27 **NIST Technical Series Publications:** <https://www.nist.gov/nist-research-library/nist-publications>

28 **Reports on Computer Systems Technology**

29 The Information Technology Laboratory (ITL) at the National Institute of Standards and Technology  
30 (NIST) promotes the U.S. economy and public welfare by providing technical leadership for the  
31 Nation's measurement and standards infrastructure. ITL develops tests, test methods, reference data,  
32 proof of concept implementations, and technical analyses to advance the development and productive  
33 use of information technology. ITL's responsibilities include the development of management,  
34 administrative, technical, and physical standards and guidelines for the cost-effective security and  
35 privacy of other than national security-related information in federal information systems.

36 **References to Other Publications**

37 There may be references in this publication to other publications currently under development by  
38 NIST in accordance with its assigned statutory responsibilities. The information in this publication,  
39 including concepts and methodologies, may be used by federal agencies even before the completion  
40 of such companion publications. Thus, until each publication is completed, current requirements,  
41 guidelines, and procedures, where they exist, remain operative. For planning and transition purposes,  
42 federal agencies may wish to closely follow the development of these new publications by NIST.

43 Organizations are encouraged to review all draft publications during public comment periods and  
44 provide feedback to NIST. Many NIST cybersecurity publications, other than the ones noted above,  
45 are available at <https://csrc.nist.gov/publications>

46 **Non-Endorsement Disclaimer**

47 Certain equipment, instruments, software, or materials, commercial or non-commercial, are identified  
48 in this paper in order to specify the experimental procedure adequately. Such identification does  
49 not imply recommendation or endorsement of any product or service by NIST, nor does it imply  
50 that the materials or equipment identified are necessarily the best available for the purpose.

51 **Call for Patent Claims**

52 This public review includes a call for information on essential patent claims (claims whose use  
53 would be required for compliance with the guidance or requirements in this Information Technology  
54 Laboratory (ITL) draft publication). Such guidance and/or requirements may be directly stated in  
55 this ITL Publication or by reference to another publication. This call also includes disclosure, where  
56 known, of the existence of pending U.S. or foreign patent applications relating to this ITL draft  
57 publication and of any relevant unexpired U.S. or foreign patents. ITL may require from the patent  
58 holder, or a party authorized to make assurances on its behalf, in written or electronic form, either:

- 59 1. assurance in the form of a general disclaimer to the effect that such party does not hold and  
60 does not currently intend holding any essential patent claim(s); or
- 61 2. assurance that a license to such essential patent claim(s) will be made available to applicants  
62 desiring to utilize the license for the purpose of complying with the guidance or requirements  
63 in this ITL draft publication either:
  - 64 (a) under reasonable terms and conditions that are demonstrably free of any unfair  
65 discrimination; or
  - 66 (b) without compensation and under reasonable terms and conditions that are demonstrably  
67 free of any unfair discrimination.

68 Such assurance shall indicate that the patent holder (or third party authorized to make assurances on  
69 its behalf) will include in any documents transferring ownership of patents subject to the assurance,  
70 provisions sufficient to ensure that the commitments in the assurance are binding on the transferee,  
71 and that the transferee will similarly include appropriate provisions in the event of future transfers  
72 with the goal of binding each successor-in-interest.

73 The assurance shall also indicate that it is intended to be binding on successors-in-interest regardless  
74 of whether such provisions are included in the relevant transfer documents.

75 Such statements should be addressed to: [nistir-8214C-comments@list.nist.gov](mailto:nistir-8214C-comments@list.nist.gov)

## 88 **Abstract**

89 This document calls for public submissions of multi-party threshold schemes, and other  
90 related crypto-systems, to support the United States National Institute of Standards and  
91 Technology (NIST) in gathering a public body of reference material on advanced cryptogra-  
92 phy. In a threshold scheme, an underlying cryptographic primitive (e.g., signature, encryp-  
93 tion, decryption, key generation) is computed in a distributed manner, while a private/secret  
94 key is or becomes secret shared across various parties. Threshold schemes submitted in  
95 reply to this “NIST Threshold Call” should produce outputs that are “interchangeable”  
96 with a reference conventional (non-threshold) primitive of interest, from various categories  
97 organized into two classes: Class **N**, for selected **NIST**-specified primitives; and Class **S**, for  
98 special primitives that are not specified by NIST but are threshold-friendlier or have useful  
99 functional features. The scope of Class S also includes fully-homomorphic encryption,  
100 zero-knowledge proofs, and auxiliary gadgets. This document specifies the requirements  
101 for submission (including specification, implementation, and evaluation), along with phases  
102 and deadlines. The ensuing public analysis will support the elaboration of a characterization  
103 report, which may help assess new interests beyond the cryptographic techniques currently  
104 standardized by NIST, and may include recommendations for subsequent processes.

## 105 **Keywords**

106 Crypto-systems; distributed systems; fully-homomorphic encryption (FHE); post-quantum  
107 cryptography (PQC); secure multi-party computation (MPC); threshold cryptography;  
108 threshold encryption; threshold schemes; threshold signatures; zero-knowledge proofs (ZKP).

## Preface

The exploration of “advanced” cryptography is a challenging endeavor from a standardization perspective, possibly requiring “advanced” or at least customized processes. *What and when to standardize or issue recommendations? Focus on building blocks or protocols? Which security properties to require? How to navigate a space of numerous possibilities?*

This “NIST First Call for Multi-Party Threshold Schemes” (or simply the “Threshold Call”) establishes a process for international community engagement aligned with the development of reference material. The call stands at the threshold of advanced cryptography, putting forward a proactive exploration of advanced cryptographic techniques of increasing relevance and utility. Primarily, the call deals with threshold cryptography and related multi-party computation (MPC) techniques, allowing distribution of trust in the implementation of cryptographic primitives, such as those standardized by NIST. The call is also open to special types of primitives not standardized by NIST, including fully-homomorphic encryption (FHE) and zero-knowledge proofs (ZKP). The process aims to establish a high-quality body of reference material, to be analyzed with public engagement.

In order to promote transparency, involvement and collaboration, the Threshold Call:

- was widely disseminated in advance, via the publication of an initial public draft in 2023 and subsequent presentations to the community;
- was open to public comments, discussed in various workshops, and subject to further review via a second public draft;
- promotes a collaborative environment, by allowing a submission package to propose multiple crypto-systems, possibly developed by different subteams;
- encourages the early presentation of plans (“previews”) for future package submissions, to enable public awareness and discussion while teams can still adapt.

Overall, this document is intended for: cryptography experts interested in providing constructive technical feedback; or in collaborating in the development of open reference material, technicians engaged in the development of recommendations for threshold schemes and advanced cryptography; and those, in academia, industry, government and the general public, who are interested in future recommendations about threshold schemes.

## 279 **Acknowledgments**

280 The authors thank their NIST colleagues Harold Booth, Chris Celi, Lily Chen, Michael  
281 Davidson, John Kelsey, Dustin Moody, Ray Perlner, Andrew Regenscheid, Angela Robinson,  
282 Hamilton Silberg, and Meltem Sönmez Turan, for their feedback on diverse aspects of this  
283 call. The authors also thank Isabel Van Wyk, from NIST, for various editorial comments.  
284 Additionally, the authors thank the 32 people that submitted feedback [[NIST-IR8214C-ipd-](#)  
285 [comms](#)] in response to the January 2023 initial public draft (ipd) of this publication, and  
286 the many other researchers who demonstrated interest throughout various conversations  
287 at events and through invitations for related presentations.

## 288 **Note to the Reviewers**

289 **Do not submit threshold schemes yet.** This publication [[NIST-IR8214C-2pd](#)] is a second  
290 public draft (2pd). Submissions should wait until the final version is published.

291 The initial public draft (ipd) [[NIST-IR8214C-ipd](#)] was released in January 2023, requesting  
292 public comments and encouraging early preparation of potential submissions. A compilation  
293 of received comments is available on the [publication webpage](#) hosted by the NIST Computer  
294 Security Resource Center (CSRC). Further public feedback was obtained during the NIST  
295 Multi-Party Threshold Schemes (MPTS) 2023 workshop [[MPTS-2023](#)].

296 This 2pd has substantial changes (see list in Appendix E) compared with the ipd, although  
297 the type of material needed for submission is largely similar. The publication of this new  
298 public draft opens an additional period for public comments, before the final version is  
299 released. Related comments for community discussion are welcome via the MPTC-forum.  
300 However, public comments intended for consideration during the final revision of the  
301 document should be sent by April 30, 2025 to [nistir-8214C-comments@list.nist.gov](mailto:nistir-8214C-comments@list.nist.gov). Teams  
302 are encouraged to prepare for upcoming submissions using the present draft as a baseline.

## 1. Introduction

### 1.1. A Variety of Cryptographic Schemes and Primitives

**Traditional techniques.** For several decades, the United States National Institute of Standards and Technology (NIST) has standardized important cryptographic schemes, in various Federal Information Processing Standards (FIPS) publications, and in Special Publications (SP) in Computer Security (the SP 800 series). For example, they specify digital signatures [FIPS-186-5], public-key encryption (e.g., for key-encapsulation) [SP800-56B-Rev2], pair-wise key-agreement [SP800-56A-Rev3], symmetric-key encryption (e.g., based on block-ciphers [FIPS-197]), hashing [FIPS-180-4; FIPS-202], and message authentication [SP800-224-ipd; SP800-185; SP800-38B].

**Recent standards.** In the last decade, NIST also started the Post-Quantum Cryptography (PQC) process [Proj-PQC] to devise new standards for post-quantum key-encapsulation methods [FIPS-203] and (stateless) signatures [FIPS-204; FIPS-205], and started the Lightweight Cryptography (LWC) process [Proj-LWC] to select primitives for a new standard for authenticated encryption with associated data and hashing-style primitives [NIST-IR8454].

**Advanced cryptography.** Beyond standardization, NIST has also taken an exploratory interest in the areas of privacy-enhancing cryptography [Proj-PEC] and multi-party threshold cryptography [Proj-MPTC]. These areas of advanced cryptography deal with secure multi-party computation (MPC), which enables collaborations while ensuring correctness, privacy and composability within more complex systems. Other important techniques in scope are fully homomorphic encryption (FHE) and zero-knowledge proofs (ZKP). The related state of the art continues evolving based on important developments by the cryptography community, including from academia and industry.

**Secret/private keys.** The mentioned schemes include: key-generation (KeyGen) primitives, which output a private or secret key; key-based primitives (e.g., signing, decryption, enciphering, which require a private or secret key as input); and key-less primitives (e.g., hashing) that can nonetheless be applied to keys with secrecy requirements. In a traditional specification or implementation of these schemes/primitives, the operations are usually considered as performed by an individual party (e.g., a computing device) with access to the private or secret key. In a conventional implementation, that party is a *single-point of failure* for confidentiality, integrity and availability.

**Threshold schemes.** Modern cryptography enables a multi-party implementation paradigm based on developments in the fields of threshold cryptography MPC and

336 distributed systems. In a (multi-party) *threshold* scheme, multiple parties perform a  
337 distributed computation that emulates the operation of a cryptographic algorithm, but  
338 without combining the private/secret key in any single place. This paradigm enables the  
339 decentralization of trust regarding the creation, storage and use of the private/secret keys.  
340 For appropriately defined notions of security, the interaction remains secure as long as the  
341 number of corrupted parties does not exceed a certain corruption *threshold*.

## 342 1.2. The NIST Threshold Call

343 The development of recommendations for threshold schemes, tapping into the domain of  
344 advanced cryptography, is an important step in addressing various challenges in cybersecurity  
345 and privacy. The increasing relevance of advanced cryptography warrants a proactive  
346 exploration [NIST-IR7977], in this case by opening a solicitation for structured inputs, to  
347 be open for for public analysis.

348 The present “NIST First Call for Multi-Party Threshold Schemes” (or simply the “Thresh-  
349 old Call”) is expected to motivate broad community engagement and result in a diverse  
350 set of high-quality submissions, followed by expert public scrutiny. The submissions will  
351 include specifications (with technical description and security analysis), implementations  
352 and experimental evaluation. The collection to be gathered is intended to form a public  
353 body of open reference material, whose analysis will help identify sound approaches, best  
354 practices, and reusable building blocks. The results will help shape future recommendations  
355 and guidelines. More concretely, the Threshold Call has the following goals:

- 356 1. **Reference material:** Create a basis of properly motivated, specified, implemented  
357 and analyzed threshold schemes, to support future recommendations and guidelines.
- 358 2. **Threshold feasibility:** Assess the viability of threshold implementations of various  
359 cryptographic primitives of interest, including selected NIST-specified primitives.
- 360 3. **Pertinence of other primitives:** In the threshold context, facilitate an initial assess-  
361 ment of the merits of other cryptographic primitives that may be mature for adoption.
- 362 4. **Quantum resistance and other features:** Examine the threshold readiness of  
363 post-quantum cryptography and other advanced functional features.

364 **Two classes in scope.** To assess the viability of threshold schemes for cryptographic  
365 primitives, the scope of the Threshold call is organized into two classes, each with various  
366 categories (as listed in Table 1) of primitives in consideration for thresholdization:

- 367 • **Class N:** NIST-specified cryptographic primitives (including quantum-vulnerable and  
368 post-quantum) used in digital signature schemes, public-key encryption schemes, sym-

metric-key encryption, message-authentication codes, hashing, and key-generation (also including elliptic-curve based primitives for pair-wise key-establishment).

- **Class S:** Special primitives not specified by NIST, including threshold-friendly primitives for schemes of the same type as in Class N, and others for fully-homomorphic encryption, zero-knowledge proofs of knowledge, and auxiliary gadgets.

**Table 1.** Multiple categories per class

	Sign	PKE	Symm	KeyGen	FHE	ZKPoK	Gadgets
Class N	N1	N2	N3	N4	—	—	—
Class S	S1	S2	S3	S4	S5	S6	S7

**Legend:** Class N = NIST-specified; Class S = Special, not specified by NIST. FHE = Fully-Homomorphic Encryption. KeyGen = Key Generation. PKE = Public-Key Encryption. Symm = Symmetric. ZKPoK = Zero-Knowledge Proof of Knowledge.

The analysis of threshold schemes for NIST-specified primitives (i.e., in Class N) will help assess threshold friendliness and develop future recommendations highlighting reference approaches, techniques, building blocks, and best practices. The analysis in Class S will help assess new interests in primitives that are not currently standardized by NIST, and characterize the possible alignment between (i) threshold-friendliness, (ii) post-quantum readiness, and (iii) additional useful features. This may also become useful input to assess the readiness to deploy MPC for applications with advanced privacy requirements.

Overall, this incursion is intended to clarify the feasibility and security of various techniques in advanced cryptography, including an analysis of threshold friendliness.

**Dissemination and feedback.** Recent NIST context leading to the formulation of this Threshold Call can be found on the Multi-Party Threshold Cryptography (MPTC), and Privacy-Enhancing Cryptography (PEC) project websites, the NIST-IR8214A (2020) with considerations toward criteria, the MPTC-Call2021a for feedback on criteria for multi-party threshold schemes (MPTS), the MPTS 2020 workshop webpage, the NIST-IR8214B-ipd on threshold EdDSA/Schnorr signatures (2022), and the MPTS 2023 workshop webpage.

Since the publication of the initial public draft in January 2023, the idea of the “Threshold Call” has also been widely disseminated and socialized with the cryptography community, through talks and conversations at international conferences, including conferences organized by the International Association for Cryptologic Research (IACR).

**Organization.** Section 2 calls for submissions and explains the partition into two classes. Section 3 conveys a vision about the collaborative process, including the context of post-quantum migration, interchangeability, provable security, and a variety of options. Section 4

401 enumerates the phases and tentative deadlines. Section 5 explains the logistic requirements  
402 for the written specification. Section 6 discusses the required reference implementation.  
403 Section 7 asks for an experimental evaluation. Section 8 presents requirements about classic  
404 and quantum security strength and threshold security. Sections 9 and 10 specify submission  
405 requirements per category. Appendices A and B give informative details about primitives  
406 in scope. Appendix C suggests a baseline system model for the threshold setting, and  
407 comments on threshold security, profiles, and input/output interfaces. Appendix D defines  
408 the acronyms used in the document. Appendix E lists changes between the two public drafts.

## 409 2. Scope of the Call: Two Classes

410 This is a public **call** for high-quality submissions of multi-party threshold schemes for  
411 selected types of primitive across two classes: **Class N** (NIST-specified) and **Class S** (special  
412 others). The latter also includes auxiliary components, such as zero-knowledge proofs of  
413 knowledge (ZKPoKs) and threshold-useful *gadgets*, which do not need to be thresholdized.

414 The term “**crypto-system**” is used in an encompassing sense to denote a main system  
415 submitted for analysis. A **crypto-system** can be a threshold scheme, a ZKPoK, a gadget,  
416 a Class S conventional scheme, or a family thereof (i.e., including variants or modes).

417 A submitted crypto-system **shall** be organized in a package that includes (i) a **written specifi-**  
418 **cation** with design rationale, technical description and security characterization, (ii) an open-  
419 source **reference implementation** with instructions, and (iii) a **performance evaluation**. The  
420 submission **shall** follow the baseline expectations set forth in Section 4.4, including a disclo-  
421 sure of known related patent claims associated with any team member. Submitted packages  
422 that are accepted for posting on the NIST-MPTC website are expected to benefit from expo-  
423 sure to public analysis. The collected reference material will inform the development of NIST  
424 recommendations and future processes, and will be referenced in a future NIST publication.

### 425 2.1. Class N: NIST-Specified Primitives

426 Class N consists of selected NIST-specified cryptographic primitives. As a mnemonic, “N” is  
427 associated with “NIST”. The class is organized into four categories: **N1** for signing; **N2** for  
428 [regular] public-key encryption (PKE); **N3** for symmetric-key and hashing-related primitives;  
429 and **N4** for KeyGen and for non-PKE PKC-primitives useful for pair-wise key-agreement  
430 (2KA). The primitives from some recent and emerging standards for post-quantum (PQ)  
431 signatures and PKE (selected by the NIST PQC project [**Proj-PQC**]), and for “lightweight”

432 (for constrained environments) symmetric-key and hashing-related schemes (selected by  
 433 the NIST LWC project [[Proj-LWC](#)]), also fit into [Class N](#).

434 **Categories.** Table 2 lists the various categories and their scope, including various “families  
 435 of specifications”. Each such family may include diverse primitives and modes/variants  
 436 (including the options for input/output interfaces mentioned in [Appendix C.4](#)).

**Table 2.** Families of specifications of interest in categories of Class N

Category: Type	Subtype	Families <sup>†</sup> of specifications	Sections in this Call
437 <a href="#">N1</a> : Signing	QV	EdDSA sign, ECDSA sign, RSADSA sign	<a href="#">9.1</a> , <a href="#">A.1</a>
438	PQ	ML-DSA sign, HBS (SLH-DSA and stateful) sign	
439 <a href="#">N2</a> : PKE	QV	RSA encrypt, decrypt	<a href="#">9.2</a> , <a href="#">A.2</a>
440	PQ	ML-KEM encrypt, decrypt	
441 <a href="#">N3</a> : Symmetric	Blockcipher	AES encipher, decipher	<a href="#">9.3</a> , <a href="#">A.3</a>
442	AEAD	Ascon-AEAD encrypt, decrypt	
443	Hash/XOF	SHA2, SHA3, SHAKE, Ascon- <a href="#">{Hash,XOF}</a>	
444	MAC	C/G/H/K-MAC	
445 <a href="#">N4</a> : KeyGen	QV-PKC	ECC KeyGen (including for 2KA), RSA KeyGen	<a href="#">9.4</a> , <a href="#">A.4</a>
446	PQ-PKC	ML KeyGen, HBS KeyGen	
447	RBG	Random bit generation (e.g., bitstring, integer)	

448 See more details in [Section 9](#) and [Appendix A](#). **Legend:** 2KA = Pair-Wise Key Agreement. AES = Advanced  
 449 Encryption Standard. C/G/H/K-MAC= Cipher/Galois/Hash/Keccak-based Message Authentication Code.  
 450 ECC = Elliptic Curve Cryptography. ECDSA = Elliptic Curve DSA. EdDSA = Edwards-curve DSA. HBS  
 451 = Hash-Based Signatures. KEM = Key Encapsulation Mechanism. ML = Module Lattice. PKC = Public-Key  
 452 Cryptography. PKE = Public-Key Encryption. PQ = Post-Quantum. QV = Quantum Vulnerable. RBG  
 453 = Random-bit generation. RSA = Rivest–Shamir–Adleman. RSADSA = RSA DSA. SHA = Secure Hash  
 454 Algorithm. SHAKE = SHA with Keccak. SLH = Stateless Hash. XOF = eXtensible Output Function.

455 In each category, each family of specifications relates to at least one NIST publication:

- 456 • [N1](#) for the signing operation in EdDSA, ECDSA, RSADSA [[FIPS-186-5](#)], ML-DSA  
 457 [[FIPS-204](#)], SLH-DSA [[FIPS-205](#)], and Stateful HBS [[SP800-208](#)]. Future signature  
 458 schemes (e.g., FN-DSA [[FIPS-206-ipd](#)]) may be added here once NIST-standardized.
- 459 • [N2](#) for encryption and decryption primitives used in PKE schemes based on RSA  
 460 [[SP800-56B-Rev2](#)] or ML-KEM [[FIPS-203](#)]. The scope may be broadened in the future,  
 461 to encompass upcoming NIST-specified PQ-KEMs (e.g., based on HQC).
- 462 • [N3](#) for symmetric-key AES encipher/decipher [[FIPS-197](#)] and Ascon-AEAD en-  
 463 crypt/decrypt [[SP800-232-ipd](#)]; for hashing and XOF'ing [[FIPS-180-4](#); [FIPS-202](#); [SP800-](#)

464 [232-ipd](#)]; and for MAC'ing based on ciphers [[SP800-38B](#); [SP800-38D](#)], hash functions  
 465 [[SP800-224-ipd](#)], and the Keccak permutation [[SP800-185](#)].

- 466 • N4 for KeyGen for ECC primitives [[FIPS-186-5](#); [SP800-56A-Rev3](#); [SP800-186](#)], RSA  
 467 [[FIPS-186-5](#); [SP800-56B-Rev2](#)], PQ-PKE (ML, SLH, FN, HBS), and random-bit  
 468 generation (bitstrings or integers) [[SP800-90A-R1](#); [SP800-90B](#); [SP800-90C-4PD](#)].

## 469 2.2. Class S: Special Primitives Not Specified by NIST

470 The goal of Class S is to enable submissions that make a strong case for relevant primitives  
 471 that are not standardized by NIST. As a mnemonic, “S” is associated with “special”.  
 472 Submissions of threshold schemes for primitives in Class S **shall** be justified on the basis of  
 473 differentiating features of the primitives (i.e., in comparison with those in Class N), such  
 474 as: (i) being threshold-friendlier (TF); (ii) relying on alternative cryptographic assump-  
 475 tions (e.g., pairings), possibly PQ (e.g., lattice-based); (iii) having useful properties (e.g.,  
 476 deterministic, probabilistic, or enabling a useful homomorphism); or/and (iv) being more  
 477 efficient in a relevant metric.

478 **Categories.** Class S has four regular categories (i.e., matching the categories in Class  
 479 N), and three others (FHE, ZKPoK and Gadgets). Table 3 lists the categories in the first  
 480 column. The second column shows corresponding types of conventional schemes (i.e., not  
 481 threshold). The third column gives examples of primitives of interest. The ZKPoK and  
 482 gadgets categories do not have to consider threshold versions of their underlying primitives.

**Table 3.** Examples of primitives in categories of Class S

Category: Type	Example types of scheme	Example primitives	Sections in this Call
483 S1: Signing	TF (threshold-friendly)-PQ signatures	Signing	10.1
484	TF succinct & verifiably-determ. signatures		
485 S2: PKE	TF-PQ public-key encryption (PKE)	Decrypt, Encrypt	10.2
486 S3: Symmetric	[Keyed] TF cipher/PRP	Encipher, Decipher	10.3
487	[Keyed] TF PRF/MAC	Tag Generate (Gen)	10.3
488	[Keyless] TF hashing and XOF'ing	Hash, XOF	
489 S4: KeyGen	Any of the above	KeyGen	10.4
490 S5: FHE	Fully-homomorphic Encryption (FHE)	Decrypt, KeyGen	10.5, B.1
491 S6: ZKPoK	ZKPoK of private key, ZKPoK of signature	ZKPoK.Gen	10.6, B.2
492 S7: Gadgets	Garbled circuit (GC)	GC.Gen, GC.Evaluate	10.7

493 See more details in Section 10 and Appendix B. **Legend:** determ. = deterministic. MAC = Message  
 494 Authentication Code. PRF/PRP= Pseudorandom Function/Permutation [family]. PQ = Post-Quantum.  
 495 XOF= Extendable Output Function. ZKPoK = Zero-Knowledge Proof of Knowledge.

496 The following list enumerates the categories identified in Table 3:

- 497 • S1 for signing (e.g., TF-PQ, or succinct and verifiably deterministic).
- 498 • S2 for PKE (e.g., TF-PQ decryption and encryption).
- 499 • S3 for “symmetric” primitives, including keyed (e.g., TF enciphering/deciphering  
500 and MAC’ing) and keyless (e.g., hashing and XOF’ing).
- 501 • S4 for KeyGen for primitives in other categories, including non-PKE PKC-primitives  
502 usable for multi-party key-establishment.
- 503 • S5 for **fully-homomorphic encryption** (FHE).
- 504 • S6 for **zero-knowledge proofs** (or arguments) of **knowledge** (ZKPoK) of secret  
505 information (e.g., a private key, consistent with a public key or with a correct  
506 secret-sharing setup) relatable to the threshold setting or other categories of the call.
- 507 • S7 for other auxiliary “gadgets” deemed useful to support the threshold setting,  
508 namely useful for implementation of threshold schemes in scope.

