**, 2837*h*.
Synthetic mixts. prepd. from silicic acid and hydrous Al_2O_3 were found to carry a pos. charge. The pH and specific conds. of the mixts. changed with time showing the presence of a slow interaction between colloidal silicic acid and $Al(OH)_3$. The potentiometric titration curves of the mixts. with NaOH did not resemble those of either the silicic acid or $Al(OH)_3$ sols. They showed inflection points between pH 6.5 and 7.5

3035. CLARK, ROBERT E. D. **New effects due to anisotropy of colloidal particles.** *Chemistry & Industry* **1943**, 348-50.—*C.A.* **38**, 10[5].
Studies were made of the orientation of the neg. colloidal bentonite clay particles in aq. suspension. By using a fine W wire with a potential gradiant of several hundred v. per cm for electrodes, it was indicated that the clay particles were arranged perpendicularly to the cathode and parallel to the anode. The expt. showed that the resistance to current flow was decreased by the arrangement around the cathode and increased by that of the anode shortly after potential was applied.

3036. ELGABALY, M. M. AND JENNY, H. **Cation and anion interchange with zinc montmorillonite clays.** *J. Phys. Chem.* 47, 399-408 (1943).—*C.A.* **37**, 5838[7].
Zn-contg. clays possessed marked anion-exchange qualities. Results indicated that the mosaic surface of the clay was capable of independent cation and anion exchange.

3037. FU, YING. **Effect of neutral salts on the adsorption of alkalies by silica.** *J. Chinese Chem. Soc.* **10**, 103-12 (1943).—*C.A.* **38**, 2867[9].
The adsorption from soln. of NaOH and KOH on silica gel was measured in the presence of the neutral salts: NaCl, $NaClO_3$, $NaNO_3$, KCl, LiCl. Freundlich's equation held for all cases. An increased amt. of OH^- ion disappeared from soln. in the presence of neutral salts, the order of effectiveness being: $Li^+ > Na^+ > K^+$. The order was independent of the anion used.

3038. GRAČANIN, M. AND VERLIČ, J. **Investigations of the adsorption complex of Croatian podzolic soils.** *Bodenkundl. Forsch.* **8**, 76-95 (1943).—*C.A.* **39**, 3613[7].
The amt. of exchangeable bases present in the adsorption complex was studied, and also the behavior of the cations in the adsorption complex, and the fixation of bases.

3039. HISSINK, D. J. **The seat of the base-adsorption power in the mineral soil complex.** *Bodenkundl. Forsch.* **8**, 72-6 (1943).—*C.A.* **39**, 3613[8].
Four Netherlands soils were investigated. The principal seat of the base-adsorption power was found to be the "weathering silicate A."

3040. JOHNSON, F. C. **Alumina hydrogel.** *Nature* **152**, 415 (1943).—*C.A.* **38**, 517[9].
Exts. from fusions of alumina with 2 parts $NaKCO_3$ and 1 part borax (as for colorimetric detn. of SiO_2) set on standing to more or less thixotropic gels.

3041. KELLEY, JOSEPH B. AND MIDGLEY, A. R. **Phosphate fixation—an exchange of phosphate and hydroxyl ions.** *Soil Sci.* 55, 167-76 (1943).—*C.A.* 37, 4847[1].
The hydrated Fe oxide, usually distributed as a film over individual soil particles, had marked activity in fixing sol. phosphate that came in contact with it. Phosphate fixation was a physicochem. exchange of phosphate ions for the exposed OH ions of $Fe(OH)_3$. When a suspension of $Fe(OH)_3$ was mixed with a soln. of KH_2PO_4, the pH of the mixt. was higher than that of either of the liquids before mixing. The increase in pH was sometimes greater than a pH unit. Unheated $Fe(OH)_3$ brought about 100% fixation of the phosphate from a soln. contg. 400 p.p.m. of P. After the $Fe(OH)_3$ had been heated at white heat for 3 hrs, it removed no P. When suspensions of $Fe(OH)_3$ were mixed with a soln. of NH_4F or Na_2SiO_3 the pH after fixation was higher than in either of the liquids before mixing.

3042. MUKHERJEE, J. N.; SEN-GUPTA, N. C., AND INDRA, M. K. **Effect of concentration and pH on the viscous and electrochemical properties of H bentonites.** *J. Phys. Chem.* 47, 553-77 (1943).—*C.A.* 38, 672[5].
The sp. cond. of dil. suspensions of H-bentonites first increased linearly with increase of concn., then rose much more rapidly, being convex to the concn. axis, after which the slope again decreased. The pH changed proportionately with -log C. The apparent sp. gr. increased with concn. and reached a const. value which agreed fairly well with the sp. gr. of dry bentonite (dried at 105°C) measured in toluene. The results suggested that as concn. rose aggregates were first formed and that at a still higher concn. these aggregates formed some sort of structure which possessed yield value.

3043. NAYAR, M. R. AND SHUKLA, K. P. **Influence of the size of exchangeable ions on the permeability of soils.** *Current Sci.* **12**, 206-7 (1943).—*C.A.* **38**, 607[9].
The rate of percolation of water through a soil satd. with various univalent alkali cations increased with increasing ionic radii of the satg. ions. A corresponding relation held for soils satd. with bivalent alk. earth cations.

3044. Pavlovschi, Gh.; Mavrodineanu, R., and Ionescu, I. **The methodology of the determination of exchangeable potassium.** *Bodenkunde u. Pflanzenernahr.* **29**, 300-9 (1943).—*C.A.* **38**, 6465^6.

The detn. of exchangeable K was based on the amt. of K going over into the extg. soln. being always proportional to the amt. of K capable of being exchanged. K added to the soil as K salts entered the absorption complex and was considered exchangeable K.

3045. Raychaudhuri, S. P. and Miah, Abul Hussain. **Preliminary study of the aging of alumina and silica gels and of the precipitates obtained from mutual coagulation of alumina and silicic acid sols.** *J. Indian Chem. Soc.* **20**, 195-6 (1943).—*C.A.* **38**, 907^2.

Buffer curves of freshly prepd. (electrodialyzed) gels of SiO_2 and Al_2O_3 and of aluminosilicates of varying SiO_2/Al_2O_3 ratios were made and compared with those aged for 1 yr and with those of naturally occurring clay minerals, such as bauxite, halloysite, kaolin, limonite and montmorillonite. Freshly prepd. substances possessed much less buffer capacity than the aged materials.

3046. Siewert, Gerhard and Jungnickel, Herst. **The alkaline reaction of commercial alumina. Adsorption analysis with alumina.** *Ber.* **76B**, 210-13 (1943).—*C.A.* 37, 5898^3.

The alk. reaction of com. Al_2O_3 (Kahlbaum and Merck) was due to the presence of Na_2CO_3 and $NaHCO_3$, and that Na aluminate could be present in only very subordinate amt. at most. When pure water was passed through a 100-g column of Al_2O_3, the filtrate was at first alk. (pH about 9.5) but ceased being so after about 1 liter had passed through. The Al_2O_3 thus washed alkali-free no longer had any appreciable adsorption effects on cations.

3047. Vendl, M. **The role of hydronium ions in the exchange behavior of siliceous clays.** *Roy. Hung. Palatine-Hoseph Univ. Tech. Econ. Sci., Pubs. Dept. Mining Met.* **15**, 344-54 (1943).—*C.A.* **41**, 6174*b*.

Data on ionic radii and exchangeability indicated that hydronium ions were responsible for previous observations to the effect that the exchange power of H in the case of montmorillonite and kaolin lay between that of Na and K in high concns. and between K and Rb in lower concns.

3048. Venturello, Giovanni. **Ion adsorption by active alumina.** *Atti reale accad. sci. Torino, Classe sci. fis. mat. nat.* **79**, 288-97 (1943-44).—*C.A.* **41**, 4992*f*.

The Brockmann Al_2O_3 (Merck) and a highly pure Al_2O_3 (obtained by the contact, in the air, of a sheet of Al (99.99%) with Hg) were used to examine the ionic adsorption of the anions and cations of the solns. of $CuSO_4$ and $Cu(NO_3)_2$. The adsorption by highly pure Al_2O_3 followed the Freundlich law, whereas Brockmann Al_2O_3 did not, particularly at the highest concns.

3049. Barbier, Georges and Chabannes, Jean. **The retention of the sulfate ion in soils.** *Compt. rend.* **218**, 519-21 (1944).—*C.A.* 39, 2609^4.

SO_4^{--} was adsorbed by the soil more strongly than Cl^- and less strongly than phosphate ions. Ca^{++} favored the retention of sulfate in soils independently of the pptn. of $CaSO_4$. Soils of av. compn. contained 10-20 mg of S per kg in the adsorbed condition.

3050. Cantino, E. C. **Semimicrodetermination of the exchange capacity of soils.** *Soil Sci.* **57**, 399-404 (1944).—*C.A.* **38**, 6457^3.

A sample of air-dry soil equiv. to exactly 1 g of oven dry soil was transferred quant. to a 3 × 16 cm centrifuge tube contg. 25 cc. of NH_4OAc. After agitation, it was digested for 25 min. on a water bath at 60-70 °C and then centrifuged for 5 min. at a force of 10^4 × gravity. After decantation a 20 cc. portion of acetate was added; the mixt. was agitated, digested for 10 min. and centrifuged again. This was continued until Ca ceased to appear in the liquid phase. A final digestion was then run with 10 cc. of reagent and after centrifuging 10 cc. of MeOH were added to the soil residue. This was digested for 5 min. at 45 °C and then centrifuged. This was continued until the color produced when 10 cc. of each of the supernatent liquid and water and 2 cc. of Nessler's reagent were mixed was equiv. to that produced with MeOH and water. The soil was then digested with a final 10 cc. of MeOH centrifuged and alc. removed by decanting. The soil was transferred quant. into a small Kjeldahl flask and the total ammonia was detd.

