TERMINOLOGY AND SCALING PRACTICES

The symbols and terminology used in this report are those adopted by the International Radio Propagation Conference, and given in detail on pages 24 to 26 of the report IRPL-C61, "Report of International Radio Propagation Conference," and in the Section on "Terminology", in reports IRPL-F1, 2, 3, 4, 5.

Beginning with data reported for September, a new symbol, L, defined as follows, is adopted for use in detailed tabulations of hourly values of ionosphere characteristics observed at Washington:

> L or l = critical frequency, muf, or muf factor for F1 layer omitted because no definite and abrupt change in slope of the h'f curve occurs either for the first reflection or for any of the multiples. (See "Report of International Radio Propagation Conference," IRPL-C61, June 1944, VI 3c, p.37).

In the past, ionospheric conditions were summarized on a monthly basis by using average or mean values, for each hour of the day, for each month. However, following the recommendations of the International Radio Propagation Conference, held in Washington 17 April to 5 May 1944, beginning with data for 1 Jan. 1945, median values were used by IRPL wherever possible. Thus, median values are given for Washington, for all stations reporting directly to the IRPL, for the Canadian stations, and for all others sending in detailed tabulations to the IRPL, from which medians can be computed.

Where averages are reported, they are, at any hour, the average for all the days during the month for which numerical data existed.

The monthly median values used here are the values equalled or exceeded on half the days of the month at the given hour. The following conventions are used in determining the medians for hours when no measured values are given, because of equipment limitations and ionospheric irregularities. Symbols used are those given in the report referred to above, IRPL-C61.

a. For all ionospheric characteristics:

Values missing because of A, B, C or F (see terminology referred to above) are omitted from the median count.

b. For critical frequencies and virtual heights:

Values missing because of E are counted as equal to or less than the lower limit of the recorder.

Values missing because of D are counted as equal to or greater than the upper limit of the recorder.

Values missing because of G are counted:

1. For $f^{o}F2$, as equal to or less than $f^{o}F1$.
2. For $h'F2$, as equal to or greater than the median.

Values missing for any other reason are omitted from the median count.

c. For muf factors (M-factors):

Values missing because of G are counted as equal to or less than the median.

Values missing for any other reason are omitted from the median count.

d. For sporadic E (Es):

Values of fEs missing because no Es reflections appeared, the equipment functioning normally otherwise, are counted as equal to or less than the lower limit of the recorder.

Values of fEs missing for any other reason, and values of hEs missing for any reason at all, are omitted from the median count.

Beginning with data for November 1945, doubtful monthly median values for ionospheric observations at Washington, D.C., are indicated by a parenthesis, in accordance with the practice already in use for doubtful hourly values. The following are the conventions used to determine whether or not a median value is doubtful:

1. If only four values or less are available, no median value is computed, the data being considered insufficient.

2. For the F2 layer, if only five to nine values are available, the median is considered doubtful.

The E and F1 layers are so regular in their characteristics that, so long as there are at least five values, the median is not considered as doubtful.

3. If more than half of the values used to compute the median are doubtful (either doubtful or interpolated), the median is considered doubtful.

It is expected that this practice will be of assistance in evaluating the monthly median Washington data.

MONTHLY AVERAGE AND MEDIAN VALUES OF IONOSPHERIC DATA

The ionospheric data given here in graphical and tabular form were assembled by the Interservice Radio Propagation Laboratory for analysis and correlation, incidental to IRPL predictions of radio propagation conditions. The following are the sources of the data;

Australian Council for Scientific and Industrial Research, Radio Research Board, Australia;
- Brisbane, Australia
- Canberra, Australia
- Cape York, Australia

British National Physical Laboratory, and Inter-Services Ionosphere Bureau;
- Slough, England
- Great Baddow, England
- Burghead, Scotland
- Delhi, India
- Capetown, Union of S. Africa
- Colombo, Ceylon

Canadian Radio Wave Propagation Committee;

The tables of "provisional data" give values as reported to the IRPL by telephone or telegraph. Any errors in these values will be corrected in later issues of the F-series reports. In final data tabulations, any omission of values previously given in provisional tabulations is indicated by a dash.