## 509 3. Vision

510 The scope of the Threshold Call is expected to motivate the submission of a variety of  
511 MPC techniques for threshold schemes, and of various underlying primitives that are not  
512 NIST-standardized (including ZKPoK, FHE, and gadgets). Overall, this call initiates a  
513 process whose success relies on the public engagement and collaboration of many experts  
514 (see Section 3.1). The combination of PQ and QV techniques (see Section 3.2) will  
515 enable an observation of the “quantum gap” (the distance between PQ and QV solutions),  
516 which is especially relevant in the ongoing setting of PQC-migration. There are also  
517 possible tradeoffs across different threshold schemes that are *interchangeable* with the  
518 same conventional primitive (see Section 3.3). The submissions are expected to include  
519 security modeling, and proofs of security, taking advantage of the wealth of knowledge  
520 in modern cryptography (see Section 3.4). The variety of choices (e.g., in system models,  
521 threshold profiles, security formulations) made across submissions will also contribute to  
522 an exploration of the threshold space (see Section 3.5).

### 523 3.1. Reliance on Contributions and Collaboration

524 The success of the process envisioned by this Threshold Call depends on: **high-quality sub-**  
525 **missions** by teams with cryptography expertise, including in the areas of multiparty compu-

526 tation and distributed systems; **expert public scrutiny**, including assessments of security;  
527 and **comments on pertinence**, by stakeholders of applications of threshold schemes.

528 A complex submission can specify various crypto-systems proposed by distinct sub-teams  
529 (see Section 5.4). This possibility can be followed as a way of facilitating collaboration be-  
530 tween teams, better modularization of crypto-systems, reducing redundancy in submissions  
531 and corresponding analysis, and promoting consistency in terminology and notation.

532 Given the collaborative process, it is also important to set clear expectations about the  
533 reviewability and usability of submitted material, the ability to produce derivative work  
534 and redistribute it, and the applicability of known related patent claims (see Section 4.4).

### 535 **3.2. Post-Quantum and Quantum-Vulnerable Cryptography**

536 This Threshold Call welcomes submissions of PQ solutions (i.e., with security resistant  
537 against an adversary with a quantum computer) and quantum-vulnerable (QV) solutions  
538 (i.e., yet secure with respect to adversaries without a quantum computer). However,  
539 submitters should be aware of the ongoing PQC-migration context, namely the planned  
540 “disallowance” of NIST-standardized QV-signatures and QV-PKE, by 2035 [[NCCoE-PQC](#);  
541 [NIST-IR8547-ipd](#)]. Correspondingly, the standalone use of threshold schemes for those QV  
542 primitives will eventually not be recommended by NIST. Still, “disallowance” in this context  
543 does not preclude a future use of “hybrid” schemes, in which a QV scheme and a PQ  
544 scheme coexist, with the security of either ensuring the security of the composite system.

545 While QV primitives are in use, their threshold implementation can be valuable. Further-  
546 more, assessing the state of the art in QV threshold schemes and in QV threshold-friendly  
547 primitives can be useful as a reference to set future goals for PQ threshold cryptography.

548 This Threshold Call values the exploration of various combinations of post-quantum readi-  
549 ness and quantum vulnerability, across conventional primitives and their threshold schemes.  
550 Each combination can be of interest when properly motivated. Four examples:

- 551 1. **QV-QV**: A **QV threshold scheme** with security reducible to the same crypto  
552 assumptions as required by the **QV conventional primitive** being thresholdized.
- 553 2. **PQ-PQ**: A **PQ threshold scheme** used to distribute trust in a PQ application of  
554 a **PQ conventional primitive** being thresholdized.
- 555 3. **QV-PQ**: A **QV threshold scheme** for an application that requires PQ only for  
556 the final output of a **PQ conventional primitive** (e.g., PQ signature), whereas the  
557 adversary is assumed to be pre-quantum during the threshold protocol execution.

- 558 4. **PQ-QV**: A **PQ distributed-KeyGen (DKG)** for generating secret-shared private  
559 and public keys (i.e., a DKG) of a **QV conventional KeyGen** primitive being  
560 thresholdized, so that the QV public-key is not exposed to quantum adversaries.

### 561 **3.3. Interchangeability**

562 This Threshold Call is interested in threshold schemes whose output can be *interchangeably*  
563 used (see §2.4 of [NIST-IR8214A](#)) by subsequent operations (e.g., signature verification)  
564 of a conventional (i.e., non-threshold) primitive (e.g., signing) in scope. EdDSA signing  
565 provides a notable example of the relevance of defining *interchangeability*: in the threshold  
566 setting, producing a valid randomized signature can be much more efficient than obtaining  
567 the standardized pseudorandom one, and both are *interchangeable* with respect to the  
568 conventional/standardized EdDSA verification algorithm (see [NIST-IR8214B-ipd](#)).

### 569 **3.4. Provable Security**

570 The security of submitted threshold schemes (see Section 8.2 and Appendix C.2.3) is  
571 expected to be assessed based on multi-party protocol analysis, which is supported by a  
572 substantial body of knowledge in *provable security*. This is different from the extensive  
573 cryptanalysis that would be required in a call for basic primitives based on new crypto-  
574 graphic assumptions. That said, the security of threshold schemes is still recognized as  
575 multi-dimensional, depending on security formulation (e.g., which ideal functionalities  
576 or security games to choose), implementation (e.g., susceptibility to side-channels), and  
577 deployment suitability.

### 578 **3.5. A Variety of Options**

579 The domain space of multi-party threshold schemes is considerably wider than that of the  
580 primitives (e.g., digital signatures) being thresholdized. Acknowledging this, the present  
581 Threshold Call allows leeway for submitters to select from a variety of system models, thresh-  
582 old configurations, security formulations, technical approaches, and benchmarking focuses.  
583 Intentionally, this Threshold Call does **not** put forward a rigid “apples-to-apples” criteria  
584 (e.g., specific number of parties, common programming language, application programming  
585 interface) for comparison across submissions. Nonetheless, the submissions are expected to  
586 adhere to certain criteria, with respect to technical documentation (see Sections 5, 6, and  
587 7), and security requirements (see Section 8), such as security against active corruptions  
588 in the threshold setting. The options followed across submissions will be informative.

## 4. Phases and Deadlines

Table 4 lists the phases and corresponding deadlines for (i) the submission of *previews* (i.e., early plans for package submission), (ii) the submission of packages, and (iii) the analysis process. See details in Sections 4.1, 4.2, and 4.3. Section 4.4 further discusses some agreements implied by submitting a package.

**Table 4.** Submission phases and tentative deadlines

Phase	Subphase	Required?	Deadline
<b>Ph1: Previews</b>	Ph1.1: Preview 1	No	$\approx X + 2$
	Ph1.2: Preview 2	No	$\approx X + 5$
<b>Ph2: Packages</b>	Ph2.1: Preliminary submission	No	$\approx X + 6$
	Ph2.2: Regular submission	<b>Yes</b>	$\approx X + 8$
<b>Ph3: Analysis</b>	Ph3.1: Public presentations	<b>Yes</b>	(2026)
	Ph3.2: Package updates	—	—
	Ph3.3: NIST-MPTC report	<b>Yes</b>	( $\approx 2027$ )

Tentative deadlines are relative (unit in months) to the publication date (X) of the final version of this Call.

**On deadlines.** If, during the process, NIST-MPTC [Proj-MPTC] has a compelling reason to extend a deadline, the corresponding update will be publicly conveyed via the MPTC-forum. Similar communication will be used for other deadlines that may emerge during the unfolding process (e.g., eventual phases for updating packages).

### 4.1. Ph1: Previews

The “Previews” phase provides two opportunities for each team to publicly share in advance their plan (or preliminary plan) to submit full packages. This is intended to (i) facilitate collaboration across teams; (ii) promote the identification of opportunities for teams to strengthen their composition; (iii) and form an early expectation of the coverage of categories of the Threshold Call, which may help determine useful mergers or differentiation of packages. The submission and public presentation of a preview are **strongly encouraged**, aligning well with the open and collaborative spirit of the process.

- **Ph1.1: Preview 1 (Optional).** A preview is accomplished by submitting a short writeup (the plan) and later giving a related presentation in a public session.

- 616 – **Submission of a plan.** By  $\approx X + 2$ , send an email to [MPTC-submissions@](mailto:MPTC-submissions@list.nist.gov)  
617 [list.nist.gov](mailto:list.nist.gov), attaching a document in portable document format (PDF), with  
618 no more than four pages (letter size, 1 inch margins, 12-point font size),  
619 with a title, a list of confirmed team members, and a summarized description  
620 of the “package” planned for later submission (**Ph2**). Suggested items to  
621 include: (i) a list of the crypto-systems to be proposed (i.e., chosen names, and  
622 (sub)categories), (ii) an outline of the main technical considerations (system  
623 model, protocol approach, security properties), (iii) comments on the intended  
624 reference implementation, and (iv) a list of relevant bibliographic references.  
625 The references do not count for the 4-page limit.
- 626 – **Public presentation.** Shortly after the Preview 1 submission deadline, NIST-  
627 -MPTC will organize a public session for each team to present their plan  
628 for [package submission](#), and showcase their preparation status. For each  
629 presentation, there will be time for comments and questions from the public.  
630 NIST-MPTC will post online (publicly available) the writeup of the preview  
631 plan, the presentation slides, and the audio-video recordings.
- 632 • **Ph1.2: Preview 2 (Optional).** Similar to Preview 1 but with a new deadline:  
633  $\approx X + 5$ . This is open to present new plans, and to revise or give a status update  
634 on previously presented plans.

## 635 4.2. Ph2: Packages

636 A complete and proper package *shall* contain the following main components:

- 637 • **Written specification:** A technical specification (including security analysis) of  
638 the crypto-systems (threshold scheme, ZKP, gadget, or/and Class S conventional  
639 scheme) proposed for analysis (see Section 5).
- 640 • **Reference implementation:** A software implementation of the proposed crypto-  
641 systems, including the open-source code, with an open-source license, comments for  
642 clarity, scripts, and instructions (see Section 6).
- 643 • **Experimental evaluation:** A report describing an experimental setting, measuring  
644 performance, and interpreting the results (see Section 7).

645 **Submission medium.** The submission of packages requires sending an email to [MPTC-](mailto:MPTC-submissions@list.nist.gov)  
646 [submissions@list.nist.gov](mailto:submissions@list.nist.gov), with each of the requested components. The [reference imple-](#)  
647 [mentation](#) will be submitted by indicating a cryptographic hash and URL to a public  
648 Git-compatible repository controlled by the team, as described in [Imp2](#) (see Section 6.2).

649 **Subphases.** The phased of package submissions is organized as follows:

- 650 • **Ph2.1: (Optional) Preliminary submission.** Packages received by NIST-MPTC  
651 by  $\approx X + 6$  will be subject to a superficial review for completeness. Within 30 days,  
652 the submitters will be notified of identified deficiencies or other suggestions, to allow  
653 for amendments before the deadline.
- 654 • **Ph2.2: Regular submission.** Packages received by NIST-MPTC by the submission  
655 deadline ( $\approx X + 8$ ) will be considered in the process of analysis. After a period  
656 expected to be no longer than 30 days, the accepted packages will be hosted on  
657 a NIST repository, and corresponding hyperlinks will be posted on the NIST-MPTC  
658 project website [[Proj-MPTC](#)].

### 659 **4.3. Ph3: Public Analysis of Crypto-Systems**

660 After the public posting of accepted packages, a period of public analysis will follow.

- 661 • **Ph3.1: Public presentations/discussion.** NIST-MPTC intends to host a seminar  
662 series for thorough presentations of the proposed crypto-systems, and to consider  
663 comments from the public.
- 664 • **Ph3.2: Future updates.** The NIST repository will allow public download of the  
665 hosted packages, and will also list links to the team's repository (external to NIST).  
666 After the submissions, each team can use the MPTC-forum to announce discovered  
667 issues, and possible updates incorporated in the team's repositories. As the process  
668 unfolds, NIST-MPTC may, infrequently, specify periods for optional submission of  
669 amendments or improvements, to update the body of NIST-hosted reference material.
- 670 • **Ph3.3: NIST-MPTC report.** It is expected that a follow-up NIST report will  
671 characterize the set of proposed crypto-systems, and assess a possible interest in  
672 future processes with more-focused analysis. This should clarify distinctions across  
673 primitives, threshold schemes, building blocks, and composition techniques.

### 674 **4.4. Expectations about Submitted Material**

675 This Threshold Call is intended to gather a public body of reference material, open for  
676 review and evaluation, to serve as a basis for potential developments and improvements, and  
677 foster a widespread, secure use of cryptographic techniques. Therefore, the process requires  
678 its participants to abide by baseline expectations about the openness of submitted material.

679 **By submitting a package** in reply to this Threshold Call, the submitting team (i.e.,  
680 all its members, possibly across various subteams) **acknowledges and agrees** that the

681 submitted material — written specification (document), reference implementation (code),  
682 and experimental evaluation (document) — is in accordance with the following expectations:

683 **4.4.1. Original work.** The submitted content is the original work of the submitters,  
684 except (where applicable) for the properly referenced and credited (i) fair-use inclusion  
685 of externally developed text from other publications, and/or (ii) externally developed  
686 open-source code (e.g., compilers and some libraries).

687 **4.4.2. Available specification, and evaluation report.** The submitted [specification](#)  
688 and [experimental evaluation](#) report (PDF files) are made freely available worldwide for public  
689 review and evaluation purposes. To enable this, by making a submission to NIST, the submit-  
690 ting team agrees that NIST is explicitly granted the right to post submitted materials online  
691 within the scope of the Threshold process, and the public is explicitly granted the right to use  
692 the material posted by NIST, including for commercial purposes. To allow further redistribu-  
693 tion by other parties, teams are **encouraged** (but not required) to submit their documents  
694 with a license, such as the Creative Commons “CC BY 4.0 International” (Attribution 4.0  
695 International) license [[CC-BY-4.0](#)]. If a different license is used, for example choosing to  
696 include share-alike terms, it **shall** not attempt to restrict use for commercial purposes.

697 **4.4.3. Availability of the implementation code.** The submitted [implementation](#)  
698 code **shall** be accompanied with an open source license (consistent with an “Open Source  
699 Initiative” approved license [[OSI-lic](#)]), as further explained in Section [6.3 \(Imp3\)](#).

700 **4.4.4. Disclosure of Patent Claims.** Since patent claims may affect the adoption and  
701 development of techniques [[ITL-Patent-Policy](#)], it is important to solicit their disclosure.  
702 Therefore, the submitted [specification](#) **shall** include a statement (in [Cv4](#); see Section [5.1](#))  
703 that: (i) discloses any known issued or pending patent (foreign or domestic) that does or  
704 could have claims that may cover the contents of the submission, where any team member  
705 is one of the inventors, applicants, or assignees, or is sponsored by or affiliated with an  
706 entity that holds the corresponding patent rights, or (ii) states that no such patent claims  
707 are known to exist. Regarding known related patents held by third-party stakeholders, i.e.,  
708 not including anyone in the submitting team, the disclosure is encouraged to take place  
709 via the MPTC-forum or/and in public presentations along the process.

710 **4.4.5. Security guarantees.** It is expected that a good faith technical effort is made to  
711 ensure the security of the proposed schemes. If the team becomes aware of vulnerabilities  
712 after the submission, then it **shall** communicate them via the MPTC-forum.

## 713 5. Package Component: Written Specification

714 The first main component of a submission package is the written specification. This  
715 section describes its organization in “parts” and “sections”.

716 **PDF File.** The written specification *shall* be submitted as a single digital file, in  
717 PDF, preferably named “<team-name>-spec-v1.pdf”. The document *shall* be written in  
718 English, aided by mathematical notation where appropriate. An (optional to follow) LaTeX-  
719 based template will be provided when the final version of the Threshold Call is published,  
720 to help achieve the intended structure, and exemplify accessibility features (e.g., PDF  
721 bookmarks for easy navigation, hyper-references, tooltiped acronyms, tagged content).

722 **Content organization.** The content *shall* be organized into various parts, as follows:

- 723 • Cover and verso (see Cv1–Cv4 in Section 5.1);
- 724 • One *front matter* (see Fm1–Fm2 in Section 5.2);
- 725 • One *main matter* part called “Preliminaries” (see Pre1–Pre4 in Section 5.3);
- 726 • One *main matter* part for each crypto-system (see CSx.1–CSx.6 in Section 5.4);
- 727 • One *back matter* (see Bm1–Bm2 in Section 5.5).

728 The use of this common structure across specifications will facilitate their parsing. Authors  
729 are encouraged to further organize the content into subsections, sub-subsections and even  
730 some paragraphs with numbered headings for easy reference. (The Cv, FmX, PreX, CSx.X  
731 and BmN indices shown here are not meant for the actual specification.)

### 732 5.1. Covers and Verso

733 A sequence of unnumbered pages, as follows:

734 **Cv1. Cover page:** A cover page with: title (and optional subtitle) of the submission,  
735 submission date, submission version (“1.0” by default), team title, names of the  
736 submitters, names (and (sub)category indices) of the proposed crypto-systems, and  
737 optional document licensing (e.g., “CC BY 4.0 International”; see Section 4.4).

738 **Cv2. Contacts:** A page that (i) repeats the submission title and subtitle, the team title,  
739 the submitters’ names, and the names of proposed crypto-systems, and (ii) addition-  
740 ally includes the team’s mailing list (i.e., single email address that relays emails to all  
741 team members); hyperlinked ORCID identifiers and applicable affiliations of all team  
742 members, and (iii) identifies a primary contact person and (optionally) up to two sec-  
743 ondary contact persons (identifying their email address and postal address). This page

744 can include additional disclosures of contributions and funding. In case of multiple sub-  
745 mitted crypto-systems, the page can identify one primary contact per crypto-system.

746 **Cv3. Submission scope:** A page that enables a quick glimpse at the submission  
747 scope. For each proposed **crypto-system**, it will identify the system name and the  
748 corresponding (sub)category(ies) of the Threshold Call, the “part” in which it is  
749 specified in the document, the proposing subteam, and (as applicable) a list of the  
750 main protocols or building blocks that compose each crypto-system (or family), and  
751 the [sub][sub]sections in which they are specified.

752 **Cv4. Patents disclosure:** A section disclosing the known related patent claims where  
753 any team member is one of the inventors, applicants, or assignees, or is sponsored by  
754 or affiliated with an entity that holds the corresponding patent rights (see Section 4.4).

## 755 5.2. Front Matter

756 A sequence of unnumbered sections (in roman-numbered pages), as follows:

757 **Fm1. Abstract:** A text with 200 to 350 words, describing the technical scope of  
758 the submission, and hinting at their main features, cryptographic assumptions and  
759 performance highlights of the submitted crypto-systems.

760 **Fm2. Index of contents:** A table of contents (TOC, i.e., index of sections, sub-  
761 sections, etc.); and (as applicable) lists of tables (LOT), figures (LOF), algorithms  
762 (LOA), and other relevant indexed components (e.g., list of design decisions),  
763 including corresponding hyper-references and page numbers.

764 **Fm3. Preface:** A 1-page section, without mathematical notation, briefly describing  
765 the motivation for the submission, including: the envisioned relevance (utility, ap-  
766 plicability, deployability) of the proposed crypto-systems (e.g., in industry and for  
767 societal applications), considering the state of the art. It can also comment on the  
768 process and personal context of package development.

769 **Fm4. Acknowledgments:** An optional section with acknowledgments.

770 **Fm5. Executive summary:** An abridged explanation of the package content, high-  
771 lighting relevant properties of the proposed threshold schemes, their applicability  
772 and performance, and other key insights. It should also describe the main challenges  
773 addressed while preparing the submission, including in the specification (e.g., in  
774 proving security), the open-source implementation, and the performance evaluation.  
775 Mathematical symbols should be used sparingly in this section, if at all.

### 776 **5.3. Main Matter — Preliminaries**

777 The main matter starts with a “Preliminaries” part, containing a sequence of decimal-  
778 numbered sections, in decimal-numbered pages, as follows:

779 **Pre1. Introduction:** An introduction that identifies the involved cryptographic  
780 primitives, the proposed crypto-systems, hints at the used technical approaches,  
781 and describes the high-level structure of the document (to help potential readers  
782 prioritize which sections to read).

783 **Pre2. Notation:** A section that lists and explains the used acronyms (§2.1), math-  
784 ematical symbols (§2.2), and terms (§2.3). It *may* contain subsections to explain  
785 certain relationships between symbols (e.g., sets, elements, operations).

786 **Pre3. Related work and design decisions:** A section with rationale about the  
787 proposed system model(s) and crypto-system(s). It *shall identify* building blocks,  
788 techniques, and ideas known to have been developed or authored in prior or related  
789 work, and that are used in or have directly influenced the specification of the crypto-  
790 systems proposed in the submission. It will include proper attribution and citations  
791 (see also [Bm1](#)), clarifying which works/authors (whether or not part of the submitting  
792 team) developed the discussed techniques. As deemed useful, this section can  
793 intertwine descriptions of related work, and related design choices. This modularized  
794 section is intended to allow later parts of the specification to be more straightforward.

795 **Pre4. Conventional primitives and building blocks:** A section that explains the in-  
796 terface, and properties of the building blocks and/or other technical components that  
797 the authors prefer to modularize away from [CSx.3](#), but which are nonetheless used in  
798 at least one proposed crypto-system. For example, this can apply to recalling the con-  
799 ventional (non-threshold) Class N primitive that will be the subject to a proposal of  
800 threshold scheme. The *explanation* of some building blocks here is meant to be thor-  
801 ougher than a possible *identification* in [Pre3](#). It should also be understandable without  
802 reading [Pre3](#), which is more concerned with providing proper attribution and rationale.

### 803 **5.4. Main Matter — Crypto-Systems**

804 Each crypto-system (i.e., threshold scheme, ZKPoK, gadget, or Class S conventional  
805 scheme) proposed for standalone analysis *may* itself be a family of protocol/primitive  
806 variants (e.g., a family of threshold schemes for one conventional primitive, using different  
807 protocols to handle different [threshold profiles](#), or with different probabilistic features).  
808 Teams are encouraged to favor modularity and team collaboration, possibly identifying

809 different sub-teams for different crypto-systems. Each crypto-system **shall** satisfy the  
810 applicable requirements indicated in Sections 8, 9, and 10, and **shall** be specified within  
811 a standalone “Part” of the specification document, including the following sections:

812 **CS $x$ .1. Cover page:** A cover page that indicates: the crypto-system name, the  
813 version and date of its last revision, the subteam composition (if different from the  
814 entire team); the names of the main algorithms, protocols, and/or variants being  
815 proposed; and the names of the building blocks (which can be referenced to the  
816 Preliminaries part or another crypto-system).

817 **CS $x$ .2. System model:** A description of the system model (see Appendix C.1),  
818 including participants and their activation, communication network, and adversary.

819 **Note:** This section is intended to be straightforward about the chosen system model  
820 (in contrast with Pre3 that explains related work and design decisions). It can also  
821 give hints about the security formulation (e.g., whether a protocol abort is a valid  
822 outcome) and the critical safety properties of the intended system (e.g., key secrecy  
823 and unforgeability). However, a formal security formulation (functionalities and  
824 security games) should be deferred to CS $x$ .4.

825 **CS $x$ .3. Proposed crypto-system:** A detailed description of the algorithms and/or  
826 protocols that constitute the crypto-system (possibly a family) proposed for analysis.  
827 The building blocks used in the algorithms/protocols need to be understandable from  
828 at least one of the following (whichever applies): (i) interface and properties Pre4  
829 described in the “Preliminaries” part); (ii) a thorough specification in another “crypto-  
830 system” part of this specification; or (iii) a modular specification in a (sub)section  
831 of this section (i.e., of CS $x$ .3). The protocol can also be described with various phases  
832 (e.g., offline, online, secret resharing), which may have differentiated requirements.

833 **CS $x$ .4. Security analysis:** A security assessment of the proposed crypto-systems, cov-  
834 ering the requirements in Section 8. It will include a security formulation (e.g., ideal  
835 functionalities or games); an identification of assumed ideal components and other  
836 assumptions (cryptographic, and/or of trusted setup); a security proof sketch (small  
837 subsection) and a thorough security proof (which can go into Bm2); a discussion of  
838 security consequences of instantiating ideal components in a realistic (possibly not  
839 ideal) manner, and of deployment in environments that are (e.g., without synchrony)  
840 different from those assumed in the system models.

841 **CS $x$ .5. Analytic complexity:** An analytical estimation of the (i) memory complex-  
842 ity, (ii) computational complexity, (iii) communication complexity, and (iv) round

843 complexity of each proposed crypto-system. See Section 7.2 about experimental  
844 evaluation. As applicable, the estimates *should* include: a breakdown across various  
845 phases of the protocol; the complexity per party and for the entire system; and the  
846 functional dependence on configurable parameters, e.g., security strength, number  
847 of parties and the thresholds.

848 **CSx.6. Deployment:** A set of deployment requirements and recommendations,  
849 including those related to security, as well as a list of known and proposed applications  
850 of the submitted crypto-systems.

## 851 5.5. Back Matter

852 **Bm1. References:** A list of external references cited throughout the document.  
853 Where possible, each reference *should* include a persistent identifier (e.g., DOI, and  
854 ia.cr) hyperlinked to a preferably free and publicly available version of the reference.  
855 The use of author-year format is suggested for citation tags.

856 **Bm2. Appendices:** Optional sections with auxiliary elements that may be deemed  
857 too detailed or cumbersome for the main matter. For example, this may include  
858 complicated proofs of lemmas needed by the proof(s) of security in CSx.4).