3051. Ensminger, L. E. **A modified method for determining base-exchange capacity of soils.** *Soil Sci.* **58**, 425-32 (1944).—*C.A.* **39**, 1714^8.

The soil sample was leached with 250 ml of a *N* soln. of the satg. salt and then with 250 ml of a 0.1 *N* soln. of the salt. The quantity of excess 0.1 *N* soln. was detd. by subtracting the dry wt of the funnel, filter paper and sample from the wt of the combination after the sample had been leached with the 0.1 *N* soln. The excess 0.1 *N* soln. and the adsorbed cation were leached out with 0.2 *N* HCl and the total quantity of cation was detd. The total cation minus that present as excess 0.1 *N* soln. was equal to the base-exchange capacity. Base-exchange capacity increased appreciably with time of intermittent leaching when Ba acetate was used. The addn. of 0.5% of BuOH to the Ba acetate soln. lowered the leaching time necessary to obtain equil. between the soil and the satg. soln.

3052. Erbring, H. and Lehmann, H. **Exchange reactions with voluminous organic colloid ions on sodium bentonites.** *Kolloid-Z.* **107**, 201-5 (1944).—*C.A.* 40, 6934^9.

The adsorption of the anion-active materials was negligible. The cation-active materials were bound in relatively large quantities through exchange for the Na ions. 1-Dodecylpyridinium bentonite showed a water absorption of 65%, owing to loading the surfaces of the bentonite platelets with the voluminous 1-dodecylpyridinium ions, whereas the untreated bentonite absorbed 700% water.

3053. Holdridge, D. A. and Francis, Marcus. **Base-exchange phenomena in clays and ceramic materials.** *Trans. Brit. Ceram. Soc.* 43, 131-54 (1944).—*C.A.* 39, 2183^8.

All clays tested were unsatd. with respect to metallic ions and were, therefore, capable of sorbing metallic ions in amts. in excess of the total quantity of metallic ions which they yielded on leaching. The Ca and Mg were immediately replaceable, whereas the Na and K were only progressively so which led to a differentiation of these ions based on their position either within or upon the clay particles.

3054. JOFFE, J. S. AND ZIMMERMAN, MIRYAM. **Sodium, calcium, and magnesium ratios in the exchange complex.** *Soil Sci. Soc. Am., Proc.* 9, 51-5 (1944).(Pub. 1945).—*C.A.* 40, 1258^9.

Solonetz or solonetz-like soils of different Ca:Mg:Na ratios were produced and the effects of these on the soil and plant growth studied. Data were given on the swelling, moisture absorption, and dispersion of the soils contg. various percentages of Na, from 5 to 50, in the exchange complex carrying various Ca:Mg ratios. A high Ca:Mg ratio (11:1) was far more effective in reducing the swelling caused by Na than was the low Ca:Mg ratio (1:1.25).

3055. KRASIL'NIKOV, K. G. AND KISELEV, A. V. **CaO-SiO_2-H_2O system. Sorption of calcium oxide by silica gel.** *J. Phys. Chem. (U.S.S.R.)* 18, 527-36 (1944).—*C.A.* 39, 2689^8.

Silica gel took up CaO from aq. solns. first by adsorption, then by formation of a hydrated Ca silicate. The curve of adsorption showed a region where equil. was established, in which there existed a new solid phase: $CaO.SiO_2.aq$.

3056. KRESTINSKAYA, V. N. AND KHAKIMOV, Z. V. **The mechanism of adsorption of silver sulfate on silica and aluminum hydroxide sols.** *J. Gen. Chem. (U.S.S.R.)* 14, 129-36 (1944) (English summary).—*C.A.* 39, 2240^5.

Silica did not adsorb Ag^+, though the latter may react with Cl^- impurities. SO_4^{--} was not adsorbed, though it may show apparent neg. adsorption due to adsorption of H_2O. There was no mol. adsorption of Ag_2SO_4. Ions reacted at different points on the gel surface and did not enter the crystal lattice of the colloid. This was confirmed by the fact that $ZnSO_4$, which could not form an aluminate, did not show even apparent mol. adsorption.

3057. MALQUORI, ALBERTO. **Behavior of humus in clay-bearing soils. II. Base-exchange capacity of organic substance and of humic acid and its relation to the base-exchange capacity of clay.** *Ann. chim. applicata* 34, 111-26 (1944).—*C.A.* 41, 3240*d*.

The base-exchange capacity of humus in 5 clay-bearing soils was detd. by the oxidation method with H_2O_2.

3058. MARSHALL, CHARLES E. **Uses and limitations of membrane electrodes.** *J. Phys. Chem.* 48, 67-75 (1944).—*C.A.* 38, 2527^3.

By the use of membrane electrodes, cationic activities could be detd. to within 4% at concns. of 0.1 *M* and 2% at 0.01 *M*. Controlled heat-treatment of montmorillonite and beidellite films could produce membranes of varying resistance, charge and sensitivity to cations of different valencies. Mixts. of cations could be analyzed by detg. the mobility ratio of 2 cations within a given membrane.

3059. MATTSON, SANTE AND LARSSON, KARL G. **Laws of ionic exchange. II. The valence effect in relation to the micellar ion concentration and base saturation of Donnan systems.** *Lantbruks-Högskol. Ann.* 12, 222-9 (1944-45).—*C.A.* 39, 4422^9.

The exchange capacity of kaolin and a laterite was very much less than that of bentonite. The bentonite adsorbed relatively more of the univalent ions the more unsatd. it became. These phenomena agreed with the valence effect to be expected from the principles of the Donnan equil.

3060. MUKHERJEE, S. K. AND NANDI, S. K. **Studies on base exchange. I. Comparison of base-exchange capacities and degree of saturation of some Indian soils obtained by different methods.** *Indian J. Agr. Sci.* 14, 74-7 (1944).—*C.A.* 42, 3886*g*.

Ca constituted about 70-90% of the base-exchange capacities of the base-satd. soils and about 20-50% of the acidic soils. Exchangeable K and Na were present in very small amts. and the Mg content was appreciable only in the black cotton types of soil. Exchangeable H constituted about 10-50% of the base-exchange capacity of the acid soils.

3061. MUKHERJEE, S. K. AND GANGULY, A. K. **Studies on base exchange. II. Comparison of different methods of estimating base-exchange capacities and of lime requirement of hydrogen clays, acid soils, and partly and completely desaturated soils.** *Indian J. Agr. Sci.* 14, 203-9 (1944).—*C.A.* 42, 3887*a*.

The amts. of Ba, Ca, and NH_4 adsorbed by the H-clay from a neutral *N* soln. of their chlorides was in the decreasing order NH_4^+, Ba^{++}, Ca^{++}. The pH of successive leachates with $BaCl_2$, $CaCl_2$, and NH_4Cl gradually increased, reaching a const. value which was higher with NH_4Cl. The adsorption of Ba^{++}, Ca^{++}, and NH_4^+ from their chloride solns. increased with the pH of the leaching solns. The adsorption of Ca^{++} and Ba^{++} showed reversal between pH 4 and 6. The base-exchange capacity of a soil remained intact when converted into the H-soil.

3062. NORTON, F. H. AND JOHNSON, A. L. **Fundamental study of clay. V. Nature of water film in plastic clay.** *J. Am. Ceram. Soc.* 27, 77-80 (1944).—*C.A.* 38, 2174^5.

A clean monodisperse fraction of kaolinite had the following characteristics: av. particle size 0.32 μ in diam. and 0.04 μ thick; av. water-film thickness in the plastic condition 0.005 μ, or about 60 mol. layers. Under conditions of permeable pressing, the thickness of the film varied inversely with the pressure up to 600 lbs/in^2, above which distortion of the particles occurred.

3063. PAVELKA, FRITZ. **Protective film on Al. III. Observations on the quantitative procedure of precipitation of hydrated aluminum oxide in aqueous solution.** *Kolloid-Z.* 107, 139-41 (1944).—*C.A.* 39, 11^9.

The quant. pptn. of hydrated Al_2O_3 was detd. with a photometer. About half of the stoichiometric requirement of base (NH_4OH or NaOH) was required to ppt. the Al_2O_3 from $Al_2(SO_4)_3$ soln. Each addn. of the base caused localized pptn. followed by redispersion of the Al_2O_3 as further small quantities were added. The complete pptn. occurred quite suddenly upon slow progressive addn. of the base.

3064. PENG, C. AND CHU, T. S. **A method for determining the total exchangeable bases of soils.** *Soil Sci.* **58**, 205-8 (1944).—*C.A.* **39**, 571^3.

A method was suggested for detg. the total exchangeable bases of soils in which the soil was extd. with 0.1 *N* AcOH. The extn. was carried out overnight in an electrically heated Soxhlet app.

3065. RYDALEVSKAYA, M. D. AND TISHCHENKO, V. V. **Cation exchange of humic acid of various soil types.** *Pedology (U.S.S.R.)* **1944**, No. 10, 491-8 (English summary, 98-9).—*C.A.* **39**, 4179^8.