The tables and graphs of "final data" are correct for the values reported to the IRPL, but, because of variations in practice in the interpretation of records and scaling and manner of reporting of values, may at times give an erroneous conception of typical ionospheric characteristics at the station. Some of these errors are due to:

a. Differences in scaling records where spread echoes are present.

b. Omission of values where $f^{o}F2$ is less than or equal to $f^{o}F1$, leading to erroneously high values of monthly average or median values.

c. Omission of values where critical frequencies are less than the lower frequency limit of the recorder, also leading to erroneously high values of monthly average or median values.

These effects were discussed on pages 6 and 7 of the previous F-series reports, IRPL-F1, 2, 3, 4, and 5. Discrepancies between predicted and observed values are often ascribable to these effects.

IONOSPHERIC DATA FOR EVERY DAY AND HOUR

These data, observed at Washington, D.C., follow the scaling practices given in the report IRPL-C61, "Report of International Radio Propagation Conference," pages 36 to 39, and the median values are determined by the conventions given under "Terminology and Scaling Practices" above.

IONOSPHERE DISTURBANCES

Table 65 presents ionosphere character figures for Washington, D.C., during November 1945, as determined by the criteria presented in the report IRPL-R5, "Criteria for Ionospheric Storminess", together with American magnetic K-figures which are usually covariant with them.

Table 66 gives provisional radio propagation quality figures for North Atlantic and North Pacific areas, for 01 to 12 and 13 to 24 GCT, October 1945, compared with the IRPL daily radio disturbance warnings, and ISIB daily warnings, the IRPL semiweekly radio propagation forecasts for the A-zone, and the half-day American geomagnetic K-figures.

The radio propagation quality figures were prepared from radio traffic data, reported to IRPL, in the manner described in detail in report IRPL-R13, "Ionospheric and Radio Propagation Disturbances, October 1943 through February 1945," issued 24 May 1945.

SEASONAL VARIATIONS IN F2-LAYER CRITICAL FREQUENCIES

The complexity of variations in F2-layer critical frequencies, which are manifest with changes in solar activity, geographical location, season, and time of day (Cf. IRPL-R4, "Methods Used by IRPL for the Prediction of Ionosphere Characteristics and Maximum Usable Frequencies") is such that their analysis is best effected by the separate consideration of each of these types of covariance. In the previous issue of this report, IRPL-F15, a preliminary survey was presented of geographical-diurnal variations of yearly-average $f^{o}F2$ at a constant value of solar activity. World-wide distribution of purely seasonal variations, expressed by ratios of monthly-average $f^{o}F2$ to the corresponding yearly-average values, is presented herewith for the months of June, September, and December, as a survey of conditions typical of summer solstice, equinox, and winter solstice.

The ratio of monthly-average to yearly-average $f^{o}F2$ for any hour, at any given location, is nearly constant, although there sometimes appears a slight variation in this ratio with solar activity. (IRPL-R4, "Methods Used

by IRPL for the Prediction of Ionospheric Characteristics and Maximum Usable Frequencies"; IRPL-R11, "A Nomographic Method for Both Prediction and Observation Correlation of Ionosphere Characteristics.") In the present report this slight change with solar activity is not considered, the ratios of monthly-average to yearly-average $f^{o}F2$ given being the mean values of these ratios for all available data.

Figs. 47 through 52 present variations of the ratios of monthly-average to yearly-average $f^{o}F2$, at noon and midnight, for the months of June, September, and December. The reliability of the points plotted on these curves is considerably less than that of the yearly-average values, plotted in similar fashion, which were presented in the previous issue of this report, IRPL-F15, since these represent averages of one-twelfth as many measurements, and, in some cases, solar activity variations in the ratio are apparent.