## 859 6. Package Component: Reference Implementation

860 The second main component of a submission package is the open-source [Packaged Code-](#)  
861 [base](#), which comprises the [Team's Core Code](#) and [Bundled Dependencies](#). The [Reference](#)  
862 [Implementation](#) is what emerges from combining the [Packaged Codebase](#) with well-identified  
863 [External Dependencies](#) and compiling them in a [Baseline Platform](#). The [Reference Imple-](#)  
864 [mentation](#) *should* enable testing the main features of each [specified](#) crypto-system.

865 **Terminology.** The following implementation-related components are distinguished:

- 866 • **Team's Core Code:** The code developed by the team to execute the specified crypto-  
867 systems. Its compilability depends on a software environment (with dependencies).
- 868 • **Bundled Dependencies:** Externally developed **open-source** libraries (i.e., not part  
869 of the team's core code) that, for convenience, have been bundled together with the  
870 [Team's Core Code](#) (i.e., cloned from another repositories into the team's repository).

- 871 • **Packaged Codebase (or “submitted code”)**: The combination of the [Team’s](#)  
872 [Core Code](#) and the [Bundled Dependencies](#), made publicly available in a Git-compatible  
873 repository in the team’s control.
- 874 • **External Dependencies**: Externally developed **open-source** libraries that were  
875 not included in the [Packaged Codebase](#), and are not part of the operating system,  
876 but are needed for compiling or executing the [Reference Implementation](#).
- 877 • **Deployment Package**: The combination of the [Packaged Codebase](#) and the  
878 [External Dependencies](#). For distinction purposes, the operating system is not  
879 considered part of the Deployment Package, but rather part of the [Baseline Platform](#).
- 880 • **Reference Implementation**: The result of compiling and/or running the [Deploy-](#)  
881 [ment Package](#) within a [Baseline Platform](#) (i.e., hardware and operating system), to  
882 test a proposed crypto-system.

883 **Summary of requirements.** The [Packaged Codebase](#) *shall* satisfy the following:

- 884 • **Imp1**: Implements the proposed crypto-systems (see Section 6.1)
- 885 • **Imp2**: Is publicly available (see Section 6.2)
- 886 • **Imp3**: Is licensed as open-source (see Section 6.3 and 4.4)
- 887 • **Imp4**: Is compatible with a [Baseline Platform](#) (see Section 6.4)
- 888 • **Imp5**: Its [External Dependencies](#) are open source and well-identified (Section 6.5)
- 889 • **Imp6**: Is clear, including inline comments (see Section 6.6)
- 890 • **Imp7**: Includes useful scripts (see Section 6.7)
- 891 • **Imp8**: Includes useful instructions (see Section 6.8)

## 892 **6.1. Imp1. Crypto-system(s) Implementation**

893 When compiled together with [External Dependencies](#) and executed in the [Baseline Platform](#),  
894 the open-source [Packaged Codebase](#) *shall* constitute a reference implementation of the  
895 crypto-systems (see Section 5.4) proposed in the submitted [specification](#), including the  
896 applicable building blocks. In the case of a multi-party threshold scheme, the software  
897 *should* enable running each “party” as one process (or more), or within a software virtual  
898 container, separate from the other parties.

899 **Networking versus cryptography.** There can be significantly different challenges between  
900 (i) implementing networking between parties (see Appendix C.1.2) and (ii) implementing  
901 certain mathematical operations (cryptographic building blocks) per party. Neglecting any

902 of these implementation aspects can lead to serious vulnerabilities. Therefore, a **strong**  
903 **alignment** between the proposed system model (see [CSx.2](#) and Appendix [C.1](#)) and the  
904 provided implementation is **strongly encouraged**, notwithstanding possible virtualizations  
905 to enable execution in a personal computer (the [Baseline Platform](#)). For example, if a pro-  
906 tocol specification relies on broadcast, then the provided implementation **should** instantiate  
907 it in alignment with the assumptions of the proposed system model. If the proposed system  
908 model depends on special hardware components (e.g., a router) beyond the threshold  
909 “parties”, then the submission **may** include code for simulating the special component.

## 910 **6.2. Imp2. Code Availability**

911 The [Packaged Codebase](#) **shall** be publicly available via a public Git repository, where “Git”  
912 denotes the distributed version-control system. The **email** with the package submission  
913 **shall** include a SHA256 or SHA3-256 cryptographic commitment to a .zip archive of the  
914 [Packaged Codebase](#), and the following auxiliary metadata: a **URL** to the .zip file; the  
915 **byte-size** of the .zip file (for preliminary checking), the SHA-256 or SHA3-256 hash of the  
916 .zip file, the **Git-commit hash** (an identifier string with at least 40 hexadecimal characters)  
917 of the given commit stage of the Git project; and a **cloning command** (valid long-term)  
918 for cloning the repository at the given commit-stage (i.e., with content matching the one  
919 in the committed .zip file). The URL to the .zip file is expected to have a syntax similar to:  
920 `https://<repo-hosting-server>/<team-name>/<repo-name>/archive/<Git-commit-hash>.zip`

## 921 **6.3. Imp3. Code Licensing and Posting**

922 The [Packaged Codebase](#) **shall** be explicitly licensed as open-source [[OSI-def](#)], consistent  
923 with an “Open Source Initiative” (OSI) approved license [[OSI-lic](#)]. Thus, the code will be  
924 freely distributable. In particular, NIST-MPTC will publicly post the code on a NIST-  
925 controlled repository, and will include a reference to the team’s public Git-repository (which  
926 can be continuously updated by the team).

927 If the license of the submitted code is found to have an issue preventing the intended  
928 posting, then NIST-MPTC may request the team to adapt the license.

## 929 **6.4. Imp4. Compatibility With a Baseline Platform**

930 The [Deployment Package](#) (i.e., the bundle of [Packaged Codebase](#) and [External Depen-](#)  
931 [dencies](#)) **shall** be compilable and executable as a [Reference Implementation](#) in a *baseline*  
932 **platform** consisting of a modern personal computer (possibly virtualized) equipped with:

- 933 1. **Central processing unit (CPU):** Eight x64 (64-bit) processing cores
- 934 2. **Fast primary memory:** 32 gigabytes (e.g., of random-access memory [RAM])
- 935 3. **Secondary memory (storage):** Four terabytes (e.g., in a solid state drive [SSD])
- 936 4. **Operating system:** Ubuntu Desktop 24.04.1 LTS (codenamed “Noble Numbat”  
937 and offering long-term support) [[Ubuntu](#)]

938 This is meant to be a platform on which all submitted implementations can be analyzed,  
939 but is not an indication of preference or recommendation for which platforms are best  
940 suitable for implementing any crypto-system. Teams are welcome, but not required, to  
941 report (e.g., in [Imp7](#) and [Imp8](#)) lighter or easier setups (e.g., lighter open-source operating  
942 systems) with which their submitted code can be compiled and executed. Experimental  
943 evaluation results can also be provided for additional platforms (see Section 7.1).

## 944 6.5. Imp5. External dependencies

945 The compilation of the [Reference Implementation](#) *may* use [External Dependencies](#) (e.g.  
946 a compiler), which *shall* be licensed as open-source [[OSI-lic](#)]. Their exclusion from the  
947 [Packaged Codebase](#) may be motivated by license incompatibilities (e.g., copyleft versus  
948 permissive), or another reason (e.g., an inconveniently large size in bytes).

949 **Precise version identification.** For testing and future reproducibility, the open-source  
950 [External Dependencies](#) *shall* be publicly available. The code *should* be precisely identified  
951 (e.g., their version) and (preferably) available in a Git-compatible public repo. See con-  
952 nection with the requirements about a build script ([Imp7.X1](#)) and compilation instructions  
953 ([Imp8.Inst1](#)). However, this precise version identification *should* be considered with **prac-**  
954 **tical wisdom:** an effort is expected, but if too challenging (e.g., due to unclear nested  
955 external dependencies) it should not hinder achieving a good [Reference Implementation](#).  
956 Further recommendations about this aspect may emerge from public feedback and the  
957 upcoming experience of analysis of implementations.

958 **Containers.** Teams are welcome (but not required) to make available or explain how  
959 to build container images and/or virtual machines that would run their code in an exact  
960 environment, including all dependencies with specific versions.

## 961 **6.6. Imp6. Clear Code**

962 The [Team's Core Code](#) *shall* promote clarity about the [Reference Implementation](#) of the  
963 proposed crypto-systems, even if at detriment of some performance. It *should* accompany  
964 most functions/modules with auxiliary explanatory comments, Optionally, additional code  
965 that is **optimized for performance** but less clear can be included to showcase better  
966 experimental performance. Similar considerations are possible for the selected externally  
967 developed dependencies. The [Packaged Codebase](#) *shall* clearly distinguish between the  
968 [Team's Core Code](#) and [Bundled Dependencies](#), and explain the functionalities that are  
969 added by the [External Dependencies](#).

970 **Language, compiler and API.** This Threshold Call intentionally refrains (see Section 3.5)  
971 from specifying a concrete programming language, compiler, or application pro-  
972 gramming interface (API). However, the [Packaged Codebase](#) *should* include rationale for  
973 the choices made, which *should* not come at the cost of clarity.

974 **Validation and verification.** This Threshold Call does not require formal verification or  
975 validation of implementations. However, it is expected that, during the phase of analysis,  
976 the public scrutiny of submitted implementations will contribute to clarifying suitable testing  
977 mechanisms across various types of submitted crypto-systems, which can promote the pro-  
978 duction of high-assurance software. The specification of a parameter set per security level  
979 may help reduce the complexity of required testing combinations. For example, if a hash  
980 function is used as a building block, then by specifying a specific one the testing may be sim-  
981 pler than in the case where all NIST-approved hash functions would have to be tested. The  
982 webpage of the NIST Cryptographic Algorithm Validation Program (CAVP) [[CAVP](#)] includes  
983 information about validation testing for various NIST-approved cryptographic algorithms.

## 984 **6.7. Imp7. Useful Scripts (X)**

985 The [Team's Core Code](#) *shall* incorporate a set of useful scripts, as follows:

986 **X1. Build script:** A script, which can be executed with a single command in the  
987 [Baseline Platform](#), to automatically download the needed [External Dependencies](#)  
988 (if applicable), and perform the code compilation required to later execute/test the  
989 proposed crypto-systems. Teams are encouraged to strive for a script that can obtain  
990 the [External Dependencies](#) with a specific version, in order to favor reproducible  
991 results (see [Inst1](#)). The team *may* include an additional script designed to use the

992 most-up-to-date version of the [External Dependencies](#) (which may later lead to non-  
993 working implementations, absent further adjustments of the [Packaged Codebase](#)).

994 **X2. KAT-script:** A script to automatically execute the crypto-systems in a way that  
995 reproduces the set of known-answer test (KAT) values provided for sanity checking  
996 (see [Inst3](#) and [Inst4](#) in Section 6.8).

997 **X3. Benchmark script:** A script to automatically benchmark the crypto-system in  
998 the [Baseline Platform](#), to produce performance measurements (similar to those  
999 required in [M3](#), in Section 7) for various configurations. If the [Packaged Codebase](#)  
1000 includes additional code optimized for performance, and whose performance results  
1001 are reported in [M3](#), then the corresponding scripts *should* also be provided, to  
1002 facilitate reproducibility of results.

1003 **X4. Other scripts (optional):** Additional scripts that are useful for gaining insights or  
1004 better testing the crypto-systems or underlying primitives.

## 1005 6.8. Imp8. Useful Instructions (Inst)

1006 The [Reference Implementation](#) *shall* include a set of useful instructions:

1007 **Inst1. Compilation instructions:** A README.md file that explains:

- 1008 (a) How clone and checkout from the team's Git-compatible repository the sub-  
1009 mitted version of the [Packaged Codebase](#).
- 1010 (b) How to execute the build script ([X1](#)) that downloads the [External Dependencies](#)  
1011 (specific or most recent versions) and compiles the [Reference Implementation](#).
- 1012 (c) Which files configure the parameters (see [Inst2](#)) for crypto-system execution  
1013 and/or testing, and which files (see [Inst3](#)) describe how to execute/test the  
1014 proposed crypto-systems.

1015 **Inst2. Parametrization instructions:** A file (possibly named PARAMETERS) or files  
1016 that explain how to configure execution parameters, such as the number of parties, the  
1017 corruption threshold, the type of communication channels, some adversarial choices,  
1018 and some client choices (e.g., input to the cryptographic primitive, such as message  
1019 to be signed). Preferably, the configuration of each parameter *should* be possible  
1020 via the editing of a human-readable text file, and/or command line arguments.

1021 **Inst3. Execution instructions:** A file (or files) that explains how to run the benchmark  
1022 script (see [X3](#)), and test various phases/modules/primitives of the crypto-systems.

1023 **Inst4. KAT values and API:** With discretionary depth and thoroughness, a set of  
1024 KAT values, and an API description, to facilitate (i) testing, correctness verification,  
1025 and interoperability, (ii) use in higher-level applications, (iii) performance comparison  
1026 with other implementations with similar API.

## 1027 **7. Package Component: Experimental Evaluation**

1028 The third main component of a submission package is an experimental evaluation of the [Ref-](#)  
1029 [erence Implementation](#). Its report (a PDFfile) *shall* describe the experimental setting (see  
1030 §7.1), provide performance measurements (see §7.2), and interpret the results (see §7.3).

1031 **7.1. Experimental Setting.** The report *shall* describe the relevant characteristics of the  
1032 implementation platform, namely the (possibly emulated) hardware, including the processor  
1033 (e.g., instruction set, number of processors, and clock frequency), communication network  
1034 (e.g., bandwidth, and latency), and memory (e.g., speed, and space). Preferably, the use  
1035 platform *should* be similar to the [Baseline Platform](#). If applicable, the report *shall* identify  
1036 noteworthy differences, and explain whether/how they are expected to affect performance.  
1037 The experimentation *may* also include additional platforms.

1038 **7.2. Measurements.** The experimental evaluation *should* report on:

- 1039 • **Perf1. Memory complexity** (in number of bytes simultaneously stored).
- 1040 • **Perf2. Processing time** (in seconds and/or number of cycles).
- 1041 • **Perf3. Communication complexity** (in number of communicated bytes).
- 1042 • **Perf4. Round complexity** (in number of inbound and outbound messages).

1043 Each metric *should* be evaluated across a representative set of configurations supported  
1044 by each proposed [crypto-system](#). The measurements *should* be reported: (i) per main  
1045 phase of the protocol, and in total across an execution; (ii) per party and collectively.  
1046 There *should* be at least one comparison between a run with all honest parties, and a  
1047 run with at least one corrupted party. It may be insightful to also identify the cases where  
1048 processing and communication are or can be pipelined to reduce latency.

1049 The results can be reported across various configurations, such as various numbers of parties,  
1050 and various security strengths. The batch of measurements *should* be obtainable automat-  
1051 ically by running a simple command for executing the benchmark script (see [X3](#) and [X4](#)).

1052 **7.3. Analysis.** The performance analysis *should* include a written explanation of the  
 1053 experimental results, interpreting the expected and unexpected observations, namely in  
 1054 comparison with the analytic complexity described in CSx.5 (see Section 5.4). For example,  
 1055 a correlation may be expected between a complexity metric and the number of parties in  
 1056 a threshold scheme. The analysis of results across different configurations is expected to  
 1057 be useful to understand, test of confirm scalability and tradeoffs. The analysis *may* also  
 1058 include comparisons with the known performance of other relatable schemes.

## 1059 8. Security Requirements

1060 The submission of a crypto-system *shall* instantiate (i.e., specify, implement and measure)  
 1061 at least one concrete parametrization. Section 8.1 discusses general goals of security  
 1062 strength, with regard to computational and statistical complexity. Section 8.2 specifies  
 1063 requirements about the threshold setting.

1064 **Critical safety properties.** The security requirements in this section are meant to apply  
 1065 to critical safety properties, to be identified in CSx.2 (see Section 5.4). For example, key  
 1066 secrecy is always assumed to be critical. The criticality of other properties depend on  
 1067 the crypto-system at stake. For example, unforgeability is a critical safety property for  
 1068 signature schemes. Properties not deemed critical *may* be sacrificed (e.g., a security with  
 1069 abort notion sacrifices availability in the presence of a malicious adversary). (Naturally,  
 1070 in practice the criticality of some properties may also depend on the use case.)

### 1071 8.1. Security Strength Levels

1072 Table 5 lists three parameters of security strength: classic computational, quantum com-  
 1073 putational, and statistical. For each parameter, there is a required lower bound of security  
 1074 strength, and a suggested lower bound for an optional second instantiation (for comparison).

**Table 5.** Security strength parameters

	<b>Security parameter</b>	<b>Required (1st case)</b>	<b>Suggested (2nd case)</b>
1075	$\kappa$ (Classic computational)	$\geq 128$	$\geq 192$
1076	$\theta$ (Quantum computational, if claimed PQ)	$\geq 1$	$\geq 3$
1077	$\sigma$ (statistical)	$\geq 40$	$\geq 64$

### 1078 **8.1.1. Computational Security**

1079 **Classic security levels.** A submitted crypto-system *shall* include (i.e., [specify](#), [implement](#),  
1080 and [evaluate](#)) at least one instantiation with classic security strength  $\kappa$  approximate to  
1081 or larger than 128 bits (i.e.,  $\kappa \gtrsim 128$ ). Preferably (when applicable, but not required),  
1082 the submission includes two instantiations, one with  $\kappa \approx 128$ , and another with  $\kappa \gtrsim 192$ .

1083 **Quantum security levels.** The five PQC security categories [[PQC-Call-2016](#), §4.A.5],  
1084 with levels  $\theta \in \{1, 2, 3, 4, 5\}$  represent the computational resources required to break  
1085 AES-128, SHA3-256, AES-192, SHA3-384, and AES-256, respectively. Here, a break  
1086 means key-recovery for AES, and finding a collision for SHA3.

1087 A submitted crypto-system claimed to be PQ *shall* include at least one instantiation with  
1088 PQ security  $\theta \geq 1$ . Preferably (but not required), when applicable, the submission presents  
1089 two instantiations: one with  $\theta \leq 2$ , and another with  $\theta \geq 3$ .

1090 **Parameter sets.** For each category in Class N, the parameter sets in scope already satisfy  
1091  $\kappa \gtrsim 128$  or  $\theta \geq 1$  (see [Section 9](#)). For Class S, the submission needs to specify at least  
1092 one such parameter set. This applies to ZKPoKs, gadgets, submitted threshold schemes,  
1093 and their conventional primitives.

1094 In the interest of research, the computational security of a submitted threshold scheme  
1095 does not need to be as high as that of the primitive being thresholdized. Also (see  
1096 [Section 3.2](#)), the PQ/QV property of the threshold scheme does not have to match the  
1097 one of the conventional primitive. In any case, submissions *should* make a strong case  
1098 for the adoptability of the proposed instantiations.

1099 **Two contrasting examples:** A submission of threshold AES-256 enciphering ([A.3.1](#)):

- 1100 • *May* use a QV threshold scheme with classical security  $\kappa \approx 128$  bits.
- 1101 • *May* use a PQ threshold scheme with quantum security  $\theta = 5$ .

### 1102 **8.1.2. Statistical Security**

1103 The security of a protocol (e.g., some threshold schemes and interactive ZKPoKs) can  
1104 also depend on a statistical parameter  $\sigma$  (the additive inverse of the binary logarithm  
1105 of the probability that a security property is broken during a protocol execution). A  
1106 submitted scheme *shall* aim to achieve  $\sigma \gtrsim 40$ . Preferably, it *should* have  $\sigma \gtrsim 64$ . See  
1107 [Appendix B.2.4](#) on transforming statistical security into computational security.

## 1108 8.2. Security of Threshold Schemes

1109 The following applies to threshold schemes submitted as crypto-systems (see Section 5.4).

### 1110 8.2.1. Threshold Profile

- 1111 • The system model (*CSx.2*) **shall** define at least one “threshold” profile applicable to  
1112 the threshold scheme. See informative notes in Appendix C.3. The term “threshold”  
1113 is used for convenience, but the actual access structure **may** be different.
- 1114 • The security analysis (*CSx.4*) **shall** clarify which thresholds apply to which main  
1115 security properties. The analysis **should** also characterize the breakdown that occurs  
1116 when threshold-profile assumptions are broken.

### 1117 8.2.2. Type of Adversary

1118 The security analysis (*CSx.4*) **shall** specify an adversary, that is:

- 1119 1. **active (malicious)**, i.e., able to corrupt parties up to one (or various) corruption  
1120 threshold(s), controlling them to deviate from the prescribed multi-party protocol;
- 1121 2. **adaptive**, i.e., able to choose which parties to corrupt after observing some of the  
1122 protocol execution; and
- 1123 3. **mobile**, i.e., persistently attempting to corrupt parties across multiple executions of  
1124 the main protocol.

### 1125 8.2.3. Security Against an Adversary

1126 The required security analysis (*CSx.4*) entails formulating an **ideal functionality** (e.g., in  
1127 the ideal-real simulation paradigm, within the universal composability framework) or/and  
1128 an idealized **game** (or set of games) that defines the capabilities and goals of an adversary.  
1129 Since security analysis is a multi-dimensional exercise, it **may** include several security  
1130 formulations/idealizations, which serve as reference to assess the security of a crypto-system.

1131 With regard to **critical safety properties**, and considering the confines of at least one  
1132 **threshold profile** specified by the team, a proposed threshold scheme **shall** aim to achieve  
1133 security against the **modeled adversary**, as follows:

- 1134 1. **Active security (against active corruptions)**. Various active security nuances  
1135 are possible, including security with abort, where a malicious party has the ability  
1136 to break the availability of the cryptographic primitive. The latter is permissible for  
1137 settings where availability is considered a non-critical property.

- 1138 2. **Adaptive security (against adaptive corruptions).** There is a strong preference  
1139 for **adaptive security**, in contrast to *static* only, with respect to critical safety  
1140 properties, even if some other security properties are only satisfied against a static  
1141 adversary. (See Appendix C.2.2 for notes on practical feasibility.)
- 1142 3. **Compatibility with recovery mechanisms (against mobile attacks).** A submit-  
1143 ted threshold scheme is **not required** to include recovery mechanisms that attempt  
1144 to identify, remove or replace (recover) corrupted parties. However, the submission  
1145 **should** discuss how it envisions possible augmentations to integrate mechanisms  
1146 for **proactive** or **reactive** recovery, which are important for handling a persistent  
1147 **mobile** adversary that continuously attempts to corrupt more parties. For example,  
1148 with respect to refreshing secret shares, a solution can be based on a modularized  
1149 phase of secret-resharing (see S7), while also specifying the needed conditions (e.g.,  
1150 requirement of some initial/final agreement by a qualified quorum) for its integration.

## 1151 9. Requirements for Class N Schemes

1152 As listed in Section 2.1 (Table 2), Class N considers four categories (types of primitive).  
1153 The present section specifies requirements for the submission of threshold schemes for  
1154 primitives in each of those categories: signing (N1; see Section 9.1), PKE (N2; see  
1155 Section 9.2), symmetric (N3; see Section 9.3), and KeyGen (N4; see Section 9.4).

### 1156 9.1. Category N1: Signing

1157 **Signing primitives in scope.** The third column of Table 6 lists the various signing  
1158 primitives of interest. For table succinctness, “[Hash]” denotes optional pre-hashing (to  
1159 differentiate between “pure” and “pre-hashed” versions); “[Det-]” indicates a possible de-  
1160 terministic variant; {...} denotes a set of options. Appendix A.1 provides additional details.

1172 **Interchangeability and security level.** A submission within category N1 **shall** specify  
1173 a threshold signature that is *interchangeable* (see Section 3.3) w.r.t. (with regard to)  
1174 verification of the conventional NIST-specified signature scheme, and **shall** provide at least  
1175 one implementation with  $\kappa \gtrsim 128$ , or  $\theta \geq 1$ , consistent with the parameters described in  
1176 Table 6. The security analysis (CSx.4) **shall** also characterize the type of unforgeability  
1177 achieved, and whether a non-aborting adversary can bias the signature value.

**Table 6.** Signing primitives in category N1

	Subcategory: Specification	NIST reference	Signing primitives to thresholdize	Cryptographic parameters		§ in this call
				$\kappa \approx 128$ or $\theta = 1$	$\kappa \gtrsim 192$ or $\theta \geq 3$	
1161	<b>N1.1:</b> EdDSA	[FIPS-186-5]	[Hash]EdDSA.Sign	Edwards25519	Edwards448	A.1.1
1162	<b>N1.2:</b> ECDSA		[Det-]ECDSA.Sign	P-256	P-{384,521}	A.1.2
1163	<b>N1.3:</b> RSASSA		RSASSA-PSS	$ N  = 3, 072$	$ N  \geq 7, 680$	A.1.3
1164			RSASSA-PKCS-v1.5.Sign			
1165	<b>N1.4:</b> ML-DSA	[FIPS-204]	[Hash]ML-DSA.Sign_Internal	ML-DSA-44	ML-DSA-{65,87}	A.1.4
1166	<b>N1.5:</b> SLH-DSA	[FIPS-205]	[Hash]SLH-DSA.sign	{SHA-256, SHAKE128}	{SHA-512, SHAKE256}	A.1.5.1
1167	<b>N1.5:</b> LMS, XMSS	[SP800-208]	{LMS, XMSS}.Sign	{SHA-256, SHAKE256}	—	A.1.5.2

1168 **Legend:** See related legend of Table 2. Det = **d**eterministic. LMS = Leighton-Micali Signature. PSS =  
 1169 Probabilistic Signature Scheme. PKCS = Public-Key Cryptography Standards. RSASSA = RSA Signature  
 1170 Scheme with Appendix. XMSS= eXtended Merkle Signature Scheme. The elliptic curves (Edwards and  
 1171 P) are specified in SP800-186. [Hash] = Optional consideration of the pre-hashed variant.