Humic acid extd. from podzols, chernozem, and peats was titrated with $Ca(CH_3COO)_2$ or $BaCl_2$ at pH 8.1 to det. the cation-exchange capacity. Also detd. were the ash content and empirical compn. of the humic acid from the 3 sources. For detn. of the participation of the H of the phenol groups, the humic acid was methylated with CH_3OH to eliminate the H of the carboxyl groups.

3066. SHUKLA, K. P. **Influence of exchangeable ions on the dispersion of soil.** *Current Sci.* **13**, 45 (1944).—*C.A.* **38**, 5037^3.

The dispersion of soil colloids produced by shaking Ca soil with the carbonates of alkali metals was due to the gradual replacement of exchangeable Ca by alkali cation.

3067. UCHIDA, MUNEYOSHI. **Test methods for bentonite. I. Determination of imbibition. II. Correlation of imbibition value and coagulation volume. III. Classification of bentonite.** *J. Japan. Ceram. Assoc.* **52**, 2-5, 39-41, 91-5 (1944).—*C.A.* **45**, 7760*d*.

Two methods of detg. the imbibition of water by bentonite were the filter paper method and the coagulation by NaCl. Place 0.5 g of dried bentonite in a glass cylinder 50 mm in diam. and 25 mm high, to the bottom of which a hard filter paper was attached by a rubber band. Place this cylinder on a porous plate half immersed in water. After 24 hrs the amt. of water absorbed by bentonite was measured by weight increase, recalcd. to 1 g of the sample, and defined as the imbibition value. The coagulation vols. of sand, kaolinite, and bentonite of low, medium, and high qualities were 0.5-1, 1-2, 2-5, 5-7, and 9-12, resp. Clay was activated by heating in a soln. of *N* NaCl and NaOH for 1 hr.

3068. VOLLMAR, HANS. **The limits of applicability of the immersion method for the determination of dielectric constant of porous solid materials.** *Z. Elektrochem.* **50**, 150-2 (1944).—*C.A.* **40**, 4582^7.

The dielec. const. of silica gel and fuller's earth gave contradictory results. The cause was shown to be adsorption of one component of the liquid mixt. used for comparison. The possible application to studies of adsorption and diffusion was indicated.

3069. ATTOE, O. J. AND TRUOG, EMIL. **Exchangeable and acid-soluble potassium as regards availability and reciprocal relationships.** *Soil Sci. Soc. Am., Proc.* **10**, 81-6 (1945) (Pub. 1946).—*C.A.* **41**, 2193*c*.

A study was made of the factors involved in the reciprocal transformations of exchangeable and fixed K. The extn. of a soil with 0.5 *N* HCl for 1 hr at room temp. removed (in addn. to the exchangeable or readily available K), a certain amt. of the fixed form which, because of being quickly dissolved, was considered moderately available. The amts. of this form extd. from various soils ranged up to 90% of that in exchangeable form. The storage in pots in moist condition of Spencer silt loam fertilized with 100 to 3200 lb per acre of K as KCl resulted in little or no fixation of K after 18 months. However, when the samples were dried at room temp. after storage, fixation took place in every case.

3070. BROAD, D. N. AND FOSTER, A. G. **Comparative isothermals of water and deuterium oxide on porous solids.** *J. Chem. Soc.* **1945**, 372-5.—*C.A.* **39**, 3786^2.

The adsorption isothermals of H_2O and D_2O were compared at 25°C on silica and Fe_2O_3 gels and on charcoal. On each adsorbent the relative pressure-vol. curves for the 2 liquids were identical. The results on the whole tended to support the capillary theory, although the behavior of H_2O on charcoal presented certain anomalies.

3071. DROUINEAU, G. AND GUÉDON, A. **Determination of exchangeable magnesium.** *Ann. agron.* **15**, 129-30 (1945).—*C.A.* **40**, 7055^2.

A method was described for detg. exchangeable Mg by pptg. it as Mg hydroxyquinolate. The soil was percolated with neutral NH_4OAc, and the Ca was pptd. as the carbonate. Three cc. of 5 *N* NaOH was added, and the Mg was pptd. by adding 2.5 cc. of a freshly prepd. 2% alc. soln. of a-hydroxyquinoline. The quinolate and the $CaCO_3$ were dissolved in HCl, and the latter was repptd. by adding $NaHCO_3$. After centrifuging, a 5-cc. aliquot of supernatant liquid was treated with AcOH and $Fe(ClO_4)_3$, from which the Mg reppts.

3072. ELMORE, KELLY L.; MASON, CHARLES M., AND HATFIELD, JOHN D. **Precipitation of alumina from sodium aluminate solutions.** *J. Am. Chem. Soc.* **67**, 1449-52 (1945).—*C.A.* **39**, 5156^3.

The pH of Na aluminate solns. was detd. during pptn. of alumina and the detn. of the mechanism of pptn. at 60°C. A cell using a H_2-Ag, AgCl system was developed for measurement of the pH of alk. solns. contg. CO_2 without their contamination by silica. The equation $2AlO_2^- + 2H_3O^+ \rightarrow Al_2O_3.3H_2O$ was found to represent the mechanism of the pptn. of alumina from Na aluminate solns. by CO_2 at 60°C.

3073. FIALKOV, YA. A. **Adsorption properties of kaolin.** *J. Applied Chem. (U.S.S.R.)* **18**, 221-9 (1945) (English summary).— *C.A.* **40**, 3035^9.

The acid treatment led to improved adsorption of acid dyes, negatively charged colloidal Ag, and I_2, while the adsorption of basic dyes, alkaloid salts, and other basic substances was decreased.

The basic treatment led to reverse results. When the kaolin was treated with 0.1-1.0 *N* HCl, there was no adsorption of procaine, dicaine, and corrosive sublimate.

3074. Gorbunov, N. I. and Tsyurupa, I. G. **Cation exchange with variable ratios of solution to solid phase.** *Pedology (U.S.S.R.)* **1945**, 369-74 (English summary).—*C.A.* **40**, 1959^4.

With an increase in the ratio of the solvent, from 0.3:1 to 50:1 the quantity of cations increased. As the replacing agent was dild. the quantity of cations replaced decreased, irrespective of the total amt. of salt used. Some soils gave up more cations as the time of contact was prolonged.

3075. Harman, C. G. and Parmelee, C. W. **Fundamental properties of raw clays influencing their use.** *J. Am. Ceram. Soc.* **28**, 110-18 (1945).—*C.A.* **39**, 2183^3.

Cation-adsorption capacity and the nature of the adsorbed cation were closely related to the heat of wetting, pH, and equil. moisture. For a given adsorbed cation these properties related directly to the intensity of adsorption of the ion. The existence of org. ions or ionized groups (from the soln. of org. matter) might be postulated to explain the anomalous behavior of clays contg. org. matter. Properties of clays might be defined as functions of ion-sorption capacity, nature of the adsorbed cation, and packing.

3076. Hendricks, Sterling B. **Base exchange of crystalline silicates.** *Ind. Eng. Chem.* 37, 625-30 (1945).—*C.A.* **39**, 3864^5.

Zeolites depended on neg. portions in the lattice framework and multiconnected voids large enough for ionic migration. The metal: SiO_2 ratio approached unity when addl. neg. groups replaced water in the voids. With montmorillonite types external cations were principally on the cleavage surfaces, with kaolin types on the lateral surfaces. In glauconite and illite, which were micaceous, both types contributed to cation exchange.

3077. Hofmann, U. and Hausdorf, A. **The settling volume and swelling of bentonite.** *Kolloid-Z.* **110**, 1-17 (1945).—*C.A.* **43**, 4537*h*.

The vol. of sediment (*SV*) depended on the diam. of individual crystals and the duration depended on the over-all structure of the bentonite. Exchange cations greatly affected the *SV* and owed their effect to the amt. of their hydration. Ca-, K-, Na-, Li-, NH_4-, Mg-, and Ba-bentonites were studied. The H-bentonite was prepd. by dialysis. Alkali-and alk. earth-bentonites showed very different results in the presence of electrolytes. Li caused the greatest change. Particles were much more disperse in the alkali- than in the alk. earth-bentonite. Energy relations were considered with respect to the double layer between solid and soln. Swelling decreased with decreases in degree of hydration at const. concn. of exchange cation.

3078. Jacobs, P. W. M. and Tompkins, F. C. **Inorganic chromatography. I. Static adsorption measurements.** *Trans. Faraday Soc.* 41, 388-94 (1945).—*C.A.* **39**, 5156^9.

Concordant results in aq. solns. at 26.5°C were obtained with Al_2O_3. The adsorbent (5 g), prewashed with 100 ml distd. water, was heated for 1 hr at 480°C, cooled over satd. salt/sugar soln., and used immediately. Isotherms for both cations and anions were approx. expressed by the Freundlich equation and by the equation $O = k_1 + k_2 \log C$. The adsorbates were $CuCl_2$ and the sulfates of Cu, Cd, Zn, Ni, Co, Mn, Mg, and NH_4. The cation was more strongly adsorbed than the anion, because of addnl. cation exchange adsorption.

3079. Lawande, Y. V. and Karve, D. D. **Adsorption of mercuric chloride by colloids. I.** *Proc. Indian Acad. Sci.* **21A**, 41-4 (1945).—*C.A.* **39**, 3990^1.

The adsorption of $HgCl_2$ from dil. soln. by dry gels of $Fe(OH)_3$, silica, $Al(OH)_3$, and Acticarbon tended to be apolar. At higher concns. of $HgCl_2$ the adsorption was polar. Addn. of NaCl retarded the adsorption of $HgCl_2$.