As in the case of the yearly-average values of $f^{o}F2$, there is pronounced variation with longitude, as shown by the difference in variation between the series of values for ionosphere stations in the W, I, and E zones of the IRPL-D series prediction charts. There is likewise a difference between northern and southern hemisphere values, apart from that due to change in solar declination, as is shown by the discrepancy between the series of values for the given month in any zone, and the values plotted at reverse latitude for opposite season, (the month six months later or earlier).

Because of constant sunlight on the north pole during June, and on the south pole during December, values of the ratio of monthly-average to yearly-average $f^{o}F2$ are higher than unity in these cases, and less than unity during opposite seasons. Midnight values are particularly high in the southern hemisphere during December, and in the northern hemisphere during June, with equinox values approximating unity in both hemispheres. In September, the average solar declination is 3^{o} north of the equator, and therefore northern-hemisphere values of the ratio are slightly greater than unity, southern-hemisphere values slightly less than unity. In all cases, there appear slightly increased values of the ratio near the subsolar point. These variations in midnight values of the ratio are principally because of the great delay in ionic recombination at F2-layer heights, probably caused by solar heating of the atmosphere.

Midday variations in the ratio are far more complex, since they entail both this change in recombination rate, and the appearance of F1-layer ionization, the former tending to increase the ratio with increasing amount of sunlight, the latter tending to decrease it. In general, less departure from yearly-average values of $f^{o}F2$ is shown for midday. The values of the ratio more nearly approximate unity during all seasons, being generally low during June and high during December.

Figs. 54 through 61 present world-wide variations of the ratio of monthly-average to yearly-average $f^{o}F2$ for W, I and E zones, during June, September, and December, in the form of contour charts on a latitude versus local-time grid, where the contour lines represent values of the ratio.

These charts were prepared by drawing, for each hour, latitude-variation curves of the type shown in Figs. 47 through 52, plotting these values as contour points, and smoothing to obtain general consistency among them, then multiplying the smoothed values by smoothed yearly-average values for a constant sunspot number obtained in similar fashion from curves of the type shown in Figs. 83 through 88 of IRPL-F15, thus reproducing typical diurnal curves for each 10° of latitude, correcting these curves where necessary (very little correction being needed, in general) to agree with actual data, as a check on smoothing estimation, and finally replotting the corrected values.

The relatively low gradients shown by the contour lines for September indicate, as might be expected, that values of $f^{o}F2$ during the equinox season approximate yearly-average values. The generally high equatorial values during night hours may be due to the terrestrial temperature lag behind seasonal variations of solar radiation.

The contour lines for the solstice months of June and December show that the most important variation of the ratio of monthly-average to yearly-average $f^{o}F2$ is associated with the seasonal change of sunrise and sunset times at ionosphere heights. It is of interest that the contours of this ratio for these seasons are roughly similar to the contours of $f^{o}F2$ for the opposite season, as may be seen by comparison of these charts with corresponding prediction charts of $f^{o}F2$, issued in reports of the IRPL-D series.

Reasons for certain seasonal variations, shown by these contour charts, are not readily apparent. It is possible that some of these are not significant, inasmuch as there are as yet insufficient data for making precise estimates of seasonal variation for certain regions. Further acquisition of ionospheric data should, however, establish their significance, and further study of these seasonal variations, especially where significant departures from regular variation with solar declination are manifest, should afford information concerning upper-atmospheric circulation and possibly concerning the effects of solar-corpuscular ionization.

ERRATA

1. In F11 (issued July 1945), Table 29, Baton Rouge, Louisiana, May 1945, $f^{o}F2$ at 1700 should have been 7.6 instead of 9.6.

2. In F13 (issued September 1945), Table 39, Slough, England, June 1945, $f^{o}F2$ at 0300 should have been 4.7 instead of 4.6.

*Ionosphere character figure (I-figure) for ionospheric storminess at Washington, D.C., during 12-hour period, on an arbitrary scale of 0 to 9, 9 representing the greatest disturbance.