1178 **Probabilistic versus deterministic signature schemes.** In a probabilistic mode (e.g.,  
 1179 RSASSA-PSS), two signings of the same input message yield two different signatures. De-  
 1180 terministic modes may be verifiably deterministic (e.g., RSASSA-PKCS-v1.5) or not (e.g.,  
 1181 EdDSA, Det-ECDSA). In the case of (i) **conventional** probabilistic signatures, and (ii)  
 1182 **conventional** non-verifiably-deterministic signatures, a submission of **threshold scheme**  
 1183 (**interchangeable** w.r.t. verification) **may** opt between probabilistic and pseudorandom  
 1184 (PR) modes, including Prob, Q-PR, and F-PR (described ahead).

1185 **Threshold modes w.r.t. (non-)determinism.** The mechanism by which the secret  
 1186 randomness (or pseudorandomness) is selected in the threshold signing scheme, combining  
 1187 contributions from the various parties, determines one of the following possible modes:

- 1188 1. **Prob: Probabilistic** (via a random or hybrid contribution per party)
- 1189 2. **Q-PR: Pseudorandom per quorum** (e.g., via a ZKP of PR contribution per party)
- 1190 3. **F-PR: Fully pseudorandom** (e.g., based on a distributed PRF computation)

1191 If the conventional signature is deterministic per standard, but not verifiably so, then the  
 1192 F-PR mode (deterministic even if the quorum changes) can still be distinguished between:

- 1193 • Functionally equivalent (FE), distributing the PRF computation (e.g., via MPC)
- 1194 • Not FE, yet fully deterministic (e.g., by implementing a threshold-friendlier PRF)

1195 **Note:** In the ML-DSA case, the signing primitive of interest for thresholdization is **ML-**  
 1196 **DSA.Sign\_internal**. Submissions are also welcome to showcase an extension to for  
 1197 [Hash]ML-DSA signatures.

1198 **9.2. Category N2: PKE (Encryption/Decryption)**

1199 **PKE primitives in scope.** The third column of Table 7 lists the PKE-related encryption  
 1200 and decryption primitives of interest to thresholdize. From RSA-based pair-wise  
 1201 key-exchange (2KE) [SP800-56B-Rev2], the primitives in focus for thresholdization are the  
 1202 RSAEP and RSADP exponentiations from the “textbook” RSA crypto-scheme. From  
 1203 ML-KEM [FIPS-203], the primitives in focus for thresholdization are those from the un-  
 1204 derlying K-PKE scheme. However, the encryption primitive K-PKE can be considered in a  
 1205 probabilistic variant that ignores the seed and, where applicable, uses threshold determined  
 1206 randomness (or some other pseudorandomness). Appendix A.2 provides additional details.

**Table 7.** PKE primitives in category N2

	Subcategory: Specification	NIST reference	PKE primitives to thresholdize	Cryptographic parameters		§ in this call
				$\kappa \approx 128$ or $\theta = 1$	$\kappa \gtrsim 192$ or $\theta \geq 3$	
1207	N2.1: RSA-2KE	[SP800-56B-Rev2]	RSAEP	$ \mathcal{N}  = 3,072$	$ \mathcal{N}  \geq 7,680$	A.2.1
1208			RSADP			
1209	N2.2: ML-KEM	[FIPS-203]	K-PKE.Encrypt	ML-KEM-512	ML-KEM-{768,1024}	A.2.2
1210			K-PKE.Decrypt			

1211 **Legend:** See related legend of Table 2. 2KE = Pair-wise Key exchange. PKE = Public-Key Encryption. K-PKE =  
 1212 ML-KEM-related Public-Key Encryption. RSADP = RSA Decryption Primitive. RSAEP = RSA Encryption Primitive.

1213 **Threshold interfaces and security level.** A submission within category N2 *shall*, for at  
 1214 least one of the primitives listed in Table 7, specify at least one of the following:

- 1215 • **Threshold scheme for Encrypt**, which *shall* be SSI w.r.t. the plaintext  $m$ , and  
 1216 *should* be NSS w.r.t. the public encryption key. This provides a secret-sharing  
 1217 protection of the secret plaintext before encryption, without hiding the “public” key.  
 1218 See Appendix A.2.2 about also hiding internal randomness, when applicable. An  
 1219 SSO mode w.r.t. the ciphertext *may* also be considered.
- 1220 • **Threshold scheme for Decrypt**, which *shall* be SSI w.r.t. the private decryption  
 1221 key; *may* be SSI or not (default) w.r.t. the ciphertext; *may* be SSO or not w.r.t. the  
 1222 plaintext. The SSO-plaintext mode can be useful for a threshold receiver in a 2KE.

1223 Additionally, the submission *shall* provide at least one implementation with  $\kappa \gtrsim 128$ , or  
 1224  $\theta \geq 1$ , consistent with the parameters described in Table 7.

1225 **Threshold higher-level primitives.** A threshold scheme in N2 *may* also showcase how  
 1226 to use or adapt it to the corresponding higher-level primitives:

- 1227 • RSASVE.{Generate, Recover} or RSA-OAEP.{Encrypt, Decrypt} (see §A.2.1.2),  
1228 based on {RSAEP,RSADP}.
- 1229 • ML-KEM.{Encaps, Decaps} (see §A.2.2.2), based on K-PKE.{Encrypt,Decrypt}.
- 1230 • NIST-standardized KAS/KTS/KEM. However, an **interchangeable** threshold imple-  
1231 mentation of one side of a full-fledged NIST-standardized 2KE protocol would require  
1232 thresholdizing threshold-unfriendly symmetric primitives (N3) used for key-derivation  
1233 and/or key-confirmation steps.

1234 **Threshold modes w.r.t. (non-)determinism.** A submitted threshold scheme for de-  
1235 cryption (the core primitive or the higher-level operation) **shall** be functionally equivalent  
1236 to the standardized one (RSADP, RSASVE.Recover, RSA-OAEP.Decrypt, K-PKE.Decrypt,  
1237 ML-KEM.Decaps), with possible negligible differences. A submitted threshold scheme for  
1238 public-key encryption **may** follow a probability distribution different from the standardized  
1239 one (RSASVE.Generate, RSA-OAEP.Encrypt, K-PKE.Encrypt, ML-KEM.Encaps), as long  
1240 as it is **interchangeable** w.r.t. standardized decryption (and preserves the usual security  
1241 notions of interest). In particular, a threshold scheme for non-deterministic or not-verifiably  
1242 deterministic encryption **may** be in any of the modes {Prob, Q-PR, F-PR} (as enumerated  
1243 in Section 9.1 for threshold schemes for non-verifiably deterministic schemes).

### 1244 9.3. Category N3: Symmetric Primitives

1245 **Symmetric primitives in scope.** The “symmetric” category (in Class N) includes:

- 1246 1. AES Encipher/Decipher (see §A.3.1)
- 1247 2. Ascon-AEAD Encrypt/Decrypt (§A.3.2)
- 1248 3. Hash and XOF (see §A.3.3), assuming a secret-shared input message.
- 1249 4. MAC TagGen (see §A.3.4). The NIST-approved MAC functions are based on primi-  
1250 tives (cipher, hash function, Keccak permutation) from the above mentioned schemes.

1251 Table 8 lists the NIST-specified primitives. Appendix A.3 provides additional details.

1269 **Threshold interfaces and security level.** A submission within category N3 **shall** specify a  
1270 threshold scheme for at least one primitive listed in Table 8, and **shall** provide one implemen-  
1271 tation with  $\kappa \gtrsim 128$ , consistent with the parameters in the table. If the package proposes  
1272 a threshold-MAC (subcategory N3.4), then it **should** first specify and implement the  
1273 corresponding threshold-cipher/AEAD/hash/XOF, and then use it to implement the MAC.

**Table 8.** “Symmetric” primitives in category N3

	Subcategory: Type	NIST reference	Spec or family	Primitive type	Cryptographic parameters		§ in this call
					$\kappa \approx 128$ or $\theta = 1$	$\kappa \gtrsim 192$ or $\theta \geq 3$	
1252	N3.1: Blockcipher	[FIPS-197]	AES	{Enc,Dec}	AES-128	AES- $\{192,256\}$	A.3.1
1253	N3.2: AEAD	[SP800-232-ipd]	Ascon	{Enc,Dec}	Ascon-AEAD128	—	A.3.2
1254	N3.3: Hash, XOF	[FIPS-180-4]	SHA2	Hash	SHA-256	SHA- $\{384,512\}$	A.3.3
1255		[FIPS-202]	SHA3		SHA3-256	SHA3- $\{384,512\}$	
1256			SHAKE	XOF	SHAKE128	SHAKE256	
1257		[SP800-185]	cSHAKE		cSHAKE128	cSHAKE256	
1258		[SP800-232-ipd]	Ascon	Hash	Ascon-Hash256	—	
1259				XOF	Ascon-[C]XOF128	—	
1260	N3.4: MAC	[SP800-38B]	CMAC	TagGen	AES-128	AES-256	A.3.4
1261		[SP800-38D]	GMAC				
1262		[SP800-224-ipd]	HMAC		SHA[3]-256	SHA[3]- $\{384,512\}$	
1263		[SP800-185]	KMAC		cSHAKE128	cSHAKE256	
1264		(The 4 above)	MAC		$ key  = 128$	$ key  = 256$	

1265 **Legend:** AEAD = Authenticated Encryption with Associated Data. AES = Advanced Encryption Standard. cSHAKE =  
 1266 Customizable SHAKE. [C]XOF = XOF or CXOF (the “C” denotes customizable). Dec = Decipher (if AES) or Decrypt  
 1267 (if Ascon). Enc = Encipher (if AES) or Encrypt (if Ascon). MAC = Message Authentication Code. SHA[3]- = {SHA-  
 1268 SHA3-}. SHAKE- = SHA with Keccak (XOF). TagGen = Tag Generation. XOF = eXtendable Output Function.

1274 **Input lengths.** The experimental evaluation *should* at least benchmark the case of  
 1275 one input that can be processed with a single primitive evaluation. For example: for  
 1276 AES enciphering, the plaintext length would be 128 bits, since it is the block size of the  
 1277 block-cipher; for SHA-256 hashing, the message can be up to 447 bits, since the minimum  
 1278 required padding of 65 bits leads it to the block size of 512 bits. To help clarify possible  
 1279 complexity amortization, the implementation *may* also benchmark the threshold execution  
 1280 of many (e.g., 256) operations. This may help clarify the feasibility of the threshold  
 1281 approach for some mode of operation that repeats the evaluation of many building blocks.

1282 **Input/Output interface.** For hashing and XOF'ing (keyless primitives), the threshold  
 1283 scheme *shall* consider an SSI mode w.r.t. the message. The hashing/XOF'ing result  
 1284 (output) *may* be obtained in NSS or SSO mode. In the case of customizable XOFs, the  
 1285 additional inputs *may* be in the clear or secret shared. For the keyed-primitives (i.e., AES,  
 1286 Ascon-AEAD, MAC), the threshold scheme *shall* consider the key is secret-shared. For the  
 1287 remaining input/output, the threshold scheme *may* consider SSI and SSO modes, such as

- 1288 • **For enciphering/encryption:** SSI w.r.t. message, nonce, and/or associated data  
 1289 (if applicable); and/or SSO w.r.t. ciphertext and/or tag; and vice-versa for decipher-  
 1290 ing/decryption.

- 1291 • **For MAC tag generation:** SSI w.r.t. message, and/or SSO w.r.t. tag. For example,  
 1292 these can be useful when using MAC for key-derivation and/or confirmation, within  
 1293 a 2KE protocol.

## 1294 9.4. Category N4: KeyGen for Class N schemes

1295 **On “private” and “secret” keys.** Various NIST publications use “secret key” in the con-  
 1296 text of symmetric-key primitives, and “private key” in the context of public-key cryptography  
 1297 (to denote the non-“public” element of a private/public key-pair). Since this Threshold  
 1298 Call deals with both symmetric-key and public-key schemes, the expressions “secret key”  
 1299 and (occasionally) “private or secret key” are sometimes used to encompass both contexts.

1300 Table 9 lists the subcategories used to organize the KeyGen primitives in scope. Table 10  
 1301 exemplifies keys that can be generated via a KeyGen operation. Variations are possible.  
 1302 Appendix A.4 provides informative details.

**Table 9.** KeyGen in schemes of Class N

	<b>Subcategory # Type of KeyGen</b>	<b>Related operations</b>	<b>Sections in this Call</b>
1303	<b>N4.1:</b> ECC KeyGen	Scalar multiplication (in additive notation)	9.4.1, A.4.1
1304	<b>N4.2:</b> RSA KeyGen	Generate modulus and/or key-pair	9.4.2, A.4.2
1305	<b>N4.3:</b> ML KeyGen	ML-DSA.KeyGen, K-PKE.KeyGen	9.4.3, A.4.3
1306	<b>N4.4:</b> HBS KeyGen	Generate hash trees (for SLH-DSA, LMS, XMSS)	9.4.4, A.4.3
1307	<b>N4.5:</b> Secret RBG	RBG for secret bit-strings or integers	9.4.5, A.4.5

1308 **Legend:** ECC = elliptic curve cryptography. HBS = hash-based signatures. KEM = Key-Encapsulation Mechanism.  
 1309 K-PKE = ML-KEM-related Public-Key Encryption. ML = Module Lattice. LMS = Leighton-Micali Signature.  
 1310 XMSS= eXtended Merkle Signature Scheme. RBG = random-bit generation. RSA = Rivest-Shamir-Adleman.

1323 **Threshold KeyGen (DKG).** Threshold KeyGen schemes are usually known as Distributed  
 1324 Key Generation (DKG) protocols. They enable a set of parties to collaborate to generate  
 1325 a secret sharing of a fresh secret or private key, such that the key is never assembled  
 1326 in one place. When applicable, the parties also obtain the public key (e.g., an RSA  
 1327 modulus obtained from the product of two secret primes; usually not secret shared), and/or  
 1328 commitments of everyone’s private keys. Some domain parameters are agreed upon before  
 1329 the DKG (e.g., elliptic curve, security strength  $\kappa$ , and RSA public encryption key  $e$ ).

**Table 10.** Examples of KeyGen purposes

	KeyGen purpose (subsequent operation)	Secret or private key	Public elements	Section (in this Call)
1311	EdDSA signing	Secret keys $(s, \nu) = \text{Hash}(d)$	$Q = s \cdot G$ (EC point)	9.4.1
1312	ECDSA signing	Exponent $d$ (integer mod $n$ )	$Q = d \cdot G$ (EC point)	
1313	ECC-CDH for 2KE	$P = (h \cdot d_A) \cdot Q_B$	$Q_A = d_A \cdot G$	A.4.1.2
1314	RSA signing, Enc/Dec	Primes $(p, q)$	Modulus $N = p \cdot q$	9.4.2
1315		Exponent $d = e^{-1} \text{ mod } \phi_N$	Exponent $e$	
1316	RSA encryption for 2KE	Bit-string $Z$	$c = \text{RSAEP}((N, e), Z)$	
1317	ML for K-PKE Enc/Dec	Secret vectors $\hat{s}, \hat{e}$	$\hat{t} = \hat{A} \circ \hat{s} + \hat{e}$	9.4.3
1318	ML for ML-DSA Sign	Secret vectors $s_1, s_2$	$t = \text{NTT}^{-1}(\hat{A} \circ s_1) + s_2$	
1319	AES Enc/Dec	Bit-string $k$	—	9.4.5
1320	Key derivation		$k = \text{KDM}(Z, \dots)$	—
1321	Key confirmation		MacTag $T = \text{KC}(\dots, k, \dots)$	—

1322 Enc/Dec = encrypt/decrypt.  $h$  = cofactor. KC = key confirmation. KDM = key derivation mechanism.

1330 **Interchangeability of random values.** In a DKG protocol, the secret key to be output  
 1331 in secret-shared form is obtained by combining contributions of randomness (or pseudo-  
 1332 randomness) from several parties. The (pseudo)randomness from each party **may**  
 1333 be obtained using NIST-specified RBG methods. A submitted DKG **shall** be **interchangeable**  
 1334 w.r.t. a subsequent operation of interest (e.g., signing or encryption). The specification  
 1335 **shall** also explain why the obtained randomness is appropriate, from a security perspective,  
 1336 considering the conventional (non-threshold) KeyGen. The implementation **shall** generate  
 1337 secret-shared keys consistent with one set of NIST-approved parameters, to ensure security  
 1338 level  $k \gtrsim 128$  or  $\theta \geq 1$ .

#### 1339 9.4.1. Subcategory N4.1: ECC KeyGen

1340 The goal of a DKG for an ECC scheme is to produce a secret-sharing  $[d]$  of the private  
 1341 key  $d$ , produce commitments of the shares  $d_i$  of each party, and calculate the public key  
 1342  $Q = d \cdot G$ . The “commitments” **may** be simple public-key shares  $Q_i = d_i \cdot G$ , or fancier  
 1343 semantically hiding commitments. The KeyGen **may** include additional elements related  
 1344 to the commitments (e.g., a ZKPoK of each secret share). A submission in subcategory  
 1345 **N4.1**, i.e., with a threshold scheme for an ECC-based primitive in Class N, **shall** include  
 1346 an implementation based on at least one elliptic curve that is NIST-approved for the  
 1347 scheme, namely from: Edwards{25519,448} for EdDSA, P-{256,384,521} for ECDSA,  
 1348 and P-{256,384,521} for ECC-2KE. Appendix A.4.1 has additional details.

1349 This subcategory also includes the ECC-based CDH and MQV primitives. In the threshold  
1350 setting, they require computing the core ECC operation: scalar multiplication of a group  
1351 element, when the scalar is secret shared. This is somewhat similar to computing a public  
1352 ECC key from a secret-shared private key (i.e., the scalar). A submission in this subcategory  
1353 **may** focus on these ECC-based primitives. A full-fledged thresholdization of one-side of a  
1354 NIST-approved ECC-based 2KE protocol would additionally require thresholdizing specific  
1355 non-ECC primitives for key-derivation/confirmation, which are threshold-unfriendly.

#### 1356 **9.4.2. Subcategory N4.2: RSA KeyGen**

1357 A submission of RSA DKG **should** obtain a modulus of size at least  $|N| = 3072$ , for  
1358  $\kappa \gtrsim 128$ . Considering the possible applications of an RSA modulus without known fac-  
1359 torization, an RSA-DKG scheme **may** be submitted as a standalone threshold scheme  
1360 (i.e., independent of subsequent RSA signing, encryption and decryption operations).  
1361 Appendix [A.4.2.1](#) has additional details.

1362 One complexity challenge of RSA DKG is the threshold handling of rejection sampling  
1363 of candidate primes. For the sake of exploration, submissions **may** choose to sample the  
1364 primes, and/or the private exponent, using criteria different from what is described in  
1365 [§A.4.2.2](#). However, any such differences **shall** be well-documented and motivated. For  
1366 example, it is acceptable for the RSA modulus to be biased toward being (or even restricted  
1367 to be) a Blum integer (i.e., with both primes being  $3 \bmod 4$ ), as their properties are useful  
1368 in some applications. Submissions that follow a generation method (e.g., direct biprimality  
1369 testing) different from what is described in the NIST publications **shall** present a rationale  
1370 to convey adequacy (e.g., adequate number of rounds).

#### 1371 **9.4.3. Subcategory N4.3: ML KeyGen**

1372 A DKG for NIST-specified schemes based on Module-Lattices (ML) **shall** obtain a random  
1373 secret-shared private key, and a corresponding public key, that are suitable for at least one  
1374 of the approved parameter sets (i.e., for ML-DSA{44,65,87} or ML-KEM{512,768,1024}).  
1375 While KeyGen is different between K-PKE (the PKE in ML-KEM) and ML-DSA, they  
1376 both produce lattice-related elements, and may have some commonalities in the threshold  
1377 setting. Appendix [A.4.3](#) has additional details.

1378 As long as the interchangeability requirement is met, the DKG **may** handle (pseudo)ran-  
1379 domness differently from the conventional case:

- 1380 • **Random sampling instead of pseudorandom.** The distributed computation of  
1381 NIST-specified threshold-unfriendly pseudorandom generations is expensive. There-

1382 fore, a submitted ML-DKG *may* use more-efficient threshold randomness-sampling,  
 1383 provided that it retains the functionality and security of the final key.

- 1384 • **Different intermediate encodings/representations.** The optimization of thresh-  
 1385 old schemes may suggest different encodings or representations, which would still  
 1386 be mathematically equivalent (e.g., whether/when to use the NTT and its inverse  
 1387  $\text{NTT}^{-1}$ ). This *may* be done, provided that the keys are *interchangeable* w.r.t. a  
 1388 subsequent threshold operation (i.e., signing, decryption or encryption).

1389 For any of the two ML-based schemes, the parties *may* use a secure coin-flipping protocol  
 1390 to collaboratively determine the public seed  $\rho$ , and then use it in the clear to pseudoran-  
 1391 domly generate the public matrix  $\hat{\mathbf{A}}$ . The parties *may* then interact in a threshold manner  
 1392 to distributively generate a secret sharing (across the parties) of the needed vector terms:  
 1393  $(\hat{\mathbf{s}}, \hat{\mathbf{e}})$  for K-PKE, and  $(\mathbf{s}_1, \mathbf{s}_2)$  for ML-DSA. Finally, the parties *may* distributively compute  
 1394 the result of the linear operation between the matrix and the vectors:  $\hat{\mathbf{t}} = \hat{\mathbf{A}} \circ \hat{\mathbf{s}} + \hat{\mathbf{e}}$ , for  
 1395 K-PKE; or  $\mathbf{t} = \text{NTT}^{-1}(\hat{\mathbf{A}} \circ \text{NTT}(\mathbf{s}_1)) + \mathbf{s}_2$ , for ML-DSA. In the case of ML-DSA, the  
 1396 element  $K$  would also be distributively produced as a secret sharing. The private and  
 1397 public keys are then the applicable encodings of the computed elements.

#### 1398 9.4.4. Subcategory N4.4: HBS KeyGen

1399 A DKG for stateless (SLH-DSA) or stateful (LMS and XMSS) hash-based signatures (HBS)  
 1400 depends on the intended type of secret sharing of the private key (e.g., of a hash tree), to  
 1401 facilitate a subsequent threshold operation. Practical threshold schemes for HBS will likely  
 1402 be based on threshold-friendlier PRFs, which would thus fit in *Class S*. Appendix A.4.3  
 1403 has additional details.

#### 1404 9.4.5. Subcategory N4.5: Secret RBG

1405 If a scheme requires a simple random value (e.g., a bit-string, or an integer) for a secret-key,  
 1406 then the DKG essentially needs to produce a secret sharing of such type of random value.  
 1407 The protocol may also produce public commitments of the shares of each party, even if  
 1408 the original primitive did not produce a public key. These commitments may change the  
 1409 security guarantees of the key. For example, AES-256 is considered PQ, but committing  
 1410 to its key a la ECC-KeyGen using an ECC-based commitment of the AES key would make  
 1411 the overall scheme QV. Appendix A.4.5 has additional details.

## 1412 **10. Requirements for Class S Schemes**

1413 **Class S** considers cryptographic schemes not standardized by NIST. However, its categories  
1414 (already enumerated in Section 2.2 and Table 3) are not intended for the submission of  
1415 every type of academically interesting scheme. A submission *shall* be motivated by a  
1416 serious intention of proposing for technical consideration a scheme that, besides being  
1417 secure and practical, is believed to have a high potential for adoption in the real world.  
1418 In particular, Class S welcomes the submission of threshold schemes for primitives of  
1419 conventional (non-threshold) schemes that have been previously or are being thoroughly  
1420 specified elsewhere, such as in other standards, or standards' proposals.

1421 **Regular categories in Class S.** The first four categories of **Class S** are **S1** for signing, **S2**  
1422 for public-key encryption, **S3** for symmetric primitives, and **S4** for KeyGen. They are called  
1423 "regular" in the sense that the types of primitives match those of the **Class N** categories.

1424 The **specification** document *shall* include a motivating comparison with the NIST stan-  
1425 dardized primitives of the same type (e.g., signature, encryption, cipher). In particular, the  
1426 proposed primitive *should* have a distinctive feature, such as being threshold friendlier or  
1427 based on different cryptographic assumptions, or have better efficiency (the conventional  
1428 scheme or its threshold version) in some useful metric (e.g., succinctness, or communication  
1429 complexity). If the motivation relates to an additional algorithm (e.g., allowing batch verifi-  
1430 cation, or being ZKP friendly), then the corresponding algorithm *should* also be explained.

1431 **Other categories in Class S.** The scope of Class S also includes primitives from other  
1432 types of schemes not standardized by NIST. Correspondingly, Class S has the additional  
1433 categories **S5** for FHE (see Sections 10.5 and B.1), **S6** for ZKPoKs (see Sections 10.6  
1434 and B.2), and **S7** for gadgets (see Section 10.7). In submitted proposals of ZKPoKs (**S6**)  
1435 or gadgets (**S7**), a conventional scheme (i.e., non-threshold) suffices, being optional the  
1436 specification of a corresponding threshold scheme. The FHE and ZKPoK cases are also of  
1437 specific interest to the NIST Privacy-Enhancing Cryptography (PEC) project [Proj-PEC].

1438 **Combinations.** A submission *may* include crypto-systems from multiple categories, e.g.:

- 1439 • A threshold scheme for a primitive in a non-KeyGen category (e.g., **S1–S3**, **S5**).
- 1440 • A DKG protocol (**N4** or **S4**) for generating the secret-shared key.
- 1441 • A related ZKPoK (**S6**).