3080. Martin, J. C.; Overstreet, R., and Hoagland, D. R. **Potassium fixation in soils in replaceable and nonreplaceable forms in relation to chemical reactions in the soil.** *Soil Sci. Soc. Am., Proc.* **10**, 94-101 (1945) (Pub. 1946).—*C.A.* **41**, 2192*i*.

Certain cations when present in the exchange complex of some soils could pass from a loosely held state to a very strongly held state. The fixation of K involved first an adsorption in exchange for other adsorbed cations and then a fixation which resulted in a reduction in the total exchangeable cations of the soil. Cations known to undergo this change of state are K, Rb, Cs, and possibly H. The degree to which the above process took place depended on the concn. of the reacting ion in the soil soln. and on its amt. in the exchange complex of the soil. The most pronounced fixation of K occurred under conditions which would favor a dehydration of the reacting ions or of the clay minerals.

3081. McGeorge, W. T. **The base exchange-pH relationships in semiarid soils.** *Soil Sci.* **59**, 271-5 (1945).—*C.A.* **39**, 5023^8.

The pH of the soil increased with increase in the percentage of Na in the complex and the relation between the 2 values was significant and linear. When the base-adsorbing complex of semiarid soils was completely satd. with Na, all soils had nearly the same hydrolytic pH at the 1:10 soil:water ratio regardless of the milliequiv. adsorption capacity per 100 g of soil.

3082. Mukherjee, J. N. and Chatterjee, B. **Electrochemical properties of silicic acid sols.** *Nature* **155**, 85-6 (1945).—*C.A.* **39**, 2021^8.

Silicic acid sols after prolonged electrodialysis had free acidities of 0.0001 N caused by mobile H^+ assocd. with the colloidal particles. The sol behaved as a strong acid as judged from the form of the titration curves with small addns. of very dil. bases, and by the manner of variation with diln., temp. of the free acid and the total acid at the first inflection point. The amt. of acid liberated from the sol by neutral salts followed the lyotrope series Ba > Ca > K > Na > Li.

3083. MUKHERJEE, J. N. AND CHATTERJEE, B. **Liberation of H^+, Al^{+++}, and Fe^{+++} ions from H clays by neutral salts.** *Nature* **155**, 268-9 (1945).—*C.A.* **39**, 2442^6.

At const. pH the amt. of displaced Al^{+++} increased with concn. of the added salt. At a given equil. pH, $BaCl_2$ liberated more Al^{+++} than did HCl. The evidence favored a direct exchange of Al^{+++} for the cation of the salt, instead of their liberation by a secondary soln. process. At low values of C, very few Al^{+++} and mainly H^+ ions were exchanged. The H^+, Al^{+++}, and Fe^{+++} leached from 2 H-clays by *N* $BaCl_2$ decreased to negligible values.

3084. MUKHERJEE, J. N.; MITRA, R. P., AND MANDAL, S. S. **Effect of concentration on the free and titratable acids of hydrogen bentonite sols.** *Nature* **155**, 329-30 (1945).—*C.A.* **39**, 2685^7.

The effect of the concn. (0-16.2%) of a H-bentonite on H-ion concn. was shown graphically. The effect on the titratable acidity was given at selected points. The bentonite contained only montmorillonite.

3085. MUKHERJEE, J. N. AND MUKHERJEE, S. K. **Effects of H-ion concentration on cation exchange in clay salts.** *Nature* **155**, 49 (1945).—*C.A.* **39**, 2021^6.

The lyotrope series was usually observed in the exchange of cations from clays and permutites. Deviations disappeared when symmetry values measured at pH 6.0-7.0 were compared. At pH 3.0-5.0 all cations had the same symmetry value, and the cation effect on the lyotrope series disappeared. At pH 3.0 HCl alone gave a higher symmetry value than when used in conjunction with the salts. Al^{+++} ions were exchanged at this pH for the cations of the added salt.

3086. NIKOLAEV, L. A. AND KOBOZEV, N. I. **Peroxidase function of silica gel.** *J. Phys. Chem. (U.S.S.R.)* **19**, 562 (1945).—*C.A.* **40**, 3046^8.

Silica gel adsorbed Cr^{+++} quantitatively from very dil. $Cr_2(SO_4)_3$ solns. One g of silica gel adsorbed at 11°C 3×10^{-4} and at 26°C 6×10^{-4} g/mol. H_2O_2. When H_2O_2 was added to a silica gel contg. adsorbed Cr^{+++}, the latter was oxidized to CrO_4^{--}, which went into the soln. The evolution of O_2 was small. In the absence of silica, Cr^{+++} was only very slowly oxidized by H_2O_2.

3087. NIKOL'SKII, P. AND GRIGOROV, O. N. **Dependence of the adsorption of barium ions by silica gel on the pH and the concentration of the solution.** *Doklady Akad. Nauk S.S.S.R.* **50**, 325-7 (1945).—*C.A.* **43**, 2498*f*.

The adsorption of Ba^{++} ions (g-equiv. per kg silica gel) was insignificant up to pH 8 and then rose rapidly with rising pH. This was consistent with previous findings with Na^+ and Ca^{++} ions.

3088. OVERSTREET, ROY. **Ionic reactions in soils and clay suspensions: the significance of soil filtrates.** *Soil Sci.* **59**, 265-70 (1945).—*C.A.* **39**, 5023^6.

Because of the inequalities in the chem. potentials of the diffusible ions, an examn. of the soil soln. in many cases would not give a correct picture of the chem. properties of the corresponding soil suspension.

3089. PEECH, MICHAEL. **Determination of exchangeable cations and exchange capacity of soils-rapid micromethods utilizing centrifuge and spectrophotometer.** *Soil Sci.* **59**, 25-38 (1945).—*C.A.* **39**, 1951^8.

Colorimetric methods were outlined for detg. adsorbed ammonium by direct nesslerization and Na by a modification of the Darnell and Walker method.

3090. SCHOLLENBERGER, C. J. AND SIMON, R. H. **Determination of exchange capacity and exchangeable bases in soil-NH_4OAc method.** *Soil Sci.* **59**, 13-24 (1945).—*C.A.* **39**, 1951^7.

Addnl. methods of analysis for the ingredients in the ammonium acetate method were given for H and Mn.

3091. TRUOG, EMIL. **A proposed system of names, abbreviations, symbols, and formulas for designating the soil base-exchange substances and their acids and salts.** *Soil Sci. Soc. Am., Proc.* **10**, 341-3 (1945) (Pub. 1946).—*C.A.* **41**, 2829*a*.

A simple system of nomenclature was proposed to designate the base-exchange substances or complexes variously satd. with cations.

3092. BEECH, D. G. AND FRANCIS, MARCUS. **Properties and testing of bentonite.** *Trans. Brit. Ceram. Soc.* **45**, 148-60 (1946).—*C.A.* **40**, 6762^9.

The swelling properties depended to some extent on the nature of the exchangeable cations. The material obtained commercially was in a very fine state of division, which accounted in part for its power of forming moderately stable suspensions and its high exchange capacity. Various properties of bentonite suspensions were discussed.

3093. GLAESER, RACHEL. **Determination of the base-exchange capacity in montmorillonite.** *Compt. rend.* **222**, 1179-81 (1946).—*C.A.* **40**, 7457^8.

The base-exchange capacity of montmorillonite was detd. and the results plotted graphically. The method with certain precautions was found to be rapid and convenient.

3094. GLAESER, RACHEL. **Effect of acid treatment on the base-exchange capacity of montmorillonite.** *Compt. rend.* **222**, 1241-2 (1946).—*C.A.* **40**, 6932^1.

The x-ray patterns of 2 montmorillonites remained unaffected after treatment of the samples with 30% H_2SO_4 until 80% of the (Al + Fe + Mg) was extd. (12-20 hrs). The pattern then disappeared. The exchange capacity, calcd. as the no. of valence bonds per "unit flakelet" (a = 5.20 A., b = 8.96 A.) was a linear function of the Mg content, passing through the origin. Exchange capacity, plotted vs. the (Al + Fe + Mg) content, gave a much greater scattering of the points.

3095. HAUSER, E. A. AND LE BEAU, D. S. **Colloid chemistry of clay minerals and clay films.** *Colloid Chemistry* **6**, 191-213 (1946).—*C.A.* **40**, 2372^7.

Chem. and thermal analysis coupled with x-ray diffraction data revealed lattice-structure differences and also cases of atomic substitutions. Base exchange and its effect on practical properties were considered, also particle size and its detn., as well as the concept of the double layer, stability of clay sols, their gelation and coagulation.

3096. Heidel, Robert H. **Direct photoelectric spectrochemical determination of exchangeable bases of soils.** *Proc. Iowa Acad. Sci.* **53**, 211-23 (1946).—*C.A.* **42**, 4298*i*.

Simultaneous analysis of the Ca, Mg, Na, K, and Mn in the exchangeable base series was accomplished by combining the use of conventional spectrographic methods and instruments with the methods of flame photometry.

3097. Hurd, Charles B. and Merz, Paul L. **Silicic acid gels. XIV. Dialysis of silica hydrosol and hydrogel.** *J. Am. Chem. Soc.* **68**, 61-4 (1946).—*C.A.* **40**, 1378^1.

The dialysis through collodion membranes was studied of sodium silicate solns., of silica hydrosol, and silica hydrogel. Essentially all of the silica in 1.35 *N* sodium silicate soln. was found capable of dialyzing through the membrane. Although a freshly formed silica hydrosol contained much of its silica in a form capable of dialyzing through the membrane, this fraction decreased with lapse of time. A small fraction remained able to diffuse through the membrane, even in the gels after setting.