**Average for 12 hours of American magnetic K-figure, determined by a number of observatories, on an arbitrary scale of 0 to 9, 9 representing the greatest disturbance.

/No major storms were observed at Washington during November 1945.

Daily:
Telephoned and telegraphed reports of ionospheric, solar, geomagnetic, and radio propagation data from various places.
Radio disturbance warnings

Semiweekly:
IRPL-J. Radio Propagation Forecast.

Semimonthly:
IRPL-Ja. Semimonthly Frequency Revision Factors for IRPL Basic Radio Propagation Prediction Reports (issued with IRPL-J series from 4 to 7 days in advance).

Monthly:
IRPL-D. Basic Radio Propagation Predictions - Three months in advance. War Dept. TB 11-499-, monthly supplements to TM 11-499; Navy Dept. (DNC-13-1( ), monthly supplements to DNC-13-1.)
IRPL-F. Ionospheric Data.

Bimonthly:
IRPL-G. Correlation of D. F. Errors With Ionospheric Conditions.

Quarterly:
*IRPL-A. Recommended Frequency Bands for Ships and Aircraft in the Atlantic and Pacific.
IRPL-B. Recommended Frequency Bands for Submarines in the Pacific.
*IRPL-H. Frequency Guide for Operating Personnel.
**IRPL-M. Frequency Guide for Merchant Ships.

Special Reports, etc.:
IRPL Radio Propagation Handbook, Part 1. (War Dept. TM 11-499; Navy Dept. DNC-13-1.)
IRPL-C1 through C61. Reports and papers of the International Radio Propagation Conference, 17 April to 5 May 1944.
IRPL-R. Unscheduled reports:
R1. Maximum Usable Frequency Graph paper.
R2 and R3. Obsolete.
R4. Methods Used by IRPL for the Prediction of Ionosphere Characteristics and Maximum Usable Frequencies.
R5. Criteria for Ionospheric Storminess.
R6. Experimental studies of ionospheric propagation as applied to a navigation system.
R7. Further studies of ionospheric propagation as applied to a navigation system.
R8. The Prediction of Usable Frequencies Over a Path of Short or Medium Length, Including the Effects of Es.
R9. An Automatic Instantaneous Indicator of Skip Distance and MUF.
R10. A method for study of the ionosphere.
R11. A Nomographic Method for Both Prediction and Observation Correlation of Ionosphere Characteristics.
R12. Ionospheric variations.
R13. Ionospheric and Radio Propagation Disturbances, October 1943 through February 1945.
R14. A Graphical Method for Calculating Ground Reflection Coefficients.
R15. Predicted Limits for F2-layer Radio Transmission Throughout the Solar Cycle.
R16. Predicted F2-layer Frequencies Throughout the Solar Cycle, for Summer, Winter, and Equinox Season.
R17. Japanese Ionospheric Data - 1943.
R18. Comparison of Geomagnetic Records and North Atlantic Radio Propagation Quality Figures - October 1943 through May 1945.
R19. Nomographic Predictions of F2-layer Frequencies Throughout the Solar Cycle, for June.
R20. Nomographic Predictions of F2-layer Frequencies Throughout the Solar Cycle, for September.
R21. Notes on the Preparation of Skip-Distance and MUF Charts for Use by Direction-Finder Stations. (For distances out to 4000 km.)
R22. Nomographic Predictions of F2-layer Frequencies Throughout the Solar Cycle, for December.
R23. Solar-Cycle Data for Correlation with Radio Propagation Phenomena.
R24. Effect of certain equipment characteristics on the usefulness of a navigation system.
R25. The Prediction of Solar Activity as a Basis for Predictions of Radio Propagation Phenomena.
R26. The Ionosphere as a Measure of Solar Activity.

IRPL-T. Reports on Tropospheric Propagation.
T1. Radar Operation and Weather. (Superseded by JANP 101.)
T2. Radar coverage and weather. (Superseded by JANP 102.)