1442 **Specification of conventional primitives.** In a submission of a threshold scheme for  
1443 a primitive in Class S, the **specification** document *shall* explain the conventional scheme,  
1444 namely in sufficient detail to derive the interchangeability requirement (i.e., to establish

1445 what is a valid output of the threshold scheme), and its setup (e.g., properties about the  
1446 initial key). For example, a submission of threshold scheme for a signing primitive not  
1447 specified by NIST needs to explain the verification and KeyGen primitives, besides the  
1448 conventional signing primitive. If the conventional scheme has additional features/algo-  
1449 rithms that can benefit its assessment, then they **should** also be specified. The required  
1450 specification of the conventional scheme **may** be done (i) thoroughly, as a standalone  
1451 proposed crypto-system (in 5.4); or (ii) at a high-level (in Pre4), but explaining at least the  
1452 notation, interface, and security properties, while including a reference to an authoritative  
1453 specification that is freely available to the public. Also, the specification document **shall**  
1454 propose at least one concrete set of parameters for implementation.

## 1455 10.1. Category S1: Signing

1456 Category S1 is for submissions of threshold schemes for the signing primitive of digital  
1457 signature schemes (QV or PQ) that are not standardized by NIST. Example motivating  
1458 comparisons with NIST-standardized signatures:

- 1459 1. Threshold friendlier and PQ.
- 1460 2. Succincter and verifiably deterministic (i.e., a function of the message and the  
1461 public-key), even if QV (e.g., based on pairings).
- 1462 3. ZKP-friendlier (e.g., easier to generate unlinkable ZKPoKs of a signature).
- 1463 4. Blinding friendly (i.e., having a structure that efficiently enables a protocol for blind  
1464 signing, with concurrent security and low communication complexity).
- 1465 5. Aggregatable (i.e., allowing the aggregation of multiple signatures into a sublinear  
1466 size result, such as just one signature).
- 1467 6. Batch verifiable (i.e., enabling the efficient verification of many signatures at once).

1468 Recall that a signature is essentially a ZKPoK of a private key, while binding the proof  
1469 to the message. Therefore, a proposed threshold signature scheme can also be framed  
1470 as a threshold ZKPoK of a distributed secret (i.e., the signing key).

## 1471 10.2. Category S2: PKE

1472 Category S2 is for submissions of threshold schemes for (non-keygen) primitives of “reg-  
1473 ular” public-key encryption (PKE) schemes that are not standardized by NIST. There is  
1474 a particular interest in threshold-friendly PQ PKE schemes. Submitted threshold schemes  
1475 **may** be applied to decryption when the private key is secret shared, or/and encryption  
1476 when the plaintext is secret-shared (e.g., when used for key encapsulation).

### 1477 **10.3. Category S3: Symmetric**

1478 Symmetric primitives (such as those in [N3](#)) have traditionally been designed to be efficient  
1479 in a single-party setting. However, they often do not lend themselves naturally to efficient  
1480 threshold implementations. The category [S3](#) enables proposals of threshold-friendlier  
1481 (TF) symmetric primitives. It is also of interest to consider friendliness w.r.t. FHE (see  
1482 [Appendix B.1](#)) and ZKP (see [Appendix B.2](#)).

1483 **Families of primitives of interest.** A crypto-system proposed in [S3](#) *should* fit one of the  
1484 following indexed family of primitives: S3.1 PRP (e.g., for enciphering); S3.2 PRF (e.g.,  
1485 for MAC'ing); S3.3 Hash function or XOF. If a design principle allows building primitives  
1486 for various families, then a submission *may* propose a corresponding family of “symmetric”  
1487 primitives and their threshold schemes.

1488 **Efficiency goal.** This category is not meant for proposals of conventional symmetric  
1489 primitives that would only marginally improve efficiency in the threshold paradigm, as  
1490 compared to a threshold scheme for primitives in [N3](#). Rather, proposed conventional  
1491 primitives *should* yield an order of magnitude or more of improvement in the threshold  
1492 setting. This improvement *may* refer to a single evaluation, or to an amortized setting  
1493 (e.g., with large input/output, or with many evaluations of the underlying primitive).

1494 **Example use for key derivation/confirmation.** The full-fledged 2KE NIST-specified  
1495 protocols are not threshold friendly (despite the use of threshold-friendly PKE primitives),  
1496 because of their use of threshold-unfriendly key-derivation/confirmation primitives. The  
1497 present category [S3](#) can, for example, be used to propose threshold friendlier symmetric  
1498 primitives that could be used for alternative key-derivation/confirmation components.

1499 **Interest in commitment schemes.** One application of interest for TF symmetric  
1500 primitives is a commitment scheme, with hiding, binding and non-malleable properties,  
1501 with either succinct commitment or opening, and possibly ZKP-friendly w.r.t. selective  
1502 disclosure. Such additional specification is allowed in this category only if based on building  
1503 blocks used to first specify one of the above mentioned family of primitives of interest.  
1504 Alternatively, it can be submitted in the category of gadgets ([S7](#)).

### 1505 **10.4. Category S4: Keygen**

1506 As in [N4](#), the category [S4](#) considers the KeyGen for schemes with primitives in other  
1507 categories of [Class S](#). This category *should* be identified in a submission that proposes  
1508 a DKG as an alternative to using a dealer for the initial secret-sharing of a secret key.

1509 If a proposed DKG is usable for primitives in both [Class N](#) and [Class S](#), then the submission  
1510 can indicate suitability with both categories [N4](#) and [S4](#).

1511 **Single-party primitives to support KA.** This KeyGen category also includes single-  
1512 party non-PKE PKC-primitives for use in multi-party key-agreement. A corresponding  
1513 submission *should* be justified based on different assumptions (e.g., possibly PQ), or even  
1514 for allowing efficient key-agreement between more than two parties. The scope excludes  
1515 PKE encryption/decryption primitives, which are already covered by the PKE category ([S2](#)).

## 1516 **10.5. Category S5: FHE**

1517 Category [S5](#) relates to fully-homomorphic encryption (FHE), which is a special type of  
1518 encryption that allows for arbitrary computation over encrypted data. Given one or more  
1519 ciphertexts produced using the same key (public or secret) under an FHE scheme, it is  
1520 then possible, from the ciphertext(s) alone (i.e., without the original plaintext and the  
1521 decryption key), to produce a ciphertext that encrypts the result of an intended operation  
1522 over the original plaintexts. Appendix [B.1](#) has additional details.

1523 **Threshold scheme.** The submission *shall* specify (in [CSx.3](#)) at least how to perform  
1524 (i) threshold decryption (i.e., with a secret-shared key), or (ii) threshold encryption of a  
1525 secret-shared value. The thresholdization of other primitives (e.g., KeyGen) is optional.

1526 **Conventional scheme.** The specification of the conventional FHE scheme, either (i)  
1527 thoroughly in [Pre4](#), or (ii) at a high-level (in [CSx.3](#)) and supported on a thorough  
1528 reference, *shall* explain at least the interface and properties of the four main algorithms:  
1529 KeyGen, Enc, Dec, hom. (The latter can be a set of algorithms, covering various homo-  
1530 morphic operations.) Depending on the FHE scheme, it may be useful to modularize  
1531 the specification of other auxiliary algorithms, such as for refreshing a ciphertext (a.k.a.  
1532 bootstrapping, producing a new ciphertext that encrypts the same element as encrypted  
1533 by the original ciphertext, but with reduced “noise”).

1534 **Benchmarking of the conventional scheme.** Since FHE is a type of encryption  
1535 scheme that has not been previously standardized by NIST, but is of high exploratory  
1536 interest, its conventional primitives *should* also be benchmarked, i.e., in addition to the  
1537 benchmarking of the threshold schemes. The selection of the benchmarking use-cases  
1538 to evaluate performance (in [M3](#)) is left to the discretion of the submitters of an FHE  
1539 scheme. Yet, submissions are encouraged to use benchmarking approaches emerging,  
1540 reviewed or endorsed by community efforts. It is known that different FHE schemes have  
1541 different applications or use cases in which they excel, depending on the type of arithmetic

1542 (e.g., Boolean, modular integer, or fixed-point) to be homomorphically evaluated. Each  
1543 submission **should** at least: (i) showcase performance for one use case in which it performs  
1544 well, and (ii) explain the anticipated real-world adoptability of that application (see [CSx.6](#)).  
1545 For comparison, the benchmarking is encouraged to also measure performance for some  
1546 operation that is anticipated to perform better by a different FHE scheme.

## 1547 **10.6. Category S6: ZKPoK**

1548 Category [S6](#) allows for the submission of zero-knowledge proofs of knowledge (ZKPoKs)  
1549 that are relatable to the other categories. These proofs enable proving knowledge (possibly  
1550 in a secret-shared sense) of a private value (e.g., a secret/private key, or some other  
1551 confidential input or output of a cryptographic operation), without disclosing it. The  
1552 ZKPoK of a private value needs to relate to some “public” value known by the verifier,  
1553 such as: a a public key, the public commitments of secret shares, or the output of a  
1554 cryptographic operation (e.g., signature, encryption, or hashing). In a threshold ZKPoK  
1555 generation, a distributed prover can interact to produce a ZKPoK of a secret-shared value,  
1556 without ever reconstructing it. Appendix [B.2](#) has additional details.

1557 **Proofs and Arguments.** When referring to ZKPoKs, this call uses the term “proof”  
1558 in a broad sense that also encompasses “arguments” (with computational soundness).  
1559 Any submission of a ZKPoK **shall** clarify its soundness type (to allow for differentiation  
1560 between “proof” and “argument”).

1561 **Conventional versus threshold.** A submission of ZKPoK **shall** at least specify a con-  
1562 ventional (i.e., non-threshold) ZKPoK. Optionally, the submission **may** also specify a  
1563 corresponding threshold scheme. In the latter, the secret input (the witness) is secret  
1564 shared across a distributed prover. If a threshold ZKPoK generation is proposed, then it  
1565 **shall** be [interchangeable](#) w.r.t. verification of an explained conventional ZKPoK.

1566 **ZKPoK scope.** A submission proposing a ZKPoK **shall** showcase an instantiation related  
1567 to a primitive in the scope of another category (e.g., a ZKPoK of a signature valid w.r.t.  
1568 a public key). Table [15](#) lists several examples (in Appendix [B.2.1](#)). The proposed ZKPoK  
1569 system can be tailored to the primitive in question, or be a general ZKPoK system (e.g.,  
1570 applicable to any non-deterministic polynomial problem, with a given representation, such  
1571 as a circuit or some other constraint system; see Appendix [B.2.5](#)). In the general case, the  
1572 instantiation **should** be achieved by modularly specifying (in a standalone file) a concrete  
1573 system of constraints, to be parsed by the proof generator and the proof verifier. The specific  
1574 ZKPoK object (what is being proven) can then be changed by simply changing that file.

1575 **ZKPoK security and characterization.** A ZKPoK submission (conventional or/and  
1576 threshold) *shall* indicate a parameter set for achieving at least one profile of security  
1577 strength for soundness and zero-knowledge, satisfying  $(\kappa, \sigma) \succeq (128, 40)$ . It is encour-  
1578 aged that a second parameter set is also proposed, for comparison purposes, achieving  
1579  $(\kappa, \sigma) \succeq (192, 64)$ . See additional notes in Appendix B.2.4.

1580 A submission of ZKPoK *should* motivate the achieved features (e.g., when applicable,  
1581 transferability or deniability, interactivity, succinctness). The instantiation of some of them  
1582 may affect some aspects of composability, which *should* also be discussed.

## 1583 10.7. Category S7: Gadgets

1584 When deemed useful for other threshold schemes, Category S7 allows for the submission of  
1585 auxiliary primitives, which this Threshold Call refers to as *gadgets*. They can be conventional  
1586 or threshold. See related notes on §5.3.1 of NIST-IR8214A, and §5.5.2 of NIST-IR8214B-ipd.

1587 **Specification.** A gadget *may* be specified as a standalone crypto-system (i.e., a formal  
1588 “part” of the specification; see CSx.3 in Section 5.4), in which case it *shall* make a strong  
1589 case for why it can be used to support crypto-systems in other categories. Alternatively, a  
1590 gadget *may* be specified directly as a module (in Pre4 or CSx.3) of a more complex crypto-  
1591 system, and still referenced as a gadget in the *specification scope*. Preferably, gadgets  
1592 that are very simple (e.g., Shamir secret-sharing and Lagrange interpolation) and expected  
1593 to appear in many independent submissions *should* be specified in the latter manner.

1594 **Implementation and evaluation.** To be considered as a standalone gadget during the  
1595 *public analysis* phase, the gadget *shall* (i) be *implemented* with corresponding *scripts* and  
1596 *instructions* for testing the gadget, and (ii) be analyzed in the *experimental performance*.

1597 **Gadgets in particular categories.** If a submission specifies a gadget that is directly in  
1598 the scope of another category, and the submission also includes a threshold scheme for  
1599 it, then the gadget *should* be organized in said category, instead of S7. For example, a  
1600 threshold-friendly hash function fits better in S3.3, within the category Class S (symmetric).

1601 **Gadget examples:** Sophisticated secret-sharing variants, such as verifiable or publicly-  
1602 verifiable; garbled circuits; oblivious transfer; generation of correlated randomness; commit-  
1603 ment schemes; secret resharing (possibly for new values  $f$  and  $n$ ); multiplicative-to-additive  
1604 share conversion; linearly homomorphic encryption; vector oblivious linear evaluation;  
1605 verifiable random functions; consensus and broadcast.

## 1607 **Appendix A. Notes on Class N Categories**

1608 This section includes informative notes about some of the categories, subcategories, and  
1609 primitives within Class N. Related requirements for submissions are discussed in Section 9.

### 1610 **A.1. Category N1: NIST-Specified Signing Primitives**

1611 Category N1 is for submissions of threshold schemes for NIST-specified signing primitives:  
1612 See submission requirements in Section 9.1. The conventional signature schemes of interest  
1613 are: EdDSA (N1.1, see §A.1.1), ECDSA (N1.2, see §A.1.2), RSADSA (N1.3, see §A.1.3),  
1614 ML-DSA (N1.4, see §A.1.4), and SLH-DSA and Stateful HBS (N1.5, see §A.1.5).

1615 **Threshold verification of signatures (secondary interest).** While some applications  
1616 may meet a privacy goal by performing a threshold verification in SSI mode w.r.t. the  
1617 signature and/or the message, this is of secondary interest in this Threshold Call. A  
1618 specification of such threshold verification is welcome (but not required) to accompany  
1619 a submitted specification of threshold signing. This is somewhat analogous to threshold  
1620 PKE-encryption of a secret-shared message, but signatures usually relate to the protection  
1621 of integrity instead of confidentiality.

#### 1622 **A.1.1. Subcategory N1.1: EdDSA Signing**

1623 **Conventional signature.** EdDSA [FIPS-186-5, §7], has pseudorandom signatures. The  
1624 standardized signing  $\text{Sign}_n[s, \nu](M)$  of a message  $M$ , requires a private signing key  $s$  and  
1625 a nonce-derivation key  $\nu$ . Ignoring some encoding details, the signing outputs a signature  
1626  $\sigma = (R, S)$ , where  $R = r \cdot G$ ,  $G$  is the base-point of the elliptic curve,  $r = H(\nu, M)$ ,  $H$   
1627 is a cryptographic hash function,  $S = r + \chi \cdot s$ ,  $\chi = H(R, Q, M)$  is the challenge, and  
1628  $Q = s \cdot G$  is the public key. Per specification, the secret keys  $(s, \nu)$  are obtained from  
1629 the two halves of a hash of  $d$ , where  $d$  is a random secret key. HashEdDSA is a signing  
1630 variant that considers pre-hashed messages as input.

#### 1631 **A.1.2. Subcategory N1.2: ECDSA Signing**

1632 **Conventional signature.** ECDSA [FIPS-186-5, §6] has a default signing mode that is  
1633 probabilistic (§6.3.1), and also has a deterministic mode (§6.3.2), here abbreviated as  
1634 Det-ECDSA. Table 11 compares the conventional notation of EdDSA and of ECDSA.

1637 The ECDSA signing  $\text{Sign}_n[d](M)$  of a message  $M$  outputs a signature  $\sigma = (r, s)$ , where  
1638 (ignoring some encoding details),  $d$  is the private signing key,  $Q = d \cdot G$  is the public

**Table 11.** Notation of EdDSA versus ECDSA (in FIPS 186-5)

Scheme	Signature (output)	Private key	Public key	Secret nonce	Nonce commitment	Challenge	“Precursor” private key
EdDSA	$(R, S)$	$s$	$Q$	$r$	$R$	$\chi$	$d$
ECDSA	$(r, s)$	$d$	$Q$	$k$	$r$	$e$	—

key;  $G$  is the base-point of the elliptic curve, the “challenge”  $e = \text{Encode}_n^{(1)}(\text{Hash}(M))$  is an encoding (mod  $n$ ) of the hash of the message being signed;  $n$  is the order of  $G$ ;  $k \leftarrow^{\$} [1, \dots, n - 1]$  is (in the probabilistic version) a uniformly selected secret nonce;  $R = k \cdot G$  is the “nonce commitment” and  $r = \text{Encode}_n^{(2)}(R)$  is a corresponding encoding (mod  $n$ ); and  $s = k^{-1} \cdot (e + r \cdot d) \pmod{n}$ . In Det-ECDSA the secret nonce  $k$  is instead obtained pseudorandomly from  $\text{Hash}(M)$  and  $d$ , requiring several calls to HMAC.

### 1645 **A.1.3. Subcategory N1.3: RSADSA Signing**

1646 RSA signature modes are specified in §5.4 of [FIPS-186-5](#), by reference to IETF [RFC8017](#),  
 1647 and with some constraints on the KeyGen and the possible hash functions. The standard  
 1648 specified two signature schemes with appendix (SSA):

- 1649 1. RSASSA-PSS (probabilistic signature scheme), using an approved hash function or XOF
- 1650 2. RSASSA-PKCS-v1.5 (deterministic), using an approved hash function

1651 Both PSS and PKCS-v1.5 schemes are of the SSA type. This means the message itself  
 1652 is required to verify the signature, rather than the standalone signature enabling message  
 1653 recovery. However, they use different encoding mechanisms for the signature with appendix  
 1654 (EMSA), namely EMSA-PSS and EMSA-PKCS-v1.5, respectively. Other than that, they are  
 1655 then based on the same core primitives: RSASP1 for signing and RSAVP1 for verification.

### 1656 **A.1.4. Subcategory N1.4: ML-DSA Signing**

1657 **Conventional signature.** ML-DSA [[FIPS-204](#)] is one of the two first NIST-standardized  
 1658 stateless PQ signing schemes. It is a PQ signature scheme with a construction inspired by  
 1659 Schnorr signatures, but based on lattices and with various tweaks for efficiency and security.  
 1660 The standard defines three parametrizations: ML-DSA $\{44,65,87\}$ , equating them to PQC  
 1661 security categories ( $\theta$ )  $\{2, 3, 5\}$ , respectively. Correspondingly, the internal random-bit  
 1662 generations are required to use security strength  $\kappa$  at least  $\{128, 192, 256\}$ . However,  
 1663 if ML-DSA-44 is implemented with randomness with strength  $128 \leq \kappa < 192$ , then its  
 1664 claimed PQC security category is decreased to  $\theta = 1$  [[FIPS-204](#), §3.6.1].

1665 **Regular, pre-hashed, and internal function.** ML-DSA has two main versions: “pure”  
1666 (ML-DSA) and “pre-hashed” (HashML-DSA). Both versions accept an input argument  
1667 with content (i.e., a byte-string  $ctx$  with length between 0 and 255). The pre-hashed  
1668 version also receives as input an identifier of which hash function to use. The specification  
1669 modularizes an internal algorithm  $\text{ML-DSA.Sign\_internal}(sk, M', rnd)$ , with the input  
1670  $M'$  already integrating the context and the plaintext message or its hash.

1671 **Probabilistic and deterministic modes in the conventional algorithm.** The ML-DSA  
1672 scheme allows (similar to ECDSA, in N1.2) probabilistic and deterministic variants:

- 1673 • A default (“hedged”) probabilistic mode, where  $rnd$  is a random 32-byte string
- 1674 • A deterministic mode (Det-), where  $rnd$  is fixed to be the all-zeros 32-byte string

1675 A standalone ML-DSA signature does not reveal which mode was used. In particular,  
1676 the deterministic mode is not verifiably deterministic. Per FIPS 204 (Algorithm 7, step  
1677 7): the internal signing algorithm  $\text{ML-DSA.Sign\_internal}(sk, M', rnd)$  obtains a secret  
1678 “random-or-pseudorandom” value  $\rho'' \leftarrow H(K || rnd || \mu, 64)$ , where  $K$  is derived from the  
1679 private key,  $rnd$  is all zeros or random, and  $\mu$  is derived from the message and the public key.

1680 One peculiarity of ML-DSA signing is that it requires a rejection sampling loop. Without  
1681 it, there would be a noticeable probability that a signature would reveal information about  
1682 the secret key. Therefore, the rejection sampling keeps trying until it obtains a signature  
1683 candidate that satisfies a number of tests. In FIPS-204, Table 1 lists the expected number  
1684 of trials: {4.25, 5.1, 3.85} for ML-DSA-{44,65,87}, respectively. The publication also lists  
1685 iteration bounds for a non-completion probability around  $2^{-256}$ .

### 1686 **A.1.5. Subcategory N1.5: HBS Signing**

1687 This section considers NIST-standardized **hash-based** signature (HBS) schemes. They  
1688 are post-quantum, with security relying solely on NIST-standardized hash functions. The  
1689 goal of this section is to identify the signature schemes in scope, distinguish between the  
1690 **stateless** and the **stateful** approaches, and motivate the exploration of threshold schemes  
1691 for (possibly alternative) HBS schemes. The section does not delve into the actual signing  
1692 mechanisms. §A.1.5.1 discusses the (stateless) SLH-DSA, §A.1.5.2 considers the stateful  
1693 HBS schemes, and §A.1.5.3 briefly comments on possible threshold HBS schemes.

#### 1694 **A.1.5.1. Conventional SLH-DSA (stateless)**

1695 The **Stateless Hash-Based** Digital Signature Algorithm (SLH-DSA) is a post-quantum  
1696 signature scheme standardized by FIPS-205. Its security does not rely on keeping track  
1697 of which internal signing keys have been used. As components, SLH-DSA uses two other

1698 hash-based signature schemes: the forest of random subsets (FORS), and the eXtended  
1699 Merkle Signature Scheme (XMSS). In turn, XMSS is based on the Winternitz One-Time  
1700 Signature Plus (WOTS<sup>+</sup>) scheme. The XMSS scheme is used within a *hypertree* signature  
1701 scheme, which uses a tree of trees, rather than a single XMSS tree.

1702 At a very high level, an SLH-DSA signature is produced as follows. the message is hashed,  
1703 and a pseudorandom index is determined from the hash, to serve as an identifier of a  
1704 FORS key, which is part of (i.e., derivable from) the SLH-DSA private key. Then, the  
1705 message hash is signed by the FORS key. The final SLH-DSA signature is composed of  
1706 the FORS signature, and an authenticator of the FORS public key, which is produced via  
1707 a hypertree signature. The latter is composed of a sequence of XMSS signatures (one  
1708 for each layer of the hypertree).

1709 SLH-DSA specifies 12 parameter sets: SLH-DSA- $\{\text{SHA2,SHAKE}\}$ - $\{128,192,256\}$  $\{s,f\}$ ,  
1710 corresponding to  $2 \times 3 \times 2$  options (see Table 12 of [FIPS-205](#)). More sets (e.g., allowing  
1711 fewer but shorter signatures) may be allowed by the forthcoming SP800-230. The inter-  
1712 mediate label  $\{128,192,256\}$  indicates a corresponding claimed PQC security category  
1713  $\theta = \{1, 3, 5\}$ . For each such level there are four possible parameter sets, resulting from  
1714 a choice of hash/XOF family  $\{\text{SHA2,SHAKE}\}$ , and a mode from between “s” (relatively  
1715 small signatures) and “f” (relatively fast signature generation). Furthermore, the signature  
1716 has a pure version (SLH-DSA) and a pre-hash version (HashSLH-DSA) that — similar  
1717 to EdDSA and ML-DSA— enables choosing whether to provide the entire message or just  
1718 its hash to the core signing algorithm.

#### 1719 **A.1.5.2. Conventional Stateful HBS**

1720 [SP800-208](#) approves the use of certain **stateful hash-based signature** (HBS) schemes.  
1721 Being stateful, they require updating state across a sequence of signing operations, namely  
1722 to prevent reusing a one-time-signature key, lest it would break unforgeability. In general,  
1723 statefulness is undesired, as it poses difficult challenges for state management, and is thus  
1724 unsuitable for general-purpose signatures. Their utility is for limited circumstances, if they  
1725 bring some efficiency advantage compared to other stateless PQ signature schemes.

1726 The approved stateful HBS schemes are Leighton-Micali Signature (LMS), specified by  
1727 reference to [RFC8554](#), and XMSS, specified by reference to [RFC8391](#). They are both based  
1728 on the Winternitz signature scheme. Additionally, their “multi-tree” variants — the Hierar-  
1729 chical Signature System (HSS) and the multi-tree XMSS (XMSS<sup>MT</sup>) — are also approved,  
1730 respectively, . The multi-tree version allows for a more efficient way of determining the  
1731 public key. [SP800-208](#) also specifies a modified version of XMSS and XMSS<sup>MT</sup>, to distribute  
1732 (not in a secret-shared sense) the implementation across multiple cryptographic modules.