3098. Marshall, Charles E. and Ayers, Alvin D. **Clay membrane electrodes for determing calcium activities.** *Soil Sci. Soc. Am., Proc.* **11**, 171-4 (1946) (Pub. 1947).—*C.A.* **42**, 2375*e*.

Membranes with high neg. charges were desirable because they acted as if they were impermeable to anions when used in solns. of low concn. Heating the clay membranes to 600°C tended to increase the effective ionic charge and to increase their mech. stability. For the cations H, Na, NH_4, K, and Ca, the montmorillonite typified by Wyoming bentonite was consistently more ionized than the beidellite typified by Putnam clay.

3099. Marshall, P. **Zeolite minerals as original components of igneous rocks.** *New Zealand J. Sci. Technol.* **28B**, 37-52 (1946).—*C.A.* **41**, 5823*a*.

Various tests involving ion-exchange and staining were developed to indicate the presence and extent of zeolite and related minerals in thin sections. Some interstitial zeolite underwent exchange processes with dyes even without previous acid treatment. A natural exchange of Na and probably K and Ca for Fe^{++} occurred in the interstitial zeolites; the feldspar microlites, aegirine, aegirineaugite, and cossyrite remained fresh even after the exchange process and the subsequent oxidation of the ferrous zeolite was well advanced to limonite. The Na-Fe exchange was well developed in chabazite, ameletite, and interstitial zeolite, but slow in analcite and natrolite. Further weathering and disintegration were greatly speeded up by the exchange.

3100. Mikhal'chenko, V. A. **Composition of the products of absorption of lime by silica.** *J. Applied Chem. (U.S.S.R.)* **19**, 1364-70 (1946).—*C.A.* **41**, 5781*f*.

Addn. of $Ca(OH)_2$ to silica gel contg. 94.61% H_2O in simple CaO/SiO_2 ratios from 3:1 to 1:3, resulted in solid ppts. with generally different ratios. Through arbitrary interruption of the reaction at a chosen stage, ppts. could be obtained corresponding to those of known minerals, $CaO.SiO_2$, $4CaO.5SiO_2$, $2CaO.3SiO_2$, $4CaO.7SiO_2$, $CaO.2SiO_2$, $CaO.3SiO_2$, but $3CaO.2SiO_2$ or any CaO-richer compn. could not be attained.

3101. Mitra, R. P. **Broken bonds as seats of ion exchange in crystalline silicates.** *J. Indian Chem. Soc.* **23**, 386-7 (1946).—*C.A.* **41**, 6106*g*.

Kaolinite had a greater capacity for cations after grinding. If this was due to an increase in the no. of broken bonds, the broken bonds would also tend to bind an equal no. of anions, i.e., the minerals must be considered amphoteric and not merely acidic. Further study is needed to prove this point.

3102. Mukherjee, S. K. and Gupta, S. L. **Limiting value of the base-exchange capacity of soils and clays.** *Indian J. Agr. Sci.* **16**, 442-4 (1946).—*C.A.* **43**, 9316*a*.

Repeated treatment with p-nitrophenol-lime soln. gave a higher base-exchange capacity than a single treatment. The amt. of lime taken up by the soil and the clay from a phenol-lime soln. at pH 8.5 was higher than obtained by the p-nitrophenol-lime method at pH 7.1. The base-exchange capacity calcd. from the amt. of Mg adsorbed from a neutral satd. soln. of $MgSO_4$ was lower than that detd. by Parker's method. The base-exchange capacity calcd. from the amt. of Ba adsorbed from a neutral satd soln. of $Ba(CNS)_2$ was the highest obtained with a H bentonite.

3103. Reitemeier, R. F. **Effect of moisture content on the dissolved and exchangeable ions of soils of arid regions.** *Soil Sci.* **61**, 195-214 (1946).—*C.A.* **40**, 3551^9.

The study was based on Ca, Mg, Na, K, NH_4, CO_3-HCO_3, SO_4, Cl, NO_3 and PO_4 ions of 6 soils detd. at 4 soil moisture levels, field moisture, satn. percentage, 200%, and 500%. With the exception of SO_4 in one soil, the sol. contents of all ions in all soils changed to some degree on diln. Na, K, NH_4, CO_3-HCO_3, PO_4, and SO_4 (with the 1 exception) increased with increasing moisture content. Exchangeable Na decreased continuously on diln., by percentages ranging from 32 to 58. The ratio of exchangeable Ca to Mg in 2 gypsiferous soils increased tremendously on diln.

3104. Schmah, Hans. **Simple preparation of well-crystallized bayerite.** *Z. Naturforsch* **1**, 323-4 (1946).—*C.A.* **41**, 5359*h*.

Al foil (99.99%) was cut up and degreased with freshly distd. acetone. The pieces were then amalgamated in 0.1 *N* $HgCl_2$ soln., thoroughly washed with distd. H_2O, then with conductivity H_2O. The Al slowly reacted with H_2O and separated as a grayish-colored product which became pure white when the reaction was complete in about a day. This amorphous α-gel on standing passed over to γ-$Al(OH)_3$, bayerite.

3105. Shishniashvili, M. and Kargin, V. **The electrochemical properties of highly purified ferrialuminosilica gels and sols.** *Acta Physicochim. U.R.S.S.* **21**, 705-22 (1946) (in English).—*C.A.* **41**, 1528*g*.

Highly purified $Al_2O_3.4SiO_2$, $Al_2O_3.2SiO_2$, $Al_2O_3.2Fe_2O_3$, which changed compn. to $Al_2O_3.2.2SiO_2$

and $Al_2O_3.1.6SiO_2$, resp., on continued electrodialysis, contained no free electrolyte or oppositely charged ions. The addn. of 1 micromole per liter of electrolyte imparted a pos. charge which decreased on further electrolyte addn. until coagulation occurred.

3106. Shishniashvili, M.; Kargin, V., and Batzanadze, A. **The action of electrolytes on highly purified ferrialuminosilica gels.** *Acta Physicochim. U.R.S.S.* **21,** 869-84 (1946) (in English).—*C.A.* 41, 2300*i*.

The adsorption of phosphate ions on Al_2O_3 gel required repeated treatment and equalization of pH between soln. and Al_2O_3 gel. Suspensions of pure aluminosilica gels treated with phosphate soln. in 0.2 *N* $BaCl_2$ were prepd. Adsorption of Ba ions was considerable at pH below 6 and increased rapidly at pH above 7, but no adsorption was evident in the absence of phosphate solns. When highly purified Al_2O_3 gels were acted upon by neutral salts, they display mol. adsorption of electrolytes, plus hydrolytic adsorption of acids and bases. Upon prolonged treatment of Al_2O_3 gel with neutral salt soln. the equil. shifts, so that the gel acquires exchange-adsorption properties. The hydrolytic adsorption of acids on pure aluminosilica gel was attended by a chem. reaction between adsorbed acid and Al_2O_3 resulting in formation of Al compds.

3107. Wiklander, Lambert. **Studies on ionic exchange with special reference to the conditions in soils.** *Kgl. Lantbruks Hogskol. Ann.* **14,** 1-171 (1946).—*C.A.* 41, 3561*i*.

Exchange materials studied included: humus, litter of beech leaves, $AlPO_4.FePO_4$, Al silicates, ferric silicates, zeolite, bentonite, kaolinite, bleaching earths, and 4 mineral soils. The exchange resins studied were Wolfatit K and M. Vardsberg clay and ordinary bath sponge were also included. The various exchange series closely followed the type $Li < Na < K < Mg < Ca < Sr < Ba < La$. The H^+ appeared between La and Na or farther down the series depending on the nature of the various exchange materials.

3108. Antipov-Karataev, I. N. and Kader, G. M. **The nature of the uptake of ions by clays and soils. I. Uptake of univalent and multivalent cations by bentonitic clay and natrolite.** *Kolloid, Zhur.* **9,** 81-96 (1947).—*C.A.* 47, 805*e*.

K bentonite (5 g) was equilibrated with 100 cc. 0.0125 *N* KCl + 0.0125 *N* NaCl, then 50 cc. supernatant soln. was withdrawn, 50 cc. of a soln. contg. more NaCl and less KCl at the same total concn. (0.025 *N*) added, etc. The ratio Na:K was then gradually reduced in the same manner. The displacement of K by Na was reversible as was that of K by NH_4 and of Ca by Mg, Ba, or Pb. Displacement of Ca by Cu^{++} was irreversible on bentonite and reversible on askangel. In EtOH Ca^{++} was adsorbed by bentonite more strongly that Cu^{++}, and the adsorption was irreversible. Natrolite exchanged its Na for K or NH_4 but not for Ca, Mg, or Ba.

3109. Antipov-Karataev, I. N. and Kader, G. M. **The nature of the uptake of ions by clays and soils. II. Uptake of univalent and bivalent cations by kaolin clay.** *Kolloid. Zhur.* **9,** 161-8 (1947).—*C.A.* 47, 805*h*.

Displacement of K by NH_4 in K kaolin was reversible and satisfied the mass action law. Displacement of K by Na and of Ca by Mg or Ba was reversible but more difficult the greater the degree of displacement. The uptake of Cu^{++} and Hg^{++} by Ca kaolin was irreversible, and of Pb^{++} poorly reversible. It decreased from Hg to Cu to Pb.

3110. Berger, G. **The structure of montmorillonite. Preliminary communication of the capacity of clay and clay minerals to be methylated.** *Compt. rend. conf. pédol. méditerran. (Alger-Montpellier)* **1947,** 119-22 (in English).—*C.A.* 43, 6347*g*.

Pure montmorillonite (2 microns) was treated with excess 0.1 *N* HCl, filtered, washed free of chloride, dried at 150°C, treated with an etheral soln. of diazomethane and dried by KOH 5 to 6 days when no more N_2 appeared. The sample was filtered, washed with abs. ether and petr. ether and dried in vacuum over P_2O_5 and the methoxyl content detd. Exchange capacity of montmorillonite and bentonites amounted to about 100 milliequiv. per 100 g dry matter. Weakly acid OH groups were present in montmorillonite and that base exchange took place at and because of OH groups. Common silica gel proved easy to methylate.

3111. Dean, L. A. and Rubins, E. J. **Anion exchange in soils. I. Exchangeable phosphorus and the anion-exchange capacity.** *Soil Sci.* **63,** 377-87 (1947).—*C.A.* 41, 7603*i*.

The essential features of the method used to det. the anion-exchange capacity of soil with different combinations of anions were enumerated. Soils were shown to have an anion-exchange capacity in that they could be alternately satd. with arsenate and phosphate ions. More phosphate than arsenate was always retained by soils as exchangeable anions. The phosphate retained by soils as an exchangeable anion was virtually completely removed by fluoride, hydroxide, and citrate solns.

3112. Francis, M. **Experimental determination of the influence of adsorbed ions on the ceramic properties of clays.** *Verre silicates ind.* **12,** 1-6 (1947); *Chimie & industrie* **58,** 165 (1947).—*C.A.* 42, 4318*c*.

The ion-exchange capacity varied with the exposed surface, the ratio of SiO_2 to $Al_2O_3 + Fe_2O_3$, and the org. matter content. The crystal network expansible by water also exerted an influence. A special study was made of the effect of Na_2O on the slip. Replacement of Ca and Mg by Na increased the fluidity.

3113. Gapon, E. N. **Electrochemical method for determining the surface of adsorbents and colloids.** *Kolloid Zhur.* **9,** No. 1, 29-36 (1947).—*C.A.* 41, 4350*h*.

The cation adsorption by soils was studied. An equation was developed whereby the normal potential, the surface area, and the capacity of the elec. double layer may be detd. From available data for humus, peat, kaolin, bentonite, and 20 soils, the surfaces (m^2 per g) decreased in the order: chernozem > red soils > podzolic soils > chestnut and grey forest soils.

3114. GRAHAM, R. P. AND HORNING, A. E. **Interaction of hydrous alumina with salt solutions.** *J. Am. Chem. Soc.* **69**, 1214-15 (1947).—*C.A.* **41**, 4395*i*.

Addn. of hydrous Al_2O_3 to 0.1 *M* solns. of K salts at pH 7.00 ± 0.01 at 25.0 ± 0.1°C caused the following max. pH: KF 9.6, K oxalate (0.05 *M*) 8.6, K_2SO_4 (0.05 *M*) 8.0, KNO_3 7.3, KCl 7.3, $KClO_4$ 7.1, K phosphate 7.0. Data were given also for the vaiation in concn. of K oxalate, variation in the mass of Al_2O_3, and variation in the nature of the Al_2O_3. The increase in pH was attributed to displacement of OH groups from the surface of the hydrous Al_2O_3 due to the tendency of anions to bind coördinately to the Al.

3115. GRIM, R. E.; ALLAWAY, W. H., AND CUTHBERT, F. L. **Reactions of clays with organic cations in producing refractory insulation.** *J. Am. Ceram. Soc.* **30**, 142-5 (1947).—*C.A.* **41**, 4902*d*.

An underclay from Grundy County, Ill., composed predominantly of kaolinite, and with base-exchange capacity of about 11 milliequivs. of exchange capacity per 100 g of clay, was used. A 1.0% soln. of each of the many org. compds. tested was employed in the expts. Results showed that porous clay bodies which did not lose their porous nature or shape could be prepd. by mixing air into clay slips that contained compds. which furnished a large org. cation.

3116. HAYNES, HAROLD G. **Precipitation of aluminum hydroxide.** *Pharm. J.* **158**, 446-7 (1947).—*C.A.* **41**, 7199*f*.

The pH curves corresponding to the pptn. of $Al(OH)_3$ with alkalies could be used to give an accurate measure of the degree of adsorption of anions at the point of min. soly. of the hydroxide, which occurred with less than 3 equivs. of alkali. The addn. of 3 equivs. reduced adsorption at the expense of a considerable loss of Al as aluminate. Adsorption of Cl^- was greater than that of the SO_4^{--},

3117. HAZEL, FRED. **Effect of freezing on the stability of colloidal dispersions. Silica sols-A preliminary report.** *J. Phys. & Colloid Chem.* **51**, 415-25 (1947).—*C.A.* **41**, 3344*d*.

Silica sols of known pH were prepd. by treating Na silicate solns. (3.3 mols. SiO_2 per mol. Na_2O) with acidic ion-exchange resins. On freezing for 15 min. at -10 °C, all sols were flocculated except those in the pH range 2.5-3.5. Diln. of the sols caused the zone of no flocculation to be extended to higher pH values. Increasing the freezing time or aging the sols before freezing narrowed the range of stability. At pH values where flocculation just occurred, stability varied with the age of the Na silicate soln. used in prepg. the sol.

3118. JARKA, JOSEF. **Composition and cation-exchange capacity of bentonite from Braňany (near Most in northwest Bohemia).** *Acad. tchèque sci., Bull. intern., Classe sci. math. nat. et. méd.* **48**, 71-6 (1947) (Pub. 1950) (in English).—*C.A.* **47**, 7179*g*.

The bentonite was mostly montmorillonite clays contg. Ca and Mg as more than 80% of the total exchangeable cations. The cation-exchange capacity was detd. by equilibrating the bentonite (dried at 105°C) with 1*N* NH_4Cl, the excess NH_4Cl removed with 70% EtOH, and the adsorbed NH_3 developed with NaOH and $Ca(OH)_2$, distd., and detd. by titration.

3119. KUBLI, H. **Information on the separation of anions by adsorption on alumina.** *Helv. Chim. Acta* **30**, 453-63 (1947) (in German).—*C.A.* **41**, 4406*i*.

The adsorption on acid-washed alumina was detd. for: OH^-, PO_4^{-3}, $C_2O_4^{-2}$, F^-, [SO_3^{-2}, $Fe(CN)_6^{-4}$ and CrO_4^{-2}], $S_2O_3^{-2}$, SO_4^{-2}, [$Fe(CN)_6^{-3}$ and $Cr_2O_7^{-2}$], [NO_3^- and CNS^-], I^-, Br^-, Cl^-, NO_3^-, MnO_4^-, ClO_4^-, AcO^-, and S^{-2}. The sensitivity for analysis of many of these ions by adsorption and subsequent developing by another reagent was detd.

3120. LEVINE, A. K. AND JOFFE, J. S. **Fixation of potassium in relation to exchange capacity of soils. V. Mechanism of fixation.** *Soil Sci.* **63**, 407-16 (1947).—*C.A.* **41**, 7604*f*.

Evidence was presented in support of the contention that K was fixed between the layers of layer-lattice minerals. Expts. using a soln. of KCl with pyrophyllite, the basic unit of bentonite or montmorillonite, further demonstrated that K must first enter the exchange complex before being fixed, and that it must be in contact with pyrophyllite over an extended period of time for fixation to occur. When fixed, K became part of the mineral structure and a shrinkage in the basal spacing of the mineral occurred.

3121. MANUELE, RÁUL. **Evaluation of the adsorptive power of argil by polarography of manganese.** *Rev. facultad cienc. quim.* **22**, 55-65 (1947).—*C.A.* **44**, 11050*f*..

Treat a 0.1-0.2 g sample of a clay with 10 ml *N* $MnCl_2$ soln. centrifuge and decant. Repeat 4 times, and wash 3 times with 9-10 ml portions of 80% alc. Displace the adsorbed Mn^{++} from the satd. clay by 4 treatments with 7 ml 1 *N* KCl soln.; agitate, centrifuge, and decant each time into a 50 ml graduated flask. Fill the flask to 50 ml with KCl soln., and transfer aliquots into the cathodic tube of a polarograph standardized against various concns. of $MnCl_2$ in 1 *N* KCl. Measure Mn^{++} concn. under N_2. A clay was found to have an adsorptive power of 16.1 milliequiv. Mn/100 g, and of 15.6 milliequiv. Ca/100 g when the clay was acid-regenerated.

3122. MARSHALL, CHARLES E. AND McLEAN, E. O. **The activities of calcium and potassium ions as related to concentration and drying in clay suspensions.** *Soil Sci. Soc. Am. Proc.* **12**, 172-5 (1947) (pub. 1948).—*C.A.* **43**, 1132*i*.

K- and Ca-ion activities showed marked increase with clay concn. for montmorillonite (Wyoming bentonite), beidellite (Putnam clay), illite (grundite), and kaolinite. The percentage ionization varied relatively little with clay concn. Montmorillonite and beidellite showed definite evidence of a reduction in K-ion activity owing to previous drying, illite only slight reduction, and kaolinite not at all. Only montmorillonite clearly showed such an effect with Ca.

3123. MUKHERJEE, J. N.; CHATTERJEE, B., AND BANERJEE, B. M. **Liberation of hydrogen, aluminum, and ferric ions from hydrogen clays by neutral salts.** *J. Colloid Sci.* **2**, 247-56 (1947).—*C.A.* **41**, 4902*f*.