1733 In each scheme, the private key consists of a large set of one-time signature (OTS) keys,  
1734 whereas the long-term public key is obtained as a succinct commitment (using a Merkle  
1735 tree) of a large set of OTS public keys. The multi-tree variants allow the one-time keys to  
1736 be organized into multiple trees, which eases the distribution of mutually exclusive subsets  
1737 of private keys. For each new call to sign a message, an unused one-time private key is  
1738 selected and used. Then, the signature also includes a proof of correct used key, to show  
1739 that the corresponding one-time public key is committed by the long-term public key.

#### 1740 **A.1.5.3. Threshold Hash-Based Signatures**

1741 Given the heavy use of threshold-unfriendly hash functions, a practical/efficient threshold  
1742 scheme is not expected to be devised for these HBS schemes, i.e., for a general  $k$ -of- $n$   
1743 case and with small state per party. It is still conceivable that a set of parties is configured  
1744 with an initial secret-sharing of all one-time private keys, enabling them to later produce  
1745 a signature for a given agreed message. This subcategory (N1.5) for HBS signing is  
1746 intended to motivate exploration of the limits of HBS-thresholdization, and/or better HBS  
1747 alternatives (see S1, in Section 10.1) (e.g., based on TFier/ signature-friendlier PRFs).

### 1748 **A.2. Category N2: NIST-Specified PKE Primitives**

1749 Category N2 is for submissions of threshold schemes for primitives of NIST-specified  
1750 public-key encryption (PKE) schemes. See Section 9.2 with submission requirements.

1751 **NIST standards with PKE schemes.** NIST specifies PKE schemes in the standards  
1752 for (i) RSA-based pair-wise key establishment (2KE) [SP800-56B-Rev2], and (ii) Module-  
1753 Lattice-based Key-Encapsulation Mechanism (ML-KEM) [FIPS-203]. These standards use  
1754 PKE encryption (Enc) and decryption (Dec) primitives as building blocks to construct  
1755 higher-level schemes, namely key-agreement schemes (KAS), key-transport schemes (KTS),  
1756 and KEMs (see Appendices A.2.1 and A.2.2). In turn, all of these can be used to enable  
1757 particular instantiations of 2KE, to allow two parties to agree on a secret key, without an  
1758 eavesdropper learning it. In these applications, the core use of the PKE scheme is in allowing  
1759 one party to encrypt a random contribution (i.e., a seed that will affect the derivation of  
1760 an *agreed* key) and send it securely (i.e., with confidentiality) to a decryptor party.

1761 In usual applications of a KAS, KTS, or KEM, it is important to prevent user access  
1762 to the interface of the low-level PKE primitives, since their misuse poses a security risk  
1763 (e.g., a dangerous decryption oracle). Thus, any actual proposal of a threshold scheme  
1764 for replacing a party in a full-fledged PKE-based 2KE application needs to consider the  
1765 security of the entire system.

1766 **Primitives of interest.** Enc outputs a ciphertext  $C = \text{Enc}(\text{pubKey}, M[, R])$ , as an  
 1767 encryption of an input plaintext message  $M$ , using a public encryption key  $\text{pubKey}$ , and op-  
 1768 tionally (i.e., depending on the scheme) a random value  $R$  that directly enables probabilistic  
 1769 encryption. Correspondingly, Dec outputs the original plaintext  $M = \text{Dec}(\text{privKey}, C)$ ,  
 1770 as decryption of an input ciphertext, using the private decryption key  $\text{privKey}$ .

### 1771 A.2.1. Subcategory N2.1: RSA Encryption/Decryption

1772 Appendix A.2.1.1 describes the conventional (non-threshold) “textbook” RSA encryption  
 1773 and decryption primitives. Appendix A.2.1.2 considers higher-level primitives useful for 2KE.

#### 1774 A.2.1.1. Conventional RSA-PKE

1775 In SP800-56B-Rev2, the RSA cryptosystem enables various pair-wise key-establishment  
 1776 (2KE) protocols. The RSA KeyGen (see category N4.2) generates a public RSA modulus  
 1777  $N$  (product of two primes), a public encryption key  $e$ , and a private decryption key  $d$ . The  
 1778 core encryption/decryption primitives of interest in the present subcategory (N2.1) are  
 1779 those from (the informally called) “textbook” RSA-PKE:

- 1780 • **RSA Encryption Primitive (RSAEP):** Obtains a ciphertext  $c = \text{RSAEP}(e, m) =$   
 1781  $m^e \bmod N$ , using the public key  $e$  to encrypt the plaintext  $m$ . RSAEP is assumed  
 1782 to be a one way function. Being deterministic, it does not on its own provide the  
 1783 IND-CPA property of an encryption scheme. Providing semantic security and beyond  
 1784 requires a higher-level construction (see §A.2.1.2), including randomness.
- 1785 • **RSA Decryption Primitive (RSADP):** Recovers the plaintext  $m = c^d \bmod N$ ,  
 1786 by calculating  $m = \text{RSADP}(\text{privKey}, c)$ , where the private key  $\text{privKey}$  is used to  
 1787 decrypt the ciphertext  $c$ . The input  $\text{privKey}$  is acceptable in three possible formats  
 1788 [SP800-56B-Rev2, §6.2.2]: basic ( $N, d$ ), prime-factor ( $p, q, d$ ), and chinese-remainder  
 1789 theorem (CRT) ( $N, e, d, p, q, dP, dQ, qInv$ ), where [SP800-56B-Rev2, §3.2]: ( $p, q$ ) is  
 1790 the pair of secret prime factors of  $N$ ;  $dP$  is  $d \bmod (p - 1)$ ;  $dQ$  is  $d \bmod (q - 1)$ ;  
 1791 and  $qInv$  is the inverse of  $q \bmod p$ .

#### 1792 A.2.1.2. Higher-Level Constructions (Based on RSAEP/ RSADP)

1793 **Conventional RSASVE and RSA-OAEP.** The two low-level primitives (RSAEP, RSAEP)  
 1794 of RSA-PKE are used in the higher-level cryptosystems RSASVE and RSA-OAEP, yielding  
 1795 four higher-level primitives, in two pairs (each § is referenced from SP800-56B-Rev2):

- 1796 1. RSASVE.{Generate, Recover}: RSA for secret-value encapsulation *generation* (of  
 1797 random value and corresponding ciphertext; §7.2.1.2) and *recovery* (§7.2.1.3).

1798 2. RSA-OAEP.{Encrypt, Decrypt}: RSA with **O**ptimal **A**symmetric **E**ncryption **P**adding  
 1799 *encryption* (§7.2.2.3) and *decryption* (§7.2.2.4).

1800 Both RSA-OAEP.Encrypt and RSASVE.Generate are probabilistic. Conversely, both  
 1801 RSA-OAEP.Decrypt and RSASVE.Recover are deterministic. At an even higher level,  
 1802 these primitives can be used for NIST-approved 2KE, which may further involve key-  
 1803 derivation/confirmation operations. Table 12 lists those RSA-based 2KE schemes.

**Table 12.** RSA-based primitives per RSA-2KE scheme, per party

	<b>Scheme</b>	<b>§ in SP 800 -56B-Rev2</b>	<b>Party</b>	<b>RSA-based primitive</b>	<b>KDM needed?</b>
1804	KAS1	§8.2	1st contributor	RSASVE.Generate	Yes
1805			2nd contributor	RSASVE.Recover	
1806	KAS2	§8.3	Any	RSASVE.{Generate, Recover}	
1807	KTS-OAEP	§9.2	Sender	RSA-OAEP.Encrypt	No
1808			Receiver	RSA-OAEP.Decrypt	

1809 **Legend:** §= section number. 2KE = Pair-Wise Key Establishment. KAS = Key Agreement Scheme. KDM =  
 1810 Key-Derivation Mechanism (not RSA-based). KTS = Key Transport Scheme. OAEP = Optimal Asymmetric  
 1811 Encryption Padding. RSA = Rivest-Shamir-Adleman. SVE = Secret Value Encapsulation. **Note:** Each  
 1812 scheme has a basic version, and another with key confirmation (unilateral or bilateral, not RSA-based).

### 1813 A.2.2. Subcategory N2.2: K-PKE Encryption/Decryption

1814 [FIPS-203](#) is the first NIST standard to specify a PQ-PKE scheme (dubbed K-PKE), whose  
 1815 use is only approved to support ML-KEM. The present subcategory (N2.2) is interested in  
 1816 the core K-PKE encryption/decryption primitives: K-PKE.Encrypt (Enc) and K-PKE.De-  
 1817 crypt (Dec). The three approved parameter sets ML-KEM- $\{512,768,1024\}$  determine  
 1818 corresponding parameters for K-PKE, respectively corresponding to PQC security categories  
 1819  $\theta = \{1, 3, 5\}$ , provided that their internal RBG has security strength  $\kappa = \{128, 192, 256\}$ .

#### 1820 A.2.2.1. Conventional K-PKE

- 1821 • **K-PKE.Enc**( $ek_{PKE}, m, r$ ): Deterministic algorithm, using a public encryption key  
 1822  $ek_{PKE}$  and a seed  $r$  to encrypt a plaintext  $m$ , and outputting a ciphertext  $c$ . It uses  
 1823 internal values  $(y[i], e_1[i], e_2)$  obtained pseudorandomly from the input seed  $r$ .
- 1824 • **K-PKE.Dec**( $dk_{PKE}, c$ ): Deterministic algorithm that uses the private decryption  
 1825 key  $dk_{PKE}$  to decrypt the ciphertext  $c$ , thus recovering the original plaintext  $m$ .

1826 For simplicity, the following text omits the prefix K-PKE, and abbreviates the primitives'  
 1827 names. For the purposes of this subcategory (N2.2), it is useful to conceptualize Enc'  
 1828 as a probabilistic variant of Enc, as follows: Enc' has the same input/output syntax, but  
 1829 randomly selects the internal values  $(y[i], e_1[i], e_2)$ , instead of computing them pseudo-  
 1830 randomly from the input seed  $r$ . Effectively, Enc' ignores the input seed  $r$ . For threshold  
 1831 purposes (see §9.2), a key observation is that Enc' and Enc are interchangeable w.r.t. Dec.  
 1832 In particular,  $\text{Dec}(\text{Enc}'(\dots)) = \text{Dec}(\text{Enc}(\dots))$  for any  $\text{ek}_{\text{PKE}}$ ,  $m$ , and  $r$ .

### 1833 A.2.2.2. Higher-Level Constructions (Based on K-PKE)

1834 **Conventional ML-KEM.** Ignoring KeyGen, the ML-KEM specifies Encaps and Decaps  
 1835 algorithms, each of which relies on an auxiliary internal function (named with a suffix  
 1836 “\_internal”), which in turn are based on primitives from the K-PKE scheme. Table 13  
 1837 lists these relationships. Essentially, the ML-KEM.{Encaps, Decaps} primitives are based  
 1838 on K-PKE.{Enc, Dec} and a number of pseudorandom calculations. They are meant to  
 1839 ensure useful security properties (e.g., IND-CCA) and functionality (e.g., suitability for  
 1840 2KE). The transformation is efficient in the conventional (i.e., non-threshold) setting,  
 1841 where the computation of NIST-standardized PRFs on secret material is cheap.

**Table 13.** Non-KeyGen Primitives in ML-KEM and K-PKE

Scheme	Primitive	Prob?	Inputs	Outputs	Alg. in FIPS-203	Internally calls
1842 K-PKE	Encrypt	No	$(\text{ek}_{\text{PKE}}, m, r)$	$c$	14	—
1843	Decrypt	No	$(\text{dk}_{\text{PKE}}, c)$	$m$	15	—
1844 —	Encaps_internal	No	$(\text{ek}, m)$	$(K, c)$	17	Encrypt
1845 —	Decaps_internal	No	$(\text{dk}, c)$	$K$	18	Encrypt, Decrypt
1846 ML-KEM	Encaps	<b>Yes</b>	$\text{ek}$	$(K, c)$	20	Encaps_internal
1847	Decaps	No	$(\text{dk}, c)$	$K$	21	Decaps_internal

1848 **Legend:** Alg. = Algorithm.  $K$  is the “agreed key” in a 2KE; Prob? = Probabilistic?

1849 **Threshold ML-KEM:** Going from threshold K-PKE.{Enc, Dec} to threshold ML-  
 1850 KEM.{Encaps, Decaps} is impractically expensive in the threshold setting, requiring  
 1851 distributed computations of threshold-unfriendly PRF functions. Submitters are welcome  
 1852 to explore the complexity of such implementations, and possibly propose threshold-friendlier  
 1853 (TF'ier) alternatives. This can be based on TF'ier symmetric primitives (see category S3  
 1854 in Section 10.3), or TF'ier PKE-based KEM schemes (see category S2 in Section 10.2).

### 1855 **A.3. Category N3: NIST-Specified Symmetric Primitives**

1856 See Section 9.3 for submission requirements related to N3.

#### 1857 **A.3.1. Subcategory N3.1: AES Enciphering/Deciphering**

1858 The Advanced Encryption Standard (AES) FIPS-197 includes an encryption (Enc) algorithm  
1859  $\text{Enc}(K, M) = P$  and a decryption (Dec) algorithm  $\text{Dec}(K, C) = P$ , where  $K$  is the key  
1860 (with 128, 192, or 256 bits),  $P$  is the 128-bit plaintext, and  $C$  is the 128-bit ciphertext.

1861 **Threshold AES enciphering/deciphering.** In the threshold AES case of interest, the  
1862 key-holder is distributed into multiple parties (i.e., a secret sharing of the key is distributed  
1863 across the parties), and the key-holder computes the ciphertext without reconstructing the  
1864 key. If implemented in an SSIO-threshold manner, then no party within the decentralized  
1865 key-holder learns the plaintext or ciphertext.

1866 **Comparison with oblivious AES evaluation.** Threshold AES enciphering with SSI-  
1867 plaintext and SSO-ciphertext is similar to but different from two-party oblivious AES  
1868 evaluation, which is a common secure 2-party computation (S2PC) benchmark in the MPC  
1869 literature. In the latter, one party (the receiver) knows the plaintext and another party (the  
1870 key-holder) knows the key. They both keep their inputs private, and yet enable the receiver  
1871 to learn the corresponding ciphertext. Despite the differences, the building blocks presented  
1872 for resolving threshold AES may also be useful for implementing oblivious AES evaluation.

#### 1873 **A.3.2. Subcategory N3.2: Ascon-AEAD Encrypt/Decrypt**

1874 The recent Ascon-based draft NIST-standards describe an authenticated encryption with  
1875 associated data (AEAD) scheme, named Ascon-AEAD128. It includes encryption (Enc)  
1876 and decryption (Dec) algorithms, as follows:

- 1877 •  $\text{Enc}(K, N, A, P) = (C, T)$
- 1878 •  $\text{Dec}(K, N, A, C, T) = \{\text{output } P \text{ if } T \text{ is valid, and output fail otherwise}\},$

1879 where  $K$  is the 128-bit *key*,  $N$  is the 128-bit nonce,  $A$  is an optional associated data,  $P$  is  
1880 an arbitrary-length plaintext,  $C$  is the ciphertext (with the same width as  $P$ ), and  $T$  is a  
1881 128-bit authentication tag (truncatable).

1882 One variant mode allows for a 256-bit key, where the extra 128 bits are used to XOR-mask  
1883 the input nonce, in order to retain the 128 bits of security in a multi-key setting. In that  
1884 case,  $\text{Enc}(K||K', N, A, P) = \text{Enc}(K, N \oplus K', A, P)$ .

### 1885 **A.3.3. Subcategory N3.3: Hash and XOF**

1886 **Hash functions.** The syntax for hashing is  $\text{Hash}(M) = H$ , where  $M$  is the plaintext (i.e.,  
1887 message) and  $H$  is the output hash. The hash functions of interest for benchmarking in  
1888 the threshold setting are those with non-truncated output and output length  $\geq 224$ , from:

- 1889 • SHA2 family [FIPS-180-4]: SHA-256, SHA-384, SHA-512
- 1890 • SHA3 family [FIPS-202]: SHA3-256, SHA3-384, SHA3-512
- 1891 • Ascon-Hash256 [SP800-232-ipd]

1892 **Extendable output functions (XOF).** At a high level, the syntax for XOF'ing is  
1893  $\text{XOF}(M, L) = H$ , where  $M$  is the plaintext (i.e., message),  $L$  is the XOF output length,  
1894 and  $H$  is the output. A XOF with a pre-defined length is essentially a hash function.  
1895 Additionally, some XOFs are “customizable” via additional input parameters. The XOFs of  
1896 interest are those based on Keccak and Ascon:

- 1897 • SHAKE128, SHAKE256 [FIPS-202]
- 1898 • cSHAKE128, cSHAKE256 [SP800-185]
- 1899 • Ascon-XOF128 and Ascon-CXOF128 [SP800-232-ipd]

1900 **Customizable XOFs.** cSHAKE128 and cSHAKE256 are customizable with a “function  
1901 name” parameter  $N$  (e.g., “KMAC” when used as part of the “KMAC” algorithm) and a cus-  
1902 tomization bit-string  $S$ . If  $N$  and  $S$  are empty, then cSHAKE matches the original SHAKE.  
1903 Ascon-CXOF128 accepts an extra parameter “ $Z$ ” (customization bit string). However, using  
1904  $Z$  as an empty string in Ascon-CXOF128 yields a function different from Ascon-XOF128.

### 1905 **A.3.4. Subcategory N3.4: MAC**

1906 The high-level syntax for MAC'ing is  $T = \text{MAC}(K, M)$ , where  $K$  is the key,  $M$  is a  
1907 message of arbitrary length, and  $T$  is the output tag. Depending on the MAC scheme,  
1908 there may be constraints on the length of the input key and of the output tag. Some  
1909 MAC constructions allow additional parameters to specify the output length and even a  
1910 customizable string to adjust the function (akin to domain separation). Depending on the  
1911 application, a tag truncation (to  $\lambda$  bits) can also be considered, but is hereafter ignored.

1912 **MAC construction.** In Class N, the NIST-approved MAC schemes are built from prim-  
1913 itives (or building blocks therefrom) already considered in the other subcategories of the  
1914 “symmetric” category (S3). The MAC families of interest for benchmarking are:

- 1915 • CMAC [SP800-38B] and GMAC [SP800-38D], based on AES. In terms of key length,  
1916 CMAC-AES-\* and GMAC-AES-\* use a \*-bit key, where  $* \in \{128, 256\}$ .
- 1917 • HMAC [SP800-224-ipd], based on a hash function (from the SHA2 or SHA3 families).  
1918 The key is of arbitrary length, but keys larger than the block of the underlying hash  
1919 function are first hashed and only then affect the message processing.
- 1920 • KMAC [SP800-185], based on cSHAKE.  $\text{KMAC}^*(K, X, L, S)$  uses  $\text{cSHAKE}^*$ , where  
1921  $* \in \{128, 256\}$ ,  $K$  is the key (of arbitrary length; possibly 0),  $X$  is the plaintext,  
1922  $L$  is the output tag length, and  $S$  is an optional customization string (possibly  
1923 empty). A related construction  $\text{KMACXOF}^*$ , with input/output syntax similar to its  
1924 counterpart  $\text{KMAC}^*$ , allows for specifying  $L$  after the algorithm starts computing.

1925 **Possibility of an Ascon-based MAC.** The NIST draft standard for Ascon-based primitives  
1926 [SP800-232-ipd] did not explicitly define an Ascon-based MAC. A conceivable construction  
1927 based on Ascon-AEAD is to encrypt an empty plaintext, using non-empty associated data,  
1928 which results in a tag that is essentially a probabilistic MAC of the associated data. More  
1929 efficient specialized constructions are possible. If/when an Ascon-based MAC is defined  
1930 by NIST, then it can be considered within this subcategory.

#### 1931 **A.4. Category N4: NIST-Specified KeyGen Primitives**

1932 See Section 9.4 with submission requirements about distributed key generation.

1933 **Conventional KeyGen.** A key generation (KeyGen) primitive determines a secret key  
1934 (sometimes called private key) that is needed by subsequent primitives. Depending on  
1935 the crypto-system, the KeyGen may also generate a related public key. For example, the  
1936 KeyGen primitive of a digital signature scheme produces a private/public key-pair. The  
1937 private key is use to sign messages, and the public key is used to verify signatures. A  
1938 typical security requirement for the secret key is high entropy, which is obtained in case  
1939 of uniformity in the corresponding key space. In practice, conventional KeyGen schemes  
1940 often require randomness that is directly output by approved random-bit generators (RBG),  
1941 which need to satisfy specific requirements [SP800-90A-R1; SP800-90B; SP800-90C-4PD].  
1942 Entropy is meant here as a measure of computational unpredictability, rather than in an  
1943 information-theoretical sense. In fact, keys can even be pseudorandomly derived from other  
1944 secrets. Also, secret keys can be persistent (e.g., for multiple-time uses, without planned  
1945 erasure), or ephemeral (e.g., for single-time use, followed by erasure).

## 1946 **A.4.1. Subcategory N4.1: ECC KeyGen**

### 1947 **A.4.1.1. Conventional ECC KeyGen**

1948 The EdDSA and ECDSA signature schemes [FIPS-186-5] and the ECC-2KE schemes [SP800-  
1949 56A-Rev3] use particular elliptic curves and encodings. Yet, at a high level they have a similar  
1950 KeyGen (i.e., their ECC component), determining a private/public key-pair, as follows:

- 1951 1. Sample a random positive integer  $d$  (mod  $n$ , the order of the subgroup of interest).
- 1952 2. Perform a scalar multiplication to obtain the corresponding public key  $Q = d \cdot G$ .

1953 **“Scalar multiplication” versus “exponentiation”.** Group operations over elliptic  
1954 curves are usually described with additive notation. When a public key  $Q$  is determined  
1955 by a repeated sum of the base-point  $G$ , a secret number  $d$  of times, their relationship  
1956 is mathematically expressed as a scalar multiplication (i.e.,  $Q = d \cdot G$ ). However, the  
1957 literature often refers to this as an “exponentiation”, and correspondingly identifies the  
1958 secret key as the “discrete log” of the public key. This a tolerated misnomer due to the  
1959 prior popularization of schemes described with multiplicative notation (e.g.,  $q = g^d$ ).

### 1960 **KeyGen for the three ECC-based schemes:**

- 1961 • **EdDSA.** The scheme uses a precursor private key  $d$  to pseudorandomly derive a  
1962 private signing key  $s$  and a nonce-derivation key  $\nu$ , as  $(s, \nu) = \text{Hash}(d)$ . The private  
1963 signing key is then used to derive the public key  $Q = s \cdot G$ . The generation of  $\nu$  is  
1964 optional in the threshold setting, since interchangeable signatures (w.r.t. verification)  
1965 can be produced without using the nonce-derivation key (see Appendix A.1.1).
- 1966 • **ECDSA.** The scheme requires establishing a private signing key ( $d$  in ECDSA), and  
1967 a corresponding public key  $Q = d \cdot G$ . The private key is later used to produce  
1968 signatures (see Appendix A.1.2).
- 1969 • **2KA.** In a threshold 2KA scheme, each party may need a secret sharing of a static  
1970 private key  $d_A$  (or  $d_{s,A}$ ) and/or an ephemeral private key ( $d_{e,A}$ ). After the private  
1971 key(s) are generated, the side holding it in a secret-shared manner needs to use  
1972 it (in a subsequent CDH or MQV operation of the 2KA protocol) as the scalar by  
1973 which to multiply the public key of the other party, and let the result still be in SSO  
1974 mode (See Appendix A.4.1.2).

### 1975 **A.4.1.2. Extension to CDH and MQV primitives for ECC-2KE**

1976 This Threshold Call also considers within the ECC KeyGen subcategory N4.1 the CDH  
1977 and MQV primitives of NIST-specified ECC-based 2KE schemes [SP800-56A-Rev3]. The  
1978 association with KeyGen is motivated by two similarities: (i) the essential operations are

1979 scalar multiplications; and (ii) the output is a secret key (to be used to derive another  
 1980 secret key). However, one difference is that the ECC-CDH and ECC-MQV primitives (in  
 1981 this section) for 2KE include a secret-shared input.

1982 **Conventional primitives.** The setting of 2KE [SP800-56A-Rev3] considers two sides (i.e.,  
 1983 parties) that want to agree on a fresh key. Let  $A$  denote one of the sides, and  $B$  the other,  
 1984  $(d_i, Q_i)$  denote a private-public key pair of party  $i \in \{A, B\}$ ,  $e$  and  $s$  denote *ephemeral*  
 1985 and *static*, and  $h$  be the cofactor. Depending on the scheme, the core ECC primitive is  
 1986 as follows, from the perspective of side  $A$ :

- 1987 • ECC-CDH primitive:  $P = (h \cdot d_A) \cdot Q_B$
- 1988 • ECC-MQV primitive:  $P = h \cdot \mathit{impsig}_A \cdot (\mathit{avf}(Q_{e,B}) \cdot Q_{s,b})$ , where  $\mathit{impsig}_A =$   
 1989  $(d_{e,a} + \mathit{avf}(Q_{e,A}) \cdot d_{s,A}) \bmod n$ , and  $\mathit{avf}(\cdot)$  is the “Associate Value Function”  
 1990 [SP800-56A-Rev3, §5.7.2.2] that converts an EC point into an integer. Its **full form**  
 1991 is as described, when both static and ephemeral keys exist and are distinct. There is  
 1992 also a **one-pass form**, when exactly one party ( $A$  or  $B$ ) does not have an ephemeral  
 1993 key, and so the algorithm replaces it with the corresponding static key.

1994 These primitives are used in NIST-specified ECC-2KE to generate an intermediate agreed  
 1995 secret  $Z$  (i.e., agreed by both sides), which is then processed by key-derivation and/or  
 1996 key-confirmation primitives that are not ECC-based (and not discussed in this category).  
 1997 Tables 8 and 9 in §A.3 of NIST-IR8214C-ipd (2023) summarize the various approved modes.

1998 **Suggested additional curves.** Submissions that implement ECC-based 2KE primitives  
 1999 are also welcome to compare the use of P-{256,384,521} versus Curve{25519,448}. The  
 2000 latter are specified in SP800-186, and suggested by RFC7748, but are not recommended  
 2001 by the older SP800-56A-Rev3.

## 2002 A.4.2. Subcategory N4.2: RSA KeyGen

2003 **Conventional primitive.** RSA KeyGen is needed for the RSADSA (signature) scheme (see  
 2004 Appendix A.1.1) and for the RSA PKE (encryption) scheme used for 2KE (Appendix A.2.1).  
 2005 In its *basic* format, RSA KeyGen is as follows (at a high level):

- 2006 • Generate a pair of random secret primes  $(p, q)$ , and output their product  $N$ ; and
- 2007 • Compute and output as private key  $d$  the inverse (mod  $\text{LCM}(p-1, q-1)$ ) of a  
 2008 public exponent  $e$  (selected before the primes).

### 2009 A.4.2.1. Size of RSA Modulus

2010 The size of an RSA modulus determines an upper bound on the security strength of the RSA-  
 2011 related primitive (i.e., signing, encryption or decryption). The following specific cases are  
 2012 fixed:  $|N| = 3072$  for  $\kappa \approx 128$ ,  $|N| = 7680$  for  $\kappa \approx 192$ , and  $|N| = 15360$  for  $\kappa \approx 256$ .  
 2013 By standard, the RSA modulus length  $|N|$  must be a multiple of 8. For benchmarking pur-  
 2014 poses, this Threshold Call further suggests that it be a multiple of 512. Implementations that  
 2015 aim for  $\kappa \notin \{128, 192, 256\}$  can interpolate an RSA modulus size by rounding up to a multi-  
 2016 ple of 512 the solution (for  $|N|$ ) of  $\kappa \ln(2) = \sqrt[3]{(64/9) \cdot (|N| \ln(2)) \cdot \ln^2(|N| \ln(2))} - 4.69$ ,  
 2017 from “§7.5 Strength of Key Establishment Methods” of the “FIPS 140-2 Implementation  
 2018 Guidance” [IG-FIPS-140-2]. For example, one gets  $|N| = 10,752$  for  $\kappa \approx 224$ .

#### 2019 **A.4.2.2. Criteria for the Private Exponent and the Prime Factors**

2020 NIST specifies requirements for the prime factors of an RSA modulus, and their primality  
 2021 testing. These are described in FIPS-186-5 (§A.1 and §C), and SP800-56B-Rev2 (§6.2–§6.3),  
 2022 respectively for signing and PKE. The output private key can also be represented in a *prime-*  
 2023 *factor* format, or *CRT* format, as explained in Appendix A.2.1.1. The following paragraph  
 2024 list some of the requirements in the mentioned publications, though (as mentioned in 9.4.2)  
 2025 submissions of threshold schemes may judiciously depart from some of those requirements.

2026 **Criteria for the Private Exponent.** The private exponent  $d = e^{-1} \pmod{L}$ , where  
 2027  $L = \text{LCM}(p - 1, q - 1)$ , must be larger than  $2^{\lceil N/2 \rceil}$  and smaller than  $L$ , where the public  
 2028 exponent  $e$ , satisfies  $2^{16} \leq e \leq 2^{256}$  and is selected before  $p$  and  $q$  are generated.

#### 2029 **Criteria for the prime factors:**

- 2030 •  $p$  and  $q$  must be of the same bit length (i.e., half the length of the modulus  $N$ ).
- 2031 •  $p$  and  $q$  must be randomly generated (but the two most significant bits of each may  
 2032 be arbitrarily set), as “probable” or “provable” primes, satisfying at least one of the  
 2033 five options from Table 14.

2041 To satisfy the “complex” type of key-generation, the auxiliary primes must exist with  
 2042 certain minimum lengths. If  $p$  and  $q$  are required to be provable primes, then their minimal  
 2043 required bit-length is roughly half of the minimal required length of probable primes.

#### 2044 **A.4.3. Subcategory N4.3: ML KeyGen**

2045 Both ML-KEM [FIPS-203] and ML-DSA [FIPS-202] require the generation of a public  
 2046 key-pair, with elements related to lattices. The algorithms of interest are K-PKE.KeyGen  
 2047 and ML-DSA.KeyGen\_internal. Both are pseudorandom per specification, using as input a  
 2048 32-byte (256-bit) random seed. The following descriptions ignore encoding aspects.

**Table 14.** Criteria for the random primes of an RSA modulus

	Type	Sub-type	Provable prime	Probable prime
2034	Simple	provable	$p, q$	
2035		probable		$p, q$
2036	Complex	provable	$p_1, p_2, q_1, q_2, p, q$	
2037		hybrid	$p_1, p_2, q_1, q_2,$	$p, q$
2038		probable		$p_1, p_2, q_1, q_2, p, q$

2039 Per §A.1.1 of [FIPS-186-5](#):  $p_1, p_2, q_1, q_2$  are called auxiliary primes and must be divisors  
 2040 of  $p - 1, p + 1, q - 1$  and  $q + 1$ , respectively, i.e.,  $p_1|p - 1, p_2|p + 1, q_1|q - 1, q_2|q + 1$ .

2049 **K-PKE.KeyGen.** See Algorithm 13 in [FIPS-203](#). Given a 32-byte input seed  $d$ , the  
 2050 algorithm starts by pseudorandomly generating a public seed  $\rho$  and a private seed  $\sigma$ . The  
 2051 public seed  $\rho$  is used to generate a matrix  $\hat{\mathbf{A}}$ . The private seed  $\sigma$  is used to generate a  
 2052 secret vector  $\hat{\mathbf{s}}$  and a secret noise  $\hat{\mathbf{e}}$ . The pseudorandom samplings are based on the algo-  
 2053 rithm “SamplePolyCBD”, and the hat  $\hat{\phantom{x}}$  signifies an application of the Number Theoretic  
 2054 Transform (NTT). The other component of the public key is then obtained by the linear  
 2055 combination  $\hat{\mathbf{t}} = \hat{\mathbf{A}} \circ \hat{\mathbf{s}} + \hat{\mathbf{e}}$ . The output encryption key is  $(\hat{\mathbf{t}}, \rho)$  (where  $\rho$  is the seed of  
 2056  $\hat{\mathbf{A}}$ ). The output private key is  $\hat{\mathbf{s}}$  (i.e., could be derived from  $\sigma$ ).

2057 **ML-DSA.KeyGen.** See Algorithms 6 and 1 in [FIPS-204](#). ML-DSA.KeyGen selects a  
 2058 random 32-byte seed  $\xi$  and calls ML-DSA.KeyGen\_internal with that seed as input. The  
 2059 latter is then deterministic, using various pseudorandom sampling routines, starting with  
 2060 generating a public seed  $\rho$ , a private seed  $\rho'$ , and another private seed  $K$ . The public seed  
 2061  $\rho$  is used to generate a matrix  $\hat{\mathbf{A}}$ . The private seed  $\rho'$  is used to generate secret vectors  $\mathbf{s}_1$   
 2062 and  $\mathbf{s}_2$ , and then compute the linear combination  $\mathbf{t} = \text{NTT}^{-1}(\hat{\mathbf{A}} \circ \text{NTT}(\mathbf{s}_1)) + \mathbf{s}_2$ , which  
 2063 can then be parsed into  $(\mathbf{t}_1, \mathbf{t}_0)$ , using the routine “Power2Round”. Finally, the public  
 2064 verification key is  $(\rho, \mathbf{t}_1)$ , and the signing key is composed of  $(K, \mathbf{s}_1, \mathbf{s}_2, \mathbf{t}_0)$ , besides (an  
 2065 encoding of) the public components  $\rho$  and  $\mathbf{t}_1$ , and what can be derived from them (e.g.,  $tr$ ).

2066 **A.4.4. Subcategory N4.4: HBS KeyGen.** See Section 9.4.4.

2067 **A.4.5. Subcategory N4.5: Secret RBG**

2068 **Conventional generation.** Various primitives require the random generation of a secret  
 2069 bit-string or an integer within an interval, without the need for a corresponding public com-  
 2070 ponent. For example, this is the case for: an AES key; a secret-key for encapsulation under  
 2071 an RSA PKE; a nonce for use in other schemes; a salt for a KDM or KC in the scope of a 2KA.  
 2072 Usually, these KeyGen are required to follow NIST-approved RBG methods [[SP800-90A-R1](#);  
 2073 [SP800-90B](#); [SP800-90C-4PD](#)], to obtain either truly randomness or pseudorandomness.

## 2074 **Appendix B. Notes on FHE and ZKPoK**

2075 This appendix includes informative notes about the FHE (S5) and ZKPoK (S6) categories.  
 2076 Corresponding schemes are welcome to be submitted and/or analyzed in connection with  
 2077 ongoing community efforts (e.g., HomomorphicEncryption.org, FHE.org, ZKProof.org),  
 2078 to promote: (i) fulfill community-based technical recommendations; (ii) align with exist-  
 2079 ing reference material/specifications; and (iii) invite further public scrutiny of proposed  
 2080 schemes; and (iv) consider reference use cases for useful benchmarking.

### 2081 **B.1. Category S5: Fully-Homomorphic Encryption (FHE)**

2082 Category S5 (see submission requirements in Section 10.5) allows for the submission of FHE  
 2083 schemes. Informally speaking, an FHE scheme allows for arbitrary computations over the  
 2084 ciphertext space ( $\mathcal{C}$ ), (i.e., over encrypted data). Therefore, in addition to key-generation  
 2085 (KeyGen), encryption (Enc) and decryption (Dec) algorithms, an FHE scheme also needs  
 2086 to specify algorithms for the efficient homomorphic evaluation of a “complete basis” of  
 2087 operations over the plaintext space ( $\mathcal{P}$ ). The composition of operations allows for arbitrary  
 2088 computations (e.g., see Ref. [HES, §1.1.1]).

2089 Traditionally, the complete basis is composed of addition and multiplication, such as, {xor,  
 2090 and} over GF(2), or {+, ×} over a field modulo a large prime. The FHE scheme supports  
 2091 corresponding homomorphic operations in the ciphertext space ( $\mathcal{C}$ ).

2092 More precisely (though for simplicity leaving the key implicit): supposed a function  
 2093  $f : \mathcal{P} \rightarrow \mathcal{P}$  or a binary operation  $op : \mathcal{P} \times \mathcal{P} \rightarrow \mathcal{P}$  over the plaintext space can be  
 2094 specified as a composition of operations in the supported basis; then, the homomorphism  
 2095  $\text{hom}$  allows for corresponding efficient operations in the ciphertext space, satisfying:

- 2096 • If  $c_1 = \text{Enc}(p_1)$ ,  $F = \text{hom}(f)$ , and  $d_1 = F(c_1)$ , then  $\text{Dec}(d_1) = f(p_1)$ ,
- 2097 • If  $c_1 = \text{Enc}(p_1)$ ,  $c_2 = \text{Enc}(p_2)$ ,  $Op = \text{hom}(op)$ , and  $c_3 = Op(c_1, c_2)$ , then  
 2098  $\text{Dec}(c_3) = op(p_1, p_2)$ ,

2099 where  $p_1$  and  $p_2$  are plaintexts, and  $F$  and  $Op$  can be computed efficiently (i.e., with at  
 2100 most polynomial overhead) from  $f$  and  $op$ , respectively.

2101 The application suitability of an FHE scheme may depend on variety of aspects, such as:

- 2102 • The type of operations (and plaintext space) for which  $\text{hom}$  is “friendly”
- 2103 • The PQC security strength [security categories](#).
- 2104 • Whether it is of public-key or symmetric-key type (and how to convert it to the other).

- Threshold friendliness with respect to various primitives of the FHE scheme.

### 2106 **B.1.1. Use Case: FHE-Based AES Oblivious Enciphering**

2107 In an “oblivious” PRF evaluation, a client ( $A$ ) holding a secret plaintext  $m$ , and a server  
2108 ( $S$ ) holding a secret key  $k$ , interact in a way that the client privately learns the output  
2109 of the PRF evaluation over the plaintext, while both parties remain oblivious to the other  
2110 party’s input. Replacing the PRF by the AES blockcipher (a PRP), the client learns the  
2111 AES-enciphering of the plaintext  $m$ . Oblivious AES-enciphering is a typical benchmark  
2112 case for secure 2-party computation, usually using techniques such as garbled circuits  
2113 and/or oblivious transfer. Compared with an FHE-based solution, usual S2PC protocols  
2114 lead to faster execution, but also larger communication complexity.

2115 As an FHE use case, §B.1.1.1 considers a non-threshold use of FHE for AES oblivious  
2116 enciphering. Then, §B.1.1.2 considers the corresponding threshold setting.

#### 2117 **B.1.1.1. Non-Threshold FHE-Based AES Oblivious Enciphering**

2118 0a. **FHE setup (KeyGen):** An FHE scheme is initialized with encryption key  $e$  (for  
2119 encryption operation  $\text{FHE.Enc}_e$ ), and decryption key  $d$  (for decryption operation  
2120  $\text{FHE.Dec}_d$ ), and allows homomorphic evaluation (over FHE ciphertexts) of any  
2121 function  $f$  (within a certain range of functions) using operation  $\text{FHE.Hom}[f]$ .

2122 0b. **AES setup (KeyGen):** An AES cipher is initialized with secret key  $k$ ;  $\text{AES.Enc}_k$   
2123 denotes the corresponding enciphering operation.

2124 0c. **Parties setup (private inputs):** (i) Client  $A$  knows a secret plaintext  $m$  and the  
2125 FHE encryption key  $e$ ; (ii) Server  $S$  knows the AES secret-key  $k$ ; (iii) and client  $B$   
2126 (possibly the same as client  $A$ ) knows the FHE decryption key  $d$ .

2127 1. **FHE-Encrypt.** The client  $A$  FHE-encrypts the secret plaintext  $m$ , obtains the FHE  
2128 ciphertext  $C = \text{FHE.Enc}_e(m)$ , and sends it to the server  $S$ .

2129 2. **FHE-Homomorphic-Evaluate.** The server  $S$  homomorphically evaluates the AES  
2130 enciphering, obtains  $H = \text{FHE.Hom}[\text{AES.Enc}_k](C)$  (which is a valid FHE encryption  
2131 of the AES enciphering of secret plaintext  $m$ ), and sends the result to client  $B$ .

2132 3. **FHE-Decrypt.** The client  $B$  FHE decrypts the received ciphertext  $H$ , to obtain  
2133 the AES-enciphering of the secret plaintext:  $\text{AES.Enc}_k(m) = \text{FHE.Dec}_d(H)$ .

- 2134 4a. **(Optional) Prove correctness.** The server  $S$  may also send to client  $B$  a ZKPoK  
2135 string  $\pi = \text{ZKPoK.Prove}[k; (H, C) : \text{FHE.Hom}[\text{AES.Enc}_k](C) = H]$ , thus ZK-  
2136 proving knowledge of a secret AES key ( $k$ ) that is consistent with the homomorphic  
2137 operation that transformed the initial FHE ciphertext  $C$  into the final FHE ciphertext  
2138  $H$ . A more sophisticated ZKPoK can also be used to prove consistency with some  
2139 additional public commitment of the AES-key  $k$ .
- 2140 4b. **Verify the proof.** Anyone with the FHE ciphertexts  $(C, H)$  can verify the correct-  
2141 ness of the ZKPoK  $\pi$ , by checking  $\text{true} \stackrel{?}{=} \text{ZKPoK.Verify}(\pi, (H, C), \text{AES.Enc})$ .

### 2142 B.1.1.2. Threshold FHE-Based AES Oblivious Enciphering

2143 Considering the example in Appendix B.1.1.1, the following is a non-exhaustive list of  
2144 conceivable decentralizations of one of the original participants (i.e., client  $A$ , server  $S$ , or  
2145 client  $B$ ) into a threshold entity composed of multiple parties.

- 2146 1. **Threshold FHE.KeyGen.** If client  $B$  is thresholdized, then a DKG can distributively  
2147 compute a secret sharing of an FHE decryption key  $d$ . If the FHE scheme is of  
2148 asymmetric-key (i.e., public/private key pair), then the encryption key  $e$  might be  
2149 simply learned by every party. (However, it is also conceivable the case of secret  
2150 sharing the public key.)
- 2151 2. **SSI threshold FHE.Enc (encrypt).** If client  $A$  is thresholdized and initialized with a  
2152 secret-shared plaintext  $m$ , then a threshold scheme can compute  $C = \text{FHE.Enc}_e(m)$   
2153 without anyone learning  $m$ .
- 2154 3. **Threshold FHE.Hom (homomorphic evaluation, of a function with a secret  
2155 parameter).** If the server  $S$  is thresholdized and initialized with a secret sharing  
2156 of the AES key  $k$ , then the parties can distributively compute the homomorphic-  
2157 evaluation, to obtain  $H = \text{FHE.Hom}[\text{AES.Enc}_k](C)$ , without anyone learning  $k$ .
  - 2158 • In an NSS mode, all server parties learn  $H$ .
  - 2159 • In an SSO mode, each server party learns a secret share of  $H$ .
- 2160 4. **Threshold FHE.Dec (decrypt).** If client  $B$  is thresholdized and initialized with a  
2161 secret sharing of the FHE-decryption key  $d$ , then a threshold scheme can decrypt  
2162 the received value  $H$  to obtain  $C = \text{AES}_k(m)$ , without anyone learning  $d$ .
  - 2163 • In an NSS mode, all clientB-parties learn  $C$ .
  - 2164 • In an SSO mode, each clientB-party only learns a secret share of  $C$ .
- 2165 5. **Threshold ZKPoK.** (See category S6 in Section 10.6 and Appendix B.2)

2166 **B.2. Category S6: Zero-Knowledge Proof of Knowledge (ZKPoK)**

2167 Category S5 allows for the submission of ZKPoKs, which are of great interest in the context  
 2168 of multi-party computation (and beyond). See submission requirements in Section 10.6.

2169 In usual ZKP terminology [ZkpComRef], a ZKPoK is used to prove a **statement** of knowl-  
 2170 edge, such as knowledge of a secret **witness** ( $w$ ) that satisfies a given **relation** ( $R$ ) with  
 2171 a public **instance** ( $x$ ) such that  $R(x, w)$  is true. For example, a ZKPoK of a private  
 2172 RSA key can have as *instance* the public RSA modulus  $N$ , as secret *witness* the pair  
 2173  $(p, q)$  of prime factors, and as *relation* the predicate that returns true if and only if the  
 2174 input *instance*  $N$  is a valid product of two secret primes. Additional refinements can be  
 2175 considered (e.g., proving the two primes have the same bit-length, and are both 3 mod 4).

2176 **B.2.1. Example Proofs of Interest**

2177 Table 15 lists various examples of ZKPoK of anticipated interest with regard to Class N  
 2178 primitives. Other examples can be conceived, including for primitives in Class S.

**Table 15.** Example ZKPoKs of interest related to Class N primitives

	Related type	Related sub-category: Primitive	Example ZKPoK (including consistency with a corresponding commitment, possibly secret shared)
2179	KeyGen	N4.1: ECC KeyGen	of discrete log ( $s$ or $d$ , e.g., a signing key) of pub key $Q$
2180		N4.2: RSA KeyGen	of factors $(p, q)$ , or group order $\phi$ (w.r.t. $N$ )
2181	Sign	N1.1: EdDSA sign	of nonce-derivation key $\nu$ (w.r.t. deterministic signature $\sigma$ )
2182		N1.2: ECDSA sign	of secret signature $\sigma$ of public msg $m$ , valid w.r.t. public key $Q$
2183	PKE	N2.1: RSA Enc	of secret plaintext $m$ (w.r.t. ciphertext $c$ and public key $N$ )
2184		N2.2: K-PKE Enc	of secret plaintext $m$ (w.r.t. ciphertext $c$ and public key $ek_{PKE}$ )
2185		N2: RSA/K-PKE Dec	of secret-shared plaintext $m$ (after SSO-threshold decryption)
2186	Symmetric	N3.1: AES enciphering	of secret key $K$ (w.r.t. a plaintext/ciphertext pair $(P, C)$ )
2187		N3.2: Ascon-AEAD	of secret key $K$ and plaintext $P$ (w.r.t. ciphertext/tag pair $(C, T)$ )
2188		N3.3: Hash/XOF'ing	of secret pre-image $M$ (w.r.t. hash or XOF output $H$ )
2189		N3.4: MAC'ing	of secret key $K$ and message $M$ (w.r.t. macTag $T$ )

2190 **Relationship between ZKPoK and signatures.** Since a NIZKPoK allows for binding  
 2191 data to it (e.g., a message), there is a tight relationship to signature schemes. For example,  
 2192 an EdDSA/Schnorr signature (see Appendix A.1.1) is a message-bound (transferable)  
 2193 NIZKPoK of the discrete log of the public key. As another example, a ZKPoK of an AES  
 2194 key connecting a plaintext to a ciphertext can be the basis of a PQC signature scheme,  
 2195 as observed in submissions to the NIST-PQC standardization process.

## 2196 **B.2.2. Distinguishing Features and Types of “Proof”**

- 2197 1. **ZKP of knowledge (versus of correctness):** The proofs in scope are ZKPoKs,  
2198 but can also serve the purpose of ZK-proving *correctness* of the secret data (whose  
2199 knowledge is being proven) and the corresponding public data (e.g., that they are  
2200 consistently related and satisfy some claimed property). In the literature, a ZKP of  
2201 correctness is sometimes also known as a ZKP of “language membership”.
- 2202 2. **Interactiveness.** A ZKPoK can involve interaction between the prover and verifier,  
2203 or be non-interactive (a single message sent from the prover to the verifier). The  
2204 latter is known as a non-interactive ZKPoK (NIZKPoK). If it is succinct, then it  
2205 is called a zk-SNARK (ZK succinct non-interactive ZK-argument of knowledge).
- 2206 3. **Transferability versus deniability.** With a deniable (i.e., non-transferable) ZKPoK,  
2207 a verifier convinced by the proof cannot transfer said confidence to a third party.  
2208 This often stems from interactivity, and/or relies on local setup assumptions, such  
2209 as a local common reference string or local random oracle. Other proofs, usually  
2210 non-interactive, can be transferred and are publicly verifiable. Another option is a  
2211 “designated-verifier” proof, which can be achieved by proving a disjunctive (“**or**”  
2212 statement such as “this statement is true, **or** I know the verifier’s private key”.

## 2213 **B.2.3. Threshold Considerations**

2214 **Threshold ZKPoK generation (distributed prover).** When the witness is secret  
2215 shared, a threshold ZKPoK protocol can generate a proof of distributed knowledge. For  
2216 example, the set of parties that interacted in a DKG can distributively generate a ZKPoK  
2217 (e.g., via MPC) of the corresponding secret/private key. The proof may relate to public  
2218 commitments of the corresponding secret shares or/and to a corresponding public key.  
2219 This ZKPoK generation can be embedded in the DKG protocol or performed afterward.

2220 **Threshold ZKPoK verification (distributed verifier).** In a threshold ZKPoK veri-  
2221 fication, a distributed verifier interacts to verify a ZKPoK, without anyone learning the  
2222 proof. This can make sense for some applications, such as when the ZKP itself or/and the  
2223 instance is supposed to be private, or when a more efficient proof is possible in that setting  
2224 and the ZK assurance requires non-collusion by a threshold number of verifier parties.

2225 **Conventional ZKPoK about distributed data.** ZKPoK generation can be conventional  
2226 (i.e., non-threshold) or distributed. For example, a dealer (single-party) of a secret sharing  
2227 can produce a ZKPoK that enables each of the various parties of a threshold entity (i.e.,  
2228 the recipients of secret shares) to non-interactively verify that a given public key and a list  
2229 of commitments of secret shares are consistent with an adequate secret sharing.

2230 **Threshold revealing/hiding.** A ZKPoK related to a public *instance* produced by a  
2231 threshold protocol (e.g., a signature, or an RSA modulus) or to a private (secret shared)  
2232 *witness* may intentionally reveal or hide the distributed/threshold setting. For example,  
2233 the threshold setting can be revealed if the proof relates to commitments of the secret  
2234 shares and/or to public keys of the various parties. This can be achieved based on (i)  
2235 publicly verifiable secret sharing (PVSS), or (ii) publicly-verifiable MPC. Conversely, the  
2236 proof can be intentionally indistinguishable from a proof in a conventional setting. This  
2237 category for ZKPoK submissions is open to the several options (i.e., revealing or hiding  
2238 the existence of a secret-sharing setting).

#### 2239 **B.2.4. On computational soundness from statistical soundness**

2240 In interactive protocols, soundness is often characterized as statistical. A transformation  
2241 to a non-interactive protocol can convert the statistical soundness into computational  
2242 soundness (i.e.,  $\kappa \leftarrow \sigma$ ), which would then be too low if  $\sigma < 128$ . However, it is sometimes  
2243 possible to consider a tradeoff with the computational cost of the transformation.

2244 For example, consider a proof generation that requires  $2^{24}$  hashings before the last random  
2245 value selection that affects the input of a Fiat-Shamir transformation. By intentionally mak-  
2246 ing a Fiat-Shamir transformation based on a  $2^{16}$ -iterated hashing, the computational sound-  
2247 ness is increased by 16 bits of security, while only increasing the computational complexity  
2248 by less than 0.5%. Examples of NIST-standardized iterative use of PRFs can be found in  
2249 key-derivation functions [SP800-108-Rev1], and password-based key derivation [SP800-132].