The liberation of Al^{+++} and Fe^{+++} by the action of a neutral salt on a H-clay was investigated to det. if there was a limit to the amt. of Al^{+++} and Fe^{+++} present at the surface. For both montmorillonitic and kaolinitic clays the amt. of Fe^{+++} and Al^{+++} decreased markedly after the first cycle, but an appreciable amt. of each ion was liberated in all succeeding cycles. With montmorillonitic clays, the amt. of Al^{+++} liberated increased after the 4th cycle. The sum of the displaced Al^{+++} and Fe^{+++} ions decreased but approached const. values with repeated treatment of both clays. Montmorillonitic and kaolinitic clays behaved quite differently during treatment to displace Al^{+++} and Fe^{+++} ions.

3124. PLANK, C. J. **Differences between silica and silica-alumina gels. II. A proposed mechanism for the gelation and syneresis of these gels.** *J. Colloid Sci.* **2**, 413-27 (1947).—*C.A.* **42**, 437*b*.

The extremely rapid gelation of SiO_2 and SiO_2-Al_2O_3 hydrosols under certain conditions and the sensitivity of gelation time to pH was demonstrated experimentally. The results suggested that the gelation reaction was ionic in nature.

3125. POLYAKOV, YU. A. **Thermodynamics of exchange adsorption of potassium and ammonium ions in soils.** *Kolloid. Zhur.* **9**, 439-46 (1947).—*C.A.* **43**, 7621*b*.

For 3 soils the validity of the equation $K = x^2/(g - x)(b - x)$ was established; x was the amt. of K adsorbed by an NH_4 soil, g the exchange capacity, and b the amt. of K in the soln. before adsorption. K was 1.4-1.9 and almost independent of temp. (18-70 °C). As the exchange adsorption was a reversible phenomenon, from the value of K the heat content, the free energy, and the entropy of the process were calcd.

3126. REID, A. AND SEN GUPTA, N. C. **Effect of sodium hexametaphosphate on the yield value and viscosity of a hydrogen bentonite suspension.** *Nature* **159**, 336-7 (1947).—*C.A.* **41**, 4994*i*.

The phosphate reduced both the yield value and the viscosity but the effect was greater on the former. More importantly, if the suspension was allowed to stand, the yield value did not increase.

3127. RENDIG, V. V. **Rapid determination of the base-exchange capacity of soils with the flame photometer.** *Soil Sci. Soc. Am., Proc.* **12**, 449-51 (1947) (Pub. 1948).—*C.A.* **43**, 2721*g*.

The soil was first base-satd. with neutral KOAc soln. and the excess salt was removed by washing with water and alc. The exchangeable K was extd. with a soln. of ammonium and Mg acetates and the amt. of K in the ext. was detd. with the flame photometer. In general, the results were slightly higher than those obtained by the NH_4OAc method and somewhat lower than by the $Ca(OAc)_2$ method.

3128. ROST, RUDOLF. **Clay minerals. II.** *Vestnik Stat. Geol. Ustavu Rep. Cekoslov.* **22**, 328-35 (in English 334-5) (1947).—*C.A.* **42**, 5381*i*.

An analysis, optical and dehydration data were given for montmorillionite from Kutna Hora. Base exchange expts. with NH_4NO_3 soln. on 2 montmorillionites and a beidellite showed 60-100% exchange of the CaO present, but only 14-30% exchange of the Mg present.

3129. RUSH, R. I.; WALKUP, J. H.; JOHNSON, FRANCES C., AND QUAST, ANN. **Banding of basic mercuric chloride in silica gel.** *J. Chem. Education* **24**, 238-9 (1947).— *C.A.* **41**, 4695*i*.

Bands of basic mercuric chloride in silica gel increased in no. from pH 7.0 to 9.0

3130. SEAY, W. A. AND WEEKS, M. E. **The fractionation and properties of clays from the surface soils of the Pearman and Maury series.** *Soil Sci. Soc. Am., Proc.* **12**, 24-8 (1947) (Pub. 1948).—*C.A.* **43**, 795*d*.

The clay was sepd. into 5 fractions. The SiO_2 decreased from the 1-2 μ fraction down to the 0.1-0.05 μ fraction. Base- and anion-exchange capacities increased directly with decrease in particle size. It appeared that the clays contained a mixt. of 1:1 and 2:1 type of clay minerals with the 2:1 type in greater proportion where the particle-size was smallest.

3131. SERB-SERBINA, N. N. AND REBINDER, P. A. **Structure formation in aqueous suspensions of bentonite clays.** *Kolloid. Zhur.* **9**, 381-91 (1947).—*C.A.* **43**, 5257*i*.

Thixotropic properties of 3 kinds of domestic clays were detd. by viscometry in a capillary plastometer and by tangential displacement of a thin Pt foil. Three types of shearing stress curves corresponded to 3 different mechanisms of structure formation and perturbation, the 1st to brittle rupture, the 2nd to thixotropic structure formation with plastic rupture, the 3rd to plastic flow.

3132. SIEFERT, A. C. AND HENRY, E. C. **Effect of exchangeable cations on hydrophylic nature of kaolin and bentonite.** *J. Am. Ceram. Soc.* **30**, 37-48 (1947).—*C.A.* **41**, 2868*b*.

The affinity of H_2O for a S. Carolina kaolin and Wyoming bentonite satd. with H, Ca, Na, and K was studied by 3 methods. The H and Ca clays showed a greater affinity for H_2O than the Na and K clays. Although the bentonite evolved more heat and sorbed more H_2O per g of clay, it evolved less heat and sorbed less H_2O per milliequiv. of exchangeable cation than did the kaolin.

3133. TEICHNER, STANISLAS. **Substitution of ions in montmorillonite.** *Compt. rend.* **225**, 1337-9 (1947);.—*C.A.* **42**, 2895*g*.

Retention of adsorbed H_2O and the specific surfaces were detd. of natural montmorillonite and of

Na-substituted montmorillonite, obtained by treating natural montmorillonite with dil. acid and neutralizing with soda. At room temp. natural montmorillonite retained 3 mols. of adsorbed H_2O per Ca^{++}, while Na-substituted montmorillonite retained 1 mol. of adsorbed H_2O per Na^+. This H_2O was given off only at about 90°C. At dehydration temps. of 20° and 180°C, resp. the B.E.T. surfaces (m^2 per g) were for natural montmorillonite 48 and 52; for Na-substituted montmorillonite 13.6 and 88. The H_2O adsorbed on natural montmorillonite appeared not to interfere with N_2 adsorption, while that on Na-substituted montmorillonite prevents adsorption of N_2 at centers where H_2O was located.

3134. Vettori, Leandro. **Determination of the need of soils for lime (determination of exchangeable hydrogen).** *Anais Assoc. Quim. Brasil* **6**, 167-80 (1947).—*C.A.* **42**, 5148*i*.

Percolate 10 g soil with 250 ml *N* $Ba(OAc)_2$ whose pH has been brought to 7 with AcOH, titrate 100 ml with 0.1 *N* NaOH to rose (5 drops 3% phenolphathalein) and subtract the vol. 0.1 *N* NaOH needed to bring 100 ml *N* $Ba(OAc)_2$ to rose.

3135. Aleshin, S. N. **Change of montmorillonite into hydro-mica.** *Doklady Akad. Nauk U.S.S.R.* **61**, 693-5 (1948).—*C.A.* **43**, 2549*f*.

The cation-exchanging part of the clay minerals in soils was usually detd. by electrodialysis and titration of the cations with HCl, with phenolphthalein as indicator. It was observed after this treatment and the exchange of the H^+ for K^+ from *N* KCl soln. that the base-exchange capacity of the product changed after repeated electrodialysis.

3136. Asselmeyer, Fritz. **Structure investigation of γAl_2O_3-gibbsite.** *Z. Angew. Physik* **1**, 26-35 (1948).—*C.A.* **43**, 3319*c*.

Eu nitrate in HNO_3 was mixed with suspended γ-Al_2O_3 in a ratio of 1 Eu ion to 200 Al ions. The prepn. was then ignited and stored over P_2O_5 until used. The ignited sample was irradiated with ultraviolet radiation and the fluorescent spectrum photographed. This method was based upon the fact that the streams of atoms in an electromagnetic field have their spectral lines split. In another method, perylene dissolved in cyclohexane was adsorbed on gibbsite and exposed to ultraviolet radiation and the resultant fluorescent spectrum photographed. The perylene spectrum showed, in the temp. region of the "fine structure," a clear displacement of intensities towards the short-wave region.

3137. Barbier, Georges and Chabannes, Jean. **Role of exchangeable cations in the adsorption of anions by clays.** *Compt. rend.* **226**, 749-51 (1948).—*C.A.* **42**, 5144*i*.

The amts. of PO_4 fixed by a suspension of kaolinite, previously treated to remove all free sesquioxides, increased with increasing pH. At a pH of 7.4, the amts. fixed varied in a manner indicative of adsorption.

3138. Barriol, Jean; Bloch, Jean Michel, and Kayser, Fernand. **Measurement of the thixotropy of suspensions of bentonite.** *Compt. rend.* **226**, 1899-1901 (1948).—*C.A.* **42**, 7601*f*.

A discussion of the comparison of results of thixotropy measurement on aq. suspensions of bentonite by a procedure which used a brass cylinder and another which used a torsion couple. Use was made of a set of hollow brass cylinders of mean d. d_c. The max. pressure that the gel can support was related to the height of emergence.

3139. Fricke, R. and Schmah, H. **The water solubility and alkali and zeolitic properties of aluminum hydroxide.** *Z. anorg. Chem.* **255**, 253-68 (1948).—*C.A.* **43**, 2070*g*.