#### 2250 **B.2.5. Specialized versus generic ZKPoKs**

2251 Some ZKPoKs (e.g., of a discrete log, or of an RSA private key) may be based on  
2252 specialized techniques that are somewhat similar to the operations (e.g., exponentiations)  
2253 used to commit the secret. Conversely, other ZKPoKs (e.g., when proving knowledge of  
2254 a pre-image of AES-enciphering or of a SHA-based hashing) may stem more easily from  
2255 a generic ZKP system that “arithmetizes” the *statement* of knowledge, the *instance*, and  
2256 the *witness* in some suitable representation (e.g., specifying a Boolean or arithmetic circuit,  
2257 or some other constrains system, and instantiating its input variables).

2258 For example, the NIST Circuit Complexity project [Proj-CC] collects a few Boolean circuit  
2259 representations of various NIST-approved primitives/families, such as of AES and SHA.  
2260 The project may, independently of the Threshold Call, eventually propose a specific rep-  
2261 resentation (file format) for Boolean circuits, to facilitate an interchangeable specification  
2262 of circuits of certain NIST-specified primitives.

## 2263 **Appendix C. Notes on the Threshold Setting**

2264 This section presents a baseline system model for threshold schemes (Appendix C.1),  
2265 discusses the need for a security analysis (Appendix C.2), suggests various “threshold  
2266 profiles” (Appendix C.3) and characterizes input/output interfaces (Appendix C.4).

### 2267 **C.1. System Model**

2268 The specification of each submitted threshold scheme will describe (in CSx.2; see Sec-  
2269 tion 5.4) one system model (and may identify possible variants), including the set of  
2270 participants, the communication model, and the adversarial model (including goals and  
2271 capabilities). In addition to the actual “parties” that hold the secret-shared keys, the  
2272 system may include coordinators, administrators, clients and other devices (e.g., routers,  
2273 clocks, random-bit generators). The model needs to explain how the parties are activated  
2274 (e.g., via an authorized/authenticated client request, or by an administrator) and describe  
2275 the applicable input/output secret-sharing interfaces (see Appendix C.4). The description  
2276 should strive for clarity about variable options across possible deployment scenarios (e.g.,  
2277 DKG versus secret sharing by a dealer).

2278 The paragraphs ahead describe baseline assumptions and options with regard to participants  
2279 (Appendix C.1.1), communication (Appendix C.1.2), and the adversary (Appendix C.1.3).  
2280 These assumptions are intended to serve as a baseline reference, neither precluding submis-  
2281 sions with sophisticated nuances, nor eliminating the utility of security evaluation across  
2282 diverse deployment scenarios.

#### 2283 **C.1.1. Participants**

2284 **The parties in a threshold entity.** There is a “threshold entity” composed on  $n$   
2285 “parties”, which is collectively responsible for executing a cryptographic primitive. At the  
2286 onset, all parties “know who” the  $n$  parties are and agree on  $n$  identifiers (e.g., public keys  
2287 to support authenticated channels). The suitability of public keys may need to be verified  
2288 (e.g., via zero-knowledge proofs) in the KeyGen phase or subsequently.

2289 The assumption of initial agreement on  $n$  identifiers is a possibility, not a requirement. A  
2290 threshold scheme *may* be bootstrapped without prior agreement about who the  $n$  par-  
2291 ties/identifiers are (or even the value of  $n$ ), case in which the protocol may an additional  
2292 initial phase for setting up some agreement. However, that may be a distributed-systems  
2293 problem outside the scope of exploring the essential cryptographic thresholdization of the  
2294 primitive at stake. A submission that considers an additional preparatory phase for the

2295 agreement of  $n$  and who the  $n$  parties are **should** present that phase modularly separated  
2296 from the remaining threshold scheme.

2297 **Beneficiaries.** For some operations (e.g., threshold KeyGen), the *beneficiaries* of the  
2298 computation are the parties that end with a new secret-sharing state (possibly requiring  
2299 agreement in the sense of “security with **unanimous** abort”), and/or an administrator  
2300 (e.g., who receives a new public key). For other operations (e.g., threshold signing), the  
2301 beneficiary can be an external client who requested the computation (from a threshold  
2302 entity), in order to obtain an output.

2303 **Client interface.** The client may or may not be aware of or be able to interact distinctively  
2304 based on the  $n$ -party composition. This ability can be affected by the input/output (I/O)  
2305 interface (see Appendix C.4). For example, a secret sharing of the I/O can affect whether  
2306 a client can separately send or receive input/output shares to or from each party.

2307 **Intermediaries.** The possibility of **concurrent** execution requests **should** be considered.  
2308 A baseline description **may** assume that there is a malicious **proxy** that can intermediate  
2309 the communication between clients and the threshold entity, and authorize requested  
2310 operations (e.g., the signing of a message).

### 2311 C.1.2. Distributed Systems and Communication

2312 When the interface and rules for composition are clear, the specification of a threshold  
2313 scheme **should** decouple the description of (i) the building blocks (e.g., consensus, reliable  
2314 broadcast) of classical distributed-systems, from that of (ii) the cryptographic operations  
2315 needed to support the secure multiparty computation over (or of) a secret-shared key.  
2316 See [Pre4](#) and [CSx.3](#) regarding recommendations for the modular specification of building  
2317 blocks. The needed networking tools (e.g., broadcast) can be instantiated based on  
2318 weaker resources (e.g., point-to-point channels) that are specified by referencing existing  
2319 specifications available to the public for free. However, the reference implementation still  
2320 needs to include code for them (see [Imp1](#)).

2321 A baseline description **may** make strong assumptions about the communication network,  
2322 including synchrony and reliability of transmission. However, different communication  
2323 environments can have different optimal threshold schemes, depending on guarantees (or  
2324 the lack thereof) of **synchrony**, **broadcast**, and **reliability** (of message delivery). A  
2325 submission **should** discuss the pitfalls of deploying a threshold scheme in an environment  
2326 with weaker guarantees (e.g., with asynchronous and unreliable channels), and possible

2327 mitigations (see [CSx.4](#)). Ideally, the security analysis (see [CSx.4](#)) explains which security  
2328 guarantees break across these environments.

### 2329 **C.1.3. Adversary**

2330 The system model also needs to consider an adversary that corrupts some of the parties.  
2331 As mentioned in Section [8.2.2](#), corruptions can be characterized in various ways, such as  
2332 active, adaptive and mobile. The suggestion to consider a mobile adversary is intended to  
2333 induce the characterization of various levels of insecurity (e.g., which properties break)  
2334 when acceptable thresholds are surpassed. In practice, the adversary’s capabilities *may* be  
2335 modeled as part of the security idealization (see Appendix [C.2.3](#))

## 2336 **C.2. Security in the Threshold Setting**

### 2337 **C.2.1. Security Analysis (Based on the Specification)**

2338 In modern cryptography, security proofs are fundamental for a proper security assessment of  
2339 multi-party threshold schemes. A “security proof” proves that a proposed threshold scheme  
2340 satisfies a proposed security formulation in a suitable adversarial context (see Section [8.2.3](#)).  
2341 Such proof *may* be given by showing “emulation” of the ideal functionality, or by showing  
2342 that a non-negligible adversarial advantage in each security game implies breaking an  
2343 assumption. The security analysis, which *may* be based on assumptions different from  
2344 those inherent to the underlying cryptographic primitive (being thresholdized), *should*  
2345 assess security under various compositions, including concurrent executions.

2346 **Coverage of security properties.** Some aspects of useful security analysis often overflow  
2347 the scope of a proof/idealization. The security analysis *should* discuss which known useful  
2348 properties are captured by the idealized security, and which ones are not. For example:

- 2349 • **Security with abort.** Even though availability is a generically desirable property, a  
2350 security formulation with emphasis on confidentiality and integrity *may* purposely  
2351 specify that an adversary is allowed to abort protocol executions, so that the  
2352 formulated security is more easily achievable.
- 2353 • **Inadvertent malleability.** A sole requirement of hiding and binding for a commit-  
2354 ment scheme would not suffice for a use (e.g., committing bids in an auction) that  
2355 would also require a non-malleability property.

2356 The security analysis *should* also discuss: (i) the security consequences (e.g., loss of some  
2357 type of composability) of foreseen real instantiations of components or setups that were ide-

2358 alized in the security proof; and (ii) whether/how the cryptographic assumptions sustaining  
2359 the threshold scheme are different from those sustaining the conventional primitive.

### 2360 **C.2.2. Practical Feasibility Versus Adaptive Security**

2361 Adaptive security (i.e., security against adaptive corruptions) may pose significant chal-  
2362 lenges in formal proofs of security, depending on the security formulation. For example,  
2363 while deniability of execution may in some cases be required for indistinguishability between  
2364 ideal and real executions, the use of non-committing encryption to achieve it could be  
2365 excessive without a necessary practical benefit. However, a proposed protocol must not  
2366 allow its critical safety properties to be trivially broken in case of adaptive corruptions, as  
2367 in the classical example of a protocol that delegates all capabilities to a small quorum that  
2368 is difficult to guess in advance, but which is announced during the protocol and whose  
2369 overall corruption would be disastrous.

2370 Certain security assurances (e.g., liveness and termination options) *may* vary across dif-  
2371 ferent adversaries. For example, a security analysis may prove security against static  
2372 corruptions with respect to some formulation (e.g., simulation-based), and then in comple-  
2373 ment show which fundamental security properties or attributes (e.g., unforgeability) remain  
2374 preserved against adaptive corruptions in another formulation (e.g., game-based), even  
2375 if some other security properties (e.g., some aspect of composability) are not preserved.  
2376 The set of security formulations across submissions of threshold schemes (some possibly  
2377 proving adaptive security based on unrealizable assumptions, such as a programmable  
2378 random oracle) will enrich the body of reference material for public analysis.

2379 Feedback is welcome on security formulations and reference approaches that simultaneously  
2380 enable both practical feasibility and security (for properties of interest) against adaptive  
2381 corruptions, as well as acceptable tradeoffs.

### 2382 **C.2.3. Implementation and Deployment Security**

2383 The security analysis required in [CSx.4](#) refers to the logical specification of the threshold  
2384 scheme ([CSx.2–CSx.3](#)). Comments about implementation or deployment security are also  
2385 welcome, including in [CSx.6](#).

## 2386 **C.3. Threshold Profiles**

2387 For each primitive (see Sections 9 and 10) considered for thresholdization, a variety of  
2388 solutions is possible across threshold parametrizations. Therefore, it is useful to consider

2389 the notion of “threshold profile”, defining a suitable threshold-parametrization range for  
 2390 secure operations. The threshold profile **should** characterize at least the total number  
 2391 ( $n$ ) of parties, and the various corruption thresholds ( $f$ ) and participation thresholds ( $k$ ).  
 2392 Note the use of plural (“thresholds”), since they may vary depending on which security  
 2393 property is being evaluated. Table 16 proposes succinct labels for several default profiles  
 2394 obtained from a restriction in the number of parties and the corruption threshold.

2395 **Motivating adoption.** There is value in identifying motivating applications for the  
 2396 adoption of threshold schemes in each threshold profile. Therefore, the submission **should**  
 2397 identify (in CSx.6) use-cases for which the proposed threshold ranges are adequate.

2398 For convenience of discussion, the following nomenclature is defined to easily identify some  
 2399 default threshold profiles, based on the total number of parties and/or some corruption  
 2400 threshold ( $f$ ) assumed clear in the context.

- 2401 • **Number  $n$  of parties:** (2) “two” for  $n = 2$ ; (3) “three” for  $n = 3$ ; (S) “small” for  
 2402  $4 \leq n \leq 8$ ; (M) “medium” for  $9 \leq n \leq 64$ ; (L) “large” for  $65 \leq n \leq 1024$ ; and  
 2403 (E) “enormous” for  $n > 1024$ .
- 2404 • **Corruption proportion  $f/n$ :** (D) “dishonest majority” for  $f \geq n/2$ ; (h) “honest  
 2405 majority” for  $f < n/2$ ; (H) “two-thirds honest majority”  $f < n/3$ .

**Table 16.** Labels for some template threshold profiles

Corruption proportion		Number of parties ( $n$ )					
$f/n$	Majority type	Two (2) $n = 2$	Three (3) $n = 3$	Small (S) $4 \leq n \leq 8$	Medium (M) $9 \leq n \leq 64$	Large (L) $65 \leq n \leq 1024$	Enormous (E) $n \geq 1025$
2406 $\geq 1/2$	Dishonest (D)	$n2$	$n3fD$	$nSfD$	$nMfD$	$nLfD$	$nEfD$
2407 $> 1/3$	Honest (h)	—	$n3fh$	$nSfh$	$nMfh$	$nLfh$	$nEfh$
2408 $< 1/3$	2/3 Honest (H)	—	—	$nSfH$	$nMfH$	$nLfH$	$nEfH$

2409 The default profiles exclude the cases  $f = 0$  and  $f = n$ . Therefore, for the “two”-party  
 2410 profile (with  $n = 2$ ) — the usual **secure two-party computation** (S2PC) setting — only  
 2411 the “dishonest majority” case matters (with  $f = 1$ ). For the “three”-party profile, the 2/3  
 2412 honest majority case does not apply.

2413 **Other threshold profiles.** Other threshold profiles can be considered in concrete sub-  
 2414 missions. For example, some threshold schemes may have advantageous properties when  
 2415 considering an even stricter honest majority, such as more than 3/4 of honest parties. For  
 2416 other threshold schemes, the magnitude of the number of possible quorums may matter

2417 more. For example, if a quorum is valid if and only if it has  $f + 1$  parties out of  $n$ , then the  
2418 number of such quorums is “ $n$  choose  $f + 1$ ” (i.e.,  $\binom{n}{f+1} = n! / ((f + 1)!(n - (f + 1))!)$ ).  
2419 A protocol may have a complexity proportional to this number  $\binom{n}{f+1}$ , in which case it will  
2420 stop being practical for certain parameters.

2421 The submission team is responsible for defining the threshold profile(s) with which their  
2422 proposed threshold schemes are secure and practical. In some cases it may be useful to  
2423 distinguish between corruption threshold and participation-minus-1 threshold.

2424 **Alternative monotonic access structures.** The use of the traditional term “threshold”  
2425 in this Threshold Call is not meant to suppress possible submissions of schemes suitable for  
2426 other useful and properly justified access structures. Depending on which secret-sharing  
2427 schemes and/or threshold schemes support the distributed computation, it is possible to  
2428 consider monotone access structures (i.e., where any superset of a quorum is also a quorum)  
2429 different from a simple threshold. In other words, a submission *may* consider a distributed  
2430 system with a well-specified monotonic access structure different from a threshold one.

#### 2431 **C.4. Secret-Shared Input/Output (I/O) Interfaces**

2432 Per §2.3 of [NIST-IR8214A](#), there are various I/O interfaces of interest w.r.t. secret-sharing.  
2433 The default case of secret-sharing the secret or private key is often left implicit. However,  
2434 other input or output arguments can also be characterized. The baseline characterizations of  
2435 interface (w.r.t. an identified input or output) are: non-secret-shared (NSS), secret-shared  
2436 input (SSI), and secret-shared output (SSO). This section describes various cases of interest.

2437 **Implicit I/O secret-sharing modes:** For keyed primitives, the secret sharing of the  
2438 private/secret key is assumed by default, which is often left implicit:

- 2439 • **[SSO] KeyGen.** By default, a threshold keygen scheme produces a secret-shared  
2440 output (i.e., a secret-shared secret/private key) and (when applicable) a corresponding  
2441 non-secret-shared public-key counterpart.
- 2442 • **Subsequent [SSI] operation.** After the KeyGen (produced by a dealer or via a  
2443 DKG), the subsequent threshold operation (e.g., signing) uses the private/secret  
2444 key as a secret-shared input to retain its confidentiality.

2445 Since the secret sharings in these modes are assumed by default, the modes can be referred  
2446 to as non-secret-sharing (NSS) modes when no other input or output (i.e., besides the  
2447 private key) are secret shared.

2448 **Other I/O secret-sharing modes:** When other elements (i.e., besides the main se-  
2449 cret/private key) are secret shared, to remain hidden from individual parties. For example:

- 2450 • **SSO-decryption.** A threshold decryption can be in SSO mode w.r.t. the decrypted  
2451 plaintext. This can be useful for pair-wise key-agreement (2KA) when one side  
2452 (thresholdized) of the 2KA decapsulates the key-contribution sent by the other side.
- 2453 • **SSI-encryption.** A threshold public-key encryption can be in SSI mode w.r.t. the  
2454 plaintext (which *may* be a secret for use in another context).
- 2455 • **SSO-KA.** In an ECC-2KA (a la Diffie-Hellman), the EC-primitive (e.g., CDH or  
2456 MQV; see Appendix A.4.1.2) produces an output that will seed an agreed key. If  
2457 one party is thresholdized, their output should be in SSO mode.
- 2458 • **SSI signing.** A threshold signing can keep the message private by using an SSI mode  
2459 w.r.t. the message. However, the needed threshold hashing then brings a significant  
2460 overhead. Instead, one can consider the message hash being secret shared by a dealer  
2461 (e.g., a client who is requesting the signature computation), such that each party  
2462 in the threshold scheme directly receives a secret share of the message hash (or, as  
2463 applicable, of the hash of a combination of various public elements and the message).
- 2464 • **SSIO signing.** An SSIO mode (combining SSI and SSO) can be useful in privacy-  
2465 enhancing contexts (e.g., for a time-stamping service). For example, a client can  
2466 provide shares of a message hash to a threshold entity, and then receive signature  
2467 shares. The result is similar to a blind-signing service, except that (i) the signing key  
2468 is further thresholdized, and (ii) the knowledge of the message/signature is within  
2469 the theoretical reach of a threshold coalition of signer-parties.

2470 Provided that at least the default private/secret key is secret shared, a submission can  
2471 choose to cover one or more secret-sharing interfaces (i.e., NSS, SSI, SSO, SSIO) for any  
2472 of the other input or output elements. Some correctness challenges with SSI and SSO  
2473 modes may be resolved with ZKPs or/and verifiable secret-sharing modes.

2474 A threshold scheme receiving an SSI input (including a secret-shared key) *may* assume  
2475 that the secret-shared input is correct. For example, this is the case if it is obtained from a  
2476 previous secure threshold execution (e.g., a DKG), or from a trustworthy dealer, or has been  
2477 verified as correct after having been dealt by an untrusted dealer. Alternatively, the threshold  
2478 scheme *may* be devised to be inherently resilient against a malicious secret sharing, (e.g.,  
2479 by starting with a joint computation to confirm correctness of the secret-shared state).

## Appendix D. Acronyms

- 2480 • **2KA**: Pair-Wise **Key-Agreement**
- 2481 • **2KE**: Pair-wise **Key-Establishment**
- 2482 • **2PD**: Second **Public Draft**
- 2483 • **ABE**: **Attribute-Based Encryption**
- 2484 • **AEAD**: **Authenticated Encryption with**  
2485 **Associated Data**
- 2486 • **AES**: **Advanced Encryption Standard**
- 2487 • **API**: **Application Programming Interface**
- 2488 • **CDH**: **Cofactor Diffie-Hellman**
- 2489 • **CMAC**: **Cipher-based MAC**
- 2490 • **CPU**: **Central Processing Unit**
- 2491 • **CRT**: **Chinese Remainder Theorem**
- 2492 • **DKG**: **Distributed Key Generation**
- 2493 • **DOI**: **Digital Object Identifier**
- 2494 • **CCA**: **Chosen-Ciphertext Attack**
- 2495 • **CPA**: **Chosen-Plaintext Attack**
- 2496 • **DSA**: **Digital Signature Algorithm**

## 2591 Appendix E. Changes Between the IPD and the 2PD

2592 Several updates have been made between the initial public draft (ipd) [[NIST-IR8214C-2pd](#)]  
2593 and the second public draft (2pd) [[NIST-IR8214C-ipd-comms](#)] of the NIST Threshold Call.  
2594 The following list describes various updates:

### 2595 Submission requirements:

- 2596 1. **Submission subphases and deadlines.** Section 4 (old §4.1) refined the specification of  
2597 phases and deadlines (see Table 4). The old “Ph1. (Optional) Early abstract” was refined  
2598 into a “Ph1. [Previews](#)” phase with two opportunities for teams to share in advance their  
2599 plans for package submission. The section also adds [Ph3. Public analysis](#) to clarify the  
2600 intended period of public analysis after the submissions.
- 2601 2. **Written specification.** Section 5 (old §4.2) defines a more refined structure for the  
2602 “[Specification](#)” component. The main matter is now composed of a [preliminaries](#) part, and  
2603 one or more [crypto-systems](#) parts. Distinct [crypto-systems](#) can be proposed by distinct  
2604 subteams. The section “[Pre3: Related work and design decisions](#)” merges the old “S5”  
2605 (Prior work) and “S11” (choices and comparisons).
- 2606 3. **Reference implementation.** Section 6 (old §4.3) clarifies [terminology](#), and [requirements](#)  
2607 about [scope](#), [availability](#), [open-source licensing](#), [compilability](#), [dependencies](#), [clarity](#), [scripts](#)  
2608 and [instructions](#) (the latter two were previously in another section). [External dependencies](#)  
2609 (e.g., compiler, and third-party libraries) are allowed if they open source, well-identified,  
2610 and automatically integrated in the compilation phase ([X1](#)).
- 2611 4. **Implied agreement and patents disclosure.** Section 4.4 (old §4.6) defines expectations  
2612 about submitted packages. Also, the section “[Cv4 Patents disclosure](#)” in the [verso](#) of the  
2613 specification requires listing known related patents associated with the submitters.
- 2614 5. **Notes specific to each (sub)category.** The content in the old §6, §7, and §A, with  
2615 information about the primitives in Class N (old Cat1) and Class S (old Cat2), was  
2616 revised and reorganized for better separation between (i) content with requirements and  
2617 recommendations (“shall” statements) in Sections 9 and 10 and (ii) other informative  
2618 content about the conventional schemes (in Appendices A and B).
- 2619 6. **Security requirements.** The new Section 8.1 gathers new notes on security strength levels,  
2620 including in relation to post-quantum security categories ( $\theta$ ). The new Section 8.2) adapts  
2621 some content from the old §5, to list requirements for threshold security. The number  
2622 of required parametrizations was reduced from two to one (aiming at  $\kappa \gtrsim 128$ , or  $\theta \geq 1$ ).  
2623 A second parametrization is encouraged (aiming at  $\kappa \gtrsim 192$ , or  $\theta \geq 3$ ) but not required.

### 2624 Organization of Categories:

- 2625 1. **Succinct indexation.** The old categories Cat1 and Cat2 have been renamed to two [Class](#)  
2626 [N](#) (for NIST-specified primitives) and [Class S](#) (for **S**pecial primitives, not specified by

- 2627 NIST), respectively. Correspondingly, the old subcategories prefixed with “C1.” and “C2.”,  
2628 have been renamed to categories prefixed with “N” and “S”.
- 2629 2. **PQC primitives in Class N.** The categories for signing (new [N1](#); old C1.1) and PKE  
2630 (new [N2](#); old C1.2) are now open to the recent NIST-PQC standardized primitives.
- 2631 3. **KA primitives in Class N and Class S.** The categories (old C1.3 and C2.3) for non-PKE  
2632 primitives for key-agreement (KA) (a la Diffie-Hellman) have been integrated into the  
2633 categories of KeyGen primitives (new [N4](#) and [S4](#)).
- 2634 4. **Symmetric primitives.** In the “symmetric” categories (new [N3](#) and [S3](#); old C1.4 and  
2635 C2.4), the primitives related to hash, XOF and MAC are presented more straightforwardly,  
2636 rather than relying on the applications of key-derivation and key-confirmation used in  
2637 pair-wise key-establishment.
- 2638 5. **LWC primitives in Class N.** The “symmetric” category (new [N3](#); old C1.4) is now also  
2639 open to Ascon primitives (for encryption, hashing, and XOF’ing) selected by NIST-LWC.
- 2640 6. **FHE category.** The old C2.6 for “advanced” primitives has been adapted into a narrower  
2641 category [S5](#) for fully-homomorphic encryption (FHE). The previously exemplified cases of  
2642 IBE and ABE are left outside the scope. (They remain of interest to the NIST-PEC project.)
- 2643 7. **ZKPoK.** The ZKPoK category (new [S6](#); old C2.7) is better described, including a  
2644 thorougher table of examples (in [S6](#)).

#### 2645 **Appendices:**

- 2646 1. **Notes on Categories.** Appendices [A](#) (about Class N; old Cat1), and [B](#) (about Class  
2647 S; old Cat2) include adapted informative notes from the old Appendix A (details for  
2648 subcategories), after moving-with-revision related requirements to Sections [9](#) and [10](#).
- 2649 2. **Notes on Threshold Setting.** The new Appendix [C](#) adapts informative content from  
2650 the old §5, excluding requirements (“shall” statements, which moved with adaptation to  
2651 Section [8.2](#)). The old §6.3 on Input/Output interfaces was revised into new Appendix [C.4](#).
- 2652 3. **Checklists.** The old “B. Submission checklists” was removed. It may reappear in the  
2653 future latex template for submissions.
- 2654 4. **Acronyms.** The list of acronyms was moved from old §2 to Appendix [D](#).
- 2655 5. **List of changes.** The new Appendix [E](#) lists changes between the two public drafts (IPD  
2656 and 2PD) of the Threshold Call.

#### 2657 **Other edits:**

- 2658 1. **Front matter.** The front matter follows a new NISTIR template. It revised the [Preface](#)  
2659 and [Acknowledgments](#), and added a new [Note to the Reviewers](#).
- 2660 2. **PQ-QV combinations.** The new Section [3.2](#) discusses post-quantum (PQ) versus  
2661 quantum vulnerable (QV) techniques, and expectations on PQC-migration.