The surface had basic properties and showed hydrolytic adsorption of KCl, K_2SO_4, and $KClO_4$ up to pH 9.5. Ion exchange with Ag occurred. With increasing age of the $Al(OH)_3$ prepn., these effects decreased. $Al(OH)_3$ could be used for chromatographic sepn. of $Fe_2(SO_4)_3$, $CuSO_4$, and $CoSO_4$. The Fe salts were in the upper zone, Cu in the middle, and Co below, as expected from their base strengths.

3140. Ganguly, A. K. and Gupta, S. L. **Hydration of exchangeable cations of clay minerals and synthetic resins.** *Science and Culture* **14**, 81-2 (1948).—*C.A.* **43**, 921*i*.

Exchangeable cations, including H, of oven-dry clay minerals were present in hydrated form. When clay minerals were converted into their resp. H systems, the exchangeable cations were replaced by H ions. On ignition of the oven-dry material, the original unconverted mineral lost a certain amt. of moisture as a result of the expulsion of the OH groups. The observed moisture loss was greater than that calcd. by assuming the exchangeable H to be present as H^+, but a close agreement was obtained if it was assumed to be hydrated as H_3O^+.

3141. Hoyos, Angel de Castro and Pascual Talavera, M. **Effect of pH on the properties of suspensions of clay materials.** *Anales inst. espan. edafol., ecol y fis vegetal* **2**, 273-313 (1948).—*C.A.* **43**, 4638*d*.

The vol. of sediment and time required for settling were specific for each material. There was a pos. relation between the properties of these suspensoids and their thixotropy and base-exchange capacity. Their properties as colloids varied with the pH and the concns. and natures of the electrolytes in the buffered solns. used. In most cases except clays and kaolins, where the ultimate particle was greater than 1.12 μ, the dispersion was max. around pH 7.8-7.9 where the concn. of electrolytes was small and dispersion was high on account of Na ions, and min. around 9.1 with high concns. of Cl and NH_4 ions.

3142. Kayser, Fernand and Bloch, Jean M. **The fixation of inorganic molecules upon bentonite.** *Compt. rend.* **226**, 251-3 (1948).—*C.A.* **42**, 4816*i*.

To fix AgCl, the clay in the Na form was agitated with $AgNO_3$ soln. and then treated with NaCl soln. In such a process 74 milliequivs. of Ag and 69 milliequivs. of Cl were fixed per 100 g of clay. In the Ag form, the Ag could easily be exchanged for K by washing with KNO_3 soln.; however, no exchange was observed after the AgCl had been formed. The ZnS and CdS bentonites were prepd. by the action of H_2S on the corresponding Zn and Cd bentonites.

3143. KIEFER, CHARLES. **The possibilities of bonding and of orientation of molecules of a liquid upon a solid.** *Compt. rend.* **226**, 1602-3 (1948).—*C.A.* **42**, 7600*i*.

The apparent viscosity depended principally on the quantity of free H_2O. Thixotropy occurred when the clay suspension contained only bound H_2O. The plasticity was explained by the friction between particles being that of H_2O upon H_2O. The variations in vols. of sediments depended partly on the proportion of bound H_2O.

3144. MIKHAL'CHENKO, V. A. **Volume change of various forms of silica on treatment with lime solution.** *Kolloid. Zhur.* **10**, 441-7 (1948).—*C.A.* **43**, 7777*f*.

The sedimentation vol. of a silica gel powder kept for days in H_2O or org. liquids did not change. The increase of sedimentation vol. produced by $Ca(OH)_2$ was greatest for silica gel fractions 10-50 μ and 100-250 μ (225% in 180 days), smaller for finer fractions, and smaller still for crushed quartz and sand, whose fraction 5-10 μ "swelled" more than the coarser and the finer fractions. In 100 days, the 1-5 μ fractions of SiO_2 gel, sand, and crushed quartz took up 0.943, 0.096, and 0.046 g CaO.

3145. MIKHAL'CHENKO, V. A. **Effect of the degree of hydration on the rate of absorption of lime by silica.** *Zhur. Priklad, Khim. (J. Applied Chem.)* **21**, 1025-31 (1948).—*C.A.* **44**, 403*d*.

The rate of absorption of lime by silica depended considerably, in addn. to other factors, upon the extent of hydration of the silica. Gel-like strongly hydrated silica absorbed lime intensively, whereas absorption by anhyd. silica was several times slower. Generally, the absorption of lime by silica had the character of a chem. process. By decreasing the hydration, the rate const. increased; for a specific degree of hydration the rate decreased with time (the measurements were taken over a 10-day period).

3146. MITRA, R. P. AND RAJAGOPALAN, K. S. **Electrical charges in layer-lattice silicates in relation to ionic exchange.** *Indian J. Phys.* **22**, 129-40 (1948).—*C.A.* **42**, 8562*f*.

Many layer-lattice silicates such as the micas and the clay minerals, when in a finely divided state, showed a marked capacity for ion exchange. The mechanism of this exchange and the nature and origin of the surface charges which held the exchangeable ions in the liquid phase at some distance from the surfaces of the crystallites were discussed. The most polar ions or groups on the surface were exchanged under suitable conditions for similarly charged ions in the liquid phase.

3147. SHAROV, V. S. **Clay as surface electrolyte and its electrolysis.** *Doklady Akad. Nauk S.S.S.R.* **60**, 829-32 (1948).—*C.A.* **42**, 8573*f*.

Diffusion of cations in clay was demonstrated by the penetration of Cu^{++} ions from a Cu-bentonite clay onto Ca-bentonite clay, both samples contg. 80% moisture and kept in close contace for 500 hrs; the depth of penetration of Cu^{++}, 0.5 cm, corresponded to a rate of diffusion of 0.001 cm/hr. The layer close to the cathode was colored blue-green by pptd. $Cu(OH)_2$ and could thus be sepd. and analyzed; its Cu content was found to be 49.8 mg, almost equal to the 50.9 mg Cu deposited in $CuSO_4$. Transference detns. between clays with various cations, Ca^{++}, Mg^{++}, Ba^{++}, Cu^{++}, all with 80% moisture, showed that, under 1 v./cm, the mobilities of these ions in clay were about 17 times lower than in dil. aq. soln.

3148. SIEWERT, GERHARD AND JUNGNICKEL, HORST. **Ion exchange in commercial aluminum oxides.** *Z. anorg. Chem.* **257**, 215-22 (1948).—*C.A.* **43**, 4076*c*.

Com. Al_2O_3 contained Na_2CO_3 and $NaHCO_3$ which could be removed by washing. Some samples thereby lost their adsorptive properties for salt solns., whereas others developed a capacity for anion exchange and could release bases such as quinine or NH_3 from their salts.

3149. YARUSOV, S. S. **A study of exchange acidity.** *Doklady Vsesoyuz Akad. Sel'sko-Khoz. Nauk im. V. I. Lenina 13, No.* **1**, 14-21 (1948).—*C.A.* **42**, 6481*d*.

By using NaF on a soil extd. after having been treated with $Ca(OH)_2$, the exchangeable Al could be titrated according to the following equations: $Al^{+++} + Ca(OH)_2 \rightarrow$ Ca soil $+ Al(OH)_3$; $Al(OH)_3 + 6\ NaF \rightarrow Na_3AlF_6 + 3\ NaOH$. It was considered that the exchange acidity in the surface horizons depended primarily on adsorbed H ions.

3150. BARSHAD, ISAAC. **Vermiculite and its relation to biotite as revealed by base-exchange reactions, x-ray analyses, differential thermal curves, and water content.** *Am. Mineral.* **33**, 655-78 (1949).—*C.A.* **43**, 8987*i*.

K-satd. vermiculite closely approximated biotite. Hydrobiotite was converted to vermiculite by leaching with $MgCl_2$ soln. The exchangeable bases of vermiculite occupied interlayer positions. Base-exchange expts. showed that vermiculite, even in large flakes, had high base-exchange capacity. The exchangeable cation was Mg only in some samples, Mg and Ca in others.

3151. BERTHIER, PAULETTE. **Variation of the refractive index of colloidal hydrosols under different influences.** *Rev. Sci.* **86**, 679-80 (1949).—*C.A.* **44**, 3768*i*.

The n of Al_2O_3 sols contg. up to 0.05 N KCl was additive; this fact indicated that within exptl. error very little KCl was adsorbed by the Al_2O_3 particles. ThO_2 sols + KCl showed comparable results. Al_2O_3 + tannin, Al_2O_3 + blood albumin, and ThO_2 sols + SiO_2 sols all showed additive values for n. The adsorption of Na_3PO_4, K_2SO_4, and tannin by Al_2O_3 sols when the sol was flocculated was detd. by calcg. the variation of n that corresponded to the amt. of electrolyte adsorbed by the Al_2O_3 particles.

3152. BHATTACHARYA, ABANI K. **The composition of ferric arsenite and ferrous arsenate. II. Composition of the so-called ferric arsenite (product of mixing ferric chloride and sodium metarsenite).** *J. Indian Chem. Soc.* **26**, 99-102 (1949).—*C.A.* **43**, 8296*c*.

When aq. solns. of $FeCl_3$ and $NaAsO_2$ were mixed at high concns., a mixt. of arsenite and arsenate of Fe was obtained with some free Fe_2O_3 and adsorbed arsenite. When $FeCl_3$ was added in more than its equiv. amt. to $NaAsO_2$, a colloidal soln. was obtained.
